Although it is too early to tell how long-lasting a tradition this may be, it would seem that the AIDS epidemic has succeeded in overcoming some of the more rigid boundaries between disciplines (Farmer et al. 1996). There are signs that as the social and biomedical fields begin to recognize each other's contributions, social epidemiologists, psychologists, infectious disease clinicians, and medical anthropologists have begun to collaborate to advance our still very basic understanding of the interactions between social, political, and cultural structural constraints and the power of individuals.

Latin American Studies: Politics

The study of politics under the rubric of 'Latin American studies' bears two important features that distinguish it from the more general practice in US university departments of political science: it has been approached from an interdisciplinary perspective and it has been influenced importantly by Latin Americans themselves. Through these methods, 'Latin Americanists' have contributed to some of the most important and influential theories and debates in political science in recent history, from dependency to democratization, from studies on the state to research on social movements. This article examines the intellectual trajectory of the study of politics within Latin American studies, noting how it has been influenced by real-world events and discussing its relationship, intellectual and political, to the discipline of political science.

1. *Emergence of the Subfield*

While some US scholars devoted themselves to the study of Latin America, including the region's politics, in the late nineteenth and early twentieth centuries, it was not until the 1960s, after the Cuban Revolution, that Latin American studies got its big boost. With important support from the Joint Committee on Latin American Studies of the Social Science Research Council and the American Council of Learned Studies, politics became a major scholarly focus for regional specialists. By 1979, articles by political scientists made up the largest percentage of submissions to the leading journal devoted to the area, the US-based *Latin American Research Review*, a trend that continued in the 1980s and 1990s. Studies on politics also composed an important percentage of articles in the *Journal of Latin American Studies*, published in England.

Notwithstanding the Cold War 'national interest' incentives for funding US scholarship on Latin America, many tensions arose over the years between the Latin American studies community and the foreign policy, defense, and intelligence circles of the US government. Beginning with the 'Operation Camelot' scandal in 1964, in which a sociologist working in Chile exposed a US Army-funded initiative to use area scholars to gather information for the US government's counterinsurgency program, scholars of the hemisphere criticized a wide array of US policies, including those toward Cuba, multinational corporations, Brazil, Central America, and especially Chile. The Latin American Studies Association, founded in 1964, has issued frequent and strong criticisms of US policy in the hemisphere. This passionate engagement of US and European Latin Americanists with policy issues in the region is one outcome of their genuine collaboration with their counterparts to the south, most of whom have been sharply critical of US imperialism, interventionism, capitalism, conservatism, and association with dictators.

2. *From Modernization to Dependency*

The mutual influence of Latin American and North American/European scholars has been evident in the evolution of political science inquiry on the region. In the 1950s and early 1960s, 'modernization' was the predominant paradigm in the field of comparative politics. Modernization theory arose in the context of decolonization in Africa and Asia and the early years of the Cold War. It grew out of efforts to understand how recently independent nations and other 'Third World' countries might achieve economic and political development similar to that of the US and northern Europe, which were viewed as the products of a linear and potentially universal process of rationalization and progress. The theory was developed largely by specialists on Africa and Asia, but Latin Americanists fell in line to offer supporting evidence and concepts.

Following the spread of US interest in the region from the Caribbean basin towards the larger, industrializing countries, scholarly attention turned towards Mexico and the Southern Cone of Latin America.

The main argument of modernization theory was that industrialization and economic growth, and the value orientations associated with them, were the engines of social and political progress. This was a vision rooted in classic, Western liberal economic and political thought. In order to develop, Third World societies needed to embrace ideas, values, techniques, and organizations commensurate with urbanization, a complex division of labor, increased social mobility, and a rational–legal, impersonal economic and political system. As countries overcame feudal, semi-feudal, precapitalist, or at least inefficient behavior patterns and institutions from the past, new urban social groups, particularly the middle classes, would emerge, and these groups would in turn push for social equality and political democracy. Thus, political scientists focused on issues such as elite and mass education, mobilization of the popular classes, interest articulation, and institutional development. Some of the pre-eminent works of this period were Johnson's (1958) *Political Change in Latin America*, Lambert's (1967) *Latin America: Social Structure and Political Institutions*, and Lipset and Solari's (1967) edited volume, *Elites in Latin America*.

Quickly, however, critics assailed the main tenets of modernization theory based on evidence and perspectives from Latin America itself. In the 1960s and 1970s, economic growth in most countries did not meet expectations, social inequalities were rarely reduced, and military dictatorships became the norm in the region. Scholars thus began to take issue with many of the underlying assumptions of modernization theory. They challenged the idea of a linear, evolutionary developmental continuum, the conception of preindustrial societies as homogeneous and static, the assumption of the Western European, capitalist experience as generalizable and desirable, the faith that new urban social sectors would be democratic and progressive, and the neglect of constraining factors exogenous to Third World societies.

The primary challenge to modernization theory was the dependency approach. The dependency school accepted modernization's economic determinism, but turned it on its head: the adoption of US and European-style economic policies had not and would not lead to healthy economic and political development, but rather to skewed and highly limited development, or 'underdevelopment.' Rather than the cure for underdevelopment, capitalism was seen as the cause. The dependency approach, developed mainly by Latin Americans but also by foreign Latin Americanists, and highly influential outside the region, melded insights from a variety of disciplines to explain the major features of Latin American societies: economic underdevelopment, social inequality, political instability, and authoritarianism. It emphasized the need to go beyond the examination of individual societies to understand the international historical process of development.

Within the dependency paradigm, economists, sociologists, and political scientists argued that a country's position in the international system is determinant of internal class behavior. Because Latin American countries occupied an inferior position in the international division of labor, producing mainly raw materials and cheap workers, they were the victims of unequal terms of trade and exploitation by foreign investors. Local entrepreneurial classes and political leaders were captives of the international market and had only limited opportunities to steer the development of their own economies and societies. In addition, the copying of consumption patterns characteristic of the advanced industrialized countries led to severe distortions within Latin American economies. According to the more radical dependency writers, foreign and national capitalists siphoned off Latin America's surplus, leaving the vast majority of people sunk in poverty and oppressed by authoritarian regimes. Some of the most influential books on dependency were Frank's (1967) *Capitalism and Underdevelopment in Latin America*, and Cardoso and Faletto's (1969) *Dependencia y Desarrollo en América Latina*.

In political science, the most important theoretical contribution to come out of the dependency paradigm was bureaucratic–authoritarianism, articulated by O'Donnell in (1973) *Modernization and Bureaucratic–Authoritarianism*. This theory argued that the bureaucratic–authoritarian state that emerged in the most economically advanced Latin American countries was a structurally determined phenomenon, produced by the alliance of local political forces and foreign capital with the objective of overcoming economic stagnation and deepening industrialization. Otherwise put, the authoritarian regimes in the region emerged because continued economic growth depended on the repression of the working classes, whose demand for higher wages and other guarantees would otherwise fuel inflation and drive out foreign investment.

Dependency arguments held sway into the late 1970s, when Latin American countries began a wave of transitions to formally democratic regimes. Already, dependency-related economic theories had been displaced by international monetarism in many countries, increasingly so as the 1980s unfolded. Both import substituting industrialization and socialism seemed to have failed to overcome underdevelopment. In addition, the examples of export-led development in East Asia, namely South Korea and Taiwan, cast heavy doubt on the pessimistic tenets of the *dependentistas*. Latin American governments thus began slashing trade barriers and encouraging comparative advantage, while they pruned the bloated

public sector. Moreover, foreign investment and loans were welcomed, particularly in the wake of the debt crisis of the 1980s. Along with the imperative for economic liberalization came pressures, from both within and without the region's authoritarian regimes, for political liberalization. Suddenly, scholars who had argued that authoritarianism in the region was structurally determined had to account for transitions to democracy.

3. *Corporatism*

A major alternative theory produced during the 1970s to explain Latin American economic and political development patterns, and one that was also challenged and swept aside with the focus on democratization in the 1980s, was corporatism. Corporatist theory had two main, sometimes overlapping, strains. One strain was institutional corporatism, fully developed first by Schmitter (1971) in *Interest Conflict and Political Change in Brazil*. Schmitter and others called attention to a pattern of interest group politics in Latin America in which the state played a dominant and controlling role. In an effort to harmonize relations among classes and other social groups, the state often sponsored the formation of functional groups, offering them a monopoly of representation but maintaining a significant degree of control over their internal organization and demand making. This pattern did not fit the pluralist model based on the American cases, but bore certain similarities to—as well as important differences from—interest group politics in some Western European countries (Schmitter 1974).

Proponents of the second version of corporatist theory, cultural corporatism, took the presence of corporatist institutions as evidence of a distinct political tradition, rooted in the Iberian and colonial past. Scholars such as Wiarda (1974), editor of *Politics and Social Change in Latin America*, held that Latin American societies had inherited a political culture that featured feudalistic master–man relations, anticapitalist preferences and incentives, patrimonial extended families, hierarchical Roman Catholic religious affinities, corporatist and organic links between the state and society, and authoritarian, verticalist governing structures. According to proponents of this point of view, such characteristics were not necessarily undesirable or destined to vanish with economic development, as modernization theorists would have it, but were part of Latin America's unique developmental path. These arguments gained currency as authoritarian regimes swept the hemisphere in the 1970s.

Cultural corporatism was criticized strongly on a number of fronts. Some viewed it as an apology for authoritarian regimes that emerged in Latin American countries. Others (including Schmitter 1974) questioned the theory's blurring of cultural and institutional elements, arguing that forms of governmental corporatism can be found in many non-Latin, developed countries, serving to organize functional groups as links between the state and society. They also pointed out that many other developing countries are plagued with poverty and authoritarianism without any Iberian heritage.

The most telling critique of cultural corporatism, however, was launched against its sweeping determinism. Despite their common colonial past, Latin American countries exhibit an extremely varied economic and political record. Some countries have made impressive strides in terms of industrialization and the institutionalization of democratic practices. Even within individual countries, people have experienced radically changing forms of economic, social, and political organization without suddenly transforming their cultural heritage. Contrasting levels of modernity exist between different cities and regions. Moreover, cultural attributes vary widely by ethnicity, race, class, and gender. Cultural corporatism could not account for this diversity, nor could it predict or explain the wave of democratization that swept Latin America beginning in 1978.

4. *Democratization and Beyond*

In the 1980s, then, real-world events forced analysts of the region to turn their attention to the politics of liberalization and transition from authoritarian regimes. Gradually they abandoned the grand theorizing and structural determinism that had characterized both the modernization and dependency eras to focus instead on the dynamics of agency, the role of ideology, the issue of political will, and the application of game theory. In this effort, scholars could draw on the work of Linz and Stepan (1978), who had emphasized the importance of agency in their important edited work, *The Breakdown of Democratic Regimes*. O'Donnell et al. (1986) produced the four-volume set, *Transitions from Authoritarian Rule*, and Przeworski (1991) wrote *Democracy and the Market*, both of which were hugely influential in the field of political science as a whole.

The 'transitology' literature, which focused almost exclusively on the interests and actions of political elites, soon gave way to analyses of the different types of democratic regimes that emerged in the region, debates about the meaning and possibility of 'democratic consolidation,' and greater attention to civil society. Scholars who, early on, were wary of upsetting the delicate equilibria achieved in the region's democratic transitions gradually became more critical. Some took strong stands in debates over institutional reform, arguing that with strong presidentialism or

poorly designed electoral rules, Latin American countries courted instability. Others, pointing to a crisis of representation in many of the region's polities, focused on the need to strengthen parties or analyzed the important role of grassroots organization.

This does not mean that either modernization or dependency was swept definitively into the dustbin of history. Like most good theories in the social sciences, both bequeathed a legacy of important lessons and middle-level hypotheses, shorn of their more grandiose pretensions. Both theories contributed an abiding concern with underlying structural conditions, especially with dependency's emphasis on historical structuralism, although most political scientists now insist that we must focus on institutions, agents, identities and/or choices as well as structures. Dependency left its mark in terms of general awareness of the important role of external factors to the internal economic and political systems of Latin America, and political economists specializing in Latin America moderated and adapted the theory to explain persuasively instances of 'dependent development,' not only in Latin America but in other regions of the globe as well (e.g., Evans 1979). Remnants of modernization theory are evident in some recent analyses which attempt to establish prerequisites, economic and/or cultural, of political democracy (e.g., Malloy and Seligson 1987). Now some argue that it just took longer than expected in the 1950s for Latin America, let alone Southern and Eastern Europe and many other parts of the globe, to achieve the socioeconomic conditions to support democratic government.

Notwithstanding this legacy, in the 1980s and 1990s, Latin American studies has been characterized by the absence of a prevailing paradigm. To be sure, analysts of Latin American politics have not been unaffected by the more recent trend toward theory-driven analysis, whether shaped by world-systems theory, rational choice theory, or postmodernism. For example, some study the politics of migration flows among peripheral, semi-peripheral, and center countries in the context of the globalization of capitalism; others examine how politicians' desire to maximize their career success affects policy; and still others analyze the political perspectives and resistance strategies of historically trampled or ignored ('subaltern') groups. For the time being, however, studies within these paradigms must share the intellectual terrain with an abundance of middle-level theories. Such theories have emerged on topics ranging from the political effects of different approaches to incorporating labor into the polity, to the sources and political effects of different institutional structures, to the emergence and effectiveness of social movements, to changing constructions of gender and citizenship. Among the most significant of these recent works are Collier and Collier's (1991) *Shaping the Political Arena*, Mainwaring and Scully's (1995) *Building Democratic Institutions: Party Systems in Latin America*, Escobar and Alvarez's (1992) *The Making of Social Movements in Latin America*, and Linz and Stepan's (1996) *Problems of Democratic Transition and Consolidation*.

5. *Political Science vs. Area Studies*

Despite all of the noteworthy contributions discussed here, Latin American area specialists are still sometimes accused, as are other area specialists, of 'ghettoizing' themselves within the discipline of political science. Few articles on Latin America (or on other 'developing regions') have appeared in the pages of the leading disciplinary journals in the past 40 years (Martz 1990). Instead, most work on Latin America has been published as chapters in edited volumes, as collaborative multiauthored books, or as articles in area or alternative thematic journals.

Perhaps as a result, an old debate has re-emerged in the pages of major political science journals and newsletters regarding the quality of contributions by area specialists in general. The nature of work on Latin American politics, as most work in 'area studies,' has tended to be more qualitative than quantitative, and generally more oriented towards a transdisciplinary audience. Latin American studies in general is characterized by methodological diversity, a fact which partially may be explained by the significant influence of Latin American scholars, whose disciplinary norms and boundaries differ from those of their US counterparts. The work of Latin American specialists is thus sometimes viewed with suspicion by colleagues at the 'hard' end of the social scientific spectrum. Most recently, a Harvard political scientist and noted Africanist (Bates 1996) has argued that comparative political scientists should follow the lead of many specialists in US politics who use rational choice and game-theoretic models to produce testable hypotheses and strive for universalizable conclusions. He and those who share his convictions view area studies in much the same way their behavioralist predecessors did: as primarily descriptive, largely atheoretical, and, above all, methodologically soft and hence unanalytical or unscientific.

The view of Latin American studies as unscientific is, however, simply inaccurate. Regional specialists, including political scientists, have helped to test the validity of discipline-specific theories and to identify new empirical puzzles that require theoretical explanations and that generate hypotheses. It was the familiarity of Latin Americanists, for example, with particular historical and structural features of Latin American societies that allowed the universalist assumptions of modernization theory to be challenged, and produced the highly influential dependency approach in the 1970s. As dependency itself came under fire, it was a close empirical analysis by Latin America area experts that produced the concept of 'dependent

development' and led to the elaboration of theories of state-led development around the world. In the fields of democratization and social movement theory, it has been transcontinental and transdisciplinary cooperation by Latin America experts that have produced some of the most significant recent works.

6. The Bigger Challenge: Globalization

Notwithstanding the critique from within the academy, the greater challenge to specialists on Latin American politics comes from the broader international political context. The end of the Cold War has meant the demise of the general 'national interest' justification in the US for funding area studies programs. The issues that affect US security interests are increasingly understood as global problems, better handled by issue experts rather than area experts. In such a scenario, Latin American studies may be particularly vulnerable, given the association of many Latin American specialists with causes often at odds with those of the Washington policy community. Relatedly, the global expansion of US power in the 1990s, both economic and political, as well as the great leaps in communications technology of that same decade, have fed the notion that the world is becoming increasingly homogeneous. English has become the *lingua franca* of the international business and political worlds, and more and more countries have accepted and even embraced the 'Washington consensus' on neoliberal economics and procedural democracy.

The challenge for those who study Latin American politics in the twenty-first century is thus to forge cross-regional ties and build a global research agenda without losing sight of the factors that have allowed for fruitful intellectual production in the past: a commitment to deep knowledge of cases through language proficiency and fieldwork, openness to interdisciplinary cross-fertilization, and collaboration with foreign scholars on an equal basis. While globalization may signify that many different countries face similar problems, it does not mean that similar solutions will work everywhere. Local and regional traditions and politics will continue to influence events and outcomes in all parts of the world, and knowledge of those traditions and politics will continue to be essential for policy makers and academic theorists.

Latin American Studies: Religion

Prior to the 1960s, religion in Latin America was an understudied phenomenon. Most observers simply assumed that the Latin American Catholic church was a conservative institution that reinforced an antidemocratic, hierarchical, elite rule in what was generally viewed as a 'Catholic continent.' To the extent that the scholars studied the Latin American Catholic church at all, they tended to focus on formal church–state relations. The essay below reviews the major developments in Latin American Catholicism since the 1960s, as well as the rapid growth of Pentecostalism in the region, and notes the central debates among academic observers of Latin American religion.

1. *Catholicism*

Several developments in the 1960s signaled to scholars that the conventional wisdom regarding Latin American religion needed reassessment. Vatican II (1962–5) launched far-reaching reforms within the international Catholic church in an effort to reconnect the faithful to the immediate and worldly relevance of Catholic belief. In Latin America, many younger priests participated in new initiatives such as worker-priest movements that resulted in a heightened social and political awareness of poverty. By the 1968 meeting of the Latin American Bishops Conference (CELAM) meeting in Medellin, Colombia, the winds of a new progressivism were blowing through the Latin American Catholic church.

The CELAM meeting in Medellin was a turning point for the Latin American Catholic church. Using the model 'see, judge, act' from Vatican II, Latin American bishops called on social scientists to paint a picture of Latin American 'reality' in order to better assess how the church might renew its relevance to people's lives. The overwhelming image of Latin American society offered by Latin American economists, sociologists and political scientists was one of chronic and grinding poverty resulting from Latin America's economic dependence on the United States, and backed up by military repression and US imperialism.

At the same time, progressive bishops, inspired by the writings of Brazilian educator Paulo Freire (1970) and liberation theologians such as Gustavo Gutierrez (1973), embraced a radical agenda of social justice, political democracy and economic redistributive policies. Liberation Theology, like other historical Christian movements, is based on the Old and New Testament prophesies of the coming of the Kingdom of God, at which time all humanity will live in peace, justice and equality. According to liberationists, traditional Catholicism supports the status quo of oppression and dehumanization by calling on the poor to bear the travails of this life in expectation of eternal salvation, and exhorting the wealthy to appease their consciences by giving to charity. Drawing on Old Testament examples of God's willingness to reach into human history on behalf of His people (for example, the Exodus), liberationists call on the church to cast its lot against the 'institutionalized violence' of the status quo. From the New Testament, liberationists argue that Jesus chose to reveal his message to the poor and meek, linking Christian faith with solidarity with the poor and their temporal struggle for social justice. Unlike traditional Catholicism that relies on charity to the poor, liberationists call on Christians to embrace political reform, even the overthrow, if necessary, of oppressive and repressive regimes.

Influenced by the contributions of both academics and theologians, the Latin American church committed itself to a 'preferential option for the poor' at the Medellin CELAM meeting. The church also adopted a pastoral strategy centered on base Christian communities (or CEBs, the acronym for *comunidad eclesial de base*). CEBs are parish-level neighborhood groups in which clergy and/or pastoral agents attempt to raise social awareness through group discussions regarding the relevance of weekly Bible readings to members' own everyday lives (Azevedo 1987). According to many observers, the 1968 CELAM meetings in Medellin signaled a change within the Latin American Catholic church from the traditional alliance with the landed elite to an activist and progressive agenda (Lernoux 1982).

The first scholar to examine the implications of changes within the Catholic church was sociologist Ivan Vallier. Vallier's interest in the Latin American Catholic church was shaped by the concern for economic, political and social modernization that dominated US social sciences in the 1960s and 1970s. Unlike others who continued to view Catholicism as a hindrance to Latin American modernization, however, Vallier (1970) looked at different ways in which the Catholic church had affected historical development patterns across countries rather than the effects of a monolithic 'Catholicism.' Vallier's work opened the way for a number of new country-specific studies examining the historical role of national Catholic hierarchies in twentieth century political and social development (Mainwaring 1986, Smith 1982, Williams 1989).

During the 1970s and 1980s, the dominant focus in US scholarship shifted from the challenges of economic and political modernization to the crises associated with military dictatorship throughout Central and South America. Between the 1960s and 1980s, democracy had failed throughout Latin America. In a number of countries (notably excepting Argentina and Colombia), the Catholic church's commitment at Medellin (reaffirmed at the 1979 CELAM meeting in Puebla, Mexico) to serve as the 'voice of the voiceless' came to mean serving as a central conduit for

opposition to authoritarianism and military rule. Under the progressive leadership of a number of highly visible and vocal bishops, national hierarchies in countries such as Brazil, Chile, and Peru supported a wide range of grassroots organizations whose purposes ranged from ensuring the survival of the poor, to protecting human rights victims of the state, to organizing massive prodemocracy mobilizations. The prodemocracy leadership on behalf particularly of the poor and political dissidents provided by bishops, priests, nuns and lay leaders made the church, itself, a target of military repression. The assassination of El Salvador's Archbishop Oscar Romero, as well as the assassination and/or torture of thousands of priests, nuns and lay workers, were the price of church leadership during this period. Not surprisingly, the majority of studies during this period focused on church progressives and the host of new forms of social organization that grew under the protection and encouragement of progressive church structures (Levine 1992, Mainwaring and Wilde 1989).

Beginning in the 1980s, Latin American redemocratization allowed a reassessment of progressive trends in the Latin American Catholic church. On the one hand, the Vatican, under the leadership of Pope John Paul II and Cardinal Joseph Ratzinger (head of the Vatican's Congregation for the Doctrine of the Faith), has orchestrated a conservative reversal of much of the progressive political commitment made by Latin American hierarchies during the dictatorships. Pope John Paul II, a populist well-beloved by Latin America's poor and dispossessed, nevertheless is a staunch opponent of church political activism on behalf of the poor. Of particular concern to the Pope and Cardinal Ratzinger is liberation theology's use of Marxist categories of analysis for understanding Latin American conditions and liberationists' calls to concrete political action, even to the point of joining forces with Marxist movements in some cases. Cardinal Ratzinger has moved to silence several well-known Latin American theologians, including Brazilians Leonardo Boff and Ivone Gebara, a noted feminist theologian. In addition, the Vatican has filled vacancies for new bishops and archbishops with strong church traditionalists who have withdrawn much of the church's previous support for grassroots organizations and political organizing in favor of a traditional pastoral focus on individuals' private morality, charity and individual sin. In addition, many have noted a certain desire, even among many progressives, for the church to withdraw from explicitly political, even partisan, activities and positions in favor of the spiritual and moral work that is the proper work of the church. In the 1990s, many younger clergy are drawn to a more traditional view of the role of the church in society than their counterparts during the dictatorships (Cleary and Stewart-Gambino 1992). Although the previous focus on progressives created the illusion of a new consensus within Latin American hierarchies, the return of democracy allowed longstanding tensions among bishops to reemerge, dividing national hierarchies and thus reducing their visibility in public debates and controversies.

The renewed debate within national churches regarding the proper role of the Catholic church in contemporary society shifted scholarly focus away from changes within the institutional Catholic church and their effects on Latin American societies, to the varying experiences of the faithful themselves. Recent studies, often authored by anthropologists and sociologists, focus less on national-level institutional behavior and more on local groups and how their religious identities shape their interaction with larger economic and political forces. Individuals and local groups differ substantially in terms of the way and degree to which their religious beliefs are influenced by official church programs and pronouncements. In turn, individuals and local groups differ in terms of how their religious beliefs shape their own political behavior, depending on such factors as local opportunity, both material and symbolic resources, and the like. Gender also affects the intersection of religious belief and individual religious, social or political behavior (Mariz 1994, Burdick 1998).

Also in the 1990s, the fall of the Soviet bloc returned US scholars' attentions to perennial questions concerning the nature and requisites for democratic institution building. Like new post-Soviet states, many newly democratic Latin American nations lack a dense or complex civil society. Consistent with the recent focus on the neo-Toquevillian benefits of a densely organized civil society for democracy, some observers of Latin American religion have began to examine how religious life can foster democratic values and/or effective checks on the nondemocratic impulses of new regimes (Oxhorn 1995). With the decline of progressivism in the Latin American Catholic church, much of the search for religion's contribution to civil society is found in studies of the continued growth and expansion of Latin American Pentecostalism.

2. *Pentecostals*

Perhaps the most dramatic change in Latin American religions in the latter half of the twentieth century is the explosion of Pentecostalism in the region. Pentecostalism is a twentieth century phenomenon, the roots of which date to a prayer meeting of Bible school students in Topeka, Kansas on January 1, 1901. The group prayed for an extraordinary sign of the Holy Spirit, whereupon one young woman began to speak in tongues. The intense euphoria and physical manifestations of the 'baptism of the Holy Spirit' spread to the other students, leading them to believe that they had experienced the Pentecost, the immediate experience of the Holy Spirit described in Acts 2. Five years later, a Pentecostal mission was founded on Azusa

Street in Los Angeles, where thousands began to convert, beginning the rapid spread of Pentecostalism not only in the United States, but also around the globe. By 1916, Pentecostal churches were recorded in eight Latin American countries (Cleary and Stewart-Gambino 1997). Latin American Pentecostal churches, always known for a central commitment to proselytism, steadily attracted converts throughout the 1920s and 1930s through the combination of public preaching, spirited and emotional worship, and claims to supernatural healing power of the Holy Spirit. The Assemblies of God, one of the largest Latin American Pentecostal churches, grew at an average of 23 percent per year from 1934 to 1964. By 1962, Brazilian Pentecostals alone numbered over one million members. At the time of writing, non-Catholic Christians in Latin America are estimated to number between 60–80 million, representing between 13–17 percent of the total population. Of these, between 75–90 percent are believed to be Pentecostal. Pentecostal growth has exceeded population growth for decades, although Pentecostal membership remains concentrated among the poor, and to a lesser extent the middle classes.

As early as the 1960s, a few academic observers pointed to the dramatic growth in Pentecostal membership. Like observers of Latin American Catholicism in the 1960s and 1970s who focused on larger processes of modernization, early observers examined Pentecostalism in terms of its potential contribution to democracy. Christian Lalive d'Epinay (1969) argued that Pentecostalism replicated the authoritarian values and social organizations of rural society, thus attracting peasants relocated to mushrooming urban centers. According to this view, Pentecostalism reinforces non-democratic political forms and hinders modernization. On the other hand, Emilio Willems (1967) argued that the lack of hierarchy or formal theology, coupled with individuals' free access to the Holy Spirit, makes Pentecostalism an inherently democratic belief structure that attracts the poor as a symbolic protest against the traditional social order.

Debates about Pentecostalism's implications for larger social and political developments were highlighted again with the 1990 publication of two studies, by David Martin (1990) and David Stoll (1990). Like Lalive d'Epinay, Stoll's examination of Pentecostal growth in countries such as Guatemala, where the greatest growth occurred during the brutal dictatorships and civil war of the 1970 and 1980s, leads him to the conclusion that Pentecostalism reinforces political authoritarianism and repression. Moreover, Stoll argues that overt and covert support for Pentecostal missionaries from both US churches and government demonstrates the insidious imperialism at the core of Latin American Pentecostalism. On the other hand, reminiscent of Willems' more optimist interpretation, Martin stresses the egalitarian and participatory nature of Pentecostal congregations that can contribute, although indirectly, to strengthened democratic values and empowerment of the poor.

Pentecostal membership appears to be particularly powerful for the most vulnerable; for example, the addicted, ill, or other social outcasts. Yet, recent studies show that the stereotypes of Pentecostals as *simply* the poor or vulnerable are false. For example, while scholars agree that Pentecostalism attracts primarily the poor, some in the middle class are drawn to the doctrines of hard work, sobriety and clean living that bring God's spiritual and, especially, temporal rewards. Solid analysis is replacing other stereotypes as well. In the past, Pentecostals' tendency to eschew 'politics' was interpreted as an inherently conservative, even authoritarian bent; however, with the return to formal democracy throughout much of the region, Pentecostals have shown themselves to be as divergent in political persuasion as the population at large.

Over time, as churches strengthen and institutionalize, many Pentecostal pastors and congregations are demonstrating an increasing willingness to enter the political arena, in spite of a general distaste for 'temporal' commitments outside the missionary zeal common to all Pentecostal groups. The assumption that Pentecostal belief, with its emphasis on traditional family patterns with strong male leadership, damages the cause of women's rights also has been questioned. Pentecostal congregations typically do exhort women to submit to their husbands and dress in a plain, conservative manner; however, several observers find that women whose husbands convert feel that their lives have improved dramatically. Pentecostalism's model for male behavior is a sober, responsible and faithful husband and father. To the extent that Pentecostal men forsake drinking, womanizing and domestic violence often associated with traditional, machista cultural values, women find that their domestic incomes increase and their marital and family burdens lighten (Garrard-Burnett and Stoll 1993, Cleary and Stewart-Gambino 1997, Smith and Prokopy 1999).

3. *Other Religions*

Although the Catholic church still continues to dominate the Latin American religious landscape, the region has always housed a range of non-Catholic, non-Christian and/or syncretist religious forms, especially those of African descent in areas such as the Caribbean and Brazil. Among the better known are Brazilian *umbanda* and *candomble*, Afro-Caribbean *santeria*, Haitian voodoo, and others. Given the Catholic church's historical inability to provide even the most basic of pastoral services adequately to the majority of urban and rural poor, Latin American popular religious forms always have flourished at the margins of institutional religion. So-called 'popular religion,' or religious forms that lie outside of official,

institutionalized religion, are expressions of the desire of common people to find and recreate religious meaning in their everyday lives. Popular religion arises out of people's own oral traditions, ancestral roots (native American, African, Iberian or other), class identities, community memories, and individual and collective creativity. Not surprisingly, a vast range of forms of popular religion endures, thrives, and mutates over time in Latin America (Burdick 1998).

The persistence and even growth of different forms of Latin American popular religion, in addition to the extraordinary rise of Pentecostalism in the region, has diminished the once hegemonic position of the Catholic church. There is, now in the twenty-first century, a far greater degree of religious pluralism in Latin America than ever before. Religious pluralism, in turn, will cause further changes within Catholicism and Pentecostalism as institutional churches struggle to maintain their memberships and appeal to new converts in the context of a broadened Latin American religious marketplace.

4. Conclusion

Future research on Latin American religious institutions and belief likely will head in several directions. The apparent retreat of many national Catholic hierarchies from political activism in the wake of recent transitions to democracy masks the fact that bishops throughout the region are trying to clarify the proper role of the church in changed national circumstances. How national Catholic churches will contribute to or undermine Latin American democracy remains a live question. Tensions between bishops' view of the proper role of the church and grassroots religious experience further complicate church–society relations, as do issues of gender, class and race. Examinations of both national Catholic churches and local-level case studies will contribute to our understanding of the evolving role of the Catholic church in Latin America. At the same time, the continued growth of Pentecostal and other non-Catholic religions will strengthen Latin American pluralism, to which all religious institutions will have to respond. Not only will Catholic hierarchies have to adapt to a more competitive religious 'marketplace,' but differing strains in Pentecostalism also will become clearer as some groups strengthen and institutionalize, while continuing schism fragments others.

We need to know a great deal more about individual Pentecostal churches, however, before adequate national or theological generalizations can be made. In addition, comparatively little is known about a wide range of popular religious forms found throughout Latin America. Beyond institutionalized religion and religious elites' decisions, we need to know more regarding people's lived religious lives and how their religious belief intersects with the workplace, family, and community. Moreover, how do changes in national economic strategies that profoundly affect people's daily lives intersect with individual religious belief? It is often said that religious belief and sentiment are widely held and deeply rooted in Latin American cultures. What this means in changing political, economic and cultural conditions will help shape future trends in Latin America in ways that we do not yet fully understand.

Latin American Studies: Society

1. *The West and Latin America: Similar Yet Distinct*

Latin America refers broadly to the whole of the American Continent south of the United States. It owes its name to the Latin root of the two dominant colonial languages spoken: Spanish and Portuguese. Colonized by the Portuguese and the Spanish, most of the region fought for and won independence by the mid-nineteenth century. Clearly set apart from Europe and the English white settler colonies that later became part of the group of developed countries, Latin America has stood for most of its history at the middle of the international system of stratification and (with the exception of Cuba) squarely in the capitalist route of development. While highly heterogeneous both in the past and the present, Latin America remains a laboratory for innovative policy creation and, as a region, it has also constituted a unique case for groundbreaking comparative studies. While most of Africa came to independence only in the twentieth century, and Asia chose different development routes well into the twentieth century, what is peculiar about Latin America is that very early on it embraced Western goals of development and also bore the closest resemblance to the countries that were the basis of Western development in Europe and the USA. Yet neither the will nor the tools of Latin American development were sufficient and the Western ideal has never been fully achieved.

Economically, Latin America chose capitalism and sought growth and industrialization; politically, though less consistently, it sought liberal republics and later mass democracy; and, socially, it believed in urban and modern societies. To put it more strongly, Latin American elites, and thinkers that discussed the Latin American case, believed that this region would one day look very much like the industrialized West, and that it would achieve that goal by adopting programs based on European history (retold in a stylized fashion). Yet in all of these endeavors, Latin America has proven that the notion of a continuous, linear, and consistent development route is largely wishful thinking. While other authors drawing on the European experience had challenged early on this linear evolutionary model, no region has, at the same time, both embraced and challenged this belief. Thus the fertility of Latin America, both for policy innovations and for cutting-edge research and theory is a function of the power that comes from differences among similars. The promise, realizations, and failures of Latin American development constitute a fascinating story for the social sciences and have consistently been food for thought and building stones of major academic debates in fields as diverse as economic theory, political science, and sociology.

2. *Latin American Development: Reality, Ideas, and Theories*

2.1 *The Colonial Past*

Officially Europeans arrived in what today is Latin America in 1492. During the sixteenth and seventeenth centuries, the Spanish, the Portuguese, the English, and the Dutch fought and settled in the Caribbean, Central America, and South America. The Spanish and the Portuguese Empires came to control all of South America and parts of the Caribbean and Central and North America. The Portuguese settled mostly in the Caribbean and especially in the far western part of South America and expanded eastwards, gaining dominions formerly belonging to the Spanish Empire until they controlled almost half of South America. Yet occupied with their expansion over the South Atlantic and monsoon Asia, the Portuguese were slow to consolidate their rule over these newly colonized lands. Spanish colonists, by contrast, settled into the Americas and expanded rapidly, battling the native population and creating military outposts and cities. By 1521 the conquest of Mexico and the Aztec Empire was completed with the fall of Tenochtitlan. Cuzco, center of the Inca Empire, was conquered in 1533, and Santiago de Chile was founded as early as the 1540s. The Spanish organized the new territories in the form of viceroyalties, resembling the monarchical structures of Spain. Cities were founded across the continent and organized with church, military, and *cabildos* (town council). At first gold and later silver were the major prizes that the Spanish sought in the New World. Extraction was controlled by the Spanish and performed by enslaved natives. Soon famine, poor working conditions, and European illnesses (especially smallpox and measles) decimated the native population.

Silver, gold, and, to a much lesser extent, tobacco and sugar became the central economic activities of the major cities and regions of South America in the sixteenth and seventeenth centuries. In the eighteenth and early nineteenth centuries, the expansion of the sugar economies, together with cacao, tobacco, salt, and later cattle (coffee as a staple came later in the

nineteenth century) combined with the slave trade to enable the fully-fledged entry of the region into the world economy. These developments also shaped a more complex economic and social system in which private enterprise and empire, local and international economic elites, collided, bargained, and cooperated. The 'hacienda' and the 'plantations' in which native and African labor was coerced became central ingredients of the South American and Caribbean economies and left an indelible mark on the region's elites and its people's power, status, and ideologies.

Towards the end of the eighteenth century, local elites developed both separate interests from those of the Empire and political and philosophical views that increasingly saw in Europe a limit to their growth and development. Napoleon's invasion of the Iberian Peninsula in 1808 was the spark needed for the ignition of a continent-wide movement for independence from Spanish dominion. Portugal, in turn, moved the center of its empire from Lisbon to Rio de Janeiro, and eventually, in 1822, the heir to the Portuguese throne, Pedro I, became Emperor of the independent Empire of Brazil. The colonial past of more than three centuries gave way to a new continent of independent nations. Yet for many comparativists, Latin Americanists, and historians of the region and the world, the colonial past was to be the key to understanding Latin America's future.

In addition to the socioeconomic legacies that mining, haciendas, and plantations left in Latin America, a centralized political organization permeated by patrimonialism and the hegemony of the counter-reform movement (that had been defeated in Europe but triumphed in Spain and Latin America) added to Latin America its Iberian, Catholic, and anti-positivist flavor. Historiography and later comparative studies from political science, sociology, and economics have sought to explain the roots of Latin American backwardness and the obstacles to the success of Western-type development in terms of its socioeconomic, political, and cultural legacies. The failure of liberal constitutionalism and capitalism in Latin America has, indeed, been accounted for by a black legend that places the blame squarely on the region's colonial heritage (for an exposition of this view, see Paz 1961, Stein and Stein 1970; it is reviewed and critiqued in Gibson 1971; see also Adelman 2000 for a review and discussion of this debate).

2.2 The Nineteenth Century: Independence, Civil War, Staples, and the Making of Latin America

While, strictly speaking, independence from Spanish and Portuguese dominion (with short interludes of French occupation in Mexico and English attempts in the River Plate area) ranged from Haiti's black revolution of 1804 to Panama's independence in 1903, the bulk of the independence process took place in a short period between 1810 and the Battle of Ayacucho in 1824. Most of the nineteenth century was dominated first by wars of independence and later by civil wars, wars among new nations, 'caudillo' struggles, and in a few cases the conquest of the frontiers (as in the Argentinean war of the desert). Yet an account of the nineteenth century that simply stresses the armed struggles and a sense of anarchy in the region misses the point. These were times of major intellectual debates that would have a long-lasting influence on Latin American scholarly debates and studies, and these were also times in which the oligarchic regimes and the export-oriented model of development took root in Latin America, only to be overcome in the first half of the twentieth century.

Cattle in Argentina and Uruguay; coffee, cacao, sugar, and tobacco in Brazil and Central America; minerals, coffee, salt, and fruits along the Pacific coast—such is a rough geography of the staples produced in Latin America throughout the nineteenth century. While nonlabor-intensive staples were required in the Rio de la Plata, in most of Latin America, production of staples was labor-intensive and based on haciendas and plantations. Coerced or semi-coerced labor dominated the latter, while forms of free or market-regulated labor dominated the former. Scholars that draw on the tradition of comparative work spurred by Barrington Moore came to view this original distinction between labor-intensive and non-labor-intensive regimes as a key to understanding democratic experiments (Stephens 1989, Rueschmeyer et al. 1992). On the economic side of comparative studies, the importance of staples and their forms of production are highlighted in Hirschman's unsurpassed work on development, and especially in his notions of forward, backward, fiscal, and consumption linkages. He proposes a simple yet powerful idea for understanding the nineteenth and twentieth centuries in developing countries. Staples create, or have the potential to create, forward and backward productive linkages as well as tax possibilities and consumption expansion. Depending on the staple and on the intensity, extensivity, and control (foreign or domestic) of those linkages, development will be more robust and balanced or less so (Hirschman 1958, 1973, 1981).

Regarding the politics of Latin America, this was a period of upheaval and intense ideological debates. Liberals and conservatives, landed elites and incipient modern capitalists, and disputes over territory or between warlords all combined to create a violent political and ideological melting pot. In particular, on the ideological side of the debate. a continent-wide movement of intellectuals was calling for Latin America's second independence (or what they called mental independence). Sarmiento and Alberdi in Argentina, Caballero in Cuba, Varela in Uruguay, Altamirano in México, to name a few, presented positivism and an unabashed faith in public primary education as the

tools for mental emancipation and political and economic development.

Out of the nineteenth century a continent evolved that was scarred with civil wars, squarely placed in the world economy as a producer of staples, oligarchic in nature, Iberian in flavor, but also carrying the seeds of positivism and liberalism, and the recognition of the Anglo-Saxon giant of the north as both a threat and an ideal.

2.3 Searching for Development in the Twentieth Century: Promises, Achievements, and Failures

As the period of civil wars came to a close, the future of Latin America was laid open to the world, and the region (or so its elites believed) became ready to embrace the path and gather the fruits of Western progress. Capitalism, republican order, and modern cities and citizens would fulfill Sarmiento's dream of moving from 'barbarie' to civilization. Reality proved more stubborn and, in reflecting on its failures and obstacles, Latin American scholars, comparativists from all over the world, and students of development found in the region a case study that supported, challenged, modified, or even created paradigms for understanding society, politics, and economic development.

2.3.1 Economic promise and failure: adapting, creating and recreating development economics. In the early twentieth century the per capita income of the working population in Argentina was similar to that in the UK; in Uruguay to France; in Chile to Norway; in Brazil to Italy; and in Mexico to Portugal, Finland, or Greece (quoted in Halperin 1997). Growth in gross domestic product (GDP) was higher in most of Latin America than it was in Europe, and the value of its exports per capita, higher than or similar to most of Europe. This, of course, obscures the structure of their respective economies with respect to industrialization, social development, and types of exports. Yet, these data provide a basis for understanding the widespread belief that an outward-oriented model of development based on primary exports, import of manufactures, free commerce, and little involvement by the state was the right path, and why classic economics with its Ricardian beliefs in comparative advantages was the dominant economic paradigm.

Still, if the comparison shifts from Europe to the United States the rate of growth and the riches accumulated in Latin America appear less than satisfactory. While there are different estimates, the USA had in the 1930s about four to six times Latin America's GDP per capita and had grown since independence at an average rate of 2 percent per annum while Latin America had grown at no more than 1 percent (Ramos 1993) Furthermore, while the data for Europe and Latin America suggest similar starting points, the points of arrival were starkly different. In the 1950s, Prebisch showed that, contrary to the hypothesis of convergence that classic and then neoclassic economic thought championed, Latin America had grown further apart from rather than closer to the developed countries during the period of its first orthodox model from early independence to roughly the 1930s.

When World War One dried up the flow of imports to Latin America, its economic elites moved, albeit shyly, to manufacturing and substituting some of the imports. But only with the world economic crisis of 1929 did the region make a drastic U-turn in its economic model. Import substitution was fact before it was theory, yet it eventually gave rise to the first homegrown theory of economic development that would have a lasting impact on the region and on comparative studies in the social sciences.

In 1948 the Economic Commission for Latin America (*Comisión Económica para América Latina y el Caribe* or CEPAL) was created and it brought together a number of innovative economists led by the already famous Raul Prebisch(for a synthesis of his work and a founding document of CEPAL, see Prebisch 1950). In Montecinos and Markoff's (2001) view, CEPAL's theoretical framework sought the ambitious project of establishing a new school of economic thought that would offer the basis for specific development policies for non-industrialized countries. Departing from the neoclassical economic vision of a single economic truth for all countries and criticizing some assumptions from Keynesianism (although also drawing ideas from it), CEPAL and Prebisch put forward the idea that core and periphery countries, advanced and developing countries, should seek different economic and development policies. The Ricardian comparative advantage did not benefit Latin America because agricultural products were subject to declining terms of trade. Thus the need to industrialize and to protect infant industries from outside competition was crucial in order to advance in terms of economic development. Active state involvement through industrial subsidies, tariff protection, and planning became central strategic devices for development. As CEPAL and 'cepalino' thought became hegemonic in the region, most countries adopted a model of development that has been summarized as Import Substitution Industrialization (ISI) and embraced an ideology that may be loosely defined as developmentalism (or '*desarrollismo*'). CEPAL argued that, through state protection and active planning, Latin America would overcome traditional agrarian relations and productivity and claim its place among modern industrial societies.

Yet by the 1960s what was called the easy phase of import substitution was over. Light manufactures had been substituted, yet the production of capital goods

and heavy machinery did not come about. Growth stagnated, inflation soared, and fiscal deficits became increasingly unmanageable. The most famous Latin American offspring for the social sciences was born out of the crises of import substitution and became known as dependency theory or '*dependentismo*' (Cardozo and Faletto 1979; see also the works of André Gunder Frank 1970, Theotonio Dos Santos 1970, and James Petros 1970). While *dependentismo* owed a great debt to CEPAL's idea of core and periphery and to its notion of declining terms of trade, it went far beyond these ideas. For dependency theorists Latin American underdevelopment was not simply a problem of core–periphery relations, but of the interaction of domestic and international capital and the internal class structure in the region. The monopolistic character of multinationals, the weakness of Latin America's domestic bourgeoisie, the analyses of enclave economies in which domestic resources were exploited by outward-looking elites and international capital, and the internationalization of the domestic markets were factors that helped explain a peculiar development, one that was unique to the developing nations and that rested on a domestic class structure of large rentist capitalists and a weak industrial bourgeoisie.

A group of scholars and universities in the US and in Latin America, while less visible, was also rethinking development in radical ways. In Chicago, in Mexico's *Instituto Tecnológica Autónoma de México* (ITAM), and in the Catholic University of Chile, a new brand of orthodoxy was spreading its wings: neoclassical economic thought. In radical disagreement with *dependentismo*, this group did not believe that CEPAL's shortcomings lay in its shyness to push forward state led development. CEPAL and ISI were a problem, but they had been a problem from the start. The moment Latin America had embraced state intervention, planning, and protection was the moment of the region's mistake. While dependency saw the need to deepen state involvement and to destroy agrarian elites, neoclassical thought saw ISI as the brake on Latin American development because of state intervention and because it punished those economic sectors that had a real comparative advantage: landowners who grew and sold staples.

If the Peru of Velazco Alvarado and the Chile of Allende embodied the radicalization of ISI and dependency theory, the coups d'etat of the 1970s in the southern cone of Latin America opened the door to yet another, and maybe the most radical, experiment in social and economic change. Chile, in particular, came to be seen as the first laboratory in the world for neoclassical economic revival and for the final demise of both ISI and Keynesianism. Through tariff bashing, massive privatization, labor market deregulation, and liberalization of financial markets Chile became, before Thatcherism and Reaganism, the darling of the Chicago Boys (a group of Chilean economists who had studied at the University of Chicago between about 1955 and 1963). The end of ISI and the defeat of the dependency agenda gave rise to a third phase in economic development: neoliberalism or what has more neutrally been called the New Export Model (NEM). While the jury is still out regarding the merits and shortcomings of this second drastic development U-turn, the experiments in Latin America since the mid-1970s have fed economic and social debates and these scholarly debates have contributed to a rethinking of development and developmentalism, and comparative studies in general.

2.3.2 The search for democracy and the lost republic. Orderly republics and democratic politics was another promise that Latin America sought to capture as it entered the twentieth century. Yet democracy and order have proven elusive in its twentieth-century history. While Argentina (1912) and Uruguay (1917) embraced mass democracy early, most other countries in the region experimented with oligarchic, military, and populist regimes with short and unstable periods of democracy throughout most of the twentieth century. Even Argentina, the most advanced and most 'European' nation reverted to authoritarianism in the 1930s, not regaining stable democracy until the 1980s. Chile, Uruguay, and Costa Rica (the last one especially after the 1940s) were the only Latin American countries with a reasonable, but by no means perfect, democratic record. A number of authors and scholars drew on the region to unveil the clues to democratic success and failure. Some of these scholars were specifically studying Latin America, others had larger samples, but almost all gave a prominent space to Latin America as a particularly promising puzzle.

Modernization theory was, as we shall see later, a dominant paradigm in regard to social change and development in Latin America, but its political version was also of importance and Seymour Lipset one of its major proponents. In his classic article, a simple yet powerful proposition was laid out: it was not simply capitalism that led to democracy, but also growth and social development (Lipset 1959). Following this hypothesis, Latin America was not democratic, because it was not rich. As economies developed, so democracy would flourish. By increasing the riches, creating a middle class and expanding education, countries that successfully traveled towards industrialized and modern economies would also increasingly become democratic. From another perspective, Robert Dahl and Samuel Huntington also proposed a hypothesis that would help explain Latin America's democratic failures: the lack of order (Huntington 1957, 1968, 1991, Dahl 1971). Dahl's strongest claim implied that countries that incorporated the masses before institutionalizing rules of the game would have frail democracies. For Huntington, praetorian

societies in which no order could be constructed together with the dislocation that rapid economic and social change brought about helped explain the role of the military as a constructor of order and institutions and as a major player in Latin American politics. Neither Lipset nor Huntington nor Dahl constructed their theories for Latin America. And, in contrast to the homegrown economics of Latin America, the region only produced one truly unique body of work that not only grew from the specific study of the region but that also questioned the former theories.

Guillermo O'Donnell (1979) asked why the richest nation in Latin America was under authoritarian rule in the 1960s and 1970s. Lipset could not answer that, nor could Dahl (as a matter of fact, in Dahl's classic work, he offers an *ad hoc* explanation for Argentina). In O'Donnell's view, a new form of authoritarianism was emerging in Latin America—one that grew out of the tensions and political bottlenecks that Import Substitution Industrialization had created—he called the governments that exemplified it, bureaucratic-authoritarian regimes. These regimes were meant to neutralize the demands of the middle and working classes in order to deepen Import Substitution. In contrast to Lipset, O'Donnell suggested that in rich economies, dictatorship was indeed a possibility. Even more, when ISI met dependency, authoritarianism was the natural outcome. The spread of authoritarian regimes in the 1970s suggests that O'Donnell was not far off the mark, even though these new authoritarian regimes would eventually bury, rather than deepen, import substitution (this was the case in Chile, Uruguay, and the last dictatorship in Argentina, but not in Brazil and Argentina in the 1960s).

In the 1980s and 1990s the region returned to democracy and a series of studies looking at the key to successful transitions from authoritarianism to democracy was to become a whole new field of study for comparativists. These studies renounced structural and long-term explanations of democracy and focused on the concrete choices and strategic devices that in short periods of time were used to move countries from dictatorship to open competitive regimes. The name adopted for this new field, which had as its major input the study of Latin American societies and of Southern Europe, is 'transitology.' Its major contribution to political science was the recognition of contingency and strategic action as critical factors to understand large political outcomes.

As democracies have endured in Latin America since the mid-1980s, a new body of literature has emerged regarding the issues of democratic quality. To the old notions of order and governability once championed by Huntington, this literature adds the problems of accountability and rule of the law. In addition, and as never before, the debates over party systems and executive-legislative relations have become a normal field of study for Latin Americanists. At the same time, Latin America has become a relevant region in these debates from which it was previously absent.

Finally, and after 'transitology,' a return to macro-narratives and structural interpretations of Latin American democracies has taken place. Collier and Collier in *Shaping the Political Arena* (1991) and Rueschemeyer et al. in *Capitalist Development and Democracy* (1992), return to the historical questions of democratic rule in Latin America's history. The former concentrate on the region and introduce the idea of critical historical junctures attempting to understand the stability and openness of regimes as a product of the forms and shapes of popular incorporation. The latter revisit Barrington Moore's classic work on *Democracy and Dictatorship* and construct probably the best neo-Marxist account of democracy and class struggle in the world and in Latin America to date.

2.3.3 Inequality, dual societies, poverty, and uneven modernity. According to Kuznets (1959) and his famous curve, countries increased inequality as they took off economically, moderated inequality as they entered a second industrial phase, and lowered it as industrialization and economic development further advanced. Latin America has in this area the dubious merit of being the most unequal region in the world. Indeed, the region constitutes for most scholars debating the issues of growth and inequality, a category apart: the bad Latinos, who increased inequality with economic take off but then never lowered it, and in many cases further increased it.

Besides the fact that inequality is extremely high in Latin America, other aspects of modern social development that were expected did not take place in the region or occurred in very uneven fashion. Modernization theory, with its faith in linear evolution and continuous development, envisaged countries moving from backward agrarian societies to modern industrial ones with all that this implied: urbanization; demographic transition; more complex social structures with dominant middle classes; and societies that, while stratified, had some sort of continuity and mobility chances for all the population. As the country modernized, the people would achieve and secure modern statuses and roles, moving from peasant to worker, from rural dweller to urban citizen, form caste to class, and very especially from uneducated to educated. Parsons' pattern variables characterized this fate in development. The adscriptive would give way to the elective, the particular to the universal, the affective to the neutral, the general purpose institutions to the specific purpose institutions, and so on.

A tiny part of Latin America looks, at first sight, precisely as modernization theory would expect, but Latin American societies remain largely 'dual,' combining aspects and regions of modernity with others of blatant backwardness. Incorporation into a modern

industrial society and its rules has occurred for less than half of its population. Truly, only the ISI model implied a major push towards de-segmentation, and then only in some countries. Latin America is thus unequal, dual and segmented and, for many, modernity is a curse rather than a possibility.

Among modernization theorists more sophisticated versions were developed in Latin America in order to cope and confront this reality. Gino Germani and Peter Heintz writing in the 1960s are perhaps the best exponents of this critical yet loyal twist on classic modernization theory (Heintz 1971, Germani 1962, 1971). Germani represents the most loyal representative of modernization theory and of structural functionalism as the bedrock of this theory. In his work, Germani recognizes the unevenness and the incomplete nature of social modernization in Latin America. Yet, in his opinion, this is due mainly to the asynchronicity with which the region has moved in different dimensions from traditional society to modern society. Critical to his understanding of Latin America's shortcomings is the limited capacity of the economy to incorporate migrants fully into modern labor markets and the political tension that such a reality creates. As labor, education, urban status, political citizenship, and modern consumption patterns converge, full and even incorporation of the population will take place. For Heintz the problem is less simple and has a tougher structural basis. As the upper classes or elites allow and even promote modernization, Heintz claims, they also endanger their own basis of power and privilege. Thus, elites are willing to expand and incorporate the masses only into certain areas of modernity: urban statuses and, later, education are the least threatening. Yet they are not willing to let go of their political monopoly and their economic basis of power, thus closing incorporation into modern labor markets and consumption patterns and into the state and the political system to a large part of the population. For Heintz this unbalanced development has no single solution and the point of arrival for Latin America need not be the Western ideal that modernization championed.

As import substitution and its promise of industrial modernity entered its crisis and eventually came to a close, social development was rethought from two distinct perspectives: dependency and neoclassic economics. For the former, social and national revolutions were the only route to egalitarian and robust social development; for the latter, a retreat from the state, and a return to free markets and open economies (that relied yet did not punish those sectors with comparative advantages) was the basis for social development. The late 1980s and the 1990s were under the hegemony of neoliberal faith, and a locomotive version of development in which market-led growth was the key became uncontested. Yet in the late 1990s the previous work of CEPAL and its notion of egalitarian productive transformation (*transformación productiva con equidad*), and the United Nations Development Program with its idea of Human Development reclaimed an autonomous space for the problems of poverty and inequality, and have forced scholars to rethink development as far more complex game than that of economic development (CEPAL 1990; see also the annual *Human Development Reports* published since 1990). The recent scholarly work coming from the IADB, American universities and Latin American scholars have contributed to reshape development and comparative studies all over the world (Birdsall et al. 1998).

3. *In Closing*

Latin America has remained a laboratory for the social sciences throughout its history. This is due both to the richness of its experiences and to its common traits. The Developmentalist experiment in Chile with Frei, the Socialist experiment of Allende, and the Neoliberal experiment of Pinochet are just a tiny part of the mosaic that includes the democratic exceptionality of Costa Rica and Uruguay; the reversal of development in Argentina; the resilience of democracy in violence-ridden Colombia; the oil promise and failure of Venezuela; the uniqueness of development and origins in Brazil; the Alvarado experiment in Peru; the Mexican Revolution and its unique legacy of a non-socialist one-party system; and the revolutionary guerrillas of Central America. There is thus more than enough material for comparativists searching for deviant and test case scenarios, and much more for those searching for the exception that confirms the rule. On top of that, Latin America remains a unit. A region that chose Western ideals and capitalism (again with the exception of Cuba, an interesting case in its own right) and that has always come short in its accomplishment, will always be a puzzle to solve, given our still faithful, yet neurotic dependence on a simplified version of Western development.

Two excellent recent books that adopt a similar metaphor illustrate the point. Sandra Halperin's *In the Mirror of the Third World: Capitalist Development in Modern Europe* (1997) claims that what is wrong with development theory is precisely its attempt to understand a different route of development for the Third World. Europe, she claims, was very much like the oligarchic, rentist, authoritarian Third World until the end of World War Two. While it is true that she makes her claim of similarity for all nonindustrialized countries, her major examples of the Third World come from Latin America. The region is again the test case scenario for evolutionary models of development. On the other hand, *The Other Mirror*, edited by M. A. Centeno and F. López-Alvez (2000), attempts to trace the usefulness of grand theory for Latin America. While they claim that Latin America has been absent from the grand theory debates, they recognize that

Africa and Asia have been even more absent. As one reads the book, and all its superb chapters, one is slowly convinced that their premise of Latin American absenteeism from major debates is blatantly wrong. Latin America has been at the center of comparative and development debates throughout most of the second half of the twentieth century. All the grand authors debated have had a lasting influence on comparativists and scholars that later left their mark in their different fields through the study or the privileged attention of Latin America. Some of those grand authors have, indeed, themselves, drawn on the Latin American experience of development.

Law and Aging

A notable demographic characteristic of the twentieth century, particularly in industrialized nations, has been the increase in the number and percentage of persons aged 65 and older. In the near future, 20 percent or more of the populations of Japan, the United States, and Western Europe will be aged 65 or older. This singular shift in the age of populations produces profound societal changes and presents significant questions about appropriate benefit programs for the elderly (Cockerham 1997).

Aging presents a number of challenges for law and policymaking. The elderly inevitably experience a decline in their physical abilities, which poses problems in employment and housing. Many older people suffer from chronic physical conditions that will limit their ability to care for themselves. Some suffer a significant loss of mental capacity due to dementia and other afflictions of the brain (Cox 1998). In part because of declining physical skills or the onset of a mental

condition, most elderly are retired. Even those who continue to work often experience diminished incomes because they are less productive or discriminated against in the work force. Surviving spouses, in particular women, often have reduced incomes either because their deceased spouse was employed at the time of death or because the couple's pension either ceased or was reduced at the death of the retired spouse. Because of these physical and mental changes, the elderly have special needs that nations often seek to address through social benefit programs and laws. Interestingly, law generally identifies the elderly through the use of chronological age (such as those over age 65), even though it might better identify the characteristics of aging through factors such as functional capacity, or physical and mental health (Arnold et al. 1998). Although chronological age is only a rough indicator of aging, it has the advantage of providing an unambiguous test that makes identification easier and more definitive. For example, if the nation provides an old age pension, it is much simpler to grant it to all above a certain age, rather than to identify those eligible by a more subjective categorization.

1. *Income Benefits for the Elderly*

The need to provide financial support for the elderly has spawned a number of social programs and laws. Most countries provide some sort of public pension, such as the social security program in the United States. Laws regulating the provision of pensions by employers to retired employees are also common. Some nations, including France, Germany, Italy, Sweden, and the United States, provide favorable tax treatment to encourage employers to provide pensions to retired employees or to increase the value of the pension to the employee; other nations, such as Canada and Japan totally or partially exempt employee pensions from income tax (Forman 1997). Laws mandating private pensions or altering the tax structure to encourage pensions often involve complex enforcement or monitoring procedures. Thus, the aging population has created a host of new laws and litigation in pursuit of adequate public and private pensions (Bodie et al. 1996).

Countries also address poverty among the elderly by outlawing age discrimination in employment (see *Discrimination*). Many elderly want to work, but they are denied the opportunity because of social attitudes that equate being old with being unproductive. While it is true that some elderly cannot perform certain jobs that require great physical strength or stamina, many are quite capable of being productive workers. Some want to retire from their current employment but wish to reenter the labor force, perhaps in a less demanding job. Unfortunately, custom and prejudice can be powerful barriers to elderly employment, and, while the United States has enacted laws that prohibit the arbitrary use of age in hiring and bar mandatory retirement on account of age, in most countries age discrimination against older workers is legal.

1.1 *Family Support Laws*

Some countries expect adult children to support their parents. In many countries such as Japan, older persons traditionally moved into the households of their children, who supplied care and financial support. However, many countries now have laws that require adult children to support their destitute parents or reimburse the state for the cost of their support. As might be expected, these laws are controversial and not necessarily enforced. The laws often lack support because it is unclear whether their purpose is to reduce the financial burden on government or simply to endorse the ideal that children should support their parents.

As a practical matter, family support laws seem antiquated in light of governmental welfare programs that provide income, medical care, and other forms of support for the elderly. For example, in the United States, the Medicaid health and long-term care program for the poor, which is jointly funded by the federal and state governments, specifically prohibits states from enforcing family support laws against the children in search of reimbursement for benefits paid to older Medicaid recipients.

There are also ideological objections to family support laws. Some believe that the support of the elderly ought to be a governmental function rather than a family obligation. Many commentators point out that in an intact family, the adult children will almost always assist their parents. If they choose not to, perhaps they have good reasons, such as financial instability. Family support laws cannot arbitrarily set a fair level of support in light of varying financial conditions, nor can they recognize in-kind assistance by children. Even more difficult are instances in which the older person may have been neglectful, abusive, or emotionally harmful to the child.

2. *Health Care Benefits*

Although many nations offer health care benefits for the elderly, payment systems vary greatly. Some countries favor tax-funded health care systems, while others rely on social insurance-based health care (Hennessy 1997). Most countries, including Canada, Great Britain, and Germany, have a single healthcare system, but in a few countries there is a separate program for the elderly. The Medicare program in the United States is an example of the latter.

Because of chronic health conditions and mental disabilities such as dementia, many elderly require long-term custodial care. To meet these needs, most economically advanced countries have enacted laws creating programs to subsidize long-term care for the

elderly. These include mandatory long-term care insurance, innovative housing to shelter dependent elderly, family support programs to encourage voluntary care of the elderly, and economic need-based assistance programs. All of these approaches spur activity in the private sector, as entrepreneurs seek to take greatest advantage of government aid. In turn, the government must regulate the private activity so that it does not place an undue burden on the government or otherwise pervert the aims of the government program. In short, the governmental response to a social problem creates a complex legal pattern of response and reaction.

3. *Housing Needs*

Housing is yet another area in which an aging population, experiencing declining mental or physical health and often financial problems as well, creates new challenges for the law. Some nations, such as Denmark, Sweden, and the United States, provide subsidized housing for the elderly. Sometimes housing for the elderly creates legal problems because it conflicts with laws that preclude discrimination on the basis of age or family status. Although age-segregated housing may discriminate against younger people, it also can create a safer environment and render more efficient the delivery of supportive services to the elderly (Frolik 1997).

4. *Mental Incapacity and the Law*

Aging populations force nations to confront the problem of an increasing number of mentally incapacitated elderly. Neurologic disorders such as dementia, depression, and strokes are common for the elderly and often cause loss of mental capacity (Beers and Berkow 2000). Because the legal world operates on the assumption that adults can make rational decisions, the legal system allows the creation of substitute decision makers, known as guardians, for individuals who lack sufficient mental capacity. Laws specify the process for establishing guardianship and the decisions that guardians may make for an incapacitated person.

5. *Legal Aspects of Health Care Decision-making*

Health care decision-making by the elderly can create complex legal issues with respect to who decides what is appropriate care (the patient, the physician, the family, or occasionally a non-marital partner). While the United States permits the patient to decide, other nations give the physician and the family more rights in the final decision. The most perplexing legal issue is whether health care can be terminated for a terminally ill patient when there is no further hope of recovery. There is considerable variation among countries with respect to the discontinuation of life support and who can make that decision if the patient is mentally unable to do so (Meisel 1995). While the United States has adopted laws that enable the individual to create a living will or an advance healthcare directive (documents that state under what conditions to terminate care or identify who should decide when to terminate care), almost no other countries have approved living wills or advance directives.

The law must also respond to individuals who demand the right to terminate their lives because they are terminally ill and do not want to undergo a painful process of dying. Whether patients have the right to terminate their lives is controversial. The right of a patient to terminate an intolerable life is gaining adherents and is legal, for example, in the state of Oregon in the United States. Most jurisdictions, however, do not permit assisted suicide.

Even more questionable is euthanasia, the legal right of someone to terminate the life of another, usually terminally ill individual. Though not officially legal, in The Netherlands physicians are not prosecuted for practicing euthanasia. Many contend that demands for physician-assisted suicide and euthanasia would greatly diminish if patients, particularly the elderly, were given adequate pain relief. It is not that older patients want to hasten death so much as that they fear pain. If assured that they would be given sufficient pain relief medications, even if that were to hasten death, they would not desire assisted suicide (Meisel 1995).

6. *Conclusion*

The dramatic growth throughout the world in the number of older persons has raised significant legal issues in many countries. The economic, health, and social needs of the elderly differ enough from the larger population to require societal and legal responses. Although the national responses are somewhat congruent, each country will necessarily evolve policies and practices that reflect its culture and laws. Thus while rising numbers of elderly persons is a worldwide phenomena, how the law reacts varies across the globe.

Law and Democracy

1. *The Relationship Between Law and Democracy*

The relationship between law and democracy is complex and dynamic, with philosophical, political, legal, economic, and socio-cultural dimensions. Simplifying matters greatly, one may define democracy as rule by the *demos* (i.e., by equal human beings who resolve their conflicts on the basis of procedures and laws agreed upon by themselves), and the law as more or less systematically ordered, formalized, and with rational rules of conduct backed by the threat of force by those in political power when these rules are violated. What is decisive in the deep links between democracy and the law is the fact that the *demos*—'the people'—is the political source of the law to which it, in turn, subordinates itself. In modern liberal societies it is also important to devise such a system of autonomous and general rules whose content would enable the protection of individuals and social groups struggling for their rights and the fulfillment of their interests against a misuse of authoritative power, and to enable them to participate in the political decision-making process.

Although issues related to the relationship between democracy and law have been debated in the West since ancient times, contemporary processes of democratization, and the growing recognition of cultural pluralism and differentiation, greatly contribute to this debate. Of special importance here is the collapse of totalitarian and authoritarian regimes, which has been decisive in the reconsideration of classic concepts and principles, such as the principle of the rule of law, the concept of rights, and the principle of majority rule, as well as in the formation of new democratic rights, such as the civic right to truth about atrocities committed by the functionaries of a totalitarian or authoritarian regime (see *Civil Liberties and Human Rights*; *Rule of Law*; *War Crimes Tribunals*).

2. *Key Areas of Interest and Disagreement*

Many scholars and politicians, ancient and modern, have maintained that democracy cannot exist without law; without law, democracy would become anarchy. It is also argued that democracy is fundamental to the development of the law and contributes to the compatibility of the legal order to changing political and social reality. Democracy also contributes to the validity and legitimacy of the law: to democratic procedure, legitimacy, and to political coercion. A key issue is the potential misuse of law by a democratic power—government may pose a threat to individual sovereignty and creativity.

Another key area of inquiry is whether citizens have an obligation to obey the law. Scholars take different positions on this issue depending upon the model of democracy and on the type of society that they study.

3. *Democracy and Law in Classic Debates: From the Ancient* Polis *to Liberal Democracy*

3.1 *The Ancient* Polis

Thinking on democracy and law in the West has been shaped by the issues and questions raised by ancient philosophers and politicians with reference to the aims, ideals, and the constitution of the *polis*, the ancient Greek city-state.

Three issues are most relevant for deliberations on democracy and law: (a) the civic and political culture (civic virtues); (b) the rule of law, due process, and constitutional government; and (c) the idea of superior argument in lawmaking, and its enforcement. The latter idea demonstrates a foundation of the most influential contemporary theory on law and democracy, i.e., the theory of procedural democracy.

Among the ancient thinkers and politicians, were Pericles, Aristotle, and Plato. Pericles emphasized that respect for the law results from a law making process in which people participate and in so doing, simultaneously subject themselves to an obligation to obey the law. The citizen's law, and respect for such law, lies in contrast to the arbitrary will of tyranny and subjugation to it through the use of brute force.

In his *Politics*, Aristotle (384–22 BC) observed that, if liberty is the first defining principle in the model of the democratic city state, it had to be closely related to an equality of opportunity to hold office: only equal

participation in legislation protects the freedoms and liberties of citizens. Therefore, liberal democracy relies on the principle that every citizen has an equal opportunity to rule, which in turn justifies obedience to laws made by a democratic majority, even if free citizens want to live 'as they like' (Aristotle 1981, pp. 195–8).

The most important criticism of democratic rule was raised by Plato. In one of the famous dialogs Plato (427–347 BC) challenges democratic rule by raising the question: Why is the tyranny of the majority better than that of an oligarchy or of an individual? This question returns in every debate on the issue of majority democratic institutions protecting individuals and minorities from a potential majority abuse of power (Aubert 1983, pp. 6, 7).

Despite the intellectual potential and contemporary relevance of issues and arguments raised by ancient thinkers, the institutional forms and ideas linked with the ancient *polis* have their obvious limitations. First and foremost, equality and freedom were restricted to those inhabitants of the city-state who were regarded as citizens, i.e., adult, male, and Athenian-born. Women, immigrants and, above all, slaves, were excluded from this category. These ideas lacked the modern liberal fundamental conviction that all human beings are 'individuals,' and bearers of inalienable rights. Ultimately, their empirical terms of reference were based on a relatively small and structurally simple, homogeneous society whose economy was predominantly based on slave labor, and whose members could participate directly in legislative and juridical proceedings because of the small numbers involved and their affinity with one another. Nevertheless, the issues raised by ancient thinkers and politicians have set a framework for debate, as well as an ideal for institutional arrangements in modern times.

3.2 Liberal Democracy

Questions and arguments concerning the relationship between democracy and the law have been especially important under conditions of rapidly growing social differentiation, of changes in social integration accompanied by diffusion of ownership, and of a developing free-market economy. This last condition entails the formation of a relatively broad class of producers and merchants on the one hand, and the growing complexity and centralization of an impersonal, bureaucratic state apparatus on the other. These conditions characterize liberal democracy in the West. Although classic, these questions and arguments—informed by processes of modernization—are reflected in basic institutional arrangements, predominantly in the constitutions of contemporary liberal democracies.

There are two important issues connecting law and democracy within the set of institutional arrangements defined as liberal democracy. One is presented by conflicting interests, the other by protection of individual rights.

In a rapidly changing, diffused society characterized by conflicting interests, relations between citizens themselves, as well as relations between citizens and the state, are developing new forms of the concept of the social contract. These relations also require specific forms of law—a medium through which compromises among conflicting interests can be struck. Moreover, they require a law with attributes of generality and autonomy in order to reflect changing social values and power relations. In the words of Unger (1976, pp. 68, 69), in liberal societies the law somehow accommodates antagonistic interests, and its procedures are such that anyone might find it in his or her own interests to subscribe to them regardless of the ends one happens to be seeking. Therefore 'the liberal type of social organization generates, and is reinforced by, a style of consciousness whose substance is the image of society as an arena of conflicting subjective interests.'

Thoughts concerning the idea of a social contract as a foundation for political institutional arrangements which accommodate antagonistic interests, and the delegation of legal sovereignty crucial for the validity and legitimacy of law and its observance are to be found in the writings of Thomas Hobbes (1588–1679). These ideas were developed and supplemented by John Locke (1632–1704), Charles Louis de Secondat, Baron de Montesquieu (1689–1755), Jean-Jacques Rousseau (1712–78), James Madison (1751–1836), Jeremy Bentham (1748–1832), James Mill (1773–1836) and John Stuart Mill (1806–73).

Generally, according to proponents of the classic model of liberal democracy, the activities of a democratic government are to be limited and controlled, since the sole aim of the state is to preserve the 'life, liberty, and estate' of its citizens (Locke 1960), or, as emphasized by John Stuart Mill, to protect the free development of the individuality of every citizen. This is possible in the form of a limited, constitutional government, subordinated to the law, whose activities are also subject to the mutual checks and balances of autonomous branches of government—in the highly developed doctrine of Montesquieu, these are the checks and balances of the legislative, executive, and judiciary powers (Montesquieu 1952).

In the public sphere of relations between citizens and the state, the idea of a contract concluded by free and formally equal citizens, together with the 'extended' franchise (initially understood as applying to male property-owing citizens), legitimizes the political and legal sovereignty of the government. These ideas are closely linked both to the notion of liberty, i.e., freedom within legal limits, and to the notion of natural, universal, and inalienable public rights of citizens whose activities are governed by reason, and who participate, directly or through their representatives, in the legislative process.

Classical thinkers located the source and foundation of individual rights and liberties in the idea of natural law as a 'higher' than man-made, positive law (see *Natural Law*). Natural laws were defined as those discovered by reason, i.e., by rational citizens acting under conditions of freedom according to the arguments of the German philosopher Immanuel Kant. However, they were also understood to be of divine origin (Locke 1960, p. 311). For Montesquieu, natural laws discovered by reason were to be interpreted in the context of local customs and traditions (Montesquieu 1952, p. 32). The utilitarians Jeremy Bentham and James Mill enunciated clear formulas of natural laws as the maximization of individual satisfaction whose source was the natural tendency of human beings to pursue individual happiness and interests, and to avoid suffering (Bentham, *Fragment on Government*; James Mill, *An Essay on Government*).

In the classic model of liberal democracy (based on the primary importance of protecting individual property rights and the utilitarian maximization of individual profits), the 'haves' are protected first and foremost, and individual goals and interests dominate the constitutional, democratic state. The concept of equality proposed by the classic thinkers, and written into the first liberal constitutions, was therefore initially still very restrictive. Only male property-owners had a right to vote or to hold public office. However, John Stuart Mill, in discussing the right to the development of individuality referred also to women and minorities, and connected this right with a postulated broad franchise (John Stuart Mill, *On Liberty*, 1982). Those postulates became enshrined in liberal constitutions.

Different ideas on the contract, the legitimacy of the law, civic virtues, civic commitment, and public government were proposed by the first representatives of the republican version of classic democracy. First, the notion of contract was understood not as a legal fiction, but as a real contract, closed by the people, in public debate and referenda on the most important public issues. The issue of civic virtue and of civic duties, and the notion of a citizen as an unselfish, committed participant in public affairs, was emphasized by Jean-Jacques Rousseau. Advocating direct participation in legislation, and defining the equality of citizens as economic independence and material security, Rousseau opted for the model of a discursive democracy (Rousseau 1973).

4. *Liberal Democracy and Law: Contemporary Issues*

'Liberal democracy was the first great secular religion in the Western history' (Berman 1983, p. 32). However, new problems in the relationship between democracy and the law have been created by the large-scale, complex, densely-populated, culturally-pluralistic, and differentiated modern societies which developed after the industrial revolution. Three different issues are most important for the current debates on liberal and democratic institutional arrangements. The first of these concerns the principle of equality which has an impact on public debate and civic engagement in the democratic process. The second issue is presented by the growing differentiation of law because of its adaptation to a complex and pluralistic, modern democratic society, and efforts to interpret universal legal standards and principles in light of local experiences. The third issue involves the growing concern with human rights protection.

One of the main questions raised in contemporary debates on liberal democracy primarily concerns the concepts of equality and justice which are no longer defined only in terms of formal justice, but rather in substantive terms such as equal opportunity, and even affirmative action and positive discrimination designed to achieve social justice. Debates about social justice point to the growing scope and range of state intervention and its consequences for law, on the one hand, and the civic engagement of the democratic electorate on the other.

It is argued that the political organization of the democratic welfare state challenges the universality and autonomy of the law, as well as its democratic legitimacy. The law becomes an instrument of state intervention, characterized by a growing number of particular substantive goals. Authors such as Unger in the United States, or Luhmann in Germany, have pointed to the specific consequences of state interventionism for democracy and law. According to Luhmann, political inclusion—i.e., the subordination of an ever-growing range of social relations to the intervention of the political democratic system of the welfare state—imposes new public tasks on the state which is considered responsible for the well-being and quality of life of its citizens. This results in rising social demands for new standards and new regulations of ever more broad and particular issues, from a minimum wage to the functioning of kindergartens, and to the regulation of public space, expressed not in the form of citizens' rights, but of citizens' claims on the state (Luhmann 1990).

This phenomenon is described as the 'socialization of the law,' on the one hand, and 'juridification' or 'legalization' of social relations on the other. These new developments led to changes in the form of legal regulation and legal intervention, and in relations between the legislative, judiciary, and executive branches of government. The integrity and autonomy of the legal system is challenged by increasingly specific demands for interventionist legal regulation and the necessity of *ad hoc* reactions to changing social needs. Moreover, instrumental legislation is produced to an ever increasing extent by governmental agencies in the form of administrative prescriptions, based on a concern for technical efficiency in the fulfilling of state

tasks of social protection—not exclusively on democratic legitimacy, and certainly not on some deeper transcendental or cultural reasons why it could be very difficult to agree in a complex, pluralistic, and culturally deeply differentiated society. A consequence is the technical nature of legal regulation; the standards on which it is based preclude public debate on the contents of the law, and could result in the growing passivity of a democratic electorate.

According to Unger, post-liberal, policy-oriented legal reasoning and discretionary justice challenge legal formalism and lead to the development of more flexible legal institutions which reflect and enhance a strong sense of community (Unger 1976, pp. 194, 196).

In the light of totalitarian and authoritarian experiences, it is, however, important to note that, in modern and complex societies, a strong sense of community may be imposed from above by a highly centralized government, and by political propaganda. Discretionary justice, based on some politically-supported standards could easily turn into repression and violation of human rights, if universal standards and autonomous law are not strong enough. This was well-illustrated by Nazi Germany, and by the so-called 'people's democracies' in Eastern Europe and the Soviet Union. In the latter, 'socialistic legality' was understood, on one hand, as the conformity of instrumental regulation to an ideology interpreted by the higher ranks of party functionaries, and, on the other, on the observance of rules by society and the lower echelons of authority (Damaska 1986, p. 197).

Increasingly technical legal reasoning, together with the growing complexity of democratic institutional arrangements, is challenged by new developments and ideas on democracy and law. One observes the growing importance of judicial review—above all, of constitutional review—as controlling not only the application of law in individual cases, but also the conformity of governmental decisions and parliamentary legislation to the constitution. Therefore, instead of a clear separation of powers, a functional interdependence of the legislative, judicial, and executive branches of government characterizes modern democracies.

Another important feature of late modernity is the impact on law-making of lobbying groups, NGOs, or spontaneous social movements representing civil society. These new developments seem to be both inevitable and benign, but the pluralism of values and lifestyles and the increasing differentiation of collective interests raise the question of how a social contract is possible.

In an attempt to solve this problem German philosopher and social theoretician Juergen Habermas postulates that discursive and procedural legitimacy of legal and political institutions should be justified not in terms of common values, but in procedures regulating the free and unconstrained public debate on values and norms, open to every citizen at any time (Habermas 1986, 1992). According to this view, norms are considered justified only if they can stand up to an unlimited and unrestricted debate.

The model of procedural democracy and the proceduralization of law leaves some questions open. The legal and political systems of modern democratic societies are not only flexible but also fragile. Their institutional arrangements and interpretations of norms depend on the results of debates and deliberations, or are left unresolved because common understanding or compromise cannot be reached. Questions remain about (a) legal certainty and legal security as components of the rule of law principle, (b) more stable and reliable foundations for the adjudication and legitimation of the democratic state ruled by law, and (c) constraints on political and judicial deliberations.

In contemporary democracies, stable foundations for the legal as well as political system are sought in the concept of rights. This increasingly more important approach to law—called 'new personalism' (Friedman 1990, p. 44–46)—refers to inalienable human rights as a higher standard for the evaluation of democratic and legal systems; these would serve as a final test of democratic and legal order.

To conclude: the relationship between democracy and law in modern, complex, and pluralistic societies must be analyzed and evaluated with reference to universal standards—encompassed by human rights—interpreted and applied in the changing social and differentiated cultural conditions of the modern world.

Law and Development

1. *Law and Development in the Beginning*

'Law and development' is a term usually used to describe legal assistance programs for developing countries and the related academic work. The movement as such, began in the 1960s with overseas projects funded by various foreign foundations and development agencies. Legal scholars at leading American law schools, as well as in some European institutions soon adopted the topic as an academic field. Following foreign aid patterns of the time, the movement primarily focused on Latin America and Africa. It sought to aid developing countries by promoting changes in laws and legal systems to make them more 'modern.' Paralleling the then popular and now defunct modernization theory, this law and development paradigm presumed that as these countries developed, they would construct legal institutions and cultures similar to those that spurred economic and political development in the West. The law and development movement assumed that convergence on the Westernized notion of the rule of law could be hastened by external assistance.

American scholars sought to develop a theory of the role of law in state and market development that could be integrated into general modernization theory. To that end, they drew on Max Weber's historical explanation of the rise of capitalist societies in Western Europe (Trubek 1972). Weber's theory asserted that in addition to the 'Protestant ethic,' the rational, formal, and logical legal system was necessary to provide the stability and predictability in economic exchange, and the protection of property rights, which facilitated economic innovation. Weber's work suggested that law would best contribute to capitalism if it was based on universal rules uniformly applied, contract law guaranteeing the security of future exchanges, and property law capable of protecting the fruits of labor.

However, this model of legal development did not fit squarely with the spirit of the 1960s and the needs of the development agencies. In an era in which development policy favored a strong and proactive role for the state, a legal theory was needed that would promote the use of law as an instrument to modernize society. In such a vision, lawyers, and judges were seen as social engineers, who would cultivate the legal norms and the changes in the formal system of law needed to promote progressive political and economic development. The emphasis on law as an instrument of a modernizing state and the Weberian idea of a set of formal rules that guaranteed predictability did not sit easily together. To bridge the gap, law and development scholars produced a hybrid theory, dubbed by some 'liberal legalism' that sought to unite a faith in the rule of law with a commitment to aggressive social engineering. It was assumed that this hybrid was the prevailing ethos of US legal culture, and if exported to the developing world it would hasten progress towards modernity. As a result, the emphasis of foreign aid was on legal education, and training was done by Western scholars and at universities in the US and other developed 'first world' countries. It was assumed that if the ideas taught in developing country law schools could be changed, then the behavior of lawyers would also change. If the right laws were created, they would be enforced and if the positive benefits of the Westernized 'rule of law' could be demonstrated, then it would be embraced.

In the mid-1970s, however, a series of articles appeared that challenged the original ideas of the law and development movement (e.g., Trubek and Galanter 1974). These articles reflected a growing unease among scholars regarding the assumptions and prescriptions of legal liberalism. A decade of experience with the original approach showed there were serious problems with the strategy of transplanting foreign legal models through an elite-driven approach that did not coincide with the cultural, social, and political contexts of the developing countries (Burg 1977, Merryman 1979). The failure of legal transplants and the stigma of 'legal imperialism' (Gardner 1980) convinced many that the movement had got off on the wrong foot.

As experience accumulated, scholars began to realize that the enterprise had not been guided by a robust theory of the relationship between law, and economic and political development. Critics pointed out that what passed for law and development theory was a somewhat idealized projection of the self-understanding of US and other developed country lawyers, concerning the role of law in their societies. This was combined with a simplistic model of history that presupposed causal and linear relationships between the evolution of a 'modern' legal system and market democracy. Needless to say, no empirical evidence was ever produced to support this theory which was little more than a romantic and ethnocentric projection of a

developed country legal culture's ideal of itself. It became clear to some that the movement suffered from an entrenched ethnocentrism and naïveté (Trubek and Galanter 1974).

This critique was intended to strengthen law and development scholarship by distancing the academic project from immediate activist policy agendas and encouraging the development of more systematic empirical research and conceptualization. The hope was that in the long run the academy could come up with better and more effective ideas for legal assistance to developing countries. But that was not the result: rather, this critique helped kill the nascent academic project. The critique was taken by many to be a denunciation of the movement. Moreover, it came at a time when the aid agencies were losing interest in law for other reasons, and when US intellectuals had become especially sensitive to charges of meddling in foreign countries as a result of the Vietnam War protests. As a result, the law and development movement lost its momentum. Comparative legal scholars turned their attention to other pursuits, funds for law and development programs dried up, and after a 'short, happy life' the movement was presumed dead.

2. *Law and Development Reawakened*

The 1990s revealed, however, that the law and development movement was not dead, but merely in hibernation (Tamanaha 1995). While some law reform activities continued throughout the 1970s and 1980s (such as USAID judicial assistance programs and foundation support for public interest law in developing countries), it was the end of the Cold War and the collapse of communism in Eastern Europe and the former Soviet Union which incited a 'rule of law revival' and gave new life to external assistance in legal and judicial reform (Carothers 1998). At the twentieth century's end, if all the current 'rule of law' portfolios of the World Bank, regional banks, major nongovernmental organizations and foundations, the US Agency for International Development (USAID), and other bilateral aid institutions and local counterparts were added up, it would equal several billion dollars worth of assistance funds being spent on law projects.

The current law and development movement emerged from the confluence of two broad forces that came to prominence in the post-Cold War era. The first of these could be called 'the project of democracy' and came out of the human rights movement of the 1970s and 1980s. The international community made great progress in specifying human rights norms, creating machinery for international action to enforce them, and ensuring that internationally recognized human rights became a part of the discourse of domestic politics in many countries. Events such as the Helsinki process drew attention to the lack of protection for human rights in domestic institutions. This highlighted the need for legal change at the national level to ensure that human rights would not only be nominally secured in the letter of the law, but would also be protected in practice. These universal human rights, in addition to the 'Third Wave' of democratization (Huntington 1991) drew attention to the need for constitutional protections for civil liberties, the independence of the judiciary from potential corrupt and weak states, and the guarantee of equitable access to justice for all of civil society.

The second—and stronger—force propelling the 'new law and development' was based on economic reform. While the burgeoning international human rights regime and democracy assistance sustained the notion of foreign legal aid in the name of justice throughout the 1980s, the dramatic revival of the law and development movement in the 1990s took on a decidedly economic character. The catalyst was the collapse of communism in Eastern Europe and the former Soviet Union, and the subsequent failure of shock therapy to produce a successful transition to the market through a tripartite plan of liberalization, stabilization, and privatization. Development specialists began to claim that initial reform strategies had failed due to a lack of attention to the 'institutional preconditions' of a capitalist economy. Foremost among these were the appropriate legal institutions.

The empirical lessons of the post-Communist transition coincided with the increasing popularity of new institutional economics, based on the Nobel prize-winning work of Douglass North, among others. In his *Institutions, Institutional Change and Economic Performance*, North (1990) argues that as economies develop from 'traditional' to 'modern,' rational economic actors seek to construct institutions that among other things will protect property rights and reduce transaction costs by providing credible and efficient means of contract enforcement. These legal institutions (both formal and informal) create incentives for rational economic actors to engage in increasingly complex modes of exchange conducive to furthering economic growth. In North's theory, it is the absence of such modern legal institutions that explains the lack of economic development in the Third World (North 1990, pp. 64–5).

Consistent with the 'Washington Consensus,' embedded in the development ideology of the Bretton Woods Institutions, this economic theory reaffirmed the role of law in creating and protecting an enabling environment for the development of the market. Unlike the previous law and development movement, when state-led economic development theories were in vogue, in this approach the state plays a largely passive role and the law assumes an autonomous and proactive role in providing the 'legal foundations of capitalism' (Commons 1924) while at the same time monitoring and constraining the arbitrary use of power or the excessive use of regulation by the state. In the context of globalization, this role of law and the

formal legal system is deemed critical to establishing the 'good governance' necessary for attracting foreign and domestic sources of private investment (Shihata 1997). In this approach, we are back to Weber, shorn of the activist, social engineering gloss of the 1960s 'liberal legalist' hybrid.

The strategies of the new law and development movement, aimed at the dual projects of human rights and markets, reflect a widened scope of legal and judicial reform. While much of external assistance continues to target legislative drafting, legal education, training, and the professionalization of the bar (including exchange trips), reform activities place more emphasis on the effective administration of justice. This includes the efficient management of cases, increased access to justice through the construction of alternative dispute resolution mechanisms, enhanced means of enforcing judicial decisions, and the promotion of judicial independence. Moreover, broader legal reform projects seek in certain contexts to create a demand for a rule of law where one is perceived to be absent (as in much of the former Soviet Union) by constructing public awareness campaigns and building domestic consensus and support for reform efforts.

3. *Comparing the 'Old' and 'New' Law and Development: Lessons Learned?*

The revived legal reform agendas do not avoid the ethnocentric, 'imperialistic' nature of the old law and development movement. There is an over reliance on legal technical assistance, which tends to neglect the deeper political and cultural environments shaping the legal systems. There is still a faith in legal transplants, a belief that Western lawyers can design systems that will work in emerging markets and new democracies, and a stress on education. However, there are also signs of dissent from this orthodoxy. For example, some activists profess to avoid the mistakes of the past by engaging in more participatory work with civil society groups, build upon existing grassroots legal reform efforts, and generally working as much as possible within the existing legal infrastructure. Critics have also rediscovered the old critique of legal transplants. It is increasingly recognized that in the absence of a clear demand from key societal actors and reform strategies that build upon (rather than against) the rooted legal culture of a country, 'supply-side' legal reform efforts focused on constructing new laws and institutions, will be insufficient for the task of creating and consolidating a rule of law (Hendley 1996).

While these breaks in the law and development orthodoxy are welcome, they represent a minority voice. The faith in legal change through top-down reforms supported by Western legal expertise remains strong. The idea that there is one best way to build the legal institutions for markets and democracy is still pervasive, as is the faith that this path has already been trod by the rich countries of the West which stand as models and as sources of expertise. People still believe that Western laws can be transplanted *tout court* to countries as diverse as Brazil and Bangladesh.

The continuing faith in law and development orthodoxy comes as no surprise. The leaders of the West have decided that the rule of law is essential for both emerging markets and new democracies. As a result, the international and bilateral development agencies are committed to legal reform on a global scale. To implement these programs in all the countries they deal with, these agencies need relatively simple models that can be easily supported by the traditional tools of foreign assistance. The last thing they want to hear is that each country is unique, that there is no easy answer to what laws and what legal system reforms are needed, or that Western expertise is of dubious value.

Billions of dollars have been spent on reforms that are guided more by intuition and hope than by any systematic knowledge or empirical evidence. Projects still rest on assumptions criticized in the 1970s. Will history repeat itself? Will the cry for a more independent and critical academic examination of 'law and development' still go unheard? While the academic side of the 'new law and development' remains modest at least in contrast to the scale of the assistance effort, at the beginning of the twenty-first century there are signs that a critical and autonomous endeavor may be taking shape in the academy.

If so, there are several questions that must be dealt with. First, scholars should study the microfoundations of the so-called 'rule of law.' The old law and development movement was a very top-down effort. It was assumed that law was a universal boon for all classes. It assumed that if the elite said they favored the rule of law, they meant it. It was assumed that most people would see law in a positive light so that legal reform would enjoy popular support. Needless to say, none of these assumptions were correct in the 1960s, yet they still pervade policy circles at the turn of the century. Scholars should investigate how various social interests benefit from law and legal order, and how interests can be mobilized to build and embed the rule of law while ensuring that legal orders do not just favor the strong and the rich.

Second, scholars must ask to what extent can there be a true trans-national discourse on law and development. Is it possible to create useful and authentic knowledge about law and development that is based on theory and has relevance beyond a single country or even a single field of law in one country? One of the cardinal accusations levied at the old law and development movement was that it tried to impose an ethnocentric bias for Western law in the guise of academic knowledge. As we approach the task of refining the new law and development, we have to be careful to avoid that trap. It is tempting to see the legal institutions of our own society as a model for

emulation by developing nations, albeit with a lag to allow for evolution to do its work. This is even more alluring when to do so happens to foster our national interest in shaping foreign markets in ways that will be congenial to Western capital and our own national firms in particular. To avoid this fallacy, the new law and development should be tentative, situational, and dialogic. We should be careful not to project our own past on others and idealize our own society. We should seek to develop knowledge only in conjunction with those directly affected by our 'science' in a truly transnational environment.

Finally, the academy needs to address the normative vision that guides scholars and activists working on law and development. The law and development movement has multiple and potentially conflicting goals. On the one hand, the promotion of democracy and human rights through legal and judicial reform promises greater access to justice and a means of enforcing accountability and transparency. On the other hand, legal reform efforts aimed at creating a market-friendly environment attractive to foreign and domestic investors (such as the growing attention to alternative dispute resolution mechanisms and the funding of economic legislative drafting) can overshadow or crowd out the social and political dimensions of reform. Even more dangerous is the possibility that market-driven legal reform that benefits an economic elite minority may run counter to democracy-oriented reform goals that are geared towards a politically powerful but impoverished majority, with the resulting potential for ethnic tensions or conflict (Chua 1998). The academic community must always be sensitive to potential conflicts, and ensure that the enterprise promotes fairness as well as efficiency, and democracy as well as markets.

Law and Economics

Under the economic approach to the analysis of law, two basic questions about legal rules are addressed: descriptive questions, concerning the effects of legal rules on behavior and outcomes; and evaluative questions, concerning the social desirability of the effects of legal rules. In answering these questions, the method employed is that used in economic analysis generally. Namely, individuals and firms are ordinarily presumed to be forward-looking and rational, and the framework of welfare economics is adopted to assess the social desirability of outcomes. The field of economic analysis of law may be traced significantly to Bentham (1789), but lay essentially dormant until the contributions of Coase (1960), Becker (1968), Calabresi (1970), and Posner (1972). The field is now rapidly growing, although it is far from mature (one indication being lack of empirical work). To illustrate the approach, this article first focuses on accident law, briefly considers other areas of law, and concludes with a section on basic foundations and criticisms of the economic approach.

1. Economic Analysis of Law Illustrated: Accident Law

By accident law is meant the law governing liability for accidents, that is, the rules determining when a party who causes an accident must pay for the harm done. Economic analysis of this branch of law centers

on three issues: incentives toward safety; insurance and compensation of accident victims; and litigation-related costs.

1.1 Incentives Toward Safety

A major effect of the liability system is that it fosters the taking of precautions against accidents. Suppose that a precaution will lower accident-caused harm for which a party would be liable from $3,000 to $2,000, that is, by $1,000, but costs less than this amount, say $500. The party would then be likely to take the $500 precaution, as it would reduce the party's liability expense by $1,000. Such logic underlies the conclusion that, under many forms of liability, parties will be led to take socially desirable precautions.

An important qualification about the general point that liability creates incentives toward safety applies to accidents caused by firms' products. In particular, a firm's interest in its reputation may lead it to take proper precautions even in the absence of liability. If a firm's water heaters tend to fail and consumers know about this, they will not pay as much for the heaters, and thus the firm will have a motive to reduce the risk of heater failure in order to avoid having to accept a lower price. Note, however, that this argument depends on consumers' obtaining information about product risk.

1.2 Insurance and Compensation

The role of insurance in the context of accidents and liability is of substantial importance due to the widespread ownership of insurance. A major form of insurance is liability insurance, which provides coverage against legal liability. Because liability insurers pay for much of the losses for which injurers are found liable, it might initially be thought that liability insurance largely negates the incentives toward safety inherent in liability. However, some such incentives are preserved under liability insurance because insurers often link premiums or conditions of coverage to the adequacy of precautions, raise premiums on the basis of accident history, and offer only partial coverage against liability.

In addition to liability insurance, standard insurance for victims, that is, their (private or public) medical, life, disability, and property insurance, is of significance. The prevalence of victims' insurance limits the need for the liability system as a means of assuring victims compensation for accidents.

1.3 Litigation-related Costs

The litigation-related costs of the liability system are the legal fees and associated expenses (including litigants' time and effort) borne by parties in resolving disputes that arise when harm occurs. Litigation-related costs are high; for every dollar received by a victim, it appears that over a dollar is spent delivering the dollar to the victim.

1.4 Evaluation Under the Economic Approach

Under the economic approach, the liability system is considered to be socially worthwhile where its social benefits exceed its litigation-related costs. The social benefits of the liability system do not lie significantly in compensation of victims, because standard forms of insurance for victims are a cheaper means of compensation than the liability system. Rather, the social benefits of the liability system reside largely in its influence on accident rates. If this accident reduction effect is sufficient to outweigh litigation-related costs, the liability system is socially worthwhile. For example, the liability system might be socially worthwhile in the area of industrial pollution—perhaps the desire to avoid liability induces firms to reduce substantially polluting activity. However, the liability system might not be worthwhile in the area of automobile accidents—perhaps the prospect of liability does not affect driving behavior, which is mainly influenced by fear of personal injury in accidents.

1.5 Traditional Analysis Contrasted with Economic Analysis

The traditional view of the liability system is that its primary effect, and its major warrant for existence, is the compensation of victims of harm. This view is at odds with the economic view. On one hand, as just emphasized, compensation is to a great extent accomplished by standard forms of insurance; and, because insurance is a less expensive means of compensation than the liability system, it would be economically unwise to employ the liability system for the purpose of achieving compensation. On the other hand, the inducement of safer behavior is usually not paid serious attention under the traditional view of the liability system. Hence, the prescriptions for use of liability under the two views may conflict. Under the economic view, but ordinarily not under the traditional view, the recommendation is that the scope of liability be reduced where liability has little influence on accident frequency, and that the scope of liability be increased where liability would substantially reduce accident frequency.

A second, related aspect of the traditional view is that liability is intended to ensure the attainment of corrective justice in the classic sense that a wrongdoer should be punished by being made to pay the victim for harm done. From the economic perspective, this

conception of the purpose of the liability system is problematic even in a descriptive sense. As stressed above, a party who is found liable usually does not pay a judgment himself but has his liability insurer pay; if there is punishment, it might be that the party is not fully covered or that his liability insurance premiums may rise. Hence, the degree to which a wrongdoer is punished owing to liability is not direct; it is attenuated and translated in character by liability insurance. Additionally, the victim often does not receive the payment made by the liability insurer; rather it is the victim's insurer that frequently obtains the payment (as reimbursement for the payment that the insurer made to the victim earlier). In all, then, the liability system does not achieve corrective justice in the way contemplated by traditional analysts, because they overlook the effects of liability and of victims' insurance.

2. *Economic Analysis of Other Areas of Law*

In this section, the contours of economic analysis of other major areas of law will be indicated.

2.1 *Property Law*

A fundamental topic in economic analysis of property law is the justification for the very existence of property rights. From the economic point of view, these rights are said to exist because they promote incentives to work, to maintain and improve things, and to trade; and, as well, because the rights reduce problems of wasteful and destructive efforts to take things and to prevent takings. Some economic literature traces historical instances of the emergence of property rights (especially in land) and certain recent property rights developments (for example, in the broadcast spectrum) to these social advantages. Property rights are seen as beneficial due to their salutary effects, not to any intrinsic belief that a person should own the fruits of his labor.

Given the general basis for the existence of property rights, many issues pertaining to property law have been addressed from the economic perspective. One concerns acquisition of property rights in things not yet owned, such as fish in the sea and undiscovered mineral deposits. Here, a theme is that the 'finders-keepers' rule has the advantage that it creates incentives to find things. Yet these incentives may be socially excessive: individuals may engage in duplicative activities to find things (a large number of fishermen may compete for fish that a smaller number could easily catch; many parties may drill oil wells, even though a small number of wells would be sufficient to extract the oil from a reservoir). When this is so, it is suggested that regulation (limiting the catch of fish, 'unitizing' ownership of an oil reservoir) may be desirable to curb the problem of excessive effort.

Another issue of interest concerns external effects associated with the use of property. These 'externalities' may be detrimental, such as pollution or noise creation, or beneficial, such as beautification of land or spraying to kill mosquitoes. Bargaining among affected parties may sometimes resolve externality problems. Suppose that a factory causes annual pollution harm of $10,000 to its neighbor but can prevent the pollution by installing scrubbers at an annual cost of $1000. In the absence of legal rules preventing pollution or imposing liability for it, the victim of the pollution might be expected to pay the factory to obtain scrubbers in order to avoid suffering harm. The victim should be willing to pay more than $1000 (perhaps $2000) for the factory to obtain scrubbers. Hence, a legal rule requiring the factory to install scrubbers, or a rule imposing liability for harm, may not be needed to achieve the result that the factory obtain scrubbers. The general possibility that externality problems may be avoided through bargaining, and that legal rules may not be necessary for their resolution, is known as the Coase Theorem, and was advanced in Coase (1960). However, much economic writing discusses reasons why bargaining may not cure externality problems: costs of bargaining (especially significant when the number of affected parties is large), breakdowns in negotiation (often arising when one side misgauges the other's situation), victims' lack of knowledge of danger (suppose the pollution is not apparent). Because bargaining will often fail to solve externality problems, attention has been paid to the use of legal rules (particularly liability rules, regulatory requirements, property rights) to accomplish their amelioration.

A very different issue in economic analysis of property law involves public property, which is to say, property like roads and libraries that the government needs to supply because the private sector will not provide them, or not in appropriate quantity. In this connection, the legal system sometimes allows the government to take land through its powers of eminent domain, but requires it to pay compensation for its takings. According to economic analysis, the power of eminent domain may be socially desirable where government would have undue difficulty in making purchases. A standard example is that, in trying to purchase land for a road, government would be likely to be stymied by even a few landowners on the road's planned path (landowners might be tempted to hold out for strategic reasons). The requirement that government compensate for takings cannot be justified as it sometimes is, as an implicit form of insurance against takings; for, in the absence of a compensation requirement, individuals doubtlessly would purchase insurance against takings. A possible advantage of the requirement of compensation for takings is that it may

discourage government from ill-advised takings, though that argument has been criticized.

Another area of property law concerns intellectual property rights: the law of patents, copyright, and trade secrets. The main theme of economic analysis of this body of law is that intellectual property rights have the beneficial effect of spurring innovations, but the detrimental effect associated with high prices and lower than socially desirable sales of goods incorporating the innovations. For example, economic thinking suggests that the copyright doctrine of 'fair use,' permitting for instance limited excerpting from a book for inclusion in teaching materials, might be socially desirable. This excerpting probably does not reduce book sales or the financial motive to author books (indeed, limited excerpting might increase sales of a book because it serves as a form of advertising), whereas the excerpting benefits teaching, because it means that teaching materials can be rapidly assembled without added cost. Most rules of intellectual property law are viewed against the background of their influence on incentives to innovate and on the sale and dissemination of goods embodying innovations.

2.2 Contract Law

A primary issue addressed in economic analysis of contract law is that of contract formation. The basic rule of contract formation is that a contract is legally recognized when and only when both sides have given explicit assent, such as by signing a document. This rule is said to be desirable for two reasons. First, it obviously enables parties to make a contract. Second, it protects parties from becoming bound against their wishes due to their having engaged in negotiations; this protection against unwanted obligations is beneficial because, without it, the negotiations that lead to the making of contracts would be inhibited.

Another issue surrounding contract formation concerns legal duties to disclose information. Economic analysis emphasizes that the social desirability of disclosure depends on the situation. For example, disclosure of a material defect (such as a leaky basement) in the home that the owner seeks to sell tends to be beneficial; for if the buyer knows about the defect, he can take steps to avert harm (avoid storing valuables in the basement or repair it). But should an oil company that learns, through costly investigative effort, that oil lies under a parcel of land, be required to disclose this information to the seller of the parcel? Perhaps not: the effect of such a disclosure obligation would be to make oil companies pay substantially more for parcels of land that they learn are romising, and thus to discourage expensive investigation of the location of oil deposits. Note from the foregoing that the economic analysis of legal rules about disclosure obligations concerns their effects on outcomes and does not derive from a possible moral call to tell the truth.

The most developed aspect of economic analysis of contract law deals with enforcement of contractual agreements. Enforcement is accomplished mainly by requiring parties who commit breach to pay the victims of breach for harm, to pay them 'damages.' One effect of the requirement to pay damages is that it induces contractual performance, which tends to raise the value of contracts to the parties and to society. A less obvious advantage of damage payments is that they constitute an escape hatch that parties can use when contractual performance becomes difficult, for they can breach and pay damages rather than bear very high costs to perform. This escape hatch element of damage payments also raises the value of contracts, as it makes parties more willing to assume contractual obligations. The escape hatch feature of damages for breach is also socially advantageous—it is not socially desirable for parties to perform when the cost of so doing outstrips the benefit to the recipient of performance. These points and others (notably, concerning risk allocation, and incentives to invest) regarding the virtues of payment of damages for breach have been analyzed intensively in the economic literature on contracts.

The orientation of economic analysis of contractual enforcement, through damage payments for breach, is very different from that of traditional legal analysis. Under the latter, damage payments for breach tend not to be regarded as incentives toward performance or as implicit escape hatches. Damage payments are seen primarily as compensation for harm or as proper desert for the wrong of breaking a promise. It should be added that, under the economic view, breach of a contract should not necessarily be identified with breaking a promise. The contracts that are written are not interpreted as detailed promises that parties truly want to be kept, but rather as incomplete promises that are only rough guides for behavior, and that the parties do not want to govern when performance would be very difficult.

Economic analysis of contracts has also been concerned with specific classes of contracts, including principal and agent contracts, insurance contracts, financial contracts, and donative contracts; the literature on some of these contractual contexts is now highly refined.

2.3 Litigation

One aspect of the economic analysis of litigation describes the motive to bring suits in terms of the potential plaintiff's costs of suit, the likelihood of success at trial, and the amount that would be obtained in the event of success.

Another element of the analysis of suit concerns the issue of whether the number of suits is socially

excessive (is there a litigation explosion?) or perhaps socially inadequate. In this regard, it is observed that when a person considers suit, he does not factor in, as a cost to himself, the defendant's legal costs or the state's costs. This indicates that plaintiffs' incentives to bring suit may be socially excessive and thus that suit should be curtailed or barred in some domains. Yet a person considering suit will not usually take into account the deterrent value of the suit—the message that suit will send, which will affect the behavior of others in the future—as well as any additional, wider social benefits. This divergence between the private and the social benefits from suit suggests that in some contexts the number of suits brought might be inadequate, and that public promotion of suit might be desirable.

Given that suit has been brought, the question arises whether the parties will settle their dispute or proceed to trial. The thrust of economic analysis of this question is that settlement is likely when the beliefs of the two sides about the trial outcome are similar, but that trial is likely when the plaintiff is much more optimistic than the defendant. For example, suppose that the beliefs of both sides are identical—each thinks the plaintiff would definitely obtain $100,000 at trial—and that the trial expenses of each would be $10,000. Then the plaintiff should be willing to accept as little as $90,000 (that is, $100,000 minus his litigation costs) in a settlement, and the defendant should be willing to pay as much as $110,000 ($100,000 plus his litigation costs). Hence, there should be room for settlement (any amount in between $90,000 and $110,000). If, however, the plaintiff's estimate of his winnings is much higher, say $200,000, than the $100,000 the defendant expects to pay at trial, the plaintiff would demand at least $190,000, which exceeds the $110,000 the defendant would be willing to pay. Accordingly, trial would be likely.

Economic analysis of litigation has also begun to address topics beyond the general ones of the bringing of suits and of settlement decisions. Among the topics considered are disclosure of information before trial, appeal of trial outcomes, class actions, and alternative dispute resolution.

2.4 Law Enforcement and Criminal Law

An additional area of economic analysis concerns public enforcement of law: the use of enforcement agents (such as police, safety inspectors, auditors) to detect violations of law; and the imposition of penalties for violations.

A theme of the literature on law enforcement is that the magnitude of penalties should be inflated from the level that would be appropriate were detection of violations certain. Inflation of penalties is needed to maintain deterrence, in effect to compensate for the possibility that a violator will not be detected. For example, if a polluting firm that causes harm of $10,000 is detected only a third of the time, then the fine that is imposed when the firm is detected should be not $10,000, but this amount multiplied by three, or $30,000. For, if the fine when the firm is detected is $30,000, the firm's probability-discounted, or average, fine is one-third of $30,000, or $10,000, providing it with incentives not to pollute similar to those that would exist if it paid a certain fine equal to the $10,000 harm.

Another point of emphasis in enforcement literature is that, because law enforcement is expensive, it will often be desirable for society not to spend so much on enforcement as to detect violations with high probability: it may be best, all things considered, to conserve on enforcement resources even though this means that many violators will escape detection. To combat the problem of inadequate deterrence that might accompany a low level of enforcement, multiplied penalties can be applied, as just discussed. Thus, there is appeal in employing an enforcement strategy that involves significant chances of escaping punishment combined with high levels of penalty. However, a problem with this low probability-high penalty strategy is that high penalties may be infeasible. Monetary penalties cannot exceed the assets of violators, which may be quite modest. Also, jail sentences can only be so long, and sanctions that conflict with retributive justice—sanctions that are out of proportion to the gravity of a bad act—might be resisted by the public.

A further issue examined in the economic literature on enforcement is the socially desirable choice between fines and imprisonment as forms of penalty. Here, it is generally said that fines are preferable to prison sentences, because fines do not themselves deplete social resources (but rather transfer command over resources from violators to the state). Whereas, imprisonment does diminish social resources, for prisons are expensive to operate, deprive individuals of their liberty, and prevent individuals from participating in the labor force. Therefore, the economic prescription is that fines be employed as the form of penalty when possible. But when fines cannot be used to deter, because the appropriate fines exceed the assets of violators (the typical robber could not be deterred by the threat of fines, given his level of assets), imprisonment should frequently be employed as the form of penalty. A closely connected point is that when fines cannot be used to deter, imprisonment may be useful as a penalty not only because it may deter, but also because it will incapacitate, that is, prevent individuals from doing further harm while in prison.

The foregoing conclusions and associated ones have been applied to criminal law. It has been suggested that many of the undesirable acts that are punished under criminal law (robbery, murder, rape) have the feature that civil suit and fines would not suffice to achieve adequate prevention of the acts. Therefore,

imprisonment is often necessary to deter and to incapacitate those who commit the acts. Further, the magnitude of sanctions under criminal law has been related to the likelihood of detection of the acts, among other elements. Additionally, various doctrines of criminal law have been interpreted as desirable from the economic perspective. For example, that the sanction for murder committed in the heat of passion is less than that for premeditated murder is said to be rational: the ability to deter acts carried out in the heat of passion is relatively low, implying that it would be a mistake for society to incur the costs of the higher level of sanctions that are imposed for planned acts for which deterrence is more effective. Economic analysis of criminal law is concerned generally with the efficacy and the social costs of enforcement and the imposition of sanctions, and does not usually view punishment as a means of achieving retributive justice or other ideas of desert.

2.5 *Additional Areas of Research*

Economic analysis has been brought to bear on a host of other areas of law. These include many business-related areas of law, such as corporate law, tax law, antitrust law, and bankruptcy law, as well as, increasingly, diverse other areas, such as family law, anti-discrimination law, and constitutional law. Moreover, economic analysis has addressed questions surrounding the role of legislative bodies in formulating and enacting legal rules and the role of courts and regulatory agencies in applying legal rules.

3. *Foundations of, and Criticism about, Economic Analysis of Law*

Economic analysis of law is premised on the general assumptions of the discipline of economics. These assumptions and their relationship to economic analysis of law in particular are sketched here. Certain commonly encountered criticisms of economic analysis of law are also mentioned.

3.1 *Basic Assumptions*

With regard to prediction of behavior, the usual assumption made in economics is, as noted at the outset, that parties are forward-looking and rational. This assumption is sometimes criticized as unrealistic. However, the assumption is usually made with the understanding that, although it is best for predicting central tendencies in behavior, various psychological and cognitive biases also influence behavior, and that these sometimes should be taken into explicit account. For example, the propensity to underestimate certain classes of risk, and thus for individuals not to take proper precautions or to insure adequately against them, has been recognized in economic analysis of law.

With regard to the evaluation of outcomes under the economic framework, the well-being or 'utility' of a person is basic. Economists' conception of utility is completely general and reflects not only the material pleasures of life to a person, but also, for example, the influence on his/her happiness of the treatment of others. From the utilities of individuals, a measure of social welfare is constructed, but there is no single, objective measure of social welfare that analysts study. Thus, utilitarianism is just one among a continuum of measures of social welfare that could be examined. The only significant presumption that is ordinarily made is that the measure of social welfare depends exclusively on the utilities of individuals. This assumption is consistent with concerns for equity in the distribution of utility and wealth, and economists have studied the implications of such concerns in depth.

3.2 *Notions of Fairness and the Law*

As has been seen in Sects. 1 and 2, classic notions of fairness, such as corrective and retributive justice, typically are omitted from the evaluation of legal rules under the economic framework, whereas these notions are traditionally viewed as of great significance to the assessment of the law. The essential reason that, under welfare economics, the notions of fairness are not accorded intrinsic importance is the assumption that they do not directly enter into individual's wellbeing. For instance, whether punishment is in proportion to the seriousness of a crime is ordinarily assumed not to affect individuals' utilities *per se*; rather, punishment may affect individuals' wellbeing through its deterrent or incapacitative effects. Because satisfaction of notions of fairness is presumed not to raise individuals' wellbeing in a direct manner, granting these notions independent weight in the evaluation of outcomes would tend to alter social decisions in ways that lower individuals' wellbeing.

Nevertheless, several qualifications to the last paragraph should be made. First, the assumption that notions of fairness do not matter to individuals may not always be apposite: individuals may have tastes for adherence to notions of fairness (individuals might feel happier if punishments fit crimes). To the extent that that is so, satisfaction of a notion of fairness properly enters into individual wellbeing and thus into social welfare, just as satisfaction of a taste for a material good does. (Notice that the importance of notions of fairness as personal tastes, being contingent on what the tastes of individuals happen to be, is different from the intrinsic importance accorded to conceptions of what is fair and right under deontological philosophical views.) Second, notions of fairness tend to have a desirable functional role (punishment only in proportion to the gravity of bad acts tends to dis-

courage bad acts at relatively low social cost). Thus, advancing notions of fairness and inculcating them in the population (perhaps partly through adoption of legal rules that embody them) may serve to promote social welfare.

3.3 Income Distributional Equity and the Law

It may have been noted in Sects. 1 and 2 that the income distributional effects of legal rules were not mentioned as relevant to their evaluation under welfare economics, even though, as noted in Sect. 3.1, distributional equity does enter into the assessment of social welfare. The reason that the income distributional effects of legal rules are usually not considered in their evaluation is that economic analysis suggests that the income tax system (combined with income transfer programs) is a better means of achieving distributional objectives than the legal system. The income tax system is overtly redistributive, reaches all individuals, and is relatively cheap to administer. The legal system is not well designed to redistribute: it directly affects only those individuals who are involved in litigation; and even among them, the legal system is difficult to employ to effect redistribution, for a given class of litigants is often comprised of individuals with widely varying incomes (consider the class of victims of automobile accidents). Furthermore, the legal system is a very expensive device for transferring income. Hence, according to economic analysis, the legal system should not be used as a tool to achieve distributional goals, and if legal rules turn out to have undesirable distributional effects, these can be remedied through adjustment of the income tax system.

3.4 Economic Explanation of the Law

Finally, a strand of economic analysis should be mentioned claiming that the legal rules that are observed can be explained as those which best advance social welfare. This hypothesis seems attractive at a very gross level of description (for instance, that liability is imposed for causing harm, rather than for doing good, is explainable in the sense that such liability discourages harmful acts); and sometimes the hypothesis is appealing at a fairly detailed level. However, many, if not most, economic analysts hold a nuanced view of the economic rationality of the law, for many legal rules do not have obvious economic rationales, and a number undoubtedly reduce social wellbeing.

Law and Economics: Empirical Dimensions

Since the 1960s, economics has extended its reach beyond the marketplace to study new subjects such as the family, education, discrimination, politics, and even the law. Empirical work plays an essential role in this undertaking, both to assess the predictive power of a given economic model with respect to the examined question, and to provide guidance as to how to amend the economic model to improve future analyses. Empirical work has often served as a touchstone for multidisciplinary discourse on law because the social sciences share common statistical methods for evaluating empirical data, and because such work has commonly suggested the utility of amending the neoclassical economic model to address issues studied in other disciplines, including sociology, political science, criminology, and psychology.

1. Economic Analysis

Economics first developed as a discipline in the seventeenth century, in close association with the accompanying social sciences of political science and sociology. During this early period of development, the social sciences enjoyed considerable overlap in examined problems and methodology. Although some works from this time can be identified as being distinctly 'economic,' early social scientists such as Adam Smith, Karl Marx, and John Stuart Mill hypothesized about economic, social, and political institutions with equal skill and aplomb. This close association between the social sciences continued into the beginning of the twentieth century with the work of institutional economists such as John R. Commons, and economically oriented sociologists such as Emile Durkheim and Max Weber. Indeed, Weber, one of the most distinguished sociologists of his time, held several academic positions as an economist.

However, early in the twentieth century, economics began to separate from the other social sciences in two important ways. First, economics began to diverge in terms of its examined subject matter. Economists began to focus more on studying the machinations of the market, leaving subjects such as social relationships and political economy to the other disciplines. Since the work of Gary Becker (1968, 1976), however, this trend has been reversed, so that now economists study a wide variety of social and political phenomena, including the law. Second, economics began to diverge in terms of its adopted methodology. Although all of the social sciences adopted modern statistical methods for analyzing data as the primary focus of empirical work, economists also undertook to develop a 'positive science' of economics under the neoclassical model.

1.1 Positive Economics

Since early in the twentieth century, most economists have endeavored to develop economics as a positive science analogous to the physical sciences. As the name suggests, the ultimate goal of a 'positive science' is to produce theories that describe observed phenomena accurately, rather than offer a normative evaluation of the desirability of the phenomena. Such theories are devised by making assumptions about the world that abstract the essential features of the examined problem, and then using logic to deduce predictions about the as yet unobserved events. The validity of the theory is then confirmed through empirical work, which examines the predicted events and tests the statistical significance of results consistent with the theoretical model. This deductive process, working from theory to data, can be distinguished from the inductive process used by many other social scientists, who tend to analyze the data before inductively deriving their theories. Accordingly, for the majority of the twentieth century, most economists aspired to conduct economics as a positive science that deduces empirical predictions from theory and then tests those predictions against data.

1.2 The Neoclassical Model

In the development of economics as a positive science, the dominant paradigm has been the 'neoclassical model.' The neoclassical model consists of a set of assumptions that economists make in analyzing problems. This set of assumptions achieved paradigmatic dominance in economics because they proved useful in analyzing market behavior, and because they were tractable mathematically. Under the neoclassical model, economists assume generally that: the appropriate unit for analysis is the individual consumer or firm, individuals and firms rationally choose among available alternatives according to their preferences to select the option that maximizes utility or profits, people's preferences are exogenous to the model, and transaction and information costs are zero. Economists have a well-defined notion of 'rationality'; they assume that people have preferences with respect to all possible states of the world, that these preferences are reflexive and transitive, and that the people will select the option they most prefer. The assumption of free information is usually referred to as the assumption of 'perfect information.' It has deceptively broad-ranging implications in that it implies that each person knows the quality of each good and the price of all alternatives, and indeed has the knowledge necessary to enter the market and produce the good if the market for the good enjoys supercompetitive profits. The assumption of zero transaction costs also has potentially far-reaching implications since, as Ronald Coase (1960) has pointed out, in a world of zero transaction costs, everything happens at once.

The conduct of economics as a positive science using the neoclassical model tends to separate the work of economists from that of other disciplines. The adoption of the perspective of the individual as the unit of analysis, and the assumption that preferences are exogenous, preclude consideration of the effect of social norms and the process of socialization that are so important to many sociological analyses. The construction of the concept of individual utility based merely on an ordinal preference ranking was undertaken with the purpose of avoiding some of the stickier problems in psychology, thus making the concept 'psychology-free.' The economists' well-defined concept of rationality is much narrower than that used in any other discipline. Moreover, since the other social sciences rely more on inductive logic, working from data to theories, they generally do not make any *a priori* assumptions about what constitutes rational choice. Accordingly, some sociologists have argued that they study rather than assume human rationality.

1.3 The Importance of Empirical Work

The assumptions of the neoclassical model are clearly unrealistic, and this fact raises the importance of empirical work in economics. Every analysis of a problem is necessarily an abstraction from reality, ignoring some of the complexities of the real word to focus on others. The art of modeling is to know which simplifying assumptions one can make and still capture the essence of the problem. Of course, an important test of how well a theory captures the essence of a problem is how well it fits the available data. Milton Friedman (1953) has argued that the realism of a model's underlying assumptions is of little importance as long as the model yields good predictive results. Indeed, Friedman has gone so far as to argue that, paradoxically, the most important hypotheses have the most unrealistic assumptions, because a hypothesis is important if it abstracts the crucial elements of a phenomenon in such a way as to explain much of the phenomenon by assuming little. Other economists have argued that there are purposes to modeling beyond mere prediction, such as explaining the phenomenon or providing a catalog of knowledge for future work. As a result, they have argued that there are reasons for considering the realism of economic assumptions that go beyond the simple predictive value of the model.

2. The Economic Analysis of Law

Beginning with the pioneering work of Gary Becker (1968, 1973), economists have sought to broaden the scope of their inquiry to all aspects of society. This movement to broaden the scope of economic analysis has brought economics into a variety of subject matters previously studied by other disciplines, including the family, education, discrimination, politics, and even the law.

2.1 The Modern Law and Economics Movement

The modern law and economics movement had its origin in the work of Gary Becker, Ronald Coase and Guido Calabresi. Becker (1968) used simple principles of labor economics to analyze the criminal's decision of whether to engage in crime, and derived implications for optimal penalties and optimal enforcement of the law. Coase's (1960) work established the proposition known as the 'Coase Theorem', showing that, in a world of zero transaction costs, the distribution of resources is invariant to the rule of law. However, Coase later made clear that he considers his work concerning how to minimize the effects of transaction costs in assigning the rule of law under the more realistic assumption of positive transaction costs to be more important. Calabresi (1970) wrote a classical study analyzing the costs of accidents and suggesting ways in which tort law might be formulated to minimize those costs. After these initial contributions, a notable and extensive body of work in the economic analysis of law was, and continues to be, authored by Richard Posner, who has applied the principle of wealth maximization to a plethora of legal problems, explaining either how the law can be understood as promoting wealth maximization, or how it might be amended to better achieve that objective (see, for example, Posner 1998). As will be discussed in detail below, in more recent years, work in the economic analysis of law has taken a variety of forms, from the traditional neoclassical analyses to socioeconomic and behavioral economic analyses.

2.2 Empirical Work in Law and Economics

Empirical work in the economic analysis of law has been slow to follow these theoretical advances. The reasons for the relative paucity of empirical work are several and varied, including a lack of training in empirical methods among legal academics, a lack of resources dedicated to such work, a lack of prestige and incentives attached to such work, and perhaps even some fear of exposure to falsification through replication on the part of law and economics scholars.

Despite these impediments to empirical work in law and economics, a number of notable studies have been done directly on issues important to the economic analysis of law. One of the earliest significant empirical works in law and economics was Isaac Ehrlich's (1975) work showing a deterrent effect from capital punishment. Ehrlich's work prompted enormous academic and public debate on the subject, and his results were later disputed by other scholars. A number of scholars have done empirical work in an attempt to verify or disprove the fundamental implication of Coase's work that, when transaction costs are negligible, the distribution of resources is invariant with respect to the rule of law. Among these works, perhaps the most notable for the purposes of this essay is Robert Ellickson's (1986) on the distribution of cattle in Shasta County, California, under alternative rules of free range and non-free range. Ellickson found that Coase was correct that changes in the rule of law did not affect the distribution of cattle; however, Ellickson attributed this finding more to the sociological reason that neighbors had informal means of dealing with animal trespasses that were not influenced by changes in the law, than Coase's reasoning that neighbors would just bargain around inefficient assignments of entitlements. Kip Viscusi (1983, 1992) has also made important empirical contributions in the economic analysis of legal issues through his analysis of the valuation of life and limb and the relative magnitude of various risks. Viscusi's work is important in

evaluating the efficiency of tort law, workers' compensation laws, and government regulation of various workplace and environmental risks.

3. *Empirical Work in Law and Economics as a Touchstone for a Multidisciplinary Discourse on Law*

It has become apparent that empirical work in law and economics often serves as a touchstone for interdisciplinary discourse on law. This is true for several reasons. First, economics shares the same accepted statistical methods for analyzing data with most other disciplines. As a result, as economists have expanded the scope of their research to areas (such as law) that traditionally have been studied by other disciplines, they have found that their empirical work is relevant to, and can be usefully informed by, empirical work already done in the subject area by other disciplines. Second, as economists have done empirical work in the economic analysis of law, or as they have borrowed from the empirical work of other disciplines, many have found reasons to relax some of the assumptions of the neoclassical model in their analysis of the law. The traditional economic model of individual rational choice does not always capture adequately the essence of legal problems in the way that it did in the study of atomistic markets, and as a result economists have sought to relax some of the assumptions of the neoclassical model in order to produce theoretical models with greater predictive or explanatory power.

By relaxing some of the assumptions of the neoclassical model, economists have found that their work becomes less distinct from that of theoretical work in other disciplines. This is true not only for the reason that such economic work is inductive rather than deductive in nature, working from the data to theory, but also because relaxation of some of the assumptions of the neoclassical model allows for the consideration of work from other disciplines. In particular, some law and economics scholars have found connections between their work and the work of sociologists who study law, while other law and economics scholars have made use of empirical work out of the behavioral sciences for their work in the economic analysis of law.

3.1 *Sociological Influences in the Economic Analysis of Law*

Some economists have drawn on the work of sociologists in their economic analysis of law. Indeed, in recent years there has been a growing interest among law and economics scholars in the influence of social norms and status production on people's behavior, and the role of law in the socialization process. In order to examine these phenomena, the economist usually has to relax one or more of the traditional assumptions of the neoclassical model. For example, to examine the influence of social norms or status production on people's behavior, the economist might adopt a perspective of analysis that takes into account group or community interests, rather than just individual interests. Similarly, in examining the role of law in the socialization process, some economists have found it useful to relax the assumption that people's preferences are determined exogenously. With the relaxation of these assumptions, it is also necessary generally to adopt an objective function other than individual utility, wealth or profit for maximization in the economic model—for example, net social benefits or social welfare.

The intensity of economists' interest in social norms in the 1990s has been rather remarkable. No less than four symposia on the subject have been published in major US law reviews since 1996 (Ellickson 1998). Although some very interesting work in the study of norms from the economic perspective has been done by Richard McAdams (1997) and Eric Posner (1996), perhaps the seminal work on the subject was the work previously alluded to by Robert Ellickson (1986). As previously mentioned, Ellickson undertook an empirical study of the effect of changes in the legal rule from open range to closed range on the allocation of cattle and fencing resources to test Coase's famous hypothesis that, in low transaction cost cases, the allocation of resources would be invariant to the rule of law because the affected parties would just bargain around any inefficient allocation of entitlements. To study this problem, Ellickson surveyed land owners in Shasta County, California, as to the number of animal trespass cases they had experienced under different legal regimes, and how those incidents were resolved. Ellickson found that the allocation of resources was indeed invariant to the legal rule, as predicted by Coase.

However, Ellickson found that this result, obtained not because transaction costs were low and the parties had bargained around the law to reach an efficient allocation of resources, but instead because resort to the law was costly, and as an alternative the affected parties were committed to a norm of cooperation with their neighbors, regardless of the rule of law. As a result, Ellickson concluded that work in law and economics would benefit from consideration of previous work on such questions in sociology, and the law and society movement. Taking his own suggestion to heart, Ellickson has used empirical work from other disciplines on norms of 'fairness' and 'civic responsibility' to analyze a variety of legal problems including rent control, the doctrine of unconscionability, the implied covenant of good faith and fair dealing, the duty to rescue, political and judicial processes, and the First Amendment.

Law and economics scholars have also demonstrated an interest in using models of individual and

group status production to analyze the efficacy of antidiscrimination laws. The seminal work in this regard is that of Richard McAdams (1995). Although Gary Becker's (1957) neoclassical analysis of discrimination based on a distaste for association has also been used to analyze antidiscrimination laws, this model has never been empirically satisfying, since it predicts that firms that discriminate will be put at a competitive disadvantage and driven from the marketplace, even in the absence of antidiscrimination laws. Drawing on work in sociology, McAdams developed a model of discrimination based on people's desire to produce inter and intragroup status. According to McAdams, whites discriminate against lower black group status and raise white group status relative to blacks. Intragroup status is used by whites to compensate individuals for costs they incur in raising whites' group status relative to blacks, for example by forgoing profits they would make in nondiscriminatory associations with blacks. McAdams' model is empirically more satisfying than Becker's, because it explains how discrimination can persist in the marketplace despite individual costs associated with discrimination. McAdams' model also explains nicely the existence and function of Jim Crow laws in the old South to reinforce group status production and prevent individual defection from this strategy. The status production model also yields very different policy prescriptions from those associated with Becker's neoclassical model since, under the status production model, antidiscrimination laws are no longer a superfluous addition to market pressures, but instead can be a useful tool to discourage wasteful competition in group status production.

A final area in which the economic analysis of law has shown connections to work in sociology is the analysis of the role of law in the process of socialization. In this area, the present author has written an economic analysis of the criminal law as a preference-shaping policy (Dau-Schmidt 1992). If one relaxes the neoclassical assumption that preferences are exogenous to the model, and instead assumes that the criminal law is intended to discourage preferences for criminal behavior, as well as to raise the costs of engaging in such behavior, then one can explain many of the fundamental doctrines of the criminal law. Under this analysis, the requirement of intent in the criminal law can be understood as part of the attempt to identify deviant preferences that should be punished to be discouraged. After all, it is only when someone intends the harm that they cause that we know that they desired to bring it about. Similarly, we criminalize attempts (in the absence of actual harm) to ideality and punish deviant preferences in need of modification. Indeed, the preference-shaping model of criminal law allows one to distinguish criminal liability from ordinary tort liability, on the basis that criminal liability is intended to modify both preferences and rewards, whereas ordinary tort liability is intended merely to modify rewards. The preference-shaping model lends itself naturally to integration with work from sociology, criminology, and psychology, because it raises questions concerning how we determine which preferences are socially deviant, and how best to discourage such preferences in people.

3.2 Behavioral Law and Economics

Other economists have drawn on the empirical work of behavioral psychologists in their analysis of law. In 'laboratory' experiments, behavioral psychologists such as Amos Tversky and Daniel Kahneman (Tversky and Kahneman 1982) have established that the human decision-making process typically varies in predictable ways from the simple model of rational choice assumed in the neoclassical economic model. In particular, they have established that people commonly exhibit 'bounded rationality' in that they can only process a finite amount of information and thus must rely on rules of thumb to help them make decisions, 'bounded willpower' in that they sometimes do things that are clearly not in their long-term interests, and 'bounded self-interest' in that they care about other people and whether the treatment in their relationship is reciprocally 'fair.' Tversky and Kahneman have also established that people evaluate outcomes based on the change they represent from an initial 'reference point,' weighting potential losses from the reference point more heavily than potential gains. This finding is referred to as 'prospect theory' in the literature, and it can be exploited to manipulate people's decision-making process by suggesting the initial reference point to 'frame' possible choices as gains or losses.

As with the influence of sociology on the economic analysis of the law, there has been a boom in the number of scholars who seek to use 'behavioral economics' in their analyses of the law. Early proponents of such work include Thomas Ulen (1989) and Robert Ellickson (1989), but they have since been joined by others including Russell Korobkin (see Korobkin and Ulen 2000), and Christine Jolls, Cass Sunstein, and Richard Thaler. These scholars argue that amendment of the assumptions of the neoclassical model concerning individual rational choice according to the empirical findings of behavioral economics is necessary to improve the predictive power of the economic model. Their critique is fundamental, in that it goes back to basic assumptions about the purposes of law, and how people will react to and enforce the law. For example, Jolls et al. (1998) have argued that the Coase theorem is often empirically false, because empirical work in behavioral economics suggests that people sometimes develop attachments to objects they possess, and this 'endowment effect' may mean that people must sometimes be paid more to part with an entitlement than they would pay to possess the

entitlement. Accordingly, people will not bargain around the assignment of entitlements in the way described by Coase. Similarly, Korobkin has argued that information heuristics will affect the efficacy of tort damages in providing efficient incentives to take care. Because work in behavioral economics shows that people are often overly optimistic in that they undervalue the chances of something bad happening, and overvalue the chances of something good happening, this suggests that, even if tort damages are set at efficient levels, people will not account adequately for the chance of accident and so will not take efficient care. Paradoxically, Jolls et al. (1998) have argued that, although potential tort feasors may be overly optimistic, the juries that later try them will suffer from 'hindsight bias' and overestimate the probability of accident, merely because an accident has in fact happened, thus too readily finding tort defendants liable. Of course, whether potential tort feasors anticipate hindsight bias on the part of later jury members, and which effect dominates in their decision-making process, are questions for future empirical work.

Law and Everyday Life

Law and everyday life have been defined historically in opposition to one another. Everyday life has typically denoted that sphere of social action characterized by being familiar, routine, pragmatic, and particular: the world of work, play, family, and leisure. By contrast, law has been conceptualized as formal, timeless, general, and transcendent. In the context of this opposition, law was understood to radiate downward toward everyday life to resolve conflict and to impart order. Everyday relationships, interactions and practices were thought to constitute the objects upon which law operated with varying degrees of success.

Alexis de Tocqueville articulated such a view of law and the everyday over two hundred years ago:

> The language of the law thus becomes, in some measure, a vulgar tongue; the spirit of the law, which is produced in the schools and courts of justice, gradually penetrates their walls into the bosom of society, where it descends to the lowest classes, so that at last the whole people contract the habit and tastes of the judicial magistrate. (de Tocqueville 1959, pp. 2–20).

During the twentieth century, the boundary separating law from everyday life has become increasingly blurred. With the blurring of this boundary, the presumed direction of effect from law ('the schools and courts of justice') downward to 'society' has likewise been challenged. Increasingly, sociolegal scholars understand law and everyday life to be mutually constituted in a dynamic and emergent process wherein law is produced and applied in the everyday domain of social action. At the same time, the practices, relationships and meanings that make up the everyday are themselves, at least in part, constructed by law, or legality.

1. *Legal Realism: The Everyday Life of the Law*

In the early twentieth century, a perspective called legal realism rejected the prevailing formalist perspective on law (see *Legal Realism*; *Legal Formalism*). Whereas legal formalism saw the law as having an internal logic that led to determinate outcomes, legal realism posited that law is more than the rules and pronouncements contained in judicial decisions or statutes. Legal realists understood that legal rules were not simply and mechanically applied by judges, lawyers, police and regulators. They proposed to account for the gap between 'law on the books' and 'law in action'; that is, between the law as envisioned by its makers, and law as it is actually enforced on a daily basis.

Legal realism taught us that, in entering the realm of lived experience, legal rules are articulated within particular social and historical contexts that shape law's effects. This proposition authorized an examination of those contexts and constraints, thus creating an opening to the everyday in the study of law.

1.1 *Law First Perspective*

Legal realism—even while it acknowledged the life, and not merely the spirit, of the law—assiduously maintained the boundary between the law and everyday life, retaining what has been called a 'law first' orientation (Sarat and Kearns 1993). Karl Llewellyn and E. Adamson Hoebel, in their classic book *The Cheyenne Way* (Llewellyn and Hoebel 1941), proposed that law performed a dual function in ordering everyday life. Frequently, the law's prescriptions operated beneath the level of notice or consciousness 'to make [people] go round in more or less clear ways.' In this regulative function, the law created routines and norms that structured people's practices and expectations. At times, however, the so-called drift of everyday life produced divergent interests, expectations, and norms that upset the orderliness of social life. Llewellyn and Hoebel referred to these instances as 'trouble cases' and proposed that a central function of the law is to process these cases to restore social order. 'Law,' they wrote, 'exists for the breach of law and has a major portion of its essence in the doing of something about such a breach' (1941, p. 20). How law responds to such breaches—how it selects cases of trouble, in what way it redresses these situations and with what consequences—ultimately comes to comprise the law. Accordingly, Llewellyn and Hoebel recommended empirically examining the selection, processing, and resolution of trouble cases as a way of elucidating and understanding the law. Research in this tradition focused on the everyday work of legal professionals, examining such processes as judicial decision-making, prosecutorial discretion, or police arrest practice within specific organizational and political contexts.

When the everyday world was examined within this tradition, it was only at the boundary that separated law from society, in those settings where citizens brought their disputes, claims and grievances to the attention of legal professionals. Social scientific research examined, for instance, the sorts of claims and awards made in small claims courts (Yngvesson and Hennessey 1975), or the advice given in lawyer's offices (Sarat and Felstiner 1995). In short, the everyday was included in these analyses of law only in those instances when its familiar routines broke down to the point the law was mobilized to restore order, to redress an injury or to protect a right.

2. *Everyday Life vs. the Law*

This 'law first' perspective shifted somewhat as scholars began to consider the social processes and institutions that preceded law. Whereas Llewellyn and Hoebel depicted the law as intervening in social life to create and restore order, Paul Bohannon (1968) presented law as emerging out of social life. He claimed that law resulted from a double institutionalization of customary practices. This process of formalization granted to custom a force and legitimacy that eventually led to law having a life and dynamic of its own. Hence, according to Bohannon, law did more than simply reflect the everyday; it interacted with social institutions. These interactions were a source of social change.

The law first perspective was also displaced in research that examined citizens' decisions to turn to the law. Studying the daily enforcement practices of legal agents revealed the extent to which most Western

legal systems are reactive; that is, they rely on citizens to mobilize the law. Obviously, this is true in the case of civil law, where citizens seek legal remedies for private disputes. It is also true in regard to criminal law, however. In a classic study of police arrest decisions, for instance, Donald Black (1971) found that approximately 87 percent of all police–citizen encounters were initiated by citizens, either in the role of victims or witnesses. The crucial role of citizens in mobilizing both civil and criminal law directed attention to how citizens interpret situations and make the decision to turn to law.

Felstiner et al. (1980) developed a model of the interpretive process that leads up to a citizen's decision to seek legal remedies. To begin, problems and situations (potential 'trouble cases') are not self-evidently injurious or legal. Therefore, Felstiner et al. refer to the first stage in this process as 'naming,' or defining a situation or event as injurious. 'Blaming' refers to the identification of a party who is responsible for the problem. Finally, 'claiming' entails bringing the grievance or complaint to a third party (which may or may not be a legal body) to obtain a remedy. Although the model postulates an individual decision maker, it stimulated interest in the cultural meanings and values that might compete with interpretations favoring legal action at any point in the process. In considering these matters, sociolegal research extended its analyses to the communities and cultures that exist beyond the legal arena.

Researchers were particularly interested in those instances where the law was rejected and legal protection or remedy was not sought. For instance, in a classic article entitled 'Non-contractual Relations in Business: A Preliminary Study' (Stewart Macaulay 1963), found that law suits for breach of contract are relatively rare between businessmen. The paramount reason for this included the availability of effective non-legal sanctions that operated within the business community such as gossip, and the giving or withholding of advice or expertise. In general, the businessmen's reluctance to use the law in lieu of these alternatives was due to the mutual desirability of maintaining ongoing relationships, and the sense that invoking the formal law would interfere with that goal. More recently, Robert Ellickson (1991) found that neighboring cattle ranchers in California rarely invoke the law in disputes involving trespass. Like Macaulay's businessmen, the ranchers, according to Ellickson do not want, or necessarily need, the law to achieve order.

Carol Greenhouse (1986) studied a very different community and found a similar pattern of law avoidance. She conducted an in-depth ethnography of a small Baptist community in Georgia and found that the religious commitments of the members of this community tended to suppress disputes and steer members away from secular legal processes in the event that disputes did occur. Robert Kidder (1990) studied other 'law-avoiding' societies, including the Amish and the Japanese, and similarly discovered in each case an incompatibility between the community's ideological or spiritual commitments and law. The research on law avoidance thus served to correct the sense that law was paramount in ordering relationships in modern societies. By proposing that law is only one of variously competing normative orders available to citizens for achieving orderly relationships, this research further underscored the need for a serious consideration of everyday lives, relationships, and beliefs of citizens.

Although this research abandoned an exclusive or primary focus on formal law—considering informal community norms and practices as well—it maintained a sense that law and everyday life are distinct and relatively autonomous from one another. Indeed, by focusing on law avoidance, the relationship between the formal law and the informal norms of everyday life was depicted as not merely distinct but oppositional. Subsequent research and theory has challenged the idea that law and everyday life are autonomous or oppositional, suggesting instead that the two are integrated.

3. *Law in Everyday Life*

Since the 1980s, sociolegal scholars have begun to examine everyday life not simply as an object of legal action or a reservoir of potential legal cases, but as a domain in which law circulates, is appropriated, invoked, and produced. This view of the law rejects the notion of law as a mere instrument to be used or avoided by citizens for achieving social or private ends. Law and the everyday are seen as mutually constitutive; that is, literally 'making up' each other in an ongoing dynamic process.

For instance, Barbara Yngvesson (1989) has argued that the invention of law is not a one-way process. Law, she argues, is invented by citizens in local struggles over the meaning of fundamental cultural symbols such as 'community,' 'neighborhood,' or 'rights.' As citizens act on their understandings, law 'emerges in the exchanges and the struggles of everyday people, in neighborhood fights and lovers' quarrels, in the framing of claims and complaints to the police, the court, neighborhood justice and other agencies, and in the response to these agencies to such claims (p. 1709).

Citizens do not, in other words, simply mobilize the police or go to court with their preconstituted legal cases. Before the formal legal apparatus has been invoked, the cases have been fashioned out of the popular legal culture circulating in everyday life. The results of that fashioning come to constitute which cases are processed, decided, and contested in formal legal settings. Rather than imagining law as existing apart from social relations, or conceiving of it as

produced solely by groups of powerful law 'makers' (such as legislatures), in this constitutive view, law is understood as emerging from the 'bottom up' as a continuing production of practical reason and action. As David Engel (1993a) writes,

> Law, despite its apparent claim to "self-totalization," is dependent on everyday life to give meaning to its central concepts (what is "reasonable," "customary," "excessive," or "appropriate"?), to root its abstract rules and principles in human understanding, and to produce implementation, compliance, and judgment. It is misleading to regard law as capable of existence apart from or in opposition to everyday life. (p. 125)

Of course, everyday life is fundamentally dependent upon law as well. Even when we act in situations that seem devoid of legal meaning, or that involve a self-conscious avoidance of law, we do not escape the constitutive power of law. The law creates roles, relationships, and obligations. It 'names the world.' To routinely enact the roles of wife, doctor, or consumer, or any social role, one tacitly implicates the law. In fact, the appearance of routine is in no small measure a consequence of those unspoken legal meanings.

This view of law and everyday life would take issue with the conclusions of research such as Macaulay's and Ellickson's. This research, in demonstrating the absence of law in the ongoing relationship between businessmen or cattle ranchers, fails to note that the very roles and relationships in which their subjects act are legal creations. Moreover, the concepts of private property or profit, for instance, draw upon legally produced and sanctioned meanings. They also fail to take into account the effect of both parties' knowing that the law exists as an alternative if extra-legal sanctions fail. As Sarat and Kearns (1993) have written, 'one is apt to catch more than a fleeting glimpse of law's presence in the putatively alegal responses' (p. 47).

Attempting to catch such a fleeting glimpse of law has led to a broadening of subjects and sites of research. One example of research that has systematically explored the presence of law in everyday life is Hendrik Hartog's analysis (Hartog 1993) of the eighteenth-century diary of Abigail Bailey. Hartog's reading of Abigail Bailey's diary reveals how this woman, over the course of many years, struggled to make sense of her marriage, her husband's sexual abuse of their daughter, and their separation and eventual divorce, as well as her own religious beliefs regarding her duties as a wife and mother.

Recently, the recognition that law and everyday life are mutually constitutive has led to an interest in legal consciousness, ideology, and resistance (see *Legal Culture and Legal Consciousness*). The study of these topics is animated by an interest in how citizens imagine and use law. This would include how and when citizens mobilize formal law, but also how they may invoke, interpret, avoid, and deploy law and legal concepts in daily interactions even when no formal or official actors or rules are involved.

For example, David Engel's work on the intersection of law and everyday life reflects this interest in legal consciousness, ideology, and resistance. In his study of the Education for All Handicapped Children Act of 1975 (Engel 1993b), he rejects a traditional analysis that would have traced the ways in which this legislation unilaterally constrained or defined the educational experiences of children, the meaning of their physical conditions, or the interactions that occurred between parents and educators. Instead, he examines how this legislation and everyday life within this community are interdependent and mutually shaped this social domain. At times, Engel notes, the law reinscribed 'commonsense' images of disability and difference, constituting the meaning and content of those social categories as they operated within the community.

In examining the interpenetration of law and everyday life, Ewick and Silbey (1998) have suggested that the concept of legality be used to augment the concept of formal law. By legality they refer to the meanings, sources of authority and cultural practices that are commonly recognized as legal, regardless of who employs them, or for what ends. In this rendering, people may invoke and enact legality in ways neither approved nor acknowledged by the law. Legality operates as both an interpretative framework and a set of resources with which and through which the social world (including that part known as the law) is constituted. In sum, they conceive of legality as an emergent structure of social life that manifests itself in diverse places, including both formal institutional settings and the everyday lives of groups and communities.

Law and Geography

Law and geography: the analysis of the manner in which law, as a set of processes, texts, and practices, is shaped by the geographic dimensions of social and political life, and the ways in which the geography of social life is in turn structured by law. Defined thus, the systematic study of the relationship between law and geography has a long, though uneven pedigree. Over the last century, scholars have defined both 'law' and 'space,' and the relationship between the two, in opposed ways, sequentially foregrounding space and then law. The last decade, however, has seen considerable interest in transcending the binary divide between law and space.

1. *Regional Studies of Law*

The earliest 'legal geographies' were concerned with the description and explanation of the regional diversity of legal systems. Thus defined, eminent eighteenth century scholars such as Montesquieu (1748/1949) could be classified as early 'legal geographers.' Regional studies of law, however, were to come into their own in the early years of the twentieth century, with the development of comparative law and the sociology of law. The American comparative legal scholar John Wigmore, in particular, undertook an extensive three-volume survey entitled *A Panorama of the World's Legal Systems* (1928) He also co-edited a collection on legal evolution in 1918 (see Picard 1918), including papers written by lawyers, sociologists, and geographers, which perhaps is the definitive summary of the regional field.

The central claim among these authors appears to be that spatial variations in law are a function of local environmental factors. For some, the latter is defined as the physical environment. Picard (1918), for example, points to variations in climate, soil, forest cover, and distance from the sea as important in explaining legal diversity: 'All these and other variations of land and atmosphere show their traces in the jural system … Brazil and Russia, because they are different geographic regions, will therefore have many differences in law' (p. 170). In keeping with the assumptions of the day, other scholars point to 'race' as an explanatory factor in legal variation. Similar regional schools also seem to have developed in interwar France and Germany. While regional studies have fallen into disfavor, at least within geography, Grossfeld (1984) proves that the determinism of this sensibility is not dead. He argues in uncompromising terms that 'geography is fate … not only for a country but also its culture and the law' (pp. 1512–3).

2. *Impact Analysis*

If regional studies read from geography to law, an influential paper by American geographer Whittlesey (1935) was to invert this relationship in his call for the exploration, as he put it, of the 'impress of effective central authority on the landscape.' Trade tariffs or embargoes, land tenure systems and the regulation of resource exploitation were all identified as laws that result in 'landscape modification.' Thus, in understanding a particular region, geographers were urged to consider those 'phenomena engendered by political forces' (p. 97). The geographer's task, it seems, was now to focus on law's spatial 'impacts,' while taking law itself as an external 'given.'

Such a definition of the relation between law and geography (which Clark 1989 terms 'impact analysis') proved influential until the late 1980s. The tendency has been to treat space as a surface upon which laws instrumentally impact. For Wije (1990, pp. 26, 30), for example, 'Law is a means of achieving social control by regulating behavior or by altering behavioral incentives while geography can study the spatial ramifications of this behavior…. Law can be considered as a geographic… variable.'

Both traditions offer specific insights. A regional analysis is useful to the extent that it reminds us of the ways in which law, despite appearances of homogeneity, can in fact be different and diverse. There are similarities to Clifford Geertz' (1983) fascinating discussion of Balinese law, which proves unsettling to the extent that it alerts us to the internal coherence and logic of systems which, from a Western perspective, can appear entirely alien. In reminding non-lawyers of the undeniable importance of laws on social life and spatial forms and patterns, impact analyses are also useful. We only need to reflect on the direct and indirect ways in which, for example, the urban landscape is a product of countless legal decisions, rulings, and mediations, relating to real property, administrative law, and so on. Yet some commentators have found these analyses partial and limited in terms of the way in which they theorize law, space, and their inter-relation (cf. Clark 1989, Blomley 1994).

3. *Critical Legal Geography*

The last decade has seen the emergence of a third school of legal-geographic enquiry which, in building upon but departing from the above, attempts to redefine both law and space, and also moves beyond the dualistic thinking that relates one to the other. This school of 'critical legal geography,' which one can trace within geography, law, socio-legal studies, anthropology, sociology, and elsewhere, is far from unified. Yet it is probably fair to identify a number of foundational claims concerning law, space, and their mutual relationship.

First, in keeping with much recent scholarship, law itself is defined as more than a set of positive, external commands, but is understood as implicated in an array of social relationships. For example, law can be productive of many social and political effects, being able to define relationships, confer status, and selectively empower, or is argued to define dominant social meanings. There is clear social selectivity to this for many legal scholars. Far from being socially neutral, law is necessarily rooted in, and protective of, prevailing social inequalities around class, race, and gender. Second, to that extent, law is 'socially produced,' rather than being transcendent and a-social; that is, law is formed under particular historic conjunctions by social actors, informed by conditional understandings of society, the State and the individual. Critical legal scholars, or those informed by feminism, for example, have clarified the ways in which broadly liberal understandings of society have informed the common law legal systems of the UK, the USA and Canada in ways that while potentially liberating (Unger 1983) can also prove confining and oppressive, naturalizing hierarchy and limiting progressive alternatives (Peller 1985). Yet, third, law is also 'socially produced' to the extent that it provides an important vocabulary for everyday life. Socio-legal writers consider the manner in which, as Geertz (1983) notes, law can become a form of 'local knowledge' that is drawn upon by people in their relationships with other individuals and the wider social and political world. Rose (1994), for example, explores the manner in which property discourse provides a vital vocabulary by which not only powerful interests, but also individual property holders communicate with one another. Again, this can prove enabling, for example, when oppressed individuals are able to lay claim to a legal right (Laclau and Mouffe 1985), yet can also prove confining. Nedelsky (1990) argues that the tendency to regard others as a threat to our individual autonomy rather than a potential source for freedom is a product of the liberal-legal imagination. Finally, debate has turned on the broader question of legal meaning. Most immediately, the issue is one of textual interpretation—what is the meaning of statute or precedent? Poststructuralist legal theorists have argued that the quest for an essential or stable meaning (which is implicit, for example, to impact analyses) is not only chimerical but also politically dangerous, given the manner in which interpretation is context specific and meaning itself is always referential and endlessly deferred (Tushnet 1984). The 'meanings' of law, from this perspective, must be sought in both dominant ideologies and representations, and also in everyday social practice, where oppositional legal meanings may possibly be discerned.

What then of space? Recent geographic scholarship on law has been critical of both regional perspectives and impact analyses for their tendency to reduce geography to a limited set of variables (for example, by thinking of space as purely a matter of regional diversity) or in presenting space as an objective, autonomous, and neutral variable that, like law, is set apart from society. In tandem with recent legal scholarship, 'critical' geographers have insisted that the effect is not only analytically misguided, given the claim that space is both socially produced and socially constitutive, but also politically problematic, given the claim that space 'is political and ideological. It is a product literally filled with ideologies' (Lefebvre 1979, p. 31).

Examples of the social and political dimensions of space can be traced at various levels of inquiry. For example, simple reflection reveals the ways in which interpersonal spatial categories such as 'near' and 'far' are not abstract concepts, but socially contingent, being very different for men and women, for example (as the concept of 'personal space' reveals), as well as being culturally diverse. Straight Italian men may publicly embrace in a way that would be frowned upon amongst men in Northern England, for example. However, the categories are also more complicated. The workings of racism, for example, depend in part upon spatial arrangements that place racialized groups identified as unlike 'us,' at a spatial remove from those

we hold 'near and dear.' Or, for another example, we need only think about the ways in which Western urbanites find it relatively easy to engage in economic practices that can prove destructive to the everyday lives of 'distant strangers,' such as *campesinos* displaced from their lands by multinational fruit growers, perhaps because of the ways in which distance hides the ethical consequences of our actions from us.

With the claim that both law and space are therefore socially and politically implicated, 'critical legal geographers' have sought to think through the ways in which the relationship between the two might be understood. Rather than treating law and space as autonomous categories, and then tracing the effect of one upon the other, both are understood as socially produced and socially productive. To that extent, the dualism between the two is recast as one of complicated recursive relations; put simply, law can shape space, yet at the same time can itself be shaped by the geographic structures of social and political life. The effect, ultimately, is to dissolve the binary split between the two. This scholarship is 'critical' not only in its attempt to go beyond the traditional categories of more mainstream social science, but also in its more engaged political and ethical stance, given the claim that prevailing legal and spatial arrangements and understandings are associated with hierarchical forms of oppression and domination, including those that center on class domination or patriarchy (Chouinard 1994).

It is hard to generalize about this research, which is still diverse and often unconnected. Scholarship has explored all spatial scales, whether particular localities (e.g. Clark 1985), national legal systems (Engel 1990), and international law (Darian-Smith 1995). Substantive areas covered include crime and policing (Herbert 1997), racism (Ford 1994), the city (Cooper 1998), gender (Sanger 1995), and property (Coombes 1995). That said, some broad areas have received attention.

3.1 Law and Place

The relationship between law and place is considered in a number of ways. For example, some writers point to the ways in which modern Anglo-American law, at least, has historically sought to distance itself or detach itself from local contexts. Blomley (1994) traces the ways in which English common law moved very consciously away from the local communities that had traditionally been the source of its meanings and interpretations to emerge in the sixteenth century as that law which was 'common' to all. This can have direct political consequences. Frug (1980), for example, explores the implications for the legal disempowerment of the city, and raises broader issues concerning local democracy. More generally, Pue (1990) condemns judicial interpretation as 'anti-geographical' in its refusal to recognize local contextual conditions. The insistence on the spatial contextuality of law is not only important in analytical terms. Such a claim can be a direct challenge to what has been termed 'legal closure,' that is, the dominant assumption that legal knowledge and interpretation is detached from the vagaries and politics of social and political life, operating according to its own closed logic. As noted, critics argue that legal closure is not only nonsensical, given the social nature of all discourse and meaning, but also ideological, naturalizing what are fundamentally political claims about society.

That said, in at least two ways place retains its legal importance. First, there has been a number of attempts to argue that formal legal interpretation is, in fact, not as detached from the locality as it claims. American constitutional law, for example, wavers between centralization and a recognition of localized contextual conditions and the integrity of community-based forms of law making and interpretation (Briffault 1990).

Second, in thinking through the relationships between law and place, others recognize that law is much more than formal, judicial decision making. As noted, law emerges as a vital medium and resource for daily life, being called upon in formal and informal ways. Given that, generally speaking, we live our lives out in particular places, that process of legal interpretation could also be said to be localized in some interesting and important ways. In a fascinating series of studies in three US towns, for example, Greenhouse et al. (1994) reveal 'the place of law and the court in the construction of community and hierarchy,' noting the ways in which local as well as extra-local conceptions of law and rights are central to the ways in which community and place are constructed. Similarly, Cooper (1998) explores the way in which an appeal to 'place and belonging,' as she puts it, is important to legal struggles in particular areas. Thus, an attempt by orthodox Jews in Barnet, London, to build an 'eruv,' allowing them to conform to Jewish legal obligations concerning activity on the Sabbath, becomes the spark for conflict with local non-Jewish residents as well as non-orthodox Jews more generally. Cooper traces the way in which this struggle turned on legal and spatial understandings of 'insiders' versus 'outsiders,' rights to place, and the construction of 'Englishness.'

3.2 Geographic Dimensions of Legal Discourse

Closely linked is the study of the geographic claims and representations contained within legal discourse, it being noted that, despite its suspicion of local contingencies, law nevertheless draws upon and helps define a range of spatial patterns, divisions, and associations. These legal representations touch all aspects of legal life, including property, constitutional law, contract, crime, and inter-governmental law. Don Mitchell (1996), for example, outlines the ways in

which judges and other legal actors help define the boundaries between public and private space in US cities, and regulate the activities that are deemed permissible in such spaces. This, he notes, has had particularly oppressive consequences for those people who are effectively denied private space — the homeless. Legal action and interpretation in this sense can actively create certain spatial arrangements, practices, or representations. So, for example, David Delaney (1998) analyzes legal decisions concerning the legality of restrictive covenants in the USA, designed to exclude black residents from white neighborhoods. Necessarily, this entailed various construals of urban space on the part of the judiciary. For Delaney, the effect of such apparently objective mappings was to position the judge as an active participant in the construction of ethnic spatial segregation.

The manner in which such legal constructions of space are contested are locally reworked by marginalized groups is also receiving attention; see, for example, Azuela's (1987) discussion of the ways in which squatters in Mexico City redefined concepts of property. Such legal understandings and representations of space, in other words, are not simply the provenance of formal legal actors. Blomley (1998) explores the way in which struggles over gentrification in Vancouver, Canada, entailed competing conceptions of property rights and land that, in turn, entailed specific representations of the landscape of a local area. For groups representing the poor of the area, opposed to gentrification, the buildings, parks, hotels, and streets of a local area were imbued with legal and political meanings, serving as a physical monument to past acts of oppression and displacement, but also a means by which a collective claim to a neighborhood could be figuratively staked out. In other words, to understand the conflict it was necessary to think about both the importance of contesting claims to property and at the same time, to explore the ways in which those claims were expressed in, and dependent upon local spaces, that were both material and representational.

3.3 *The Politics of the Law–Space Relationship*

As already noted, critical scholarship in law and geography begins with the claim that the two are deeply political. That is, legal–spatial relationships can serve to reproduce prevailing inequalities in power and resources, yet can also serve as a site for struggle and resistance to such forms of domination. Santos (1987), for example, borrows from critiques of cartography to argue that state law deploys particular scales, projections, and symbols that can serve to advance dominant interests. Similarly, Peters (1997) has documented the ways in which law has been used to geographically 'place' (and hence 'displace') First Nations in Canada —both by spatially locating Native peoples in marginal reserves and by socially and politically locating them within Canadian society. In a related vein, Borrows (1997) documents the manner in which dominant forms of Canadian legal knowledge have no place for indigenous understandings of place and nature. Others seek to turn the political tables. Chouinard (1989) focuses on local law clinics in Ontario as a site for class-based resistance while Kobayashi (1990) opposes legal closure in relation to racist legal practices.

4. *Future Research*

While suggestive, the critical legal geography literature is still in a state of formation. To date, it has (perhaps fortunately) avoided a clear self-identity. While the work of many scholars is legal and geographic, most would not necessarily identify themselves in those terms. This is thought to be a good thing, encouraging the sort of truly interdisciplinary inquiry that is called for. That said, these writings have managed to begin to pose some suggestive and novel questions. Yet many issues still await careful inquiry. More generally, the theoretical basis for critical inquiry into law and geography is still somewhat undeveloped, despite some attempts (e.g., Clark 1989, Blomley 1994, Chouinard 1994). Some have embraced the postmodern turn, focusing attention on discourse and the construction of meaning. Others have worried at the degree to which this constitutes a rejection of political–economic and socialist–feminist insights (Chouinard 1994). Similarly, a focus on the meanings and discourses of law has meant the neglect of its more practical dimensions. To that extent, careful engagement with 'impact analyses' might be productive. Detailed, empirical accounts of the workings of law within particular locales are also still needed. Revisiting the regional school might again be useful here, if only as a counterpoint. The relationships between law, space, and nature, another traditional area of geographic concern, have only just begun to be explored. The ethical dimensions of law—for example, the complicated politics of rights—are also worth thinking about, particularly given recent geographic scholarship in the area. While some work has been done, the manner in which social and spatial differentiation and inequality along axes such as class, 'race' and gender are expressed in, facilitated by, or reconstituted through law also calls out for careful analysis. The geographic relationships between law and other socially and politically powerful forms of knowledge, such as planning, or medicine, could also be profitably considered. More generally, the manner in which law represents the monopoly of organized violence has not been thought through, particularly from a geographic perspective.

Law and Morality: A Continental-European Perspective

Under the general rubric of the concept and nature of law, one of the most fundamental problems is the relation between law and morality. Two positions have been locked in combat for over 2000 years: positivism and nonpositivism. All positivists share the separability thesis; all nonpositivists contest it in at least one respect.

1. *The Separability and Separation Theses*

The separability thesis says that there is no necessary connection between law and morality. This implies that all connections between law and morality are merely contingent in character. There exists no neces-

sary relation between what the law is and what morality or justice requires, or between the law as it is and the law as it ought to be. The great positivist Hans Kelsen has put it this way: 'Any content whatever can be law' (Kelsen [1934] 1992).

The separability thesis defines the softest version of legal positivism. Its only claim is that it is possible to have law with any content whatever, independently of any and all demands of justice. It does not rule out the possibility that the positive law of a certain community includes moral principles, for instance, through constitutional provisions that transform human rights into positive law. Where the concept of law is understood positivistically, the only requirement stemming from the concept of law itself is that the inclusion of moral content is considered as a matter of fact, that is, as merely contingent and not in any way necessary.

A stronger form of positivism is expressed by the separation thesis. The separation thesis necessarily presupposes the separability thesis, and adds to it that there are good normative reasons for defining the concept of law in a way that excludes all moral elements. This means that the separability and the separation theses refer to two different kinds of arguments. The separability thesis, along with its opposite, the nonseparability thesis, is concerned with what is necessary, analytic, or *a priori*. The separation thesis, too, depends of course on these arguments, for there cannot be separation without separability. But it claims more. It does not confine itself to determining what definitions of law are possible. It also tries to identify the best definition. For this purpose, normative arguments are indispensable. There is, therefore, a division of labor between the separability and the separation theses. Arguments supporting the first thesis attempt to show that it is possible to exclude all moral elements from the concept of law; arguments on behalf of the second thesis seek to establish that this exclusion is preferable.

If the separation thesis applies, only two elements remain as candidates for the definition of law: appropriate enactment and social efficacy. The concept of social efficacy refers to such matters as habits, orders backed by threats, and to beliefs, emotions, and attitudes. Authors of a legal realist persuasion have tried, following this lead, to reduce law to social or psychic facts conceived as natural facts (Olivecrona 1939). The concept of appropriate enactment is more refined. It is impossible to distinguish between what is appropriately, and inappropriately, enacted without reference to norms conferring and defining the power of enactment. The most famous power-conferring norm is Kelsen's Basic Norm (*Grundnorm*). Introducing a basic power-conferring norm, Kelsen aims at normativity without morality (Paulson and Litschewski Paulson 1998).

The elements of social efficacy and appropriate enactment can be interpreted and combined in very different ways. For this reason, a great many variations on the theme of legal positivism are conceivable. What is common to all of them is that the concepts of social efficacy and/or appropriate enactment are sufficient for the definition of law. Morality as such is neither a necessary element nor an optimal third element of the concept of law. Precisely this is contested by nonpositivism. All nonpositivists share the view that the concept of law must or ought to include moral elements. If the inclusion of moral elements is conceived as necessary, one can speak of a strong connection thesis. The strong connection thesis is the contradictory of the separability thesis. If the inclusion is conceived only as preferable, not necessary, one can speak of a weak connection thesis. The weak connection thesis is the contradictory of the separation thesis.

The most radical nonpositivist concept of law consists in the complete substitution of social efficacy and appropriate enactment by moral correctness. This would be a pure natural law theory. In practice, such a radical pure natural law theory would amount to anarchism. For this reason, serious natural law theorists such as Thomas Aquinas stress the necessity of positive law as defined by appropriate enactment and social efficacy (Aquinas 1988). The crucial question, therefore, is not whether law is to be defined either by social efficacy together with appropriate enactment or by moral correctness but rather whether or not social efficacy and appropriate enactment are to be connected with moral correctness in one way or another. There are three ways in which such a connection can be conceived. Morality can be connected with positive law, first, by including moral principles and arguments in the law, second, by limiting the possible content of law, and, third, by providing an appropriate foundation for the obligation to obey the law. One can, therefore, distinguish three different problems concerning the relation between law and morality: the inclusion problem, the limitation problem, and the problem of an appropriate foundation.

2. *The Inclusion Problem*

The logical basis of the inclusion problem is the open texture of law. Positivists and nonpositivists agree, first, that law has an open texture (Hart 1994) and, second, that cases falling within the open sphere of positive law are often decided on moral grounds. Such a purely factual connection is fully compatible with legal positivism. What is more, if one now goes on to assume that moral principles are incorporated by virtue of their correctness into the law through a rule of recognition *qua* 'conventional normative practice' (Coleman 1996), even then one remains inside the positivist camp. A conventional practice is a practice that either exists or does not exist. Whether or not it

exists is a matter decided by the positive legal system at hand. The classification as 'inclusive positivism' is, therefore, correct (Coleman 1996).

Positivism yields to nonpositivism only if it is maintained that the inclusion of moral principles and arguments into law is necessary and not merely contingent. A central argument for the necessity of this inclusion is the argument of correctness. It proceeds in two steps. In a first step, the attempt is made to show that law necessarily raises a claim to correctness. The second step consists in explaining that this claim implies a necessary connection between law and morality.

Implicit claims can be made explicit by showing that their explicit negation involves absurdity. One has only to imagine a judge who hands down the following judgement: 'The defendant is hereby sentenced to life imprisonment, albeit wrongly, because valid law was interpreted incorrectly.' The absurdity of this judgment stems from the contradiction between the claim to correctness implicit in acts of law and its explicit negation. This contradiction can be avoided only if the claim to correctness is given up and some sort of power claim is introduced in its place. But this would be to abandon law. A social practice claiming nothing but power or force would not be a legal system. In this sense, the claim to correctness is necessarily connected with law.

A positivist can agree with this and nevertheless maintain that the necessary connection between law and the claim to correctness does not imply that there exists a necessary connection between law and morality. All he needs to say is that the claim to correctness has a purely legal content and that this legal content has no moral implications.

This leads to the second step of the correctness argument. That a case falls within the open sphere of positive law means that positive law does not determine the answer. If the judge were bound only by positive law, he could, whenever the positive law reasons run out, decide the case by appealing to his own personal preference or by tossing the dice. This, however, would be compatible with the claim to correctness only if there existed no reasons for the correctness of a legal decision outside the class of positive law reasons. Now legal decisions are answers to practical questions, and there exists a variety of reasons as answers to practical questions that are found outside the class of positive law reasons. The spectrum comprises consideration of utility, familiar ideas from the tradition about what is good and bad, and principles of justice.

Justice is correctness of distribution and balance, and questions of justice are moral questions. Legal decisions essentially concern questions of balance and distribution. Therefore, legal decisions essentially concern moral questions. This, together with the claim to correctness necessarily raised by legal decisions, leads to a necessary connection of legal and moral argument. This necessary connection of arguments does not mean that morally mistaken legal decisions cannot be legally valid. It does mean, however, that they are not only morally but also legally mistaken. In this way, the idea of justice is incorporated into the concept of law. This affects the picture of law fundamentally (Alexy 1998).

3. *The Limitation Problem*

If the correctness argument is sound, legal norms and legal decisions that for moral reasons do not fulfil the claim to correctness are legally mistaken, but they do not necessarily lose, on this basis alone, their legal character or their legal validity. Anarchy would be the consequence if each and every moral defect were sufficient by itself—that is, without any institutional act or decision—to undermine legal validity or even the very legal character of the norm or the decision. So far, there exists a broad consensus. Highly contested, however, is the question of whether gross injustice undermines legal validity or legal character. This question was the topic of Hart's well-known critique (Hart 1958) of Radbruch's famous formula (Radbruch 1946). The shortest conceivable formulation of this formula runs as follows: extreme injustice is not law. This formula, which was applied by German courts after the defeat of National Socialism in 1945 and after the collapse of the German Democratic Republic in 1989, does not require any sort of complete fit between law and morality—as the claim to correctness does. Rather, it allows that appropriately issued and socially effective norms are valid law even if they are severely unjust. It is only in cases of extreme injustice that the formula gives priority to material justice over legal certainty. In this way, it builds into law an outermost limit. This limit is substantially defined by the core meaning of human rights.

The acceptability of the Radbruch formula essentially depends on whether it is judged from the observer's point of view or from that of a participant. It is not a problem for the nonpositivist to grant that an observer, wanting merely to describe the law of a wicked legal system, can and should use a positivistic concept of law based exclusively on appropriate enactment and social efficacy. The controversy over Radbruch's formula begins once the participant's perspective is considered. The participant's perspective engages one who, from within the legal system (for instance, as an official who has to apply the law or as a citizen who has to abide by it), asks what the law requires, forbids, and permits.

The dispute about whether or not an outermost moral limit ought to be built into the concept of law cannot be decided merely by means of conceptual arguments. The meaning of the expression 'law' excludes neither Radbruch's formula nor its negation. The decision can only be grounded on normative

arguments. In other words, the inclusion or exclusion of an outermost moral limit cannot be based on a conceptual necessity, but only on a normative necessity.

There are good reasons for both positions. The main argument of the positivists is the argument of legal certainty. They claim that the Radbruch formula leads to hidden retroactivity which, in penal law, boils down to a violation of the principle *nulla poena sine lege*. This is the case because Radbruch's formula invalidates statutes of an iniquitous legal system that permit extreme injustice. This is said to be unacceptable for, it is argued, the principle *nulla poena sine lege* protects everybody, even the henchmen of an iniquitous regime, so long as their atrocities are covered by the positive law of that system. The nonpositivist responds that legal certainty and, in particular, especially the principle *nulla poena sine lege* are, indeed, lofty values, but that they are not the only values at stake. They are in conflict with the material justice to which past and future victims of iniquitous regimes have a claim. In the end, these problems are to be resolved by weighing the principles at issue. In normal situations, the *nulla poena sine lege* principle must have priority. In cases of extreme injustice, however, the situation is more difficult. There are good arguments for giving priority to the protection of the rights of past and future victims over the protection of those who, implicated in the acts of an unjust state, have relied on a legal justification of their deeds on the basis of a 'legal positivization' of injustice (Dyzenhaus 1999).

4. *The Problem of an Appropriate Foundation*

The third problem of the relationship between law and morality concerns the question of whether there is a moral obligation of all addressees of the legal system to obey the law simply because it is the law, independently of its content. This is the question of a general moral obligation to obey the law (Raz 1979). If such a general moral obligation exists, morality offers an appropriate foundation of law.

The problem of an adequate foundation is related to legal positivism in a way that is completely different from the relation of the inclusion and limitation problem to legal positivism. Positivism is compatible with the assumption of a general moral obligation to obey the law as well as with a complete denial of such an obligation. The first version can be called moral positivism, the second, neutral positivism. Moral positivism is the strongest form of positivism. It combines a moral obligation to obey even the most immoral law with the thesis that law can be as immoral as possible as long as it does not lose social efficacy. Neutral positivism expresses a far weaker form of positivism. Law imposes only legal obligations. These legal obligations need not be in conflict with moral obligations, but they can be. Neutral positivists can even say that in case of conflict, moral obligations enjoy priority. They remain positivists so long as they say that the priority of a moral obligation *qua* moral obligation does not undermine the legal validity of the conflicting legal obligation. The situation of nonpositivists is more complex. Not all, but some conflicts between law and morality are already solved for them before the question of a moral duty to obey the law arises. Cases of extreme injustice are conceptualized by nonpositivism not as conflicts between valid law and morality but as instances of the limits of law. Thus, from the nonpositivist point of view, there is no confrontation of a general duty to obey the law with the problem of extreme injustice. Beneath the threshold of extreme injustice, the problem of a general duty to obey the law is, however, the same for a positivist and a nonpositivist. Nonpositivism mitigates the problem but is not able to solve it. Its solution poses a moral question.

The most general reasons for the general duty to obey the law are the values of nonhostile conflict resolution and social cooperation. Neither of these can be achieved without law, and both ought to be achieved, for rights are endangered where social conflicts are resolved by brute force, and general welfare and well-being are not possible without social cooperation. This is the classical argument for a general moral obligation to obey the law as it is found—with respect to the protection of rights—in Kant (Kant [1798] 1991).

There are two kinds of objections to a general moral obligation to obey the law. The first attempts to undercut such an obligation, the second, to rebut it. The undercutting objection maintains that there are cases in which transgressing the law does not affect the values of nonhostile conflict resolution and social cooperation at all—or at any rate, so minimally that the effect can be neglected. Two examples, frequently given, are not stopping at a red traffic light in a remote area late at night where no one is around to notice it and small tax offences that no one will ever discover. If it can be taken for granted in these cases that no one will take notice of the offences, no bad example is set that might endanger the general willingness to abide by the law and, through this, law's social efficacy. Where this point is concerned, the two cases are indeed on the same footing. There is, nevertheless, a fundamental difference. If the conditions of the traffic light case prevail—no danger, and no observer—this case is indeed a case in which violating the law has no negative effects. The decision here turns on the solution to a general problem of moral philosophy, namely, the question of whether acts or rules are the genuine objects of moral assessment. This is the focus of the debate between act and rule utilitarianism (Rawls 1955). If one follows the dictates of act utilitarianism, the general duty to obey the law will be undercut in cases such as the stoplight case. The practical impact

of this solution, however, is small, for the occasions on which one can be completely confident that the two conditions—no danger, and no observer—are fulfilled, are rare.

Whilst it is possible to conceive the general obligation to obey the law as being undercut in the red traffic light case, this is impossible in the tax case. Even if only a small amount of money is at stake, it is clear that the offence will affect negatively the overall public financial situation. The advantage on the side of the offender corresponds to a disadvantage on the side of the community. Taking advantages by failing to contribute to a common enterprise where others contribute is—at least *prima facie*—unfair. In the tax case, the moral obligation to obey the law is, therefore, not undercut—even if, where no one knows anything about the offence, the general willingness to abide by the law is not endangered.

The bad example problem must be distinguished from the problem of whether there is a moral obligation to obey immoral law. What is at stake here is the question of rebutting the general obligation to obey the law. Essentially this problem is a problem of balancing legal certainty against moral correctness. Only those who give absolute priority to the moral value of legal certainty will never allow that the general moral obligation to obey the law may be rebutted by moral reasons. All the others have to solve difficult moral dilemmas case by case. For the others, too, there exists a general obligation to obey the law, but this obligation is not indefeasible. This is true not only for positivists, who have to take up the weighing procedure with an unlimited concept of law, but also for nonpositivists, who with their extreme-injustice clause are able to solve the most serious—if by no means all—moral dilemmas posed by law.

Law and Morality: An Analytic Perspective

As complementary and competing systems of normative social order, law and morality have much in common. Not only is there substantial overlap in the content of the moral and legal norms of all societies, but law may readily be seen as both an expression of and an influence on a society's morality. Judges are expected to have regard to moral considerations when interpreting, applying, and developing law and, in most democratic countries, they have the power to override legislation which conflicts with those basic moral rights, such as freedom of expression, which are enshrined in the constitution of their polity. Further, legislatures are expected to make law in the light of the moral beliefs of the population, particularly those which relate to peace, well-being, and social justice.

Moreover, legal systems depend, in varying degrees, on securing the conformity of citizens, which in turn depends, in part, on satisfying their moral expectations as well as their self-interest. The moral constraints which citizens impose on each other and on themselves through the informal processes of social approval and disapproval are crucially reinforced by the sanctions of criminal law and the remedies for such matters as breach of contract and negligence, which are enforced by the civil law. The ethics of public officials is underpinned by administrative as well as criminal law. Moreover, legal and moral discourse shares a whole range of basic concepts. Justice, fairness, rights, utility, equality, and freedom are the common vocabulary of both normative systems. In less developed societies there is little or no institutional divide in the normative structure between law and morality.

These commonalities of law and morality must be kept in mind when examining attempts to distance law and morality. They suggest that the social functions of law and morality are similar and overlapping, part of a wider system of normative order arising out of the requirements of an ordered human society. That said, however, there are important differences between law and morality which call for analysis, explanation, and evaluation.

1. *Critical and Positive Morality*

Focusing on apparent differences between law and morality, several key factors emerge: (a) law is said to be mandatory, even coercive, whereas morality is voluntary; (b) law is said to be an institutionalized system of norms, with specialized officials and procedures, whereas morality is informal and diffuse in its operation; (c) law is public and associated with the state, morality is private, a matter for the individual to determine for herself; (d) the identification of law requires reference to past events and previous authoritative decisions, whereas moral determinations are not so restricted; (e) laws and legal systems may or may not be just or justified depending on their content and procedures but there is something incongruous in the notion of an unjust moral principle.

Some of these points can be clarified by distinguishing between two senses of morality, the first referring to the collection of norms of conduct which are generally observed and used to criticize conduct in a given social group. This is sometimes called 'positive morality' (Austin 1954, p. 122). The second sense of morality is the activity of criticizing and evaluating the norms which make up positive morality. It is critical morality (Hart 1961, pp. 176–80) in which the content and form of positive moralities are assessed and judgments are made about what actually is right and wrong that give rise to most of the differences between law and morality. Making critical moral judgments cannot be coerced or forced on others and it makes no sense to come to the critical conclusion that it is right to act unjustly, unless injustice is defined by reference to norms of positive morality. Critical morality may be contrasted to both legal and positive moral systems of norms, with the law and positive morality sharing the characteristics which typify ongoing cultural structures and critical morality standing outside and above these phenomena.

Of course, positive systems may encourage and include critical attitudes towards prevailing norms so that critical morality can itself be viewed as part and parcel of positive morality, but the importance of the distinction between positive morality and critical morality has more to do with the perspectives involved, in particular the distinction between describing the moral beliefs and actions of an individual or group and evaluating those beliefs and actions from the moral rather than the sociological point of view. Precisely what that moral point of view may be is a controversial issue within moral philosophy, but we may take it to be the point of view which seeks to determine the ultimate criteria for assessing the worth of human conduct from an impartial or universal perspective (Baier 1958).

Having distinguished positive and critical morality, we can frame the questions which arise in relation to law and morality in a more sophisticated way. Thus we may raise, as a matter of critical morality, whether (a) law ought to incorporate the positive morality of the citizens of that jurisdiction, (b) the critical moral principles which we adopt to criticize positive morality ought to be the same as those we use to criticize law, and (c) there is such a thing as critical as opposed to positive law, similar to the distinction between critical and positive morality.

1.1 *Legal Positivism and Natural Law*

The relationships between law and morality have long been prime sites for the articulation of competing legal philosophies, particularly classical natural law and legal positivist approaches to the understanding and evaluation of law and legal systems. However, as we have seen, the relationships involved are varied in type and substance and it is by no means clear that the traditional packages of theses associated with the classical theories still hang together. Indeed there are real prospects for conceptual realignments which render some of the historical debates on law and morality outmoded.

Legal positivism, which received its classical formulation in the work of Jeremy Bentham and John Austin during the eighteenth century, is the legal theory which emphasizes the separation of law and morality, and the subordination of morals to the will of the sovereign (Austin 1954). Following on from Hobbes' analysis of political authority as based on the requirements of mutual survival in a predatory social world, the state is seen as imposing a morally arbitrary rule of order so as to secure peace between warring factions, religions, and moralities. This characteristically modern theory of the state replaced the medieval European synthesis of government, religion, and morality which received its classical formulation in the *Summa Theologica* of Thomas Aquinas whose definition of law as 'a rational ordering of things which concern the common good; promulgated by whoever is charge with care of the community' (Aquinas 1966, Art. 4) sums up the fusion of law and morality in the natural law tradition.

Austin, through whose work legal positivism became the reigning orthodoxy in Anglo-American legal theory, presents his position in a series of definitions designed to identify law in empirical terms, such as

command, sanction, and habitual obedience. Law is defined as the general commands of a sovereign, that is, the person or group who is habitually obeyed in a certain territory and does not himself habitually obey anyone else. A command is the expression of a wish relating to the conduct of another which is backed by threats of force, legal obligation being the likelihood that failure to comply with the a command will be followed by the imposition of sanctions. Each state has one such sovereign (which may comprise an individual or a collectivity) who is at the giving but not the receiving end of such commands. The existence of this unitary sovereign is the core of the positivist analysis of the modern sovereign state.

It is a defining feature of this mode of legal positivism that there is no necessary connection between law and morality (Hart 1961, p. 181). The classical positivist separation of law and morality is intellectually based on Hume's distinction between 'is' (statements about what is and is not the case) and 'ought' (statements about what ought or ought not to be the case). In Austin's ringing words 'the existence of law is one thing, its goodness or badness another' (Austin 1954, p. 184). Ever since, legal positivists have insisted that it is possible to separate out the description of law from our moral evaluation and criticism of that law: legal argument is not moral argument, legal authority is not moral authority, and a law is a law whether it is just or unjust, good, or evil. All this applies only to what is called 'positive law,' that is, the law as it is actually experienced in human societies.

Such a dichotomy depends on our capacity to identify law in an empirical manner and this Austin does with his analysis of law as the command of a political sovereign. In the terminology of a more recent and equally famous legal positivist, H. L. A. Hart, the law of a jurisdiction can be identified by means of its 'rule of recognition' (Hart 1961, pp. 92–3), which lists the criteria used by officials to determine legal validity, that is, what is and what is not part of the law of that jurisdiction. In Austin's case that rule nominates the commands of the sovereign as the criterion which is necessary and sufficient for the determination of legal validity.

A similar approach is taken by the classical legal positivists to positive morality. The rules of conduct which are widely followed in a given society and are backed by the sanctions of public approval and disapproval are seen as a system of identifiable norms analogous to positive law. Both of these are distinguished from 'natural law,' a term which Austin is happy to apply to what is actually morally right and wrong in human conduct, which he himself, following Bentham and perhaps Hobbes, identifies with the utilitarian standard of acting or refraining from acting so as to maximize human happiness and minimize human pain. While such natural laws can be regarded as the commands of the ultimate sovereign, God, they feature in the critique of positive law and not in its identification. The classical natural law position, in contrast, is that knowledge of right and wrong as manifest in God's law speaking through human reason or conscience plays an essential part in the identification and understanding of all laws, including positive laws.

For some natural lawyers this means that there can be no such thing as an 'unjust law.' However, John Finnis, one of the most influential natural law theorist currently writing, denies that natural lawyers have always or have needed to deny the existence of unjust laws. He also points out that natural law has a developed view on the role of positive law as a social institution that is necessary to give concrete application to the general moral principles which derive from natural law (Finnis 1980). Further, there are powerful arguments to the effect that, while individual laws may or may not be just, the concept of law, as distinct from the content of particular laws, is necessarily connected with justice, for law is an institution that must not only claim to be just but seek to be (Beyleveld and Brownsword 1989).

Put in these terms, it appears that the disagreement between legal positivists and natural lawyers is about the meanings of the terms 'law' and 'morality,' in which case the apparently major theoretical division between legal philosophies is in the nature of an uninteresting irrelevance. Stipulative definitions of law and morality may give rise to a logical separation between the terms, but there are no essential and unchanging meanings which we are required to adopt, so that it becomes a matter of choice, individual or cultural, whether or not we conceive of law and morality as conceptually tied.

A crucial matter of interpretation is whether the role of natural law in both classical approaches is an exemplar of positive or critical morality. In the case of legal positivism there seems no doubt that the utilitarian morality used to assess legal systems is presented as a critical morality. Indeed, Bentham gives this activity the title 'censorial jurisprudence.' In the case of natural law theory, the situation is less clear. This is because of the moral methodology of natural law which depends on reasoning about 'nature,' which includes human behavior, particularly normative behavior, that is conduct which involves the control of natural appetites in a way which makes social life and individual spiritual development possible. In effect this means that universal positive morality has a key evidential role in determining what is in accordance with right reason. However, it is clear that classical natural law theory presents as a critical morality, and modern 'natural law' theories, which are standardly uncoupled from theological backgrounds or moral deference to what is 'natural,' hold that it is critical not positive morality that is central to the very idea of law.

This does not mean, however, that the classical theories are simply presenting competing schemes of

critical morality with the utilitarianism of legal positivism pitted against the theological naturalism of natural law. Indeed, both theories have outgrown their original moral affiliations. Exactly what is now at stake between the two approaches is best explained by reference to more recent controversies over the 'separability thesis.'

1.2 Separation and Separability

With the introduction of Hart's rule of recognition and, before that, the impact of Kelsen's 'pure theory of law' which includes the idea of a presupposition about the authority of law from which all legal validity derives, the classical debate about law and morality has come to be formulated in terms of what is known as the 'separability thesis.' This goes behind the positivist idea that positive law can all be traced to social sources, such as commands, or enactments, or court decisions, to an examination of the content of the rule of recognition that is used in the processes which make up those human sources of law. In other words, the focus has shifted to the sources of law as understood by the officials whose pronouncements constitute the social origins of law, namely the criteria given in the operative rule of recognition.

The separability thesis, as formulated by Jules Coleman, is the view that a rule of recognition need not include moral criteria, such as justice or utility, but can consist entirely of empirical identifiables such as human commands or legislative enactments. Because this thesis is compatible with all actual rules of recognition including moral criteria, this minimalist form of legal positivism is called 'soft', or sometimes 'inclusive' legal positivism (Waluchow 1994), as opposed to the 'hard' or 'exclusive' variety which admits only nonmoral criteria into anything which counts as a rule of recognition. According to soft legal positivism it is a contingent matter how far a legal system officially incorporates moral considerations into its criteria of legal validity. Such a view is regarded as positivist because it requires that morality enters into legal reasoning through an empirically identifiable rule of recognition which happens to include moral criteria and not, as it were, in its own right. Hard positivism also accepts that moral criteria are, indeed ought to be, utilized in the making of law through legislation, but insists that what makes that morality or anything else into law is its adoption by authorized law makers. The difference between soft and hard legal positivism seems to come down to whether legal officials, such as judges, can make law through the direct application of their own moral views or by reference to the moral views of others or whether they must identify law in much the same way as a social scientist seeking to describe the law of a particular jurisdiction. It can be argued that if soft positivism allows that some legal systems require judges actually to make correct moral determination in determining what the law is, then it is really a soft natural law theory.

Important empirical issues then arise for social science as to whose positive morality finds its way into the law, how that law in turn affects morality in general, which elements of morality most commonly find legal expression, and which are more often excluded from law. It is also a matter for empirical study how far the morality within the law stems from legislative or judicial activity.

Viewed as a descriptive thesis, soft legal positivism is clearly superior as all legal systems appear to allow some role for moral judgments in the legal reasoning which determines legal validity. Common law systems permit judicial development of law in the light of broad moral principles, albeit subject to the theoretical right of legislators to amend the common law. More and more legal systems incorporate a bill of rights with general moral principles which it is the court's duty to interpret, something which can be done only by reference to the moral preferences of those who give concrete application to such vague moral standards as equality and freedom. All this seems to accord more with a natural law approach, at least with respect to the idea of fundamental rights as the point where law and morality are inseparable (Dworkin 1996).

It is true that the moral reference in rules of recognition often serve only to incorporate positive morality or some identified aspect of it within the law; often this is done by the idea that the law must enforce reasonable expectations. However, if only because there is seldom any indisputable agreed content to positive morality on any topic, in effect these approaches call for the judicial exercise of critical moral judgment. For the soft positivist to claim that this need not be the case seems a relatively minor point to make about law and morality.

The retreat into soft positivism is explicable because of the emphasis that legal positivists have historically placed on providing a descriptive theory of all developed legal systems. However, there are good reasons for seeing legal positivism in a more normative light as an approach which is actually setting forth an idea of a 'good' system of law, so turning the separability thesis into a prescriptive claim about what a rule of recognition ought to contain. Thus, hard positivism may be viewed as a more or less disguised prescription which is recommending that a rule of recognition ought not to include moral criteria and that all positive law should be framed in such a way that it can be understood and applied without recourse to the moral opinions of citizens or judges (Campbell 1996, p. 72).

This normative approach to the separation of law and morality derives from a complex political philosophy that points to the role of authoritative rules in human society (Raz 1979). Social cooperation and coordination, dispute resolution and maintenance of

public order, it is alleged, require that there be rules which are followed and enforced according to an authorized formulation that leaves as little room as is possible for doubt as to their content and implications. These arguments often relate to the utility of rules as social devices which give effect to conventions that make it possible for individuals and groups to anticipate each others conduct with considerable reliance. The utility of these rules is relatively independent of their precise content since what matters is that there is some generally recognized convention rather than precisely what that convention may be (Postema 1982).

While these considerations give us reason to see why it may be socially important for some laws to be clear and applicable without controversy as to their meaning, other laws, such as those forbidding clearly harmful conduct, are more dependent on the moral acceptability of their content. Even here, however, there is a role for an official determination of which conduct is punishable and which is merely open to social criticism. The need for definitive rulings in morally salient cases derives from the fact of moral disagreement, the fact that there is rarely any one coherent system of positive morality, particularly where the culture encourages critical approaches and individuals have some autonomy in making up their own minds as to what they believe ought to be punished or recompensed. The political need to reach a working agreement on matters with such potential to generate conflict and disorder gives a role for the positivist idea of law as a system of mandatory rules whose authority depends on their adoption as law and not on their specific content.

Other moral arguments in favor of such a formalist conception of law are powerfully presented by Lon Fuller (1964) who demonstrates the connection between what he calls governance of rules, rules which are clear, promulgated, prospective, practicable, and stable, and a society in which there is respect for autonomous moral agents who can reasonably be held responsible for their actions and accept that their obligations are part of a mutually beneficial political system. Fuller calls his theory a procedural form of natural law. Its formal requirements of 'good' law are part of a morality of mutual respect. He goes further than this and argues that a government which abides by the requirements of good procedural law will thereby tend to produce good substantive law. In a classic exchange with Fuller, H. L. A. Hart pointed out that Fuller's procedural natural law is 'compatible with great iniquity' (Hart 1957). However, the general thesis that there are moral reasons for government in accordance with rules has clear affinities with prescriptive legal positivism, and it can be argued that Hart himself includes elements of this prescriptive approach (in a largely descriptive analysis) when he describes the benefits which arise for social order when the informal 'law' of simple societies is supplemented by 'secondary rules' which enable official determinations about what the primary rules of a society are and who has the right to interpret and change them (Hart 1961, pp. 77–96).

1.3 Enforcing Morality

Issues of law and morality as often framed in terms of whether or not law should enforce morality. It is generally accepted that there is a sense in which morality cannot be enforced because truly moral conduct involves the willing acceptance of moral obligations. Thus, Immanuel Kant defined moral goodness as doing what is morally right because it is morally right and not, for instance, because the law requires it of us.

Further, it is rarely argued, as a matter of critical morality, that the law should require conformity to all and only conduct that is morally correct. Natural law theory tends to identify justice and the common good as that part of morality which is binding on human beings in a way which makes it appropriately enforced through positive law. The theory also provides for governments to fill out positive law with lots of moral neutral ways which are required to give specific application to natural law values.

Classical legal positivists apply the general principle of utility to all moral questions, but point out that choosing a law is not making the same moral choice as choosing how to behave as an individual. Law involves sanctions and restricts liberty of action, which human beings enjoy and use to achieve their own happiness. Therefore, there are always moral reasons against enacting a law. This approach was developed by John Stuart Mill (1910) into the famous harm principle according to which only harm-producing conduct may be prohibited and then only when the negative effects of enforcing conduct are outweighed by the positive effects of reducing harm. He confined this harm to that which is caused to others, an anti-paternalist position which is a dominant strand in all liberal political philosophies.

This highly individualistic approach encouraged by the utilitarian moral theory is standardly countered by various forms of communitarian analyses of society, including natural law theory. This conflict is well illustrated in a classic debate between Lord Devlin (1965) and H. L. A. Hart (1963) on the matter of decriminalizing homosexual conduct between consenting adults. Devlin argues that the basic institutions of a society, such as marriage, have to be protected in the interests of that society as a whole, therefore, it is treasonable to allow forms of conduct which undermine such foundational social institutions. It follows that society has a right to enforce a particular type of sexual organization. This was a response to H. L. A. Hart, who takes the view that sexual conduct of this

sort is a purely private matter so that any disgust which the majority might feel towards such conduct has no bearing on the moral question of whether or not homosexual conduct should be a criminal offence.

Debates of this sort may be approached in a number of ways. Sociologically, Devlin's communitarian point can be investigated to see whether it is the case that the preservation of monogamous marriage as the dominant social institution with respect to sex and reproduction does require prohibition of incompatible forms of sexual conduct. Other arguments center on the concept of toleration, the idea that it is morally desirable to allow people to follow out their chosen way of life even when you think that they are wrong to behave in this way. The arguments for toleration are complex (Mendus 1988). For some people toleration is an acknowledgment of the significance of moral goodness. For others it is simply morally right not to interfere with the conduct of others when this does not harm our interests. For others it is a response to moral disagreement and the difficulty of reaching an objective decision about which competing form of life is morally superior. A more extreme form of this position is that choices between competing ways of life cannot themselves be moral choices, since all moral choices have to assume values which arise from a particular set of cultural circumstances. All these approaches neither permit nor encourage a pluralism of positive moralities which make it impossible for the law to enforce morality without a choice being made as to whose morality or which morality is to be enforced.

Responses to the problem of choosing which morality to enforce can be broken down into at least three categories.

(a) Those which aspire to a neutral principle which is not moral at all. Mill's harm principle has been presented in this light, but it is clearly part of the utilitarian maxim which values pain negatively. Indeed, it is clear that many theories smuggle moral ingredients into the concept of 'harm,' identifying it with the approved interests of those affected by the actions of others.

(b) Those who seek to distinguish between private and public spheres, arguing that the morality which pertains to law is public morality, that is, morality about political and state relationships, while private has to do with the individual and her freely chosen associates. This shifts the argument to what is public and what is private, a principal battlefield being the sphere of family relationships. Feminists have powerfully pointed out that to classify the family as private is to leave this male dominant sphere unregulated. Ultimately 'private' comes to mean simply those matters which the law ought not to deal with, making it uselessly circular as a principle for determining the proper sphere of the law.

(c) Those who seek to identify a certain number of basic rights which while not morally neutral, allow for an extensive range of different forms of life to flourish as each individual and group pursues its own conception of what is good. This is the position developed by Rawls in *A Theory of Justice* (1972) and enunciated by Dworkin in a series of works which represent the most sustained recent attempts to identify a morality which the law ought to enforce (1985, 1996). His position allows us to say that judges should, within the confines of inherited legal decision, exercise their own critical morality in determining a point of law. These theories do not however limit law to the enforcement of basic rights, rather they permit law to enforce conduct as long as this enforcement does not violate these rights. If they succeed then we can have a form of natural law theory which makes it a necessary condition of legality that a mandatory rule does not violate a human right, leaving considerable scope for the generality of law to be determined on democratic lines, the right to self-determination being itself a human right.

Such theories do not however enable us to achieve actual agreement as to what these rights are or should be. We are therefore left with the problem of determining whose system of rights to enforce. In effect this comes down to the question of who has the right to decide which rights are human rights. This takes us back to constitutional questions which are crucial to contemporary arguments about law and morality. If we believe that there is a moral method which enables us to identify human rights in an objective manner, then it is reasonable to enact by plebiscite or legislative processes a general Bill of Rights which is then filled out and applied by courts in their determination as to whether the law produced by elected assemblies do or do not violate these rights. This may be regarded as a natural law position since it assumes an identifiable law-like morality particularly related to fundamental justice. It therefore makes sense to have rules of recognition which list these rights and leave it to the critical morality of the judiciaries to give them concrete application.

If we are sceptical about our capacity to solve disagreements about fundamental rights in this way and give high priority to the right of self-determination, then we can draw on a prescriptive form of hard legal positivism and suggest that it is for elected assemblies and popular plebiscites to determine the content of all law in the light of the critical moral judgments of the people as a whole, and the duty of the courts to apply such laws without reference their own moral views, in which case the morality which is in the law is determined independently of and externally to the process of law application.

Law and People with Disabilities

Understanding the relationship between law and disability requires an analysis both of the idea of disability and of the role and function of law. Law is primarily concerned with the regulation of social behavior and is implicated in the orderly function of society; it constitutes, constructs, and applies social values. Law relevant to people with disabilities can be found in legislation and policy developed at a national or local level, as well as in international instruments. The complexity of the law stems from the fact that the law relating to people with disabilities consists not just of laws specifically directed at people with disabilities, but also of the full range of laws.

1. The Scope and Function of Law

Laws targeting people with disabilities include anti-discrimination law, laws relating to competence, laws relating to the provision of services, guardianship law, and the regulation of mental health. They also include laws of general application which are relevant to people with disabilities such as family law, criminal law, social security law, and international human rights law. In each case the law may play a role in the lives of people with disabilities by defining disability, by excluding people with disabilities, by regulating activities relating to disability, or by providing remedies for wrongs suffered by people with disabilities. Law also has the potential to promote an inclusive society by articulating the rights of people with disabilities and by constructing a legal framework for the achievement of substantive equality (Jones and Marks 1999).

2. Approaching Disability

The inconsistency in the values contained in law is a reflection of the different views held about disability at any given point in time, as well as over time. For many years the dominant approach to disability centered around what has become known as the 'medical model' of disability. More recently the social model has come to the fore, with minority rights and identity politics being adopted as strategies for change. A human rights model related, but not identical, to the universal approach to disability is beginning to emerge as an alternative mechanism for improving the position of people with disabilities. These models coexist and each model has different implications for the relationship between law and disability.

The 'medical model' of disability invokes a 'common-sense' definition of disability (Bickenbach 1993; Shakespeare 1999). Disability is conflated with impairment and incapacity and is seen as an individual deficit. Disability is therefore viewed as a personal tragedy and people with disabilities are to be regarded with pity and concern. Medicine, rehabilitation, and social welfare are mobilized to overcome or alleviate the consequences of impairment and to provide a basis for identifying those in need of support. Adopting a

negative view of disability and of people with disabilities legitimizes strategies such as recommending abortion of disabled fetuses, relegating people with disabilities to institutions, sterilizing them for eugenic purposes, or denying them citizenship rights.

The 1980 World Health Organization International Classification of Impairment, Disability, and Handicap (ICIDH) exemplifies the medical approach to disability. Although it attempts to separate the person from the biomedical condition by defining impairment as 'any loss or abnormality of psychological, physiological, or anatomical structure or function,' disability as 'any restriction or lack (resulting from an impairment) of ability to perform an activity in the manner or within the range considered normal for a human being,' and handicap as 'a disadvantage for a given individual, resulting from impairment or a disability, that limits the fulfilment of a role that is normal (depending on age, sex, and social and cultural factors) for that individual,' it nonetheless fails to locate any aspect of disability in the social and political environment. It is recognition of the limitations of the medical approach that has led to the current revision of the classification schema.

The challenge to the medical model has come from those claiming that reducing the person to their 'abnormality' has the effect of legitimizing the exclusion of people with disabilities from the benefits of society. The social model of disability (Oliver 1990) assumes that disability is not internal to the individual, but is the external response of society to bodily or behavioral difference. As such, disability is considered to be socially produced and what is disabling is not so much the impairment as the complex array of conditions, activities, and relationships created by the social and political environment. Disempowerment and exclusion of people with disabilities are therefore viewed as the direct result of the exercise of power, through political and cultural practices, which bears little relationship to the reality of physical or intellectual difference (Barnes 1998, cf. Shakespeare 1999). The politics of disablement locates the source of the disadvantage in the failure of the social environment to accommodate difference rather than in the failure of the body (Thompson 1997).

While the medical model of disability focuses solely on the impaired body and ignores the barriers to participation arising from legal, social, economic, and political forces, the social model suggests that it is these forces alone which are responsible for the disadvantage arising from disability. This has led to a call for theorists to rethink the social model so as to 'include all of our lives' (Crow 1996, Wendell 1996). While the social model discloses the barriers to full participation, it offers no insight into the means of resistance to exclusion, nor strategies for change. The minority rights approach to disability (Zola 1994), on the other hand, provides a framework for social action.

Drawing on the experience of the civil rights movement, disability activists have invoked identity politics in order to encourage people with disabilities to see themselves as members of a minority social group (Hahn 1987). His civil rights strategy encourages people with disabilities to work together to challenge their common experience of oppression and recommends legal strategies similar to those used in other civil rights movements. Antidiscrimination laws are seen as an appropriate response to discrimination experienced, while the role of education in achieving equality is not ignored. However, the minority rights model is problematic because it attempts to equate all disabilities/impairments with each other. Yet the experience of those, for example, with visual impairments is not the same as the experience of a person with mental illness or an intellectual disability. Further, the historical treatment of different disability types has been inconsistent. Hence, the analogy between people with disabilities and women or racial minorities does not hold (Rioux 1994). Moreover the minority rights model ignores the reality of multiple identities and suggests that people need to focus on their difference in order to achieve equality and the difference to be demonstrated is 'abnormality' (Corker 1999).

The human rights model starts from the point of view of the universal entitlement of all people to rights, equality, and justice (Rioux 2000). People with disabilities, like all other people, are entitled to have their rights recognized and to be treated with dignity and respect. An inclusive theory of human rights takes the celebration of diversity and difference to be fundamental and equality to relate to both the process itself and the outcome of that process. An inclusive human rights model does not accept formal equality as an appropriate standard, nor does it accept that equalization of opportunity will result in inclusion. People with disabilities can only have their human rights respected when society makes accommodations for difference, not just when asked to do so, but at every step along the way. This model does not elevate people with disabilities to a special status nor require that the primary identity of the person be that of a person with a disability. Rather, the human rights model proposes a fluidity of treatment and a flexibility in policy and practice. The needs of all people are to be equally acknowledged and respected such that accommodations will be made independent of status of the person.

3. *Legal Responses to Disability*

There is more than one perspective of the relationship between law and disability. One view is that law has the potential to empower people with disabilities by fostering an inclusive society. This is the objective for

law sought by people with disabilities who see law as an important strategy for achieving justice and equality. Another perspective focuses on the way in which law is implicated in the construction of values around disability. Law is a significant institution of state power and has a hegemonic force. The reflection of values in law has a legitimating effect over and beyond the particularities of the legal issue in question (Jones and Marks 1999).

Two examples of the importance of interrogating law's relationship with disability will suffice. First, while the medical model is considered to be disempowering by social theorists, it is the model most frequently adopted in law. Where the law provides goods and services to people with disabilities, including pensions and other financial support, it will usually be contingent upon classifying the person with a disability. In this way, the law has a gate-keeping function and is designed to ensure that only specified individuals benefit. The process adopted by law will often be disempowering to the individual concerned, as he or she will be required over and again to prove 'abnormality' and to focus negatively upon his/her difference before any support will be forthcoming. In many circumstances medical practitioners will be called as experts to provide evidence about the disability.

The second example of the role of law in constructing disability relates to the many ways in which law imports ideas of competency in order to include or exclude individuals. Rules of competency come into play in matters as diverse as voting rights, access to justice, rules of evidence, medical treatment, criminal responsibility, rules relating to sexuality, the age of consent, and the care and custody of children. A true understanding of the relationship between law and disability requires a thorough analysis of the operation of law in these areas. Further, attitudes toward people with disabilities and the role of the law in determining values in relation to disability can be seen through an assessment of competency in areas such as mental health law and the rules relating to guardianship of people with disabilities.

These two examples are indicative of the analysis that needs to be undertaken if we are better to understand the relationship between law and disability. It would be possible to do the same sort of analysis focusing on the way in which people with disabilities are differentiated from those without disabilities, such as with respect to education, or areas of law where people with disabilities are simply left out of the equation. Further, the differential impact of supposedly neutral rules on people with disabilities is largely hidden. Evidence of the way in which law values or devalues people with disabilities can also be found in an analysis of any law which, consciously or unconsciously, excludes a disability perspective.

There are two basic strategies invoked by those who believe that law has the potential to achieve equality for people with disabilities. The first of these is the antidiscrimination model, which is tied closely to the civil rights/minority rights perspective on disability. The alternate approach can be found in international law. This latter approach has the potential to be interpreted in line with the human rights model.

4. *Antidiscrimination Law*

Antidiscrimination law is designed to redress historic social and economic disadvantage of certain groups in the society. It has been used as a strategy to achieve equality with respect to race and gender, and more and more jurisdictions are adopting antidiscrimination law with respect to disability. Antidiscrimination law is an individual complaints based law, where action to challenge the discrimination may be brought in a court of law or, in many jurisdictions, to an administrative body which may have the power to use alternative dispute resolution techniques of arbitration conciliation and mediation. The assumption of antidiscrimination law is that it is possible to level the playing field by outlawing discriminatory practices. The focus is on equalization of opportunity in the hope that, once historic disadvantage has been remedied, the status of the individual will cease to be relevant in the application of law.

Each piece of antidiscrimination legislation outlaws certain types of discrimination, but in no case is all discrimination considered unlawful. The legislation is always limited to a specified target group, in the case of disability law to those defined by the legislation to be 'people with disabilities.' Antidiscrimination laws involve the action of an individual complainant (and in the case of some laws, groups of complainants) who brings an action against a specified alleged discriminator. The sorts of discrimination covered by legislation include both direct and indirect discrimination, as well as harassment. Direct discrimination involves a situation where a complainant is discriminated against because of his or her disability and can be understood in terms of a 'but for' test. Direct discrimination, then, occurs in circumstances where, if not for the status of disability, the person would have been treated differently. The concept of indirect discrimination, sometimes referred to as 'disparate impact,' involves discrimination where an apparently neutral law has a differential impact on people with disabilities. Indirect discrimination, then, is an attempt to respond to systemic discrimination which poses barriers to full inclusion. The prohibition of harassment is an important addition to direct and indirect discrimination, for the actions of an harasser may not constitute discrimination *per se* but may create an environment in which a person with a disability is unable to function. Some legislation also includes provision for affirmative action.

While a number of jurisdictions have introduced antidiscrimination law, the contrast between the United States and Australian legislation is perhaps the most telling (Quinn et al. 1993). The *Americans with Disabilities Act* (ADA) is based on the minority rights approach to disability and is designed to respond to the needs of a class of qualified individuals. In most cases under the ADA, court decisions revolve around the question of whether or not the applicant fits within the class of people with disabilities protected by the legislation. As a result, there is little jurisprudence on the question of what constitutes discrimination and when discrimination is unlawful. The Australian *Disability Discrimination Act* (DDA) approaches the question of disability discrimination from an entirely different standpoint. More in line with the human rights approach than the minority rights model, the Australian legislation defines disability so broadly that almost any member of the community could qualify as a person with a disability. This has allowed the courts to focus on the action of the alleged discriminator and to consider whether or not the discriminatory conduct is unlawful. As a result of the broad definition of disability in the DDA, there is no need to focus on the 'abnormality' of the applicant, or to prove that he or she falls within a particular classification. What is important is the action of the alleged discriminator (Jones and Marks in press).

Whatever form the antidiscrimination law takes, this approach to empowering people with disabilities is limited. First of all, antidiscrimination law perpetuates the status quo and assumes that the primary form of disadvantage confronting people with disabilities is discrimination. However, antidiscrimination law can neither deal with systemic issues nor bring about the fundamental change in values and attitudes which is required for a truly equal society. This is the case even where affirmative action is encouraged through the use of, for example, taxation law. Further, the technical requirements of antidiscrimination law limit its ability and potential success (Redman and O'Connell 2000). Antidiscrimination law depends upon there being an individual complainant and a named alleged discriminator. As such, many instances of discrimination are unable to be challenged by antidiscrimination law. The limitations of antidiscrimination law are well known and the issues for people with disabilities are the same as those experienced by other disadvantaged groups.

5. *Human Rights Law*

Human rights law provides an alternative legal approach for achieving equality for people with disabilities. The rights-based approach is found in international law and sometimes is incorporated into constitutions or statutes. For example, the Canadian Constitution specifically guarantees the equality rights of people with disabilities. Section 15 of the *Constitution Act* 1982 provides

> (1) Every individual is equal before and under the law and has the right to equal protection and equal benefit of the law without discrimination and in particular without discrimination based on … physical or mental disabilities
> (2) Subsection (1) does not preclude any law, program or activity that has as its object the amelioration of conditions of disadvantaged individuals or groups including those that are disadvantaged because of … or physical disability.

This guarantee applies to all Canadian law, at all levels, and covers both substantive and procedural rights and provides for affirmative action. The Canadian Supreme Court has recognized that section 15 provides protection against discriminatory impact as well as intent. In *Andrews* vs. *Law Society of British Columbia* 1989 154, the Supreme Court takes a contextual, effects-based approach which recognizes disadvantage as central to the analysis of discrimination. In addition, in Canada there is a federal *Human Rights Act* as well as provincial and territorial Human Rights Codes, which provide protection from discrimination, harassment, and reprisal, and extend into all realms of public and private activity (Rioux and Frazee 1999). The advantage of adopting a human rights approach is that any disadvantage, whether or not it takes the form of discrimination, can be addressed.

The international community has developed a number of international human rights instruments which have relevance for people with disabilities. People with disabilities can make claims under the International Bill of Rights—the *Universal Declaration of Human Rights*, the *International Convention on Civil and Political Rights*, and the *Convention on Economic, Social and Cultural Rights*. Equally, people with disabilities may take advantage of the *International Convention on the Elimination of All Forms of Racial Discrimination*, the *Convention Against Torture and Other Cruel, Inhuman, or Degrading Treatment or Punishment*, the *Convention on the Elimination of All Forms of Discrimination against Women*, the *Refugee Convention*, and the *Convention on the Rights of the Child* (Degener and Koster-Dreese 1995). While each of these international law instruments is said to have universal application, none but the last convention makes any specific reference to its applicability to people with disabilities. However, each of the treaties contains a nondiscrimination provision which requires the human rights instruments to be applied independent of the 'status' of the individual concerned and there is jurisprudence to the effect that 'disability' is included within the category 'other status' (e.g., *Vienna Declaration and Programme of Action*, para 63 (A/CONF.157/24, 25 June 1993)).

International covenants have greater legal force than other instruments of international law. Instru-

ments such as General Assembly resolutions, declarations, and statements of human rights bodies are nonetheless important both for their support for people with disabilities and for their value in the interpretation of the treaties themselves. There are a range of 'soft' international instruments including the *Declaration on the Rights of Disabled Persons*, *Declaration on the Rights of Mentally Retarded Persons*, and the *Standard Rules on the Equalization of Opportunities for Persons with Disabilities*. The last mentioned resolution of the United Nations General Assembly is by far the most significant and far reaching international instrument regarding the rights of people with disabilities. The *Standard Rules* adopt a social constructionist perspective of disability and call upon governments to provide for the equalization of opportunity for people with disabilities in all aspects of their lives. However, the *Standard Rules* do not fully incorporate a rights perspective as they are not directed at resolving systemic disadvantage.

There is no specific convention or treaty dealing with the rights of people with disabilities. There is some dispute about whether a convention on the rights of people with disabilities is strategically appropriate, for it is argued that by separating people with disabilities from the mainstream one falls into the trap of differentiating between people when the primary objective of a rights perspective is to include outsiders, rather than to treat their needs as distinct from the needs of all other members of the community. However, in the absence of a convention on the rights of people with disabilities, it has been extremely difficult to ensure that these rights are included on the general human rights agenda and to develop mechanisms to ensure a disability perspective is maintained with respect to the operation of rights in practice. A disability convention would not guarantee, in itself, the implementation of rights for people with disabilities. Such a convention would, however, offer a starting point for those seeking equality for all members of the community.

6. Conclusion

On one level, international law could be considered to be only as valuable as its enforcement mechanisms and the implementation measures of ratifying States. This could equally be the case with respect to domestic law. Even where enforcement and implementation measures are less than ideal, it could be argued that the very existence of law sets standards for the treatment and inclusion of people with disabilities in the community. Aspirational instruments have the strategic possibility of empowering people with disabilities. They can be used as leverage in negotiation, both with governments and with service providers, and can be held up as a blueprint for acceptable behavior. International law, on its own, cannot bring about equality for people with disabilities. Equally, the possibilities of domestic law are limited, but adopting a human rights approach creates the greatest opportunity for moving towards an inclusive society. While law has a part to play in providing rights for people with disabilities, it must not be forgotten that law also may be implicated in the creation of disadvantage. An appreciation of the relationship between law and disability therefore is essential before confidence can be placed in any legal strategy and before law should be invoked as a solution for the problems associated with disability.

M. Jones and L. A. B. Marks

Law and Risk

Contemporary society can be described as a 'risk society' (Beck 1992). This term indicates a fundamental change in the relationship between society and nature. As in the nineteenth century, when modernization meant the dismantling of agrarian society, the 'second modernity,' as Beck calls the period at the end of the second millenium, has broken down the nucleus of industrial society. The emerging new forms of technology challenge society with a new type of risk (Perrow 1984). Social behavior creates new hazards in various situations but it is not able to cope with them adequately. Scientific and technological development mean new risks for every individual—for social groups, for minorities, for society as a whole, and for future generations. This is true, for instance, with respect to nuclear energy, information and communication technology, modern biotechnology, and genetic engineering. Moreover, social change, reflected in growing individualism, patchwork biographies, or changes in the organization of labor, can be understood as an expression of the risk society.

Usually the law is considered to be an instrument of risk regulation. Any damage done to another person can be judged in terms of the legal questions of guilt, liability, or compensation, for example. Criminal law, civil law, and public law provide individuals, companies and administrative bodies with a number of instruments designed first and foremost to prevent damage but also to recover compensation for its consequences. The principle of causality and the instrument of absolute liability can be seen as legal reactions to the typical forms of risk encountered in modern society. However, under the conditions posed by the 'risk society,' this simple notion of regulation begins to appear doubtful. Legal instruments fail to work when confronted with cognitive uncertainty. Scientific experts are no longer expected to produce valid knowledge for every single case; more often they demonstrate deep-rooted dissent over the issues of risk and inherent danger. In many cases, the economic as well as the technological capacity to manage risk is restricted. Therefore, in theory and practice, the question arises whether the law is really an adequate instrument for regulating risk (Jasanoff 1995).

1. *Information and Decision—Two Concepts of Risk*

The term 'risk' has two dimensions: information and decision. Both are legally relevant. Historically, the information-based understanding of risk dates back to the maritime trading companies of the early modern age. In order to minimize economic loss on long journeys overseas, merchants were forced to calculate possible damage. Therefore, the idea of risk was understood to be based upon sufficient information about the circumstances of an individual case. Risk was defined as the probability of the occurrence of some event causing damage, multiplied by the amount of the damage anticipated. The risk problem, therefore, was to forecast both quantities: the probability of the event and the projected financial loss. This concept of risk is fundamental to every insurance business; it is also the basis for legal risk management. The connection between the law, legal regulation, and risk is knowledge generation and certainty as the bases for such regulation. Where the law is used to prevent damage or to recover compensation for its consequences, we need risk assessment, that is, an estimate of probable risk upon which a legal judgment or decision will be based. This calculation provides the necessary certainty underlying legal attribution of events and their consequences. Let us illustrate the case with some examples. For instance, standards fixing maximum daily intake or exposure to potentially toxic substances, or determining the duration of exposure to x-rays, or setting maximum values for the hazardous emissions, give the law the certainty to adjudicate—to affix blame, guilt, liability, or degree of compensation. Combined with scientific expertise, the law creates predictability, that is, we know what to expect and we know what should or should not be done. One could say, then, that the law absorbs the risk inherent in everyday activities, as well as in economic ventures or administrative decision making.

Decision-based understanding of risk shows, on the other hand, that decisions are inevitably afflicted with

the problem of uncertainty and insufficient knowledge, and that there is never enough information to rid us of all risk altogether. Risk, then, is understood to be the tension resulting from the necessity to make a decision and the impossibility of attaining perfect justification for that decision. This means that, given a social situation where adjudication is necessary—where a decision is expected—any possible variation or deviation in behavior under these circumstances will be understood to be a result of that decision. In this case, even doing nothing constitutes deliberate behavior, and any possible consequence that could turn up subsequently will be attributed to the decision made. Here, the risk is the tension between not knowing completely and perfectly what events will result from the causal chain that begins with the decision and, simultaneously, being compelled to decide. In other words, risk is a characteristic dilemma between the temporal dimension and the social dimension of behavior. In particular, the decision aspect shows that risk is closely connected to the distribution of responsibility and the attribution of consequences to a specific decision. It is precisely at this point that regulation of risk becomes the focal point, because the law is not necessarily a perfect means to manage risk. The law says what ought to be done to somebody who has damaged somebody else but it does not lend much support to forecasting, to deciding which of two alternatives would lead to negative outcomes. In other words, under the condition of uncertainty and imperfect knowledge, it is doubtful whether the law can really contribute much to the prevention of risk. Under this supposition, the question is whether risk regulation is indeed part of the function and performance of the law in modern society (and, if it is, what form should it take).

2. *Stabilizing Expectations vs. Regulating Risk—The Function and Performance of the Law*

The function and performance of the law are distinct: function refers to the type of tasks the law must fulfill with respect to society as a whole; performance is used to describe the relationship between the law and other social subsystems, such as the political and policy arena, the economy, or the educational system.

The social function of the law is designed to stabilize social expectations. In general, we can distinguish between two modes of expectation, the cognitive and the normative. Cognitive expectations are open for correction; they are the basis for learning processes. For example, one may expect the Dow Jones to fall during the next 24 hours, but if that expectation proves false, one does not hold stubbornly and steadfastly to the same hypothesis: rather, one adapts one's estimate accordingly and corrects one's behavior. Cognitive expectations are not stable; they are open for modification or amendment (learning). The contrary is true for normative expectations. Normative expectations are upheld even in the case of deviant behavior. For example, one expects others to respect one's property. If others behave deviantly, in a manner disrespectful of one's property, one does not abandon this expectation: rather, the principle of 'respect for property' will be reiterated all the more emphatically. Normative expectations remain unchanged even *contra factum*, and it is counterfactual stabilization of expectations that reveals their normative character. With respect to society as a whole, the law is a means to stabilize such expectations. The law is usually guaranteed by a state authority with the power to enforce legal norms through sanctions. This function of the law, stabilization, makes its very structure relatively resistant to flexibility or to the modification of expectations that would seem appropriate for the decision aspect of risk. A negative outcome that results from a decision, disappointed or unfulfilled expectations inherent in the decision itself, can best be coped with through learning, not by clinging to false expectations. Some theorists argue that this demonstrates the impossibility of regulating risk with legal instruments (see Sects. 4 and 5).

The performance of the law in relation to other societal subsystems (that is, what the law does for them) is fivefold:

(a) Conflict resolution: competing social expectations can generate internal conflicts in societal subsystems, such as in science, the economy, or in the educational system. The law provides these subsystems with the ability to identify conflicts and to export them to the legal context. If a risky decision has harmful consequences, then science, research, and development can learn—theories can be modified or technical equipment revamped. The law takes over the task of conflict resolution and thus frees science to operate without normative interference.

(b) Regulation of conduct: the law provides the political system with a means to regulate individual behavior.

(c) Legitimation of the social order: the law defines the framework or sets the parameters for political action. Under the rule of law, this framework is commonly laid out in the form of constitution.

(d) The law permits planning and prevention of risk.

(e) The law can act as a means of surveillance.

Under each of these five aspects of performance, the law absorbs risks by providing rules for decision making for the other societal subsystems, or relieves others of the burden of justifying a decision. The question is how and to what extent the law is really able to provide this service to the other subsystems under the condition of risk. As pointed out above, under the condition of risk, the function of the law *qua* stabilizer of expectations over time tends to run contrary to its intended performance for the other subsystems.

3. Different Perspectives on Regulation—Theories of Risk in the Social Sciences and Consequences for the Law

The degree to which risk regulation may be deemed successful or not will depend upon the theoretical perspective one takes. Three main approaches can be distinguished: psychological risk theory, cultural theory, and systems theory.

3.1 Psychological Risk Theory

The psychological, cognition-oriented approach is based upon the difficulties arising from the dilemma of decision. If it is true that the information basis for a valid risk assessment is generally inadequate, then the question of how individuals come to make certain decisions about risk becomes increasingly significant (Jungermann and Slovic 1993). Psychological risk analysis seeks to determine how individuals judge the level of risk and decide upon some behavior in a given situation, and psychological risk research has generated some interesting findings. Voluntary risk is more readily accepted than involuntary risk. Acceptance of risk depends upon the amount of control one believes one has. The risks associated with new technologies are estimated to be much higher than those from older technologies. Risks are also judged to be more acceptable, the further away one perceives the consequences of a decision to be. After all, acceptance of risk depends upon a believable estimate of how easy or difficult it will be to repair damage. In terms of psychological risk theory, whether or not regulation of risk is possible will depend upon the impact of the law on individual behavior. Insofar as the law generates commitment, it may be able to influence or even to regulate individual behavior. Under this supposition, therefore, the law can be a suitable means to regulate risk within the scope of known risks. In such cases, the law can be used to program conduct with reference to science-based information. A basic problem nevertheless remains: how to reconcile the complex relationship between attitude, legal incentives, and sanctions on the one hand, and behavior on the other.

3.2 Cultural Theory

The decision problem shows that risk assessment cannot be solely understood as deliberate behavior. On this premise, cultural theory introduces social actors and conceptualizes risk as a collective construction. The concrete form of a risk concept depends on certain qualities of the social field in which this concept is shaped. Cultural theory devises a matrix of social fields based upon two dimensions (Douglas and Wildavsky 1982); 'Group' describes the external boundaries between a social collective and the outside world, while 'Grid' means all the other social distinctions determining how individuals behave towards one another. We can distinguish four types of social interest groups with distinct perceptions of risk and, correspondingly, four regulatory models:

(a) A hierarchical culture is characterized by high grid group scores. This means that it will handle risks through routine procedures and that it will probably use legal instruments to establish such procedures.

(b) An individualistic market culture is characterized by low grid and low group scores. It will incorporate risk into the domain of individual concern; calculated risk is accepted and the law is used to provide a framework for individual, competitive, and risky activities.

(c) An egalitarian (sectarian) culture is characterized by low grid and high group scores. Normally it has high resistance to risk and it is the culture most sensitive to possible hazards. The law is seen as an impediment to the right way to live, because it allows risky behavior in many cases.

(d) A fatalist culture is characterized by high grid and low group scores. Risks are perceived as imposed from the outside by others and they provoke passive resentment. On this view, legal regulation can hardly make any difference whatsoever.

3.3 Systems Theory

The most radical version of the decision dilemma can be found in systems theory, especially in the work of Niklas Luhmann (1993). Risk is understood as the tension between the temporal dimension and the social dimension of decision making. In modern society, the introduction of the concept of risk means that our relationship to the environment, to the future, and to social disparity have been redefined. First, risk communication indicates that damage previously perceived as a consequence of some natural phenomenon is increasingly attributed to social conduct (decisions). The question of accountability becomes a core issue together with the law as a means to distribute that accountability. Second, following on from that, the future becomes increasingly relevant for justifying social activities. It is no longer sufficient or appropriate to disregard the future; it must be treated as a calculable element. The issue of risk assessment and risk forecasting begins to infiltrate every part of the social system. The law does not seem able to deal with this kind of cognitive orientation towards the future. Third, risk communication indicates a social disparity based upon a division between those who decide and those who are affected by the consequences of the decision. This kind of disparity means that the concept of risk is most suitable for generating social movements where individuals place themselves on the side of the affected parties. They challenge policy makers and confront the law with their interests. On this view,

the law can be seen either as a means for political action or as a political obstacle.

In sum, according to all the theories, the problems of legal risk regulation will occur in the areas of information and behavior, the cultural determinants of behavior, and the temporal structure of legal communication. According to psychological and cultural theory, in certain situations and with respect to certain social fields, the law will be able to resolve conflicts, regulate conduct, practice surveillance, and, through all of these, underscore the legitimation of a given social order. Finally, according to systems theory, it is doubtful whether the law is adapted to and adequate for planning and prevention insofar as these require cognitive orientation.

4. *Options, Limits, and Risks of Legal Risk Regulation*

In all legal fields a dense network of risk regulation and control can be found (Bora 1999). Civil law provides us with instruments mainly to prevent or to compensate for damage. Contract law, liability law (including rules of evidence), and business law are continuously adapted upon the basis of new information and possible risks. The same is true for public law, especially administrative law, which is traditionally concerned with issues of technological risk. Administrative law has developed to become the standard instrument for dealing with environmental problems and policies. Technology assessment and environmental impact assessment have been instituted in numerous organizations, industry, and governmental or administrative agencies. In the field of biotechnology, for instance, a whole set of institutions concern themselves with regulatory risk and safety issues, including environmental protection agencies, food and drug administrations, and animal and plant health inspection services. In the USA, for instance, consider the Environmental Protection Agency (EPA), Food and Drug Administration (FDA), United States Department of Agriculture (USDA), and the Animal and Plant Health Inspection Service (APHIS), among others. In Germany, comparable organizations are the *Umweltbundesamt* (the German Federal Office of Environment), the *Biologische Bundesanstalt* (the national agency for biological affairs), the Robert Koch Institute, the *Bundessortenamt* (the national regulatory agency for plant and seed types), and the various *Pflanzenschutzämter* (plant protection agencies). Many forms of regulation can be observed, from the traditional—legal intervention, proscription and sanction—to voluntary agreements.

This highly developed system of legal risk regulation also has its limits. First, there is no absolute benchmark for risk regulation; the law always depends upon a comparison of risks, typically the comparison between a traditional, conventional technology and a new one. Second, legal regulation needs the criterion of causality, the rule of law stands in opposition to regulation based upon mere suspicion. Third, the task of regulating unknown risks confronts the law with the problem of reversal of the burden of proof. This, in turn, generates empirical and logical problems, because it is impossible to demonstrate empirically the nonexistence of a fact. Fourth, the law always requires concrete damage as a material fact. The politically motivated aim to guarantee environmental quality is insufficient. Fifth, there is typically no check-and-balance system for social needs within the scope of the law; legal norms are in fact the result of political disputes over social needs. Sixth, the law will therefore not be a suitable political instrument to curtail innovation, nor can it function as an instrument of innovation control in general.

Whenever we speak of limits, we must also address the special risk of the law itself. To an increasing extent the other societal subsystems (politics, the economy, etc.) dump their risks onto the law. Unless the law can somehow redistribute the risks, it runs the risk itself of being overloaded with risky decisions. This is the case, in particular when programming of the law via political decision fails—a frequently observed phenomenon. The citizenry expects even the most hypothetical dangers to be regulated or managed by the state, a fact that undermines the usual means of programming the law through new information, established knowledge, or causal attribution. Thus, the law will always be condemned to promise more prevention than it will be able to deliver. We can say, then, that as the regulation of risk becomes increasingly necessary, it becomes increasingly risky itself at the same time.

5. *Is Global Regulation Possible? Future Developments in Theory and Research*

The empirical and theoretical challenge for the future relationship between law and risk is globalization. Globalization is characterized by the worldwide perceptibility of communication, the worldwide relevance of events, and the plurality of world views. Under these circumstances, risk takes on new dimensions. Global warming, deforestation, and biological safety are problems that reach far beyond the range of regulatory instruments available to the classic nation-state. The law tends in some respect to become global law without a state. Is the law in the global age a reliable means to regulate worldwide risk, or will it, as some theories predict, be replaced increasingly by nonlegal instruments which focus more on cognitive expectation and the mechanisms of learning? The future of the law in the global risk society seems to be open.

Law and Society: Sociolegal Studies

Scholars who have sought to integrate law and social science have united under various banners, and the most important of these are 'law and society,' which refers mainly to the USA (Garth and Sterling 1998), and 'sociolegal studies' (Campbell and Wiles 1976), which refers mainly to Great Britain.

There are scholars in many parts of the world who share these identities, but the field, even in Britain, owes much to origins in the USA. The emergence in the USA relates to the fact that the legal profession has long held a dominant professional position in economic and state power, and social science disciplines in the USA developed very differently from their counterparts elsewhere. In the USA, the disciplines became more differentiated, more empirical, and more positivistic than in other settings. Those trained in the disciplines could challenge the hegemonic position of law in the USA, and this continuing challenge helped to produce the field of law and society. The relative success of this field in the USA made it attractive to others, including most notably the British. The two largest organizations are the Law and Society Association (LSA) in the USA and the Socio-Legal Studies Association in Britain. By 2000, the LSA had more than 1,500 members and the SLSA about 750. Both groups contain a diverse array of scholars, interests, and approaches. Common frames of reference include work on the legal profession, issues of gender and race, state regulation, courts and dispute resolution, and crime and criminal justice. These research topics define the mainstream of the field, which includes the full range of social science methods.

Recognizing the importance of the USA in defining the field of law is not inconsistent with seeing these fields as part of an international phenomenon. First, there are many scholars in a number of countries, including India, Japan, Korea, Europe, and Latin America who have been influenced strongly and have contributed to this field. The influence can be traced in large part to the law and development movement in the 1960s and 1970s, which promoted educational interchange and a range of interdisciplinary work on the legal profession and the courts in particular. Notable examples include the work of Rogelio Perez Perdomo in Venezuela, and Upendra Baxi and Rajiv Dhavan in India. Much work in the law and society tradition continues to be produced by these individuals and others.

A second international influence came from the fact that participants in the law and development movement from the USA, such as Lawrence Friedman, Marc Galanter, and David Trubek, took their insights from abroad and used them to develop theories and models that could be applied to the USA. The best-known of such approaches is Galanter's famous article on 'Why the haves come out ahead' (1974), which was in large part based on his experience in India.

More generally, a related but distinguishable field of 'legal sociology' took shape at roughly the same time that 'law and society' developed in the USA, and it continues to be important in Europe and elsewhere. The major institution is the Research Committee on the Sociology of Law, which is affiliated with the International Sociological Association and which also meets with the US Law and Society Association every five years or so. One of the pioneers of legal sociology in the USA, William Evan, joined with Adam Podgorecki of Poland—then visiting in the USA—to take the initiative in 1962 to form the Research Committee. The first president was Renato Treves of

Italy, who built the Research Committee as a distinct entity devoted to legal sociology. Again, while there have long been overlaps with law and society, the scholarship associated with the Research Committee is more 'European,' which can be defined as more theoretical and less empirical than that typically associated with law and society or sociolegal studies.

The development of 'law and society' in the USA occurred at almost the same time as the founding of the Research Committee, but the story begins with the Legal Realists, who used the growing prestige of social science and especially sociology in the 1920s to mount an attack against the formalism of the generation that controlled the legal academy at the time. Centered at Yale and Columbia, the Realists carried out empirical studies of the legal system and challenged the assumptions of those they labeled as 'formalists'—those who believed that the law was a self-contained system such that legal precedents actually dictated the results in legal cases. Among the prominent legal realists were Charles Clark, William O. Douglas, Jerome Frank, Underhill Moore, and Walter Wheeler Cook. Although the Legal Realist movement as such died by the end of the 1930s, its leaders had been absorbed into the mainstream of the legal profession, and the interest in social science had seemingly disappeared. The orientation of the Realists, however, helped set the stage for later developments (see *Legal Realism*; *Legal Formalism*).

A gradual revival of the interest in law and social science after World War II generated the people and momentum to create the Law and Society Association (LSA) in 1964. During this period the Ford Foundation invested substantially in empirical projects that focused on the legal system. One major grant was to the newly established American Bar Foundation to fund the Survey of the Administration of Criminal Justice, which was directed by Frank Remington of the University of Wisconsin. Another important grant was to the University of Chicago to support a variety of research projects, the best known of which was by Harry Kalven and Hans Zeisel on the American jury.

In the 1950s, one of the promoters of the legacy of Legal Realism, David Cavers, used his position as Associate Dean at Harvard Law School to influence a prominent alumnus, Walter E. Meyer, to provide in his will for the establishment of the Walter E. Meyer Research Institute of Law, which was to encourage law-trained researchers to use the tools of social science in their research. Once established in the late 1950s, the Institute made numerous grants over a 20-year period to help develop the field of law and society.

Even more than the Ford Foundation and the Meyer Institute, the Russell Sage Foundation's grants served to institutionalize these collaborative ventures in the 1960s. Prior to the time of the establishment of the LSA, itself promoted by the Russell Sage Foundation, the Foundation had already invested more than a million dollars in law and social science. The major investment began with a grant to the Center for the Study of Law and Society at the University of California at Berkeley, and other grants were made to establish centers at Wisconsin (1962), Northwestern (1964) and Denver (1964). Later in the 1960s, after the establishment of the LSA, the Meyer Institute and Russell Sage Foundation funded six years (1967–73) of summer institutes in Denver for legal academics in a program entitled SSMILE: Social Science Methods in Legal Education. The National Science Foundation program in law and social science began in 1972 and reinforced the idea that this set of topics comprised a distinctive field.

The 1960s and early 1970s represented a kind of golden age for law and social science. There was a strong relationship between what was happening in the production of knowledge and what was happening in the streets and in the civil rights movement outside of the academy. Social science provided a new professionalizing expertise that offered ways to manage the new social agenda. Sociological knowledge thus gained in value as a new generation helped to define a political agenda of concern with urbanization, race relations, poverty, and crime. This social science learning could be used to challenge the postwar complacency of law schools and the training and expertise of lawyers for governing the state.

Remaining followers of Legal Realism, including such figures as Cavers and Willard Hurst of the University of Wisconsin, used this rising prestige of the social sciences to renew their own attacks against legal traditionalism and formalism. As both a cause and a reflection of this challenge, a few philanthropic foundations made it their missions to build institutions that would fly the banner of this new sociological expertise. Their investments in learning and in building institutions succeeded in bringing a new expertise to law and to the activist state.

The period of relatively high prestige for scholars bridging law and social science was in retrospect quite brief. The 1980s again brought a period of rapid social change, but social science generally and 'law and society' in particular declined in relative prestige. Indeed, just as law and society helped to build and legitimate the activist state (and the role of law in its construction), the competing movement of law and economics provided much of the learning and legitimacy for the later turn away from social welfare and state activism.

The way that law and society linked with the activist state, and the tensions within the law and society field, can be seen in the stories of two of the Russell Sage centers—Berkeley and Wisconsin. The Russell Sage Foundation grant to establish the Law and Society Center in Berkeley in 1962 began a process that continued through the closing of the School of Criminology and the establishment of the Jurisprudence and Social Policy program at the law school in the late 1970s. Phillip Selznick was the key individual

in developing the idea of the Center. Selznick's early work focused on organizations as institutions (Selznick 1949), but he became increasingly interested in law and its relation to the normative lives of organizations. In 1969, Selznick et al. published *Law, Society, and Industrial Justice* (1969), written in collaboration with Philippe Nonet and Howard Vollmer and published by the Russell Sage Foundation. Drawing on his studies of institutions, Selznick and his collaborators examined the general institutional setting of labor management relations, asking how 'emergent law'—including due process—could be brought to and realized in the industrial setting as 'industrial justice.' Paralleling Selznick's own move from institutionalism toward legal and even jurisprudential issues, the book asked 'what it means to *legalize* an institution, that is, to infuse its mode of governance with the aspirations and constraints of a legal order' (Selznick et al. 1969, p. 8).

Others who joined the Center followed in Selznick's footsteps, advancing the study of law as an institution; these scholars included Sheldon Messinger, Jerome Skolnick, and Jerome Carlin. Within the law school, there was relatively limited but growing support for the Center and for sociolegal studies, in particular from Geoffrey Hazard and Caleb Foote. A new cohort of law professors, led by Sanford Kadish, began to move much closer to the Center later in the 1960s. Carlin initially decided to focus his research on solo practitioners, and the result was a pioneering account of that world, entitled *Lawyers on their Own* (Carlin 1962). He moved to the Bureau of Applied Social Research at Columbia, where he produced another major work, *Lawyers' Ethics* (Carlin 1966). He then moved to Berkeley to work at the Center and the sociology department. Beginning in 1963 at the Center, his first project explored the relationship between the legal system and the class system. The project, which also involved Messinger and Jan Howard, resulted in the well-known article in the first issue of the *Law and Society Review* on 'Civil justice and the poor' (Carlin et al. 1966), and a book on the same topic. The conclusions emphasized the unequal access to law by the poor and helped make the case for the redistribution of legal services. It fitted very well with the 'war on poverty' and the ferment that was building around new legal services programs. The research connected closely to the social and legal activism of the time.

Also in Berkeley, but less oriented toward the Center, was Laura Nader, one of the few women involved in the early years of LSA and also a creator (or re-creator) of the subfield of legal anthropology. Nader's Harvard dissertation was based on fieldwork in Mexico with a focus on law cases. She joined the Berkeley anthropology department in 1960 with a specialty in the anthropology of law, which she then helped to develop. She organized the first major conference on law and anthropology, which resulted in a book that helped define this emerging subfield of legal anthropology. She also organized her students into the Berkeley Village Law Project, which focused on villages and 'disputing,' and became very influential in law and society as well as in legal anthropology. Legal anthropology continued to be a very live field into the 1970s, contributing to the emerging interest in alternative dispute resolution.

Eventually the Center moved into the law school, in part because of the Berkeley administration's decision to close the School of Criminology. What was left of the criminology school was merged in 1977 with the Center for Law and Society under the auspices of the new Jurisprudence and Social Policy (JSP) program. The social scientists moved to the law school. The law school, for the most part, remained dominated by the legal mainstream, but the legacy of the origins in sociology remained evident—even in the jurisprudential component of the JSP program.

Wisconsin, in contrast to Berkeley and the other centers, already had a thriving interdisciplinary community in the 1950s. It centered in the law school and was built on Willard Hurst and the legacy of Legal Realism. The Hurst contribution can be traced to Lloyd Garrison, the Dean at Wisconsin Law School during the 1930s. At Wisconsin, Hurst worked enthusiastically with Garrison to develop first-year teaching materials for a course on 'law in society,' and he also invested substantially in the cohort of young professors in the law school. The group built an identity that helped to constitute law and society.

Following Hurst's lead, Stewart Macaulay also moved toward the sociology of law and the attack on legal formalism. Hurst also encouraged Lawrence Friedman, and many others, to write about law in the specific context of the state of Wisconsin, which led to the publication of *Contract Law in America* in 1965 (Friedman 1965). Macaulay and Friedman teamed up to produce one of the early sets of materials on 'Law and the behavioral sciences' (Friedman and Macaulay 1969). This Hurst-inspired group then expanded in the 1960s with the law school at the center.

One of the most important individuals was Harry Ball, a sociologist recruited initially to work on the ABF Survey of the Administration of Criminal Justice. Not only was he a key person in the Russell Sage grant, but also he was one of the leaders with Robert Yegge (Dean at the University of Denver College of Law) and Richard (Red) Schwartz (the first editor of *Law and Society Review*) in establishing the Law and Society Association in 1964. Along with Ball, Friedman, Hurst, and Macaulay, the law and society contingent grew to include Joel Grossman (Grossman 1965, Grossman and Grossman 1971), Joel Handler (Handler 1967, Handler and Hollingsworth 1971), Herbert Jacob (e.g., Jacob 1965), Stanley Katz (Katz 1971), Jack Ladinsky, Frank Remington, and others.

The Wisconsin tradition built around Hurst, which can be characterized as that of 'law as the dependent

variable' or, perhaps more accurately, 'law in context,' provides one enduring approach in the field of law and society. It is characteristic of the work of Friedman and Macaulay, for example, and others from the same group such as Joel Handler. To take an example from the early days of the 'war on poverty,' Handler criticized the proposition, identified with Yale's Charles Reich, that the legalization of welfare and the provision of due process hearings would be sufficient to deliver concrete gains for welfare recipients. Criticizing the faith in legal formalism, he suggested that a careful examination of social context could make sure that the law would deliver better substance. In the writings of Hurst and other followers, the idea that law is a dependent variable was not inconsistent with idealism or an active role for law. Educated lawyers aware of social and economic contexts could make law a much more effective instrument for social progress.

Wisconsin was able to maintain a critical mass within the law school, nourished by the other departments of the university. It was able to sustain a law and society tradition that self-consciously offered a different model than that found in the elite law schools, which remained outside of the LSA orbit. The group in Madison identified its approach with the LSA organization, with Friedman, Macaulay, Handler, Jacob, and Marc Galanter, who came later, all serving as presidents, and Joel Grossman, serving also as editor of the *Review*.

This University of Wisconsin approach—built around law professors—both complemented and competed with the more sociological and jurisprudential orientation in Berkeley. Wisconsin's center was dominated by the law school and the personality of Hurst, while Berkeley's center was initially dominated by sociology—especially Selznick. The law professors at Wisconsin developed their approach by emphasizing in their struggles with the legal establishment that law was the dependent variable. This strategy allowed them to use social scientists and social scientific tools to attack legal formalism and the legal establishment on behalf of the concept of 'law in context.' The idea, especially in Hurst's works, was that the context was necessary to make the law more effective and better able to solve social problems.

The Berkeley sociologists, in contrast, emphasized jurisprudence and legal philosophy, which they—in particular Selznick—could see that sociology lacked. Scholars of institutions, as Selznick argued, needed to bring law to those institutions. The sociologists also could emphasize their superior training for social research. The law professors, they suggested, were incapable of making serious contributions to important theoretical questions of concern to social science, which was necessary to solve social problems. When the Berkeley sociologists and the Wisconsin lawyers found themselves on similar terrain, however, the opposition tended to turn into one between law and social science. Depending on what position one took in this competition, therefore, the sociologists at Berkeley could be seen as 'merely sociologists,' lacking any real legal expertise, or they could be characterized as 'real scholars,' in contrast to 'atheoretical' or dilettante lawyers.

The relative positions can be seen in the approaches to legalization and procedural due process. While Handler, from the perspective of law and context, based his criticism of law professors such as Charles Reich on their neglect of the social factors that would limit the impact that welfare rights and hearings would have on the lives of the poor (Handler 1966), Selznick's *Law, Society, and Industrial Justice* (Selznick et al. 1969) emphasized due process as 'the primary source of concepts and doctrines used in bringing the rule of law to new settings' (Selznick et al. 1969, p. 274). The different approaches relate to the fact that Handler was initially using social science to challenge legal formalism, while Selznick was initially using law to show its relevance to the study of social institutions.

The same basic contrast between law and sociology was also evident in the approaches of the Walter Meyer Institute, which was close to law, and the Russell Sage Foundation, which was closer to sociology. The Law and Society Association was initially the creation of people who, in terms of this relative opposition, were much closer to Russell Sage and to sociology. Yegge was the only law professor among the major founders, and the Russell Sage Foundation provided the initial funds. The contrasting structural positions, however, should not obscure the close proximity of these players on the emerging field. These were the lawyers closest to social science and the social scientists closest to lawyers. Even at the personal level, the protagonists were all friends and collaborators in building interest in the field of law and society. They shared a position against legal and sociological traditionalism, but they disagreed about how to define the new field of law and social science—and the relative positions of lawyers and social scientists within that field. They tended naturally to want to define the field in terms of their own expertises and approaches.

By the mid-1960s, this general field of law and social science had not only developed a number of institutions and adherents, but also served to define and build much of the expertise of the state as the 'war on poverty' began and added further resources to the field. Many of the people intersected with the new set of state programs, and indeed the relative success of the field is reflected in the career successes of those who developed this field. At the time of the development of the LSA, in short, the expertise of law and social science—including but not limited to the LSA—was gaining legitimacy and moving rapidly into the state.

The field that was constructed and the LSA itself gradually tilted in favor of law. By the late 1960s law had incorporated enough social science to stave off the social science challenge. This shift in the center of gravity of the field of law and social science generally

was also evident in the 1970s in the relative power within the LSA of law professors and in particular professors linked to Madison. The presidents of the LSA were almost all law professors linked to Madison. A later indicator of the shift in the center of gravity occurred when the Berkeley Center for Law and Society was brought into the domain of the law school. Put another way, much of the investment in the field of law and social science in the 1960s ultimately found its way into the LSA and the law schools. Indeed, for a short period of time in the early 1970s, this movement seemed to have found a place at the core of the law.

The relative value of social science expertise declined in the 1980s. A know-how that served to help construct an activist state seemed to lose some of its relevance. Academic investment in economics by the mid to late 1970s tended to pay richer legal career dividends than investment in the disciplines that were built more into the LSA. Just as bright and ambitious people were drawn to social science in the 1950s, many were drawn to economics in an era where inflation and the state were considered the great enemies of progress. Economics seemed to define the problems and the solutions for the 1980s just as sociology did for the 1960s.

Nevertheless, once established, the LSA developed its own organizational dynamic. A second generation brought up within the LSA came to define the scholarship around the LSA as a 'field' distinct from law and from the social science disciplines. The link of the LSA to the progressive politics of the 1960s also helped to give the LSA an enduring progressive political imprint.

The next group of leaders in the LSA, followed an approach similar to that of the Wisconsin pioneers. Rather than emphasizing 'law and context' as an antidote to optimistic progressivism, however, the new generation—many educated at Wisconsin by the pioneers—took aim at the politically leftist legal scholars of the Critical Legal Studies movement and suggested that they needed more social science to understand and substantiate their leftist critiques. The 'Amherst seminar,' which produced much of the LSA leadership in the 1980s (including Austin Sarat, Susan Silbey, Sally Merry, Christine Harrington, Barbara Yngvesson, and Kristin Bumiller), showed how the 'constitutive' nature of law prevented the social change that had been sought in the 1960s.

As an ongoing organization with both established scholarly tools and an openness to those looking for an identity to challenge the legal mainstream, the LSA continues to thrive as an organization many decades after it was founded. The tensions and hierarchies present at its creation, however, continue to play a prominent role in shaping the organization and the field that it represents.

As the field entered the new millennium, it renewed the commitment to internationalization that characterized it in the 1960s and 1970s. There is a new law and development movement anchored in places such as the World Bank that adds momentum to the internationalization of the field. With unprecedented educational interchange both in the social sciences and in law, in addition, the US-centered field is opening up to many scholars from outside the USA. Much of the growth of the LSA in recent years, for example, has come from its international membership. It remains to be seen whether the field will continue to be a vehicle for primarily US-based scholarly approaches—dominated by the domestic tensions that have characterized it since its formation—or will become a more broadly based and cosmopolitan scholarly domain.

Law: Anthropological Aspects

Anthropologists approach law from a comparative perspective and examine it in social context. Law refers broadly to the rules and processes that regulate social life. Although there are frequently institutionalized systems for making decisions and enforcing them, legal anthropology does not restrict its attention to formal systems of courts nor to the law of the nation state. It also examines the legal ordering of villages, bands, and urban neighborhoods—places, which usually lack specialized legal institutions and codified rules. The anthropological study of law began from nineteenth-century evolutionary theories in which the form of law revealed the stage of social development. Twentieth-century legal anthropology examines processes of resolving disputes and maintaining social order. Law is understood as a form of power. Recent scholarship focuses on the relationship between law and culture, law and language, and the intersections among plural legal orders rooted in the community, the state, and the region. It examines the contemporary legal complexity produced by postcoloniality and globalization.

1. *Historical Developments in the Anthropology of Law*

The great nineteenth-century theorists of social evolution used law as a measure of civilization and savagery. Sir Henry Maine, for example, theorized that with the shift from kin-based to territorially-based societies, there was a change in the law affecting persons from one based on status to one based on contract. In Emile Durkheim's evolutionary scale, societies ranged from 'primitive' societies held together by mechanical solidarity—the sameness of all constituent members—to complex societies organized by an organic solidarity between different and specialized but interdependent members. Societies with mechanical solidarity are characterized by repressive, punitive law that maintains cohesion, while those with organic solidarity have restitutive law and damages arranged through more specialized tribunals and functionaries. Although Durkheim's theory is empirically wrong its tendency to link civilization with the form of law affected subsequent debates within anthropology about the definition of law and its link to 'civilization.' In the early twentieth century, some anthropologists argued that law was universal, not characteristic only of people labeled 'civilized.' Bronislaw Malinowski, for example, argued that the Trobriand Islanders had no law in the sense of a state institution but governed their relationships with one another through reciprocity (1926). But the assertion that all societies had law raised the question of what 'law' was. During the early twentieth century, two major schools of thought developed. One school defined law in terms of institutions, requiring socially authoritative mechanisms for enforcing rules through the imposition of sanctions. Radcliffe-Brown pioneered this perspective, defining law as 'social control through the systematic application of the force of politically organized society' (1933, p. 202). Under this definition, all societies have customs and sanctions, but not all societies have law. E. A. Hoebel defined law more broadly, but also within an institutional context, as 'the legitimate use of physical coercion by a socially authorized agent' (1954, p. 26). Critics of this view of law argue that his definition is based on Western conceptions of law (Comaroff and Roberts 1981, pp. 6–7).

A second school of thought, following Malinowski, defined law in functional terms, identifying it with a broad range of social processes that produce social conformity through social pressure and inducement (1926). Reciprocity was a fundamental mechanism for maintaining social control. With Malinowski's definition, every society has law. Critics of this view contend that defining law as social control is too broad and includes practices such as gossip, ostracism, and nicknaming that are not law-like. By the 1970s, the debate over the definition of law became increasingly sterile and was largely abandoned in favor of understanding law as a social process (see Nader 1969).

2. *Law and Dispute Processes*

Between the 1930s and 1960s anthropologists sought to describe the nature of rules of whole societies. Yet they confronted the paradox that there were frequently discrepancies between these rules and everyday forms of behavior. In the early 1970s anthropologists turned to studying processes by which conflicts are handled and resolutions achieved (see Moore 1978). Laura Nader and her students researched how litigants pursued disputes, and how these disputes were resolved in a wide variety of societies (Nader and Todd 1978). This approach used extended case study analysis and emphasized the perspective of litigants rather than judges. It broke dramatically with the earlier focus on rules and looked instead at the processes by which individuals pursued grievances. At the same time, it built on a tradition of analyzing extended case studies in the context of social relationships. For example, Max Gluckman argued that close-knit villages tended to have compromise settlement processes, while more

loose-knit ones favored more adversarial processes (Gluckman 1955). The focus on dispute processes remains a basic framework for the anthropology of law. By the early 1980s, however, it became clear that a focus on the processes of resolving conflicts could not be separated from a consideration of rules and how they were formed. Comaroff and Roberts found in their study of the Tswana that the meaning and relevance of rules is negotiated in disputes (1981, pp. 5–17). Arguments among disputants are framed by rules, but the content of rules are negotiated as disputes are argued and resolved (1981, p. 19). This more interactive understanding of rules and processes has proved valuable for examining the operation of law in communities as well as in more formal settings, such as courts. It offers a way of understanding how different systems of rules can develop in different settings, a situation described as legal pluralism.

3. *Legal Pluralism*

In the contemporary world, societies typically have more than one legal system. Legal pluralism refers to situations of legal coexistence in a single social field. Initially described in colonial situations, in which the colonial power superimposed a European legal system over an existing indigenous system, legal pluralism is now understood as a fundamental characteristic of all legal systems. Advanced capitalist states as well as colonial and postcolonial states have multiple legal systems. Some are rooted in semiautonomous social fields that are self-regulated but also subject to regulation by the larger society, such as commercial networks (Moore 1978) or criminal communities. Many institutions such as schools and corporations develop forms of private governance. Informal but rule-governed relationships are characteristic of families, communities, and voluntary organizations, although there is considerable debate about whether such forms of normative ordering should be called law.

Early descriptions of plural legal systems examined each in isolation, but more recent work emphasizes the way plural systems shape one another. Thus, one legal system may offer the right to appeal decisions from another, or a litigant may be able to choose among several competing systems. Plural legal systems typically differ in power, so that the more powerful has the capacity to trump the actions of the less powerful. In colonial situations, the colonial authority often established one legal system for the subjugated and another for the colonial authorities (Moore 1986, Merry 2000). Local social groups such as schools, communities, businesses, and even gangs, have their own systems of law-like ordering, but these function within the framework of nation state law. The term 'interlegality' has been used to describe the interactions between multiple legal systems.

Globalization increases legal pluralism in two ways. First, it fosters the circulation of legal forms and practices from one nation state to another. Constitutions, codes, and legal institutions are commonly transplanted, much as they were during the earlier period of colonialism. These transplants introduce codes and procedures quite different from those of the receiving society, often with the intention of reform. Colonial transplants characteristically were phrased as furthering civilization; mid-twentieth-century transplants as modernizing institutions; and late-twentieth-century ones as promoting democracy and the rule of law.

A second way in which globalization increases legal pluralism is by constructing a global legal order. This includes international commercial law, fostered by the accelerating flow of transnational commercial activity. In recent years, global institutions which regulate international business, such as the International Monetary Fund and the World Bank, have become increasingly central to this legal order, along with a group of legal experts who help to manage international business transactions. The human rights system, made up of rules and sanctioning systems embedded in international institutions such as the United Nations, is another facet of the new global legal order (see *Human Rights, Anthropology of*). Although premised on a system of sovereign states, the pressure for compliance with human rights by states and transnational nongovernmental organizations is redefining the nature of state sovereignty itself. Local actors, such as indigenous peoples, make claims for legal and political sovereignty within the nation state, using international principles of self-determination and rights to protection of culture. The creation of new regional legal entities such as the European Union is also exploding the autonomy of local legal orders (Darian-Smith 1999).

4. *Law and Power*

Since the 1980s, the anthropology of law has become concerned increasingly with the relationship between law and the exercise of power (see Starr and Collier 1989). Inspired by Marxist and Foucauldian theory, and by the Critical Legal Studies Movement in law schools which argued that law reflects the interests of dominant groups rather than simply the logic of legal reasoning, anthropologists examined the way law supports relations of power in a wide range of social contexts (see Lazarus-Black and Hirsch 1994). But this research also demonstrated how law challenges dominant groups. It showed law to be a double-edged sword, expressing the rules and sanctioning authority of established political authorities and at the same time offering opportunities and justifications for resisting political authorities. For example, social movements that call on civil rights, such as the US civil

rights movement against racial discrimination in the 1950s and 1960s, challenge existing power hierarchies.

Feminists have used the criminal law to challenge male privilege by demanding penal sanctions for those who use violence against women in intimate relationships. The discourse of human rights has been deployed by indigenous peoples, women, victims of war atrocities, prisoners of war, and many other groups to claim protection from state authorities. Thus, law usually reinforces existing power arrangements, but can provide an avenue of resistance through its institutions and the discourse of rights.

Attention to the way legal forms and institutions exercise power, legitimate power, and resist established forms of power leads to a concern with the way laws are produced and enforced as well as with the linguistic and social exchanges which take place in courtrooms, police stations, and lawyer's offices (e.g., Conley and O'Barr 1990). Law constitutes social identities and understandings of social relationships through its regulations and through the spectacular as well as the mundane processes of arrest, trial, and mediation through which these regulations are enforced and failure to comply is punished. Even when laws do not impinge directly on social life, they exercise power through the ways in which they shape individuals' legal consciousness. This refers to the way people see themselves defined by and within law, the rights they can assert, and their entitlement to seek legal remedies for grievances (Merry 1990).

Law is a fundamental aspect of the exercise of power in colonial situations, since colonizing nations characteristically imposed a metropolitan legal code on to societies with very different legal orders. Such legal transplants were usually legitimated by goals of reforming family and community life. But they also privatized land ownership and created the basis for wage labor on plantations and mines. Several historically grounded studies have explored the complex relationships between this new European law and the shifting legal terrain of the colonized peoples of Africa (e.g., Moore 1986), Latin America (e.g., Collier 1973), and the Pacific (e.g., Merry 2000), among many others (see *Colonialism, Anthropology of*).

5. *Law, Culture, and Language*

Law is embedded in culture. The legal system of a society reflects its fundamental values and its normative order (Rosen 1989, Geertz 1983). At the same time, law constitutes cultural practices and defines basic identities such as citizen and criminal. Moral and religious understandings of self and community determine when and how people use law (Greenhouse 1986). The law also provides a rich vocabulary for describing and legitimating relationships of unequal power. It contributes in significant ways to the hegemony of a political system by engendering consent and fostering legitimacy for its exercise of power. Law is essentially a language and legal procedures are fundamentally linguistic. A body of recent work on law and language combines sociolinguistic analysis and law and society scholarship to look at the way law creates meanings and exercises power through linguistic exchanges in courtrooms and other legal settings (Conley and O'Barr 1998). This work provides a way to look at the detailed interactions that determine how the law exercises power. For example, many features of the kinds of talk which are persuasive in American courtrooms are more characteristic of male than female speakers, and of powerful rather than powerless speakers, so that male litigants in these courtrooms have an advantage (Conley and O'Barr 1998). But legal language and institutions also offer avenues for resistance. In particular, the language of rights has proved a powerful framework for social justice movements, especially since the end of the Cold War. Rights talk has been central to labor movements, indigenous peoples movements, the anti-apartheid movement in South Africa, and movements for women's rights, to name a few examples. Local groups around the world now draw on global conceptions of human rights for inspiration. Much of contemporary social justice talk and activism takes place within the domain of law.

6. *Conclusion*

The anthropology of law changed dramatically over the twentieth century. While earlier theories saw law as a structural feature of a whole society and used it to classify societies, more recent anthropological studies examine dispute processing, the linguistic and cultural features of legal settings that shape the way power is exercised, and the extent to which legal categories and concepts are embedded in individual consciousness and local culture. At the same time, the notion of culture as an integrated, homogeneous, and consensual system has been replaced by models of law in society which focus on the multiple and contradictory nature of rules and procedures. Contests among these systems of power and symbolism account for social change. Some of the competing frameworks are the product of alternative systems of legal regulation developed through colonialism or globalization. Contemporary legal anthropology views law as the product of contestation about meanings and identities in social fields constituted by multiple legalities. It examines the way law exercises power and sees this process as mediated by legal procedures, linguistic forms and exchanges, and cultural practices that shape legal settings and provide individuals access to these settings.

Law as an Instrument of Social Change

The relationship between law and social change is highly controversial among legal and sociological theories, between different philosophical orientations, and between legal cultures. There is no consensus regarding the role of law in past, present, or future developments. Consequently, opinions as to the impact of law in the processes of social reform differ according to the areas of law under scrutiny.

For some theorists law is only or mainly a dependent variable in society. Class structures, levels of economic development, culture, gender and so forth explain the specific characteristics of legal institutions and their changes. The opposite position conceives law as a tool for steering society in any possible direction. Human behavior is in their view largely determined by the existence of legal rules and sanctions. Intermediate positions which recognize both influences on the law and from the law are found in interdisciplinary studies, in particular in the field of the sociology of law (see *Law and Society: Sociolegal Studies*).

1. Law as Social or Supernatural

Western approaches share an understanding that law is part of the social world in its broadest sense. It emerges from social life or is intentionally created by social actors to steer society in intended directions. Law in the books is as much a product of society as is law in action. Depending on how law is defined, it is regarded as part of the culture or of the structure of society. But this view was never shared by all legal cultures and is at present mainly challenged by Islamic cultures. Muslim law—the *Shari'a*—is an integral part of Islamic religion. Divine revelation is its source. No authority in the world is qualified to create law or to change it, and not to obey Muslim law is a sin leading not only to criminal sanctions but also to punishment in another world. Hence state regulation through legislation encounters serious obstacles in some of the more orthodox Islamic countries and law contributes little to much needed social reform.

2. Differences Between Law and Society

Law is then necessarily different from society in Islamic logic. Western thinking also observes a necessary incongruence of law and society. In this case it does not follow from the divide between the secular and the divine but from the normative element characteristic for legal methodology. Although legal doctrine and legal practice in great part describe prevailing opinions and customs, they also develop new rules and always add value judgements (see *Legal Reasoning and Argumentation*). Normative expectations are by definition (Luhmann 1985) different from actual social behavior and a certain tension between them both exists in all societies. The gap between law and social practice is getting wider with increasing legislative activities observable since the middle of the nineteenth century, first in Europe and then in most other parts of the world. On closer inspection there are a number of

gaps (see *Legal Realism*) in every legal system: between higher courts and daily legal practice, between legislative acts and administrative routines, between lawyers and their clients, and between legally relevant behavior in different strata of the society (see *Law and Society: Sociolegal Studies*).

3. *Social Change*

Societies are complex networks of patterns of relationships constantly influenced and changed by new situations, new ideas, new social values, new technologies, and new innovations. Social change is a product of factors such as conflict and structural strains, economic pressures, political and ideological preferences, technology or the natural environment. However, none of these factors deserve undue weight as unique or prevailing 'cause.' Disregarding exceptional events like natural disasters, wars, or revolutions, societies change on the basis of a multitude of influences and do so permanently. Although 'modern' economic structures, cultural patterns, and technological innovations accelerate the social dynamic, traditional societies have always been able to adapt and to develop to a greater or lesser degree. Current social theories believe that change and disorder are normal and what needs sociological explanation is not disorder but exceptional phenomena like order, stability, and stagnation.

4. *Social Change and the Law*

Law is an element of society, and as such, is continuously changing with its surrounding social environment (see *Law: Change and Evolution*). More static societies like tribal communities and those societies which define law as divine show a smaller degree of permanent legal change, whereas 'modernity' is characterized by rapid change in most areas of law. Market economies create their legal support structures, grass root groups strive for civil rights or environmental regulation, and organized crime is a constant challenge for the administration of justice, creating pressures for more sophisticated legal devices. But the opposite is also observable: law influences or even creates social change. Most reforms initiated by state agencies use law as a tool for their policy aims.

The tension between law as a result of changing social demands or as a mover of social change is a much debated subject in the sociology of law (Vago 1997, Macaulay et al. 1995, Roach Anleu 2000). At issue is not so much the social control function of the law and even less the role of the law as a support structure for contractual relations. Rather, there is an apparent consensus that law is a key instrument for those purposes. However, it seems highly questionable how much law can change established traditions like discrimination against women, colored people, foreigners, or outcasts, or to change habits like the use of the automobile, or to establish a market economy in post-communist countries.

5. *Potentials for the Instrumental Use of the Law*

Since the rise of the nation-state, law was employed as one of the major instruments of political power, either criticized as a means of brutal oppression or welcomed as a democratic element in close connection with the rise of the *Rechtsstaat* or rule of law (see *Rule of Law*; *Rechtsstaat (Rule of Law: German Perspective)*; *Critical Legal Studies*). More and more areas of social life, from public affairs to intimate relationships, from local issues to global problems, are structured by laws emanating from municipal, regional, federal, international, or supranational legislative bodies. Courts intervene in virtually all social settings. Societies under the Civil Law complain about the 'juridification of social spheres' (Habermas 1984, 1987), whereas in the Common Law countries the litigation explosion (Olson 1991, Posner 1985) has become a major issue (see *Legalization*). These observations have led to a debate of a 'regulatory crisis' in Western societies pointing to inflationary use of legal tools, to predominant ineffectiveness of law in reaching its goals, and to wrong perceptions of law's 'realm' in society (Teubner 1992, Rottleuthner 1989).

6. *Theoretical Assumptions*

Although policy makers and legal scholars tend to assume that law is an effective instrument of social change and that the only relevant debate is about the way the law is modeled, sanctioned, or implemented (see *Compliance and Obedience: Legal*), social scientists struggle for the best explanation of the extent of behavior in conformity with the law (Fisahn 1999). Hobbes, as the forefather of utilitarianism and in particular of current economic theories of law, emphasized rational choice. Law is instrumentally effective if law-abiding behavior is more beneficial than deviant behavior (Posner 1992). Current sociology is heavily influenced by Durkheim (1964 [1893]) and Parsons (1951) who both explain legal behavior as expressing a value structure shared by all members of society. Legal rules are followed where they are supported by such values and rejected where they are not. The internalization of new normative patterns takes place in accordance with an existing structure of generalized expectations and of specific roles for specific social situations. Equally influential is Weber's (1954, originally 1913–19) theory of legitimation. In order to guide social behavior, law requires acceptance of charismatic, traditional, or legal authority. In 'modern' governmental structures, 'legality' prevails as the major legitimation mechanism: legal rules are accepted if formal procedures are followed in the legislative process. This emphasis on 'formal ration-

ality' is a dynamic but highly problematic aspect of the law in modern societies. Luhmann (1969) extends this idea to claim that the legitimation of law and legal decisions depends on participation in the decision-making process—rather than the outcome of that process. Potential protest is absorbed by participation as a voter in democratic elections or as a party in a court case.

Subsequently, Luhmann (1995) and Teubner (1993) rejected the very idea of law as a tool. According to an 'autopoietic' systems theory (see *Law, Autopoiesis in*), the study of effectiveness of law contracts into a study of legal discourses with those of other social systems. Giddens (1984) modified the prevailing sociological paradigm by explaining society as a reflexive process whose societal structures are less 'imperialistic' continuously produced and reproduced by individual actors. Daily routines not only follow existing rules but also create their own normative order. In this view rules are an instrument for achieving social change 'for everybody'—not only for those in power. Bourdieu (1990) develops similar assumptions about the individual actor as a structured and a structuring element—both being part of the 'habitus' which enables the actor relative freedom in a societal 'field.' The instrumental power of state law is, according to these 'postmodern' social theories, severely limited.

A universally applicable theory of the instrumental use of law is difficult to imagine since law is created in too many forms and is implemented (or not) in a great variety of situations. But further research can lead to situation-specific theories which may help to differentiate between both sociological and legal variations in legal regulation. Examples of research are reported in Daintith (1988) (law as an instrument of economic policy) and Gunningham and Grabosky (1998) (role of law in environmental policy). Each publication emphasizes the importance of a regulatory mix that includes nonlegal instruments as complementary or even dominant devices of policy implementation. Law is a useful and even necessary element in social reform processes, but more radical social changes cannot be accomplished solely by legal means. Economic incentives, structural and institutional support and educational programs are required for successful implementation strategies.

7. *Empirical Studies*

Measurement of legal regulation is difficult (see *Regulation and Administration*). Traffic signal behavior is observable but the impact of antidiscrimination law is not. Most legal initiatives have some direct effects and many indirect consequences which are hard to imagine and impossible to verify. Welfare laws regulate benefits for the poor but at the same time they have an impact on family structures, on the labor market, on the economy, and on all other goals of public policy which have to share with welfare a common public budget. Even direct effects are difficult to ascertain in complex societies where the new law might respond to a need in one sector and confound the interests of another. Some examples from different countries and legal cultures to show the kinds of information they can deliver:

(a) The impact of *Brown* vs. *Board of Education*, a US Supreme Court case decided in 1954, was studied by Rosenberg (1991). The judgment outlawed segregation in elementary and secondary schools which at that time was mandatory in 17 states and allowed in four others. According to Rosenberg's data, although the use of courts in the civil rights movement was considered the paradigm of a successful strategy for social change, courts had virtually no direct effect on ending discrimination in the field of education. Only when the Civil Rights Act was promulgated in 1964, and the executive branch acted forcefully to implement it, was segregation effectively ended.

(b) Like race discrimination, protection of the environment requires new and creative forms of state regulation. Two studies examine in great detail the regulatory efforts of German and English authorities to prevent pollution of open watercourses. Winter (1975) observed a single case in which a number of legal devices were used over a period of 25 years in order to stop the discharge of waste water into the river Rhein and lake Konstanz by three adjacent factories. The regulatory goals were reached only partially and after considerable delay and public investment. Winter explains this in terms of specific characteristics of German law and also the economic and political interests of the affected actors such as administrative agencies, business units, environmental groups, experts, and the local press. Hawkins (1984) was less interested in legal devices and structural influences on law enforcement than in the interaction processes between administrative bodies and industry. His research on two Water Authorities in England and Wales, based on interviews with field officers and representatives of industrial plants, found a distinctively conciliatory approach. Field staff, instead of initiating formal legal (criminal) proceedings against the polluter, enlist active cooperation. Decisions either to prosecute or to negotiate are made on the officers' own discretion and his/her own moral judgments. Indirect forms of control confer on field staff an authority which, for practical purposes, is in most cases ultimately persuasive.

(c) Independent India embraced equality as a cardinal value against a background of a culturally and religiously established caste system. The programs legislated after independence include compensatory discrimination (preferential treatment) for scheduled classes, scheduled tribes, and other backward castes as well as the opportunity for untouchables to use the courts in civil rights complaints. Galanter (1984, 1989) has evaluated their success. Although preferential treatment for victimized groups was carried out

forcefully by a complex system of reservations (granting of educational facilities, sharing of political power), Galanter observes considerable unfairness and negative side effects (not only for the upper strata of Indian society). A detailed study of court cases reveals an ambivalent picture. On the one hand, the High Courts where compensatory discrimination litigation takes place are highly respected and trusted institutions. The proceedings are inexpensive and quick. But litigation is initiated not by the beneficiaries of protective discrimination but by those complaining of schemes which affect their interests. The beneficiaries fail to get the benefits the law seems to promise. One of the reasons is the lack of adequate legal services providing beneficiaries with continuing and skilled support. After half a century of independence, India displays the effects of the limits of law in achieving social change: the gap between the economic opportunities of upper classes and upper castes on the one hand and scheduled classes on the other remains wide.

8. *Legal Exports to Defeated, Colonized, Developing, and Postcommunist Countries*

Historically, law has often been used as an instrument for achieving change in economic and social conditions in foreign countries (see *Law: Imposition, Reception, and Colonial*). Legal exports were part of colonial dominance and of postwar influence on defeated nations. In the 1960s and 1970s a US foundation and government programs attempted to use law to combat underdevelopment (see *Law and Development*). Similar programs have been initiated in the 1990s in post-communist countries by US scholars and also by European institutions. Since the fall of the Berlin Wall, many French, German, and Italian universities have been heavily involved in legal assistance activities; the Netherlands are exporting their new Civil Code to Eastern Europe and the European Community supports legal and educational reform programs in countries interested in becoming members of the European Union.

The assumption is that the setting up of an 'adequate' (Western) legal system including legal education and an efficient court structure is a precondition for rapid social and economic change (see *Markets and the Law*). Legal scholars are sent abroad, governments in developing countries employ Western legal experts; sometimes entire law codes are prepared by Western institutions or individuals and promulgated in the target country. Experience shows, however, that success is very limited and that the models have had at most a modest and incremental impact. In Latin America as well as in Eastern Europe, law and development programs proved to be counterproductive, leading to greater class differences, to distorted markets due to monopolistic structures, and to legal cultural rejection of imported models. Some authors talk of legal imperialism and the use of legal assistance as a Trojan colt (Gardner 1980). Oftentimes, the Western models are imported and legislated without the required legal infrastructure such as a well-educated legal profession, an honest and efficient court system, or some simple but necessary institutions like public registers. Positive examples of law and development activities (Japan in the nineteenth century, Germany after World War II, Poland and Hungary after 1990) point to a decisive intermediate factor in the instrumental use of law for development, namely the existence of a strong legal scientific community. Local legal scholars are able to filter foreign imports, adapt them to local needs, and teach the new law in the local cultural context. Since very few developing countries have such a strong academic community, law and development activities usually fail or remain incomplete.

9. *Instrumental Use of State Law*

Lawmakers have become aware of the contribution that empirically oriented social scientists can make to improve the instrumental use of law. Implementation and evaluation research accompanies many legislative initiatives. Critical studies in the fields of sociology of law, administrative science, sociology of deviance, and criminology influence regulative measures and judicial behavior. Concerns about the 'regulatory crisis' focus on dismantling forms of state intervention or on improvements in regulatory techniques including private ordering. The traditional focus on sanctions as a major resource in the use of law has been largely abandoned in favor of more participative methods. Lawmaking has sometimes been replaced by self-regulation (see *Legal Systems: Private*). Increased discretion has been given to administrative bodies as well as to judicial decision making. The overall result is a 'civil society' with state law as only one of many mechanisms to achieve social order and welfare. Social regulation takes place 'in the shadow of the law,' but it is not monopolized by the law.

10. *Law and Global Social Change*

The phenomena of globalization seem to support the argument that social change is a social rather than a legal process. Law only follows this change without the ability to take the lead and define the goals. Financial transactions are no longer limited by national borders, mergers of capital tend to monopolize global markets, communication is facilitated by the Internet, and environmental damage is caused on a global scale. The perspectives of law as an instrument of global change are rather somber. Most devices developed on the level of the nation-state for improving the implementation of regulatory law simply do not work on the global level where legislative

processes are deficient, common enforcement institutions and procedures are absent, and judicial institutions with global competencies are scarce (see *Globalization: Legal Aspects*).

There are legal initiatives which should nevertheless be mentioned (see *International Law and Treaties*). The GATT/WTO agreements have changed the conditions for global economic transactions and have created a quasi-judicial institution for handling disputes. In the area of Human Rights, a number of institutions such as the International Criminal Court in the Hague, the European Court of Human Rights in Strasbourg, and the International Labor Organisation in Geneva have been able to make some modest steps toward better protection of the individual. A number of international agreements attempt to prevent cross-border pollution, waste trafficking, global warming, and protect endangered species. Experiences in these fields might in the future provide useful know-how for global regulatory efforts.

Much more problematic are the effects of harmonization of regulatory law. One problem is the 'race to the bottom' which leads to regulation on the lowest levels of intervention in order to attract the greatest number of participants. Another problem is caused by differences in the application of harmonized or unified law. Even the EU, with its highly sophisticated regulatory structure, suffers from political or legal-cultural obstacles when EU law is transposed into law of the Member States (Duina 1999).

The globalization of law also takes place in the activities of nongovernmental actors (Gessner 1998, Appelbaum et al. 2001) who create what is called *lex mercatoria* (see *Lex Mercatoria*), who use their own private tribunals for the settlement of cross-border disputes (see *International Arbitration*), who make use of international law firms (see *Law Firms*) in order to set up new business structures and open new markets, or who draft codes of conduct, for example, concerning child labor or timber from tropical forests. Although expectations are high regarding these nongovernmental activities, few cases are reported where these activities have led to social change in a more narrow understanding—a change that replaces existing social structures and privileges with new ones and defines new priorities.

Law as Constitutive

The idea that law not merely regulates but also constitutes or creates social phenomena has been a powerful component of recent sociologically oriented approaches to the study of law. Yet it is an old idea, resurfacing in social science and legal studies after having been marginalized through much of the modern development of sociology of law in the second half of the twentieth century. In its recent forms, the idea of law as constitutive focuses particularly on law's power to shape fundamental moral or political assumptions, and general conceptions of the nature of social relations and social institutions. In this sense, law is seen as a mechanism shaping consciousness, establishing frameworks of thought and evaluation in terms of which social life is structured.

1. *Classic Conceptions*

Classic legal sociology, represented especially by the work of the Austrian jurist Eugen Ehrlich at the beginning of the twentieth century, confronted the constitutive role of law as an urgent political question: to what extent can the law of the nation state define the nature of social relations in the face of powerful competing moral forces? (Ehrlich 1975). In a multicultural society (such as the disparate and fragmented Austro-Hungarian empire of Ehrlich's time) in which diverse religious and ethnic influences on social life remained strong and sometimes antagonistic to the values enshrined in state law, Ehrlich concluded that state law's constitutive power is limited and it must learn from, as much as seek to control, informal norms of social life. Many other theories in the formative era of modern legal sociology carried similar messages: law was either rooted in existing culture and established collective understandings, or was enfeebled by its separation from them. The idea is expressed in Sumner's (1960) view in 1906 that effective legislation must be consistent with social mores, in Pound's (1917) insistence on the 'limits of effective legal action' and in persistent echoes of von Savigny's (1975) claim in 1814 that law must be rooted in a 'common consciousness' (*Volksgeist*) of the people, which it expresses but cannot change.

According to all such views, because law is strong when it represents popular understandings and weak when it runs counter to them, its power to constitute social relations is circumscribed. Law has a degree of independent social power only in so far as it avoids intruding on matters of belief or deeply rooted traditional practice. Technically-oriented law can be effective, while expressive (ideologically charged or value-infused) law is relatively weak in effect unless the values and understandings it presupposes are already in place in social life.

Thus, an important agenda for sociology of law in the second half of the twentieth century became the exploration of the conditions under which law's regulatory techniques could be used to bypass the assumed inertia of culture, or to shape specific kinds of social relations in ways that might indirectly encourage more general social change. In an era (especially from the 1960s) in which urgent attempts were made to harness law to tasks of social engineering (for example, in preventing racial and sexual discrimination), the idea that law could only mirror established systems of values and beliefs symbolized legal sociology's practical task: to confront cultural obstacles that stood in the way of the successful use of law as an instrument of social change (see *Law as an Instrument of Social Change*). Law as an instrument of social control or social change was limited by its cultural dependence and by its general lack of power to constitute popular understandings, values, and beliefs.

Classical social theory supported this view of law obliquely only. Émile Durkheim's sociology treats law as merely one dimension of a larger moral universe. Law neither constitutes nor is constituted by moral understandings and moral bonds, but is an aspect of them; it is these bonds and understandings that constitute society (Cotterrell 1999). Max Weber, associating modern law with a particular kind of rationality, sees the development of law as running parallel to other kinds of rational reordering of Western experience (Kronman 1983), though his sociology remains ambiguous as to the nature of law's specific contribution to a more general modern 'rationalization' of life. Karl Marx's conception of law as part of the superstructure of a mode of production is also ambiguous about law's 'independent' constitutive role, but suggests that this role will, at best, be limited. Thus, while law may provide indispensable support (ideological and repressive) for a mode of production, it cannot, according to standard Marxist analyses, constitute such a mode, or change it in any historically fundamental way (see *Marxism and Law*. Nevertheless, law constitutes, in the sense of formalizing and defining, relations and understandings of contract and property. To that extent it contributes powerfully to ideology in capitalist societies.

2. *Modern Critical Perspectives*

The Marxist-derived idea of law framing consciousness (by shaping ideas of responsibility, ownership, freedom, consent, agreement, causality, authority, etc.) has been a very important basis of recent ideas of the constitutive power of law, especially as a result of its advocacy as a central tenet of the modern critical legal studies movement. Critical legal studies (CLS), developed in many Western countries and especially in the United States from the 1970s, had a major influence on the destruction of old ideas of law as a

passive reflection of other social forces (see *Critical Legal Studies*). Its effect on sociology of law has been to help to turn attention away from questions about how law might be made more effective as an instrument of social change, and towards studies of law's power to reinforce established social practices and institutions, primarily by influencing collective understandings. Thus, because of the continual invocation of basic legal concepts, especially those of property and contract, in everyday regulatory practice, law, in the CLS view, contributes importantly to the 'reification' of concepts, that is, the turning of debatable ideas into settled, widespread, usually unchallenged understandings.

Marxist legal theory in its most sophisticated forms (e.g., Pashukanis 1978) and modern critical legal theory emphasize that law shapes ideas of personality and subjectivity which influence much wider currents of social thought. Thus, law defines who can be responsible for actions and who can engage in transactions that will be legally recognized. In particular societies at particular times, children, married women, mentally handicapped people, prisoners, and aliens of the state (foreigners) have been treated as wholly or partly lacking legal capacity (for example, to own property directly). Thus, for certain purposes, law constitutes human capacities or denies them (see *Legal Personality*). Correspondingly, law routinely gives personality and capacity to nonhuman entities. In various societies these have included religious idols and animals, but in modern law by far the most important example of the construction of nonhuman personality is the attribution of legal personality to the business corporation. This attribution constitutes the corporation as an entity entirely separate from the human individuals who work within it. In recent critical legal scholarship, the concern with law's constitution of personality has broadened to focus on the wider range of effects of law on the construction of identity.

Feminist theory has emphasized that law has typically constituted the human person in terms of male characteristics. In the past this legal stance was often explicit, with legal doctrine's denial of women's legal personality in certain contexts (for example, as property owners). Modern feminist theory (see *Feminist Legal Theory*) has shown how legal thought and practice ignores differences between women's and men's experience, or covertly assimilates the former to the latter, applying a 'male standard' to the definition of all social relations, capacities, and responsibilities. It has been claimed that law constructs women (in its typical rhetoric and evaluations) as 'terrorized, sexualized and maternalized' (Frug 1992). In a host of studies, critical socio-legal scholarship has also focused on the legal construction or denial of the social identities of minority groups and, more generally, on law's power to define and exclude 'the other' in sharp opposition to an image of the 'normal' subject of law (see *Critical Race Theory*; *Sexual Orientation and the Law*; *Law and People with Disabilities*).

The effect of this cumulation of critical work is a widespread rejection among socio-legal scholars of the doubts about law's social importance that long haunted legal sociology. In their place is a confidence that legal ideas and practices are central matters for sociological study. The older legal sociology sometimes slipped into the self-defeating position of holding that law 'mirrored' society (thus implying not only law's lack of social scientific importance but also its 'non-social' identity as 'merely' technical regulation and so its substantial immunity from conceptualization as a social phenomenon in itself). The newer emphasis on law as constitutive asserts law's power to shape fundamental collective understandings and practices that define the nature of social life. Taken to extremes, this position can suggest that law constitutes the very idea of society, rather than society constituting law (Fitzpatrick 1995). A further step might be to discard all reified conceptions of 'society' or even of 'the social' as a category (on the basis that the social picture is now too fluid and complex to allow such encapsulations or to allow these concepts to retain analytical power). The aim then would be to focus specifically on the particular kinds of social conceptions (for example, of identity, community, culture) which legal doctrine itself proposes, assumes, or sustains. In a sense, such an approach entirely reverses the conception of law as mirror of society; the social (whether or not it remains possible to conceptualize this as any kind of totality) is seen as the construction of law.

3. *Limitations of Constitutive Approaches to Law*

The danger of these approaches is partly that of greatly exaggerating law's constitutive power (how can we know that *law* does the constituting and, even if it does, under what conditions and constraints?). Jurists have long been tempted in this way, some even speculating that law largely determines morality by contributing to socialization (Olivecrona 1939). Philosophers and jurists note law's 'word-magic,' the power of legal words as 'performatives' to bring about social effects, such as inaugurating marriages, creating personal statuses, or transferring property (Austin 1982). But these formal effects raise rather than answer questions about law's social character. The risk is of attempting to analyze law in isolation from other social forces, treating it (as the earlier 'mirror' conceptions tended to do) as separate from other aspects of social life, with a causal relationship existing between the two. This danger has been especially serious for CLS which, being essentially a law school movement rather than a movement in social science,

has tended to assume law's social significance and power (in conformity with the main trend of lawyers' thinking throughout modern times) rather than seeking to assess it systematically and empirically in a wider social context.

Equally, it is not always recognized sufficiently that law's constitutive power may vary greatly in different societies. In some societies, its power to shape ways in which politics is conducted, social movements are formed and their campaigns or collective strategies are pursued, may be clear if complex in its effects (Brigham 1996). In other societies, complex cultural factors make law much less capable of constituting the form and character of social relations. Indeed, they might make it largely irrelevant.

It is also significant that one influential and sophisticated theoretical approach in contemporary legal sociology entirely rejects the idea of law as constitutive of society, because it denies that law as a system can communicate with, and so influence, social life in any direct way (Teubner 1993). Autopoiesis theory (see *Law, Autopoiesis in*) sees modern law as a discourse that normatively constitutes (more specifically produces, reproduces, and observes) only itself. One consequence is that its conceptions of agency, responsibility, personality, subjectivity, etc. are produced solely for its own purposes and processes and have no necessary relation to anything existing outside these. Far from constituting economic, scientific, political, or cultural life, law produces decisions to which these other social systems may respond on their own terms. Autopoiesis theory denies all conceptions of law as a mirror of society. At the same time, its assertion of law's radical discursive autonomy deliberately provokes endless questions as to how law can engineer social effects that are other than intolerably unpredictable.

4. *The Plurality of Legal Experience*

Some recent sociolegal approaches have discarded both the idea of law as mirror of society and that of law as a more or less independently constitutive force in social life, and have replaced these with a view of law as social mediation (e.g., Mertz 1994). Law thus appears as one way (or perhaps a cluster of ways, if it is not seen as a unitary discourse or practice) in which social experience is mediated, conceptualized, defined, and evaluated.

Such an approach presents its own difficulties as a sociological conception of law. If law mediates the social in some way, what enables it to do so, and from where does its power or authority to mediate derive? What is the nature of law if it is, in some way, separate from the social life that it mediates? These questions are ultimately no different from those which haunt the idea of law as constitutive. (Where does law derive its power or authority to constitute social life? And how, in what way, is law separated from social life in order to constitute it?)

In answering these questions the temptation is often to dissolve one term into the other. Thus, law may be seen as, for all practical purposes, constituting the social, so that the latter ceases to exist (at least for purposes of sociolegal analysis) as something independent of legal categorizations and evaluations. According to this view, law may certainly be studied in a social context, but its significance as an object of study requires no validation by social science. Alternatively, law can be seen merely as a mirror of social forces and social structure, meriting no special, independent sociological analysis; juristic concerns are socially insignificant unless reducible to general sociological categories and concepts.

A productive approach may be available to avoid both of these positions. Law is sometimes conceptualized sociologically as an aspect or field of social experience (e.g., Cotterrell 1995). In this sense, it is a component of social consciousness, a normative patterning of experience or a framework of understandings or practices. As an aspect of social life, it is to be separated from other social phenomena only provisionally and contingently for purposes of study. Important antecedents of this approach exist in legal sociology (Gurvitch 1947), but they have been obscured, to some extent, by approaches that treat law entirely as an instrument of the state. Viewed in this state-focused way, law's constitutive power appears problematic or mysterious, given (a) the state's frequently noted remoteness from the local milieux it regulates and (b) the increasing production of law by agencies other than the state. Law may, however, be understood pluralistically (see *Legal Pluralism*) as existing not only in the practices and procedures of state agencies, but in the everyday circumstances, sites, and settings of a wide variety of social groups and networks. Legal experience, according to this view, is the subjective experience of individuals and groups confronting, in these diverse environments, 'local' issues of governmental regulation and social control. An approach along these lines will see law as constituting social life insofar as it is itself embedded in social life, in expectations about security, responsibility, and other matters. At the same time, state law (the legal practice of lawyers and courts serving the centralized state) needs not merely to be politically constituted, according to criteria of political legitimacy, but also (from a pluralist perspective) morally constituted by its relation to the social experience of the populations it purports to regulate. From this perspective, the issue of law's moral authority identified by Ehrlich a century ago still remains crucial for modern law.

Law, Autopoiesis in

Legal autopoiesis refers to the idea that the legal system presupposes and reproduces itself. Modern sociological systems theory employs the concept of autopoiesis to emphasize the self-constituting nature of social systems. In analyses of the legal system it constitutes a hybrid form of a legal theory and a sociological account of law.

1. *Autopoiesis and the Functionally Differentiated Society*

Autopoiesis describes the capacity of an entity to reproduce itself. As a concept it was first introduced in theoretical biology to explain cognition and the essence of life (see Maturana and Varela 1980, 1987 and was then further developed in general systems theory (for example, von Förster 1984). It has been widely applied in mathematics, in the study of cognition, and in studies of the nervous system as well as in information systems, cognitive science, and artificial intelligence (see Mingers 1995).

In general systems theory, the following definition is widely accepted: autopoietic systems 'are defined as unities and as networks of production of components that recursively, through their interactions, generate and realize the network that produces them and constitute, in the space in which they exist, the boundaries of the network as components that participate in the realization of the network' (Maturana 1981, p. 21). Maturana's definition operates with a notion of recursive closure of the system. An autopoietic system is not only able to produce and eventually to change its structures, but is also capable of reproducing its components, and in particular its undecomposable elements, through recursive self-reference of these elements. Thus, its self-reproduction relies exclusively on internal operations and is not dependent on the environment.

Niklas Luhmann (1927–98) (see *Luhmann, Niklas (1927–98)*) is responsible for introducing the concept of autopoiesis to social systems theory (Luhmann 1986. His approach transcends the Parsonian version of sociological systems theory, which operates with an input–output model of the social system and its environment. A crucial element of Luhmann's concept is the idea of communications as the ultimate, non-decomposable elements of an autopoietic social system. Social systems are capable of reproducing themselves because they are communication systems (Luhmann 1995, 1997).

Autopoietic social theory distinguishes between society and functionally differentiated social systems. Society is seen as a first-order social system, whereas the legal system is viewed as a second-order social system or societal subsystem. Society as a first-order social system differs from second-order social systems insofar as it has no other social system as an environment; society's environment consists of natural and psychic systems. In fact, human beings do not form part of society or any social system but belong to their environment; the individuality and the consciousness of human beings are features of highly complex psychic systems that operate separately from social systems (Luhmann 1995, Chap. 7).

2. *Autopoiesis of the Legal System*

In accordance with general systems theory, autopoietic legal theory assumes that law is a special communication system that reproduces itself in self-referential processes. Legal communications, such as legal norms, legal decisions, or legal doctrine, are central to the

autopoiesis of the legal system (Teubner 1993, Luhmann 1993). In order to determine whether a communication is part of the system, the legal system operates with a specific binary code: law/nonlaw or legal/illegal (Luhmann 1990).

However, the code itself is not sufficient for the creation of law. The code must be translated into legal programs, which are rule-bound. Furthermore, the function of law is to deal with expectations, and in particular with disappointments of expectations. The legal system operates with a specific combination of normative closure and cognitive openness (Luhman 1987). It upholds the existing norms and procedures but it is also capable of learning in response to disappointments, and provides mechanisms for its own change. An important feature of autopoietic legal theory is the radicalization of the notion of legal autonomy. It is the peculiar character of autopoietic law that 'only the law can change the law. This is not to deny that the environment (in particular the political system) has an impact on the legal system. But the legal system reproduces itself through legal events and only by legal events' (Luhmann 1990, p. 229). On this basis, the modern legal system becomes positive and adopts a reflexive identity.

A further consequence of radical legal autonomy is the emergence of a special legal understanding of the external world. Like other function systems, the autopoietic legal system develops an epistemology according to its own criteria (Teubner 1989). It is this specific worldview that guides its internal operations and thereby influences legal development.

3. *Legal Evolution and Structural Coupling*

The legal system forms part of the functionally differentiated modern society (other functional systems include the economic, the political, and the religious systems). Each system within society evolves separately along its own trajectory, with its own internal structures and processes determining its development.

However, the evolution of social systems is not determined exclusively by internal conditions. Specific external relations that derive from structural couplings also have an effect. These structural couplings are constant sources of mutual irritations and perturbations of the coupled systems. Structural coupling can neither overcome the identity and autonomy of the coupled systems nor rank functional subsystems in an asymmetrical hierarchical fashion. Structural coupling allows only selective exchanges between the systems. Structural coupling produces irritations inside the system which are implemented by the system through its network of operations into further operations.

These perturbations do not actually cause changes; rather, they serve as triggers that may initiate internally controlled operations in operationally closed systems. Thus, structural coupling of social systems does not contribute directly to the reproduction of the systems. It is simply the specific form in which the system presupposes specific states or changes in its environment and relies on them.

The constitution provides an example of the role of structural coupling between the legal and the political systems. When constitutions emerged in the eighteenth century, they helped to recombine the functionally differentiated political and legal systems. From an autopoietic perspective, constitutions were adopted in response to problems of self-reference, paradoxes, and asymmetries in the legal and the political systems of the respective countries. Factors such as independence from colonial domination in the USA, or the formation of political sovereignty in a revolutionary situation in France, reflected only specific historical constellations. In both cases, the functionally differentiated legal and political systems had to realize that law completely determines what is legal or illegal, and that the political system had to design its own self-binding sovereign power.

The concept of the constitution offered the solution for both systems because it separated the political and the legal systems, yet provided for their structural coupling. The legal system made reference to the political system by acknowledging that the constitution derived from the political will of the people, and the political system made reference to the legal system by endowing the latter with the power to determine the constitutionality of positive law.

4. *Reflexive Law and Legal Regulation*

The concept of reflexive law, which arose from a debate of a new form of reflexive legal rationality in modern law, accompanies autopoietic legal theory. In particular, Gunther Teubner has argued that the modern legal system is characterized not only by formal and substantive rationality but also, increasingly, by reflexive legal rationality (Teubner 1983). The reflexive law concept was originally intended to combine the social theories of Jürgen Habermas and Niklas Luhmann. However, as the construct of reflexive law became more integrated with autopoietic legal theory (Teubner 1993), the influence of Habermas' theory decreased and Luhmann's systems theory became dominant.

The reflexive law concept emphasizes the limits of legal regulation and processes of self-regulation in other social systems. It analyzes the regulatory capacities of the legal system, both in relation to the regulation of other systems and in relation to the legal systems capacity to regulate itself. Law is confronted with a regulatory dilemma. It encounters ineffective-

ness when the regulated system simply does not respond to the regulatory attempt. Furthermore, if law imposes its own solution, it risks legalizing politics; but if law yields to the political imperatives, it risks becoming politicized. Teubner (1985) suggests that by facilitating self-regulation by the regulated system, law can sometimes overcome the dilemma.

There have been a number of attempts to use the reflexive law concept to analyze developments in particular areas of law. For example, Collins (1999) sees modern contract law as a form of reflexive regulation. Reflexive environmental law (Orts 1995) and reflexive labor law (Rogowski and Wilthagen 1994) have been suggested as concepts that can provide new insights in legal developments of legal subdisciplines. There have been attempts to combine reflexive law and postmodern legal theory in constitutional law (Ladeur 1992, 1997).

5. *Law in the World Society*

An 'unavoidable consequence of functional differentiation' (Luhmann 1982[1990, p. 178]) is that society becomes global. By concentrating on one function and excluding other functions, each subsystem gains a capacity to include all function specific communicative behavior, unlimited by territorial boundaries. Traditional subsystems that are constituted by specific communications can spread over the globe. Society as a whole can no longer integrate its subsystems by common territorial frontiers. Indeed, a modern, functionally differentiated society is a world society. It is this dimension with which the reflexive and autopoietic law concept fundamentally challenges traditional legal analyses.

Autopoietic legal theory predicts that legal globalization is unavoidable, and that a world legal system will emerge. This global law develops without support by any particular state (Teubner 1997). Despite considerable confusion about the meaning of globalization, it seems clear that there is not one trajectory that law follows within the world society. It is thus a further feature of reflexive law that it observes and compares legal developments in different parts of the world. For autopoietic legal theory, the study of global law requires a reflexive comparative law that is both empirically informed and theoretically aware of the autopoietic nature of world law (see *Globalization: Legal Aspects*).

Law: Change and Evolution

1. Legal Evolution

There has been a good deal of speculation on the question whether legal systems 'evolve,' that is, is there some kind of natural, automatic process or direction in which legal systems move and change over time. A distinction may be made between macroevolution—a theory of long-term change, involving whole systems or groups of systems of law; or law in general—and microevolution, which would concern single systems of law, and short-term changes. Of course, there might be many gradations in between. An interesting theory, more micro than macro, but not entirely, is the theory that common law doctrines evolve over time toward economic efficiency; the theory assumes a process, somewhat like Darwinian natural selection, that winnows out wasteful or irrational rules (for a discussion, see Elliott 1985, pp. 62–71). But microevolution merges with the theory of legal change in general. This essay will focus first on macroevolutionary change; then, briefly, on more general theories of legal change.

A (macro) evolutionary theory of law would mean, first, that it is possible to speak about stages in the growth or development of legal systems. It would imply a patterned, orderly progression: legal systems begin in stage one, then move to stage two, then three, and so on. Few if any legal scholars believe in 'evolution' in the sense of an inevitable progression from stage to stage. Practically speaking, historians and legal scholars have thought of evolution in a weaker sense: not all systems will reach the highest stage (whatever that might be), but the order will always be one, then two, then three (Friedman 1975).

The whole concept of evolution is, in a sense, distinctly modern, for the simple reason that many or most traditional legal systems regarded themselves as essentially immutable. Law was divine or magical or the product of natural reason, hence basically timeless and beyond human power. Change was, if anything, dramatic intervention by the gods. On the other hand, insofar as evolution implies progress, it is as unfashionable an idea in contemporary times as is the idea of progress in general.

Any theory of legal evolution has to posit some source of evolutionary change, that is a force that impels legal systems to move along given paths. Essentially, there are three general answers to the question of the source. One is that the evolution of society drags legal systems along with it, so that stages of legal development correspond to stages of social development. Most of the theorists discussed below fall into this category. A second is that law is independent of society, but that it contains within itself some principle of growth or evolution, which unfolds gradually over time.

Such an idea is at least implicit in legal formalism, both of the common law and civil law varieties; development either occurs automatically, or depends on the craftsmanship of judges or jurists; in either event, the law unfolds like the flower from the bud. Among modern authors, Alan Watson perhaps most strikingly illustrates this view: law, for Watson, is 'largely autonomous and not shaped by societal needs'; it 'evolves from the legal tradition' and not from the forces and demands of the surrounding society (Watson 1985, p. 119.) Still a third view would be that changes in law are basically random or accidental, following no special path, and tending in no special direction. This view does not seem to have any serious support in modern legal thought.

Many classical works in legal sociology and in social thought generally have at least touched on the subject of legal evolution, and most of them fall squarely within the first type mentioned above (Raiser 1995, pp. 318–334, Elliott 1985). Marx expressed an evolutionary theory, after all, in his views of the relationship between ownership of the means of production, and the organization of society; and this theory had definite implications for the legal order. Sir Henry Maine, in his important book, *Ancient Law* (1861), expressed the view that there was a definite pattern in the way legal systems grew and changed. Ancient law began in a patriarchal stage, in which the family, not the individual, was the unit of legal analysis; moreover, the father had basically the key rights and authority within the family. Birth order, gender, and age determined one's legal rights and duties. Society was based on status. The movement of 'progressive societies,' he stated, has gone in a 'uniform' direction; the individual replaces the family; voluntary, arrangements replace ascriptive ones; legal systems, to use his famous phrase, evolved 'from Status to Contract.'

Implicit evolutionary theories appeared also in other classical theories of law and society, Durkheim, for example, drew a distinction between primitive and modern societies. In *The Division of Labor in Society*, Durkheim distinguished between 'mechanical' and 'organic' solidarity. In traditional societies (societies of 'mechanical' solidarity), rules and norms were held in common. Violations threatened social cohesion; and had to be punished. The law was therefore mostly concerned with punishments. On the other hand, in modern society (characterized by 'organic' solidarity), there is a tremendous amount of complexity and interdependence; and legal rules are mostly civil and 'restitutive.' In Durkheim's scheme, as in Maine's, there is strong emphasis on contract, that is, societies as they enter the modern world are characterized more and more by voluntary agreements.

The most subtle, and influential, of the classic writings on legal evolution is Max Weber's (Rheinstein, 1954). Weber was interested in the question: what makes modern law different from older and traditional systems? The distinctive quality he saw was

what he called rationality—essentially, the process of making and interpreting law on the basis of general principles and rules. Oracles, ordeals, law-making by charismatic leaders—these are 'irrational' forms of making or finding law. Modern legal systems, in developed countries, tend (according to Weber) to replace the irrational with the rational. In particular, modern legal systems are characterized by formal rationality, a 'peculiarly professional, legalistic, and abstract approach to law.' A formally rational system uses logic and deductive reasoning to derive results from rules, concepts, and principles. Irrational systems do not produce predictable results—results that can be controlled by the intellect, and therefore results that a citizen can rely on. Modern law, the law of the modern capitalist state, has a natural preference, therefore, for Weberian rationality.

Weber falls short of arguing that this progression, from the irrational to the rational, is inevitable or predetermined. His discussion of legal history cannot be summed up in this single formula, since Weber describes, in rich detail, at least four stages of development (Sterling and Moore 1987). Charismatic legal revelation is succeeded by formally irrational 'kadi' justice—*ad hoc* decision making based on general social norms; then comes a stage of substantive rationality; in this stage a systematic body of rules is imposed on society, but less in terms of juristic reasoning than in terms of religious, ethical, or economic considerations. The stage of formal rationality comes last; in this stage the jurists create a more or less self-contained, highly logical and systematic body of law, in which abstract legal concepts are arranged in some definite and principled order. But this is merely a more or less idealized picture of the growth of law in the West. Weber does not claim that this is bound to happen elsewhere; and he never quite argues that the movement he describes is irreversible. In particular, modern law has tended to drift away from formal rationality in the direction of what Weber called substantive rationality, making or finding law in accordance with principles and policies (economic, social, cultural) that are not strictly 'legal.'

Richard Schwartz and James C. Miller (1964, see Wimberley 1973) tried to put the concept of evolution on a systematic basis, They drew material from 51 different societies, and tried to 'scale' the development of legal institutions. Their scales were in terms of legal institutions: the least advanced societies had no police, lawyers, or forms of mediation. Societies develop mediation first, then some form of policing, and a legal profession last of all. Most of the societies that Schwartz and Miller discussed were preliterate.

In a sense, Weber and Maine (although they wrote long before Schwartz and Miller) pick up where Schwartz and Miller leave off, since their main concern was with advanced societies. Galanter (1966), in an important essay, tried to define what makes a legal system 'modern,' which was, of course, Weber's chief interest as well. He suggests a list of 11 traits, which, in his view, set modern law apart from pre-modern law. The scheme, then, is implicitly evolutionary. For Galanter, modern law is bureaucratic, professional, rational, and universalistic; it is also 'amendable,' that is, it lacks 'sacred fixity.' Friedman (1994) returns to this theme and lists six traits which, in his view, together go to make up 'modern legal culture.' Modern law is committed to change, reform, adaptation; it lacks the conception of timelessness of traditional legal systems. It is pervasive and ubiquitous, and is frankly instrumental. At the same time, it does contain strong notions of fundamental rights. Rehbinder (2000) also lists a group of 'tendencies' which characterize contemporary law: a strain toward universalism (this was also one of Galanter's traits), but at the same time specialization, bureaucratization, and an increase in the sheer amount of legal material.

Most of these discussions of legal change focus, then, on 'modernity,' and they are descriptive and explanatory. There is a strong normative strain, however, in the work of Selznick (1969). Selznick was concerned, above all, with the evolution of 'legality.' In a later work, Philippe Nonet and Selznick discuss a tendency for laws to evolve toward 'responsiveness' (Nonet and Selznick 1978). These ideas have influenced the work of Gunther Teubner (1983), who described a form of evolution from a kind of dry, rule-bound bureaucratic system, to a more 'reflexive' one, in which the law, particularly within administrative systems, would be responsive to the needs and wants of the governed, and which would develop rules and procedures that would be just and adaptive. Teubner, like Nonet and Selznick, adds a distinctively normative flavor to the more descriptive tone of Weber. Teubner's views touched off a lively debate (see Blankenburg 1984); some of the empirical issues raised in this line of work remain to be definitively examined.

2. *Legal Change*

The subject of the theory of legal change has to be dealt with rather briefly, not because it is less important than the theory of legal evolution, but precisely because it is so totally pervasive. One of the most obvious aspects of modern legal systems is the fact that they are constantly changing. Every session of every legislature in every country makes at least some amendments or modifications of the law. The public expects change: every political party in modern Western countries has to have a program of legislation. Legal systems are very much dynamic systems, and it is part of the legal culture to expect them to be such.

Thus all modern legal systems accept change as normal. Not all legal systems, historically, have done so. In many classical systems, and in non-literate systems, the body of laws, or at least crucial aspects of them, were felt to be immutable—or, in any event,

beyond, the reach of ordinary humans. Since circumstances in fact changed, and the needs and wants of society changed, these legal systems were in fact changeable, and did in fact change with changing times. But legal change typically came in disguised or muted form; such systems often resort to devices such as legal fictions to conceal what had taken place.

Theories of legal change—theories about what produces legal change—depend, in the first instance, on the answer to larger questions, very notably, the question of the 'autonomy' of the legal system. A fully autonomous legal system would be one which operates according to its own inner logic or program, independent of the forces of the outside society; and changes within that system would accordingly proceed according to that inner logic or inner program. A totally non-autonomous system would, on the contrary, faithfully reflect changes in the outside society, and mirror them almost mechanically. Needless to say, most jurists and legal scholars are not found at either pole of this continuum, but somewhere in between. Most orthodox legal scholars cluster closer to the autonomous end of the continuum; social scientists who study law cluster closer to the other end.

In discussing legal change, there are obviously many factors to be taken into account (for a general discussion, see Ferrari 1997, Chap. 6). Not every legal system will change in the same way. This is true both for internal and external reasons. Societies undergoing rapid change will naturally process more legal changes than relatively static societies. Legal systems, particularly advanced ones, which legitimate change, will contain rules and procedures and institutions for making and processing change. Modern parliamentary democracies put the burden of change in formal law on legislatures, for example, though administrative rule-making is an extremely important vehicle of change as well; and the role of courts as change-agents is important in most of these societies. Much change also originates in customs, practices, and norms, which then influence the change-making institutions.

External forces lead to legal change, but the exact causal mechanism varies from instance to instance. A major event—war, plague, revolution—or a major technological or social development (the Industrial Revolution, or globalization, or the so-called sexual revolution) will inevitably lead to legal change, sometimes on a massive scale; but the exact form of the change is never precisely predictable. The 'outside' event or situation will impact a society which has a particular pattern or structure, and that existing pattern or structure will bend and mediate the influences of the 'outside' forces prismatically. In any event, these forces will create their impact through making changes in the general legal culture—that is, in the pattern of demands, expectations, and values that bear on the legal system—and legal change will result from this change in legal culture, rather than flowing immediately from the 'outside' event or situation. Moreover, once a legal structure, doctrine, or institution is in place, it can exert its own force on the legal culture; it affects legal ideology, and it may come to seem natural or inevitable. The process of legal change, then, is dynamic and interactive and forms a never-ending chain of causes and effects.

In theory, one can distinguish four types of legal change, depending on the point of origin of the change, and its final point of impact (Friedman 1975): (a) some change originates inside the legal system, and also spends whatever impact it might have within that system; (b) some change begins inside the system, but in fact does have an impact on society; (c) some change originates outside the legal system, but affects only the legal system, and ends there, with no further impact on society; and (d) some change originates outside the legal system, but ultimately has some impact on society, that is, it is more or less effective.

The first two are examples of technical change, and include many projects of 'law reform' or codification, within legal systems—technocratic work of jurists, which has little or no effect on the actual operation of the legal system. Many examples can be mentioned. Codification often falls into this category. But sometimes, wittingly or unwittingly, what begins as purely technical change has unforeseen consequences in the larger society. When this occurs, it is likely that the technical change simply furnishes a convenient 'hook' or formal excuse for some group in society which uses the technical change as a way to advance its goals. The last two are instances of change that begin with social forces or social movements. Legal change that results from demands arising out of social forces or social movements should, in theory, produce an impact in society. Where this does not happen, it is usually because some other social force or social movement is able to resist change, and the result is a kind of stalemate: a 'law' is passed, for example, after a bitter struggle between interest groups, but the 'losing' group has enough power to prevent effective enforcement.

The fourth type is, in many ways, the most interesting and pervasive, and it ranges all the way from revolutionary changes in the law—such as the changes that took place after the Russian or the Chinese revolutions; or, contrariwise, that took place in Russia after the collapse of the Soviet Union—to relatively small, incremental changes, which produce only a minor effect on some portion of the population.

The discussion above has mostly assumed change in formal, overt aspects of law. But legal systems are complex, and there are many instances where one aspect of the system changes while others remain (on the surface) unchanged. For example, the formal or official law might remain unchanged, while the operating system changes, perhaps quite drastically. One example would be divorce law and practice in the United States, in the late nineteenth and early twentieth centuries. The formal law of some states (New

York, for example) preserved rules that made divorce difficult and expensive; but at the operating level, collusion and other devices made it possible for citizens of New York to get divorces that in theory they were not entitled to have. What prevented formal change, and led to this example of a dual system, was apparently a political situation which for various reasons was deadlocked. Enactment of reform was politically impossible. The growing demand for divorce had to seek other channels, which it did quite successfully. Legal systems very commonly change in this ragged and complex manner.

One should also distinguish between long run change and short run change (and various gradations in between). In the long run, legal systems are almost infinitely plastic, and change to fit the shape of the society they are embedded in. A feudal system will generate a legal system that deals with the problems and institutions of feudal society and reflects its norms and structures; a capitalist, or socialist, or tribal society will behave in a similar manner. But in the very short run, random, accidental, or 'internalist' factors may condition or shape forms of legal change. It is this fact in modern societies that gives the impression of legal autonomy—an illusion that the legal system has a tough and impermeable outer skin. Another factor is the strength and power of the legal profession itself, which may have a vested interest in resisting certain kinds of change.

The rate and forms of change also depend on whether the society is relatively open and democratic, or relatively closed and aristocratic or totalitarian. In an open society, 'public opinion' is an important factor in shaping the law. Public force would be a more accurate way of putting the matter. 'Public opinion' as such—whatever it is that polls and surveys measure—has no role in itself in bringing about legal change, except insofar as it influences legislators or judges, or is translated into public action 'Public opinion,' therefore, as a formative element in legal change, cannot be equated simply with the wishes of the majority, as measured by some survey instrument. Salience of opinion is of crucial importance, because it affects whether or not attitudes are translated into behavior. Moreover, in no society, no matter how democratic, can one assume equality of power and influence; quite the contrary. As an axiom of legal change, one can start with the notion that a legal rule, doctrine, practice or institution will change if the social force exerted against it is greater than the force generated to preserve it intact.

This is a very abstract, and perhaps not very helpful, formulation. The interesting questions are more specific: in any given situation, what *are* the social forces that are in play, and what lies behind the exertion of social force?

In any society, some people have more actual or potential power than others; and more of a propensity to use it. A wealthy corporation simply counts for more than (say) an impoverished and uneducated slum-dweller. Moreover, it can be assumed that at any given time, the actual social force exerted on an issue is much less than the potential social force, since most people and institutions, even the powerful ones, most of the time, are indifferent to or ignorant of the majority of the legal issues and problems within a given society. For this reason, scandals, incidents, and 'horror stories' are particularly important sources of legal change in open societies: they can arouse the sleeping giant and turn potential force into actual exerted force. Hence the role of the media—which communicates these scandals, incidents, and 'horror stories'—is a particularly powerful, but insufficiently studied, catalyst for socio-legal change.

Particularly in common law systems, there is much discussion of the role the courts have played in bringing about social change. To what extent, for example, did *Brown vs. Board of Education* (1954) make a difference to American race relations? This is a much discussed, and somewhat controversial question (Rosenberg 1991). That the courts are an important institution in American society and play some role in bringing about social change cannot be denied; the question is how much. There is a small literature on the impact of judicial decisions, but it seems impossible to generalize, since the amount of change, if any, which a judicial decision brings about seems to vary with the circumstances; no two cases seem alike. The issue is not confined to common law countries. Modern courts, in many countries, have the power of judicial review, and their potential for pushing society along certain, paths has certainly increased. There are some signs of dramatic change in judicial culture in the Western world in general. Crusading judges in Italy led to the collapse of the party system; and an activist Spanish judge touched off a legal and political crisis when the judge issued an order directed against General Pinochet, the former dictator of Chile. With regard to judicial decisions, and to legal innovations in general, impact depends on many factors. One obvious factor is whether and how the innovation has been communicated to its audience—a factor we have already mentioned, with regard to scandals and incidents. One should also distinguish between immediate changes (on the litigants, or on a particular group which is the subject of legislation), and more remote, indirect, and long-term types of change. Many legal commands have effects which ripple out into society. As is generally the case, the research on all such issues is thin, and it is difficult so far to generalize.

Law: Defense of Insanity

1. United States

The United States criminal law presumes that a person must generally act in accordance with the acceptable range of norms of conduct adopted by society. A person exercising free will should be held accountable for his actions, because individuals do in fact have at least a minimum capacity for making the voluntary and rational choices required for criminal responsibility. Thus, the ordinary criminal defendant is viewed as 'culpable,' 'blameworthy,' or 'responsible' because that person could have chosen to abide by the dictates of the law. But there are a few individuals who cannot be held accountable. A mental disability or disease deprives them of even the minimal capacity for rational and voluntary choices on which the law's expectation of responsibility is predicated. Because of their inability to comply with the law, such persons are not held culpable, and are not criminal sanctions invoked or applied consequent to their conduct.

The insanity defense, therefore, is the exception that 'proves' the rule of free will. Supporters of the defense view it as vital to a healthy society, which uses its criminal law to build and buttress self-reliant action on the part of its citizens. Eliminating the insanity defense would remove from criminal law and public conscience the vitally important distinction between 'illness' and 'evil.' Throughout history, it is this vision of law that has rallied supporters to resist efforts to abolish the insanity defense. There is a deeply entrenched human feeling, as old as recorded history, that persons who are grossly disturbed (whether called 'madmen,' 'lunatics,' 'insane,' or 'mentally disordered') should not be punished as ordinary criminals would be.

The insanity defense also conforms to our ideas about the purposes of punishment. For the few who cannot be held accountable because of mental disability or disease, social control may be best served by confinement in a secure hospital setting (especially in the case of those who are dangerously insane). Similarly, the general deterrence theory underlying punishment suggesting that a person's awareness and fear of unpleasant consequences will restrain him or her from engaging in criminal behavior will not apply to the insane. Deterrence is effective only with persons who can understand the signals directed at them by the criminal code, who can respond to warnings, and who can understand the significance of sanctions imposed on violators (see *Punishment: Social and Legal Aspects*; *Deterrence*). Thus, punishment is not likely to deter seriously disturbed individuals from future antisocial conduct.

Finally, the insanity defense is seen by supporters as quite consistent with the notion of specific deterrence or restraint. If the defense is invoked successfully, the defendant is not merely incarcerated for a fixed period of time, but instead can or should be committed until such time as he or she is no longer dangerous.

Those who favor abolishing or severely limiting the insanity defense have advanced the following arguments: (a) the key terms in the various insanity tests are so vague as to invite speculation and intuitive moral judgments in the guise of factual determinations; (b) there is little or no basis in psychiatry for allowing expert witnesses to testify—as they often do, in conclusory terms—concerning the differentiation between persons who are personally blameworthy and those who are not; (c) it is therapeutically more desirable to encourage treatment of persons as actors responsible for their conduct, rather than as involuntary victims 'playing a sick role,' (d) the insanity defense discriminates against persons who commit

crimes because of influences on their personalities other than mental disease or defect. In addition, opponents of the defense argue that, if it be therapeutically desirable to provide a medical-custodial disposition, then such a decision should be made directly—immediately following the defendant's conviction, rather than indirectly during the trial. Finally, opponents of the insanity defense claim that, in practice, it is a 'rich person's defense' because usually it is only the wealthy who can afford the array of experts needed to mount a convincing defense. These scarce psychiatric resources, they argue, should be spent in treatment of those who have been committed or imprisoned.

Of the 47 states in the United States that allow a defense of insanity (Idaho, Montana, and Utah have abolished it), about half apply the American Law Institute (ALI) standard, first adopted in 1962; the others continue to apply the M'Naghten standard originally adopted in England in 1843 and then in federal and most state courts in the US in 1851. The ALI test states: 'A defendant is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirement of the laws.' The M'Naghten rule states: a person cannot be convicted if, at the time the criminal act was committed, that person was laboring under such a defect of reason (from a disease of the mind) as not to know the nature and quality of the act he or she was doing—or, if that person did know it, as not to know that the act was wrong.

In 1984, largely in response to the public outcry at the jury's acquittal of John Hinckley, Jr., the attempted assassin of then President Ronald Reagan, the US Congress enacted the Insanity Defense Reform Act. It represents the first federal codification of the insanity defense. The new standard provides for the affirmative defense that 'the defendant, as a result of a severe mental disease or defect, was unable to appreciate the nature and quality or the wrongfulness of his acts.' This formulation does not allow an insanity defense based on a defendant's inability to conform his conduct to the requirements of the law, as provided by the American Law Institute standard.

The act also shifts the burden of proof from the prosecution to the defendant, who must prove insanity by clear and convincing evidence. It changes the verdict form to 'not guilty only by reason of insanity' and establishes a federal procedure for commitment of persons who have been found not guilty only by reason of insanity. The act also limits the role of experts: No expert witness testifying with respect to the mental state or condition of a defendant in a criminal case may state an opinion or inference as to whether the defendant did or did not have the mental state or condition constituting an element of the crime charged or of a defense thereto. Such ultimate issues are matters for the trier of fact alone (Simon and Aaronson 1988).

Although the insanity defense is introduced in fewer than one percent of all criminal trials, it has provoked on intense amount of interest and attention. Allen said of it: 'The issue of criminal responsibility has attracted more attention and stimulated more controversy than any other question in the substantive criminal law' (Allen 1964).

The defense of insanity attracts so much attention because it touches on ultimate social values. It was founded on the concept of individual responsibility as a prerequisite for criminal punishment. In the words of Stone: 'The defense of insanity purports to draw a line between those who are morally responsible and those who are not, those who are blameworthy and those who are not, those who have free will and those who do not, those who should be punished and those who should not, and those who can be deterred and those who cannot' (Stone 1975).

2. *European Countries*

The following paragraphs provide a brief review of the legal criteria and procedures surrounding the defense of insanity in Western European and selective other societies (Simon and Aaronson 1988).

2.1 *Great Britain*

Great Britain still uses M'Naghten as the criterion of nonresponsibility but the defense is invoked very rarely. More popular is the partial defense of 'diminished responsibility' for persons charged with first-degree murder. Mental illness (which does not involve use of the M'Naghten right–wrong criterion) is introduced as a partial defense—to reduce a charge of first degree homicide to manslaughter—manslaughter does not result in mandatory life in prison anywhere. This is true for murder, not manslaughter.

A convicted criminal defendant who is considered mentally ill, although not legally insane, can be sent either to a prison or to a hospital. If a person is sent to a mental health hospital, it is usually for an indeterminate period. The court can and usually does impose a 'restriction order' on such a person if it considers him or her dangerous. If a person is not subject to a restriction order, he or she can be released by the hospital staff, subject to a determination that he or she can safely return to the community. But if a person is subject to a restriction order the Home Secretary must concur in the decision to release. Thus, the release of a mentally ill offender from a psychiatric facility or from a prison in England is usually a combined medical–political decision. Courts have virtually no control over the decision.

2.2 France

Article 64 of the French Penal Code provides: 'If the person charged with the commission of a felony or misdemeanor was then insane or acted by absolute necessity, no offense has been committed.' The defense need not establish any causal relationship between the mental illness and the behavior.

If insanity is raised as an issue, the court appoints an attorney as an officer of the court to conduct an inquiry into the state of the defendant's mental health at the time of the offense. The court-approved psychiatrists make their evaluations as to the sanity of the defendant and report their findings to the judge. The judge has the final say as to the defendant's sanity or insanity. The defendant found to be insane then undergoes further examination to determine whether he or she is mentally ill and dangerous at the present time. The defendant so found is sent either to a prison or to a hospital, where he or she remains until both the medical experts and the civil authorities give approval for release.

2.3 Germany

The German Penal Code drafted in 1972 reads much like the criteria spelled out in the ALI test. It states: 'Whoever is incapable, at the time of committing the offense, of appreciating the wrongfulness of the offense or of acting according to such appreciation because of a pathological mental defect, a seriously disturbed consciousness, feeblemindedness, or another serious form of mental deviance, acts without blameworthiness.' The code also allows for diminished responsibility: it states: 'If the actor's capability to appreciate the wrongfulness of the offense or to act according to such appreciation is, at the time of committing the offense, significantly reduced for one of the reasons named in Article 20, the punishment can be reduced in accordance with paragraph 49.'

If the defendant meets the criteria defined in Articles 20 or 21, the court will order an evaluation of his or her act and a determination of his or her dangerousness to the public. If the offender is found to be dangerous, he/she will be committed to a psychiatric hospital.

The court can, at any time, examine whether the further execution of detention is to be suspended on parole. Such examination would occur after the offender has been in a psychiatric hospital for one year.

2.4 Switzerland

Switzerland—like Germany—applies a criterion for determining insanity that is similar to the ALI test. It states: 'If a defendant was mentally ill at the time of the offense and had no capacity to appreciate the wrongfulness of his act or to conform his conduct to the requirement of the law, he has a personal excuse which precludes his being punished for his conduct.'

When the insanity issue is raised, the court appoints an expert to examine the defendant. The judge invariably follows the opinion of its own appointed expert.

If the defendant is declared not guilty by reason of insanity, he or she may be released or committed to a prison or a hospital. Release is usually a medical decision, which needs approval by an executive authority.

2.5 Spain

The Spanish code drafted in 1982 has the breadth and lack of specificity noted in the French code. It states that a person who is considered mad or in a state of temporary mental confusion, and who has committed an act that the law has sanctioned as a criminal offense—is exempt from criminal responsibility. A tribunal will decree the offender's committal into a mental hospital, where he or she will remain until otherwise authorized by the same tribunal.

3. Comparison between US and Europe

Many of the West European Countries are less concerned about attributing specific individual blame and responsibility than the US, which emphasizes the relationship between specific characteristics of the defendant's mental state and the act committed. The European systems tend also to focus more on treatment of the offender and on protection of society. In the US, the system works harder to establish blame or the lack of it, and expends less energy on treatment.

The West European countries are also more likely to defer to medical opinion and to extract medical testimony from the partisan system. Experts' views have greater influence in European courts than in US proceedings—not only on the issue of the defendant's responsibility, but also in decisions concerning commitment and subsequent release.

4. Selective Other Societies

4.1 Argentina

Argentina's statute concerning the defense of insanity adopted by Argentina in 1963 reads much like the ALI standard. Article 34 of the penal code states that the following persons are not criminally liable: 'Anybody who at the time of the commission of the crime could not appreciate the unlawfulness of the deed or control his actions by reason of insufficiency or diseased disturbance of his mind, or by unconsciousness, or by error of fact or ignorance for which he is not responsible.'

A defendant found not guilty by reason of insanity is automatically committed to an insane asylum. Release is dependent on a judicial hearing in the presence of a public prosecutor and on the presentation of a medical expert's report that, in his or her view, the patient no longer constitutes a danger to self or others.

4.2 Israel

The Israeli Penal Law updated in 1983 reads as follows: 'A person shall not bear the criminal responsibility for an act that he has committed if, by reason of a mental illness or defect, he is incapable of choosing between performing the act and refraining from doing so.'

4.3 Kenya

Kenya's standard also reads much like M'Naghten: 'Where an act or omission is charged against a person as an offence, and it is given in evidence in the trial of that person for that offence that he was insane so as not to be responsible for his acts or omissions at the time when the act was done or the omission made, then if it appears to the court before which the person is tried that he did the act or made the omission charged but was insane at the time he did or made it, the court shall make a special finding to the effect that the accused was guilty of the act or omission charged but was insane when he did the act or made the omission.'

If a defendant is found to be insane, the case is reported to the president; the accused is placed in custody—in either a mental hospital or a prison—and remains under the jurisdiction of the court.

4.4 Japan

The Japanese Criminal Code—amended in 1954—states simply: 'An Act of a person of unsound mind is not punishable. Punishment shall be reduced for acts of weak-minded persons.'

4.5 South Korea

The South Korean Criminal Code—amended in 1960—reads as follows: 'A person is not punishable if, because of mental disorder, he is unable to pass rational judgment or to control his will.'

South Korea also allows for diminished responsibility: 'The punishment of a person who, due to a mental disorder, is deficient in the capacity mentioned in the preceding Section, shall be mitigated.'

Law: Economics of its Public Enforcement

In this article we consider the economic theory of the public enforcement of law—the use of public agents (inspectors, tax auditors, police, prosecutors) to detect and to sanction violators of legal rules. Economically-oriented analysis of public law enforcement dates from the eighteenth century contributions of Montesquieu (1748), Beccaria (1767), and, especially, Bentham (1789). Curiously, after Bentham (1789), the subject of enforcement lay essentially dormant in economic scholarship until the late 1960s, when Becker (1968) published a highly influential article that has led to a voluminous literature. In Sects. 1 through 3, we present the basic elements of the theory of public enforcement. Our concern is with the probability of imposition of sanctions, the magnitude and form of sanctions, and the rule of liability. In Sects. 4 through 14 we then examine a variety of extensions of the central theory, including accidental harms, costs of imposing fines, mistake, marginal deterrence, settlement, self-reporting, repeat offenses, and incapacitation. (A more expansive treatment of the subject of this article is contained in Polinsky and Shavell 2000.)

1. The Basic Framework

An individual (or a firm) chooses whether to commit an act that for simplicity is assumed to cause harm with certainty. If he commit the act, he obtains some gain, and also faces the risk of being caught, found liable, and sanctioned. The rule of liability could be either strict—under which he is definitely sanctioned; or fault-based—under which he is sanctioned only if his behavior fell below a fault standard. The sanction

that he suffers could be a monetary fine, a prison term, or a combination of the two.

Whether an individual chooses to commit a harmful act is determined by an expected utility calculation. He will commit the act if that would raise his expected utility, taking into account the gain he would derive and the subsequent probability of being caught and sanctioned. We will usually first examine the assumption that individuals are risk neutral with respect to sanctions, that is, that they treat an uncertain sanction as equivalent to its expected value; but we will also consider alternative assumptions.

Social welfare is presumed to equal the sum of individuals' expected utilities. An individual's expected utility depends on whether he commits a harmful act, on whether he is a victim of someone else's harmful act, and on his tax payment, which will reflect the costs of law enforcement, less any fine revenue collected. If individuals are risk neutral, social welfare can be expressed simply as the gains individuals obtain from committing his acts, less the arms caused, and less the costs of law enforcement.

We assume, as is conventional, that fines are socially costless to employ because they are mere transfers of money, whereas imprisonment involves positive social costs because of the expense associated with the operation of prisons and the disutility due to imprisonment.

The enforcement authority's problem is to maximize social welfare by choosing enforcement expenditures, or, equivalently, a probability of detection, the level of sanctions and their form (a fine, prison term, or combination), and the rule of liability (strict or fault-based).

2. *Optimal Enforcement Given the Probability of Detection*

We consider here optimal enforcement given the assumption that the probability of detection is fixed (the probability will be treated as a policy instrument in the next section). Thus, we ask about the optimal form and level of sanctions under strict and fault-based liability, and about how the two liability rules compare.

2.1 *Strict Liability*

Assume initially that fines are the form of sanction and that individuals are risk neutral. Then the optimal fine is the harm h divided by the probability of detection p, that is, h/p; for then the expected fine equals the harm (observe that $p(h/p) = h$). If, for example, the harm is \$1,000 and the probability of detection is 25 percent, then the optimal fine is \$4,000, and the expected fine is \$1,000. This fine is optimal because, when the expected fine equals the harm, an individual will commit a harmful act if, and only if, the gain he would derive from it exceeds the harm he would cause. Essentially this basic formula was noted by Bentham (1789, p. 173) and it has been commented upon by many others since.

If individuals are risk averse with regard to fines, the optimal fine would tend to be lower than in the risk-neutral case for two reasons. First, reducing the fine reduces the bearing of risk by individuals who commit the harmful act. Second, because risk-averse individuals are more easily deterred than risk-neutral individuals, the fine does not need to be as high as before to achieve any desired degree of deterrence.

Next assume that imprisonment is the form of sanction. In this case, there is not a simple formula for the optimal imprisonment term. The optimal term could be such that there is either underdeterrence or overdeterrence, compared to socially ideal behavior. On one hand, a relatively low imprisonment term, implying underdeterrence, might be socially desirable because it means that imprisonment costs are reduced with respect to those individuals who commit harmful acts. On the other hand, a relatively high term, implying overdeterrence, might be socially desirable because it means that imprisonment costs are reduced due to fewer individuals committing harmful acts.

Now consider the combined use of fines and imprisonment. Here, the main point is that fines should be employed to the maximum extent feasible before resort is made to imprisonment. In other words, it is not optimal to impose a positive imprisonment term unless the fine is maximal. (The maximal fine might be interpreted as the wealth of an individual.) The rationale for this conclusion is that fines are socially costless to impose, whereas imprisonment is socially costly, so deterrence should be achieved through the cheaper form of sanction first. This point is noted by Bentham (1789, p. 183) and Becker (1968, p. 193); see also Polinsky and Shavell (1984).

2.2 *Fault-based Liability*

Assume again that fines are the form of liability. Then the same formula for the fine that we said was optimal under strict liability—namely, h/p, the harm divided by the probability of detection—will lead to compliance with the fault standard (assuming that the fault standard is optimally selected).

If individuals are risk averse, they are deterred more easily than if they are risk neutral, so the fine does not need to be as high to induce compliance with the fault standard. Moreover, assuming that compliance occurs, no one actually is sanctioned because no one is found at fault (provided that there are no mistakes). Thus, fault-based liability has the attractive feature that it can accomplish desired deterrence of harm-creating conduct without imposing risk on risk-averse individuals (Shavell 1982).

Next, consider imprisonment as the sanction; see Shavell (1987a). Here, for essentially the reasons given in the case of fines, any sanction above a threshold level will ensure compliance with the fault standard, and the minimum sanction necessary to induce compliance is higher the lower is the probability of detection. Also (Shavell 1985), fault-based liability can accomplish deterrence without the actual imposition of costly imprisonment sanctions.

Finally, consider the joint use of fines and imprisonment. In this case, it does not matter what the combination of sanctions is, provided that the sanctions achieve compliance with the fault standard.

2.3 Comparison of Liability Rules

Because sanctions are not imposed under fault-based liability (in the absence of mistakes), this form of liability has an advantage over strict liability when the sanction is a fine and individuals are risk-averse, or when the sanction is imprisonment. However, fault-based liability is more difficult to administer. Namely, to apply fault-based liability, the enforcement authority must have more information than under strict liability: it must be able to calculate optimal behavior to determine the fault standard and it must ascertain whether the fault standard was met. Under strict liability, the authority need only ascertain harm. (Moreover, for reasons we discuss in Sect. 6 below, strict liability encourages better decisions by injurers regarding their level of participation in harm-creating activities.)

3. Optimal Enforcement Including the Probability of Detection

We now consider the optimal system of enforcement when expenditures on enforcement, and hence the probability of detection, are allowed to vary. Consideration of this issue originated with Becker (1968).

3.1 Strict Liability

Assume first that the sanction is a fine and that individuals are risk neutral. Then the optimal level of the fine is maximal and the optimal probability is low (in a sense to be described). The basic explanation for this conclusion is that if the fine were not maximal, society could save enforcement costs by simultaneously raising the fine and lowering the probability without affecting the level of deterrence. Suppose, for example, that the fine initially is \$4,000 and that the probability of detection is 25 percent. Now raise the fine to \$10,000, presuming that the maximal fine is at least this high, and lower the probability of detection to 10 percent. Then the expected fine remains equal to \$1,000, so that deterrence is maintained, but expenditures on enforcement are reduced significantly, implying that social welfare rises. This process can be continued, and social welfare augmented, whenever the fine is below the maximal level f_m. Becker (1968) suggested this result; Carr-Hill and Stern (1979, pp. 280–309) and Polinsky and Shavell (1979) note it explicitly.

The optimal probability is low in the sense that there is some underdeterrence; that is, the optimal p is such that the expected fine pf_m is less than the harm h. The reason for this result is that if pf_m equals h, behavior will be ideal, meaning that the individuals who are just deterred obtain gains essentially equal to the harm. These are the individuals who would be led to commit the harmful act if p were lowered slightly. Lowering p will be socially beneficial because these individuals cause no net social losses (their gains essentially equal the harm), but reducing p saves enforcement costs.

If individuals are risk averse, the optimal fine generally is less than maximal, as first shown in Polinsky and Shavell (1979) (and elaborated upon in Kaplow 1992). This is because the use of a very high fine would impose a substantial risk-bearing cost on individuals who commit the harmful act.

Next, assume that the sanction is imprisonment and that individuals are risk neutral in imprisonment, that is, the disutility of imprisonment is the same for each additional year. Then the optimal imprisonment term is maximal. The reasoning behind this result parallels that used to show that the optimal fine is maximal when individuals are risk neutral in fines. Specifically, if the imprisonment term is raised and the probability of detection lowered so as to keep the expected sanction constant, neither individual behavior nor the costs of imposing imprisonment are affected (by construction, the expected prison term is the same), but enforcement expenditures fall.

Suppose instead that individuals are risk averse in imprisonment. In other words, the disutility of each year of imprisonment grows with the number of years in prison, perhaps because imprisonment becomes increasingly difficult to tolerate. In this case there is a stronger argument for setting the imprisonment sanction maximally than when individuals are risk neutral (Polinsky and Shavell 1999). This is because, when the imprisonment term is raised, the probability of detection can be lowered even more than in the risk-neutral case without reducing deterrence. Thus, not only are there greater savings in enforcement expenditures, but also the social costs of imposing imprisonment sanctions decline because the expected prison term falls.

Last, suppose that individuals are risk preferring in imprisonment, that is, the disutility of each year of imprisonment falls with the number of years in prison. This assumption seems particularly

important: the first years of imprisonment may create special disutility, due to brutalization of the prisoner, or due to the stigma effect of having been imprisoned at all. Additionally, the fact that individuals discount the future disutility of imprisonment makes earlier years of imprisonment more important than later ones. If individuals are risk preferring in imprisonment, the optimal sanction may be less than maximal (Polinsky and Shavell 1999). In particular, the type of argument used above does not necessarily apply. When the sanction is raised, the probability that maintains deterrence cannot be lowered proportionally, implying that the expected prison term rises. Because the resulting increased cost of imposing imprisonment sanctions might exceed the savings in enforcement expenditures from lowering the probability, the optimal prison term might not be maximal.

When the probability of detection is set optimally, together with the imprisonment term, underdeterrence may well result, not only to save enforcement expenditures, but also to reduce the costs of imposing imprisonment sanctions.

3.2 Fault-based Liability

The least expensive way to accomplish compliance with the fault standard is to use the highest possible sanction and, given this sanction, the lowest probability of detection that deters individuals who would be at fault. The reason is that, if all individuals who would be at fault are deterred, the only cost incurred is associated with the setting of the probability; this cost is minimized by using the maximal sanction and a correspondingly low probability. This is true regardless of whether the sanction is a fine or imprisonment and regardless of individuals' attitudes toward the risk of fines or of imprisonment.

3.3 Comparison of Liability Rules

As we emphasized earlier, under fault-based liability sanctions are not actually imposed (in the absence of mistakes), which often is an advantage over strict liability. However, this advantage of fault-based liability would have to be weighed against the disadvantages of this rule that we mentioned at the end of Sect. 2.

4. Accidental Harms

Until now, we have assumed that individuals decide whether or not to commit acts that cause harm with certainty, that is, they decide whether or not to cause intentional harms. In many circumstances, however, harms are accidental—they occur only with a probability. For instance, if a firm stores toxic chemicals in a substandard tank, the firm only creates the probability of a harmful spill.

Essentially all that we have said above applies in a straightforward way when harms are accidental. If parties are risk-neutral, sanctions are monetary, and the expected sanction equals harm, then induced behavior will be socially optimal; further, the optimal magnitude of sanctions is maximal if individuals are risk neutral because this allows enforcement costs to be saved; and so forth.

There is, however, an additional issue that arises when harm is uncertain. A sanction can be imposed either on the basis of the commission of a dangerous act that increases the chance of harm—storing chemicals in a substandard tank—or on the basis of the actual occurrence of harm—only if the tank ruptures. In principle, either approach can achieve optimal deterrence. If liability is based on the dangerous act, the expected fine should equal the expected harm, while if liability is based on actual harm, the expected fine should equal the actual harm.

Several factors are relevant to the choice between act-based and harm-based sanctions (Shavell 1993). First, act-based sanctions need not be as high to accomplish a given level of deterrence (because expected harm is less than actual harm), and thus are more likely to be able to be paid. Second, because act-based sanctions can be lower, they tend to be preferable when parties are risk averse. Third, act-based and harm-based sanctions may differ in the ease with which they can be applied. Act-based sanctions may be simpler to impose (it might be less difficult to determine whether an oil shipper properly maintains its vessels' holding tanks than to detect whether one of the vessels leaked oil into the ocean); or harm-based sanctions may be easier to impose (a driver who causes harm might be caught without difficulty, but not one who speeds). Fourth, it may be hard to calculate the expected harm due to an act, but relatively easy to ascertain the actual harm if it eventuates, thereby favoring harm-based liability.

5. Costs of Imposing Fines

Now suppose that there are costs borne by enforcement authorities in imposing fines. Our principal observation is that such costs should raise the level of the fine. To see why, suppose for simplicity that the probability of detection is fixed, that liability is strict, and that individuals are risk neutral. In this setting, recall from Sect. 2 that the optimal fine is h/p, the harm divided by the probability of detection. Now let there be a public cost k of imposing a fine. The optimal fine then becomes $h/p+k$; in other words, the cost k should be added to the fine that would otherwise be desirable (Becker 1968, p. 192, Polinsky and Shavell 1992). The intuition behind this result is that, if an individual commits a harmful act, he causes society to bear not only the immediate harm h, but also, with probability p, the cost k of imposing the fine—that is, his act results in an expected total social cost of $h+pk$.

If the fine is $h/p+k$, the individual's expected fine is $p[(h/p)+k] = h+pk$, leading him to commit the harmful act if and only if his gain exceeds the expected total social cost of the act. Hence, he will behave in a socially appropriate way.

6. Level of Activity

We have been assuming that the sole decision that an individual makes is whether to act in a way that causes harm when engaging in some activity. In many contexts, however, an individual also makes a choice about his activity level—that is, whether to engage in that activity, or, more generally, at what level to do so. For example, besides deciding how to behave when driving (whether to exercise care in changing lanes), an individual also chooses how many miles to drive; the number of miles driven is the individual's level of activity.

The socially optimal activity level is such that the individual's marginal utility from engaging in the activity just equals the marginal expected harm caused by the activity. Thus, the optimal number of miles driven is the level at which the marginal utility of driving an extra mile just equals the marginal expected harm per mile driven.

Will parties' choices about their activity levels be socially correct under the two major forms of liability? The answer is that under strict liability, their choices about activity levels will be correct, but under fault-based liability, they generally will participate in activities to a socially excessive extent. Under strict liability, parties will choose the optimal level of activity because they will pay for all harm done. Under fault-based liability, however, parties generally do not pay for the harm they cause because, as we have discussed, they will tend to behave so as not to be found at fault. Consequently, when deciding on their level of activity, they will not take into account the harm that their participation in the activity causes, and therefore they will participate too much.

The interpretation of the preceding points in relation to firms is that under strict liability, the product price will reflect the expected harm caused by production. Hence, the amount purchased, and thus the level of production, will tend to be socially optimal. However, under fault-based liability, the product price will not reflect harm, but only the cost of precautions; thus, the amount sold, and the level of production, will be excessive.

The tendency of parties to choose an excessive level of activity under fault-based liability, but not under strict liability, was first emphasized in Shavell (1980) and Polinsky (1980).

7. Mistakes

An individual who should be found liable might mistakenly not be found liable—a Type I error. Alternatively, an individual who should not be found liable might mistakenly be found liable—a Type II error. For an individual who has been detected, let the probabilities of these errors be ε_1 and ε_2, respectively.

Given the probability of detection p and the chances of Type I and Type II errors, an individual will commit the wrongful act if and only if his gain g net of his expected fine if they do commit it exceeds his expected fine if they do not commit it, namely, when $g-p(1-\varepsilon_1)f > -p\varepsilon_2 f$, or, equivalently, when $g > (1-\varepsilon_1-\varepsilon_2)pf$.

The first point to note is that, as emphasized in Png (1986), *both* types of error reduce deterrence: the term $(1-\varepsilon_1-\varepsilon_2)pf$ is declining in both ε_1 and ε_2. The first type of error diminishes deterrence because it lowers the expected fine if an individual violates the law. The second type of error, mistaken liability, also lowers deterrence because it reduces the difference between the expected fine from violating the law and not violating it—in effect, making a violation less costly to the individual.

Because mistakes dilute deterrence, they tend to reduce social welfare. Specifically, to achieve any level of deterrence, the probability p must be higher to offset the effect of errors.

If individuals are risk averse, the possibility of mistakes may increase the desirability of lowering the fine because, due to Type II errors, individuals who do not violate the law are subject to the risk of having to pay a fine (Block and Sidak 1980).

When liability is based on fault, an important implication of mistake is that some individuals will bear sanctions even if they comply with the fault standard, tending to make fault-based liability operate like strict liability. Moreover, as stressed by Craswell and Calfee (1986), individuals will often have a motive to take excessive precautions in order to reduce the chance of erroneously being found at fault.

8. General Enforcement

In many settings, enforcement may be said to be general in the sense that several different types of violations will be detected by an enforcement agent's activity. For example, a police officer waiting at the roadside may notice a driver who litters as well as one who goes through a red light or who speeds. To investigate such situations, suppose that a single probability of detection applies uniformly to all harmful acts, regardless of the magnitude of the harm.

When enforcement is general in this sense, the optimal sanction rises with the severity of the harm and is maximal only for relatively high harms; this point was first made in Shavell (1991) (Mookherjee and Png 1992 is closely related). Suppose, for example, that liability is strict, the sanction is a fine, and injurers are risk neutral. Let $f(h)$ be the fine given harm h.

Then, for any given general probability of detection p, the optimal fine schedule is h/p, provided that h/p is feasible; otherwise the optimal fine is maximal. This schedule is optimal given p because it implies that the expected fine equals harm, thereby inducing ideal behavior, whenever that is possible. The result that, when enforcement is general, sanctions should rise with the severity of harm up to a maximum also holds if the sanction is imprisonment and if liability is fault-based.

9. *Marginal Deterrence*

In many circumstances, a person may consider which of several harmful acts to commit, for example, whether to release only a small amount of a pollutant into a river or a large amount. In such contexts, the threat of sanctions influences which harmful acts individuals choose to commit. Deterrence of a more harmful act because its sanction exceeds that for a less harmful act is sometimes referred to as marginal deterrence (apparently so named by Stigler 1970).

Other things being equal, as observed by Beccaria (1767, p. 32) and Bentham (1789, p. 171), it is socially desirable that enforcement policy creates marginal deterrence, so that law violators have a reason to moderate the amount of harm they cause. This suggests that sanctions should rise with the magnitude of harm and, therefore, that sanctions generally should not be maximal. Note that marginal deterrence also can be promoted by increasing the probability of detection for more severe harms. For formal analyses of marginal deterrence, see Shavell (1992), Wilde (1992), and Mookherjee and Png (1994).

10. *Principal–Agent Relationship*

Although we have assumed that an injurer is a single actor, injurers often are more appropriately characterized as collective entities, and specifically as a principal and the principal's agent. For example, the principal could be a firm and the agent an employee.

When harm is caused by the agent of a principal, many of our prior conclusions are not fundamentally altered; they simply carry over to the sanctioning of principals. Notably, if a risk-neutral principal faces an expected fine equal to harm done, he will in effect be in the same position vis-à-vis his agent as society is vis-à-vis a single violator of law (see Newman and Wright 1990 on a closely related point). Consequently, the principal will behave socially optimally in controlling his agent, and in particular will contract with him and monitor him in ways that will give the agent socially appropriate incentives to reduce harm (but see Arlen 1994).

The allocation of a financial sanction between the principal and the agent would not matter if, as would be the natural presumption, the parties can reallocate the sanction through their own contract. The allocation of the sanction would matter, however, if it would allow the parties to reduce their total burden, for example, if the agent is unable to pay a fine because his assets are less than the fine; see Sykes (1981) and Kornhauser (1982). Then, the fine should be imposed on the principal.

The imposition of imprisonment sanctions on agents may be desirable when their assets are less than the harm that they can cause; see Polinsky and Shavell (1993). Because an agent's assets are limited, the principal may be unable to control him adequately through use of contractually determined penalties, which can only be monetary. It may be socially valuable to use the threat of personal criminal liability and a jail sentence to remedy this problem.

11. *Settlements*

We consider here how settlements affect deterrence and the optimal system of public enforcement, and whether settlements are socially desirable.

There are two general reasons why parties might prefer an out-of-court settlement to a trial (see generally Cooter and Rubinfeld 1989, and regarding settlement in a criminal context, see, for example, Reinganum 1988 and Miceli 1996). First, a trial is costly in terms of time and/or money. Second, settlements eliminate the risks inherent in the trial outcome. For these reasons, settlement tends to be socially valuable.

But a complicating factor is that settlements dilute deterrence: for if injurers desire to settle, it must be because the expected disutility of sanctions is lowered for them (see generally Polinsky and Rubinfeld 1988). The state may be able to offset this effect by increasing the level of sanctions; if so, settlements are socially desirable for the reasons mentioned in the previous paragraph.

12. *Self-reporting*

We have assumed that individuals are subject to sanctions only if they are detected by an enforcement agent, but in fact parties sometimes disclose their own violations to enforcement authorities. For example, firms often report violations of environmental and safety regulations. There are two basic reasons why self-reporting is socially advantageous; see Kaplow and Shavell (1994b). First, self-reporting reduces enforcement costs because the enforcement authority does not have to identify and prove who the violator was. Second, self-reporting reduces risk. For example, drivers bear less risk because they know that if they cause an accident, they can report this to the police and suffer a lower and certain sanction, rather than face a substantially higher sanction (for hit-and-run

driving) imposed only with some probability. Self-reporting can be induced by lowering the sanction for individuals who disclose their own infractions. Although this will tend to reduce deterrence, the reward for self-reporting can be made small enough that deterrence is only negligibly reduced.

13. Repeat Offenders

In practice, the law often sanctions repeat offenders more severely than first-time offenders. This may be beneficial for two reasons. First, as developed in Polinsky and Shavell (1998), raising the sanction for repeat offenders may create additional deterrence: if getting caught violating the law implies not only an immediate sanction, but also a higher sanction for any future violation, an individual will be more deterred from committing a violation presently. Second, as studied, for example, in Rubinstein (1979) and Polinsky and Rubinfeld (1991), making sanctions depends on offense history and allows society to take advantage of information about the propensity of individuals to commit offenses: individuals with offense histories may be more likely than average to commit future violations, which might make it desirable for purposes of deterrence to impose higher sanctions on them. It also may be desirable to incapacitate such individuals by imprisoning them (see the next section).

14. Incapacitation

We have focused on the use of sanctions to reduce harm by deterring individuals from causing harm. However, an entirely different way to reduce harm is by incapacitating individuals so that they cannot cause harm. Imprisonment is the primary incapacitative sanction; on the economic theory of incapacitation, see Shavell (1987b).

If the sole function of sanctions were to incapacitate, the optimal sanction would be determined by comparing the expected harm, net of gains, an offender would cause if not in prison to the private and public costs of imprisonment. Jail should only be used to incapacitate individuals whose net harm is relatively high.

Law Firms

The overwhelming majority of lawyers in private practice in most countries around the world practice alone or in very small and relatively informal groupings (Abel and Lewis 1988–95). Beginning in the 1960s, however, there has been a steady trend for lawyers who represent business interests to practice in larger and more bureaucratically organized law firms. Although lawyers for individuals have also attempted to organize larger firms, these efforts have been largely unsuccessful (Van Hoy 1997). As a result, at the end of the twentieth century the large corporate law firm is the dominant organizational model for private practitioners.

1. *The Evolution of the Large Law Firm: From Cravathism to Megalawyering*

The American law firm of Cravath, Swaine, and Moore is widely credited with creating the blueprint for the modern large law firm in the first decade of the twentieth century. The 'Cravath System' consists of four interrelated practices. First, lawyers, typically called 'associates,' are hired directly out of law school, paid a fixed salary, and required to work exclusively for the firm. Second, these new recruits are hired for a probationary period during which they are trained by the senior lawyers in the firm, called 'partners,' to handle matters of increasing responsibility for the firm's clients. Third, at the end of the probationary period, the partners select only the best associates for promotion to partnership, requiring those who are not selected to leave the firm. Finally, partners share in both the firms' profits and management, including, most importantly, the selection of new partners (Swaine 1946).

Firms patterned on the Cravath model grew dramatically in size and geographic scope from 1960 to the end of the twentieth century. In 1960, there were 38 US law firms with more than 50 lawyers, with the largest consisting of 125 attorneys (Smigel 1969). Forty years later, there were 250 law firms in the USA with more than 100 lawyers, with several exceeding 1,000 attorneys (National Law Journal 1999). In 1960, virtually all firms consisted of a single office. By 2000, most large firms had multiple offices, with many practicing in several jurisdictions. In 1960, only a handful of US firms had foreign offices. Forty years later, foreign offices of the top 250 American law firms were located in 72 foreign cities and employed almost 5,000 US and foreign lawyers.

During this same period, 'megafirms' (Galanter and Palay 1991) patterned on the Cravath model began to emerge in the UK, Europe, Asia, and other commercial centers. England was the first to develop comparable firms to those found in the USA (Flood 1989). By the end of the century, these firms were among the largest and most globalized firms in the world. Lawyers in the Netherlands (Blankenburg and Bruinsma 1994), Germany (Gerber 1999), Spain (Stewart 1991), Canada (Arthurs et al. 1988), Australia (Galanter and Palay 1991), China (Alford 1995), and Venezuala (Perez Perdomo 1988) have also developed their own versions of the large law firm. Although the structure and culture of these firms reflect important national and regional differences (Trubek et al. 1994), the Cravath System continues to exert a powerful influence on the development of large law firms around the world. As a result, theories about how US law firms are structured are likely to have important implications for firms in other countries that are patterned on the American model.

2. *Explaining Law Firm Growth*

Theorists offer three related explanations for law firm growth: tournament theory, portfolio theory, and demand theory. Although each theory highlights important truths, none captures the dynamic interaction between markets, institutions, and lawyer

entrepreneurship that has fueled the expanding market for corporate legal services.

2.1 The Tournament of Lawyers

Tournament theory posits that law firms must promote a fixed percentage of their entering associates to partnership in order to overcome the mutual monitoring problems of partners and associates inherent in the Cravath System (Galanter and Palay 1991). Partners, on this view, must protect their human capital (i.e., reputation, skill, and relationships with clients) from associates who might be tempted to damage partners by shirking on their assignments or grabbing the firm's clients and leaving. Associates, on the other hand, must protect themselves against partners who appropriate their hard work during the probationary period only to renege on their promise to promote those who perform well to partnership. Promoting a fixed percentage of every entering class of associates to partnership, tournament theorists assert, solves both problems by giving associates the incentive to maximize their chances for one of these prized slots by working hard with relatively little supervision, and at the same time providing associates with an objective measure (the number of associates promoted to partnership in any given class) of whether the partners are keeping their promise to reward the best associates. Since firms must hire at least one new associate for every new partner they promote (to leverage the new partner's human capital), tournament theorists conclude that the Cravath System's 'promotion-to-partner tournament' creates an internal growth engine that causes firms to grow exponentially in size.

Tournament theory contributes to understanding—but does not fully explain—the growth of large law firms. For the reasons outlined in Sect. 3.3, the internal labor markets of large law firms are not structured as rank order tournaments. Although the competition for partnership continues to play an important role in these institutions, two aspects of contemporary law firms limit its usefulness as an explanatory variable in law firm growth. First, many associates joining large law firms at the beginning of the twenty-first century have no intention of staying long enough to become partners in the firm (Wilkins and Gulati 1998). Second, rather than growing primarily by promoting associates who begin their careers with the firm, many of the largest and most successful law firms have grown through lateral hiring of senior associates and partners and by mergers with other firms (Johnson 1991). Each of these developments demonstrates that something other than the quest for promotion is driving law firm growth.

2.2 Portfolio Theory

Portfolio theory offers a potential explanation for why firms have increased their lateral hiring, particularly at the partner level. According to this view, law firms exist primarily to help lawyers manage and spread risk (Gilson and Mnookin 1985). A solo practitioner who loses her biggest client will face catastrophic consequences. A lawyer working in a law firm—particularly one that shares profits equally among the partners—is partly protected from this risk by the presence of a portfolio of firm clients. The more diversified the portfolio, the greater the protection e.g., firms can do initial public offerings when the economy is strong and bankruptcy work when the economy is weak. As a result, firms have strong incentives to grow by acquiring new partners (who bring new clients to the firm) and by developing new practice specialties.

Portfolio theory also fails to provide a full explanation for law firm growth. There has been a steady shift toward full service law firms. But this development does not appear to be fueled by the desire to minimize risk. Plaintiff's lawyers, who in the USA receive the bulk of their income from contingent fees that are only awarded at the end of successful litigation, are subject to far more downside risk than corporate lawyers who are typically paid by the hour. Yet plaintiffs firms generally are small and comprised almost exclusively of lawyers who are doing similar work (Coffee 1986). Moreover, as firms have grown larger they have tended to switch from lock step compensation for partners to 'eat what you kill' arrangements that reward partners for their individual contribution to the firm's profits. Marginal productivity compensation systems defeat the entire purpose of risk-spreading among partners.

2.3 Demand Theory

By concentrating on the internal dynamics of law firms, both tournament and portfolio theory neglect one obvious influence on the size of law firms—the demands of clients. Since 1970, there has been a tremendous increase in demand for all legal services in the USA (Sander and Williams 1989). Demand is strongest in the corporate sector, which in 1992 purchased more than $60 billion in legal services from American law firms (Galanter 1999). Law firms have obvious incentives to hire new lawyers, open new offices, and acquire new specialties to meet this demand.

Although client demand undoubtedly spurs law firm growth, it too is only a partial explanation. Demand side theories treat lawyers as passively responding to client pressure. American lawyers, however, have always played an active role in promoting the demand for their services. Thus, the lawyers who encouraged their corporate clients to use litigation as a tool for resolving business disputes are partly responsible for the increase demand for litigators. Similarly, law firms such as Skadden, Arps,

Meagher, Slate and Flom, helped fuel the mergers and acquisition boom by developing new strategies for hostile takeovers. It is this entrepreneurial style of lawyering that is spreading around the world.

2.4 Toward a Dynamic Theory of Growth

A complete theory of law firm growth must take account of the dynamic interaction among institutional structures, client demands, and lawyer entrepreneurship. Large law firms in the USA initially developed at the turn of the twentieth century as the large industrial concerns and financial institutions consolidated and formalized their power. The lawyers who sought to be the trusted advisers to these new economic enterprises adapted their practices—including developing expertise in specialties such as finance, reorganization, and antitrust, and creating internal practices (such as *de facto* tenure for partners, associates who owe their entire loyalty to the firm, and locating their offices in the buildings of their largest clients) that created symbiotic and durable relationships with their clients' owners and managers. As corporations reorganized and globalized a century later, it is not surprising that the law firms that serve these multinationals followed suit, expanding in size and geographic scope to better serve the competitive needs of their clients, while at the same time driving their clients to seek out and cultivate new markets. As the revolution in information technology opens the door for new forms of industrial and financial organization, we should not be surprised to see law firms creating new products and services, including ancillary businesses or joint ventures with nonlawyers to deliver nonlegal business and consulting services, designed to persuade companies to retain law firms—as opposed to other professionals—to guide them into the new economy (National Law Journal 1992).

3. Large Law Firms and the Public Interest

In addition to explaining the growth of large law firms, the dynamic interaction between the entrepreneurial initiatives of lawyers in these institutions and the expanding demands of their corporate clients has important implications for the distribution of legal services, the integrity of the public legal framework, and the gender and racial integration of the bar.

3.1 Why the 'Haves' Continue to Come Out Ahead

Corporations consume an increasingly large share of the legal services produced by US lawyers (Heinz et al. 1998). As a result, individuals have a more difficult time finding advocates willing and able to protect their legal rights (Hadfield 2000). Moreover, because access to law is a relative, as well as an absolute good, the more legal resources corporate interests employ the harder it will be for individuals to challenge corporate power in those areas—tort litigation, labor negotiations, health and safety regulation—where the interests of the two kinds of clients are likely directly to conflict (Galanter 1974).

3.2 The Paradox of Professional Independence

The American bar's ethical rules mandate that lawyers must be both zealous advocates for the interests of their clients and officers of the legal system who uphold the public purposes of the legal framework. To fulfill these dual obligations, lawyers are expected to be independent from both the state and their clients. Large law firms have always posed a potential threat to the public responsibilities of the bar. As early as the 1930s, critics complained that the emerging 'law factories' threatened the profession's independence by fostering a business perspective and an obsession with money that undermined the bar's commitment to autonomy and public service (Berle 1933). For the next 50 years, corporate lawyers were largely successful in rebuffing these charges by pointing to the important public service performed by high profile partners in leading law firms and by asserting that lawyers in large firms maintained the highest standards of professionalism. Although law firm partners continue to assert that they are the ultimate independent professionals, studies of the actual practices of large firms underscore the degree to which corporate lawyers are increasingly beholden to the interests of their powerful clients (Nelson 1988).

This fact has important implications for the rule of law and the integrity of the public legal framework. As corporate lawyers work longer and more diligently to attract and retain corporate business, they have less time for the public service and *pro bono* legal work that in the past helped to mitigate the imbalance of legal resources between corporate and individual clients (Kronman 1993). More important, corporate lawyers who come to identify strongly with their clients' interests are more likely to adopt an instrumental view of legal rules that treats regulatory constraints as little more than the probability of detection discounted by the price of enforcement (Gordon 1988). As the American savings and loan crisis in the 1990s amply demonstrates, such an approach to corporate counseling can have disastrous consequences for the public fisc in circumstances where the clients who receive this kind of instrumental advice are in a position to subvert important public regulatory protections (Wilkins 1993).

3.3 Winners and Losers in the Tournament of Lawyers

Many who are skeptical that tournament theory explains the growth of large law firms nevertheless

continue to use the tournament model to describe the internal labor markets of these institutions. The hiring, promotion, and compensation practices of law firms, however, differ from those assumed in tournament theory in four important respects (Wilkins and Gulati 1998). First, as indicated above, not everyone who 'enters' the tournament as an associate is competing for partnership. Second, unlike a sporting event, associates do not compete on a level playing field. Instead, the high associate-to-partner ratios of large law firms ensure that only a few associates will receive the training and mentoring that they need to develop the legal skill and business contacts that will transform them into credible partnership candidates. Third, far from being neutral umpires who seek to promote only those associates who will best serve the interests of the entire firm, partners are actively competing with each other to promote associates who will further their personal interest in servicing their own clients. Fourth, firms award partnership prizes to those they believe will be the best partners—i.e., ranking associates on the basis of their perceived ability to bring in business and other revenue generating tasks rarely performed by associates—as opposed to rewarding those who have billed the most hours or otherwise demonstrated the most loyalty in their past work for the firm.

These differences from standard tournament theory affect who is likely to succeed in a large law firm. US law firms have abandoned most of the overt discriminatory policies that until the 1960s excluded most women, racial minorities, Jews, and even many Catholics. Nevertheless, 40 years later these institutions have made only modest progress in hiring, and most especially promoting to partnership, women and racial minorities (Chambliss 2000). The real rules of the tournament of lawyers help to explain this continuing lack of progress. The well-documented tendency for people to see potential in protégés who remind them of themselves makes it more difficult for minority associates to receive scarce training and developmental opportunities from white male partners (Wilkins and Gulati 1996). Women face the additional burden of being perceived as not as committed as male associates and therefore a riskier bet for partners who want to invest their time in associates who they believe will have long-term careers with the firm (Epstein et al. 1999). And, should they surmount these barriers, women and minorities both face important obstacles to developing the kind of client relationships with major corporations that would enable them to become powerful partners in firms that are increasingly driven by the bottom line (Epstein et al. 1999, Wilkins 1999).

4. *The Future of the Large Law Firm*

Large law firms face increasing competition from accounting firms, consultants, investment bankers, and technology companies. This competition is proceeding on three fronts. First, nonlegal professional service firms are forming multidisciplinary partnerships with lawyers that are capable of 'practicing law' and giving integrated advice at the intersection of law, business, and competitive strategy. Although prohibited in the USA, such partnerships are legal (albeit with certain restrictions) in many European countries, including France, Germany, and the Netherlands as well as in England, Canada, and Australia (New York State Bar 2000). Second, even in jurisdictions where multidisciplinary practice is prohibited, nonlegal professional service firms continue to advise corporate clients how to manage and reduce legal risk. Third, nonlegal professional service firms are increasingly competing with law firms for legal talent, both by hiring lawyers directly out of law school and raiding associates, and sometimes even partners, from large firms.

Large firms have responded to these competitive pressures by: (a) invoking professionalism norms to condemn multidisciplinary firms as unethical, (b) merging with mega law firms from other jurisdictions (or entering into global legal alliances or networks) for the purpose of creating law firms that can successfully compete with global nonlegal professional service firms, (c) creating new categories of workers (e.g., nonequity partners, senior counsels, permanent associates, and contract lawyers) to enable firms to grow and provide more services without decreasing partner profits, and (d) dramatically increasing starting salaries for entering lawyers (New York State Bar 2000). It remains to be seen whether any of these measures will be sufficient to maintain the dominant position that large law firms achieved in the twentieth century in the more competitive and knowledge-driven economy of the twenty-first century.

Law: History of its Relation to the Social Sciences

Any attempt to discuss the history of the relationship between law and social science encounters a number of problems of definition. For the purposes of this contribution, it is most important to draw attention to some of the problems which can flow from the range of meanings attached to or associated with the term or idea of law. Deriving from this range of meanings, the variety of projects associated with the idea of a legal science can be problematic. As a result of both of these elements, when an attempt is made to formulate the boundaries of the question about the relation between law and the social sciences, indeterminacy results.

1. *Two Images of Law*

At its simplest, the idea of 'law,' at least in Occidental or even Indo-European culture, conjures up two broad images. One is of legislation or rule making. The other is of adjudication or judgment. Cognate distinctions, for example between law and policy or law and politics, and principled statements of the supposedly modern requirements of a democratic order (for example, the doctrine of the separation of powers), all play with or draw upon this much more

deeply rooted distinction, tension, and ambiguity in the idea of law. And even this primordial distinction becomes more complicated with the emergence of a self-thematized modern era, in which the idea of law as rule-making falls apart or splits into two broad patterns. On the one hand, the idea of making highly general, abstract, decontextualized rules which establish the framework to govern the operations of society (the so-called European codes; for this see Caenegem 1987). On the other hand, the idea, which persists in Anglo–American or 'common law' jurisdictions, that rule-making is a matter of detailed, specific rule-making targeting specific problems which come to the attention of the legislator, whether, in the traditional model, through deficiencies brought to light in the course of adjudication, or, in the modern model, because of problems demanding policy adjustments which come to light in, for example, governmental bureaucracies through the growth in knowledge of the shapes and characteristics of society and its pathologies. Some have argued that, at least in the common law world, the increasing volume and significance of legislation so overwhelms our idea of law that it comes to be projected back on to the activity of adjudication, which comes to be understood as a kind of inferior lawmaking, rather than a distinct process with its own specific forms of intelligibility (Simmonds 1984). Since Bentham (and to some degree Montesquieu before him), the idea of a link between a science of legislation and a science of society has seemed obvious. More obscure to social science is the idea of adjudication as such a science. Paradoxically, perhaps, the view has long been generated from within the discipline of law that it is in the domain of adjudication or adjudication-related activities that a knowledge of society is both required and developed, and from this perspective acts of legislation are seen as arbitrary or at least as the product of political will rather than an understanding of society. This kind of lawyer-knows-best attitude carried over, especially in England, into the new encounter between adjudicators and social scientists, especially in the sphere of criminal justice and criminology.

2. *Law and Social Science*

The reason why it is necessary to highlight these divergent emphases is simple: there persists an enthusiasm in many quarters, and by no means just among lawyers, to thematize the idea that law is the oldest social science, that law was and/or remains a 'science of society,' and, in some versions, that the modern social sciences represent merely a continuation of this science or in some cases a derogation from it, a diminution in what society knows about itself.

The question of the relation between law and social science and the history of this relation is further confused or complicated by many of the uncertainties involved in the specification of what is or is not within the ambit of social science. Confining this enormous issue to a narrow focus for our present purpose, we need to separate three kinds of question. The first is the relation between law and the empirical or positivistic branches of the social sciences. The second is its relation to the interpretive and/or phenomenological branches of the social sciences. The third, which cannot neatly be separated from the second, is the relationship between law—or, to switch gear, legal theory—and social theory, which becomes relevant if we assume that there is some kind of connection or link between the conceptualizations of social theory and the problematizations which emerge in the diverse fields of the empirical social sciences.

It is perhaps unsurprising that the closest affinities and even influences between law and social science seem to emerge in the domain of social theory. It is increasingly acknowledged that the writings of some of the founding fathers of social theory, and, indirectly perhaps, of sociology, had a legal background and that their theoretical constructions and projects bear the imprint of legalistic or law-inspired concerns. If, however, this is true of both Durkheim and particularly of Weber (Turner and Factor 1994), then this observation does suggest that legal influences and origins could lead late-nineteenth-century aspiring social theorists to formulate very different questions and very different theories of society, assuming that the construction of 'social theory' was what they sought to achieve. A legal background, in other words, did not seem to lead to any particular kind of theoretical orientation. In something of the same spirit, one of the leading post-war texts in legal theory describes itself as an exercise in 'descriptive sociology' (Hart 1961). This focus makes it possible to see strong continuities between law and (the theory underpinning) social science. Some contemporary political philosophers (Rose 1984), lawyer/psychoanalysts (Goodrich 1997), and historians of political thought (Kelley 1990) have not hesitated to drive home the point, with the polemical claim that modern social theory masquerades as different or new, whereas the basic framework of Western social thought is already contained in the law and indeed that the tradition of law already contains a more sophisticated understanding of the central issues than much modern social theory.

Alternatively, some influential theorists adopt what is more or less the opposite position (e.g., Foucault 1976, Luhmann 1981). On this view, there is a sharp break between an era of social thought in which law provides the basic conceptual scheme for understanding society, and the modern or late modern era in which this vision of society is undermined or displaced by the growth of positivistic social sciences. Hacking (1990) encapsulates what is perhaps the central dimension which underlies this view of historical change

in contrasting the role played by the concept of the 'normal' in the projects of Durkheim and Galton respectively. Durkheim's notion of the normal is still legalistic; in Galton it becomes entirely probabilistic. And in his view it is Galton's version in the twentieth century which wins—in science, at least.

The second area is the relation between law and the interpretive social sciences. Here the connections are in one sense much clearer and visible, especially if we have the 'European' law-as-code model of law in mind. At first sight this seems to be a terrain on which law, history, and interpretive social science meet in the sense that they are engaged in the same kind of endeavor. This is because each is engaged in an exercise of interpretation, and the paradigmatic interpretive situation is the 'presence' of a text which is in some sense 'other' to the person required to interpret it. In hermeneutical science, for example, the enterprise of interpretation from this starting point is characterized as precisely the bringing together, via the text of author/creator and reader/interpreter and as the quest for a fusion of horizons, a merging of perspectives which endeavors not to transcend temporality (as does analytical philosophy) but to make it work, productively, at both ends of its spectrum. It is apparent, viewed historically, that this style of science (whether it is 'scientific' is not a question for this contribution) owes much to law and just as much to theology, and to the study of texts in each discipline in the universities of medieval Europe (Smalley 1983). Already in these disciplines interpretive protocols had been formalized and their shapes were largely carried forward into the emergence of more explicitly philosophical projects by the eighteenth century. Many have traced an unbroken genealogy from that point, in the writings of, for example, Boekh and later Schliermacher through to Gadamer (1965) and contemporary practitioners of this approach to 'truth' (Rorty 1979). Much was made of 'meaning' in these narratives of the history of a partial discipline-under-construction, and therefore in many versions Weber or Verstehenssociologie were annexed to the narrative as part of the same story. 'From the actor's point of view,' a slogan variously popularised (at least within the academic world) by Malinowski and Geertz (1973, 1988), could lay claim to being the heir to this perspective or 'methodology' and claims that this involved a direct succession to the lawyer's perspective that, for example, '*actus non sit reus nisi mens sit rea*' (the doctrine of *mens rea* which seemingly involves investigation of inner mental states and 'intentionality' and its degrees) possessed and still possess a certain plausibility.

But it is precisely at this point in the history of law and the social sciences that continuities may need to be balanced by discontinuities. First, the once innovative proposition that social science can proceed on the basis that culture is a text has been much debated and criticized (e.g., Clifford and Marcus 1986). Secondly, political and legal anthropology in particular has raised a number of questions about the tendency in earlier studies to posit a 'jural perspective' when investigating acephalous societies, which presented a particular challenge because no visible structures of government or law in the familiar western sense were available for outside observers to observe (which is not to say that they could not find them virtually present) (Comaroff and Roberts 1981). Under the influence in part of some of this work, some historians came to question the top-down model of social integration and/or development which has had a habit of permeating social as well as political history.

The net result of these overlapping concerns has been to move away from or be suspicious of the deployment of a 'juridical' model in the interpretive social sciences, and this has served to highlight the difference in the concerns or preoccupations of lawyers and social scientists. For lawyers, the key question is what beliefs, assumptions, values, intentions it is reasonable or rational to impute to actors or legal subjects—therein lies the craft, one might say, of the law, and there is nothing new about this. Social scientists making use of interpretive procedures are increasingly concerned to understand or uncover the logic of individual and social action, including motivations, aspirations, intentions, and use concepts like culture, horizon, context, situation, to help render these intelligible. These social scientific ambitions are not new, but a combination of background factors (postcolonialism, for example) and increasing sophistication in formulating these components, means that interpretation has lost what innocence it ever possessed, and that the kinds of protocols employed by lawyers whenever they need to concern themselves explicitly with actors rather than texts are increasingly divergent from the highly reflexive methods now required of social scientists. Indeed, legal self-understandings have come to look to these interpretive disciplines for some corrective to what are increasingly perceived to be deficiencies in epistemic capacity and practical deliverability within the legal world itself. The sharpest symptom of this (though appearances can sometimes deceive) is the rapid rise to prominence in policy-making, especially in the Anglo-American common law world, regarding the adjudicative process of Alternative Dispute Resolution (ADR), an approach to conflict resolution which has unambiguous roots in 1950s colonial and post-colonial anthropology. One example can perhaps serve as a sharp reminder of how far apart in some respects the preoccupations of the law and of modern interpretive social sciences have become. For the law, an axiom of prudence and indeed an operational condition of possibility has more or less for ever been the postulate that '*ignorantia juris haud excusat*.' Contrast this with the role which '*docta ignorantia*' plays in Bourdieu's not-quite-Marxist sociology of domination (Bourdieu 1980). Axiomatically the law disregards what people claim they do not know (based on the suspicion that

such disclaimers are easy to make and dubious in the first place—a protocol rooted in scepticism, in other words). By contrast, Bourdieu perhaps leads the contemporary field in focusing on a modern version of Marxist false consciousness, detached from economic determinism as such, but emphasising the prison-house of cultural schemes which prevent people from knowing what they do. What for the law is something to be ignored is for the social sciences something to be explored. For the law ignorance is sterile; for social sciences it is productive.

3. *Law and the Empirical Social Sciences*

What is surely unambiguous is the relationship between law and the development of the empirical social sciences, especially to the extent that these sciences are underpinned by the burgeoning of statistical knowledge and growing sophistication in statistics-gathering methods and techniques. Yet this contains within itself new ambiguities. Specifically, at least at the level of images of truth and the supporting rhetoric or legitimation strategies available to science, it is noticeable how a number of writers from the side of science—including natural science—seek to invoke the image of the law court or some of its components—notably the jury—as the central basis for the image of truth or of what it means to claim validity for scientific statements. Trial by your peers has much ideological resonance, especially in North America; but whether it is more than a cultural theme or idiom is a more intricate question which requires explicit if not detailed discussion here.

The metaphor of scientific truth as something resolved in a court of appeal in which the judges or jury decide following adversarial confrontation is a powerful and longstanding one in Western thought, albeit one which is by no means universal (see Lloyd 1996, Needham 1969). While it is not the same idea, it dovetails with the notion of truth as a matter of gentlemen's agreement (Shapin and Schaffer 1985, Shapin 1994) which in turn rests and relies upon the presence of implicit paradigms which are not themselves usually open to inspection or discussion (Kuhn 1970, Foucault 1966). Yet all of this perhaps amounts to little more than the recognition that truth is contestable and the claim that scientific practice has developed—or has always possessed—procedures for resolving epistemic conflicts which arise in the natural course of scientific discovery and invention.

These metaphors of judgment (whether by judges or juries) draw upon the experience of the world of law but do not in reality replicate it. It is interesting to note that they appeal rather more to the common law adversarial style of legal argumentation in the courtroom than the so-called inquisitorial style of the European codified tradition. But whatever precise analogy is used, it runs the risk of obscuring the important and significant gulf which opens up in the modern world between legal science—or the practice of adjudication—and empirical social science.

The most significant here is revealed in the distinction between the level of the individual (for lawyers, a 'subject,' for many social scientists, an 'actor') and the aggregate or collective ('society'). The law has been and remains concerned with disputes between individuals and with the attribution of liability to individuals and with the language of individual responsibility. All of this requires a focus, much of the time, on individual mental states, on postulates about what these can be taken to be or how they can be sensibly understood—or on appeals to 'ordinary people' to use their own experience of life to decide what they believe or disbelieve in the claims about such matters made by the parties in court. Judges operate within a similar framework, although they bring to their decision making the added rigmarole of professional training and/or experience of previous kinds of problems or disputes in a forensic setting. In other words, legal schemes combine two types of individualism—the individual as decision maker relying on his or her experience and capacities to draw analogies from this reservoir of experience in order to make decisions, and the individual as the object of decision, as a person who can be assumed to be like or not like the person asked to make a judgment, in matters relating to responsibility for events or actions. The law therefore struggles with supra-individual entities like corporations, states, nations, cultures. Can a corporation be made liable for manslaughter or culpable homicide? This individualism of the law extends beyond persons and into events. A typical legal scenario, for example in the field of tax avoidance, is the problem of deciding whether a chain of events is to be understood as a multiplicity of individual events or as a composite ('quasi-individual') event. For lawyers, these are not simple questions.

Empirical social science, by contrast, is preoccupied, at its most subtle, with the often perplexing relationship between 'micromotives' and 'macrobehavior' (Schelling 1978). Correspondingly, individualization of events is of much less if any interest than patterns, tendencies, logics, trends. Critical to these perspectives are perhaps two modern capacities—measuring and modeling. And underpinning these new epistemic possibilities are modern notions of probability and of statistical thinking which diverge sharply from the traditional idea of probability still largely at work in the ideational schemes of the law (Hacking 1975, Porter 1986, Gigerenzer et al. 1989, Murphy 1997).

These developments challenge legal schemes of reality. They create a reality through practices and procedures which are remote from the mechanisms through which law constructs 'its' truth. Surveys, data analysis and number-crunching, the quantification of the qualitative (and the very emergence of an explicit

distinction between these two and the consequent problematization of the relationship between them), probabilistic judgment—all these epistemic practices are quite different from the argumentative, judgmental, and commonsensical manner in which law decides what is true. Even before this became obvious, there were pressures upon law to acknowledge what was changing and to incorporate into itself the findings or the protocols of social science (most famously in the so-called 'Brandeis Brief' in the USA, in which statistical information was introduced into court as part of the case). In modern US and UK law for example, a concept of indirect discrimination has been introduced, which makes it unlawful to discriminate not just intentionally but by applying to, for example, job applicants a requirement or condition with which members of the protected group—principally race or sex but these definitions can be expected to expand over time through new legislation—are disproportionately unable or less able to comply. This kind of formulation inevitably invites the introduction of statistical data into the forensic setting. Other outputs of modern social and behavioral sciences increasingly find their way into such settings, notably in the criminal law and family law. Social inquiry reports for offenders before sentencing, or all manner of inputs on child welfare, have come to play a role in the way cases are disposed of in the areas of sentencing and child custody disputes. It is also increasingly the case that the output of the social sciences plays a role in the evaluation of current law, and generates critique, proposals for new legislation, and arguments for changes in the outcomes of judicial decision making.

These kinds of developments lead some observers and commentators to discern an historical process at work in which the legal sphere steadily succumbs to the influences of the social and behavioral sciences. Foucault's thesis about normalization and disciplinary power (Foucault 1975), for example, can be read in this way (see also Donzelot 1977). Others stress rather the rise of differentiation. Among many legal theorists if not social theorists, one of the most influential has been the function-systems theory of Niklas Luhmann (1984). At its simplest, what is at issue here is whether the 'worlds' of law and of social science are converging or merging or pulling further apart. The answer is probably that both tendencies are simultaneously visible. Convergence of course now means the 'colonization' of law by social science, and this is most likely to occur in the area of individual and especially cognitive psychology. In the future, we can anticipate that genetics will play a greater role here. But pulling in the opposite direction are strong tendencies towards the assertion of legal autonomy, in the international as well as national and sub-national spheres. As often in the previous history of law, legal thought often proceeds ahead of successful institutionalization, while without the latter the former remains stuck in the ebb and flow of opinion and fashion. However, to the extent that this tendency towards autonomy is becoming a 'reality', it potentially means that the pre-social-scientific epistemic schemes of the law will succeed in extending their life and even consolidating their position into the future, disregarding the findings of social science on the grounds of increasingly abstract principle.

W. T. Murphy

Law in Latin America

Latin America is usually taken to comprise the 20 independent countries in America that were Spanish, Portuguese, or French colonies before the nineteenth century. (The countries are Argentina, Brazil, Bolivia, Chile, Columbia, Costa Rica, Cuba, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Dominican Republic, Uruguay, and Venezuela.) It is doubtful that other former Latin colonies now integrated in Canada and the United States (Quebec, Puerto Rico, Louisiana) should be considered part of Latin American legal culture. This article concentrates on the former Spanish colonies and Brazil.

There is no such a thing as Latin American law, since the nations each have completely independent legal systems. The issues to be discussed here are whether there are general features of these legal systems and if their legal culture could be distinguished from that of the colonizing countries.

Latin America is usually placed in the civil law, or Roman law, tradition. The main reason for this inclusion is the colonial link to the Latin countries of Europe. In fact, the way law is taught and practiced, as well as the place of judges and legal scholars in society, are quite similar in Latin Europe and Latin America. But there are significant differences due mostly to the more heterogeneous character of Latin American societies. The history of Latin American countries is usually divided into the pre-Columbian, the colonial, and the national periods. The pre-Columbian goes up to the sixteenth century; the colonial, from the sixteenth to the early nineteenth centuries, and the national covers the nineteenth and twentieth centuries. The pre-Columbian period can hardly be called Latin, but is included because it is a part of the history or prehistory of each country. The Spanish kings decreed that those indigenous customs not contrary to the Catholic faith should be applied to their Indians subjects and they should keep their 'principals.' In fact, very little pre-Columbian political organization and law survived the colonization.

During the colonial period, Castilian law was applicable in the Spanish dominions to the White and Mestizo population. There were special royal regulations that applied only to the colonies—the so-called the *Indiano* law. The main official compilation is the *Recopilación de Leyes de Indias* (1680). There was not an equivalent compilation for Brazil. Modern historians prefer to call *derecho indiano* the law as it was applied in the colonies. The legislation tended to be uniform for all Spanish colonies, as it was for the different parts of Brazil. The structure of colonial administration (King—colonial council—viceroys—*audiencias*) and the mechanisms of administrative and judicial control (*visita* and *residencia*) were similar for Spain and Portugal.

Universities and law schools were established from the early sixteenth century onwards in several Spanish American cities (Santo Domingo, 1538; Mexico, 1551; Lima, 1551; Quito, 1586; Cuzco, 1598). By the early nineteenth century there were law schools in the main cities and several thousand lawyers were part of the political elite in the different countries. Portugal followed a different path and no university or law school was established in colonial Brazil, but wealthy colonists educated their scions in Coimbra. Two were established in 1826, shortly after independence. By 1830 there were near 500 *bachareis em direito* in the country.

Lawyers were extremely important during the independence period in the early nineteenth century. They drafted constitutions and were conspicuous members of congresses and cabinets. Their political and social importance is parallel to the proliferation of constitutions in the early nineteenth century. The Spanish and Portuguese legislation survived independence, but there were strong movements for a national law that usually led to national codes in the second

part of nineteenth century. In fact, the codes are quite similar to the European codes. A scholarly tradition dating from the colonial period in the most important capitals extended to most countries during the nineteenth and twentieth centuries.

The number of lawyers grew slowly in the nineteenth and early twentieth centuries, but they kept a high political profile. By mid-twentieth century the growth pace increased substantially due to the generalization of higher education and increased legal activity related to the economic growth. The codes became relatively less important due to the proliferation of regulatory legislation. A substantial effort of judicial reform and an increased political and social importance of judges characterize the late twentieth century. Since the mid-1980s there have been important deregulation efforts.

Latin American legal culture has been characterized in many different ways. Legalism, formalism and, at the same time, lack of penetration of the formal legal system, are usually noted (for example, Karst 1965). Many Latin American countries have an important native population, mostly rural, and in all of them the urban population has a high proportion of poor and very poor people. Cultural and economic factors lead them to avoid the formal legal system and have serious difficulties when they encounter it. This is the root of the lack of penetration of the formal legal system, or more appropriately, of legal pluralism in Latin America. This distinguishes the Latin America legal culture from that of Latin Europe.

The importance of law and lawyers has coexisted with dictatorships, local *caudillos*, and political turbulence. The heterogeneous character of society and the fear of disorder or anarchy are at the root of strong men government and the sometimes massive violations of human rights. The primary difference between Latin American and European dictators is that the former have paid more attention to constitutional formalities. They usually change the constitution to accommodate to their needs. Nevertheless, the tendency in the last 25 years of the twentieth century has been for democratization and rule of law. This new trend is closely related to the increased importance of judges and judicial reform efforts.

Law: Imposition, Reception, and Colonial

Conceptually, legal imposition is set against the demotic acceptance or creation of law. The colonial situation is usually seen as the extreme of legal imposition, a situation where an alien law is brought to bear on a subjugated people without their consent. Reception is commonly and sharply distinguished from that situation. Although the law received is still alien, it is accepted voluntarily by the people to whom it applies—something of a self-imposition. There is indeed a sustainable truth to this straightforward distinction between the voluntary and the involuntary application of law, but that truth has to be complicated in two respects: one concerns an ambivalence in the relation between law and the demotic, and the other responds to the variety of colonizations and receptions. Each complication will now be dealt with in turn and, in the process, legal imposition, reception and colonial law will be refined and given content.

1. Imposition

All law is imposed, but never entirely so. Law's operative mode is the decision—the decision of the judge, the legislator, or the legal subject. The decision cannot be reduced to, or rendered merely in terms of, some prior determination or mandate, demotic or otherwise. If it could, there would be no 'call' for the legal decision, no demand for 'fresh judgment' (Derrida 1992, p. 26). Law, then, always comes from beyond any existent situation, and is an imposition from without. In this movement from beyond into 'fresh' determination, however, the effective legal decision cannot be imposed purely. If law is not to be

a 'dead letter,' it has to assume an engaged responsiveness to the demotic and to anything else involved in its making or application.

This is the point at which criticism of the idea of imposition usually enters. Summarily, this is a criticism of the idea of 'imposition as a fait accompli rather than an interactional process affected by power differentials' (Kidder 1979, p. 291). The criticism could be said to take a weak and a strong form. The weak variant has it that imposition is an inadequate conception, because indigenous legal modes persist and are even necessarily recognized by the would-be imposer. The system of so-called indirect rule in British colonies provides one of the more explicit types of such recognition. Imposition can, however, be more nuanced. This very 'recognition' of indigenous law will often transform that law in ways conformable to the exogenous imposition (Fitzpatrick 1984).

This penetrative force of imposed law is countered in the second, and strong, criticism of the idea of imposition. Such a criticism would extend the efficacy of the indigenous into the very domains of imposition. Here the epistemic arrogation of imposed law is 'got around,' and such law operatively subordinated to indigenous contexts and purposes (Fitzpatrick 1989). This process is facilitated by what is often a rigidity, an unresponsiveness in imposed law, something which particularly affects modern colonizations with their myopic claims to a completeness or, at least, an exemplarity of being. The premonitory quality of this myopia and the limits of simple imposition can be discerned in a hiatus vexing the colonial governor of Bombay in the middle of the nineteenth century when he remarked on 'the perilous experiment of continuing to legislate for millions of people, with few means of knowing except by rebellion, whether the laws suited them or not' (see Thornton 1965, p. 181).

This ambivalence of law's imposition—the ambivalence between its determinant fixity and its responsiveness—will now be returned to the initial distinction between the voluntary and the involuntary imposition of law, and both the ambivalence and the distinction will be used to provide instances and some ordering of the varieties of legal reception and of colonial law. At the risk of being over-schematic, the combination of these two oppositions can provide four types of reception/colonial law: the involuntarily determinant, the voluntarily determinant, the involuntarily responsive, and the voluntarily responsive. Each of these will now be illustrated in turn.

2. *Colonial Law*

It would be difficult to imagine a scene more adapted to the involuntarily determinant type than that offered by the modern colonial situation. To the imperial eye, law was pre-eminent among the gifts of an expansive civilization, one which could extend in its abounding generosity to the entire globe. The supreme justification of colonial law in its 'civilizing mission' was that it subjected the colonized to a new and beneficent order. It was solely the colonist who was to provide civil and civilized order. There were no rights for the colonized in this scheme, apart from 'rights' to have things done to them so as to bring them within the ambit of civilization (Thornton 1965, p. 158). To sustain this scheme of things, however, the colonized were also labeled and maintained as intractably apart from that civilization. They had to become the same as the civilized colonists yet remain unalterably different from them. That unsettled ambiguity permeated the whole of colonial law. The colonist took on the 'burden' of pervasive legal powers in the cause of an inclusive civilization, only to use them to exclude, dissipate, and generally 'hold down' the colonized as incorrigibly deviant. Despite this, some effective action had to be allowed to the colonized because legal imposition could not be simply or totally determinate, an inhibition heightened by what was usually called the limited penetration of colonial rule. Various systems of 'indirect rule' and of 'recognition' of native modes necessarily proliferated. Nonetheless, colonial law always sought to circumscribe effective action on the part of the colonized. Not only was it characterized as static, repetitive, and mimetic but, for good measure, such action was held or attempted to be held within a supervisory system of administration. Indigenous custom, for example, was 'recognized' solely in subordination to the law of the colonists and denied recognition where it was 'repugnant to natural justice, equity and good conscience,' or contrary to 'the general principles of humanity,' to take two standard and indicative formulations.

The legal mechanics of this colonial type of imposition both underline its monadic quality and set a significant distinction. Here one must accommodate, in very broad brush, a variety of the laws of colonizing nations and an immensely convenient international law, so-called, which reflected their practices and interests (see, for example, Roberts-Wray 1966, Chaps. 2, 11). All the legal modes of acquiring territory and imposing laws upon it were founded on the distinction between the civilized and the uncivilized, or on something akin to that distinction. According to what was, with an indulgent exactitude, called the 'doctrine' of discovery, a 'European' nation could lay claim to territory it had 'discovered' and have its laws applied there, only if that territory were uninhabited or considered insufficiently settled, and it was rare for any uncivilized settlement to be taken as sufficient. With territorial acquisition by conquest or cession, if the territory belonged to a European country, generally the law of that country continued in force, but the position was usually otherwise if the territory was occupied by the uncivilized. When territory was acquired by way of colonial settlement, the colonists were most often taken to have brought their law with

them at the expense or subordination of the law or custom of the colonized. It was the case, however, that with all these modes of acquiring territory and of imposing law, there was often a vague requirement that the metropolitan law would not apply where it was not suited to local conditions. One important area of unsuitability corresponded to the civil rights frequently found in metropolitan constitutions. These were only very rarely extended to the colonized.

3. *Reception*

If the colonial situation exemplifies the involuntarily determinant, the first in the quartet of law's imposition, then the reception of law is usually taken to exemplify the second in the quartet, the voluntarily determinant. This seeming self-imposition of law is associated typically with the European reception of Roman Law. 'The Reception,' as its chroniclers often put it, was a long and many-stranded process (Ibbetson and Lewis 1994, Stein 1999). This reception is tied conventionally to the new learning, which in most accounts comes onto the scene from the late eleventh century, eventually forming one of a momentous trio of 'Renaissance, Reformation and Reception.' This company perhaps renders reception more historionic than it was predominantly. It did play a large part in telling political conflicts but, in the main, its mode was one of quiet infiltration into existing legal processes. That infiltration was fueled, however, by a spectacular increase in the number of lawyers educated at the great medieval universities, most notably Bologna. Despite its operative adaptability, this was a reception of a collection of laws temporally remote and contrary to much of the then existing law—a reception of the Digest, Code, and Institutes of Justinian. This distanced quality of the reception was softened by a massive accumulation of scholarly annotations of these texts which, although purportedly exegetical, were not without their contemporary connections. And such connections also qualify the voluntary quality of this reception. Roman Law was responsive to new or emergent economic and political interests, and it would not have been uniformly acceptable. This supranational impact of Roman Law terminates with the national codifications of the late eighteenth and the nineteenth centuries, but these codes themselves exhibit some commonality influenced by Roman Law, a commonality reflected in the designation of 'civil law countries.'

4. *Variations*

It is these codes which have continued the history of this type of reception most conspicuously. Perhaps the most noted example comes from the adoption by Turkey in the nineteenth century, and after the declaration of the Republic in the twentieth century, of a range of codes from a variety of European countries (Güriz 1978). This was part of a project of full-scale modernization and, in line with this, these laws were received as determinant. Another notable example is provided by the purposively modernizing Meiji Constitution of 1889, in which Japan drew greatly on the constitutions of several European states (Fujikura 1996). This type of reception has spread widely of late, through what has most compendiously been described as 'structural adjustment' or 'conditionality,' modes of reception which can be described with some paradox as involuntarily responsive. This is a putatively contractural mode of domination in which the requirement to enact or enforce certain laws is a condition attached by the International Monetary Fund or by the World Bank to loans made to nation states. Formally, these institutions operate as banks, and the relevant conditions are attached to loans to enable countries to deal with financial exigencies, or to assist in their development. More recently, conditions have also become attached to qualifying for the relief of debt. These conditions, which have by now assumed enormous and seemingly enduring significance, usually entail the promoting of the rule of law and the 'transplanting' of occidental laws, especially those of a commercial variety. The unabashed aim in relation to the 'new nations' is 'to reform the legal system and make it more like those in the core countries' (Trubek et al. 1994, pp. 481–2).

Doubtless it should not be overdrawn, but the contrast between such 'conditionality' and the earlier reception of law under the labels 'law and development' or 'law and modernization' is quite marked, and can serve to introduce the final member of the quartet, the voluntarily responsive. Although this earlier transplantation of laws to the 'new nations' could be accompanied by a considerable degree of outright imposition, it did nonetheless have some regard to indigenous elements and it did aim, ostensibly at least, to impart or enhance their own capacity to achieve development or modernization. Still, the responsive element here was usually quite attenuated and this particular type of reception is much more exuberantly present at the beginning of the twenty-first century in 'Eastern Europe,' in East Asia, and in China, even if this presence is not always without an admixture of the dependent compliance which has to accompany conditionality. This is sometimes a matter of the revival of earlier borrowings from the codes of Western Europe, but with the new transfers Anglo-American law does tend to predominate. In this situation, it is not only the case that the imported law responds to what elites in these societies want, but there is usually some effective adaptation of the laws by these elites in the process of their reception (Sharlet 1998).

Sweeping as this conspectus has been, it has only touched on some significant aspects and instantiations

of legal imposition, reception, and colonial law. These legal phenomena, perhaps because of the focus in modern legal studies on the singular nation, have not been given the attention which their enormous impact and influence would suggest they deserve. Being graphically situated between the voluntary and involuntary purchase of law, and being situated between law's determinant and responsive qualities, these phenomena raise fundamental questions about the constitution of law which have for too long been obscured within the national domain.

Law, Mobilization of

Theories of mobilizing the law try to explain under which conditions problems come to be defined and socially accepted as legal issues, and under which conditions they are taken to lawyers and courts. They look at the process of (a) moving from perception to motivation, (b) the interaction of parties and their strategies, and (c) finally at courts as institutions which define the frontiers of law.

1. Access to Courts as a Process

'Naming, blaming, and claiming' are the catchwords by which Felstiner et al. (1981) describe the steps of framing social conflicts in legal terms. They discuss how experiences come to be felt as injurious (naming), how a party might be singled out as responsible (blaming), and under which conditions claims might be formulated on the basis of these experiences. They turn around the assumption of market researchers who identified 'unmet legal needs' (Curran 1977, ABA 1994) by surveying people for injurious experiences which in the minds of lawyers would give rise to a legal claim. In fact, claiming does not automatically follow upon naming and blaming (Genn 1999). A representative British survey documents the various strategies of self-help people pursue before mobilizing the the law (Blenn 1999). It shows the importance of informal access to law for which Britain with its citizens' advice bureaux and legal aid provisions offers a wide range. People make choices: the greater the interest in a continuous social relation, the higher social costs would be. In a survey of everyday injurious situations which people encounter in a German modern city (such as Frankfurt), Hanak et al. (1989) show that only a tiny fraction of all potential legal disputes actually reach lawyers or appear in court. 'Naming' and blaming are everyday reactions to disappointment and injury, but 'claiming' is a far rarer phenomenon. To preserve ongoing relations, it can be entirely 'rational' to avoid engaging in legal steps of any kind. Consequently, Hanak et al. declare people who directly frame their social problems in legal terms as 'socially incompetent.'

An empirically well-documented example is given by the selectivity with which people claim compensation for accidents: Harris et al. (1983) sampled 3,600 people in England who had been absent from work for more than two weeks during the previous 12 months: while 60 percent said that they had been seriously ill, 34 percent blamed their absence on an accident, of which 90 percent occurred at home or during their free time, one tenth during work, and every fifth as traffic accidents. The point of the study is that 'blaming' others for causing an accident is largely independent of whether victims proceeded to 'claiming' compensation. Accidents at home or in free time might just as well be caused by others, but they would be seen as mishaps without legal consequences, while accidents at work which might be seen as 'one's own fault' would nevertheless give rise to claims for compensation. The explanation lies in the everyday logic of the social relation: while a claim for injury which remains in the

Table 1

Fault?	Claim compensation?		
	Yes	No	
Yes, the same who has to pay	20%		
		10%	
Yes, somebody else	8%		
No	10%	52%	
			100%

sphere of personal social relations is avoided because it would outweigh the social costs of alienating that relation, a legal claim is easily made if covered by employers or other kinds of insurance. Often the claim consciousness works back into the perceptions: framing in terms of legal liability colors the perception of social fault. See Table 1.

Accidents are easily identifiable as a basis for damage compensation. Other potential sources of liability claims are less obvious: damages in consumer protection, medical malpractice, and tobacco litigation were discovered (and as liability claims 'invented') by pioneering lawyers and consequently advertised to help people climb over the barriers of mobilizing the litigation process. From the point of view of the providers of legal services it becomes a marketing problem that only a tiny fraction of all potential legal disputes actually reach lawyers or appears in court. However, people do not always have a choice but to enter into legally defined handling of situations. Frequently it is the other party who invokes the law. In dealing with them, people mobilize the law defensively rather than proactively (Black 1973), and they are forced to do that the more they are interacting with formal organizations and in anonymous situations. Also, not all social relations are designed for continuity. The more urban and mobile people get, the more they handle incidental and anonymous social relations. After a traffic incident or as clients of a big organization, parties are confronted with predefined ways of dealing with conflicts. Especially formal organizations and government agencies pattern their relations in legal terms to begin with. The bigger they are, the more likely they contract with employees, partners, or clients in written terms, and these in turn are bound by general regulations. Therefore there is no choice but to take legal steps. Black (1973) generalizes these findings into the proposition 'the greater the social distance, the more law.'

Thus, if asking why the frequency of litigation is rising in all modern societies, the explanation has to move from micro-sociology to macro-sociological conditions. A number of trends come together to increase 'judicialization' of many walks of life, be they world-wide such as urbanization, or specific to certain societies and to lower social classes, such as welfare state systems which bind people's life chances into dependency. In other countries and in the middle classes it may not be the state but rather private insurance systems which increase the dependence of formal bureaucracies—the trend remains that the coverage of life risks is less provided by informal care and personal ties but rather contracted and insured with large formal organizations. Culture critics (like Habermas 1981) have called this trend of modernity 'legal terms patterning the modern lifeworld.'

2. *Strategies of Mobilizing the Law: Enforcing, Mediating, Adjudicating*

The perspective of social actors, taken in the above studies, can be contrasted with that of legal institutions. Government, by definition, regulates by statutory law, but if state regulation is compared with the contract terms of big organizations, there appears to be not much difference between being a citizen of the regulative state or a client of organized enterprises. For individual actors, the difference from state regulation lies in the initial choice and the chances for exit which markets might offer, but once chosen many long term contracts turn out to be just as bureaucratic and regulatory, while for multinational actors even the regulatory regimes of states appear as a matter of choice. The likelihood of social relations being defined in legal terms depends on the size of organizations and the degree of their formalization.

However, within a more or less formal relationship actors do differ in the way they bring grievances forward. Disputes are seldom purely adversary; often both parties have at least some interests in common. That is even the case when parties battle furiously as in a divorce suit: typically the parties have at least one goal in common—the desire to separate. In fact, most divorces are settled; in only a minority is there a battle about the terms of separation. The same is true for other constellations where courts are invoked to set the terms of separation. Labor dismissal and landlord–tenant conflicts seldom try to regulate the terms of an ongoing relationship; they typically end with a settlement on how to part. As most countries require a court decision for divorce, parties regularly appear with a settlement negotiated in advance; they need the court to function as quasi-notary. The largest number of

Table 2
Goals and outcomes: functions/goals of law suits

	Outcome predictable	Outcome unpredictable
Parties have some interests in common	Quasinotarial act	Settlement
Interests form zero-sum	Enforcement decree	Adversary decision

Table 3

Naming /Blaming Framing	Claiming		Litigating	Implementing
------->	---------->		---------->	
Social-distance		Capability of handling legal institutions	Burden of proof	Decision to enforce a legal degree
	Burden of invoking courts		Duration	
Formalization–of social relations		Infrastructure of access to law: lawyers, legal aid	Costs	Infrastructure for executing a legal degree
	<---------- anticipation: chance of success / chance of implementation			

court cases, however, concern undisputed claims: the plaintiff simply needs a court decree to force the defendant to comply; the defendant may not even show up and the case ends with a default judgment. In most courts the dispute that is fought all the way to an adversary decision forms the minority of cases (Blankenburg 1980/95) (see Table 2).

The distribution of court functions varies with the issue at stake. Miller and Sarat (1980/81) depict the different distributions as pyramids. Discrimination grievances are very frequent, but rarely is a lawyer consulted by the aggrieved; only 8 out of 1,000 appear in court, thus the top of the pyramid gets extremely thin. Tort more often develops into a dispute, but still not as often as postdivorce cases which are regularly fought all the way to an adversorial decision—thus the top of the pyramid covers 45 percent of the baseline.

However, court decisions are not the end of the conflict story. Implementation studies after litigation have shown that parties who won in court do not necessarily make use of the entitlement they have fought for, either because the losing party is incapable of paying or satisfying the claim, or because the winner in court is using the entitlement for out-of-court negotiations in a wider social context than that of the court verdict. Invoking a law suit means entering an interaction system with the roles of several actors being determined by procedure: plaintiffs and defendants are determined by their proactive, respectively defensive strategies; decision makers by the requirements of due process which implies a highly dramatic presentation of impartiality. Actually, the strategic game starts before the suit itself: a decisive factor bearing on the likelihood of whether legal institutions are invoked at all is the rule on who has the burden of invoking the law. Litigation costs time and money: the procedural losses may outweigh the gain of even a favorable verdict. Plaintiffs have to assess their evidence, anticipate the strategy of the defendant, and evaluate the chances of being able to implement a legal title, should they get it. Basic preconditions for involving a court are already prescribed in the legal construction underlying social relationships: if the party which has the 'burden' of invoking the court has insufficient legal expertise or hesitates for motivational reasons, the other party can exploit the situation until challenged. The asymmetric party constellation in the majority of court cases suggests such exploitation of mobilization thresholds on a massive scale: most plaintiffs before civil courts are business firms and other organizations, while the majority of defendants are private parties. Organizations that routinely deal with legal problems can often turn the differential access conditions to their advantage.

Anticipation of the potential costs and the possible gains of a procedure adds to the advantages of the repeat player in court (Galanter 1974). Good lawyers and experienced court users will have better foresight than others will. Whether parties go all the way to a court decision or even an appeal depends on continual re-assessment, anticipating not only the chances of success, the costs of the procedure and the opportunity costs, but also the assessments of the other party likewise anticipating its chances. The scheme in Table 3 helps to organize the variables which are relevant in the process.

Assessing the juridical configuration in different social fields is daily work for lawyers. Their strategies and those of their clients interact within the frame of the given legal order. Their assessments vary with national jurisdictions and possibly local regimes. Comparing litigation frequencies of similar disputes between countries and states (or even court districts) reveals the overriding impact of legal regimes. To compare legal cultures, researchers look at similar grievances, like the regulation of injury and damage

after accidents. The most obvious example might be traffic accidents: traffic tort in some legal cultures frequently entangles the victims in legal procedures, while in others insurance companies regulate largely outside the courts. Comparison of American with Japanese accident regulation demonstrates that it is not cultural mentality or personal skill which explains how the Japanese avoid legal costs, but rather the legal and institutional conditions which frame their avoidance of litigation (Haley 1978). The same can be said of the infrastructure of avoidance that explains why the Dutch litigate considerably less frequently than the neighboring Germans: accident victims in these countries hardly differ in conflict mentality nor does their tort law differ. The explanation for different litigation frequencies lies in institutional conditions of the legal regime: burdens of proof, lawyer fees, legal cost insurance, and the availability of alternative modes of regulation (Blankenburg 1994). Similar comparisons can be drawn with respect to other comparable disputes: divorce, employment dismissal, landlord–tenant disputes, or debt enforcement need to be dealt with by courts in some countries while others treat them as routine regulation, reserving litigation in court as a last resort for a few, serious cases.

3. *Frontiers of the Law: Test Cases and Strategies of Mobilizing Rights*

If in the eyes of the occasional litigant 'serious' refers to the stakes which are at dispute in a particular case, to the legal profession and the legal academy, serious implies that there are principle questions of law to be resolved. The greater chances of *repeat players* (*RPs*) to win in court (Galanter 1974) are amplified in the long term: repeat players can pursue strategies over a series of cases, and they can aim at precedents and high court decisions which change the interpretation of the law. The strategic advantage enables big players in courts, such as insurance, banking, and manufacturing corporations to set the terms of statutes and standard contracts in their favor. Occasional litigants (one shooters (OSs) in Galanter's (1974) terms can only fight the legal battle by organizing as interest groups and getting together for class actions. Interest groups implicitly threaten with a potential of future litigants. Parties with especially diffuse interests, such as consumers, parties, or victims of environmental damage, whose single case might not be worth fighting a legal battle, can see their strategic chances in mobilizing courts rather than trying to win in the legislative process.

A number of institutional features favor such public interest strategies among American lawyers and in American courts: the tradition of case law, the instruments of class action, the possibility of contingency fees, and the chances for popular support by juries have made American lawyers especially inventive in thinking up novel sorts of claims, mobilizing collective expectations, and framing them in legal terms. Media coverage of pioneering cases like the asbestos and tobacco liability litigation have made their way around the world. These claims have been spectacularly successful in changing the perception and the legal liability of producers and service providers in North America and, consequently, also in continental legal systems. Another feature of the American legal system which has turned courts into a law-making forum has been the possibility of Supreme Courts to set aside statutory law by the application of human rights and constitutional jurisprudence. Many continental systems have introduced similar possibilities of overturning legislative codes by establishing constitutional courts—the collapse of fascist, communist, and apartheid regimes, with their experience of abuses of legal institutions, have facilitated such institutions. Mobilizing the global forum of human rights has opened a wave of innovation challenging traditional codes of law, and turning courts into law making rivals of parliamentary legislation (Shapiro 1980).

Of course, strategies of mobilizing courts for pioneering cases are even more demanding than the mobilization of courts by occasional litigants. The selectivity of invoking legal institutions on all levels makes us aware of a general feature of any kind of law: so long as actors comply with legal norms we cannot know whether conformity reflects the impact of law or is motivated by custom, by their present interests, or mere inertia. Under conformity, law rests dormant; it manifests itself only under special circumstances of deviation and disagreement when law is mobilized explicitly (Geiger 1947). Paradoxically, one might conclude that law works best if it does not need to be mobilized.

Law: New Institutionalism

Although institutionalist approaches have seen a resurgence in many of the social sciences (sociology, political science, economics, and economic history), the 'new institutionalism' in the study of law is primarily an outgrowth of organizational sociology. The new institutionalists have focused especially on the process of institutionalization—the process by which a practice or structure is diffused, adopted by an increasing proportion of the organizations in a field, becomes a prerequisite for legitimacy, and comes to be taken for granted as a normal and expected part of organizational life. In organizational sociology, neo-institutionalism emphasizes symbolic over instrumental reasons for adopting policies and practices and organizations' attempts to gain legitimacy with key members of their environments. Researchers who import this approach into the study of law tend to emphasize the symbolic effects of bringing organizational practices into conformity with the law.

1. *Old and New Institutionalisms*

The 'old institutionalism' in sociology, as represented in the work of Selznick (especially 1957), distinguished between organizations as tools to accomplish particular purposes and organizations as entities to which people formed commitments. In pointing to processes by which an organization, originally formed for instrumental purposes, garnered the loyalty of participants who then became committed to keeping the organization alive, researchers argued that some organizations became institutions. Moreover, Selznick (1969) identified legalization as an important part of this transformation of instrumental organizations into institutions. When workers acquire rights in the workplace, he argued, they become members of an emerging polity and cease to be simply subordinates in a hierarchy.

In the classic studies of the old institutionalists, the evolving relationship between an organization and its environment was a central focus; this interest was retained by the new institutionalists. But where the old institutionalists might have looked at the process by which an organization itself (e.g., a university, a government agency) became institutionalized, the new institutionalists (starting with Meyer and Rowan 1977) instead look at the ways in which performing a broad set of tasks becomes institutionalized in particular areas of social life (what Bourdieu 1985, calls 'fields'). They investigate the processes by which particular practices come to be regarded as the 'usual' ways of, for example, providing medical care (e.g., fee for service), organizing higher education (e.g., the conventional division of university training into disciplines and departments), or choosing among potential suppliers of goods and services (e.g., the bidding practices that link government agencies with contractors).

Developed as correctives to utilitarian or economistic approaches, the old and new institutionalist perspectives contend that (a) organizational phenomena cannot be explained solely by efficiency considerations or by the performance goals of organizations, and (b) the relationship between organizations and their environments is central to institutionalization. Institutionalists also share an interest in (c) the staying power of social phenomena, and (d) the process by which social phenomena come to be taken for granted and regarded as a normal, enduring part of the social landscape. Old and new institutionalists differ, though, in (a) what social phenomena they scrutinize (the institutionalization of organizations vs. the process by which institutionalized practices diffuse throughout a field), (b) the emphasis placed on normative forces (such as commitments to the organization) as compared with cognitive factors (such as scripts and schemas), and (c) whether they believe that organizational processes are shaped deeply or more superficially by institutionalization.

2. *Law and Institutionalization*

When new institutionalists ask about the relationship between organizations and their environment, they are especially interested in the common elements of organizational environments. Laws, legal actors, and regulatory bodies are important common elements of organizational environments. Even when organizations in the same industry interact with different suppliers or market to somewhat different consumers,

they are likely to be governed by the same laws. Further, the legal environment probably has more capacity to coerce conformity than do other members of the social landscape, although conformity is also induced by the capacity of law to enunciate values and expectations and to resolve uncertainties by offering models for action. The legal environment, then, is an important source of uniformity and an important pressure for institutionalization (DiMaggio and Powell 1983).

This insight has been developed in a series of investigations of when and how specific statutes (particularly US employment law) have affected the practice of organizations. In order to gain legitimacy, researchers have argued, organizations adopt policies that conform to legal requirements (e.g., about equal opportunity hiring, wrongful discharge, or due process), develop procedures (e.g., grievance procedures) that build legal requirements into organizational routines, create positions for affirmative action officers, and charge human resources departments with the duty of implementing the law. Researchers often use event history techniques to study the diffusion of these procedures and positions that bring an organization into compliance with the law (e.g., Edelman 1992, Sutton et al. 1994, Dobbin 1998). Other researchers investigate the metamorphosis of law into organizational routine, the diffusion of legal innovations, and the role of the professions in spreading, constructing, and implementing law (e.g., Edelman 1990, Edelman et al. 1993, Carruthers and Halliday 1998, Grattet et al. 1998, Heimer 1999; for a general discussion of new institutionalist research on law, see Suchman and Edelman 1996).

3. *Symbolic and Instrumental Effects of Law in Organizations*

A key argument of the new institutionalists is that policies are adopted for symbolic purposes. In adopting a policy, an organization signals its willingness to play by the rules endorsed by other actors in its environment. It claims membership in a world in which organizations doing roughly the same thing agree on a core set of rules that make the game 'fair' and a style of interaction with regulators, suppliers, customers, and other publics. But the adoption of a policy need not alter organizational practice in any fundamental way, particularly when members of the environment are unable to monitor how deeply organizational practice is transformed.

When organizations adopt policies that bring them into conformity with the law, is organizational practice altered? Or are practices decoupled from ceremony as institutionalist theory would predict? Researchers have discovered that the answer is more complex than anticipated. Although organizations often seem to adopt conforming policies for the expected symbolic reasons, and although such policies seem to have mainly symbolic effects at the start, over time the policies may have deeper effects. For instance, affirmative action officers appointed to send a signal of conformity without disrupting organizational practices may be more deeply committed to affirmative action than those who hired them. Organizations are not unitary actors and new hires bring with them links to new constituencies. Affirmative action officers may augment an organization's ties to associations of personnel professionals. They may also feel some loyalty to minority communities as potential consumers or as labor pools.

But even symbolic effects are more complex than anticipated. For instance, in affirmative action, equal economic opportunity has more often been translated into a right to make a complaint than a right to a job. Likewise, medical organizations have responded to informed consent statutes by introducing consent forms that often do not ensure that patients and their families are informed about and have consented to a particular treatment.

However, researchers have also discovered that going through the motions of conforming to the law may lead ultimately to changes in the culture of organizations or modifications in the values of key employees. Decreases in pressure from the legal environment to adopt affirmative action policies had little effect on the adoption or implementation of such policies in American businesses, Dobbin (1998) argues. These policies had in the meantime taken on positive associations in the corporate world and been incorporated into a new story about how 'diversity' contributes to efficiency. In medicine, where physician autonomy remains an important value, scholars nevertheless concede that although in the 1960s, the vast majority of American physicians did not inform patients of cancer diagnoses, by the late 1980s, the vast majority of them claimed that they did inform their patients. Initially resistant to informed consent procedures and still inclined to implement them in a perfunctory way, physicians have nevertheless come to believe in patient rights (Heimer 1999). Symbolic effects may in the long run lead to instrumental effects, and initial symbolic gestures should perhaps be seen as the first phases in a protracted engagement whose ultimate outcome depends on whether new constituencies are created and new rationales developed that transform an imposed policy into an indigenous project.

New institutionalists have made legal scholars more cognizant of the importance of thinking about organizations as sites for the implementation of law. Because laws often are implemented by organizations, such as through the adoption and enforcement of new procedures or the creation of new departments and positions, the efficacy of laws depends deeply on what goes on inside organizations. If the creation of new posi-

tions leads to new affiliations, builds constituencies, or creates a forum for voices that have previously not been heard, then a policy adopted only to mollify a government agency may ultimately have some of the effects that the government agency intended. As often happens as a new perspective matures, the novel observations of the new institutionalists about the symbolic aspects of organizational policy have been recombined with earlier streams of thought. The new synthesis acknowledges that policies may have both instrumental and symbolic effects, and asks when each is especially likely to occur. Interestingly, the very scripts and schemas that have been identified as part of the process of institutionalization are now seen as routes to instrumental effects. Some policies remain window dressing; others are written into routines. Some organizational routines restructure work, others do not.

4. *Institutions, Uniformity, and Innovation*

Institutionalist arguments tend to focus on the production of uniformity. As institutionalized practices are more widely adopted in a field, it becomes deviant to do things differently: not to have an affirmative action officer, not to have an informed consent form, not to include a statement about diversity in advertisements for jobs, not to have rules about hate crimes. But these observations about legitimacy and uniformity raise questions about whether institutionalization produces stagnation and how innovation is possible.

Institutionalist arguments about decoupling of ceremony from day-to-day practices provide a partial answer. If legitimacy can be secured by superficial conformity, organizational handbooks may be brought into conformity with law while instrumental practices remain as before. Institutionalization may produce organization handbooks that portray organizations as rigid, and in particular as scrupulously conforming to the law, when they are in fact quite supple and quite innovative in devising ways to redefine the law. Resistance in decoupling ceremony from practice and in devising policies that satisfy the letter if not the spirit of the law, then, is one form of innovation. Edelman et al. (1993), for instance, discovered that in the hands of human resources officers responsible for processing discrimination complaints, civil rights law moved into the managerial realm. As a result, a right to complaint resolution replaced a more political right to a nondiscriminatory workplace.

We should also remember, though, that the standard practices of one field can be significant innovations when imported into another. Thus, increasing uniformity of some sorts may bring with it increasing diversity of other sorts. For instance, uniformity in strategies for solving a category of problems may bring with it diversity in the problems to which an institutionalized solution is applied. Thus Grattet et al. (1998) found that, in the United States, the variety of legal solutions used to combat hate crimes (e.g., criminalizing interference with civil rights, creating new categories of crime, increasing penalties for preexisting categories of crime) has decreased over time. At the same time, the number of 'protected statuses' (e.g., race, religion, ethnicity, sexual orientation) has increased.

These arguments that innovation occurs when actors invent ways to signal compliance without altering mundane organizational practice, transform unpalatable laws into more circumscribed routines, or transport institutionalized practices to new settings, all refocus attention on the innovators. In a variety of settings—employment law, corporate bankruptcy law, medical regulation, to name a few—scholars have found that professionals have played important roles. Rather than being identified solely with the organization, professionals retain commitments associated with their professions. They may dampen or amplify the impact of the law depending on whether legal tools are useful in advancing professional interests and achieving professionally valued goals (Edelman 1992, Heimer 1999). In their investigation of corporate bankruptcy law in the USA and the UK, Carruthers and Halliday (1998) argue that the role of professionals in legal innovation varies with their status and autonomy. Members of strong professions are not limited to devising ways of decoupling ceremony from practice or molding the routines that implement the law. Instead, high status professionals shape more directly the laws that govern an organizational field and frame their own work. They originate the practices that will eventually become the institutions that others adopt. Similar arguments have been made about the creation of international legal regimes (Dezalay and Garth 1996).

5. *Institutional Competition and Legitimacy*

In addition to the questions about efficacy and innovation discussed above, new institutionalists' work on law also raises questions about the difficulty of gaining legitimacy with one portion of an organizational environment without alienating others. Initial formulations of the institutionalist argument suggested that the divergence of interest between internal and external audiences would often lead to a decoupling of ceremony from instrumental practice. Policies conforming to law might be adopted formally but ignored in practice. But because organizations' environments cannot be expected to have unitary interests, and because environments actively compete for the right to construct the institutions that will govern a field (Bourdieu 1985), signals must be crafted carefully to appeal to, or at least not to alienate,

multiple audiences. This fine-tuning of organizational policy often takes into account the relative power of members of the environment, the differential capacity of environmental elements to discern the difference between superficial and deeper adjustments to their interests, and the ease with which people and ideas pass between the organization and some parts of its environment.

In medical settings, for instance, the adoption of legally mandated 'patient friendly' policies may make medical practitioners nervous and so decrease the chances of recruiting prestigious departmental heads or the most attractive residents. At the same time, though, reluctance to bring hospital practice into conformity with new statutory requirements (e.g., ethics committees, medical care power of attorney, or advance directives) may increase state scrutiny. How, then, do hospitals simultaneously curry favor with both the state and with professionals? Organizational boundaries are, to varying degrees of course, porous, and some members of the environment have more capacity to cross such boundaries than others.

In medical settings, for instance, legal regulators are more completely outsiders than are members of medical professional societies. Those who span the boundary (e.g., professionals working in a hospital who are also members of professional associations) will be able to detect when policy and practice are decoupled. They will also be more able to ensure that day-to-day practice is more deeply shaped by the institutionalized policies to which they are committed. When the interests of medical practitioners and legal actors coincide, as when laws create tools that increase the power and autonomy of medical professionals, organizational routines that implement these laws can be expected to have substantial effects on practice.

Questions of legitimacy inevitably lead back to concerns about efficacy, then. Legitimacy can be purchased with ceremony only when powerful outside audiences cannot tell the difference. When organizational boundaries are more permeable and outsiders are able to form alliances with key insiders, an organization will be regarded as legitimate only to the degree that symbol and substance coincide. For legal actors, that can mean forming alliances with other professionals who are deputized to represent state interests inside organizations, or even in hospitals, moving court sessions inside the physical boundaries of organizations.

6. *Conclusion*

New institutionalist investigations of legal phenomena have led to important findings about the metamorphosis of statutes as they are transformed into organizational routines, the role of these routines in creating new constituencies, and the location of innovation. These studies have modified the agendas both of institutionalists, by altering their understanding of the place of legal actors in the process of institutionalization, and of sociolegal scholars, by clarifying thinking about the efficacy of law.

Law: Overview

Law refers to systems of rules and standards connected to social institutions that pronounce and apply them. Law is not just a discipline of inquiry but a set of practices, roles, and ideas embodied in distinctive institutions and reflected in general culture. There are two kinds of knowledge about law. The first 'internal' kind of legal learning is generally found among the professional groups that operate legal institutions (judges, lawyers, academics, administrators, and so forth) (see *Legal Scholarship*; *Legal Reasoning and Argumentation*; *Legal Formalism*). These actors carry and expound a body of authoritative normative learning that regulates and instructs both officials and citizens. This 'internal' kind of legal learning is entwined with an emergent 'external' kind of learning about law and legal institutions most often found among academics. The external kind of learning seeks explanation rather than justification, emphasizes social process rather than rules, and appreciates the dynamics of law as part of more inclusive patterns of social life.

Although these two kinds of knowledge about law are entwined and not entirely distinct, the articles about law and legal institutions in this encyclopedia draw primarily upon the second 'external' kind of inquiry, known variously as 'law and society,' sociolegal studies, the sociology of law, or simply legal studies. This social inquiry into law is itself varied. The late twentieth century saw a great proliferation of rival and overlapping 'schools of thought about law' (see *Legal Positivism*; *Natural Law*; *Legal Realism*; *Law and Economics*; *Critical Legal Studies*; *Critical Race Theory*; *Feminist Legal Theory*; *Law and Everyday Life*; *Law, Autopoiesis in*; *Law: New Institutionalism*; *Law as Constitutive*; *Law and Society: Sociolegal Studies*), many affiliated with various disciplines in the social sciences and humanities, and with movements in the wider political culture. Although there were distinguished precursors and ancestors (e.g., Maine, Durkheim), systematic social inquiry into law was envisioned only in the early years of the twentieth century, and the emergence of a community of scholars actively and continuously pursuing such inquiry, involved in a cumulative discourse across disciplinary boundaries, dates from the middle of the century (see *Law and Society: Sociolegal Studies*).

With the emergence of 'external' scholarship about law, the focus of scrutiny has broadened and decentralized, moving downward from peak decision makers to the field level, from Supreme Courts to trial courts, from professionals to the law's users and customers, from formal process to backstage bargaining, from comprehensive policy making to strategic maneuvering, from distinctive legal institutions to understandings of law in everyday activities. Attention has moved backward from lawsuits to disputes, grievances and injuries, and forward from judgments to impacts and wider effects, and outward from legal doctrine to perceptions and understandings of law among citizens. As these new external discourses proliferate and infiltrate mainstream 'internal' legal discourse, internal discourse itself becomes more receptive to facts and theories that would have been rejected as 'extra-legal' a generation earlier. For example, American courts cite law reviews less frequently, and newspapers more (Schauer and Wise 2000), while appellate briefs routinely marshal empirical arguments. By the end of the twentieth century, the discourses of and about law had become less distinct, hermetic, and self-contained.

Various entries in this encyclopedia describe some of the most prominent legal systems (see *Common Law*; *Civil Law*; *Hindu Law*; *Jewish Law*; *Chinese Law*; *Socialist Law*; *Lex Mercatoria* and others). Other entries describe the social institutions in which such rule systems are embodied (e.g., *Courts and Adjudication*, *Supreme Courts*, *Constitutional Courts*, *Juries*, *Law Firms*, *Prosecution*, *Policing*, *Punishment: Social and Legal Aspects*, *Prisons and Imprisonment*, *Liability: Legal*), the distinctive social roles associated with those institutions (*Judges*; *Lawyers*), and the distinctive values to which they are oriented (see *Rule of Law*; *Rechtsstaat (Rule of Law: German Perspective)*; *Due Process in Law*; *Legitimacy*; *Equity*; *Justice and Law*). Another set of entries take up some of the characteristic features and processes of legal institutions in complex societies (see *Procedure: Legal Aspects*; *Discovery: Legal Aspects*; *Expert Testimony*; *Scientific Evidence: Legal Aspects*; *Trials: Cultural*; *Appeals: Legal*; *Remedies and Damages: Legal Aspects*; *Statutes of Limitations*) and some of the fields of legal regulation (see *Property: Legal Aspects*; *Intellectual Property: Legal Aspects*; *Torts in Law*; *Contracts: Legal Perspectives*; *Bankruptcy*; *Family Law*; *Administrative Law*). Other entries address the attempts of legal institutions to regulate various spheres of activity (see *Markets and the Law*; *Regulation Theory in Geography*; *Environment Regulation: Legal Aspects*; *Employment and Labor, Regulation of*; *Occupational Health and Safety, Regulation of*; *Race and the Law*; *Affirmative Action: Empirical Work on its Effectiveness*; *Affirmative Action: Comparative Policies and Controversies*; *Law and Aging*; *Law and People with Disabilities*) and the impact of these other spheres on the law and its institutions (see *Class and Law*; *Crime and Class*; *Crime and Ethnicity (Including Race)*; *Crime and Gender*; *Organizations and the Law*).

Finally, other entries focus on the ways the legal complex is changing over time (see *Law: Change and Evolution*; *Globalization: Legal Aspects*; *Legalization*). This article attempts to distill some of the major themes and findings of social inquiry into law, and to suggest their interrelationships.

1. *The Gap*

Much scholarship in the sociology of law has focused on what is seen as a gap between 'law on the books' and 'law in action.' 'Law on the books' refers not simply to laws codified in statute books or judicial decisions, but more broadly to the formal legal system and to assumptions about how that system ought to operate. In contrast, 'law in action' refers to how law in fact operates in society, taking into account power, discretion, social roles, deviance, and other social realities. For example, Macaulay's seminal article on contract law showed that businesses often preferred informal agreements to formal contracts, and rarely invoked formal contractual remedies when contracts were breached (Macaulay 1963). A good deal of law and society research examines aspects of this gap in the contexts of courts, legislation, administrative justice, lawyers, organizations, law enforcement, and the behavior of parties with legal complaints (see, e.g., *Courts and Adjudication*; *Lawyers*; *Rights: Legal Aspects*; *Race and the Law*; *Class and Law*; *Civil Rights*; *Injustice: Legal Aspects*). The focus on the gap has also led to inquiries into the conditions under which law can bring about social change (e.g., Rosenberg 1991, McCann 1994), the circumstances under which people obey law (Lind and Tyler 1988, Tyler 1990), and the role of law in social control.

Although the idea of the gap has motivated some important inquiries into the workings of law in society, late-twentieth-century scholarship found the idea of the gap to be flawed theoretically. Feeley (1976) suggests, for example, that the characterization of the gap depends on an overly narrow conception of the formal law and inability to identify or measure the goals of that law. Because formal law is often quite ambiguous, in part because its creators had diverse interests and objectives, it is misleading to characterize the actual operation of law as a deviation from the clear goals of formal laws. Rather, law can only be understood as embedded in its social context, where it is both the product and the source sociolegal practices.

2. *Law as a Symbolic System*

The pronouncement and implementation of legal norms are attended invariably by indirect and unanticipated consequences. Law rarely works as anticipated by lawmakers. The rules and rights that are promulgated by legislatures and courts are usually broad and ambiguous, in large part because lawmakers agree more on broad symbolic meanings than on detailed constructions. Especially because legal measures are only partially funded by the state and depend on inputs from interested parties, the way that rules and rights are interpreted and enforced depends on the contention among interested parties, who vie for resources and attention and negotiate the meaning of compliance according to their interests or institutionalized ways of thinking. Even though laws are promulgated by the state and intended to penetrate downward through society, law is in many ways driven from below by litigants, clients, and other intended subjects of regulation. Citizens are not law's passive subjects; rather, they are active interpreters of legal ideas and symbols and, at least sometimes, strategic actors who mobilize the law selectively to pursue their own visions of advantage and justice.

Law operates not simply as a body of regulatory controls and public edicts, but also as a set of symbols, with different meanings for different social groups. The symbolism of law, by invoking ideals and principles such as due process or equal opportunity, may ermpower citizens to take political action or to make stronger claims in informal negotiations (see Rights). However, the symbolism of law may also diminish the substantive role of law. When contests over morality are fought on legal terrain, parties may care more about the symbolic victory than about the actual effects of law (Gusfield 1963). And political actors benefit from laws that provide symbolic victories to powerless parties without disturbing the status quo (Edelman 1964). Critical legal scholars and neoMarxists emphasize the hegemonic role of law: Laws that appear to provide rights irrespective of class, gender, or race help to solidify the power of the elite (see *Critical Legal Studies*; *Marxism and Law*).

Law may engender symbolic forms of compliance as well. In response to civil rights law, for example, work organizations have created an array of structures designed to symbolize attention to civil rights: These include affirmative action or equal employment opportunity programs, plans, procedures, offices, and functionaries. Over time, these 'symbolic structures' become institutionalized forms of compliance with law. Once in place, however, symbolic structures may enhance employees' rights consciousness and make it more difficult for employers to deny employees' law-related claims, thus enhancing indirectly the impact of law (Edelman 1992; see also *Organizations and the Law*). Studies of law must therefore be attentive not only to the direct and substantive role of law but also to its symbolic role in society.

Law as a symbolic system also has important effects on 'legal consciousness.' Although there is no consensus as to the meaning of this construct, it refers broadly to an institutionalized set of ways in which individuals come to think about law and to employ legal ideas and principles in their daily lives. Over time, certain ideas about law acquire stable and objectified

meanings, which in turn limit and constrain future meaning-making vis-à-vis law and legal rights (see *Legal Culture and Legal Consciousness*;). Legal consciousness scholarship seeks to decentralize the study of law, emphasizing the role of law in everyday life rather than the behavior of distinctively legal institutions and actors. Scholars seek to show how legal constructs acquire meaning through everyday social interaction, contest, and routine. Although somewhat inspired by neoMarxist scholarship, this work is more influenced by studies of culture and institutions. It does not generally see legal consciousness as false consciousness, but rather as a site of resistance to, or engagement with, law and legal institutions.

Legal consciousness has been studied within particular social arenas such as families, religious communities, or welfare offices. Other work focuses on legal settings. For example, Conley and O'Barr (1990) studied how litigants in small claims courts identify and analyze legal problems, and observed a difference between experienced players, who adopt a rule-oriented style, and less experienced (especially female, poor, and minority) players, who focus on relationships and narrative. Some authors emphasize shared experience as a source of legal consciousness (suggesting, for example, that law would have similar meanings to people on welfare, or Hispanic women) while others focus on the development of legal consciousness in a community (so that, for example, people in a particular geographic locale would share a legal consciousness irrespective of their economic status, race, or sex). Others emphasize that legal consciousness is multiple and varied: Ewick and Silbey (1998) suggest that legal consciousness is not a direct reflection of legal structures or personal experience, but that the same individuals in their daily lives can manifest mutually 'inconsistent' relations to law, with their view of law alternating between a remote and majestic authority, a game, and an oppressive power.

3. *The Distributive Tilt of the Legal Processes*

The mobilization of law is a social process, one that is dependent on access to information, resources, legal representatives, and organization (see *Mobilization of Law*). Mobilization requires that a potential claimant recognize an injury, attribute blame to a legally relevant party, and pursue a claim against that party (Felstiner et al. 1981). The very social characteristics that make people more likely to suffer legal injuries, such as poverty or minority identity, also act as barriers to mobilization (Bumiller 1988). Those whose lives are characterized regularly by discrimination or rights denials are less likely to perceive a particular injury as worthy of legal redress, and are more likely to view the legal system as inaccessible or unjust (see *Injustice: Legal Aspects*; *Equality and Inequality: Legal Aspects*). As a result, social reform laws—especially to the extent that they depend on victims to mobilize their rights—infrequently to effect major social change (see *Law as an Instrument of Social Change*).

Although modern adjudication is infused with ideals of equality before the law, and the isolation of the dispute from the identity, connections and resources of the parties, this isolation is always realized imperfectly. Those possessed of wealth, power and other resources can hire better lawyers, invest in marshaling proofs and arguments, use delay to their advantage, and adopt strategies that deflect unfavorable rules and reap the full advantage of favorable ones (see *Injustice: Legal Aspects*; *Equality and Inequality: Legal Aspects*). The advantages of stronger parties who are recurrent users of the legal system is even more pronounced in nonjudicial forums such as legislatures and administrative agencies. So legal regimes that accord a central place to equality norms may at the same time enable 'the "haves" [to] come out ahead' (Galanter 1974).

In response to this paradox legal systems have incorporated various devices to overcome the disparity in legal resources (see *Justice, Access to: Legal Representation of the Poor*; *Class Actions: Legal*; *Public Interest Law*). The achievements and deficiencies of these devices have been a focus of law and society research. Although the presence of lawyers tempers the disparities in legal resources, it does not overcome them fully, for legal services are typically purchased in markets where those with superior resources can attract the most proficient practitioners. Apart from differences in quality and quantity, legal representation is infected with agency problems. Lawyers have goals and needs that do not align perfectly with those of their clients. It is not simply that financial incentives may induce lawyers to do too much or too little, but that even the lawyer who eschews financial gain may be deflected by appetite for fame, honor, or for 'interesting' work. For example, the low monetary stakes and repetitiveness of the legal needs of the poor run against the powerful pull of craft satisfactions and the aspiration to heroic distinction.

4. *Regression Toward Bargaining*

One of the 'discoveries' of law and society research is the pervasiveness and centrality of bargaining throughout the legal world. Processes of authoritative decision-making turn out in fact to revolve around negotiation. Ostensibly adjudicative processes decompose into negotiative ones; decision makers clothed with arbitral powers are transformed into mediators. The negotiated outcome in the shadow of the law turns out to be the master pattern of disputing in American courts and administrative agencies.

Bargaining often takes place in the 'shadow of the law' (Mnookin and Kornhauser 1979). The rules of formal law confer on the parties what Mnookin and Kornhauser call a 'bargaining endowment,' that is, a set of 'counters' to be used in bargaining between disputants (Ross 1970).

The bargaining endowment that the formal law bestows on parties derives not only from the substantive entitlements conferred by the legal rules but also from the adjectival rules that enable those entitlements to be vindicated. But rules are only one source of the endowment conferred by the legal process: The delay, cost and uncertainty of eliciting a favorable determination also confer bargaining counters on the disputants. Delay, cost and uncertainty may themselves be the product of rules, but they also result from such nonrule factors as the number, distribution, fees, and work patterns of courts and lawyers. The meaning of the endowment bestowed by the law is not fixed and invariable, but depends on the relative characteristics of the disputants: their preferences, negotiating skill, aversion to risk, ability to bear costs and delays, to respond to deadlines and emergencies, and so forth. A different mix of disputant capabilities may make a given endowment take on a very different significance.

Knowledge about the legal system is often incomplete or inaccurate, however, so that social, business, and professional norms have a greater impact on how parties bargain than do their putative legal bargaining positions (Ellickson 1991, Galanter 1986, Edelman, Erlanger and Lande 1993). Parties may be influenced less by what would happen in court than by how their neighbors or business partners or co-workers think they ought to behave. The preservation of relationships often trumps the assertion of legal entitlements.

5. *Plurality*

Some legal systems openly yoke together several bodies of law from different origins. For example, some ancient and modern societies have had a system of 'personal law' in which the incidence of particular rules depends on the religious or tribal identity of the parties (see *Legal Pluralism*; *Folk, Indigenous, and Customary Law*). In most modern societies, the law presents itself as unitary, but nonetheless consists of multiple systems of regulation that coexist and intertwine. In addition to primary rules, the law contains various sets of secondary rules about the recognition and application of its own rules (Hart 1961) and the recognition and reinforcement of regulatory activity in other institutions. Religious bodies, universities, trade groups, and associations of all kinds devise and broadcast norms, regulate their affairs, and impose sanctions—often by means of proceedings that mimic, if imperfectly, those of state law.

Regulation is not an official monopoly; there are multiple arenas of normative enterprise, innovation and interpretation. The state's law does not preside over a landscape barren of regulation, but over a thick tangle of rivals and companions. Its effects depend on the way that it interacts with the various sorts of indigenous ordering that surround it; the core official institutions themselves are the scene of persisting and pervasive local variation. These various departures from unity and uniformity have been studied under the rubrics of private government, indigenous law, semi-autonomous social fields, and local legal culture. Pluralism is very much with us: The centralist view of a monolithic integrated legal order turns out not to be a description of modern law, but part of its ideology.

Even though law regulates increasing areas of social life, most social regulation goes on within various institutional and relational settings; only a small and unrepresentative minority of disputes proceed to a formal legal institution for resolution. To a large but perhaps diminishing extent, when formal legal institutions devise rules to regulate conduct in institutions and relationships, they refine and restate norms that already prevail in those settings (Bohannan 1965); legal norms in turn transform and feed rather than eradicate the regulatory activity indigenous to these settings. The continuance of *de facto* pluralism is fostered by various ideological currents, including movements to preserve and extend cultural diversity, promote local control, and de-emphasize adjudication in favor of 'alternative dispute resolution.'

6. *Convergence and Difference*

For several centuries, there has been a worldwide diffusion of legal norms, materials and devices from Western Europe, lately joined and surpassed by North America as a source of legal inspiration. Voluntary reception by settler societies, the imposition of colonial rule, and importations by independent regimes seeking a badge and instrument of advancement have been followed by a worldwide spread of constitutionalism and continued influence of Western legal models to promote new forms of economic activity stimulated by increased in global trade (see *Postcolonial Law*; *Law and Development*). Diffusion of Western models was accelerated by the demise of communism and the subsequent importation of Western experts to write constitutions and oversee the democratization of formerly communist regimes. Comparative analyses of constitutional borrowing, adaptation, and hybridization have become prominent in sociolegal scholarship (see *Constitutionalism, Comparative*).

Notwithstanding some convergence of formal legal doctrines and institutional structures, there remains broad variation in the amount and character of litigation, the number and roles of lawyers, and the styles of dispute resolution across nations and social

contexts. Even when constitutions and statutes are imported directly from one country to another, their interpretation and significance reflect persisting differences in social, political, and legal settings.

7. The Legalization of Society

Law has become more pervasive, both as a set of social structures and as a component of consciousness, and this process is likely to continue. The latter half of the twentieth century saw a steady increase in the amount and complexity of regulation; the frequency of litigation; the number, coordination, and productivity of lawyers; the number of legal actors and the resources they devote to legal activity; the amount of information about law, and the velocity with which it circulates; and a concomitant rise in consciousness of law and awareness of legal rights (Galanter 1992) (see *Rights: Legal Aspects*).

An increasingly global economy together with new communications technologies have fueled the rise of legal activity, in areas such as intellectual property (see *Property: Legal Aspects*). The number of lawyers increased dramatically in many countries and became markedly more diverse (in terms of gender, ethnicity, and class origin) (see *Law Firms*).The large law firm devoted to chaperoning business clients, born in the United States in the late nineteenth century, spread throughout the common law world and began making inroads into civil law jurisdictions as well (see *Law Firms*). Regulation has increasingly taken on the features of adjudication (Teubner 1987). The role of courts has been enlarged by the spread of constitutionalism and judicial review, together with an increase in multi-tier regulation deriving from federalism or from participation in international institutions. Increasingly, courts are accepted as the final arbiters of many public issues (Cappelletti 1985).

In many quarters, these changes have engendered a recoil against law and regulation, not least among elites who are best protected by the legal order. Concerns about excessive legalization, 'juridification,' the 'litigation explosion,' and the dominance of lawyers have led to the advocacy of deregulation, delegalization, and embrace of alternatives to traditional litigation. The term 'alternative dispute resolution,' virtually unheard of prior to 1970, has become part of the standard policy lexicon. With the rise of forums such as mediation, mini-trials, and other private or court-annexed modes of dispute processing (see *Mediation, Arbitration, and Alternative Dispute Resolution (ADR)*) the locus of some legal activity has shifted away from adjudication and into nonpublic forums, but it remains doubtful that the tide of regulation has been reversed.

As discussed below, the prospect is that the legal system has an ever-expanding agenda. But the process of remedying injustice or simply assuaging grievances consumes resources and society gets an increment of justice instead of medicine or missiles. In addition to the costs of operating legal institutions and costs borne by the participants in the legal process, the use of law to address injustice imposes another kind of cost, as it accumulates into a thick layer of rules to be learned, permissions to be obtained, forms to be filled out, and records to be kept, adding to expense and burdening activity. These costs of law are visible and palpable, while the benefits of legalization are less so: Victims may enjoy vindication or honor or a heightened sense of self-worth—goods that are not subject to the same zero-sum distributional rules as money. The legal process may generate public goods by crystallizing and broadcasting norms, preventing injustice by deterrence and education, and providing channels for interaction and coordination (e.g., driving on the right or left, as the case may be). The more successful, the less visible..

8. The Organizational Incline

As law has become more complex, technical, expensive, and pervasive, it has become increasingly a realm in which organizational actors flourish and into which natural persons enter only in life's exigencies (although their vicarious experience of it through the mass media has increased). An increasing portion of lawyers' effort is devoted to work for organizations. Law firms, courts, and other legal institutions become more managerial, more rationalized, and more bureaucratic (Heydebrand and Seron 1990), and organizations have become legalized (Edelman 1990).

Organizational life is increasingly influenced by law. (Edelman and Suchman 1999; see *Organizations and the Law*). As the amount of law regulating organizational life grows, organizations respond by creating internal rules that specify the meaning of ambiguous legislation in terms of corporate interests; hiring knowledgeable in-house counsel who have organizational objectives at heart; using private police forces who answer to corporate rather than public concerns; and creating internal dispute resolution forums in which both procedural and substantive rules reflect managerial training and values. The internalization of law makes organizations ever more powerful legal actors in the public realm as well, and they drive up the ante by dominating the dockets, playing for favorable statutes and judicial interpretations of those statutes, and employing strategies and experts that tend to increase the cost and complexity of the legal game. The result is that law is mediated increasingly through organizations (Edelman, Uggen and Erlanger 1999) and becomes less accessible to individuals.

9. Law's Moving Frontier

The scope of potential legal intervention expands with the growth of knowledge and the development of technology. As the risks of everyday life have declined dramatically there is a sense that science, technology, and government can produce solutions for the remaining problems. As more things are capable of being controlled by human institutions, the line between what is seen as unavoidable misfortune and what is seen as imposed injustice shifts: The realm of injustice is enlarged. (Shklar 1990). Hurricanes are misfortunes, but bungled relief efforts are injustices. Once having an incurable disease was an unalterable misfortune; now a perception of insufficient vigor in pursuing a cure can give rise to a claim of injustice. As the scope of possible interventions broadens, more and more terrible things become defined by the incidence of potential intervention. Thus poverty, disease, and disability are not unalterable matters of fate but a matter of appropriate interventions. Our consciousness of injustice—and the undone work of law—increases not because the world is a worse place, but because it is in important ways a better, more just place.

Advances in human capability and rising expectations result in a moving frontier of injustice. Like medicine, law enlarges both the supply of answers and the supply of unanswered questions. For the most part, the advances in human capability and control that drive the justice frontier are located in or managed by corporations and governments. New claims of injustice arise in response to this management. These organizations produce new injustices not because they are bad guys, but because they are good guys doing their thing. We rely on law to respond to some of these claims by inducing actors (through education and threats) into better (less unjust) practices.

Whatever the return on legal initiative, the supply of injustice is endless, and there are attractive competitors to investment in justice-seeking, so that doing justice inevitably entails questions of rationing, priorities and efficiency. Whose grievances are addressed, and which of these get substantive remedies and which symbolic succor, is affected by differential access to law and capacity to mobilize the law.

L. B. Edelman and M. Galanter

Law, Sociology of

Sociology of law is a distinctive form of sociology—the nexus of two disciplines within the social sciences. As such, it is essentially interdisciplinary by nature, and therefore of interest to both jurists and sociologists. Although law historically is considered one of the oldest institutions structuring society, its definition still remains problematic. For the purposes of this article, 'law' will be defined restrictively—as the norms, rules, and normative principles established by a political authority (legislator, courts) in order to secure social order and cooperation among members of a given society. A more extensive and more sociological definition would, however, include the institutions and professionals vested with the legitimacy to produce, interpret, and apply the rules.

Sociology of law has been developed as an empirical knowledge, with theoretical foundations, aimed at describing and explaining the mutual relationships between law in its various forms, and social structures, social institutions, culture, ideologies, and values. Its objective is to unravel the various social and cultural influences that shape the law, whether law is produced by the legislator, the courts, or professionals of law and, conversely, to throw light on the action exerted by law in social life, social structures, and social change.

1. *The Origins of Legal Sociology*

Two sources can be identified as the origins of legal sociology. The first is the questioning of legal formalism (by American legal realism and Roscoe Pound's 'sociological jurisprudence'), of legal positivism (by the German Free School of Law), and of the dominant theory of natural law (Weber). Maybe more than any other school of thought, American legal realism has exerted a longlasting influence upon Anglo-Saxon sociology of law (US, Canadian, Australian) through its emphasis on 'living law' (i.e., law as it is currently interpreted and applied by the courts) and through the mixture of scientific and pragmatic orientation that characterized an approach largely inspired by the experience that judges had gained of the judiciary decision-making process (Hunt 1978).

The second source of legal sociology can be assigned to the importance attributed to law by the founders of sociology in understanding and explaining society, especially modern society. Accordingly, the origins of legal sociology go back to the origins of sociology itself. Montesquieu's *L'Esprit des lois* (1748) was the first treatise of general sociology as well as of legal sociology. The founding fathers of sociology in the nineteenth century and the beginning of the twentieth century (Marx, de Tocqueville, Weber, Durkheim, Tarde, Ross) were all aware of the central position occupied by law and the legal professionals in the structuring of social life. Law appeared to them as one major source of social control, and as being variously implied in social change. After being so predominent in the works of the founders of sociology, the interest in law declined among succeeding generations of sociologists (almost to the point of its disappearance) —with the exception of criminology. It is mainly since the 1970s that a renewed interest in legal sociology has become evident and that it has been officially reintegrated into sociology.

Modern sociology of law extends in various directions: it is a building with many rooms. But the building lacks a blueprint. The insufficiency of any broad general theoretical scheme to unite the scattered pieces of the whole is often lamented. This article can do no more than reflect this state of affairs.

2. *Law and Social Order*

The founders of sociology were mesmerized by the fact that, despite the individualistic and egotistical tendencies of members of society and the potential reservoir of conflicts between them, there existed something resembling a general social order, to which they turned for some kind of fundamental explanation. In the production and reproduction of the 'conscience collective,' which he regarded as the basis of social order, Durkheim assigned a dominant role to religion and, to some extent, law. Law is partly responsible for the constraint that society imposes upon the individuals. Even though it is generally said that Durkheim did not produce a systematic sociology of law, law is found in practically all his writings (Lukes and Scull 1983) and he is responsible for the place that law occupied in the *Année sociologique* and in the *École française de sociologie* under his intellectual leadership.

In answer to his quest for a concrete symbol and index for the broad concept of social solidarity, Durkheim turned to the law. The two types of social solidarity he identified were represented by two types of law: the mechanical solidarity of traditional societies was associated with repressive law, while the

organic solidarity of the advanced division of labor in industrial societies was associated with restitutive law. Within the realm of repressive law, Durkheim explored the social functions of crime and its punishment through the permanent reproduction of the essential values of the 'conscience collective' and society. Contract, a legal form typical of restitutive law, also received Durkheim's attention. But here again Durkheim insisted on the social dimensions of contract—society being the 'third party' with the rituals, symbols, and general rules it provides to the individual parties.

Because of his views, Durkheim is regarded as the founder of the functionalist approach to law. Through its various functions, law plays a central role in the production and reproduction of different types of social order; the presence of law is an essential factor to explain how society perpetuates itself over time (see *Functionalism in Sociology*).

Durkheim's functionalist approach to law was subsequently transformed into the systemic scheme developed by Parsons. It is the integrative function of law as part of the social system that Parsons emphasized. The systemic approach, however, has also been used to explore in greater detail the relative autonomy of the legal subsystem in its relations with other subsystems within the social system.

3. *Law, Social Class, and Capitalism*

Marxism has exerted a strong influence on modern legal sociology, giving way to various interpretations of law. Beyond its variations, Marxist approach to law is founded on Karl Marx's materialistic model of society and historical evolution. Marx himself had been trained in law and philosophy of law and although, like Durkheim, he did not provide a systematic sociology of law, he addressed law throughout both his work and that in which he collaborated with Engels. In class societies, he argued, law and legal institutions reflect and serve the interests of the dominant class. This is even more the case in capitalist societies where social classes are polarized and class struggle has come to its extreme intensity. Marx foresaw that the proletarian revolution would eventually result in the withering away of both law and the state.

After the Soviet Revolution of 1917, an intense debate took place in the new USSR between those who adhered strictly to Marx's views about the future of law and those who saw law as playing an essential 'parental' role in educating the new socialist citizen (Berman 1963). Ultimately, Marx's predictions were not retained. But his analysis of law in terms of class dominance, class struggle, the production and reproduction of economic and social inequalities has remained at the core of modern Marxian sociology of law. Marxian legal sociology has taken pains to emphasize the role of law in structuring and reproducing the capitalist economy based on the alienation and exploitation of the labor class, in generating the ideological superstructure for justifying the class society and the interests of the dominant bourgeoisie, and in formulating an abstract legal definition of the citizen detached from his or her real life conditions (Cain and Hunt 1979, Michel 1983). Marxian legal sociology has also had a more indirect, but nonetheless real, influence on the various orientations taken by critical approaches to law, whether in European legal sociology (Miaille 1976) or in the US movement called 'critical legal studies' (Unger 1983) (see *Class: Social*; *Marxism in Contemporary Sociology*).

4. *Law, Rationality, and Capitalism*

Among the founders of sociology, Max Weber was the first to elaborate an explicit and quite detailed sociology of law, and to treat law, legal professionals, and legal institutions in a rigorous and systematic way. In what is considered his major work, *Wirtschaft und Gesellschaft*, an entire section was entitled 'Sociology of law' (Weber 1954). Moreover, Weber often referred to law in his great comparative analysis of religion, in his *Economic History*, and in his history of economy and society in antiquity.

Weber made both theoretical and empirical contributions to legal sociology. His theoretical contribution lies in his typology of legal forms of thinking along two axes: the irrational/rational one and the formal/substantive one. These forms produced four types of legal systems: the formal irrational, the substantive irrational, the formal rational, and the substantive rational. In the increasing rationalization that he identified as unique to the Western world, Weber used this theoretical scheme to underline empirically the dominant role played by law. Law evolved toward more and more rational justice, which was an outcome as well as a factor in the process of Western rationalization. At the same time, more rational law contributed to ease the emergence of the capitalist economy by the greater predictability it provided, as well as by the connection established between contractual freedom and the expansion of the market. Weber also emphasized the part played by various types of legal professionals (legal *honoratiores*) in the structure and evolution of law throughout the ages and in the progressive divorce of law from religion, politics, and morals.

It has been argued that a full understanding of Weber's sociology of law requires interpretation within the broader framework of his *Wirtschaft und Gesellschaft*, as well as that of his sociology of religion (Kronman 1983, Coutu 1995). Such is the case because

the roots of the notions of rationality and rationalization and their relationships to capitalism, which are central to his sociology of law, are to be found in his comparative historical analysis of the various types of economic ethics. Max Weber's contribution to the sociology of law is the most systematic and, at the same time, the most broadly and deeply sociological.

5. *Law and Inequalities: The Feminist Sociology of Law*

Feminist studies that have questioned the legal assumption of 'equality of all before the law' and of a value-free justice represent the most vibrant branch of critical legal studies. Feminist legal sociologists, more than any others, have been critical of what has been called 'the official version of law' which they describe as a view of law as being rational, objective, impartial, and neutral (Naffine 1990). It is this view of law that feminist legal studies hold to be mostly responsible for the sexist dominant legal ideology, essentially dictated by a male view of law and humankind (i.e., mankind) (Comack 1999). Feminist legal sociology has been very efficient in pointing out the male stereotyped definition of the subject of law and the unequal treatment of women by the law and its myriad authorities.

Being both theoretically and pragmatically oriented, feminist legal sociologists have documented many of the problems faced by women when dealing with the law and the courts. They have especially emphasized how judges and lawyers tend to use a discourse that dichotomizes reason and emotions, with the consequence that reason is inevitably identified with masculinity and emotions with feminity: male reason becomes opposed to female unreasonableness (Lees 1994). The analysis of how courts have been dealing with cases of rape and homicide of women has served more than any other to highlight the sexist interpretation currently resorted to by police, lawyers, juries, and judges in defense of male offenders (Busby 1999).

More than any other branch of critical legal sociology, the feminist approach has been activist and militant—involved in lobbying to change the law and to influence the courts in favor of a more just treatment of women.

6. *Sociology of the Legal Profession and the Courts*

Following Weber's emphasis on legal professionals, sociology of law has actively investigated the legal profession. Legal sociology joins here with the sociology of professions (see *Professions, Sociology of*). Several studies have dealt specifically with various aspects of the legal profession. Far from being unified and homogeneous, the legal profession has been found to be highly differentiated. The increasing complexity of modern law has given rise to a growing number of specialties within the profession. The variety of the client interests has also been a major factor in differentiating between, for instance, legal practice with corporate clients and that with individual clients, as well as between lawyers working in public services and those working in private offices, in large or small offices, in criminal law or civil law. With differentiation comes a prestige scale within the profession, concomitant with the social prestige of the client (Heinz and Laumann 1982).

The lawyer's relations with capital, their contribution to the evolution of Western capitalism, the mediating functions they take up between state and capital, as well as the role they play in the defense of powerless and socially excluded groups are among the main topics of a more critically oriented sociology of the legal profession. This approach has emphasized the various forms of power enjoyed by the legal profession (Cain and Harrington 1994). An alternative line of research has brought to light the contributions of legal professionals to the emergence of civil society in Western democracies, of political liberalism, and of liberal policies (Halliday and Karpik 1997).

Because judges are members of the legal profession, the functioning of the courts and the jury system has also been the focus of legal sociology. Much of what has been written on this topic has dealt with the judiciary decision-making process, with the explicit objective of improving it (Cramer 1981, Devlin 1979).

7. *Legal Culture and Legal Socialization*

Law is especially susceptible to constructivist interpretations. From this point of view, law is essentially a collective normative symbolic universe of linguistically conditioned mental representations, which are continuously reconstructed through their current use in active life. Social construction and reconstruction is part of law's very nature. Two varieties of such constructions can be distinguished. The first legal culture is that of legal professionals who have been trained in knowledge of the law of a given land and who share the ideological universe of the profession as well as its corporatist interests. The other is the legal culture of lay people and the relative and (more or less) approximate knowledge they have of the law as well as their attitudes and behavior toward the law, its institutions and professionals. The interaction between these two legal cultures varies both in terms of distance and intensity; both are greatest in modern society, following the professionalization of law.

The socialization process into a legal culture is an important chapter in legal sociology. Two major

theories of the psychology of learning have been tested: the cognitive development paradigm based on Piaget's and Mead's works and the social learning paradigm that emphasizes the role of affectivity and environmental context. Legal socialization is one way to explain why a particular individual is either a law-follower or a law-breaker (Cohn and White 1990). At the same time, compliance with the law has proved to be determined or conditioned by other contextual factors, such as rewards and sanctions, regulating agencies, and social environment (Friedland 1990).

It is especially in relation to culture and socialization that the indirect symbolic power of the law (based on nonlegal values and sanctions) can be appreciated, as opposed to its direct instrumental efficiency.

8. *Law, Law Making, and Social Change*

The association between law and social change is complex and many faceted. It is often said that law always lags behind changes taking place in society. A good number of examples can, however, be brought forward to illustrate the fact that law is quite often used by the legislator and sometimes by the courts to bring about various (sometimes radical) kinds of social changes, and that different segments of society must progressively adjust to changes generated by the law. Law can launch social change as well as block or inhibit it (see *Alienation, Sociology of*).

The law-making process in modern democracies has been one vantage point from which to explore the role of law in social change. An important distinction has been made between the instrumental and the symbolic function of law making (Tomasic 1985). It sometimes happens that the legislative process is part of a political strategy aimed more at symbolically exhibiting the legislator's good will than implementing the law.

On the other hand, 'legislative sociology' has emerged as a special branch of legal sociology, which is used to help the legislator enhance the effectivity of the law (Carbonnier 1978). Within this branch, the legal sociologist is explicitly invited to get actively involved in contributing to social change. This approach has also been interrogated as part of what has been called the political sociology of law—an analysis of interstices of the legal and political regulation of society (Commaille 1994).

9. *Legal Pluralism*

An important current of thought which has recently developed and expanded, emphasizes the fact that law is but one of the regulatory agents in society. In this pluralistic approach, law is theorized and empirically analyzed as part of a broader normative system that includes ethics as well as various kinds of technical, professional, and administrative normativities.

A major source of legal pluralism has been anthropological analyses of the meeting of indigenous and colonial laws (Rouland 1988). But even in modern societies, where the legal system has proliferated and become dominant, many other types of social control and social regulation exist alongside the state legal system. This is especially the case with the formal and informal disciplinary procedures currently operating in industrial and bureaucratic organizations (Henry 1983, Arthurs 1985).

Legal pluralism has also served to highlight the ways in which law is produced by the legislator and interpreted by the courts via the incorporation and legalization of rules and norms from other normative systems external to the law itself. It has also underlined how the effectivity of the law is often dependent upon the interaction between formal legal rules and nonlegal principles—between rules and norms.

10. *Conclusion*

Law is never created, applied, or used without some kind of relationship with the various powers in any given society. The most obvious case is, of course, the role played by political power (in the form of 'the state') in any matter involving the law. Political power is the main producer of law, both as legislator and judge. It is political power that guarantees the legitimacy of the law at the same time that the law grounds the legitimacy of the political power: modern society is especially characterized by a fundamental circularity of the foundations of legitimacy between state and law.

Economic power has a less visible, but nonetheless effective, influence upon the law. Big business is generally well organized and has the expertise to lobby legislators and to successfully bring its case before the courts.

In modern democracy, a growing number of interest groups promoting ideological (as well as other) interests have learned how to both influence and use the law. Finally, the media—supposedly the voice of public opinion—also play an active role in influencing legislators and, sometimes, the courts.

In sum, it can be said that in most social conflicts, law is an issue dividing parties as well as a tool they use to promote their interests.

Laws, Conflict of

1. Definitions

1.1 Conflict of Laws

The term 'conflict of laws' describes generally the body of law that seeks to provide solutions to international or interstate legal disputes between private or public persons or entities other than countries or states *as such*. A dispute is considered international, interstate, or multistate if one or more of its constituent elements is connected with more than one country or state. For brevity's sake, the word 'state' is used hereafter to denote any country or any territorial subdivision of such country, such as a state or province, that has its own system of private law. The law of conflict of laws deals with both international (country-to-country or country-to-state) and intranational (state-to-state) cases, so long as they have one or more foreign elements. These elements may relate to the parties' nationality, citizenship, domicile, residence, or other affiliation with another state, to the location of the events that give rise to the dispute, or to the location of the object of the dispute. Thus, a contractual dispute between citizens of different countries or domiciliaries or residents of different states, or a property dispute between residents of one state regarding assets situated in another state, or a tort resulting from conduct occurring in one state and causing injury in another state are all examples of disputes that fall within the scope of this subject.

1.2 Private International Law

The term 'conflict of laws' was coined in Europe by the Dutch jurist Ulricus Huber (1624–1694) and is the term primarily used in the United States, Canada, and more recently in England. In the rest of the world, the corresponding term is 'private international law,' which was coined in the United States by Justice Joseph Story (1779–1845). Neither term is fully descriptive of the subject matter.

The term 'conflict of laws' seems to assume that, in all cases that have contacts with more than one state, each involved state has an active or passive desire, claim, or 'interest' to apply its law, and that these claims 'conflict' in the sense of being of roughly equal validity and intensity. Both of these assumptions have been questioned throughout history. Indeed, even accepting the propriety of using anthropomorphic terms to describe state objectives, both the hypothesis that a state is 'interested' in the outcome of disputes between private persons and the concomitant assumptions that such an interest is implicated in each multistate case or that the application of a state's law indeed effectuates that interest are subject to intense debate.

The term 'private international law' seems less loaded and more descriptive, but also more idealistic than the term 'conflict of laws.' The word 'international' describes an important aspect of the disputes that fall within the scope of this subject—they are international (or interstate) in that they have contacts with more than one state. The word 'private' echoes the civil-law division between private and public law and signifies that only private-law disputes fall within the scope of this subject, that is, disputes arising from relations between persons other than a state or its subdivisions acting in the exercise of governmental authority. In contrast, public-law disputes of an international character, such as those between sovereign countries or other international-law persons, fall within the scope of the public international law, also known as the law of nations (see *International Law and Treaties*).

1.3 The Source of Conflicts Law

The term 'private international law' can be misleading to the extent it gives the impression that there exists a distinct body of law universally observed by most nations which provides solutions to multistate private-law disputes. Reality is much different. Except for a few international conventions that avoid or resolve conflicts through substantive or conflicts rules, international law has little to say on the subject. Thus, for the most part, the task of resolving multistate private-law disputes is left to individual countries, subject to certain mild restraints imposed by international law. Accordingly, conflicts law is essentially *national* law. Similarly, within the United States, conflicts law is—*de facto* and for the most part—*state* law rather than federal law. Although the United States Constitution provides the power to federalize the law of interstate conflicts, this power has not been exercised in any appreciable degree. Thus, the initiative for resolving interstate and international conflicts remains with the states, albeit subject to some federal constitutional, treaty, and statutory constraints.

2. The Source of Conflicts of Laws

2.1 Legal Diversity

Conflicts of laws occur because each state has its own system of private law and because human activity often is not confined to a single state. If either one of these conditions is missing, conflicts do not arise. One who lives in complete isolation and avoids contact with nonlocal residents and foreign products need not be concerned with conflicts of laws. Similarly, one whose contacts with nonlocals are confined to residents of states that have identical laws would not need to be concerned with problems caused by legal diversity. Needless to say, human activity transcends national borders and countries do have different laws. For example the contracts law of France differs from that of England, which in turn differs in some respects from that of Scotland, and the torts law of the Mexican province of Sinaloa differs from that of the State of Arizona, which in turn differs from that of California. Indeed, differences exist not only between countries that belong to different legal traditions, such as France and England which belong to civil-law and common-law traditions, respectively (see *Legal Systems, Classification of*), but also between countries that partake of the same legal tradition, such as France and Italy, or England and the United States, respectively. Moreover, such differences also exist as between or among the component units of a single country, such as the states of the United States, or the provinces of Mexico or Canada, or in the United Kingdom between England and Scotland (see *Legal Pluralism*).

2.2 Interpersonal or Intertemporal Conflicts Law

This legal diversity is usually coextensive with a distinct territory that is administered by a governmental unit with authority over that territory. In some instances, however, the existence of a distinct body of law, such as family law or the law of personal status, is not attached to a particular territory but rather to a particular ethnic or religious group, regardless of territory. Conflicts among these laws are referred to as interpersonal or interreligious conflicts and are not discussed here. Also not discussed here are the so-called intertemporal conflicts of laws, namely conflicts that arise when a law purports to regulate or is sought to be applied to events or transactions that occurred before its enactment (retroactive application).

3. The Three Parts of Conflicts Law

While many problems of conflict of laws are resolved through negotiation, mediation, or arbitration, most of them end up in litigation. In planning for this eventuality, or when forced to confront it, parties involved in multistate activity must keep in mind three major questions: (a) Where can or should litigation be initiated? (b) Which law will the court apply? and (c) Where can the resulting judgment be enforced? These three questions correspond to the three consecutive phases that comprise the process of judicial resolution of most conflicts problems, namely: (a) jurisdiction; (b) choice of law; and (c) recognition and enforcement of judgments. In the United States and other common-law systems, these are also the three major divisions of the law of conflict of laws. In contrast, in civil-law systems, jurisdiction and judgment-recognition form

part of 'international procedural law' rather than of private international law, which deals primarily with choice-of-law and secondarily with the law of nationality and citizenship and the condition of aliens.

The jurisdictional question and the choice-of-law question are analytically distinct questions although in many cases they are practically interrelated. Indeed, the two questions are oriented in different directions and seek to satisfy different ends. The jurisdictional question focuses on the relationship between the defendant and the state of litigation ('forum state') and asks whether that relationship is sufficiently close as to justify subjecting the defendant to litigation in that state and utilizing that state's judicial resources to adjudicate the particular dispute. The choice-of-law question focuses on both parties and their dispute and seeks to identify that state, be it the forum state or another state, whose relationship to the dispute is such as to render most appropriate the application of its law to the merits of the dispute. In many cases, the same relationship that forms the basis of a state's jurisdiction to adjudicate the case can also be the basis for applying that state's law to the merits. This, however, is by no means true in all cases.

As said above, the law of conflict of laws does not deal with public-law disputes, namely, disputes involving a state in the exercise of governmental authority, such as in the enforcement of its criminal laws. Indeed, in such disputes, all three of the above questions are merged into one—the question of jurisdiction. When a state has jurisdiction to try a criminal case, that state applies its own law and enforces the resulting judgment. It does not apply the criminal laws nor enforce the criminal judgments of another state. Cases in which more than one state have concurrent jurisdiction, such as cases involving transborder crimes, are addressed and resolved as jurisdictional conflicts—for example through extradition—rather than as choice-of-law conflicts.

4. *Jurisdiction*

In its broadest sense, jurisdiction is the power of a decision-maker to resolve a dispute in a binding manner. When, as in the context pertinent here, the decision-maker is a court or other tribunal, the dispute is resolved through adjudication and the power to do so is called judicial or adjudicatory jurisdiction. It can be contrasted with legislative or prescriptive jurisdiction, which is the power to enunciate norms governing the merits of the dispute. The source of judicial jurisdiction is the law that constitutes the particular court and thus it is a national or state law rather than a supranational or suprastate law. However, in some countries the exercise of jurisdiction is restricted by international treaties, such as the Brussels-Lugano conventions among several European countries, while in some federal systems like the United States, the exercise of jurisdiction by the constituent states must conform to certain outer limits imposed by federal law, primarily the due process clause of the federal constitution. Although these super-arching sources impose a certain degree of uniformity on the affected states, the jurisdictional laws of the various countries or states continue to differ widely in both nomenclature and substance.

Thus, each state delineates for itself the bases on which its courts are authorized to adjudicate cases with nonlocal elements (jurisdiction in the international sense) and then allocates internally that authority among the various geographical subdivisions or judicial districts within that state (internal or local jurisdiction or venue) and among its various general or specialized courts, tribunals, or other adjudicating agencies in each locality (competence or subject-matter jurisdiction). To render a valid judgment, a court must, in the absence of acquiescence by the defendant, satisfy all three types of jurisdiction.

In the United States, for historical reasons, a state court's interstate or international jurisdiction is divided into personal jurisdiction (*in personam*) and jurisdiction over things (*in rem*). Personal jurisdiction, which is the power to adjudicate claims against a defendant and to bind him or her personally, is further subdivided into general and specific jurisdiction. General jurisdiction exists when the defendant is domiciled, incorporated, has its principal place of business, or conducts 'continuous and systematic' business in the forum state. Historically, the service of process on the defendant within the territory of the court was also a basis of general jurisdiction but the constitutionality of this basis is now questionable, at least when it is not supported by other defendant contacts. When a court has general, jurisdiction, the court may adjudicate any claims against the defendant, even claims unrelated to the defendant's contacts with, or activity in, that state. In contrast, when a court has only specific jurisdiction, the court may only adjudicate claims against the defendant that arise from the defendant's contacts with, or activity in, the forum state.

Jurisdiction over things is based on the presence of a thing within the territory of the forum state and is subdivided into jurisdiction *in rem* and *quasi in rem*. When the lawsuit seeks to determine the parties' rights in, or relating to, that thing, the court has jurisdiction *in rem* and may adjudicate those rights even if it does not have personal jurisdiction over the defendant. In contrast, when the lawsuit seeks to vindicate claims against the defendant that are unrelated to that thing, the court is said to have *quasi in rem* jurisdiction. Since 1977, this basis of jurisdiction is—in the absence of other defendant contacts—constitutionally insufficient unless the claim has been previously reduced to a judgment rendered by another court that had jurisdiction over the defendant.

In other countries, jurisdictional bases are in some respects broader and in other respects narrower than

those described above. For example, some European countries theoretically allow the exercise of what might be called *quasi in rem* general jurisdiction, namely, the adjudication of claims against a defendant who owns property within the forum state, even if the claims are unrelated to the property or vastly exceed its value. On the other hand, while most countries agree that the defendant's domicile, incorporation, seat, or principal place of business in the forum state is a basis for general jurisdiction, they reject general jurisdiction based on either service of process alone or 'doing business' within the forum state.

Beyond this, most countries and states agree that the defendant's actual or imputed consent is a sufficient basis of jurisdiction even when jurisdiction is otherwise lacking, that contractual claims can be adjudicated in the place where the contract was to be performed, and that claims arising from torts can be adjudicated in the place where the wrong was committed or the injury foreseeably occurred.

Because of the differences between the jurisdictional bases recognized by the various states, but also because, even when they do not disagree, these states may authorize more than one jurisdictional basis for certain categories of cases, a given case may often be subject to the concurrent jurisdiction of more than one state. In such a case, the plaintiff, who always has the choice of where to file the lawsuit, may shop for the most advantageous forum, a phenomenon known as forum shopping. One of the mechanisms devised by common-law systems to discourage this phenomenon is the doctrine of forum *non conveniens* which allows a court to decline to adjudicate the lawsuit if, despite the existence of jurisdiction, litigation in that state would be seriously inconvenient and another more convenient forum is available to the plaintiff, Another mechanism which is sanctioned in varying degrees by most systems but which is available only when the disputants are parties to a pre-existing contractual relationship, is a choice-of-forum clause, namely a clause by which the parties agree that disputes arising from that relationship will be litigated in the courts of the agreed upon state.

5. *Choice of Law*

When a court exercises its jurisdiction to adjudicate a case with foreign elements, the court applies its own *procedural* law to the conduct of the proceedings before it. With regard to the merits of the case, however, the court may or may not apply its own *substantive* law. This is the choice-of-law question and it is answered by the forum's choice-of-law rules, which may be established legislatively as in most civil-law systems or through judicial precedent as in most common-law systems including those of the United States. These rules may point to the law of either the forum state or to another state, depending, *inter alia*, on each state's pertinent contacts with the case. For example, in tort cases, these rules may point to the state where the tort was committed or the injury occurred (*lex loci delicti*), in contract cases to the state where the contract was made (*lex loci contractus*), and, in cases involving immovable property, to the state where the property is situated (*lex rei sitae*).

The above three rules are typical of what is usually referred to as a traditional choice-of-law system. For much of the twentieth century, these rules and others like them were more or less uniformly followed in most countries. These rules place a high premium on providing certainty and predictability in the choice of the governing law, leaving little room for judicial discretion. As the above examples illustrate, these rules give no preference to the forum state and indeed they aspire to produce international or interstate uniformity, that is, make it more likely that each multistate case will be governed by the same law regardless of where the case is litigated. The choice of the governing law is based not on the content of the laws of the involved states but rather on the territorial or other contacts of those states to the case at hand. Once a state is found to have the predesignated contact, e.g., the place of the injury, that state's law is applied almost automatically and—save for some limited exceptions—regardless of its content, its underlying policy, or the substantive quality of the result that such application produces. Indeed, the objective of the traditional choice-of-law process is not supposed to be to ensure a substantively 'just' result (material justice), but rather to ensure the application of the spatially appropriate law (conflicts justice).

Traditional choice-of-law rules like the ones described above continue to be followed in many countries, including some parts of the United States. However, in the 1960s, a movement emerged in the United States which has been characterized as a conflicts revolution, and which appeared to reject both the rules and the goals of the traditional choice-of-law process. At least in tort and contract conflicts which are the most numerous, preconceived choice-of-law rules were abandoned in favor of various 'approaches' which, although different in many respects, reject the notion of pre-selecting the applicable law on the basis of a single territorial contact and instead leave the selection to be made by the court on a case-by-case basis. The choice is to be based on multiple contacts and factors, such as the content of the conflicting substantive laws and their underlying policies, the presumed 'interests' or claims of the involved states to apply their respective laws, and the substantive quality of the result that the chosen law will produce in the individual case.

Parallel movements have also appeared in other countries, though nowhere with the same intensity. For example, European systems now appear more willing than in the past to entrust courts with a certain

degree of flexibility in choosing the applicable law. Although most of these systems still rely on statutory choice-of-law rules, the rules enacted in the last quarter of the twentieth century are 'softer' than those of the preceding era. For example, some of these rules base the choice of the applicable law not on a single territorial contact but rather on multiple contacts, usually described by the phrase 'strongest' or 'closest connection,' while other rules contain clauses that authorize courts to deviate from the predesignated law in appropriate circumstances, depending on the needs of the particular case.

As a result of the above movements, the choice-of-law process at the beginning of the twenty-first century is more flexible, less predictable, and more ethnocentric than it was only one generation earlier. The possibility that the forum state will apply its own law to most multistate cases adjudicated by its courts is now greater than in much of the previous century, especially in the United States. In turn, this increases the possibility that a given case will be governed by a different law depending on where it is litigated, and this in turn reinforces the incentive for forum shopping described earlier.

Yet, while national conflicts systems have been gradually diverging in most respects, they have also been converging in at least one important respect. Most of them now recognize the principle of party autonomy, namely the notion that parties to a contractual relationship should have the power to agree in advance on the law that will govern disputes arising from that relationship. Although this is an ancient principle whose origin can be traced as far back as ancient Greece, it has had a checkered history through the centuries. By the second half of the twentieth century, however, this party autonomy acquired the status of a universal principle and is now sanctioned in one form or another by most countries in the world. In fact, some of these countries have extended this principle beyond ordinary contracts and have made it available to matrimonial agreements, other family-law agreements, and even unilateral juridical acts such as testaments.

The use of a choice-of-law clause, especially when combined with a choice-of-forum clause or an arbitration clause, can provide parties with a modicum of predictability. This is a good antidote to the uncertainty generated by the movements described above. This antidote, however, can only work in some cases. For example, the principle of party autonomy is not available in cases such as torts in which the disputants are not parties to a pre-existing relationship. Second, while this principle is recognized in most countries, it is also subject to several limitations and exceptions that differ from country to country. Thus, the possibility that choice-of-law clauses can be enforced in some countries but not in others remains, and with it the possibility of a different outcome depending on where the case is litigated.

6. *Recognition and Enforcement of Foreign Judgments*

One of the many differences between local and multistate cases is the increased possibility that in multistate cases a judgment may have to be enforced in a state other than the one in which it was rendered. This will be the case if the defeated litigant (judgment debtor) does not voluntarily comply with the judgment and does not have sufficient assets in the forum state against which the successful litigant (judgment creditor) can execute the judgment. In such a case, the creditor will seek to have the judgment recognized and enforced in another state that has jurisdiction over the debtor and in which the debtor has sufficient assets. This section discusses the requirements under which the second state will recognize such a judgment.

As between states of the United States, these requirements are prescribed by federal law, primarily the Full Faith and Credit Clause of the Constitution. As interpreted by the Supreme Court, this clause requires each state to give to a judgment of a sister state the same effect that the judgment had in the state of rendition, provided that the judgment is 'final,' it is 'on the merits,' and it was rendered by a court that had jurisdiction under its own law which must conform with federal due process standards. Once these requirements are met, the judgment must be recognized and may not be reviewed on the merits, even if it applied the wrong law or reached a result that contravenes the public policy of the second state. The reason for this strict regime is the national policy of finality embodied in the doctrine of *res judicata*, which seeks to conserve judicial resources and protect party expectations by prohibiting re-litigation of disputes that have been finally decided.

The Full Faith and Credit Clause does not apply to the judgments of foreign countries and thus American courts are not constitutionally compelled to enforce such judgments. Nevertheless, as a matter of comity, American courts recognize foreign-country judgments that meet the requirements for recognizing a sister-state judgment, but also reserve the right to refuse recognition on certain grounds that are not available with regard to sister-state judgments. For example, recognition may be refused if the judgment does not satisfy American jurisdictional standards, even if it does satisfy the foreign-law standards; if the judgment is one for taxes or penalties; or if it was rendered in a system that does not provide impartial tribunals or does not satisfy certain minimum standards of procedural fairness, or contravenes the public policy of the recognizing court.

In many other countries foreign judgments are recognized under similar but somewhat less hospitable standards. For example, in some countries recognition depends on whether the rendering court had applied the law that would have been chosen under the choice-of-law rules of the recognizing court or had reached a

substantially equivalent result. In other countries, recognition is usually denied on public policy grounds to judgments awarding 'excessive' sums of money, especially American judgments imposing punitive damages. Finally, some countries condition recognition on reciprocity, that is, on whether the country of rendition would recognize similar judgments from the second country, while other countries refuse recognition outright in the absence of a treaty requiring such recognition.

One such treaty of increasingly growing importance is the Brussels/Lugano Convention on Jurisdiction and the Recognition and Enforcement of Judgments among the member states of the European Union and the European Free Trade Association. This Convention establishes a comprehensive regime for jurisdiction and judgment-recognition that approximates in important respects the regime that exists within the United States. With regard to defendants domiciled in a member state, the Convention defines the permissible bases of jurisdiction and then provides that a judgment rendered by a court that satisfies those bases must be recognized in the other member states without review of the merits and subject to only limited exceptions such as public policy, lack of proper and timely notice, or conflict with a prior judgment entitled to recognition under the Convention or a judgment of the recognizing state. As of the time of this writing, an international convention on jurisdiction and judgment recognition is being negotiated under the auspices of the Hague Conference of Private International Law which includes countries from all continents.

Lawyers

Lawyers are defined by function—manipulating rules (usually governmental)—and structure—a profession with credentials based on education, examination, and experience. In the common law world (England and its former colonies) the profession is dominated by private practitioners (sometimes divided into solicitors or attorneys, who do everything but appear in the higher courts, which is reserved for barristers or advocates), though more lawyers are becoming civil servants or corporate counsel. In the civil law world (the rest of Europe and the countries it colonized or influenced) jurists (endowed with a university law degree) are divided into private practitioners (*avocats, abogados, avvocati, Rechtsanwälte*), the magistrature (judges and prosecutors), and lawyers employed by business and the state; these roughly equal categories diverge in qualifications, collective interest, and professional association (Abel and Lewis 1989–95). Movement between them is much less frequent in civil law jurisdictions. These differences articulate with the relative roles of judicial precedent and legislative code as sources of law, judges and legal academics in rationalizing and reforming law, and lawyers and judges in litigation. Most socialist regimes enlarged the role of lawyers in the state (jurisconsults) at the expense of private practitioners. With the fall of communism and globalization of capital, common law professional practices are colonizing the world.

1. Commodifying Law

Lawyers, like law, have social preconditions. There must be a state: in acephalous societies, where power is dispersed among kinship groups and age grades, parties typically represent themselves. Secular power must be differentiated from religious: the priesthood performs legal functions in theocracies. There must be a market: administrators replace most lawyers in command economies. Power must be exercised

through general rules: totalitarian states deploy force rather than law. The amount of law and lawyering vary with the proportions of state and nonstate social control, secular and religious authority, market and plan, legality and autocracy, as well as the distribution of wealth, power, and status (dispersed or concentrated, equal or stratified) and the nature of the economy (goods or services; land, natural resources, capital, and intellectual property).

But even if law is differentiated from informal social control, religion, plan, and diktat, lawyering must be commodified. Most societies value meaning and salvation (religion), health (medicine), physical comfort (engineering) even financial security (accounting) over justice (which is inherently ambiguous—one's justice is another's outrage). Knowledge occupations advance their professional project by capturing vital arenas: church, hospital, factory, stock market, tax office, court, document registry. (This advantages advocacy over transactional lawyering.) Potential clients must be persuaded to buy another's services rather than represent themselves, as we do whenever we comply with or evade, mobilize, or resist law (Kritzer 1998). The division of labor makes generalist consumers dependent on specialist producers (although some societies may resist this in the name of revolutionary ideology or religion, e.g., Wahabi Islam). Lawyers draw upon the devices of other professions—ritual, dress, esoteric language—though they lack some of the most effective (technology, scientific validation). Legal knowledge can effloresce (like science) and decline (like religion). Although law is proliferating, its techniques have been challenged by economics and its legitimacy by legal realism and critical legal studies (including feminism, antiracism, and queer theory). Knowledge, to be commodified, must balance technicality and indetermination (Jamous and Peloille 1970): too technical and it becomes an algorithm consumers perform for themselves (ATMs replacing bank tellers); too indeterminate and the only performance criterion is artistic taste. This balance between theory and craft, symbolic and practical mastery, is related to the tension between university and apprenticeship (Schön 1987). Information technology is restoring some lawyering functions to more educated consumers (both individual and commercial). Constant change in the knowledge base influences the careers and turnover of personnel, professional fission into subspecialities, and the relationship between knowledge producers (teachers and researchers) and consumers (practitioners).

2. Controlling Supply

Once consumers have been persuaded that they need legal services, producers seek to dampen competition by limiting supply. In other markets producers control access to natural resources (South African diamonds, Zanzibari cloves, Chinese silkworms), capital, or technology (patents). Because services are incorporeal, control must be exercised over producers (Larson 1977).

2.1 Production of Producers

Professions use guilds to control the production of producers (Krause 1996). Recruitment processes differ in who selects, when, and by what criteria. Many European law faculties admit all secondary school graduates but choose few to become judges; elite American and British law schools are intensely selective but place most graduates in prestigious firms. In the civil law world the state is the central actor, regulating the number of practitioners (there is still a *numerus clausus* for French *notaires*) and university places (the sole means of qualification), the difficulty of examinations, and employment in the magistracy and civil service. (Controlling supply has become increasingly important to the growing number of private practitioners produced by expanding universities and unable to obtain employment in the public or private sectors.) In the common law world, professional associations successfully erected numerous hurdles: apprenticeship (articles for solicitors, pupilage for barristers, entrants paying substantial premiums to work unpaid for years, barred from other sources of income), through which practitioners themselves limit competition; formal education (secondary school, liberal arts and law degrees, and accreditation of educational institutions); size and length of professional courses; number and difficulty of professional examinations; citizenship; residency; character examinations; even the number of starting positions (tenancies in the Inns of Court, assistant solicitorships in firms). The mass of lawyers sought shelter from competition; the elite were more concerned to elevate collective status. Functionalist social scientists, following professional apologetics, portrayed these barriers as quality assurance (Parsons 1964). Economists (Friedman and Kuznets 1945) and critical social scientists beginning with Weber (1978, see also Freidson 1970, Johnson 1972, Parkin 1979, Collins 1979) accused professions of preventing consumers from trading price for quality while failing to validate the hurdles against performance. Each national legal system insists its unique qualification process is essential for lawyers to perform tasks that vary little across national boundaries. But lawyers never mobilize most of the formal knowledge they must demonstrate to qualify (Genn 1987, Sarat and Felstiner 1995).

Until recently, ascribed characteristics dominated selection. Qualifying was very expensive. Apprenticeship and hiring allowed superiors to indulge class, race, gender, and religious biases. The French *notariat* could be inherited and bought. Indeed, traditional

professions invoked the warrant of character, transmitted by lineage and acculturation and reinforced by collegiality (Inns of Court dinners) and example (during apprenticeship). Entrants conferred status on the profession rather than receiving it from the profession.

Because of its centrality to the state, the legal profession is under particular pressure to reflect societal demographics. Character has been largely supplanted by the warrant of expertise (associated with science), acquired through formal education and demonstrated by examination. Apprenticeship and employment are increasingly meritocratic. But that, too, reproduces inequality, leading some jurisdictions to adopt gender and race targets. Women are half of entrants in many jurisdictions, but they may have accommodated to legal practice rather than transforming it.

Supply control, like any cartel (e.g., OPEC), is constantly eroding. The monopoly rents it extracts increase pressure to enter and undermine the legitimacy of barriers. Novice lawyers, like doctors, engage in conspicuous production, partly to justify future privilege. All meritocratic hurdles can be surmounted. Both the university—synonymous with expertise—and private courses for professional examinations have incentives to increase production. It is difficult to deny mandatory apprenticeships to university graduates (if easier for the 'market' of legal employers to deny them jobs). Globalization undermines barriers to transnational migration. State funding for education becomes the new regulator (alternatively, graduates become virtually indentured to repay heavy debt). The rise of women entrants to numbers equal with men virtually doubled entry (though childrearing leaves created periodic shortfalls) (Epstein et al. 1999). Because of the lengthy qualification process, professions oscillate between over- and under-supply (Freeman 1975). The ratio of lawyers to population, constant or falling for the first half of the twentieth century (partly from exogenous causes like the Depression and world wars), everywhere rose dramatically in the second half (to about 1:300 in the United States). Countries where less than 5 percent of aspirants succeeded (Japan, Korea, and Taiwan) have significantly relaxed their examinations.

Professions not only control the number and characteristics of entrants but also allocate them to roles. Although professions proclaim egalitarianism by virtue of their common qualification, all are stratified (Brint 1994). Civil lawyers traditionally accorded greatest respect to the magistracy, civil service, and professoriat, common lawyers to private practitioners (and advocates in divided professions) and the higher judiciary. Independent practitioners typically have enjoyed higher status than house counsel. With increasing individual inequality and economic concentration, private practitioners fission into two hemispheres, differing in the size and structure of the productive unit, clientele (individual or corporate, poor or wealthy, publicly or privately funded), and rewards (money, status, and power) (Heinz and Laumann 1982). Although the profession invokes meritocracy and 'choice' to justify stratification, parallels with gender and race tend to delegitimate the hierarchy (Epstein 1981, Thornton 1996, Sommerlad and Sanderson 1990).

2.2 *Production by Producers*

Once a profession limits entry it can manage competition among producers in order to enhance both economic rewards and (perversely) status by feigning indifference to material concerns (Abbott 1988). Lawyers secure state-protected monopolies or conclude market-division agreements with other occupations (concerning legal advice, land transactions, probate, authentication of documents, and advocacy) which they defend against 'unauthorized practice.' They allocate markets among legal professions—advocacy to barristers, conveyancing to solicitors. They stratify professional categories (Queen's Counsel and junior barristers). They prohibit foreign lawyers from practicing domestic law or with domestic lawyers. In federal polities, they restrict practice to one jurisdiction. They limit firms to one office. They mandate overstaffing (Queen's Counsel requiring a junior, barristers accepting briefs only from solicitors; conflict of interest rules requiring a lawyer for each party). They prohibit lawyers from seeking business—sometimes even from representing another lawyer's client without permission—and require referral schemes to distribute business equally. They outlaw contingent fees and regulate fees (at least minima). They limit the size of partnerships or forbid them (barristers). They prohibit partnerships with or capital investment by nonlawyers and curtail the activities of lawyers employed by nonlawyers. That some jurisdiction rejects each of these rules argues that none is essential to preserve quality or protect clients.

Like controls on production of producers, these restrictions contain the seeds of their own destruction. Cocooned in the conveyancing monopoly (which generated more than half their income), English solicitors ceded taxation to accountants; proudly litigating, French avocats allowed *conseils juridiques* to capture commercial work. Lured by lawyers' monopoly rents, claims adjusters, immigration advisers, and will writers encroach on legal work. Consumers frustrated by price, inaccessibility or inefficiency look elsewhere: to commercial arbitration or alternative dispute resolution (Dezalay and Garth 1996), accountants or other business consultants (Dezalay and Sugarman 1994), tax and administrative scriveners in Japan, offshore transactions or fora. Large consumers (guided by in-house lawyers) make

firms participate in 'beauty contests'; third-party payors (government, insurers, banks) dictate contractual terms. The erosion of control over production of producers intensifies competition among them. Fractions that had accepted subordination (employed barristers, *conseils*, *juridiques*, *Syndici*) demand equality. Disadvantaged lawyers may evade professional rules (chasing ambulances, advising an employer's clients) or attack them frontally (test cases overturning minimum fee schedules, advertising bans, and limits on number of offices). Although judges are lawyers, their interests and perspectives differ from those of private practitioners.

The conjunction of a movement of consumers (enlarged and emboldened by postwar prosperity), who make demands like price quotations, and the growing hegemony of market ideology undermined restrictive practices. A successful challenge to one erodes the legitimacy of all others. English solicitors, forced to share land transactions with licensed conveyancers and mortgage lenders, challenged the barristers' monopoly of rights of audience. The latter retaliated by extending direct access to professional and even lay clients, bypassing solicitors. When solicitors accused banks of tying conveyancing to mortgage lending, barristers charged solicitors with tying litigation to advocacy. The global economy (embodied in the European Union (EU), NAFTA, and the World Trade Organization) and communication technology have limited the ability of national professions to obstruct foreign competition (notwithstanding differences between the attitudes of exporters, like the common law world, and importers, notably France and Japan).

Restrictive practices are falling ever faster. The professional monopoly has contracted. Internal divisions have diminished or disappeared. Foreign lawyers can practice in more countries, form partnerships with domestic lawyers, and requalify to practice domestic law. Intranational barriers have been lowered or razed. Lawyers can advertise, and many do so aggressively, cutting prices to attract a mass clientele (Seron 1996). Jurisdictions abolished minimum fees, and more permit contingent fees. Public funding encourages competition between private practitioners and employed lawyers. Vertical integration is increasing, e.g., among estate agents, mortgage lenders, conveyancers, surveyors, and even moving companies. Multidisciplinary partnerships intensify competition between lawyers, accountants, and other financial advisers.

Lawyers have invoked new warrants—consumer choice and independence—against the state's power as employer and paymaster. Practitioners discourage competition by withdrawing referrals from foreign lawyers or accounting firms who threaten their turf; banks respond by boycotting solicitors who engage in mortgage lending. Lawyers create subspecialities, defined by additional credentials and endowed with new monopolies (rights of audience in specialized courts, legal aid eligibility). Nevertheless, the real incomes of many lawyers have declined (though those of elite lawyers continue to rise, further differentiating the hemispheres).

3. *Demand Creation*

Producers can respond to market pressures by both curtailing supply and increasing demand. Although law's adversarial nature means that for every action there tends to be an opposite (if unequal) reaction (like the escalation of offensive and defensive military strategies), lawyers displayed little collective interest in stimulating demand until the postwar era. Professional associations initially were suspicious of public subsidies, although significant fractions quickly became dependent on them, and professions studied lawyer use to demonstrate 'unmet legal need.' The rights revolution (in national constitutions and legislation and international treaties) conferred entitlement to legal representation in criminal, if not civil, matters. The erosion of supply control motivated some lawyers to seek clienteles through newly legalized forms of advertising.

Demand for legal services is highly elastic, influenced by the economy (size, concentration, proportions of goods and services, relative importance of natural resources, finance capital, and intellectual property), demographics (age, class composition), governmentality (informal social control, state regulation), globalization, frequency of legal events (divorce, crime, accidents, mergers, bankruptcies, housing sales), and rights consciousness. Lawyers can invent new legal claims (palimony) and transactions (premarital agreements, poison pills against hostile takeovers). But lawyers have never matched doctors and dentists in selling individuals preventive services. Demand creation can provoke backlash against litigiousness, waste, fraud, and lawyer greed. And the substitution of state payment for lawyer philanthropy (services rendered *pro bono publico*, or *pro deo*) can erode the profession's tenuous symbolic capital.

Just as solicitors were seduced into the monoculture of conveyancing, so barristers became unduly dependent on legal aid and thus on a fickle, and increasingly parsimonious English state. Whereas professional efforts to control supply tend to unite the profession (or its subdivisions), efforts to create demand are either collective and largely futile or individual and divisive. They also accelerate concentration among providers. Although lawyers who charge private clients astronomical fees may be envied, 'fat cats' feeding at the public legal aid trough are reviled. Partly because that budget is large and growing, partly because lawyer-bashing elicits populist cheers, the state energetically seeks to control legal

costs: fixing fees, capping budgets, and compelling price competition; shifting the burden to the parties (through contingent fees); substituting salaried lawyers for private practitioners, paralegals for lawyers, and parties for representatives (small claims court); and delegalizing entire domains of social life (divorce, accidents).

There are sharp disagreements about the consequences and desirability of extending legality. Some lawyers persuade clients to virtue, but others create legalistic obstacles and loopholes. Some see legality as essential to economic activity (Weber 1978) or a natural bulwark against state power (Halliday and Karpik 1998). But capitalism antedated commercial lawyers and thrives in countries where they remain marginal (Japan, Korea, Taiwan). Clientelism, corruption, and terror coexist with equal or greater rates of economic growth, and entrepreneurs and their lawyers tolerate, even welcome, autocracy. While some observers extol the formal equality of law, epitomized by the icon of blindfolded justice, others show how formal equality amplifies substantive inequalities (Galanter 1974). Lawyers can aggregate the unorganized (personal injury victims, especially through class actions), but they also engage in union-busting. Some observers applaud the proliferation and enforcement of rights; others blame the victim culture and nanny state for economic stagnation and political correctness.

4. *Relations of Production*

Whereas Weberian and economic theories of professions analyze the distribution of services, Marxist theories focus on relations of production. Extrapolating from the fate of nineteenth-century craftsmen, some have predicted the progressive deskilling of professionals. Certainly lawyers delegate much work to paraprofessionals (Van Hoy 1997), and information technology increasingly substitutes capital for labor (Katsh 1995, Susskind 1996). As multinational firms have grown to thousands of lawyers they also have extended the internal hierarchy among professionals: executive committee, equity and salaried partners, senior, junior, and permanent associates, and contract lawyers. If partnership no longer entails a financial investment, it does require human capital in the form of rainmaking (business-getting). Remuneration is changing from lock-step seniority to 'eat-what-you-kill.' Some firms have hired nonlawyer managers (beginning the separation of ownership and control, whose logical conclusion would be capital investment by nonlawyers). But, as Derber (1982) argues, the knowledge base of all professionals (including lawyers) constantly expands, protecting them from technical proletarianization while increasingly subjecting them to an ideological proletarianization: others determine why they will deploy their expertise, not how. Common law professions have seen the proportion in private practice decline relative to those employed by government and corporations (Spangler 1986). The large-firm practitioner's heavy dependence on a few clients seriously compromises the claim to 'independence' (Nelson 1988). Monopsonistic state consumers make legal aid firms bid for contracts and then sweat profits out of their workers. Elite lawyers also have seen work conditions worsen and hours lengthen. That associates bill approximately three times what they are paid, while few become the partners who profit from this arrangement, has been explained as a tournament that compensates for the difficulty of monitoring the quantity and quality of work, partners leasing surplus reputational capital in a precarious pyramid scheme (Galanter and Palay 1991) and capitalist extraction of surplus value.

Theorists have speculated about the political leanings of the 'knowledge class,' but lawyers, like other professionals, exhibit more differences among themselves than with other occupational groups (Brint 1994) and tends to sing the tune of their paymasters (Derber et al. 1990). Although lawyers are greatly over-represented in most legislatures, they behave little differently from other occupational groups.

5. *Collective Action*

The core of all professions is the claim to collective disinterest (Durkheim 1933, 1957). The information asymmetry engendering professionals make them uniquely capable of protecting consumers. As lawyers multiplied and diversified, informal social control lost efficacy, but professional associations were slow in promulgating and lax in enforcing ethical rules. Lawyers are perpetually torn between client loyalty, personal morality, and obligations to the legal system (Luban 1988, Simon 1997). The dissatisfaction of increasingly assertive and organized consumers is forcing lawyers to improve their complaint mechanisms and exhibit independence from professional associations (perhaps adding lay members) under threat of losing self-regulation altogether. At the same time, external regulation proliferates: malpractice claims (and insurers), courts (supervising litigation), ombudsmen, competition authorities, supranational bodies (EU, NAFTA), and administrative agencies with jurisdiction over the host of ancillary services lawyers are beginning to offer (such as investment, mortgages, estate agency, and insurance). Within the profession, factions struggle over substantive rules (advertising, confidentiality) and the cost of regulation and mutual insurance funds.

Governance is similarly contested. Geographic and functional divides (e.g., barrister–solicitor) are being supplanted by specializations. The refusal of alienated lawyers to join associations forces them to choose

between declining numbers and influence (aggravating free rider problems) and compulsion (limiting their capacity to represent members) (Halliday 1987, Powell 1989). Participation rates are low, belying democratic pretensions. The growing proportion of lawyers in public or private employment and large firms sees associations as irrelevant or hostile. Special interest groups proliferate, based on gender, race, religion, ideology, age, employment, firm size, clientele, dependence on public funds, and functional or substantive specialization. As associations aggressively pursue self-interest (in battles with regulators and oligopsonistic consumers) they abandon the disinterest grounding their claim to self-regulation. Furthermore, the usual forms of industrial action (strike, boycott, go-slow) are ineffective and impair professional status.

The changes sketched above have forced the legal profession to re-evaluate its collective ideology. Large consumers, even individuals represented by third-party payors, disdain professional paternalism. Professional rules have been exposed too often as restrictive practices swelling monopoly rents to retain much public credibility (for instance, contemporary opposition to multinational and multidisciplinary partnerships, or employed advocates). The obscene wealth of highly visible lawyers (which provokes greater resentment than that of entertainers, athletes, or entrepreneurs) has, perversely, undermined the profession's collective status, as shown by the proliferation of lawyer jokes and demeaning media portrayals. Self-regulation appears to favor the accused lawyer over the aggrieved client. Consequently, legal professions increasingly base their legitimacy on 'independence.' But this is an ambiguous value. Lawyers opposing state power on behalf of unpopular clients risk accusations of uncritical loyalty and indifference to crime victims. Few lawyers actually engage in criminal defense, especially of political dissidents, and those lawyers tend to be outsiders, not the establishment (Sarat and Scheingold 1998). If lawyers instead claim independence to pursue justice, clients understandably fear their representatives will seek outcomes (tort damages, divorce settlements, plea bargains) optimizing lawyer, not client, interest. Lawyers are derided as ideological when they invoke personal morality to reject clients or tactics. Legal professionals proclaim their independence by reforming law and legal institutions; but as they move beyond technicalities (where expertise is visibly relevant) to broader social issues—judicial appointments, the death penalty, discrimination, abortion, drug abuse—they risk appearing political. Paradoxically, just as earlier forms of legal professionalism nostalgically invoked aristocratic ideals of *noblesse oblige* and material indifference (Weber's *honoratiores*) just when these were being rendered increasingly anachronistic by the market, so lawyers now proclaim their independence just when it is being increasingly threatened by employment, bureaucracy, subordination to large consumers, and external regulation.

6. *The Future*

Having relinquished control over supply to universities, subcategories are trying to reclaim it, but through credentialing more than licensure. As these specialisms are increasingly differentiated and stratified, legal professions move toward fission. Lawyers find it more difficult to justify restrictive practices, especially as consumers become more concentrated and sophisticated, resorting instead to flexing their own market power. Private efforts to stimulate demand provoke a backlash against litigiousness. States seek to control and even contract their legal aid budgets. Within law firms, productive relations are increasingly capitalist, as differences in control and reward widen. The divisions and hierarchy among lawyers, often mirrored by ascribed characteristics, greatly complicate both self-regulation and governance—the hallmarks of a profession. The professional constellation, which lawyers successfully struggled to attain in the nineteenth and twentieth centuries, is gradually being rendered obsolete by the combined forces of market and state.

R. Abel

Lawyers, Regulation of

The 'regulation of lawyers' includes the regulation of criteria for admission to practice (such as training and testing requirements and criteria for the admission of foreign lawyers); the regulation of lawyers' professional conduct (such as rules governing confidentiality, conflicts of interest, fees, advertising, and so on); and the regulation of lawyers' monopoly over certain types of work (for instance, through interprofessional treaties and unauthorized practice legislation).

Traditionally, such regulation has been written and enforced on a local (state or national) basis, such that the rules varied significantly from jurisdiction to jurisdiction. Regulators and scholars have focused primarily on the regulation of lawyers' individual conduct by way of professional ethics codes.

Recently, however, rapid changes in the legal services market have strained this local, individualistic approach to lawyer regulation. Lawyers increasingly practice in firms, rather than alone or in two-person partnerships; thus their professional conduct increasingly is shaped by firm-level policies, procedures, and culture.

Further, firms themselves have grown exponentially and expanded geographically, such that lawyers increasingly practice across state and national borders. The emergence of a global economy and the growth and globalization of law firms have made the facilitation of 'transnational' practice a central regulatory issue.

Finally, lawyers increasingly practice in firms staffed by other types of professionals, such as accountants and management consultants; and accounting firms increasingly are seeking formal and informal alliances with law firms. The emergence of 'multidisciplinary' practice and its associated organizational forms has created a host of regulatory issues outside of the traditional regulatory paradigm.

Bar associations and other regulators are in the process of responding to the many challenges presented by the changing conditions of law practice. In 1988, the Council of the Bars and Law Societies of the European Community (CCBE) adopted a common Code of Conduct for Lawyers to facilitate transnational practice with in the European Union (Goebel 2000, Terry 1993). State and national bar associations have been hotly debating the regulatory issues raised by multidisciplinary practice—particularly whether lawyers should be permitted to form partnerships with other professionals (e.g., see ABA Commission on Multidisciplinary Practice 2000).

Scholars, too, have begun to call for a rethinking of the traditional regulating paradigm. Rather than focusing only—or primarily—on professional self-regulation by way of ethics codes, scholars have called for increasing attention to other sources of regulation, such as judicial and administrative action, malpractice liability and risk management, and constitutional and international law (Cone 1996, Davis 1996, Schneyer 1998, 1999, Wilkins 1992). In the USA, the field of study that used to be called 'legal ethics' is increasingly referred to more broadly as 'the law governing lawyers.'

Scholars have also called for increasing attention to the organizational contexts in which lawyers practice, and the effects of organizational structure and culture on lawyers' individual conduct (Chambliss 2000, Nelson 1988, Wilkins 1998). Given that lawyers increasingly practice and are socialized within firms, both regulators and scholars have begun to focus on how such firms are managed and what firm-level regulatory controls, if any, should be required (Schneyer 1991, 1998). The emergence of new organizational forms, such as multinational and multidisciplinary partnerships, has only underscored the need to develop a strategy for firm-level (or 'entity') regulation (Chambliss 2000).

Thus, while the 'regulation of lawyers' traditionally has focused on the local regulation of lawyers' individual conduct, both the regulatory system and regulatory scholarship are in the midst of dramatic development and change. As lawyers increasingly practice in firms, across jurisdictional borders, and with other professionals, the regulation of lawyers increasingly will demand collaboration between nations, professions, and regulators. This essay provides a brief overview of regulatory debates for the beginning of the new century.

1. *A Threshold Issue: Defining 'Lawyer'*

Comparing the regulation of lawyers from different jurisdictions requires a shared definition of 'lawyer.' Yet the Anglo-American, common law concept of 'lawyer' has no counterpart in civil law countries because most civil law countries do not have a unified legal profession. Instead, civil law countries recognize multiple legal occupations, such as judge, prosecutor, civil servant, and private practitioner, with private practitioners typically constituting a relatively small proportion of the total (see *Lawyers*). Further, in civil law countries the list of 'legal' occupations includes jobs that in common law countries would be performed by those without legal training, such as notaries (everywhere), police chiefs (in Brazil and Norway), and bailiffs and process servers (in France). None of these groups sees itself as part of a unified legal 'profession'; typically, each group has its own occupational associations and licensing criteria (Abel 1988). Thus, while it is relatively easy to compare 'lawyers' from the USA, the UK, Canada, Australia, and New Zealand, there is no comparable professional group in most other countries.

This article focuses on the regulation of private practitioners in the USA, Europe, and the financial centers of the Pacific Rim (e.g., Australia, Japan). It focuses specifically on regulatory issues arising from the increasing globalization and consolidation of professional services, such as the regulation of transnational and multidisciplinary practice.

Although only a small fraction of all lawyers practice in large, global firms, transnational practice is one of the fastest growing sectors in the legal services market (Abel 1994, Cone 1996, Terry 1999). Likewise, though only a small fraction of lawyers practice in multidisciplinary partnerships, the emergence of multidisciplinary practice raises fundamental questions about the definition of 'legal' services and the boundaries between law and other occupations and professions (e.g., see Abbott 1988, Daly 2000). Regulatory developments regarding transnational and multidisciplinary practice therefore promise to have a significant impact on the organization and regulation of lawyers around the world.

2. *An Overview of the Regulatory System at the End of the Twentieth Century*

Theoretically, the power of self-regulation is a defining feature of the 'professions.' Because there is an 'asymmetry of expertise' between professional and client, clients and nonprofessional regulators may be ill-equipped to monitor professional standards or the quality of professional service. As a result, professionals must regulate themselves—ideally, in view of the public interest. (This justification for self-regulation is associated with 'functional' theories of the professions, see *Lawyers*.)

In the USA and other common law countries with strong national professions, private practitioners historically have enjoyed substantial powers of self-regulation. US lawyers are regulated primarily by way of ethics codes promulgated by state bar associations

and enforced by professional disciplinary authorities. Professional associations control the criteria for admission to practice, including the accreditation of law schools and the substance of bar examinations; and professional ethics codes (though they try to avoid it) shape the standards for malpractice liability. Likewise, in England and Wales, the regulation of solicitors is controlled substantially by the Law Society, a voluntary association formed by solicitors in the 1820s.

In civil law countries, private practitioners are regulated primarily by the state, which controls the number of university places and the difficulty of qualifying exams (see *Lawyers*). Though bar associations may play an important role in promulgating ethical rules, they tend to be subordinate to the state in the disciplinary process. In Denmark, Norway, and Sweden, for instance, professional associations have no coercive authority; disciplinary sanctions must be enforced by the state. In Germany, Italy, and Switzerland, most disciplinary bodies are state agencies or contain only a minority of private practitioners (Abel 1988).

In both common law and civil law countries, the professional regulatory system was established during a time when most lawyers practiced alone and within the boundaries of a single jurisdiction. As a result, much professional regulation is out of step with the conditions of modern law practice—especially the conditions of large firm practice in the global legal services market. Meanwhile, external regulation (by government agencies, malpractice insurers, and international trade organizations) is proliferating. It remains to be seen whether bar associations can adjust to the changing conditions of law practice in time to prevent their own marginalization in the regulatory process.

3. *The Growth of Transnational Practice*

The export of US legal services increased from $97 million in 1986 to $1.9 billion in 1996, while the US import of legal services increased from $40 to $516 million (Terry 1999 [citing US Department of Commerce Statistics]). In both the US and Europe, large law firms increasingly are hiring foreign lawyers, establishing foreign offices, and merging with foreign law firms to create multinational partnerships (Abel 1994, Terry 1999). In 1999, UK firm Clifford Chance merged with US firm Rogers & Wells and German firm Punder, Volhard, Weber and Axster to become the largest law firm in the world (Terry 1999).

The rapid growth of 'transnational' practice has created enormous pressure on bar associations to relax local restrictions on the admission and practice rights of foreign lawyers. In general, however, local regulation has not kept pace with market demands. While some jurisdictions have relaxed restrictions on foreign lawyers in recent years, many continue to impose significant barriers to cross-border practice, and there continues to be significant jurisdictional variation. Lawyers have responded to the complexities of local regulation in part by non-compliance (Abel 1994, Bevernage 1995) and many scholars and regulators urge deregulation (e.g., Goebel 2000). In the coming years, this promises to be an important arena for regulatory reform.

3.1 *Regulation at the End of the Twentieth Century*

All countries regulate the admission of lawyers from other countries. The rules vary enormously, but in general there are two categories of 'admission.' First, foreign lawyers may seek admission to the local profession. Such admission confers full practice rights but typically is difficult to attain. Members of the European Community are required to admit lawyers from other member states subject only to an aptitude test or three years experience, but some countries (France, Spain) have been slow to comply. Outside of the European Community, most countries require foreign lawyers to re-qualify completely—that is, to satisfy all of the criteria for the admission of new lawyers—unless there is a reciprocity agreement between the home and host countries (Abel 1994).

Foreign lawyers also may seek admission to practice as 'foreign legal consultants.' Typically, such admission requires foreign lawyers to: (a) register as foreign legal consultants and pay a registration fee; (b) have three to eight years of experience in their home countries (most countries also demand reciprocity with the home country); and (c) comply with local rules of professional conduct, especially rules governing advertising and fees (Abel 1994). Most countries limit the areas in which foreign legal consultants can practice, reserving for local lawyers such areas as litigation, advocacy, conveyancing, domestic relations, wills and trusts, and advice on local law. In some jurisdictions, foreign lawyers can practice only the law of their home country (Abel 1994).

In general, the European Community offers the most liberal regulatory regime. EC lawyers and law firms may establish a permanent office in any member state and practice most areas of law under their home title. This rule eliminates the need for EC lawyers to become members of the local profession. EC lawyers also may form multinational partnerships with other EC lawyers in any member state (Goebel 2000).

Some EC countries also have liberal rules regarding the admission of non-EC lawyers. England allows non-EC foreign lawyers to set up permanent offices and practice under their home title, as long as they do not practice local law. In 1995, there were over 120 foreign law firms practicing under their home title in London (including over 60 US law firms) (Adamson 1995). Both England and Belgium allow multinational

partnerships between local lawyers and foreign lawyers from outside the EC (Adamson 1995, Bevernage 1995).

Other countries are more restrictive. Until 1980, most US states treated any activity by foreign lawyers as the unauthorized practice of law (Abel 1994) and as of 1998, only 21 states had rules recognizing foreign legal consultants (Needham 1998). New York's rules are the most liberal, allowing foreign lawyers to set up offices under their home firm name and practice local as well as national and international law (Cone 1995). California, on the other hand, prohibits foreign legal consultants from giving advice on anything other than the law of their home country. State-by-state variation makes it difficult for US representatives to negotiate reciprocity agreements with representatives from other countries (Needman 1998). State-by-state variation also makes it difficult for US lawyers who engage in multistate practice domestically.

In Japan, foreign legal consultants must have five years of experience in their home country and that country must offer reciprocity. Foreign legal consultants are prohibited from practicing under the name of their home firm, prohibited from advising on any law other than the law of their home country, and prohibited from hiring or entering into partnerships with local private practitioners. In response to these restrictions, most foreign law firms handle their Japanese business from home (Abel 1994, Myerson 1995). France allows foreign law firms to hire local lawyers and practice local law, but in 1992, France introduced more stringent requirements for non-EC lawyers, which has obstructed the establishment of US law firms (Abel 1994).

3.2 *Likely Twenty-first Century Developments*

The primary justification for restricting the admission and practice rights of foreign lawyers is to insure the quality of professional services. Because 'foreign' lawyers by definition practice in jurisdictions other than the jurisdiction in which they were trained, foreign lawyers may be less competent than local lawyers in matters involving local law. Because clients are presumed to lack the training to judge the quality of professional service, they must be protected, so the argument goes, by professional and state regulation.

Restrictions on foreign lawyers also serve an obvious anti-competitive function, because they restrict foreign competition with the local profession. To the extent that foreign lawyers seek to practice foreign or international law—and to the extent that sophisticated clients manifest a demand for foreign lawyers—restrictive practices are difficult to justify (especially when they are more restrictive than the rules of competing jurisdictions). Restrictive practices that are more burdensome than necessary to ensure the quality of professional services may violate international trade agreements, such as the General Agreement on Trade in Services (GATS) and the North American Free Trade Agreement (NAFTA) (Terry 1999).

In 1999, representatives from 29 national and international bar associations met in Paris to discuss regulatory issues raised by transnational practice, and to consider various strategies for reform. In general, participants in the 'Paris Forum' urged greater cooperation between national bar associations, and greater uniformity in the rules governing foreign legal consultants. In 2000, the American Bar Association established a Commission on Multijurisdictional Practice to reconsider the state-by-state system for licensing lawyers in the US. Concerned in part with remaining competitive with other professionals providing multijurisdictional service (such as accountants), the Commission is considering a variety of proposals to facilitate multistate and transnational practice (including a proposal to establish a national licensing system for foreign legal consultants).

Eventually, the current decentralized system for the regulation of foreign lawyers promises to give way to a more centralized system governed in part by external regulators (such as the World Trade Organization). Meanwhile, however, bar associations are scrambling to respond to the increasing demand for transnational legal services.

4. *The Emergence of Multidisciplinary Practice*

Since the mid-1990s, the 'Big-Five' accounting firms (Arthur Andersen, Deloitte Touche Tohmatsu, Ernst & Young, KPMG, and PricewaterhouseCoopers) have been aggressively expanding their capacity to provide integrated professional services—including legal services—on a transnational basis. They have done so, first, by employing lawyers to perform 'consulting' services: as of 1998, the Big Five collectively employed over 5000 lawyers in the area of tax consulting and approximately 5500 lawyers in areas other than tax (Terry 1999). Ernst & Young alone employs approximately 3300 tax lawyers worldwide (Farrell 2000). Currently, the Big Five accounting firms are among the largest employers of lawyers in the world.

The Big Five also have led recent efforts to establish 'multidisciplinary partnerships' (MDPs) between accountants and other professionals, such as lawyers, investment bankers, and management consultants. MDPs differ from other forms of multidisciplinary practice (including the employment of lawyers as consultants), in that they explicitly offer *legal* services and therefore implicate lawyer regulation (Daly 2000).

The move to integrate legal and other professional services has prompted heated debate among lawyers in the US and elsewhere. Opponents argue that lawyers' participation in multidisciplinary partnerships threatens core values of the legal profession, such as lawyer

independence, competence, confidentiality, and loyalty to clients (NSBA Special Committee 2000). Opponents argue, further, that some 'consulting' services currently offered by the Big Five—such as litigation support, estate planning, and some forms of business planning—constitute the unauthorized practice of law.

Nevertheless, client demand for multidisciplinary services is increasing. Regulation that inhibits lawyers' participation in—and ownership of—firms providing such services threatens to compromise lawyers' competitiveness in this growing and lucrative market.

4.1 Regulation at the End of the Twentieth Century

Only a few jurisdictions expressly allow multidisciplinary partnerships (Germany; Switzerland; New South Wales, Australia; Spain; and, to some extent, the UK), though some countries (Canada, France) appear to be on the verge of allowing them (ABA Commission on Multidisciplinary Practice 2000). Meanwhile, however, various forms of (informal) multidisciplinary practice are proliferating and for the most part have escaped regulation (Daly 2000). The tension between bans on multidisciplinary partnership and the evident increase in multidisciplinary practice threatens to undermine the authority of professional regulation.

In the US, for instance, all states prohibit the formation of multidisciplinary partnerships, if any of the activities of the partnership involve the 'practice of law.' (The District of Columbia is an exception: DC permits MDPs if the *sole* purpose of the partnership is the delivery of legal services.) Yet the enforcement of such regulation depends on a distinction between what lawyers in law firms do and what lawyers in non-law firms do—a distinction that often is difficult to maintain (Daly 2000). When does the 'practice of tax' become the practice of tax *law*? When does business consulting that includes strategies for legal compliance (for instance, with environmental regulation or anti-discrimination law) become the 'practice of law'? Though state bar associations have challenged accounting firms for engaging in unauthorized practice, such challenges have been unsuccessful.

In 1998, the American Bar Association established a commission to study the emergence of multidisciplinary practice in Europe and make recommendations regarding the recognition and regulation of MDPs in the US. After a year of study, the Commission unanimously recommended that MDPs be allowed; but that non-lawyer controlled MDPs be subject to annual certification and audits by state bar associations (ABA Commission on Multidisciplinary Practice 1999). The ABA House of Delegates rejected this proposal and directed the Commission to engage in further study.

In 2000, the Commission again recommended the recognition of lawyer-controlled MDPs, accompanied by the elaboration of firm-level controls (to be defined over time by the states). The Commission noted the increasing demand for multidisciplinary services, especially in the areas of tax, estate planning, and business and management consulting (ABA Commission on Multidisciplinary Practice 2000). The House of Delegates again rejected the Commission's recommendation—and disbanded the Commission. As a result, the US debate over MDPs has shifted to the states.

4.2 Likely Twenty-first Century Developments?

Proponents argue that MDPs offer unique benefits to clients, such as the benefits of one-stop shopping and integrated professional advice; and that clients should have the opportunity to choose multidisciplinary service. Proponents note, further, that many of the ethical challenges associated with MDPs are handled effectively in other settings (such as when lawyers are employed as house counsel); as well as in other jurisdictions that allow MDPs (e.g., see ABA Commission on Multidisciplinary Practice 2000). Most pointedly, perhaps, from the perspective of lawyers' collective economic interests, proponents argue that multidisciplinary practice, in some form, is here to stay; and that the main challenge for lawyers is to remain competitive in a multidisciplinary market.

One potential benefit to lawyers of forming MDPs is that MDPs provide lawyers with greater access to capital for technological development and geographic expansion. Most jurisdictions forbid non-lawyer investment in law firms (though legislation was introduced in New South Wales, Australia that would allow passive investment in law firms, and allow firms to sell shares on the Australian Stock Exchange). Some argue that restrictions on non-lawyer ownership limit law firm productivity and the efficiency of law firm management (Adams and Matheson 1998). MDPs also offer opportunities to 'cross-sell' professional services, and to capitalize on investments in professional reputation (Ribstein 1998).

Abbott (1988, p. 2) argues that the professions 'make up an interdependent system' whose 'boundaries are perpetually in dispute.' The dispute over the recognition and regulation of multidisciplinary partnerships promises to be a fascinating moment in the history of the legal profession. Its resolution will shape the organization of law practice and the boundaries of lawyers' monopoly in both local and global markets for years to come.

E. Chambliss

Lazarsfeld, Paul Felix (1901–76)

Paul Felix Lazarsfeld was born in Vienna, Austria, on Feb.13, 1901 to a middle-class professional couple—his father was a lawyer and his mother an Adlerian psychologist—and died in New York City on Aug 30, 1976. During his Vienna youth he was active in the political and intellectual milieu of Austrian socialism and was a leader in a number of socialist student organizations. He earned a Ph.D. in mathematics from the University of Vienna in 1925 and became Charlotte Bühler's assistant at the Psychological Institute. With the Bühler's backing he established the Wirtschaftspsychologische Forschungsstelle (Institute of Economic Psychology). Its best-known accomplishment was the study of an industrial village with long-term, massive unemployment (Jahoda et al. 1971).

As antisemitism was intensifying in Austria, Lazarsfeld arrived in the US in 1933 with a Rockefeller Foundation fellowship and decided to remain when it was extended for a second year. From the late 1930s, in a succession of positions at the universities of Newark, Princeton, and Columbia, and in research institutes and projects he led and/or founded, the Office of Radio Research and the Columbia Bureau of Applied Social Research, Lazarsfeld and his associates virtually created the field of mass communications research together with new methodologies and techniques in empirical social research (1940). In 1940, he was appointed to the faculty at Columbia University where he served until his retirement in 1969. At Columbia he initiated a program in political sociology marked by two pioneering longitudinal studies of the

1940 (*The People's Choice* 1944) and the 1948 US presidential elections (*Voting* 1954), of opinion leadership (1955), and of the effects of McCarthyism on higher education (1959). Methodological innovations such as panel (longitudinal) analysis, snowball sampling, and contextual analysis were pioneered and developed in this research. During this time the Bureau of Applied Social Research became the premier academic social research institute in the US.

In the 1950s Lazarsfeld and his collaborators turned to the codification and systematization of these methods which resulted in many journal articles and edited volumes (*Language of Social Research* 1955; *Continuities in the Language of Social Research* 1972). Later still he focused on the uses and applications of social research (*Introduction to Applied Sociology* 1975). He was convinced that training, methodology, implementation, and utilization of social research in a professional manner were best carried in organizational settings such as those he had created at the Bureau rather than as solo pursuits by individual scholars, and that these organizations should be aided financially and administratively attached to universities (1962). He himself participated in creating such institutes elsewhere in Washington DC, Oslo, and Vienna.

Although known primarily as a methodologist, Lazarsfeld had a theoretical vision and program he called the empirical analysis of action (1955). It was inspired by Max Weber's (see *Weber, Max (1864–1920)*) action theory, methodological individualism, and the operation of '*verstehen*,' framed in a realistic, empirical social psychology (*Max Weber* 1965). Its foundation was the choice studies of Lazarsfeld and his associates, on buying, voting, occupational choice, choice of friends, moving residence, and others (1959). Lazarsfeld's studies in the history of social research found precedents for a sociological theory built from the ground up on empirical foundations rather than top down abstract philosophyzing (1961).

Throughout his life, he pursued other interests and lines of work, notably mathematical sociology (*Mathematical Thinking in the Social Sciences* 1954), scaling techniques, in particular latent structure analysis which he invented (*Latent Structure Analysis* 1967), and multivariate statistical analysis with attribute variates. He had a close professional relationship with Samuel Stouffer. At Columbia, he became in 1962 the first Quetelet Professor of Social Sciences. He had a unique 30-year working and professional relationship with his colleague the theorist Robert K. Merton (Merton 1998). Many leading sociologists in successive cohorts of students at Columbia were educated, trained by, and collaborated with these two outstanding scholars. Lazarsfeld's personal style of doing social science was to recruit capable students and colleagues to work with him and to co-author books and articles. During his career, he received many honors, including honorary degrees from the universities of Columbia, Chicago, Vienna, and the Sorbonne. He was president of the American Sociological Association and the American Association for Public Opinion Research. He was a member of the National Academy of Sciences and the National Academy of Education. He was an institution builder who forged transatlantic ties by inviting European scholars to Columbia, and who served frequently as a visiting professor in Europe, helping create research institutes and programs in France, Poland, Norway, and Austria.

1. *Lazarsfeld's Methodology*

He distinguished philosophizing about social knowledge and how-to-do-it techniques from methodology, which is a systematic analysis and codification of what social scientists were doing on data collection, measurement, and drawing inferences from findings, i.e., explication and critique of the work of social scientists. Methodology was a creative act: 'intuition reconsidered in tranquility.' He identified four steps in measurement:

(a) imagery, or the sifting through intuition and disparate findings for an articulate idea. The goal was 'depth of conceptualization' (1959);

(b) concept specification and dimensionalizing;

(c) selection of indicators for each dimension; and

(d) the combination of indicators into an overall measure or index.

Indicators have a probabilistic relationship to an underlying dimension. With several indicators, however, the probability of describing a respondent correctly increases; thus, multiple indicators should be used (1958). Though the choice of indicators from a large pool is somewhat arbitrary, and though some respondents' answers will change depending on specific indicators, findings in the aggregate will remain the same as will the correlation between variables. This principle of interchangeability of indices removed an important challenge to internal validity in survey research.

Other advances in method included the 'accounting scheme' and 'reason analysis' for getting at an assessment of why people make certain choices by measuring dispositions and attributes, exposure to various influences, and the respondents assessment of their importance (*Analysis of Reasons* 1942).

In Lazarsfeld's approach to survey research much attention was expended on getting these four steps right and on creating a questionnaire that captured the process accurately. During the research that led to *The Academic Mind* (1958), the questionnaire went though eight versions over six months as the central 'apprehension' variable was sorted into a 'worry' and a 'caution' dimension in pretests, and indicators and wording appropriate for a faculty population ranging from small religious colleges to major research universities were carefully crafted. Lazarsfeld liked to end up

with a 'pivotal' variable that he said was 'less than a theory but more than a label for just one or two measurements' (1959). It organized a range of findings into a key concept or typology that provided deep insight into the topic and linked the research to other social science research. In Jahoda et al. (1971), the pivotal variable was apathy or resignation.

Although identified with quantitative techniques, Lazarsfeld favored combining information from a variety of sources. In Jahoda et al. (1971), the researchers made use of participant observation, census statistics, election results, library circulation records, newspaper circulation, school essays, family records, life histories, psychological tests, expert reports, even measurements of the walking speed of villagers. Mindful of critics who argued that survey research forced an individualist straightjacket on sociological topics, Lazarsfeld created contextual analysis. Groups, social units, organizations, and social milieus were characterized by global, relational, and aggregated variables called collective properties. These enabled hypotheses to be researched on social influences, climates of opinion, and other sociological processes (1961, *Continuities in the Language of Social Research*, 1972). Other methodological innovations that came out of the Lazarsfeld–Columbia tradition were deviant case analysis (*Language of Social Research* 1955), concept of property space and substruction for systematizing typologies, and snowball sampling (*Personal Influence* 1955).

2. Data Analysis and Statistical Inference

Lazarsfeld presented findings in a simple, understandable form to a wide public: two and three variable contingency tables and bar charts. He favored data collected in natural settings to controlled experiments carried out in a laboratory. Discrepancies between findings in survey research and in controlled experiments in communications research he attributed to selection effects, i.e., in natural settings people exposed themselves selectively to information and influences they tended to agree with. To compensate for the lack of control groups in natural settings, he developed a multivariate analysis derived from the English mathematical statistician G. Udny Yule, a pioneer in the analysis of covariance for categorical data (*Continuities in Social Research* 1950). The complex effect of three variables on one another is decomposed into a weighted sum of two variable effects. Starting with a hypothetical two variable relationship, a third 'test' variable is introduced to check whether the original relationship is spurious, contingent on the level of the test variable, or exhibits other patterns called specification and interpretation (*Language of Social Research* 1955, Sect. 2, pp. 111–66). Survey analysis is the art of probing hypothesis with test variables for ascertaining the conditions, contexts and domains, and extent to which they are true. In the 1940s and 1950s, computers were not available and statistical operations were performed on IBM countersorters using IBM data cards. For quantitative variables, desk calculators took much time and concentration to grind out even the simplest correlations. Thus, survey analysis seldom went beyond the simultaneous study of three variables. Although analysis of findings for causal patterns is nowadays done with multivariate regression techniques with statistical packages in computers in a matter of minutes, the logic of explanation in quasi-experimental design has remained the same.

In the Lazarsfeld's quasi-experimental designs, the time order of the variables was crucial because it ruled out some patterns of causation. Repeated observation on the same units, called 'panel' analysis and known today as longitudinal sample design pinned down a specific time order and became central in major Lazarsfeld studies. The 1940 election campaign study (*People's Choice* 1944) was based on five waves of interviews with the same respondents over several months. The method allowed a deep understanding of how various groups and types of voters formed political opinions and choices as a result of campaign, media and personal influences. Lazarsfeld (1955) realized that the study of long term effects, e.g., the cumulative impact of television viewing on children's attitudes and behavior, was beyond both the experimental and quasi-experimental methods then current.

3. Mass Communications and Political Sociology

Lazarsfeld and associates undertook two major election campaign studies, in 1940 (*People's Choice* 1944) and in 1948 (*Voting* 1954), both using a longitudinal design of repeated interviews with potential voters over several months in typical towns, and a study of opinion leadership among 800 women about marketing, fashion, movies, and public affairs (*Personal Influence* 1955) which used snowball sampling enabling influentials repeatedly named by the initial sample to be interviewed in turn. The findings challenged the conventional wisdom on democratic theory and on the mass media.

Political opinions and voting are only in part based on informed, calculated interest reflecting the arguments of parties, platforms, and candidates. Voting and opinion are social validations of group membership by conformity to social milieus and family tradition. Campaigns reinforce existing views rather than change them, reactivate those who were disengaged from politics, and foster turnout and participation. Much of the public have their minds made up early in the campaign. The least informed and those under cross-pressures from multiple group memberships delay making choices, are the most likely nonvoters, and are the most likely to switch their vote

between parties. Lazarsfeld's discoveries challenged the common notion that democracy would only work with an informed and enlightened public.

The impact of the mass media on voting is modest. Voters expose themselves selectively to views they tend to agree with. Moreover, in what he called the two-step flow of communication, people seek political guidance from opinion leaders in proximate social milieus—at work, in neighborhoods, in families—who are a transmission belt for public affairs and attitudes from the political class to the citizenry. Interpersonal communication is flexible and casual, from a trusted source, which makes it more effective than mass communications. Opinion leaders are found in every group and social stratum, and reinforce the dominant views of these social milieus. Thus, there is no large political influence from elites and top strata down to the lower strata. The impact of the mass media is limited and interpersonal communication has a conserving and differentiating effect on political opinion, attitudes, and choices. These findings challenged the views of many intellectuals, culture critics, and mass society theorists.

Lazarsfeld was open to criticism and was his own critic as well. On political sociology, he knew that he had neglected the institutional side of politics—political parties as organizations, platforms, choice of agendas. In mass communications, he regretted not studying the 'inside of the communications industry.' There were also missed opportunities: the pioneering campaign studies were not followed with studies of national campaigns that the University of Michigan's Survey Research Center undertook. And when television became the dominant mass medium, Lazarsfeld and the Bureau failed to develop a research program that was both acceptable to and supportable by the foundations and the networks.

4. *Lazarsfeld's Influence*

His greatest influence and lasting legacy is on social science methodology, on survey analysis, mass communications theory and research, and political sociology and political science, in which he created entirely new fields of scholarship, as has been described above. Public opinion polling and research has diffused worldwide. In a broad sense his research highlighted the importance of small groups and proximate social milieus, and personal influences on attitudes, opinions, and behaviors which sheltered people from macrosociological forces. Much of what Lazarsfeld accomplished has been incorporated thoroughly into social science and is not even referred to or footnoted. This is true not just in academic disciplines and university settings but in journalism, business schools, communications departments, market research, policy studies, and practitioners and professionals in related fields. Though he thought of himself as a marginal man in academia, both in Vienna and in the US, which he overcame with an entrepreneurial style of action combining intellectual and administrative innovation, he became internationally influential and recognized. His legacy and thinking live on in the pursuits and accomplishments of his colleagues, collaborators, associates, and students. At one time or another, and sometimes over many years, he was working with Robert Merton, Marie Jahoda, Hans Zeisel, Bernard Berelson, Patricia Kendall, Samuel Stouffer, Alan Barton, Elihu Katz, Ernest Nagel, Mira Komarovsky, Robert Lynd, C. Wright Mills, Arthur Kornhauser, Theodor Adorno (see *Adorno, Theodor W (1903–69)*), Morris Rosenberg, William McPhee, Frank Stanton, David Sills, Edward Suchman, Herbert Menzel, Leo Lowenthal, Joseph Klapper, Marjorie Fisk, Neil Henry, Sam Sieber, Wagner Thielens, Jr., Seymour Lipset, James Coleman, (see *Coleman, James Samuel (1926–95)*), Juan Linz, Herbert Hyman, Raymond Boudon, Bernard Lecuyer, Anthony Oberschall, and others. He was a man of broad learning and enormous energy who, in addition to social science was well-versed in history, the humanities, and the philosophy of science.

Leadership in Organizations, Psychology of

The primary focus of leadership in organizations is on managerial leadership as opposed to religious, political, and educational leadership, or informal leadership in peer groups.

1. *Leadership in Organizations*

Leadership in organizations is commonly defined as having and being seen to have the ability to influence, motivate, and enable others to contribute toward the effectiveness and success of a working group or an organization of which they are members. This conception is an essential component of most of the numerous definitions of organizational leadership that have been proposed in the literature (Yukl 2001). The same conception also emerged as a universal definition from discussions among scholars from about 60 countries worldwide as part of the Global Leadership and Organizational Effectiveness (GLOBE) cross-cultural research project (House et al. 1997).

The many definitions of leadership reflect serious disagreement, especially about the identification of leaders and leadership processes. Researchers who differ in their conception of leadership are likely to investigate different phenomena and to interpret empirical results differently. Yukl (2001) argues that at this point, it is neither feasible nor desirable to attempt to resolve the controversies on the appropriate definition of leadership. Leadership research should be designed to provide information relevant to the entire range of definitions.

Of equal importance is that particular initial definitions of leadership should not predetermine the answer to the central questions investigated in organizational leadership research, such as 'How to identify leaders?,' 'What are leaders doing?,' and 'What makes a leader effective?' Taking the identification of leaders as an example, a major proportion of leadership research was concerned with identifying personality dispositions, individual values, motives, and behavioral skills that would differentiate leaders from nonleaders or effective leaders from ineffective leaders. Smith (1995), speaking of leadership from a social psychological perspective, defines leadership as 'a quality attributed to people as a result of their interrelations with others.' This definition implies that leadership is not inherent in people (e.g., personality characteristics like intelligence or strength of power motives) or in the positions that they occupy (e.g., role scripts and specifications of rights and duties attached to a particular leadership position). Personal characteristics and peculiarities of positions should be seen as conditions that facilitate or inhibit the expression of leadership and its effectiveness, and as such, they are matters for scientific discovery rather than defining constituents of the terms 'leader' and 'leadership.' An example in the field of leadership processes is that some theorists argue that individuals who rely on coercion and manipulation for influencing followers are not really 'leading' them if leadership is understood in terms of exercising influence which results in fervid commitment by followers. This conception of leadership, however, is too restrictive in situations when force and manipulation are recognized as legitimate means of exerting beneficial influence on followers due to, for example, corresponding cultural values, or the followers' later assessment that the use of coercion and manipulation in particular cases was the best option.

2. *Context of Inquiry*

Throughout history, proper identification of effective leaders has frequently determined the survival or demise of groups, organizations, and entire societal cultures. Thus, it is no wonder that leadership has been of concern to the foremost thinkers and social philosophers in history (e.g., Plato, Machiavelli). Today, identifying and developing effective leaders are major concerns of industry (and the military).

The scientific research on leadership did not begin until the twentieth century. It is informed by conceptions and methods of science, that is, terms are defined in observable and measurable ways, theoretical assumptions are tested with objective evidence and the desire to find general principles guides theory development as well as the design of empirical studies. Leadership research mainly focused on factors that determine how well a leader is able to influence followers and to accomplish group and organizational objectives (i.e., leadership effectiveness). Also of interest were the reasons why certain persons emerge as leaders, the determinants of the way leaders act, and the perception of leaders and leadership in the 'eye of the beholders.'

3. Approaches to the Study of Leadership

Three major categories of leadership research can be distinguished based on where they place their emphasis for explaining leadership effectiveness:

(a) leader oriented trait and behavior approaches;

(b) situational or contingency approaches that incorporate situational factors; or

(c) approaches that address power and influence processes.

3.1 Trait and Behavior Approaches

The trait approach, focusing on a variety of relatively stable individual dispositions of personality, temperament, motives, and values, was dominant in early leadership research. However, the early trait approaches did not reveal a particular set of universally relevant traits to be successful (Stogdill 1948). Recently, personality traits have regained credibility in leadership research through advance in personality assessment. Today, traits such as high energy level, high self confidence, internal locus of control, emotional maturity, and integrity appear to be positively related to leadership effectiveness (cf. Yukl 2001).

A widely accepted research program on managerial motives was introduced by McClelland (1965) who suggested identifying unconscious individual motives with the projective Thematic Apperception Test (TAT) (see *Projective Methods in Psychology*). The optimal pattern of managerial motives, namely a moderately high need for achievement, a strong (socialized) power orientation, and a low need for affiliation, was shown to correspond with managerial advancement in various studies and somewhat less clearly with managerial effectiveness.

The research focus has changed from abstract traits to particular personal attributes that relate more directly to specific behaviors required for effective leadership, termed 'skills,' that is, the ability to do something in an effective manner. Leadership skills can be classified into technical skills concerned with things, conceptual skills concerned with ideas and abstractions, and interpersonal skills concerned with people (cf. Yukl 2001). Particular leadership traits and skills increase the likelihood of success but they don't guarantee it. For developing sound theories about how traits and skills affect leadership effectiveness, we need to understand how traits and skills are expressed in actual behavior.

Leadership behavior has been more widely researched than any other aspect of leadership. Throughout the 1950s and 1960s descriptions of leadership behavior and styles and their relationship to followers' attitudes and performance were investigated. Research at Ohio State University sought to classify relevant aspects of leadership behaviors and found that subordinates perceived the behavior of their leaders primarily in terms of two independent dimensions, initiating structure (i.e., task-oriented behaviors) and consideration (people-oriented behaviors). The questionnaire used in this research, called the Leader Behavior Description Questionnaire (LBDQ), is a hallmark in the history of leadership research. Various theoretical models capitalized on these two conceptions of leadership style, however, they perceive them to be two antagonistic poles of one dimension (bipolar models), by contrasting for example, theory X vs. theory Y, democratic vs. autocratic, participative vs. directive, or task vs. group maintenance oriented leadership behaviors.

A taxonomy of a variety of specific leadership behaviors was suggested by Yukl and associates (cf. Yukl 2001) distinguishing between task behaviors (e.g., clarifying role expectations), relations behaviors (e.g., mentoring), and transformational behaviors (e.g., empowering people to implement new strategies). Specific leadership behaviors seem to be better predictors of leadership effectiveness than abstract dimensions. For example, the cumulative empirical evidence speaks for 'clarifying role expectations,' in particular, the setting of specific challenging but realistic goals, as strongly predicting leadership effectiveness on followers' motivation and performance (Locke and Latham 1990).

Trait and behavioral approaches have the tendency to look for simple answers to complex problems. Particular leadership styles and behaviors may be effective only in certain situations or at some point in the leadership process but not at others. For example, monitoring behavior is useful for discovering problems, however, unless something is done to solve problems when discovered, it will not contribute to leadership effectiveness. By looking at situational conditions and patterns of behavior rather than at traits and isolated behaviors it is possible to predict leadership effectiveness in organizations to a higher extent.

3.2 Situational and Contingency Approaches

Situational approaches emphasize the role of contextual factors and how they either influence leadership behavior directly or moderate the relationship between leadership and measures of leader effectiveness (i.e., contingency). Several theories have been proposed, each of which stresses the importance of a particular array of situational factors (for reviews, see Bass and Stogdill 2001, Yukl 1998). There is no unified theory from which the most critical situational factors for leadership can be derived.

Fiedler's *Contingency Theory* concentrates on three situational factors (task structure, quality of leader-member relations, power inherent in the leader's position) that affect the leader's ability to influence followers depending on whether the leader prefers a task-oriented or a people-oriented leadership style.

Although the conceptions of Fiedler's theory and the empirical evidence are controversial, overall his work suggests that people-oriented leadership is more influential in moderately favorable situations than task-oriented leadership which works best in very favorable (high task structure, high quality of leader–member relations, high power) or very unfavorable situations.

Path-goal Theory by Robert House concentrates on an array of situational factors (task ambiguity, characteristics of followers, and the work environment) and suggests a situation-sensitive use of either directive, supportive, participative, or achievement oriented leadership styles in order to clarify for subordinates the path between performance and reward. The assumption is that the clearer the path is laid out, the higher is the followers' task motivation and performance. Despite inconclusive research results and conceptual deficiencies, path-goal theory provides a valuable conceptual framework for identifying situational factors relevant to leadership effectiveness.

Vroom and Yetton's *Contingency Theory* focuses on characteristics of short-term decision-making tasks. Their normative model prescribes the use of different leadership behaviors, ranging from autocratic, through consultative, to group decision-making, depending on the extent to which there is an objectively 'good' task solution available and the extent to which the followers' acceptance is required for proper enactment of the decision made. This approach received considerable empirical support and has been successfully used for leadership training purposes.

Implicit Leadership Theory developed by Lord and Maher (1991) is concerned with the cognitive processes of the led when confronted with leaders and leadership attempts. The theory posits that when a certain set of conditions and events is observed (or not), then individuals attribute that leadership has occurred (or not). Thus, leadership is regarded as a subjectively perceived rather than an objective construct. Individuals not only hold conceptions of prototypical leaders and evaluate actual leaders accordingly, but they also use their implicit leadership theories to judge the degree of leadership effectiveness. In so doing, they derive judgments about behavior that they actually have not observed. Implicit leadership theory poses a problem for the assessment of leadership through questionnaires such as the LBDQ because it underlines the long-ignored fact that we don't know whether such questionnaires measure the actual behavior of the leader or the leadership conceptions of the raters. Implicit leadership theory is to be viewed as a contingency approach because it suggests that the better the match between perceived leader attributes and behaviors, and the leadership concept held by the perceivers (the led), the more likely it is that the perceivers actually 'see' an individual as a leader (or an excellent leader) and allow the leader to exert leadership influence on them.

One basic message of these and many other situation-oriented approaches is that leaders must be able to flexibly adapt and cope with different and changing circumstances, otherwise they lose their influential status. However, adaptation and coping do not mean accepting situational factors as unchangeable conditions. Thus, we finally turn to power and influence approaches that address the issue of transforming attributes of the led, and the issue of transcending values and concepts so as to create an appealing vision (or a narrow-minded ideology) via leadership influence.

3.3 Power and Influence Approaches

Power approaches seek to explain leadership effectiveness in terms of the amount and type of power possessed and exercised by leaders. A classic distinction of forms of power was presented by French and Raven (1960): reward and coercive power, that is, the capability to offer incentives and to make use of organizational sanctions; legitimate power, when followers believe that the organizational or positional power over them is rightful; expert power, when high experience, knowledge, or ability are attributed; and referent power, when a person is referred to, or group norms are identified with, due to appealing personal qualities or values systems. Yukl (2001) describes three qualitatively different outcomes for the followers that result from employing these sources of power: commitment is most likely to be associated with referent and expert power, compliance with legitimate and reward power, and resistance with coercive power. The link between the use of power and behavioral approaches of leadership influence has been established by research on so-called influence tactics, for example, rational persuasion, consultation, ingratiation, exchange, coalition building, or pressure (cf. Yukl 1998).

Leader-member Exchange Theory (LMX) by Graen and his associates focuses on the development and the quality of the mutual relationship between leader and follower. Leaders are assumed to differentiate their followers according to their competence, trustworthiness, and motivation to assume ever more responsibility. Followers whom the leader perceives to display these attributes are categorized as so-called in-group members and in exchange are given more attention, support, and sensitivity by their leaders. The other, so-called out-group members, attract the more routine tasks and maintain a formal relationship with their leaders who in return exert influence with formal authority. Three 'currencies of exchange' between follower and leader, namely personal contribution, loyalty, and affect, have been identified. A meta-analytic review of LMX has been presented by Gerstner and Day (1997).

Transformational Leadership (Bass 1998) describes leaders to transform followers' attitudes and values, to activate their higher order motives and to stimulate them to transcend the organizations' higher order goals by their self-interests. The four components of transformational leadership (idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration) are measured in the Multifactor Leadership Questionnaire (MLQ) and were found to be empirically distinguishable and to relate to work unit effectiveness. Transformational leadership is often contrasted with transactional leadership which is based primarily on compliance and norms recognized through leader–follower exchanges, that is, reward and praise are given by the leader for task completion and loyalty given by the follower.

Charismatic leadership is defined more narrowly than transformational leadership. It specifies an idolized leader's characteristics as perceived and attributed by followers. Behaviors typical of charismatic leaders are for example, the articulation of appealing visions, communication of high expectations, and expression of high confidence in followers. Some evidence of the principally positive relationship between personal charisma and effectiveness, especially in situations of crisis, was presented by House et al. (1991) in an investigation of US American presidents and various measures of national effectiveness during each president's term.

There is also a 'dark side' to charismatic leadership. Problems that can occur with 'negative' charismatics are, for example, that they seek to induce commitment to narrow-minded ideological goals or to themselves, start projects with often unrealistic premises, omit properly investing in the implementation of their visions, and fail to develop competent successors.

4. *Issues of Concern for the Future*

The current body of leadership research includes over 5,000 studies and we know much more about leadership than is usually recognized (cf. Yukl 2001). However, there is a lack of research integrating the different aspects outlined above (leadership traits, skills, behaviors, situational factors, power, and influence processes). Today, a general theory of leadership is not available, but some authors have described the basic conceptual components that should be part of it (e.g., Yukl 2001).

On the way to developing general theories of leadership, two issues seem to be of particular importance. First, the psychological theories of personal leadership which dominate the field should be complemented by social psychological and sociological theories of 'shared' leadership which integrate situational factors within the social context and consider the social interactive nature of leadership processes. Second, the prevailing 'western' style leadership theories should be complemented by culture-specific and cross-cultural theories which are more appropriate for different societal cultures and for informing expatriate managers and a multicultural work force.

4.1 *Personal vs. Shared Leadership*

Most theories of leadership favor conceptions of unilateral influence by a single leader who is perceived as a person with outstanding characteristics. In order to understand how leadership is embedded in the dynamics of the social systems that constitute an organization, the unrealistic expectation of an 'heroic leader' who is more informed and confident than anyone else in an organization needs to be complemented by the view that leadership in organizations is a reciprocal influence process (cf. Smith 1995) involving many people from the various social systems in an organization. Bradford and Cohen (1984), speaking of 'shared' leadership, contend that the predominant conception of an 'heroic leader' undermines the principally positive effects of shared responsibility for leadership functions and empowerment of followers on leadership effectiveness. The questions of how power and leadership can be shared in organizations, and of identifying the conditions that increase the effectiveness of shared leadership deserve more research. However, this kind of research needs to employ social psychological and sociological conceptions of social interaction processes, leadership, and power as well as more elaborate research methodologies for investigating the complex nature of leadership within social systems that have been developed for studying the unilateral relationship between a single leader on followers.

4.2 *Cross-cultural Leadership Research*

The quantity of leadership research performed in cultures other than 'western' societies (e.g., USA, Canada, Western Europe) is very limited. This leaves it open as to whether the currently available leadership theories are universally applicable. We have good reasons to assume that there are some similarities but also marked differences in conceptions about leadership across cultures (House et al. 1997), even within particular regions that share a common market, like Europe (Brodbeck et al. 2000). For example, the GLOBE research program found that differences in the implicit leadership theories (Lord and Maher 1991) held by middle level managers are linked to the degree of societal cultural differences of the nations studied (Brodbeck et al. 2000, House et al. 1999). To move beyond a formal role in influencing others, one must first be perceived as a leader (or an effective or a trustworthy leader etc.). It is unlikely that someone

not perceived as a leader can exercise the influence on others necessary for performing effectively. With regard to culturally endorsed implicit leadership theories, it is expected that the less they overlap in terms of cross-cultural leader–follower relationships, the less likely it is that the leader will be accepted and the respective interpersonal relationships will be characterized by trust, motivation, and high performance.

The removal of trade barriers and the growth of global markets increases the permeability of organizational and national cultures. Managing a culturally diverse workforce and the transitions it entails requires that insights derived from research inform participants in a multicultural workforce, as well as the trainers and consultants facilitating them in accommodating values, skills, and behavior and adjusting the managerial context in suitable ways. Thus cross-cultural leadership research is clearly an important issue for future research.

Leadership in Organizations, Sociology of

1. A Definitional Confusion

The Anglo-Saxon etymological origin of the words lead, leader, and leadership is *laed*, which stands for 'path' or 'road.' The verb *laeden* means 'to travel.' Thus a leader is one who shows fellow travelers the way by walking ahead. This metaphor of the leader as helmsman is still very much on the mark. Unfortunately, the clarity of leadership's etymology is rarely matched with clarity of meaning. Papers, books, and articles claiming to delineate leadership proliferate, yet their conclusions can be confusing and even conflicting. Among the more popular are descriptions in terms of traits, behavior, relationships, and follower perceptions.

The proliferation of literature on leadership in recent years is amply reflected by the increase in the number of articles listed in the latest edition of the *Handbook of Leadership* (Bass 1990). Reading through this gargantuan tome, however, is a sobering and often bewildering experience. The content of the book demonstrates that the popularity of leadership research is not always equaled by its relevance. Rather than concentrating on what key decision makers at the strategic apex of their organization are doing in the context of their work environment, researchers all too frequently draw their major conclusions from laboratory experiments, observations of leaderless groups, or the activities of lower-level supervisors. If leadership is to be a viable area of study—and that study is to be of service to a constituency of executives—its research focus needs to be closely tied to observations of the behavior and actions of individuals in leadership positions.

2. A Proliferation of Theories

Broadly speaking, two extreme positions can be identified in leadership research. On one side of the spectrum are the 'personalists'—researchers who argue that specific personality variables determine leadership effectiveness. On the other side of the spectrum are the 'situationists'—those who deny the influence of individual differences and attribute all variations in leadership effectiveness to environmental constraints. While personalists views leaders as heroic helmsmen, in control of whatever situation they find themselves, situationists turn leaders into figureheads—puppets manipulated by the forces of the environment.

These opposing positions set the stage for a cornucopia of theories, each backed by strong defenders. We can find 'great man' theories, trait theories, situational theories, psychoanalytic theories, political theories, humanistic theories, cognitive theories, leader-role theories, reinforced change theories, path-goal theories, contingency theories, multiple linkage theories, vertical dyad linkage theories, exchange theories, behavioral theories, and attribution theories. This lack of apparent convergence has caused some scholars to abandon the subject altogether.

One of the problems in dealing with the subject of leadership is that it can be looked at as both a property and a process. As a property, leadership is seen as a set of characteristics—role behaviors and personality attributes—that make certain people more effective in attaining a set of goals. As a process, it is seen as an effort by a leader, drawing on various bases of power, to influence members of a group to direct their activities toward a common goal. Taking the property–process debate as a point of departure, let us turn first to the property perspective.

2.1 Order Out of Chaos

The trait theory (or great man theory) offered one of the earliest conceptual ways of looking at leadership. This theory holds that there is one best way to lead and that deeply seated personality variables allow certain people to master that best way. According to this theory, there are a number of universal characteristics of personality that determine a leader's effectiveness, without regard to behavior in a given situation. Because leadership is viewed as a set of relatively stable and enduring personal traits or physical properties, specific personality characteristics distinguish effective from ineffective leaders.

The initial search for these universal traits applicable to any setting was not overly successful, however. The results was conflicting, with methodological problems in research design cited as the major reason. Disappointed by the results of these studies, many scholars interested in leadership abandoned this line of research altogether, turning to other approaches to leadership. Recently, however—after a long hiatus in trait research (and with the help of better measuring techniques)—a revival of trait theory has been observed. Those studies that have gone beyond the simplistic, atomistic approach of previous trait studies have identified a number of personality characteristics that consistently emerge, differentiating leaders from nonleaders—dimensions of character that can be mapped into the Big Five model of personality structure (Hogan et al. 1994). These various dimensions can be described in terms of surgency (a broad term that embraces competitiveness, achievement orientation, self-assuredness, and dominance), agreeableness, conscientiousness, emotional stability, and intelligence (including emotional intelligence). In addition, these studies regularly list factors such as physical energy and extraversion.

Another group of leadership scholars espouses a behavioral theory. Distinguishing between the technical actions of a leader and the human actions, these behaviorists emphasize a set of observable role behaviors rather than traits. Like trait theorists with their individual characteristics, these scholars see certain role behaviors as being universal—that is, as producing leadership effectiveness regardless of the setting. Generally, however, the constructs employed by these scholars have been too rudimentary. This approach often looks at behaviors via dimensions such as consideration versus initiation, or task orientation versus relationship orientation (Bales 1958, Fleishman et al. 1955). Another popular typology with a behavioral slant on leadership contrasts autocratic and democratic approaches (Tannenbaum and Schmidt 1958).

From this approach to leadership behavior, we move on the continuum to contingency theory. Instead of taking the position that leadership traits or behaviors are applicable to any situation, those supporting the contingency theory claim that the emergence of any one style is contingent on the environment in which the leader is operating. According to this point of view, the most effective leader is the one who is able to adapt his or her actions depending on the situation. In the model of one of the most prominent advocates of this point of view, the effectiveness of task- or relationship-oriented leaders depends on the favorableness of the situation as defined by the power of their position, the task structure, and the quality of the leader-member relationship (Fiedler 1967).

2.2 The Importance of Attribution to Leadership

Another group of scholars espouses the attribution theory of leadership. According to these situationists, leadership is not a viable scientific construct; it is a mere label given to behavior. Only people's inferences about and reactions to leaders are viable (Calder 1977). Because individuals have an inherent need to

explain events that surround them, they assume that certain types of behaviors and actions can be attributed to the leader. Thus leadership is a perceptional issue, an illusion: individuals infer causation from observed behavior. The knowledge of the outcome causes individuals to attribute certain qualities to a leader.

This more situational point of view has been reinforced by a number of scholars of leadership who doubt whether leaders affect organizational performance. Advocates of this line of thinking contend that there are powerful external forces that shape organizational activities. Each leader is embedded in a social system—a system in which other actors not only have expectations regarding appropriate behavior but also make efforts to modify the leader's behavior—that places serious constraints on leader behavior. Leadership turns into a set of myths encouraging social construction of meaning, creating an illusionary causality (Pfeffer and Salancik 1978).

The symbolic role of leadership has been further explored by other leadership scholars (Meindl et al. 1985). In an extension of the attributional school of thought, these researchers call attention to the 'romanticized' conception of leadership. Ironically (given the attributional school's situational roots), these scholars suggest that leaders can play an important role through the manipulation of symbols in the management of meaning—activities that can be highly effective in influencing others. Using the vehicle of symbolism, many advocates of the situational point of view have been inching toward an interactionist approach to leadership studies, positioning the leader/led relationship clearly at central stage.

2.3 Leadership as a Charismatic Process

Like the attributional school of thought, the contingency approach has also set the stage for a more relational slant on the study of leadership. Believing a leader cannot be studied meaningfully in isolation from his or her surroundings, this approach views leadership as an interactive process between the leader, the followers, and the situation. This orientation, transcending earlier, more naive approaches to leadership behavior, is an important step forward.

The problem with many relational theories in the past is that their point of convergence was too narrow. Initiation vs. consideration, social orientation vs. task orientation, autocracy vs. democracy—such dimensions are overly simplistic in describing leadership in its context. Furthermore, these earlier relational studies focused far too much on exclusive superior–subordinate relationships, ignoring (or slighting) the various constituencies of the leader: the industry environment, the national culture, and the culture that characterizes the organization.

This shortcoming has opened the door for a fresh look at charismatic leadership. Another impetus for this line of research has been the prevalence of a business climate of uncertainty and unpredictability—a breeding ground for the emergence of charismatic leadership. In our competitive, global world, where the transformation and revitalization of organizations holds a central position, the leader is increasingly seen as a crucial agent of change.

The new focus, then, is on the inspirational role of leaders. Researchers are turning to the study of leaders who by force of their personality have an extraordinary effect on their followers. The challenge for leaders of organizations becomes how to affect the mind-set of the organizational participants through value creation, through influencing the organization's culture, and through building commitment to the organization's mission, objectives, and strategies to obtain well-above-average organizational performance.

The first person to take up this new challenge was political scientist MacGregor Burns (Burns 1978). In his writing, he extends Max Weber's reflections on charisma (Weber 1947), making a distinction between transactional and transformational leadership. While transactional leadership can best be viewed as a mundane contractual exchange based on self-interest (often described in the literature as the manager's role), transformational leadership seeks to satisfy the higher needs of followers—to engage in a process of mutual stimulation and elevation whereby followers will transcend their own self-interests for the good of the group (Bennis and Nanus 1985, Conger and Kanungo 1998).

A number of researchers have built on Burns' notion of transformational leadership, using observed behavior of leaders to break the concept down into various components, in an effort to broaden early charismatic conceptualizations. For example, Bass and Avolio (1993), who view charisma as a subset of transformational leadership, list four behavioral components in the context of transformational leadership: (a) charisma or idealized influence, (b) inspiration, (c) intellectual stimulation, and (d) individualized consideration. According to them, charisma alone is insufficient to put in place a successful transformation process. Shamir et al. (1993), building on earlier work done by House (House 1977), contend that charismatic leadership affects followers' self-concepts and has motivational consequences due to (a) changing follower perceptions of the task that has to be accomplished, (b) offering an attractive vision of the future, (c) creating a group identity, and (d) heightening individual and collective feelings of self-efficacy.

These various offshoots of a focus on the inspirational role of leadership contribute to a rich description of what the leadership mystique is all about. Researchers who view leadership as a charismatic or transformational process give proper attention to the

contextual and cultural dimensions that are part and parcel of leadership dynamics. They are sensitive to the impact of the environment on leaders and on their behavior. Furthermore, they reject narrow instrumentalism in favor of a perspective whereby the leader is seen as the transformational agent of change. Some scholars have made the point, however, that the transactional role of leadership should not be ignored. They suggest that the most effective leaders take on two roles: a charismatic role (consisting of envisioning, empowering, and energizing) and an architectural role (designing the organization, setting up structures, and formulating control and reward systems (Kets de Vries and Florent-Treacy 1999)).

Some scholars of leadership argue, however, that in spite of the new, richer color given to leadership research, additional steps need to be taken to deepen our understanding of the leader's relational interchanges. And the challenge is formidable. In spite of the various rational ways in which researchers attempt to deconstruct leadership and charisma, charismatic leadership is not rational in the traditional sense of the word. By its very nature, it is unstable, in that it exploits what can be interpreted as irrational processes. We need now to find ways to explore the forces that transcend rationality. Critics also argue that the study design of many researchers evaluating inspirational leaderships treats all leaders and all followers as amorphous, interchangeable groups of people; in other words, they fail to attend to differences in personality style. To rectify these shortcomings in leadership research, deeper insight into people's desires, wishes, and needs is needed; and that insight can be provided by a clinical focus.

2.4 The Clinical Paradigm

The clinical orientation to leadership research uses findings from psychoanalysis, cognitive theory, developmental psychology, and family systems theory to arrive at a richer understanding of personality and leadership. In the deconstruction of the dynamics of leadership, this orientation looks to the triangle of mental life consisting of emotion, cognition, and behavior. While in other approaches to leadership the focus is generally on cognition and behavior, in the clinical approach emotions enter the equation. Research on how people alter has revealed that cognition alone does not create change; cognition needs to be complemented by emotion. The clinical paradigm also factors in unconscious processes.

The clinical orientation toward the study of leadership has helped achieve greater understanding of the leader–follower interchange. Research into the dyadic relationships created by leaders (and acquiesced to by followers) suggests that failure in leadership can also be considered failure in 'followership': just as influence moves down from the leader to followers, so also does it move up. Understanding the impact of transferential processes such as 'mirroring' and 'idealizing'—processes characterized by confusion of time and place between leader and led—helps researchers clarify otherwise inexplicable phenomena.

The clinical paradigm, with its belief that every thought and action has a reason, sheds new light on irrational behavior in organizations. Processes such as projection, projective identification, splitting, collective regression, identification with the aggressor, *folie à deux*, the fear of success, scapegoating, narcissism, vindictiveness, and containment—along with other elements of the clinical paradigm—can help researchers better understand the leader–follower exchange. The clinical paradigm can provide insights into the dynamics of group behavior and the role of the leader; illuminate male–female differences in leadership through the analysis of fantasies around gender; and provide an understanding of the positive and negative effects leaders have on the corporate culture, structure, and decision-making processes (Kets de Vries and Miller 1984). By looking at a leader's inner theater, scholars can better appreciate the reasons why that leader derails and his or her company fails.

3. Future Concerns

Although, at first step, venturing into the domain of leadership research may seem like walking on quicksand, this brief overview demonstrates the considerable advances that have been made over the last decades. Due to promising new research directions, especially those working toward a gradual convergence of situationist and personalist positions, the prevailing attitude of disillusionment with leadership studies is experiencing a turnaround. Most researchers of leadership now perceive the importance of a relational, interactionist point of view that looks at actual leaders in their 'natural' setting. As a result, there is now considerable agreement that less laboratory and more field studies of leadership are needed. Moreover, it is no longer difficult—given the rapid changes of our era—to convince researchers of the relevance of the transformational side of leadership.

Although leadership research has come a long way, more work needs to be done. One key factor in the selection of topics that require further investigation should be relevance of a topic to leadership's various constituencies. But 'relevance' needs to be broadly construed: the subject of leadership should be seen as applicable not only to a few highly exceptional individuals at the top of the organization but to a much broader audience.

Meeting these criteria, a number of issues feature prominently on the research agenda of the future. Many of them address challenges growing out of the exponential rate of change in this age of transformation:

(a) The role of leaders as catalysts of change needs further exploration. All too many organizational transformation efforts fail, at great cost to people and society.

(b) As global mergers, acquisitions, and strategic alliances become increasingly common, more attention needs to be given to the cross-cultural dimensions of leadership. To what extent does effective leadership behavior vary from culture to culture?

(c) Given the cross-cultural focus of business today, we need to attempt identification of the required competencies for leaders who run global organizations.

(d) Likewise, we need to investigate the leadership implications for running cross-cultural teams.

Many issues centered around corporate governance are begging for further investigation:

(a) Top-executive role constellations need to be further explored. What new insights can be provided about complementarity of roles? What kind of underlying dynamics can be identified?

(b) Better methods of selecting people with leadership potential need to be developed. What can be said about early identification of leadership potential?

(c) Given the costly dramas that frequently surround top-management succession, how can we better understand the emerging psychological processes that go with it?

Those establishing a future research agenda must remember that leaders do not work alone. They need followers, and (with rare exceptions) they themselves are also followers; they also have many colleagues. Future research needs to address that collaboration:

(a) Followership needs to be given a more prominent place in leadership research. How, for example, do followers manage their leaders?

(b) Research money also needs to be devoted to the question of how leadership can be distributed throughout the organization. What can be done to 'stretch,' to get the best out of the most people? Given the increased reliance of organizations on creativity and innovation, what can leaders do to stimulate this process?

A final research category includes issues related to leaders' self-understanding:

(a) To guide others effectively, leaders must—absolutely must—know themselves. As part of that process, they need to recognize and explore their blind spots. Leaders who fail to take their irrational side into account are like captains who blindly plow their ships into a field of icebergs: the greatest danger is hidden below the surface.

(b) How we can develop leaders' emotional intelligence? Recognizing the limits of rationality, leaders must become more sensitized to the irrationality in themselves and in others.

Leaders fulfill many different roles in people's imagination. They are catalysts of change; they are symbols; they are objects of identification; and they are scapegoats when things go wrong. Leaders are also prone to hubris. As Napoleon (an expert on the topic of hubris as well as leadership) once said, 'Glory is fleeting, but obscurity lasts forever.' All leaders are susceptible to the darker sides of power. The most effective leaders, however, are the ones who know how to balance action with reflection by using self-insight as a restraining force when the sirens of power are beckoning.

Leadership: Political

Students of political leadership are faced with a paradox. On the one hand, the subject has been studied widely. There are many books and articles which deal with the concept from a theoretical perspective (e.g., Blondel 1987, Burns 1978, Edinger 1975, 1990, Paige 1977, Tucker 1981) and there is even more work which examines the actions of political leaders from an empirical point of view (e.g., Blondel and Müller-Rommel 1988, Elgie 1995, Jones 1991, and Rose and Suleiman 1980). On the other hand, though, the concept remains poorly understood. There is still no agreed definition of the term 'leadership.' Indeed, there are thousands of competing definitions (Rost 1991, pp. 37–98). In addition, over the years the study of political leadership has been associated with an almost bewildering variety of approaches based on radically different assumptions about the fundamental nature of the political process. The result is a situation where the main strength of leadership studies is also its principal weakness. That is to say, there is at once a tremendous richness to the study of political leadership *grosso modo*, but at the same time it remains an ill-defined and sometimes even slightly esoteric subfield of the political science discipline as a whole.

1. The Two Meanings of the Terms 'Leader' and 'Leadership'

The terms 'leader' and 'leadership' are understood in two particular ways. First, the terms are used in an institutional sense to mean the equivalent of office-holding. Here, they are merely shorthand ways of referring to people who hold particular positions of authority. So, for example, reference might be made to the president as the leader of the United States (US) or to a person having been elected to the leadership of the British Conservative Party. Second, the terms are also used in a behavioral sense to mean a certain type of relationship which occurs between the various members of a particular group. In this case, the 'leader' is the person who is able to convince the other members of the group to follow a particular course of action and 'leadership' refers to the process of interaction between the leader and the followers. In this sense, leadership is a reciprocal and essentially noncoercive relationship.

The fact that the terms 'leader' and 'leadership' can be used in these two different ways means, first, that leadership does not have to be exercised by leaders and, secondly, that there can be leaders who do not lead. The first of these initially perplexing statements refers to the situation where leadership in the behavioral sense is exercised by someone who does not occupy a formal position of authority. For example, social movements are often formed by individuals who are able to articulate demands which are latent within a community. By creating a sense of mutual purpose towards a particular goal, political leadership is present. However, it is often exercised in this case by unelected people who do not hold any formal office. Such people are, as Tucker (1981) puts it, non-constituted leaders, Martin Luther King being a prime example. The second statement refers to the situation where people who occupy formal positions of authority are unable to convince others that a particular course of action should be followed. These people are still office-holders and, thus, are leaders in the institutional sense of the term, but they are unable to influence others and exercise leadership in the behavioral sense of the word. One writer has suggested that 'headship' rather than 'leadership' might best describe the relationship between the leader and the other members of the group in this type of situation (Kellerman 1984).

2. The Study of Political Leadership

The study of political leadership reflects the two basic understandings of the term.

The first type of leadership studies examines the roles and powers of office-holders. The study of political leadership in this sense is intrinsically bound up with the fields of constitutional law, public administration, and government generally. Thus, the focus of inquiry is very broad. Amongst other things it includes country-specific or comparative studies of government figures at the central and subcentral level, the powers of state officials and party leaders, the profiles of elected representatives and political appointees, as well as the conduct of electoral campaigns and political contests. As befits the generality of this type of leadership studies, the subject may also be approached from a variety of methodological standpoints, behavioral, rational choice, and/or institutional. The result is a rich and very varied literature indeed. Classic examples include Neustadt (1965) and Linz and Valenzuela (1994).

The second theme in the work of political leadership concerns the study of how and why leadership in the behavioral sense comes about, if at all. This aspect of

the literature is somewhat more specialized. It is also more informed by work in other disciplines, especially social psychology and business and management studies.

The earliest studies of this type suggested that leaders were born not made. They were said to possess innate qualities which set them apart from others and which meant that they had a natural gift for bringing about followership and, thus, for creating history (Carlyle 1907—written in 1840). This approach, however, subsequently was opposed. Leaders, it was argued, were imprisoned by social forces with events being determined by the impersonal interplay of social and cultural forces over which individuals had little or no control (Spencer 1884). These two mutually exclusive approaches have long since been superseded. There is now general agreement that the study of political leadership should be approached from an interactionist perspective (Greenstein 1992). That is to say, the extent to which individuals are able to influence the political process is considered to be contingent upon the interaction between individuals and the environment in which they find themselves. Whether or not people who hold official positions of authority are able to affect the behavior of others depends on the qualities of the people concerned and the circumstances with which they are confronted at any given time.

Contemporary examples of this type of leadership studies have concentrated overwhelmingly on the first element of the interactionist approach, namely the motivations of individual political leaders. One aspect of this work concerns the long-standing issue of whether or not certain personality traits (such as intelligence or appearance) are positively correlated with successful leadership. The findings suggest that the importance of traits is situationally specific (Van Fleet and Yukl 1989). Another aspect relates to the concept of leadership styles, meaning the rigorous classification of the different ways in which leaders tackle the tasks before them. The most well-known example of this sort is Barber's study of the US presidential character (Barber 1972). One of the main reasons for the interest in Barber's thesis was because it appeared to have predicted that Richard Nixon would not be a success as president. So far, though, it has yet to be applied systematically outside the context of US politics. A further aspect relates to the work on political psychology. The literature in this subfield is very broad, but of particular interest to leadership studies is the work on psychobiography, or the explanation of political events in terms of an explicit theory of personality. A fine example of this approach is the study of Woodrow Wilson by George and George (1956).

All told, the study of political leadership encompasses a wide variety of work which approaches the subject from many different perspectives. This is, of course, a strength. That said, one of the weaknesses of the literature as whole is the absence of a unifying theory, never mind contending theories. The nature of the subject matter is such that it scarcely lends itself to such a grand project.

3. *The Future of Leadership Research*

In one sense the study of political leadership has gone somewhat out of vogue. The behavioral studies of the 1960s and 1970s proved to be less than compelling in their attempts to identify the essence of the concept. Indeed, it is perhaps telling that one of the most influential books of this era (Burns 1978) appears to have had a greater impact among students of management than within the political science community itself. In another sense, though, the study of political leadership is central to some of the most basic puzzles of political science: the relationship between structure and agency, between individual and collective action, between free will and determinism. Thus, there is still great scope for the advancement of this subfield. In this context, there are some specific research agendas to be promoted. Rejai and Philips (1997) note seven such areas: agreement about the definition of leadership; classifications of types of leaders; studies of women leaders; refining the distinction between leaders and elites; studies of minority and third-world leaders; the nature of crisis leadership; and the determinants of leadership duration. More generally, though, there is perhaps an even more urgent need to integrate the leadership factor into both rational choice analysis and the 'new' institutionalism. In terms of the former, to what extent does leadership affect preference formation and the articulation and definition of political choices? In terms of the latter, to what degree does leadership affect the creation of institutions and the process of institutional change? In these ways, the study of political leadership has the potential to continue to be at the heart of the political science project for the foreseeable future.

Leadership, Psychology of

Leadership is a process of social influence in which one person is able to enlist the aid and support of others in the accomplishment of a task or objective. *Effective* leadership requires that the person in the leadership role establish trust and credibility to enlist the support of followers; build relationships with those followers that motivate them to contribute their energy and resources to the collective effort; and manage, direct, and apply those collective resources to accomplish the group's mission or task. The study of leadership has focused on the characteristics of leaders, followers, and situational contexts. It has sometimes taken an individualistic focus and sometimes a group orientation. It has concerned itself both with the 'realities' of leader and follower behavior and situational parameters, as well as with the perceptual constructions and biases surrounding the leadership relationship. The paragraphs which follow will present the major empirical and theoretical trends in the leadership literature and will end with an integrative summary.

1. Early Attempts: Blind Alleys and Dead Ends

1.1 Traits

The first 50 years of scientific leadership research (roughly 1910–60) were characterized by failed attempts to find simple explanations for a complex phenomenon. The earliest research on leadership was influenced by the successes in the development of the first intelligence tests and pursued a search for a leadership trait, i.e., a stable, personal characteristic associated with leadership status or effectiveness. A wide range of obvious traits was chosen for examination, including intelligence, social sensitivity, dominance, physical height or bearing, and so on. Stogdill (1948) reviewed over 125 leadership trait studies and concluded that no single trait or collection of traits was consistently related to leadership status, nor, he concluded, should one expect them to be. He based his conclusion on two points of analysis. First, leadership was such a complex process and occurred in so many different contexts with different tasks and goals (e.g., combat leadership vs. academic leadership) that no one trait should predict leadership in all situations. Second, he believed that a truly useful theory of leadership would require the integration of leadership traits and situations and specify the nature of their interaction.

1.2 Behaviors

After traits, research focused on the description and measurement of leader behavior. A broad range of methods included interviews with workers describing their supervisors; observations and categorization of the behavior of student groups in the laboratory; and questionnaire ratings of military and industrial leaders. The most extensive and influential of these projects was the development of the Leader Behavior Description Questionnaire (LBDQ) (Hemphill 1950). The LBDQ included 150 descriptions of leadership behavior grouped into a questionnaire that allowed for the rating of leader behavior by subordinates, peers, superiors, or trained observers. Subsequent analyses of these ratings indicated that leader behavior fell into two general categories. The first, labeled *Consideration*, included leader attempts to create a positive group climate through attentiveness and consideration of the feelings and concerns of subordinates. The second factor, labeled *Initiation of Structure*, reflected leadership efforts to accomplish the group's assigned task by organizing, directing, and structuring the work of subordinates. These two

general behavioral orientations—a concern with task and a concern with followers—was common to many measures and observations of leader behavior, but did not, unfortunately, seem to have much predictive power to distinguish effective from non-effective leadership.

1.3 Situations

Although not at the mainstream of early leadership research, a few investigations of the effects of situational variables on leadership were done. While no common theory of situations emerged, it was found that situational factors such as the nature of the group's task, the structure of communication networks, and the number of people in the group could affect leadership patterns. The failure of the trait, behavior, and situational approaches highlighted the cogency of Stogdill's (1948) suggestion that a good theory must integrate these elements and set the stage for the emergence of the 'contingency theories.'

2. The Contingency Theories

The notion underlying contingency theories is that the relationship of a leader's characteristics (e.g., personality, behavioral style) to group performance is moderated by (i.e., *contingent* upon) aspects of the leadership situation or environment.

2.1 The Contingency Model of Leadership Effectiveness

The first and most extensively researched and validated of the contingency theories is the Contingency Model (Fiedler 1967, Fiedler and Chemers 1984). The leader characteristic included in the model is the leader's 'motivational orientation' which determines the priority of task accomplishment relative to interpersonal harmony. So-called 'task-motivated' leaders who emphasize structure, order, and clear directions are differentiated from 'relationship-motivated' leaders who emphasize cohesion, flexibility, and participative decision-making. The situational variable in the Contingency Model is the degree of predictability and orderliness in the task environment which is, in turn, determined by the supportiveness of followers, the clarity and structure in the task, and the amount of formal authority accorded the leader. Task-motivated leaders are most effective in situations where their emphasis on clear direction and structure fits well with existing levels of orderliness (i.e., highly predictable situations) or might contribute what is lacking and needed (as in highly unpredictable situations). Relationship-motivated leaders fare best when their more flexible and responsive style fits with the ambiguities of moderately predictable situations where some elements contribute to orderliness, but others might detract from it (e.g., situations requiring creativity or sensitivity to potential conflict).

Elaborations and extensions of the Contingency Model have shown that the fit between leader and situation was related to the leader's experienced stress and stress-related illness (Chemers et al. 1985), and that such stress affected the ability of the leader to make effective use of cognitive resources such as intelligence and job-related experience (Fiedler and Garcia 1987).

2.2 The Path–Goal Theory of Leadership

The basic premise of Path–Goal Theory (House 1996) is that the leader's most important function is to enhance subordinate motivation by clarifying the paths to the subordinate's goals and making it easier for the subordinate to traverse those paths. The empirical research on the model focused on how situational factors (including the subordinate's personality, needs, and task-relevant ability and the nature of the task environment), moderated the relative impact of the leader's 'structuring' or 'considerate' behavior on subordinate motivation, satisfaction, and performance. Path-goal theory predicts (with moderate to good empirical support) that leader structuring and direction will be most helpful and have their most positive effects when subordinates lack ability or are confronted with situations of task demand or complexity beyond their capability. Conversely, considerate and supportive leader behavior will be most satisfying and motivating for subordinates who are confronted with boring or aversive situations. In other words, leader behavior which provides what the subordinate needs most to cope with the situation will be most well received.

2.3 Normative Decision Theory

Vroom and Yetton (1973) presented a theory of group decision-making that argues that the most accurate and effective decisions will be made when the leader employs a decision strategy that is compatible with the characteristics of the decision situation. Decision strategies vary with the degree to which the leader allows subordinate participation in decision-making. Situational variables reflect the clarity of the decision environment (i.e., how much structured, interpretable information is available) and how cooperative and supportive the subordinates are. Autocratic decisions are most efficient when information is clear and followers are supportive. As decision-making ambiguity increases, because of follower resistance or equivocal information, more participative, democratic decision strategies offer the potential for greater

follower involvement leading to better information processing and higher motivation.

These three major contingency approaches, as well as a number of less prominent theories, share an emphasis on leader variables related to structuring vs. consideration and power-sharing and on situational variables related to clarity, predictability, and order. They all agree that the most effective leadership style depends on the fit or match to the situational contingencies.

3. Exchange Theories: From Transaction to Transformation

Leadership is a relationship between leader and follower, and like all relationships, must be grounded in both parties' perceptions that the relationship is fair and mutually beneficial. The quality of the relationship between leader and follower can vary widely.

3.1 Legitimacy

The act of choosing to follow a leader is based on the perception that the surrendering of some degree of personal autonomy will be advantageous to the follower. Hollander (1964) found that the legitimacy of an individual's status as a potential leader was based on followers' perceptions that the potential leader possessed task-relevant competence and loyalty to collective values and goals. A competent and trustworthy leader holds the promise of facilitating the goal attainment of the followers.

3.2 Quality of Exchange

Relationships between leader and follower can range from poor to excellent. Graen and Scandura (1987) report that high quality exchanges are characterized by a leader's willingness to afford the follower greater participation in decision-making, wider job scope, and more opportunities for personal development, and lead to greater follower motivation and commitment.

3.3 Transformational Leadership

The leader–follower relationship can move beyond a self-interested, *quid pro quo* transaction between leader and follower to an interaction which transforms the follower into a fully committed, mission-dedicated team member. House and Shamir (1993) argue that such transformative relationships are made possible by attaching the follower's personal identity and self-esteem to the collective mission. Bass (1998) has shown that transformative relationships are characterized by the perceptions of the leader as (a) possessing exceptional task-related competencies, (b) defining the group's mission in inspirational ways, (c) showing personal and individualized consideration for follower needs, and (d) providing a work environment for followers that is intellectually challenging and growth promoting. Teams led by such transformational leaders evidence much higher levels of motivation, commitment, satisfaction, and performance than average groups.

4. Perception and Judgment

Relationships depend on the perceptions of the parties involved—both perceptions of leaders by followers and other observers and judgments of followers by leaders.

4.1 Perceptions of Leadership

If leaders gain legitimacy by being perceived as competent and trustworthy, how are such judgments made? Extensive research by Lord and his associates (Lord and Maher 1991) reveals that judgments of leaders are influenced by two processes, labeled 'recognition' and 'inference.' People have expectations or 'prototypes' (i.e., sets of traits and behaviors associated with a social role) for leaders which provide the basis for recognizing a good leader. When a person behaves in a way that is seen as sufficiently similar to the leadership prototype, followers and other observers make the judgment that the person is, indeed, a leader or a good leader. Subsequent perceptions and memories of the leader are guided by the prototype, meaning that an individual already judged as a leader is more likely to be perceived and remembered as leaderlike in the future. Observers also infer a leader's competency by association with the outcomes of the group led. When groups are highly successful or unsuccessful, inferences are made to the leader. This tendency to attribute almost all group outcomes to the effects of leadership can be so exaggerated that it has been labeled the 'romance of leadership' (Meindl 1990).

4.2 Judgments of Followers

Leader actions toward subordinates are heavily determined by judgments of follower ability and motivation which are based on observations of follower behavior and task-related success and failure. Research indicates that leaders use a variety of contextual cues to understand the causes of a subordinate's success or failure, including the consistency of the performance, its uniqueness compared to the performance of other subordinates, and situational factors that might have affected performance (Mitchell and Wood 1980). However, the success and failure of subordinates have important implications for the

success or failure of the leader—a fact which makes leaders prone to ego-defensive judgments that can lead to placing the blame for failure on the individual subordinate while other possible causes (e.g., poor training, inadequate organizational support) are not considered (Brown 1984).

5. *An Integrative Summary*

The extensive empirical literature on leadership effectiveness can be summarized into three pervasive elements: image management, relationship development, and resource deployment. Effective leaders must be able to project an image of competency and honesty that legitimates the validity of their authority. They must establish motivating and rewarding relationships with followers by understanding follower needs and capabilities, and providing coaching and guidance that both facilitate good current performance and provide the possibility for personal growth. Finally, effective leaders must use the energies and resources of groups efficiently by matching the processes of communication, problem-solving, and decision-making to the task and organizational environment, i.e., by using directive and structuring process when the environment is clear and predictable and by using more flexible and participative process when the situation is equivocal and unpredictable.

Learned Helplessness

Learned helplessness refers to the maladaptive passivity shown by animals and people following experience with uncontrollable events. Learned helplessness also refers to the cognitive explanation of this phenomenon. The individual learns in one situation that responses and outcomes are independent, represents this learning as an expectation of helplessness, and then generalizes this expectation to other situations to produce passivity even if outcomes objectively can be controlled.

Researchers first described learned helplessness in the 1960s. Dogs were immobilized and exposed to a series of electric shocks. Regardless of what the dogs did or did not do, the shocks went on and off. Twenty-four hours later, these animals were placed in a long box with a barrier in the middle. Shocks were delivered periodically through the floor of the box, and the dogs could escape them by jumping over the barrier and

running to the other end of the box. Researchers found that animals previously exposed to uncontrollable shock acted passively when placed in a shuttle box. They simply sat there and endured the shocks. In contrast, animals without prior experience with uncontrollable shocks had no difficulty learning to escape the shocks.

These investigators proposed that the dog had learned to be helpless. When originally exposed to uncontrollable shock, it learned that nothing it did mattered because the shocks came and went independently of the dog's behaviors. They hypothesized that this learning of response-outcome independence was represented cognitively as an expectation of future helplessness that was generalized to new situations to produce a variety of deficits: motivational, cognitive, and emotional.

The deficits that follow in the wake of uncontrollability have come to be known as the *learned helplessness phenomenon*, and their cognitive explanation as the *learned helplessness model*. Learned helplessness in animals continues to interest experimental psychologists, in large part because it provides an opportunity to investigate the interaction between mind and body.

1. The Learned Helplessness Model

The learned helplessness model is at odds with a stimulus-response (S-R) view of learning because it proposes that the helpless animal learns not specific responses but rather general expectations affecting responses across a variety of situations. The helplessness model is a cognitive account of learning, and in the 1960s, it was a radical theory in a field long dominated by strict behaviorism.

Accordingly, much of the early interest in learned helplessness stemmed from its clash with the tenets of traditional S-R theories. Alternative accounts of learned helplessness were proposed by theorists who saw no need to invoke mentalistic constructs. Different alternatives were proposed, many of which emphasized an incompatible motor response learned when animals were first exposed to uncontrollable shock. This response was presumably generalized to the second situation where it interfered with performance at the test task. Said another way, the learned helplessness phenomenon is produced by an inappropriate *response* learned in the original situation rather than an inappropriate *expectation* (of response-outcome independence). For example, perhaps the dogs learned that holding still when shocked somehow decreased pain. If so, then they hold still in the second situation as well, because this response was reinforced previously.

Maier and co-workers conducted a series of studies testing between the learned helplessness model and the incompatible motor response alternatives. Several lines of research implied that the expectations emphasized by the learned helplessness model were operative. Perhaps the most compelling argument comes from the so-called *triadic design*, a three-group experimental design that shows that the uncontrollability of shocks is responsible for ensuing deficits. Animals in one group are exposed to shock that they are able to terminate by making some response. Animals in a second group are yoked to those in the first group, exposed to the identical shocks, the only difference being that animals in the first group control their offset whereas those in the second do not. Animals in a third group are exposed to no shock at all in the original situation. All animals are then given the same test task.

Animals with control over the initial shocks typically show no helplessness when subsequently tested. They act just like animals with no prior exposure to shock. Animals without control become helpless. Whether or not shocks are controllable is not a property of the shocks *per se* but rather of the relationship between the animal and the shocks. That animals are sensitive to the link between responses and outcomes implies that they must be able to detect and represent the relevant contingencies. A cognitive explanation of this ability is more parsimonious than one phrased in terms of incompatible motor responses.

Also arguing in favor of a cognitive interpretation of helplessness effects were studies showing that an animal can be 'immunized' against the debilitating effects of uncontrollability by first exposing it to controllable events. Presumably, the animal learns during immunization that events can be controlled, and this expectation is sustained during exposure to uncontrollable events. Learned helplessness is thus precluded.

Along these same lines, other studies show that learned helplessness deficits could be undone by forcibly exposing a helpless animal to the contingency between behavior and outcome. In other words, the animal is forced to make an appropriate response at the test task, by pushing or pulling it into action. After several such trials, the animal notices that escape is possible and begins to respond on its own. Again, the presumed process at work is a cognitive one. The animal's expectation of response-outcome independence is challenged during the 'therapy' experience, and hence learning occurs.

The studies described so far exposed animals to aversive stimuli (i.e., shocks). But it is also possible to produce helplessness by providing uncontrollable appetitive stimuli: food or water regardless of responses. Here an explanation in terms of incompatible motor responses becomes quite difficult to support. What is gained by holding still in response to food or water? Certainly not the reduction of pain.

Psychologists interested in humans, and particularly human problems, were quick to see the parallels between learned helplessness as produced by uncontrollable events in the laboratory and maladaptive passivity as it exists in the real world. Thus began

several lines of research looking at learned helplessness in people.

In one line of work, helplessness in people was produced in the laboratory much as it was in animals, by exposing them to uncontrollable events and seeing the effects on their motivation, cognition, and emotion. Unsolvable problems usually were substituted for uncontrollable electric shocks, but the critical aspects of the phenomenon remained. Following uncontrollability, people showed a variety of deficits.

Other studies further attested to the similarity between the animal phenomenon and what was produced in the human laboratory. Uncontrollable bad events made anxiety and depression more likely. Previous exposure to controllable events immunized people against learned helplessness. Similarly, forcible exposure to contingencies reversed helplessness deficits.

In another line of work, researchers proposed various failures of adaptation as analogous to learned helplessness and investigated the similarity between these failures and learned helplessness on various fronts. Especially popular was Seligman's proposal that reactive depression and learned helplessness shared critical features: causes, symptoms, consequences, treatments, and preventions.

2. *The Attributional Reformulation*

As these lines of work were pursued, it became clear that the original learned helplessness explanation was an oversimplification when applied to people. Most generally, it failed to account for the range of reactions that people displayed in response to uncontrollable events. Some people indeed showed pervasive deficits, as the model hypothesized, that were general across time and situation, whereas others did not. Further, failures of adaptation that the learned helplessness model was supposed to explain, such as depression, were sometimes characterized by a striking loss of self-esteem, about which the model was silent.

As used to explain human behavior, the learned helplessness model was therefore revised by Abramson et al. (1978) to emphasize the role of the person's interpretation of the cause of the original events. According to this reformulated theory, depression follows uncontrollability when a person explains an uncontrollable event with causes that are internal ('it's me'), stable ('it's going to last forever'), and global ('it's going to undermine everything I do'). Explanatory style refers to the causal explanations that people habitually offer for negative events. An internal, stable, and global style for explaining negative events is often described as a pessimistic explanatory style. Research shows that pessimistic causal explanations and explanatory style relate to depression as proposed by the reformulated learned helplessness model.

Explanatory style has since been extensively studied in its own right. Here is some of what has been learned. Explanatory style seems to take form as a coherent individual difference around 8 years of age, when children's cognitive abilities allow them to think in causal terms. Twin studies suggest that explanatory style is moderately heritable, but there is no reason to believe that there is a specific optimism-pessimism gene. Rather, such characteristics as intelligence, physical prowess, and attractiveness—which are themselves heritable—set the stage for success or failure in a variety of domains, and it is these experiences that lead the individual to entertain optimistic or pessimistic explanations for important outcomes. Early loss, such as death of a parent, or early trauma, such as sexual abuse, makes an individual more pessimistic. Early success makes an individual more optimistic.

Social learning is also implicated in the origins of explanatory style. Studies show convergence between the explanatory styles of parents and their children, although the fine detail of how an explanatory style is transmitted across generations has yet to be explored. Messages from schoolteachers, peers, and the media about the causes of events may also be critical.

Explanatory style has a vast array of consequences other than depression. Pessimistic explanatory style has been linked to various negative emotions and poor morale, to giving up and ineffective problem solving, to academic, athletic, military, occupational, and political failure, to social estrangement, to poor health, and even to untimely death. The mechanism by which explanatory style leads to these disparate outcomes has yet to be fully specified, but it is likely that the pathway is overdetermined, involving biological, psychological, and interpersonal processes.

3. *Conclusions*

Learned helplessness has become a popular line of investigation because it sheds light on humans' ills involving passivity. Helplessness theory, along with the attributional reformulation, suggests a ready explanation of such instances of passivity as well as interventions to prevent or remedy them. There is a downside to the availability of powerful theory. Some applications have been too zealous, overstating the similarity between learned helplessness on the one hand and a given failure of adaptation on the other. When applied carefully, however, helplessness theory can be highly useful, suggesting how maladaptive passivity can be changed or prevented.

Investigations of learned helplessness are ongoing. Laboratory studies with animals have delved into the biochemical basis of the helplessness phenomenon, suggesting that learned helplessness may have as much to do with anxiety as with depression. Furthermore, animal studies suggest that experience with uncontrollable events can sometimes disrupt the immune system, making illness more likely. Survey researchers

have started to look at how explanatory style and its consequences differ across cultures. What is identified in the Western world as a pessimistic style may be more common in Asian cultures that emphasize the collectivity and individual modesty. Finally, community intervention studies are exploring the use of cognitive-behavioral strategies for immunizing children against helplessness and its negative consequences.

Learning and Instruction, Social-cognitive Perspectives

1. Learning and Development in the Nature–Nurture Debate

Development and learning were for decades a matter of distinct ways of research and theoretical discussion, with a switch from the primacy of one of the poles, for example, from development as a basis for learning, to learning as a cause of development, with some radical positions, for example, learning without development. But the development–learning dilemma and the larger nature–nurture debate, even in the more recent forms of genetics and experience, has long hindered theoretical and methodological attention to the communicative social and cultural framing of the learning and testing situations considered. In the last decades of the twentieth century, important shifts in the research paradigms under consideration brought forward data that could not be interpreted anymore in terms of social factors as external variables affecting the learning of biopsychological individuals from the outside. It also required the consideration of the critical role played by social interaction in learning and instruction and the social construction of cognition within cultural activities.

This research has been built on a long tradition (e.g., the seminal works of scholars like Baldwin, Piaget, Wallon, Vygotsky, or Luria, and more recently, Bronfenbrenner). However, although it is one of the fundamental tenets of the social and behavioral sciences that human behavior and development is, at least in part, a creation of social forces, social interaction, and social appropriation, it is also true that theory and method do not always coincide in developmental work. Thus, there is a continuing search for the role of the 'social-interactive' in developmental theory and research.

One persuasive example is the enrichment and transformation of social-learning theory by cognitive dimensions to get a better understanding of the social and collective foundation of action and thought. Another example of this continuous struggle for a better match between theory and method is the revisitation of early twentieth century social constructivist scholars, such as Baldwin or Piaget . A third example is the ongoing mandate of interactionism, or the recent stream of 'postmodern' efforts at articulating reality as social construction. Finally, the recent debates about collectivism versus individualism deserve mentioning in this context.

On the surface, the fundamental role of social forces and social processes in the evolutionary and ontogenetic origins of behavior and the human mind seems clearly and widely acknowledged. Yet the translation of the intellectual agenda into scientific evidence continues to be incomplete. The non-social person-centered research paradigms seem to persist in the study of cognition, even when the fundamental role of context is obvious.

Many have tried to achieve a greater match between theory and empirical methods. At the turn of the century, several reviews have appeared that aim at similar goals (e.g., Baltes and Staudinger 1996, Carugati 1999, Resnick et al. 1991, Van der Linden et al. 2000, Perret-Clermont et al. in press).

These shifts in the perspectives on learning have been accompanied by changing views on the nature of

psychological development, the interdependencies between cognition, language, socialization, motivation and identity; and also on the nature of knowledge, no longer tied to individuals but relative to a community and subject to change. All of these approaches could still gain by devoting more attention to the critical role played by the communication and the construction of meaning in learning and instruction. This could enhance a revisitation of the current understanding of cognitive development, and contribute landmarks to the current educational endeavors that aim at encouraging learning together (not as isolated individuals), with relevant semiotic mediations on substantive issues.

2. *Gradual Shifts of the Paradigms: from the Individual to the Societal*

Studies on learning have operated gradual shifts of paradigms, from the overemphasis of the biopsychological functioning of the individual learner, where failure is necessarily seen as a sign of incompetence, to taking into account other social factors, either in a perspective inspired by Lewin's notion of field, or in a more macrosociological approach. Notably, the latter has called attention to major social problems in discrepancies in learning performances in students in schools, according to their social position (socioeconomic background, gender, ethnicity), educational methods and their hidden curriculum, the streaming structure of school institutions, etc.; and differences between the same subjects' performances in and out of schools. At the psychosocial level, evidence has pointed to field effects on performances. Since Orne's pioneering work in 1962, many studies have shown that the assessment of the subjects' competencies is affected by social factors such as the linguistic, motivational, attributional, identity characteristics of the subjects; teachers' expectations; individual and public dimensions of the situation; and the climate of cooperation or competition. The rather controversial results of these studies have called for a more integrative theoretical framework, articulating the various levels of analysis from the individual to the societal, in order to take into account the ways in which these factors interact. This relies upon precise descriptions of the networks of sociocognitive processes within which subjects think, behave, and learn (e.g., in the laboratory, at home, at school, in the street), and observations of the impact these experiences have on individual and collective cognition.

This has led to a new shift from determinism to constructivism, and from product-oriented studies to process-oriented ones. Studies were made on the interdependency between successful formal learning in schools and family socialization. Closer attention was paid to the teacher's role in defining precise expectations and giving adequate feedback to the students, on the one hand, and to the communication modes and patterns elicited in the learning and testing situations, on the other.

3. *Learning as a Sociocognitive Activity in Which Partners have an Essential Role*

It has been established that interaction, in order to be instructive, does not always have to be between a child (or novice) and an adult (or teacher/expert), but can be just as effective if it takes place between equally novice peers, given a certain number of conditions and for certain tasks. But this called for detailed studies of the influence of social interaction on the appropriation of cognitive tools. Some authors have illustrated the effects of the destabilization of the previous subjects' procedures (e.g., in problem-solving tasks). Destabilization triggers the questioning of, and the change in procedures and representations concerning, a given task (e.g., reasoning by recurrence; the notions of left and right; hypothetico-deductive reasoning in a fictitious weighting task). The control function takes on various forms: control can be exerted by triggering a verification of a statement or solution proposed by the partner, or by simply agreeing with or reformulating the partner's proposal. There appears also to be an interdependency between the type of problem to be solved, the cognitive functioning of the individual and the sociocognitive functioning of the two or more partners.

Recovering the importance of conflict, both in social and in developmental psychology, the notion of 'sociocognitive conflict' was introduced in order to stress the effect of the simultaneous confrontation of different individual perspectives, or points of view, during social interaction that necessitates and gives rise to their integration within a new cognitive organization. These experiments have explored under which conditions such confrontations with other points of view induce learning.

A further claim is made in studies on 'social marking' that show that the social regulations that govern a given interaction constitute an important factor for the building of a new cognitive coordination, because they bring a symbolic order that conveys meaning to the tasks.

4. *Learning as Participation in Social Discourse*

The problems of the meaning of a cognitive task, and the expectations activated in the subjects questioned both in experimental and in a more concrete school situation, are well-known in developmental psychology. Rose and Blank's studies (1974) on the role of double questioning in Piagetian tasks and Donaldson's (1978) study of tasks which 'make human sense' for young children, are only several examples of well-established studies that have had an important

influence on the study of communication in learning and testing situations, bringing forth evidence for the inextricability of meaning and expectations in every cognitive activity. A series of studies whose common ground is often the notion of 'contract' (inspired by Rommetveit's communication contract) have renewed the general claim that experimental and pedagogical situations are interactional settings governed by specific contracts, made up of explicit and implicit rules on the basis of which social actors adjust their behavior.

Failures in learning are reappraised as failures to communicate, and to convey meaning. Attention is then paid to the interactional patterns between teachers and students, and to the nature of the regulations that permit interlocutors to establish joint attention as a common object of discourse and maintain this common ground and mutuality. Learning is understood as participation in a social process in which meaning takes form (Bruner 1990), scaffolded by language and culture. And on the instructional side, authors explore the role of discourse in teaching.

5. *Studies of Learning Have Encouraged a Reconsideration of the Idea of Development*

Gradually, learning is appearing as the sociocultural experience of a person who is experiencing his or her agency within a history of social encounters, joint activity or *post hoc* individual or social meta-reflection. The basic research paradigm can no longer take the simple form of 'pretest–treatment–post-test,' as this chain of events itself gets its meaning partly from the setting and social context in which it is embedded. The pretest is already an interaction and in some ways a treatment from which the subject will draw information and experience on how to behave at the next step. What is it then that develops or that is learned along the different moments of a person's encounters with his or her social, semiotic and physical environment? The metaphors of children's developmental growth have usually been that of ascending lines, ranging from straight lines and scales to curves and spirals, all having in common, some vector towards fixed endpoints, with a general flavor of biological or cultural absolutes (such as formal reasoning, autonomous thinking, generalized and transferable competencies, etc.). The cognitive competency of the adult (teacher, mother, etc.) was usually taken for granted.

When the learner is considered as being the partner of joint activities and conversations in which he or she has stakes and continuously unravels and renegotiates rules, norms, and expectations, in changing social environments, then the form of development loses its determinism. New metaphors have been emerging to designate this sociocognitive activity in terms of gradual participation in socially shared cognition, and moves from peripheral participation to more central social positions in communities of practice, apprenticeship and guided participation, distributed cognition, the socialization to discourse in activity settings. It is becoming clearer that not only individual novices and tutors learn, they learn to become social learners, but also social entities.

Hence the shifts in the research paradigms have brought about very different understandings: learning as nurturing, a stage (or step-by-step) process of individual development; or learning as apprenticeship, via guided participation into the skills, discourses, and competencies of given communities of practices; or learning as co-construction and negotiation of activities, discourses, understandings, and identities.

Learning and Memory: Computational Models

Models of neural basis of learning and memory (also known as computational models or neural networks) are computer programs that simulate the perform-

ance of various brain structures in learning and memory, based on the theorized function of those brain structures. These models are able to produce results that match the behavioral results from human and animal studies. These models test the ability of existing theories to simulate behavioral results and also make novel predictions which lead to new experiments.

The basic structure of neural networks is a set of units (or nodes) which represent neurons in the brain. The connections between these units represent the synaptic connections between neurons. The connections are plastic and can change their strength based on some learning algorithm. The nodes are grouped into layers that have both forward and backward connections. These backward connections may be recurrent, whereby active units can feedback their activity onto other active units and form a pattern of activity for each input. In this way, inputs can enter the network, cause changes in connections within the layers, and produce an output that represents the learned behavior.

Models can be applied to learning and memory at different levels of specificity. At a general level, psychological models deal with a mathematical formula which is theorized as a mechanism for learning but do not apply this mechanism to any particular brain region. At a more complex level, qualitative models consist of a central concept or metaphor that attempts to capture the essence of the function of a brain region. Finally, neural networks apply mechanisms to particular brain regions based on the known circuitry of the brain region thought to be responsible for a particular learning task.

1. *Psychological Models*

The most influential psychological model of learning and memory is the Rescorla–Wagner (1972) model. This model proposed a mathematical equation which could account for learning simple associative tasks such as classical conditioning. In classical conditioning, a neutral stimulus (the conditioned stimulus or CS) is paired with a response-evoking stimulus (the unconditioned stimulus or US). Early in training, a reflexive response is elicited by the US while the CS elicits no response. Following repeated pairings of the CS and US, the CS begins to elicit a learned response (the conditioned response or CR).

The Rescorla–Wagner (1972) model assumes that the change in association between the CS and the US is a function of the difference between the US and an animal's expectation of the US given all CSs present on the trial. Because the discrepancy, or 'error,' between the animal's expectations and what actually occurs drives learning in this theory, the theory is referred to as an 'error-correcting' learning rule.

The Rescorla–Wagner model with this single simple error correction mechanism can account for much learning in classical conditioning including simple acquisition, discrimination learning, blocking, and conditioned inhibition. While the Rescorla–Wagner model can account for many learning phenomena it does not address where in the brain their proposed mechanism acts.

2. *Neural Network Models*

Psychological models such as the Rescorla–Wagner rule have been incorporated into subsequent neural network models. Therefore the mechanism of error correction can be solved within the context of specific neural circuits.

Neural network models have been put forth which address various kinds of learning and memories such as motor learning in the cerebellum, declarative memory, spatial learning, classical conditioning in the hippocampus, and conditioned fear in the amygdala.

3. *Motor Learning and the Cerebellum*

Motor learning is best understood through work on classical eyeblink conditioning in the rabbit. In classical eyeblink conditioning, a tone CS is paired with a corneal air puff US. The US elicits a reflexive eyeblink. Following repeated pairings of the tone and air puff, the tone begins to elicit a conditioned eyeblink response. Not only is a conditioned eyeblink elicited, but it is timed so that maximal eyelid closure occurs at about the time of the air puff arrival. In other words, not only is it learned that the tone predicts the air puff, but that the tone predicts the air puff's arrival at a specific point in time.

The acquisition of a conditioned eyeblink has been found to involve the cerebellum and brainstem structures (for review see Anderson and Steinmetz 1994). All of the cerebellar models of eyeblink conditioning to be discussed have a foundation in the earlier theories of Marr (1969) and Albus (1971). They proposed theories for a role of the cerebellum in motor learning and the error correction of ongoing movements. The cerebellum has two distinct input pathways: the mossy and parallel fiber system, and the climbing fiber system. These two inputs converge both on Purkinje cells in the cerebellar cortex and on neurons in the deep cerebellar nuclei. Marr and Albus proposed that these two systems are involved in motor learning. The convergence of these two inputs was thought to alter Purkinje cell responsivity to parallel fiber inputs. Marr (1969) proposed that the Purkinje cell responsivity would be facilitated by conjunctive activity in the parallel and climbing fiber systems while Albus (1971) proposed that the Purkinje cell responsivity would be reduced. Albus's (1971) prediction was demonstrated by Ito and Kano (1982) who discovered the phenomena of long-term depression or LTD, in which sim-

ultaneous activity in the parallel and climbing fiber systems caused a reduction of Purkinje cell responsivity to parallel fiber inputs. This change in Purkinje cell responsivity is the basis for many computational models of cerebellar function in motor learning.

As mentioned previously, the cerebellum and brainstem structures are necessary for eyeblink conditioning. The tone information is transmitted to the cerebellum via the mossy and parallel fiber pathway while the air puff information is transmitted via the climbing fiber pathway. The convergence of tone and air puff information in the cerebellum causes an increase in activity in the cerebellar deep interpositus nucleus which is associated with the conditioned response. Models of eyeblink conditioning have attempted to simulate the action of the cerebellum through a variety of mechanisms.

Some cerebellar models have been put forth which work on the error-correction principle of the Rescorla–Wagner (1972) model (Gluck et al. 1995). In this model, the cerebellar CR output is fed back to the inferior olive, which is the source of the climbing fiber input that conveys air puff information to the cerebellum. This feedback from the cerebellum is inhibitory. Therefore, as learning occurs, the cerebellum is inhibiting the air puff information from entering the cerebellum. In this way, the error signal of the air puff is reduced as learning to respond to the tone occurs.

Other cerebellar models are more concerned with the real-time aspects of the conditioned response. Not only is a conditioned eyeblink learned, but this response is well timed with regard to the arrival of the US air puff. Many models have been put forth which can account for the well-timed nature of the conditioned response through various mechanisms. Some cerebellar models simulate the real-time characteristics of the conditioned eyeblinks by way of a feedback loop that is similar in nature to the error-correction feedback loop to the inferior olive (Gluck et al. 1995). The feedback loop that is responsible for the well-timed nature of the conditioned eyeblink returns cerebellar CR output to the pontine nuclei, which are the source of the mossy fiber inputs. Therefore, there is a convergence of CS and CR information that allows for the proper timing of the CR. Another recurrent cerebellar model produces well-timed CRs due to recurrent connections within the cerebellar cortex between granule, Golgi, and Purkinje cells (Buonomano and Mauk 1994). Another type of real-time cerebellar model is based on tapped delay lines (Desmond and Moore 1988). In a tapped delay line model, the well-timed CR is due to a series of synapses arranged so that the CS arrival to the Purkinje cells is delayed until the proper time to coincide with the US.

A more physiologically accurate model of the cerebellum was put forth by Fiala et al. (1996) who modeled cerebellar timing of the conditioned eyeblink response using a model of the metabotrophic glutamate receptor in cerebellar Purkinje cells. The metabotrophic glutamate receptors elicit slow responses by way of phosphoinositol hydrolysis and calcium release, which bridges the time interval between the CS and US onsets. Temporal correlation of the metabotrophic responses and climbing fiber inputs produce phosphorylation of AMPA and calcium-dependent potassium channels. This phosphorylation leads to long-term depression (LTD) of AMPA receptors. The phosphorylation of calcium-dependent potassium channels reduces baseline membrane potential and also reduces Purkinje cell firing rates in the CS–US interval. The decrease in Purkinje cell firing rates releases interpositus cells from inhibition and allows them to fire at the proper time. Overall, the Purkinje cells are responsible for timing the conditioned response while the interpositus is responsible for calibrating the strength of the response.

All of these cerebellar models are based on the same anatomy and connections and can simulate most of the same set of trial-level and real-time characteristics of eyeblink conditioning through various mechanisms. The question which remains is whether all of these mechanisms are physiologically realistic and may be operating in parallel in the cerebellum, or whether only one of these proposed mechanisms is correct. In this way, computational models are driving future empirical studies that should further advance the understanding of the exact mechanisms of motor learning in the cerebellum.

4. *Hippocampal Models*

Another brain region which has been modeled by many investigators is the hippocampal region. The hippocampal region consists of the hippocampus, dentate gyrus, subiculum, and entorhinal cortex. The hippocampus is thought to be involved in many forms of learning including declarative and episodic memory (the remembering of facts and events), spatial learning, and some forms of classical conditioning.

One of the earliest and most influential models of hippocampal region function was proposed by Marr (1971). Based on the hippocampal anatomy and physiology, Marr sought to infer the information processing capacity of the region. Marr's basic idea was to distinguish separable roles in memory for the archicortex (including the hippocampus) from the neocortex. He assumed that the chief role of the neocortex was to store large complex event memories. The role of the hippocampus was to be a separate processor which could rapidly store event memories and then allow gradual transfer of this pattern to the neocortex.

Marr's model consisted of two layers of cells. Inputs cause activity in the first A layer of cells which project onto the second B layer of cells. The B cells in turn project back to the A cells. All connections between

cells are modifiable, but they are simplified to allow only binary on or off values. A stored pattern can be retrieved if, when part is presented to the A cells, the evoked activity on the B cells feeds back to complete the original firing pattern on the A cells.

The network described by Marr is a form of autoassociator. An autoassociator network learns to associate an input pattern with an identical output pattern. An autoassociator requires three basic features: (a) a high degree of internal recurrency among the principal cells; (b) strong, sparse synapses from external afferents, which could function as forcing synapses; and (c) plasticity at the synapses between co-active cells. These requirements are satisfied by the known physiology of the CA3 region of the hippocampus.

Fast temporary storage in an autoassociator is an important component of an episodic or declarative memory system (Alvarez and Squire 1994, Hasselmo et al. 1996, Hasselmo and Wyble 1997, Murre 1996). It is generally assumed in these models that a relatively small temporary store in the hippocampus interacts with a relatively large long-term storage neocortical system.

For example, in a network model of hippocampal function in episodic memory (Hasselmo and Wyble 1997), a stimulus enters the neocortex via the sensory system and subsequently activates cells in the entorhinal cortex. Entorhinal inputs funnel multimodal sensory inputs to various portions of the hippocampus by forming a very compressed or fused representation of the inputs. The dentate gyrus serves as a pattern separator and forms less overlapping representations of the entorhinal activity patterns. These differentiated patterns of activity are sent to the CA3 region of the hippocampus. The CA3 region serves as a recurrent autoassociator and encodes and retrieves the features. The CA1 region of the hippocampus receives inputs directly from the entorhinal cortex and forms representations of these compressed inputs. These CA1 representations are then compared to the recalled CA3 representations. Through these interactions between the entorhinal cortex, dentate gyrus, CA3, and CA1, specific episodic memories can be formed and accurately retrieved. Presentation of a portion of the original input can lead to retrieval of the entire memory by retrieval of the correct episodic memory representation by CA3.

The hippocampus in turn feeds back to the neocortex and initiates activation patterns there. It may activate new cell populations, which are then added to the representation, or it may allow connections to form between active cells in the neocortex. The hippocampus may be required to present memories to the neocortex repeatedly, over some period of time, to allow the neocortex to integrate new knowledge without overwriting the old. This process is termed memory consolidation. Over time, as consolidation occurs, the sensory input is able to activate these neocortical cells directly, without hippocampal intervention, in order to retrieve the stored memory.

Spatial memory is a hippocampal-dependent task in rats (O'Keefe and Nadel 1978), and many models of hippocampal processing in spatial learning have been based on autoassociative models of the hippocampal region. One strategy is to define spatial maps as composed of sets of complex associations representing places (McNaughton and Nadel 1990). In one place, there would be many views, depending on which direction the animal is facing. The hippocampal autoassociator would be able to map from one of these views to the full representation of the current place. Given this interpretation, spatial learning need not differ from other types of hippocampal learning.

The hippocampus is also thought to be involved in classical conditioning tasks that require learning about nonreinforced configurations of stimuli, contextual information, or relationships that span short delays. Several recent computational models have focused on possible information-processing roles for the hippocampal region (e.g., Eichenbaum et al. 1992, Gluck and Myers 1993, Myers et al. 1995, Schmajuk and DiCarlo 1991, Sutherland and Rudy 1989). Most of these models assume that while the hippocampus is required for some complicated forms of stimulus association, the neocortex and cerebellum are sufficient for simpler stimulus–stimulus associations such as those that underlie classical conditioning.

The key idea of one of these models, the Gluck and Myers (1993) cortico-hippocampal model, is that the hippocampal region is able to facilitate learning by adapting representations in two ways. First, it is assumed to compress, or make more similar, representations of stimuli that co-occur; second, it is assumed to differentiate, or make less similar, representations of stimuli that are to be mapped to different responses.

This model fits nicely with the hypothesized function of the entorhinal and hippocampal function previously mentioned. That is, entorhinal activity patterns are compressions of all the sensory inputs to the hippocampal system and the dentate gyrus separates these inputs into different patterns of activity.

More recent computational models have not only dealt with the hippocampal region in general, but attempted to differentiate the function of the hippocampus from the entorhinal cortex (Eichenbaum et al. 1994, Myers et al. 1995). In this way, these models have served to drive new empirical studies that test the predictions of the effects of different types of selective lesions within the hippocampal region.

It is very interesting that while the hippocampus is thought to be involved in a variety of apparently diverse memory types, the application of the autoassociator mechanism can account for these different memory functions. In this way the modeling work has served to form a more united understanding of the function of the hippocampus which is consistent

for spatial learning, episodic memory, and stimulus representations that may not have been apparent from the diverse empirical data.

5. Conditioned Fear and the Amygdala

Another brain region which has been modeled is the amygdala. The amygdala is thought to be involved in emotional memories, especially conditioned fear responses. The amygdala, specifically the lateral nucleus, receives sensory inputs from all modalities as well as highly processed sensory information from the association cortices and hippocampus. The fear circuit is best understood for auditory conditioned stimuli. Sensory information reaches the amygdala from the thalamus via two parallel pathways: a direct connection from the extralemniscal areas of the thalamus, and an indirect connection via primary and secondary auditory cortices.

Armony et al. (1995) implemented a model of the conditioned fear network. The architecture of the network is modular; relevant structures are represented by interconnected modules based on the anatomical connectivity of the amygdala. In the model the input patterns represent a range of tone frequencies. As a result of training with the input patterns, each unit develops a receptive field, that is, it responds only to a subset of input patterns centered around a best frequency. For simulating conditioning, all the input patterns are presented with one pattern chosen as the CS and paired with the US. This pairing resulted in some units showing frequency-specific retuning of their receptive fields, which matches with empirical results.

6. Future Physiological Models

A criticism of the computational models described above is that while the network nodes capture some of the response characteristics of real neurons, they are too simplistic in their input–output functions to represent the full range of physiological complexity in real neurons. Obviously, many factors such as neurotransmitter types, different receptor types, and membrane dynamics play an essential role in the responsivity and plasticity of neurons. The computational models previously described do not represent these features. Another class of models addresses these issues by modeling the biophysical, structural, and synaptic characteristics of individual neurons (e.g., Fiala et al. 1996). While these physiological models can simulate the action of individual neurons, they do not deal with large numbers of neurons in network connectivity. Future computational models should attempt to account for both network properties of learning and memory while maintaining physiologically precise mechanisms.

Learning and Memory, Neural Basis of

1. *Basic Learning- and Memory-related Neural Changes*

Much of our current understanding of basic memory-related neuronal changes and modifications stems from the pioneering research of Eric Kandel and his co-workers (Kandel 1998) who largely used an invertebrate, the marine mollusc *Aplysia* for their studies. Initially, they investigated simple memory mechanisms such as sensitization and habituation and found that there are both short- and long-term forms hereof and that the physiological correlates of the short-term forms are facilitated neuronal responses (increases in the magnitude of the excitatory post-synaptic potentials formed between sensory and motor neurons), and that of the long-term forms (repeated stimulus applications) required new ribonucleic acid (RNA) and protein synthesis (see *Protein Synthesis and Memory*), involving the growth of new synaptic connections between sensory and motor neurons. Later, they extended their work to gene expression and transcription factors which provided the genetic switch for memory consolidation and storage (see *Memory, Consolidation of*). A specific protein, named CREB, which stands for cAMP-responsive element binding protein, became a new standard label within this kind of research. cAMP stands for cyclic-adenosine monophosphate, a substance important for providing energy to cells. Other workers from both the invertebrate and vertebrate side demonstrated, for example, that adenylyl cyclase is an important enzyme for short-term memory (Zars et al. 2000) and long-term potentiation (LTP) as well as long-term depression (LTD). These are important mechanisms for memory consolidation (Lynch 2000) (see *Long-term Potentiation (Hippocampus)*; *Long-term Potentiation and Depression (Cortex)*; *Long-term Depression (Hippocampus)*). There is evidence that LTP and LTD lead to changes in the morphology of nerve cells, particularly to so-called synaptic plasticity (Coussens and Teyler 1996) and to changes in dendritic spine density (Engert and Bonhoeffer 1999).

The crucial questions are whether these findings can be directly transmitted to mammals and whether they hold for different kinds of memories (Eichenbaum et al. 1999). Here is less safe ground from current research (see, e.g., the findings of Zamanillo et al. [1999] against LTP as an essential prerequisite for memory formation) and the focus lies more strongly on metabolic changes which can be related to brain circuitries.

2. *Memory Representation Within the Mammalian Nervous System*

Amnesias (see *Amnesia*) in humans occur after a wide range of disease conditions (Markowitsch 2000). This fact alone implies that information processing in the mammalian brain is not controlled by a single center but, instead, by a distributed network. Furthermore, memory is also dependent on a large number of sensory, perceptual, attentive, emotional, and motivational processes each with its own anatomical substrates. The investigation of brain-damaged individuals consequently is of only limited predictive value for the action of the normal brain, as it demonstrates only what the brain can or cannot do without a particular region (Sometimes, a brain with a damaged region is compared with a chain in which a link is missing; this implies that with the lesioning approach the functions of the damaged area are, in a way, never attainable, as the respective region is missing). Therefore, the complementary approach of studying the intact brain with neuromonitoring (EEG, evoked potentials, magnetoencephalography) and the functional brain imaging methods methods (positron emission tomography, functional magnetic resonance imaging, single photon emission tomography) provides the necessary completion for inferences on the action of the brain (see *Functional Brain Imaging*).

In spite of the present-day range of methodological approaches for studying learning and memory representations in the brain, the old dichotomy between localizationists and antilocalizationists remains and can be perceived as one of ideology. The localizationists have a more mosaic-like view of information representation, they speak of 'centers' and 'modules,'

the antilocalizationists prefer a Gestalt-like view and emphasize interactions and networks. A bridge between the two can be built by assuming a mixture of hierarchical and parallel processes of information representation (McClelland and Rumelhart 1986; Barnden and Pollack 1991).

3. *Memory Systems and their Functional and Anatomical Correlates*

The study of mammalian and in particular of human memory has to acknowledge the existence of several memory systems and their different neural representation. Aside from short-term memory (see *Short-term Memory: Psychological and Neural Aspects*, there are at least four major long-term memory systems: (a) the perceptual representation system (PRS), (b) procedural memory, (c) the knowledge system (or semantic memory), and (d) episodic memory (Schacter et al. 2000, see also *Episodic and Autobiographical Memory: Psychological and Neural Aspects*). The PRS refers to the fact that nonconscious presentation of a stimulus may lead to a higher probability of re-identification of it at a later time point; procedural memory is usually skill based, examples are riding a car, skiing, or playing the trumpet—that is, nonconscious, automatic processing of information. Both of these systems, but sometimes also the knowledge system, are termed implicit memory (see *Implicit Learning and Memory: Psychological and Neural Aspects*). The knowledge system (semantic memory) refers to general facts ('world knowledge') of the kind: 'Madrid is the capital of Spain' or '12^2 is 144.' While the knowledge system consists of context-free facts, the episodic memory system (see *Episodic and Autobiographical Memory: Psychological and Neural Aspects*) represents context- (time, locus) embedded information. These episodes allow a mental time travel. One of the important distinctions between semantic and episodic memory is therefore that the latter allows to remember the episode and the former simply to know the fact.

3.1 *Short-term and Working Memory*

The concept of working memory derived from the earlier one of short-term (and long-term) memories. While, however, short-term memory is seen as the on-line holding of information for an initial time period after first confrontation with it, working memory refers to a multicomponent, active processing of information which also includes the transmission of already long-term stored information in a temporary buffer prior to retrieval, and which is composed of a controlling central executive system and a number of subsidiary slave systems (Baddeley 2000).

Numerous experiments using monkeys, cats, and rats have reported that bilateral damage to the prefrontal cortex interferes with the short-term storage of information and that single units in this region display working memory related neuronal firing (Goldman-Rakic et al. 2000, see also *Working Memory, Neural Basis of*). Results from evoked-potential recordings and functional imaging studies have confirmed the dominant role of prefrontal regions for working memory in the human brain. Some reports found that damage to parietal regions impairs the on-line processing of information. Consequently, a frontoparietal network is seen as engaged in the control of attention and in processes of on-line working with memory.

3.2 *The PRS and Procedural Memory*

The two principal memory systems, which function independent of limbic system structures and of conscious reflections, are procedural memory and priming. There are two basic forms of priming, perceptual and conceptual—perceptual priming refers to the direct match between the presently and the previously perceived stimulus, while conceptual priming refers to the same category or class of the present and the previously perceived stimuli. The distinction between these two forms is important as conceptual priming apparently is more complexly represented in the brain, recruiting more or other neural structures than perceptual priming. Consequently, conceptual priming deteriorates in age-related brain diseases and possibly even in patients with limbic-system related amnesias, while perceptual priming does not (see *Amnesia*). Conceptual priming has been related to prefrontal and even partly to medial temporal regions, while perceptual priming has much stronger affinities to unimodal areas of the posterior neocortex.

The procedural memory system is closely related to motor regions of the brain—to the basal ganglia, to portions of the frontal lobe, particularly of the premotor and motor cortex, and to cerebellar structures (some authors question, however, a specific role of cerebellar structures in procedural memory). Therefore, diseases such as Parkinson's disease are taken as models—at least during the initial disease process—for selective procedural memory deficits (Thomas-Ollivier et al. 1999).

While not much is known about the processes from information encoding to information retrieval, there is at least preliminary evidence that principally the same structures activated during the initial stages of information transfer are also relevant for the late ones and even hold for storage of this implicitly learned information.

3.3 *Brain Regions Relevant to Episodic Memory and the Knowledge System*

Episodic memory and the knowledge system are sometimes combined and then named declarative

Figure 1
The medial (Papez) (right) and the basolateral limbic circuits (left). The Papez circuit is composed of the hippocampal formation, mammillary bodies, anterior thalamus and (conventionally) the cingulate cortex. These regions are interconnected via the fornix, mammillothalamic tract, thalamocortical peduncles and the cingulum. The components of the basolateral limbic circuit are the amygdala, the thalamic mediodorsal nucleus and the subcallosal area (basal forebrain); here interconnections are the ventral amygdalofugal pathway, the inferior thalamic peduncle, and the bandeletta diagonalis. It is assumed that both circuits are relevant especially for encoding of information associated with the episodic and knowledge memory systems and that the medial circuit is more strongly engaged in the cognitive and the basolateral one in the affective side of information processing

memory (Squire and Knowlton 1999, see also *Declarative Memory, Neural Basis of*). Both systems have in common that they—at least during the stages of memory encoding and consolidation—rely on structures of the limbic system (Mesulam 2000), the episodic memory system most likely in addition on prefrontal structures (see *Limbic System*). For retrieval of information, there seems to be a distinct lateralization; it appears that primarily right-hemispheric regions are engaged in episodic and primarily left-hemispheric ones in semantic-memory retrieval (Tulving et al. 1994, Markowitsch 2000).

The structures of the limbic system have long been discussed as important for transferring information from short- to long-term memory (see *Limbic System*). More recently, components of this system have been combined under the headings 'medial temporal lobe' and 'medial diencephalic memory system' and have been named bottlenecks for information transmission from short- to long-term memory (Markowitsch 2000). For the first system, the hippocampal formation was (and still is) seen as its hub for the second, medial thalamic nuclei and the hypothalamic mammillary bodies are core structures and Korsakoff's syndrome is one of the most well-known diseases associated with it (see *Hippocampus and Related Structures*; *Temporal Lobe*; *Hypothalamus*; *Korsakoff's Syndrome*). However, it is more a matter of philosophical preferences whether one sees both systems as separate entities or as one. Likewise, there has been a waxing and waning discussion of the contributions of individual regions to memory formation (Tulving and Markowitsch 1998). Aside from the hippocampal region, the amygdala and paralimbic cortices have to be listed for the medial temporal system, and certain medial and anterior thalamic nuclei, the mammillary bodies, and interconnecting fiber bundles for the medial diencephalic one; structures of the basal forebrain and the ventral striatum may be added (Mesulam 2000, Markowitsch 2000).

There is another division of the limbic system which receives support from a number of sources, namely the distinction between two interacting circuits: (a) the medial (or Papez-) circuit centered around the hippocampus, and (b) the basolateral limbic circuit (amygdaloid circuit). While Papez (cited in Markowitsch 2000) considered his proposed circuit (hippocampal formation → fornix → mammillary bodies → mammillothalamic tract → anterior thalamus → thalamocortical peduncles → cingulate cortex → cingulum → hippocampal formation) as principally engaged in the analysis of emotions, subsequent work showed that it plays a critical role for the transfer of information into long-term memory. The basolateral circuit is more closely related to emotional processing, but is also relevant for encoding the emotional valence of experiences. It includes the amygdala, the mediodorsal nucleus of the thalamus and associated regions, largely situated in the basal forebrain and in its extensions to anterior insular and temporopolar cortical areas plus interconnecting fibers such as the ventral amygdalofugal pathway, the anterior thalamic peduncle and the diagonal band (Fig. 1).

Bilateral damage to structures within the medial circuit is usually followed by severe memory disturbances—a fact which led researchers to speculate that

amnesia might arise from an interruption of interconnections within this circuit and that the structures of this circuit are necessary for consolidation and for the transfer from short- to long-term storage (see *Amnesia*). Bilateral damage to structures within the basolateral limbic circuit, on the other hand, seem to degrade memory processes by disconnecting the emotional from the mnestic properties of a given set of stimuli. For example, bilateral damage to the amygdaloid region may induce the Klüver–Bucy syndrome characterized by hyperorality, hyperphagia, agnosia, amnesia, hypersexuality, tameness/placidity, and hypermetamorphosis. Since information encoding is, especially for episodic (autobiographic) information, dependent on emotional content, damage to the amygdala is likely to have detrimental effects on memory. This indeed was shown in patients with Urbach–Wiethe disease; such patients manifest a selective bilateral damage (mineralization) of the amygdalae. Two such patients were presented stories containing emotionally charged items and asked to recall them. They were significantly impaired because they could not show the preferential encoding of emotionally-laden vs. neutral items (Cahill et al. 1995).

Lesions in the basal forebrain (e.g., medial septum, basal nucleus of Meynert) may also disturb memory processing, though the deteriorations on the memory side are usually less severe and enduring than those after medial temporal or medial diencephalic damage; personality disturbances and tendencies to confabulate, on the other hand, are more common.

The similarity between the amnesic conditions arising after bilateral damage to medial temporal and medial diencephalic structures led Squire et al. (1993) to conclude that these structures might be components of a common memory system and to speak of 'medial temporal–diencephalic amnesia.' While this seems likely, there may also be regional functional specializations. Patients with bilateral diencephalic damage seem to have less awareness of their memory, a higher tendency to confabulate, and a larger span of retrograde amnesia than those with medial temporal lobe damage.

3.3.1 Encoding and consolidation. While encoding refers to the more early stage of information acquisition, there are different views on the beginning and end of the consolidation phase. Sometimes, it is seen as directly succeeding the encoding phase, sometimes it is viewed as a process occurring after information has already been stored long term. As both encoding and consolidation of episodic and semantic memories engage structures of the limbic system, they can be perceived as closely related.

There are nevertheless single cases of patients with amnesias of various origins showing a wide range of unstable memory processing periods (Markowitsch 2000) so that it has to be concluded that there are several states and stages of memory consolidation which depend on complex anatomico–behavioral interdependencies. A comparison with repeated attempts of producing a complex painting may be apt. Still, medial temporal and diencephalic regions contribute substantially to both the stages of encoding and consolidating by triggering, accompanying, and assisting the steps from initial binding to the final assignment. Especially the hippocampus has been proposed to index (previously encoded) information and assign it to specific cortical loci. Amygdaloid and septal regions may evaluate and filter for importance—that is, they screen the biological and social significance of perceived stimuli.

Aside from the more 'classic' limbic regions, functional brain imaging results have pointed to a strong role of prefrontal cortical areas in both encoding and retrieving of information. Among the first studies were those of Tulving and co-workers (1994) who condensed their findings in what they termed the 'hemispheric-encoding-retrieval-asymmetry' (HERA) model of information processing. This model considers prefrontal regions as important for information processing, but assigns different roles to the left and right frontal lobes: the left one being necessary for encoding of semantic and episodic information and the right one for the retrieval of episodic memories. While this model has sometimes been questioned or modified, there is still accumulating evidence for its principal validity. Current research tries to specify whether there are differential contributions of dorsolateral, polar, and inferolateral prefrontal regions and to what degree the prefrontal contribution can be regarded as a process of working memory.

3.3.2 Storage of information. The ways in which information is—frequently life-long—stored in the brain, is one of the biggest riddles of the neurosciences. Most scientists agree that the nervous system contains or forms the medium for storage, the more concrete mechanisms vary between species—invertebrates with their more 'rudimentary' nervous system may indeed have adopted other representations than mammals. Genetic and biochemical processes may nevertheless be common denominators (Kandel 1998). For mammalian nervous systems, information may very likely be distributed along widespread cerebral cortical networks (McClelland and Rumelhart 1986) with or without auxiliary engagement of subcortical limbic structures (Markowitsch 2000). The expanded cortical association areas with their large number of neurons and neuronal connections are primary candidates for information representation. Especially for emotionally colored memories—such as our biographical episodes—the

Figure 2
The regions of the temporal pole and the inferior lateral prefrontal cortex which are interconnected via the uncinate fascicle. This regional constellation of the right hemisphere is assumed to control the retrieval of episodic memories, and the left-sided one that of the knowledge system

cortical nets may engage and trigger affect-coding limbic regions for their rerepresentation or 'ecphory' (Markowitsch 2000, Sara 2000, Tulving and Markowitsch 1998). (Tulving reintroduced the term ecphory to describe the process by which retrieval cues interact with stored information so that an image or a representation of the information in question appears.)

There are, however, a few scientists who are of the opinion that most of our memories are represented outside our nervous system. Romijn (1997) considers a submanifest order of being as the principal storage place of memories. He is of the opinion that the whole universal in its spatial–temporal configuration would be permanently present in the submanifest order of being. Of this, a small portion would continuously materialize and thereby become available for psychic processing. Declarative memory would be found somewhere in the individual area of the submanifest order of being. Similar views are held by Sheldrake (1988) and Hameroff et al. (1998).

3.3.3 Retrieval of information. The conventional view is that retrieval activates similar (namely mainly limbic) brain structures as does encoding. This view may, however, be false or at least only partly correct: As mentioned above in connection with the HERA model of Tulving et al. (1994), the prefrontal cortex is a primary region for information retrieval. Converging evidence from brain-damaged patients and from studying normal subjects with functional imaging methods points to the necessity of (inferolateral) frontal and anterolateral temporal cortical regions for triggering the network-like stored information for successful retrieval (Markowitsch 1995, 2000) (Fig. 2). While a few authors even assume the temporal cortex to be the actual storehouse of information, here the view is favored that it provides the most direct access to the cortical network, while the prefrontal cortex is responsible for providing the effort necessary for a successful overall neural activation. Limbic structures of the medial diencephalon and the medial temporal lobe may have supporting roles in

context-rich information retrieval (Markowitsch 2000).

Retrograde amnesia—the failure of ecphory—may occur as a consequence of a progressively decaying cortical network—as is the case in patients with cortical dementia (e.g., Alzheimer's disease) or, sometimes, after a condition of severe hypoxia (e.g., after a heart attack and coma state). In this group of patients, the information is lost permanently. When the damage is restricted to the hippocampus and related structures in the medial temporal lobes, the retrograde amnesia may be temporally limited (covering a period of weeks in rodents, up to years or even decades in humans, leaving remote memories intact), suggesting to several authors that the hippocampus may play a role in the initial formation of new memories, and may somehow contribute to the gradual integration of new memories into neorcortical memory circuits (Squire et al. 1984, McClelland et al. 1995).

Alternatively, retrograde amnesia may be the consequence of a disrupted access to the net. Here, the expression 'mnestic block syndrome' has been coined to describe this phenomenon (Markowitsch 2000) which can be found both after manifest brain damage in the frontotemporal cortex and after so-called functional amnesia which is seen in patients with dissociative personality states (see *Amnesia: Transient and Psychogenic*). Such functional amnesias especially appear as a consequence of stress and trauma experiences (see *Stress, Neural Basis of*). In this second category of patients, the mnestic block is usually selective, affecting primarily emotion-laden personal episodes, and it is assumed that the information—the engram—is in principle still manifest in the cortical nets.

Furthermore, static and functional imaging results from both neurologic and psychiatric patients point to alterations in especially the right temporofrontal regions when autobiographic information retrieval is disrupted and to corresponding changes in the left temporofrontal regions when semantic retrieval is impaired (Markowitsch 1995, 2000).

4. *The Learning and Memory Networks—Conclusions*

Learning and memory engage a wide range of brain regions—nevertheless, a conclusion that it is the total mass of the nervous system which codes information for storage would be a false one. Instead, the principles of convergence and divergence of information transmission hold throughout the nervous system and there are both modality- and material-specific channels for information encoding, storage, and even retrieval and there are bits of information which are rich in affect and consciously reflected (and consequently require wide neural nets), while others are processed only subliminally and may never gain conscious representation. Furthermore, information is not represented in a static manner within the brain – mood, the environment, focused attention, internal associated cues, hormones, and many additional factors influence, modify, and rearrange our knowledge. The phenomena of state-dependent learning and retrieval and of false memories are examples for the susceptibility and vulnerability of our memories. The concept of plasticity has gained considerable support from invertebrate to human research and also the concept of life-long learning, proposed by the social sciences, demonstrates that information representation is much less hard-wired and rigid than formulated by traditional frameworks.

Learning by Occasion Setting

1. *Simple Conditioning and Occasion Setting*

In classical conditioning, organisms learn to predict the presence or the absence of an unconditioned stimulus (US) upon presentation of a conditioned stimulus (CS). Whereas prediction of the presence of the US seems to be mediated by excitatory CS–US associations, prediction of the absence of the US seems to be mediated by inhibitory CS–US associations. When the CS predicts that the US will be present, a conditioned response (CR) is generated. When several CSs are presented together they can combine their predictions and determine whether the CR is generated.

Although CSs are generally considered to only act in the role of 'simple CS' as described in the previous paragraph, experimental data show that a CS can also play as an 'occasion setter.' Whereas as a simple CS a CS forms excitatory or inhibitory associations with a US, as an occasion setter, it modulates the CR generated by another CS.

These alternative roles played by a CS were established in experiments that included different temporal arrangements of feature positive (FP) and feature negative (FN) discriminations. In a FP discrimination, the 'feature' (X) and the 'target' (A) are presented together with the US, and these presentations alternate with presentations of A alone. In a FN discrimination, XA compounds are presented in the absence of the US while A is presented with the US. FP and FN discriminations are simultaneous when X and A are presented at the same time, and serial when the presentation of X precedes the presentation of A.

Using simultaneous and serial FP and FN discriminations, Holland (1983, 1992) offered the following three criteria to distinguish simple conditioning from occasion setting roles of a CS.

1.1 *Response Form*

Under food deprivation, the form of the CR evoked by a light and tone compound reveals its associative origins: if the CR is rear behavior, then responding is the consequence of light-food associations, but if the

CR is head jerk behavior, responding reflects tone-food associations. Taking advantage of this fact, Ross and Holland (1981) reported that in the simultaneous FP, the form of the CR during XA presentations was characteristic of X–US associations, whereas in the serial FP, the rats displayed CRs characteristic of A–US associations. Thus, Ross and Holland's observations suggested that in a simultaneous FP discrimination X acts as a simple CS, but with a serial FP discrimination X acts as an occasion setter. A more complicated pattern of results for simultaneous FP discriminations as a function of the relative intensity of the feature and target stimuli was later reported by Holland (1989c).

1.2 Extinction and Counter-conditioning

If performance on FP and FN discriminations is based on simple associations between X and the US, then elimination of those associations after discrimination training should abolish discriminative performance. Therefore, to the extent that rats solve FP discriminations by forming simple excitatory associations between X and the US, then repeated presentation of X alone after training should extinguish those associations, and consequently eliminate responding to the XA compound. Similarly, to the extent that rats solve FN discriminations by forming simple inhibitory associations between X and the US, then repeated reinforced presentations of X after training should establish excitatory X–US associations, and hence eliminate X's simple inhibitory powers. Accordingly, in simultaneous FP and FN discriminations, Holland (1989b, 1989d) found that post-training extinction of X produced severe decrements in performance on FP discriminations, and post-training counter-conditioning of X abolishes performance on FN discriminations. In contrast, in serial FP and FN discriminations, thought to establish occasion setting, post-training extinction or counter-conditioning of X had minimal effects (Holland 1989b, 1989d, Rescorla 1985, 1986).

1.3 Transfer

The result of combining simple CSs and occasion setters with other CSs has been studied in transfer experiments. For example, if a feature X previously trained in a simultaneous FP discrimination is paired with a trained-then-extinguished CS, B, the simple CS–US associations of the feature will immediately generate responses on XB trials (Holland 1986a, 1986b, Holland and Lamarre 1984). By contrast, if a feature X previously trained in a serial FP discrimination is paired with a trained-then-extinguished CS, B, the occasion-setting properties of the feature might (Davidson and Rescorla 1986, Jarrard and Davidson 1991) or might not generate responses on XB trials (Holland 1986a).

2. A Real-time Model of Pavlovian Conditioning

The alternative roles played by a CS can be best understood when described in terms of a formal model of classical conditioning presented by Schmajuk and DiCarlo (1992) and Schmajuk et al. (1998). The model is a real-time neural network in which CS inputs are connected to different CR outputs both directly and indirectly through a hidden-unit layer that codes configural stimuli. In the network, a CS acts as a simple stimulus through its direct connections with the output units and an occasion setter through its indirect

Figure 1
Simultaneous feature-positive discrimination. Top panel: real-time representations of X and A, their traces, and of the US on an XA+ and a A− trial. Bottom panel: simplified diagram of the Schmajuk and DiCarlo (1992) network. When A and X are of similar intensities, X acquires a direct excitatory association with the US. The hidden units do not acquire a strong association with the US. Associative strengths are represented by plus or minus signs placed next to the arrows connecting the nodes. Only significant associative strengths are indicated

Figure 2
Serial feature-positive discrimination. Top panel: real-time representations of X and A, their traces, and of the US on an X6A+ and a A− trial. Bottom panel: Simplified diagram of the Schmajuk and DiCarlo (1992) network. X acquires an inhibitory association with the hidden units (H). A acquires an excitatory association with the US and an excitatory association with the hidden units (H). The hidden units acquire an inhibitory association with the US. Associative strengths are represented by plus or minus signs placed next to the arrows connecting the nodes. Only significant associative strengths are indicated

configural connections via the hidden units. Schmajuk et al. (1998) showed through computer simulations that the network accounts for a large part of the data on occasion setting. Two examples for FP discriminations are shown in Sects. 2.1 and 2.2, (a) the conditions in which CS behaves as an occasion setter, and (b) how occasion setters are impervious to extinction.

2.1 Conditions in which a CS Behaves as an Occasion Setter

The model explains why a CS behaves (a) as a simple CS in a simultaneous FP discrimination; or (b) as an occasion setter in a serial FP discrimination.

Simultaneous FP discrimination in Fig. 1 (top panels) illustrates the real-time values of X, A, and the US during reinforced and non-reinforced trials in a simultaneous FP discrimination. Figure 1 (bottom panel) summarizes the model's solution for a simultaneous FP discrimination. Whereas X acts as a simple CS because it acquires a strong direct association with the US, A acquires a very weak association. Because direct associations of A and X with the US determine the response form, the model generates mostly CRs characteristic of X–US associations during compound XA presentations.

Serial FP discrimination in Fig. 2 (top panels) illustrates the real-time values of stimuli during reinforced trials in a serial FP discrimination. Figure 2 (bottom panel) shows a simplified depiction of the associative structure established in the network after serial discrimination trials. Because of their different temporal relations with the US, A accrues strong A–US associations but X only accrues weak X–US associations. Since the direct associations of X and A with the US determine the form of responding, responding on XA presentations comprises mostly CRs characteristic of A–US associations. Furthermore, responding on A-alone trials is small because it is strongly inhibited by the hidden units (which are activated by A), and responding on XA presentations is large because the inhibitory influence of the hidden units is ameliorated by the inhibitory action of X on the hidden units.

2.2 Occasion Setters are Impervious to Extinction

Since simultaneous FP discriminations are solved by the model almost completely by direct X–US associations (see Fig. 1), the effect of X extinction is dramatic, abolishing CR responding on both X and XA test trials. By contrast, compound responding for serial FP is controlled by A–US associations which are attenuated by the inhibitory H–US associations (see Fig. 2). Since X–H and H–US associations are only minimally affected by X extinction, very little decrement is observed in XA compound responding after extinction.

3. Conclusion

A CS can behave either as a simple CS or as an occasion setter. In the first case, the CS acquires excitatory or inhibitory associations with the US, in the second case the CS might enhance or depress the effect of the simple association accrued by another CS. The properties of simple CSs and occasion setters have been thoroughly studied (for a review see Swartzentruber 1995).

A neural network model presented by Schmajuk et al. (1998) can accurately describe most of the available data. Other learning models that also include direct

and indirect associations between CS inputs and CR outputs (e.g., Bouton 1994) also provide correct depictions of the phenomena. Neural networks without direct connections (e.g., Gluck and Myers 1993, Wagner 1992) can only describe some of the experimental results. Some of the physiological mechanisms of occasion setting have been addressed in terms of neural networks (Gluck and Myers 1994, Schmajuk and Buhusi 1997). A recent volume, published by Schmajuk and Holland (1998) presents the latest data and theoretical approaches to the subject.

N. A. Schmajuk

Learning Curve, The

Most tasks get faster with practice. This is not surprising because we have all seen this and perhaps know it in some intuitive sense. What is surprising is that the rate and shape of improvement is fairly common across tasks. Figure 1 shows this for a simple task plotted both on linear and log–log coordinates. The pattern is a rapid improvement followed by ever lesser improvements with further practice. Such negatively accelerated learning curves are typically described well by power functions. Thus, learning is often said to follow the 'power law of practice.' Not shown on the graph, but occurring concurrently, is a decrease in variance in performance as the behavior reaches an apparent plateau on a linear plot. This plateau masks continuous small improvements with extensive practice that may only be visible on a log–log plot where months or years of practice can be seen. The longest measurements suggest that for some tasks improvement continues for over 100,000 trials.

There are some related regularities. There is evidence to suggest that standard deviation and skew in

Figure 1
Time to perform a simple task on a linear and log–log plot as well as a power law fit to the data (adapted from Seibel 1963)

performance time also decrease according to a power law, but with worse correlations. Indeed, in some cases the decrease in standard deviations appears to cause the improvement, because the minimum time to perform a task does not change (Rabbitt and Banerji 1989).

The power law of practice is ubiquitous. From short perceptual tasks to team-based longer term tasks of building ships, the breadth and length of human behavior, the rate that people improve with practice appears to follow a similar pattern. It has been seen in pressing buttons, reading inverted text, rolling cigars, generating geometry proofs, and manufacturing machine tools (cited in Newell and Rosenbloom 1981), performing mental arithmetic on both large and small tasks (Delaney et al. 1998), performing a scheduling task (Nerb et al. 1999), and writing books (Ohlsson 1992). Further examples are noted in reviews (e.g., Heathcote et al. 2000). In manufacturing this curve is called a progress function. It can be demonstrated by taking a task—nearly any task—and timing how long it takes to complete over 10 trials, or better over a hundred trials. An example might be to try reading this article upside down. The time per paragraph will generally decrease, but with some differences caused by the different words and paragraph lengths.

In general, the more averaging, the smoother the curve. The learning curve appears smoother when the data is averaged across subjects, across tasks, or both. When the tasks are known to vary in difficulty, such as different complex mental arithmetic problems (e.g., 27×5 and 23×28), the learning curve only appears when averaging is performed because the different problems naturally take different times. Even when problems are of comparable difficulty, subjects may use different strategies. For example, arithmetic problems can be solved by two at least strategies, retrieval and calculation. The power law applies across strategies, but the fit is better to each strategy (Delaney et al. 1998), or even an individual's strategies (Heathcote et al. 2000).

Averaging can mask important aspects of learning. If the tasks vary in difficulty, the resulting line will not appear as a smooth curve, but will bounce around. Careful analysis can show that different amounts of transfer and learning are occurring on each task. For example, solving the problem 22×43 will be helped more by previously solving 22×44 than by solving 17×38 because there are more multiplications shared between them. Where subtasks are related but different, such as sending and receiving Morse code, the curves can be related but visibly different (Bryan and Harter 1897).

The learning curve has implications for learning in education and everyday life. It suggests that practice always helps improve performance, but that the most dramatic improvements happen first. Another implication is that with sufficient practice people can achieve comparable levels of performance. For example, extensive practice on mental arithmetic (Staszewski reported in Delaney et al. 1998) and on digit memorization have turned average individuals into world class performers.

To sum up, the learning curve is visible with enough aggregation of dissimilar tasks or across similar tasks down to the level of individual subject's strategies.

1. *Mathematical Definitions*

The shape of the curve is negatively accelerated—further practice improves performance, but with diminishing returns. Power laws and exponentials are both functions that provide this shape. Mathematical definitions are given in Table 1. The exact quality of the fit depends on innumerable details of averaging, the precise function used, and the scale. For example, the full power law formula is the most precise, but it has additional terms that are difficult to compute, and

Table 1
Functions that fit practice data

Time = MinTime + $B \cdot (N+E)^{-\beta}$ [Full power law formula]
Time = $B \cdot N^{-\beta}$ [Simple power law formula]
Time = $B \cdot e^{-\alpha N}$ [Simple exponential formula]
B is the range of learning N is the trial number E is the number of previous practice trials α,β are the learning rate parameters

the asymptote is usually only visible when there are over 1,000 practice trials (Newell and Rosenbloom 1981). The typical power law formula is simpler, but leaves out previous practice. When using this formula, the coefficients of the power law for a set of data can be easily computed by taking the log of the trial number and log of task time and computing a linear regression. That is, fitting a regression in log–log space.

In general, the power function fit appears to be robust, regardless of the methods used (Newell and Rosenbloom 1981). However, recent work (Heathcote et al. 2000) suggests that the power law might be an artifact arising from averaging (Anderson and Tweney 1997), and that the exponential function may be the best fit when individual subjects employing a single strategy are considered. Distinguishing between the power and exponential functions is not just an esoteric exercise in equation fitting. If learning follows an exponential, then learning is based on a fixed percentage of what remains to be learnt. If learning follows a power law, then learning slows down in that it is based on an ever decreasing percentage of what remains to be learnt.

Regardless of the functional form of the practice curve, there remain some systematic deviations that cause problems, at the beginning and end of long series. The beginning deviations may represent an encoding process. For example, it may be necessary to transform a declarative description of a task into procedures before actual practice at the task can begin (Anderson and Lebiere 1998); the residuals at the end may represent approaching the minimum time for a given task as defined by an external apparatus. These effects appear in Fig. 1 as well.

2. *Process-based Explanations of the Learning Curve*

The power law of learning is an important regularity of human behavior that all theories of learning must address. For example, Logan (1988) suggests that the retrieval of memory traces guides responding in speeded tasks. Response times represent the fastest retrieval time among the memory traces racing to

Figure 2
The time to perform a trouble-shooting task by both a cognitive model and a subject (after Ritter and Bibby 2001)

guide the response. The power law falls out of this analysis, because with practice the number of redundant memory traces increases, which, in turn, increases the chances of observing fast retrieval times. Olhsson's (1996) theory notes how the learning curve could arise out of error correction. Different assumptions (e.g., how fast errors are caught) give rise to different curves including the exponential and power law. The learning curve has also been demonstrated for connectionist models as well.

ACT-R (Anderson and Lebiere 1998) and SOAR (Newell 1990), two cognitive architectures, generally predict a power law speedup, but for different reasons. ACT-R does this because rules and memory traces are strengthened according to a power law based on the assumption that the cognitive system is adapted to the statistical structure of the environment (Anderson and Schooler 1991). Several models in SOAR (see *Cognitive Theory: SOAR*) have been created that model the power law (e.g., Nerb et al. 1999, Newell 1990). These models explain the power law as arising out of mechanisms such as hierarchical learning (i.e., learning parts of the environment or internal goal structure) that initially learns low-level actions that are very common and thus useful, and with further practice more useful larger patterns that occur infrequently are learned. The SOAR models typically vary from human learning in that they learn faster than humans, and they do not learn for as long a period. SOAR and ACT-R also predict variance in the improvement on all tasks due to different amounts of transfer across problems and learning episodes. Figure 2 shows how such a model can predict differential transfer as well as continuous learning as it appears in human data.

3. *Summary*

The learning curve is a success story for cognitive psychology, which has shown that learning is ubiquitous and has provided mathematical accounts of the

rate. The learning curve is also a success story for cognitive modeling, which has explained many aspects of the curve and the noise inherent in it partly as differences in transfer of knowledge between tasks and how the curve arises out of mechanisms necessary for processing. The multiple explanations also suggest that there may be multiple ways that the curve can arise.

Learning from Text

In many everyday situations we need to acquire information from texts, both oral and written, such as newspaper articles, manuals, talks, or telephone conversations. Learning from text is a ubiquitous occurrence. Of course, the exceptional interest that the topic has received is driven by the need to improve learning from text in formal educational settings. Research on this issue has been motivated by different, but related, goals. Educational research is mostly concerned with the development and evaluation of teaching methods (Hynd et al. 1998), linguistic theory is concerned with the description and analysis of the texts used as learning materials, and the psychological literature focuses more on the cognitive processes subserving comprehension and learning (e.g., Kintsch 1998). In the late twentieth century, the advancement of text comprehension theories has made it possible to apply concepts from psycholinguistic research to educational issues, so that there is now more and more overlap between these areas.

1. Definitions

How do we define learning from text? Learning from text is often equated with learning *of* text, that is, with memory for the text information proper (e.g., the memorization of a poem). In contrast, Kintsch makes a clear distinction and defines learning *from* text as 'the ability to use the information acquired from the text productively in novel environments' (Kintsch 1998, p. 290).

Using concepts from psycholinguistic theories of text comprehension, these definitions can be further sharpened: van Dijk and Kintsch (1983) distinguish three levels of representation. First, the surface level encodes the verbatim wording of the text information. On this level, the syntactic and lexical realization of the text is represented. The second level is a semantic representation, called the textbase, closely corresponding to the propositional, or meaning-based content, but independent of the exact wording. In addition, the textbase contains some information not explicitly mentioned in the text, such as associative elaborations, certain inferences, and macropropositions. Finally, and most importantly, the situation model is an integration of the reader's prior knowledge and experiences with the information currently encountered. This representation of 'what the text is all about'

does not need to be in a verbal or propositional format, and it depends both on the text information, and on the individual background the comprehender contributes.

These three levels of representations are differentiated not only by their content, but also by their retention characteristics: The surface level is forgotten quickly, the textbase might be available over several hours, but the situation model is what survives in the long term. Thus, learning *of* text is located at the surface and textbase levels, whereas learning *from* text needs to be conceptualized as the construction, retention and utilization of a situation model representation (Ferstl and Kintsch 1999).

2. Empirical Methodology

For dissociating memory for text and learning from text, we need measures that tap these levels of representation differentially. Traditional measures for the textbase are recall and recognition, as well as the factual comprehension questions, that is, questions about information explicitly mentioned at a particular point in the text. Moreover, those inference questions that probe information on presumably automatic inferences (e.g., bridging inferences) are also located on the textbase level.

In contrast, for assessing the situation model, tasks requiring the 'productive use' of the acquired information in 'novel environments' are needed. When a manual is read, for instance, we can directly test the nonverbal ability to operate the device explained. For testing learning from a physics textbook we can ask students to perform problem-solving tasks requiring the transfer or the application of text information. However, even when the text information cannot be tested nonverbally, we can devise 'novel situations' going beyond the explicit text information. From recall protocols, we can score those statements that were not mentioned in the text, but were inferred or elaborated by the learner. An evaluation of their plausibility within the ideal situation model provides a score of the creative, reconstructive use of the information. In recognition tasks we can include words or statements that are consistent with the situation described, although they were not directly included in the text. In designing questions, the situation model is probed when a combination of prior knowledge with text information or the integration of statements from different parts of the text is needed.

Another approach attempts empirically to describe learning from text as the change of the reader's prior knowledge structure (Ferstl and Kintsch 1999). After identifying key concepts of the text's domain, each learner's internal organization of these concepts is estimated based on relatedness ratings, results from sorting tasks, or cued associations. The resulting associative network is considered an approximation of the learner's knowledge structure. After reading the text, the same task is repeated, and the resulting network is considered an approximation of the learner's situation model. The changes from before to after reading are taken as an index of learning from text. Moreover, the knowledge networks after reading can be compared with an ideal structure, obtained, for instance, from an analysis of the text content, or from an expert's assessment of the same domain.

Many inconsistencies in the literature on learning from text might be explained by evaluating in more detail the methods used for assessing learning. However, it is important to note that, although there are empirical dissociations, in most cases building a good textbase representation goes hand in hand with establishing an elaborate situation model. Therefore, in describing learning from text, the vast knowledge about text memory accumulated to date should not be neglected.

3. Text Characteristics

An obvious answer to the question of how we can improve learning from text is to just write better texts. Consequently, there have been numerous suggestions for writers on how to increase the readability of their texts (e.g., Taylor and Taylor 1983), most of which seem to consist of simplifying the style. On the word level, short and familiar words are recommended, and on the sentence level, syntactically complex constructions are to be avoided.

On the text level, the notion of coherence has been shown to be crucial for readability, that is, for comprehensibility. Local coherence refers to the connection between subsequent sentences, while global coherence refers to the connection between parts of the text, such as paragraphs. For instance, when moving back from a concrete example to the general topic of the text, global coherence is preserved, while local coherence might be violated. Coherence facilitates comprehension because no additional inferences are required for deriving the text structure. Situation model construction can be facilitated by adding explicit cohesive ties, that is, lexical information signaling the type of connection between successive sentences.

A second important factor is the macrostructure of a text, corresponding roughly to the outline or a summary of the text. The macrostructure has to be constructed by using macrorules, such as marking some propositions as particularly important or subsuming others under a more general one. Writers can facilitate the application of macrorules, for instance, by using a canonical, expected structure. The macrostructure of an existing text can be clarified by adding explicit information in the form of subheaders, introductory or structuring statements (e.g., 'the following three examples … '), or underlining of important information. Using these macrostructure cues

helps to set up the textbase, and in turn frees resources for processing on a situation model level (for an early approach to text structure, see Meyer 1975).

4. Adjunct Information

Another way of improving learning from text is to provide additional materials that extend the text information. Very influential suggestions, in particular in educational research, are advance organizers and illustrations.

Outlines or summaries given before reading explicitly provide the macrostructure of the text to be read. Similar to headers or explicit organizing statements within the text, this additional information facilitates comprehension. An advance organizer, as proposed by Ausubel (1968), goes beyond a simple outline or summary. Rather, it uses a different level of abstraction and has the function to 'provide ideational scaffolding for the stable incorporation and retention of the more detailed and differentiated material that follows in the learning passage' (Ausubel 1968, p. 148). Although this concept seems compelling, there was considerable debate about the efficacy of advance organizers. While some studies showed a beneficial effect, others failed to replicate. One reason for these inconsistencies was that early studies did not have available the tools for analyzing the content and structure of both text and advance organizer, and that the levels of representation were not carefully distinguished. As an example of a more recent study controlling these factors, Mannes and Kintsch (1987) studied the interaction between organizer structure and representational level. When the organizer and the text were of a similar structure, readers formed a better textbase representation, because the advance organizer provided the macrostructure for the text read later. Different structures, on the other hand, improved the verification performance on situation model statements. In this case, the macrostructure of the target text had to be derived and the availability of the information from the advance organizer made a more elaborate situation model likely.

One of the most intriguing demonstrations of the effect of illustrations on text comprehension is the study by Bransford and Johnson (1972). They demonstrated that looking at a picture showing an unusual serenade substantially improved comprehension and recall of a vaguely worded text describing the scene on the picture. Since that early study, numerous experiments attempted to delineate the possibilities and limits of illustrations for improving learning processes (Mandl and Levin 1989). The kind of picture used depends on the text information to be illustrated. For instance, a narrative can be embellished by a portrait of the protagonist, a manual might contain a schematic depiction of the device, and the description of a hiking trail is facilitated by a map. Illustrations aid learning from text when they are available before or during processing, and when the information provided by the picture is relevant to and redundant with text information. Purely decorative illustrations do not have a beneficial effect. One theory for explaining the facilitative effect of illustrations was proposed by Paivio (1986), who postulated that dual coding of the information, in a verbal and in a visual representation, increases the likelihood of the information becoming available through one of the codes. However, illustrations tend to have a smaller effect on recall of text, but often facilitate situation-based inferences and elaborations. Rather than merely doubling the amount of information, as the dual coding theory suggests, the illustrations provide background knowledge, and they encourage the mapping of the text information to the visually presented information. Thus, illustrations and other nonverbal sources, such as the demonstration of a procedure, are utilized for constructing the situation model.

5. The Learning Process

As we have seen, the external information not only enhances the reader's background knowledge, but also has a direct impact on the type of processing. How a text is being read determines the kind of representation being built up. More careful, effortful reading, with more time spent on the task, increases performance. In addition, there is no doubt that instructions can be used to induce effectively certain reading goals. For instance, when told to memorize a text for later recall, readers focus more on the construction of a good textbase representation than when told to read for comprehension. When instructed to attend to a certain type of information, encoding takes place selectively and irrelevant information gets neglected. When provided with an illustration, the reader processes the text information overlapping with the picture more thoroughly.

A more direct way to influence processing is to ask the right questions (Graesser et al. 1994). Questions are asked by the learner to clarify points that are not readily comprehensible. Questions are asked by the teacher to test comprehension, or lead students' processing into a specific direction. When the effect of this type of question is to be evaluated, the questions are interspersed in the text or added afterwards. These so-called adjunct questions have two functions. First, they can induce comprehension monitoring, an activity that readers often neglect. An important strategy during learning from text is to amend comprehension failures, for example, by rereading passages, or by activating additional background knowledge. Difficulties with answering an adjunct question, in particular, if feedback is provided, can signal problems that might otherwise go unnoticed.

The second function of adjunct questions is to support directly situation model construction. Ques-

tions can be formulated so that they point to particularly relevant factual information (e.g., definitions), or so that they promote inferences needed for deep understanding. Most studies document a benefit of adjunct questions mainly for the information probed, but little transfer to other information in the text. When the questions are not provided, but are to be generated, learners often face considerable difficulties. Without extensive training, effective questioning is more likely to be the result of an already established situation model, rather than an aid to constructing it.

6. *Individual Differences*

In his account of meaningful learning—which encompasses learning from text—Ausubel (1968) stresses the role of the learner. 'Meaningful learning presupposes that the learner manifest a meaningful learning set, that is, a disposition to relate the new material nonarbitrarily and substantively to his cognitive structure' (Ausubel 1968, p. 37). In this section we look at research on individual differences, and consider some specific factors influencing whether a 'meaningful learning set' is available.

Learning studies encompass groups as varied as children just barely able to read, high-school students, and adults. Hence it is important to take into account the learner's age. One important finding is that younger children tend to rely more on verbatim encoding of text, and that strategies needed for situation model construction, such as structure building, analogical reasoning, or active integration with previous knowledge, become available only at a later stage during development.

Studies grouping adult learners according to their reading skills find that it is exactly those strategies that less skilled readers tend to use for compensating their weaknesses on the textbase level. For instance, poor readers rely more on contextual constraints and causal structures. Poor readers have lower recall scores, and benefit from good writing, but these textbase differences are less noticeable on the situation model level—at least as long as the situation model of the particular text is consistent with expectations based on general world knowledge.

Another learner characteristic concerns motivational factors, such as the interest the learner brings to the task at hand. Within a text, interesting information is more likely to be recalled, but embellishing a text with interesting tidbits does not necessarily improve comprehension for the remainder of the text. Thus, few 'seductive' details do not increase the overall motivation to become more involved in text processing. Because it is unavoidable that some content areas are not inherently interesting for each student, strategies for increasing the learners' motivation are important (Wade 1992).

One of the most crucial individual differences is the learner's background knowledge. In the serenade example, for instance, the illustration provided the necessary background knowledge for constructing a situation model, and in this case, even for constructing a coherent text representation. Some advance organizers also have the function of providing necessary background knowledge. Often, however, it does not suffice to look at a picture or read a second text. Instead, the reader needs more extensive domain knowledge. Experts have better vocabulary, they know more facts, but most importantly, these facts are closely interrelated and well structured. When readers are experts in the text's domain, they recall more text information, they can distinguish important information from details, they can bridge coherence gaps, and they are more likely to derive goal structures.

The disadvantage caused by not being able to relate the current information to already existing cognitive structures (Ausubel 1968) or to 'hang it on the right hooks' in general world knowledge (Kintsch 1998) can be overcome by the better writing. As we have seen before, explicit coherence cues facilitate understanding. And indeed, when learners with high or low knowledge read an explicitly coherent text, their problem-solving performance and card-sorting results are comparable. Only for less coherent text do these situation model measures show a clear benefit for the high knowledge participants (McNamara et al. 1996). A particularly interesting result in the same study was an interaction between knowledge and coherence. High-knowledge readers developed better situation models when they read the less coherent text than when they read the better, more explicit text. An explanation for this somewhat counterintuitive result is that the coherence gaps elicited more active processing. Each coherence gap asks an adjunct question, 'how does this fit together?' The high-knowledge readers generated the necessary inferences on their own, but they needed some processing effort for doing so, which in turn helped them in developing deep understanding (for replications see Kintsch (1998)). Thus, just by providing the right text for the right learner, the learning success was increased for both high- and low-knowledge groups.

7. *Teaching Strategies*

An important driving factor of this area of research is the possibility of developing teaching programs incorporating the educational and psycholinguistic findings. The facilitating factors mentioned before can be provided by the teacher or within the text. Alternatively, the use of any comprehension strategy can be taught to students. For instance, underlining helps the reader distinguish important information from details, summarization puts a focus on the macrostructure, providing background knowledge is helpful, and prior

activation of a relevant domain can foster integration of text information with available background knowledge. Some programs incorporate several of these techniques. For instance, the well-known PQRST technique recommends an elaborate sequence of processing: preview, question, review, state, and test (Robinson 1970). Of course, such a technique can only succeed when the learners are able to take advantage of it. As we have seen before, though, it is a skill to ask the appropriate questions for facilitating deep processing. On the other hand, explicitly teaching learning techniques provides a benefit to the learners only if they do not yet employ self-initiated processing strategies. Therefore, empirical confirmations of the efficacy of such programs, that almost everybody would intuitively agree upon, are difficult to obtain. Not just the right text for a given learner, but also just the right teaching technique for that learner is what is needed.

8. *Conclusions and Outlook*

While it may seem that empirical studies too often produce the answer 'it depends' to the question of how we can improve learning from text, this should not discourage further experimental research. We now have the theoretical background for analyzing text characteristics and for assessing learner-centered factors. In addition, there are some promising attempts to automate these (Kintsch 1998). Of course, sometimes, the intuitions of good educators are worth more than a multitude of controlled studies. Nevertheless, we should strive to objectify and delineate these intuitions, in order to support the learning process of many student generations to come.

The way printed media have shaped our intellectual world for centuries accounts for the exceptional interest in the issue of learning from text. This influence of books is gradually changing with the advent of new electronic media. Traditional textbooks or newspapers may soon be a relict of the past, but research on learning from text will become even more important. The large majority of information presented will remain verbal. Existing research on the interactions between text information and other, mostly visual, presentation forms can help to understand and improve modern communication. The usual way of writing texts as coherent wholes that are best read in their sequential order has also changed with the advent of technologies such as the Internet and other hypertext media. Using these tools provides the freedom to select, review, or enhance the learning material on a step-by-step basis. Thus, the learners' active role in shaping their individual learning environment will become more and more important.

Learning: Organizational

Organizational learning is a metaphor that matches two concepts—learning and organization—and enables exploration of the organization as if it were a subject which learns, deals with knowledge, reflects on

experiences, and is endowed with a stock of knowledge, skills, and expertise. A metaphor works by matching what is distant with what is close, similar features with dissimilar ones, and it is a cognitive tool that develops creativity and social imagination and reveals the importance of language and symbols in the construction of reality and in the formulation of theory. In this way, cognitive transpositions come into operation that make it possible to imagine and to talk about the object in question (the organization) as if it were another already-known object (learning).

Therefore, study of organizations as if they were systems of knowing and learning may be of assistance in the design of knowledge intensive organizations and of networks of organizations that create and transfer knowledge. At a theoretical level, the representation of the learning organization may stand as a valid theoretical alternative to the rational organization because it replaces the classical concept of the organization that acts according to the principles of rational choice with that of the organization which acts according to principles of experimentation, of trial and error, of success and failure, of discovery and invention.

The following sections outline the history of the concept of organizational learning, the divergences between two bodies of literature—organizational learning and learning organization—as they grew in the 1990s, and the further development in the field.

1. *A Brief History of the Concept of Organizational Learning*

The first mentions of the concept can be traced back to March and Simon (1958), but for long it was peripheral to organizational theory. March has always alluded to learning and to the link between learning and decision-making processes, although only few of his works are specifically devoted to this topic.

The work generally recognized as pioneer in the field is by Argyris and Schön (1974) and a brief historical excursus into the literature on organizational learning will illustrate how researchers interested in knowledge have examined specific organizational phenomena in terms of learning defined in variety of ways:

(a) *As learning curves* (Yelle 1979), a concept which probably stands at the basis of the most long-standing interest in learning. Learning curves rest on the principle that the man-hours required to produce a unit of output decrease in proportion to the experience accumulated. Productive processes display characteristic learning curves in relation to a set of organizational factors. Hence derives the idea that there is something more than mere individual learning and that experience constitutes a transferable body of knowledge that may become institutionalized and incorporated into situations different from the original ones.

(b) *As behavioral change through trial and error*. Learning is a self-regulating process which detects errors and corrects them or, if preferred, which checks actions against their outcomes and makes appropriate adjustments to subsequent actions. This conception may be applied to the organization as an information processor or as a producer of knowledge on the nexuses between input and output and their reception by the environment.

(c) *As adaptation to the environment*, and therefore as the capacity to 'fit in,' to adjust to external stimuli which must be discovered opportunely and rapidly. Learning is, therefore, synonymous with structural change and acts as a signal of successful evolution. Moreover, learning as systemic wisdom does not come about solely within organizations or within competitive relationships among organizations. It also appears in the networks of informal learning (Trist 1983) established among numerous organizations by means of collaborative exchanges.

(d) *As economy of search*. The economizing of cognitive energies in problem solving has been demonstrated by Newell and Simon (1972). New solutions are first looked for in familiar settings and then, because the costs of the search increase proportionately, in progressively more unfamiliar ones. Those solutions that have proved valid in the past are more likely to be the ones adopted in the future. They are learnt and retained as long as they continue to function. Learning takes place through the incorporation of experience into search rules, attention rules, and organizational goals.

(e) *As the modification of mental maps*. Since Argyris and Schön (1974) pointed out the gap between what organizations say they do (exposed theory) and what they actually do (theory-in-use), learning resides in the ability to bring explanations and the ideas guiding what is done into alignment with the organizational changes introduced. These authors make explicit reference to the cybernetic analogy; but at the same time they stress that organizational change requires modification of the way in which organizations represent reality to themselves. Organizational change and learning proceed in parallel.

The diverse knowledge interests of researchers have located learning at various positions along a continuum with adaptation to the environment at one extreme (together with the analogy of the cybernetic system) and the autonomous elaboration of thought at the other (together with the analogy of the organization as a mind).

In order to show the polysemy of the term 'learning', I shall refer to four systematic surveys of studies on organizational learning (Argyris and Schön 1978, Shrivastava 1983, Fiol and Lyles 1985, Huber 1991) that were published when the aim was to integrate the field and which comprise approximately 200 titles.

Argyris and Schön (1978) identify six conceptualizations of learning, according to how the organization is conceived:

(a) *if it is a group*, then learning takes place at the level of the interactions among individuals performing a task;

(b) *if it is a collective actor*, it learns from the experience stored in organizational maps and action-plans;

(c) *if it is a structure*, it learns by changing in accordance with the external and internal environment;

(d) *if it is a system*, it learns through error-regulating mechanisms;

(e) *if it is a cultural system*, learning is a process of socialization, of transformation of cognitive and judgmental patterns, as well as deliberate transformation of reality;

(f) *if it is a political arena*, the subject-matter of learning is the strategies—competitive and co-operative—employed to control organizational dynamics.

Shrivastava (1983) identifies four conceptualizations of organizational learning: as institutionalized experience, as adaptation, as knowledge of action-outcome relationships, as assumption sharing. In the first conception, by organizational learning is meant only that learning embedded in standard operating procedures, methods of communication and co-ordination, and shared understanding about tasks that have a persistent effect. In the adaptive approach, organizational learning is a complex process of mutual intraorganizational regulation triggered by the combination of different kinds of perceived stress. From the perspective of organizations as systems of knowledge of action-outcome relationships, organizations are purposeful systems or information processors relying on available inputs to confront the turbulence of their environment. From the assumption-sharing perspective, organizations are artifacts based on the cognitive maps that their members use to orient themselves in their interactions, and organizational learning consists of the process whereby these maps are modified.

The third typology (Fiol and Lyles 1985) seeks to prescribe what can be legitimately defined as organizational learning. Fiol and Lyles distinguish between the development of behavior and the development of cognition, so that changes of behavior constitute adaptation while learning only takes place within cognition where it is hierarchized into low-level (single-loop) and high-level (double-loop) learning. For Fiol and Lyles, organizational learning consists in the improvement of actions through better knowledge and understanding, while cognition is the development of reflections, knowledge and associations between past actions, their efficacy and future actions. But if we examine the definitions of learning and cognition more closely we discern the profound embarrassment, shared by all inquiries in the field, over a too-sharp distinction drawn between thinking and doing, over the difficulty of establishing a logical priority between thought and action, between the self-constitution of the subject (individual or organization) and its self-relationing to the environment.

Although complex, Fiol and Lyles (1985) distinguish three areas of agreement among studies on learning:

acknowledgment of the importance of adjustment to the environment;

a distinction drawn between learning by individuals and learning by organizations;

identification of four contextual factors which create and reinforce learning, and which are created by learning in turn: culture, strategy, structure, and environment.

Another influential survey of the literature is by Huber (1991), who proposes closer integration among studies of organizational learning. Huber identifies four constructs correlated with learning: knowledge acquisition, information distribution, the interpretation of information, and organizational memory. There is an abundant and diversified literature on the first two constructs, but the last two have been relatively ignored and require a great deal of further empirical research.

Huber concentrates on knowledge acquisition, which he divides into five subprocesses by which an organization acquires knowledge. It should be stressed, in fact, that Huber views learning as a process which he defines as follows: 'An entity learns if, through its processing of information, the range of its potential behaviors is changed' (Huber 1991). Unlike other authors, therefore, Hubert does not assume that learning immediately translates into either change or increased learning or into competitive advantage.

2. *The Growth of the Field and the Growing Divergences within It*

At the same time that Huber's review was published another authoritative voice remarked that: 'people in organization theory began to talk about learning … just about the time psychologists began to desert the concept' (Weick 1991). One of the main liabilities of the concept of organizational learning is that the traditional psychological models of learning (based on stimulus-response theory) have been transferred acritically to the study of organizational learning and with them a realist ontology, notwithstanding that the growth of the field began in those years since the field attracted the attention of scholars from different disciplines.

The growth of the field can be explained by at least three external factors: the speed of technological change, the advance of globalization, and growing corporate competition (Easterby-Smith et al. 1998).

The speed of technological change means that there is continual pressure on firms to reduce the time from conception to launch of new products, and communications innovations mean that companies and knowledge workers within them may have to adapt radically and in unforeseen directions. As a consequence, firms cannot rely on established practices, they need to learn new ways of doing things. The advance of globalization provides an additional source of pressure. It started with the opening up of labor markets in Asia in the early 1980s, and in Central Europe in the late 1980s, and it has accelerated with the establishment of global financial markets and with the establishment of global consumer markets nourished by the spending power of new middle classes in emerging economies such as India and China. To compete on a global scale, companies need to increase radically their scales of operation in order to keep up with the evolution of new technologies and businesses anywhere in the world. The preceding factors lead to a widely-held view that the most important contributor to corporate competitiveness in the future is going to be the ability of each organization to learn faster than its rivals.

In a scenario of fast economic and technological changes, knowledge came to be seen as an invisible asset and many consultants and firms caught onto the commercial significance of organizational learning. Two concepts express this move: the economics of knowledge and the leaning organization. What they have in common is the managerial interest in bringing knowledge under control at the service of production or innovation.

The exploitative ethos is particularly evident in the economics of knowledge and in knowledge management, whose starting point has been the identification of knowledge as a production factor distinct from the traditional ones of capital, labor, and land. The resource-based theory of the firm has conceptualized knowledge as 'core competencies' or 'core capabilities,' naturalizing the relationship by means of the metaphor of the tree of knowledge: the trunk and major limbs are core products and the root system is the core competence (Prahalad and Hamel 1990). The reification of knowledge has grown more overt with the 'objectified transferable commodity' envisaged by the knowledge-management approach, which treats knowledge as practically synonymous with information created, disseminated, and embedded in products, services, and systems. A number of theorists have focused on making practical interventions in organizations in order to help them to become 'learning organizations.' Some models of learning organizations have been based on observations of organizations that appeared to be good at learning and elements of good practice have been extracted and synthesized. Although the idea of a leaning organization is drawn on insights from organizational learning, nevertheless the two literatures have developed along different tracks and around them two different scientific communities are gathered. The divergences concern the questions of the why, what, and how of organizational learning, and also dilemmas about how to conduct research into it (Easterby-Smith et al. 1998):

(a) *Why organizational learning?* Two bodies of literature have developed according to whether the aim is analytic and descriptive or action oriented and prescriptive. The former focuses on 'How does an organization learn?' The latter focuses on 'How should an organization learn?'

(b) *What is organizational learning?* This question debates ontologies and the choice between a realist or a constructionist approach. It is about whether organizational learning is best seen as a rational and technical process or whether humanistic and political perspectives provide the best insights. A focus on data and information processing is likely to lead to assumptions of rationality which can be aided with appropriate learning technology, whereas the focus on human behavior inevitably leads to concern about hidden motives, emotions, and the possibility of political calculation.

(c) *Which methods of inquiry?* This area of divergence involves epistemologies and the preferred ways of inquiring into the nature of organizational learning. The major divide is between positivist methods with the emphasis on measurement and constructionist methods which emphasize language and the uniqueness of meaning systems. In general, there is a preference for quantitative methods (and for an individual/cognitive framework) in the USA due to the influence of academic journal house styles and research training in the management field; this contrasts with the strong development of qualitative methods (and a social/cultural framework) in European countries.

(d) *How to implement organizational learning?* A debate is open between incrementalists and radicals. Incremental learning is not only seen to be most common in organizations but also rather useful. A more radical perspective is represented by those who argue that because organizations normally operate on single-loop learning principles, it is more important for them to develop the capability of double-loop learning. A second debate is between those in the organizational development community who employ stage theories and those who use cyclical models. The former would suggest variously that there are qualitative differences between organizational processes and that these form progressive hierarchies. Those who propose cyclical models prefer to see the learning organization as a continual process of striving and improvement, that incorporates successive stages of data gathering, reflection, conceptualization, and experimentation.

The dilemma—as March (1996) expressed it—is between exploration and exploitation in the use of

knowledge. The same dilemma is reflected also in the way knowledge is conceived and situated in the relationship between the knowing subject and the object of knowledge.

3. Looking Forward to Knowing in Practice

The utopia of unifying and integrating the field that characterized the 1980s failed in the 1990s and gave way to the encouragement of the existing diversity of perspectives. Within diversity, a 'bandwagon' of theorists started to move behind the concept of practice (or activity) and the idea of community of practice as the place of learning.

Practice is the concept that allows the processes of 'knowing' at work and in organizing to be articulated as historical processes, material and indeterminate. In practice-based theorizing, different traditions of studying learning merge without losing their identity: situated learning theory offers the concept of community of practice, actor-network theory brings the idea of knowledge grounded in materiality, activity theory offers a pragmatic theory of action, and the ethnographic study of knowledgable communities brings a research method which is anti-individualistic.

The specific contribution of practice-based theorizing to the study of organizational learning consists in the following propositions:

Knowing is situated (Suchman 1987), resilient but provisional.

Learning is acquired through participation in communities of practice (Wenger 1998).

Knowledge and action are located in ecologies of social-material relations (Star 1995).

Organizing can be seen as a 'activity system' which reveals the tentative nature of knowledge and action (Blackler 1993). Incoherences, inconsistencies, paradoxes, and tensions are integral parts of activity systems.

Practice involves the accomplishment of alignments across human and nonhuman elements (Law 1994) from particular positionings at a particular times, within a network of relations.

The field of organizational learning has grown very rapidly, attracting the attention of scholars from disparate disciplines such as psychology, sociology, economics, and information systems. As a consequence, the field has become conceptually fragmented but there may be considerable value in distinguishing between groups of researchers in order to sharpen the clarity with which elements of the field are understood and may be developed in a noncompetitive way.

Learning Theories and Educational Paradigms

Theories of learning changed dramatically during the 1980s and 1990s. New ways of thinking about learning and knowledge have emerged to challenge traditional views of what learning is and how people acquire new knowledge and skills. The various theories, however, are not necessarily incompatible with one another. Rather, they provide different perspectives on the complex phenomena of learning and, in general, are relevant to different situations in which learning occurs.

Traditional theories of learning focus on changes in behavior. During the 1970s and 1980s, these theories gave way to cognitive theories that focus on mental processes and the understanding of complex material. In the 1990s, these cognitive theories were challenged by theories emphasizing social interaction and the sociocultural context. Many psychologists and educators no longer consider learning to be a process that occurs strictly within an individual. Rather, they see

learning as something distributed among several individuals (and/or environmental affordances—e.g., tools such as calculators) or existing within a 'community of practice' or a community of learners.

This evolution from behavioral to cognitive to social theories of learning was accompanied by new conceptions of knowledge, and how it is acquired. Traditional theories conceive of knowledge as a commodity that is transmitted, more-or-less intact, to individuals who learn it in a manner that permits them to reproduce the knowledge. According to these theories, knowledge is something an individual acquires.

More recent theories, however, view knowledge as something the learner constructs rather than assimilates. Thus, each person's knowledge is, to some extent, unique. According to these theories, truly objective knowledge, as we normally think of it, does not exist. Rather, knowledge resides in the community of learners (individuals) that creates it. This knowledge is distributed among members of that community and various environmental characteristics that support it.

The various theories of learning can be summarized in several ways. The most common is to classify the theories with regard to the type of theoretical explanation each provides: i.e., behavioral, cognitive, and social. Each of these three general views of learning and knowing is associated with a particular philosophical and methodological perspective: empirical, rational, and pragmatic-socio-historical, respectively (Greeno et al. 1996).

These and other theoretical approaches to learning are discussed in more detail below. First, however, the meaning (definition) of 'learning' and several general issues will be considered.

1. *Definitions of Learning*

Understanding any theory requires a clear idea of what the theory is trying to explain. As new theories of learning emerged, the conception of learning changed. In short, 'learning' was defined in new ways. These fresh perspectives add to our understanding of learning, but to the extent the theories explain different aspects of the learning process, fitting the pieces together is not a simple task.

Traditionally, learning has been defined in terms of a change in a person's behavior, knowledge, or ability to perform some task (including intellectual tasks). These definitions usually stipulate that the change must result from the learner interacting with his or her environment, although most researchers would include the mental, as well as the physical, environment.

Change is the main criteria in these definitions, although changes that result from physiological maturation and temporary changes (e.g., those that result from drugs or fatigue) are explicitly excluded from the definition. This definition remained pretty much the same with cognitive theories, although as might be expected, the focus shifted to changes in mental processes, knowledge structures, and understanding.

With the advent of constructivism and sociocultural theories of learning, knowledge no longer was seen as a commodity to be transmitted. Knowledge was now seen as being distributed among several individuals and 'affordances' (tools, artifacts, etc.) provided by the environment. The definition of learning changed to interacting with other learners (including individuals with more experience) on a meaningful task. Some psychologists might question whether this is truly a definition of 'learning,' but it does describe the phenomena in which these investigators are interested.

Lave and Wenger (1991), for example, are explicit about redefining learning, thinking, and knowing as 'relations among people in activity in, with, and arising from the socially and culturally structured world' (p. 51). From this perspective, learning is largely a matter of becoming attuned to both the constraints and affordances (what the situation makes possible) of participating (learning) in this social setting (Greeno et al. 1996, 1998). As Greeno et al. (1996) suggest, 'When knowing is viewed as practices of communities and the abilities of individuals to participate in those practices, then learning is the strengthening of those practices and participatory abilities' (p. 23).

Thus, several different definitions of learning are apparent in the literature. If a phenomenon is defined in different ways, it is reasonable to expect that substantial and qualitative differences will exist in the theories proposed to explain the phenomenon. It sometimes seems as if a single theory should be able to explain learning in all situations. The various theories of learning often compete with one another as to which is 'best,' but actually they complement rather than contradict one another. One theory may provide a better explanation than another theory for a particular type or aspect of learning, but there is plenty of room for more than one theory, for learning is multifaceted.

2. *General Issues*

Several general issues provide a context for interpreting what is presently understood about the nature of learning, how it occurs, and how it can be facilitated.

2.1 *More than one Type of Learning*

As noted previously, there are several different types of learning. Those working within a particular theoretical perspective often ignore (occasionally deny) the importance or existence of other types of learning. To fully understand learning, one must realize that a particular theory may provide a good explanation of

learning in one situation but a poor explanation of learning in a different situation.

There is little agreement on exactly how many different types of learning exist. Nevertheless, several different kinds of learning are evident in the following examples: (a) learning to tie one's shoes; (b) becoming fearful of the dark after being scared by a loud clap of thunder after the lights went out during a storm; (c) explaining the causes of World War II; and (d) negotiating the meaning of 'learning' with a person holding a different theoretical perspective. Different theories are good at explaining each type.

When evaluating the validity of a particular theory, it is wise to consider what the person is learning and what is taken as evidence that learning has occurred. For example, a teacher might assume that a student has gained an understanding of a topic when he or she has only memorized certain facts.

2.2 *What is Learned? Learning vs. Understanding vs. Participation*

Theories of learning differ with regard to what they assume a person is learning. Traditional theories suggest that individuals acquire associations between stimuli and responses. These associations are reflected in specific behaviors, including verbal behavior (words), and various skills.

Cognitive theories, on the other hand, emphasize the acquisition of knowledge and mental processes rather than behavior. Highly organized knowledge structures, rather than isolated facts, are seen as the outcomes of learning. The focus of these theories is on understanding, problem solving and conceptual change rather than the memorization of inert knowledge.

'Understanding' is difficult to define in a rigorous manner. Nevertheless, certain characteristics of the concept can be identified. Knowledge must be structured and organized in order for it to be meaningful and capable of being understood. Few people would suggest, for example, that one could understand a particular telephone number, although most would agree it is possible to learn, know, or remember one. Understanding a body of knowledge involves establishing relationships among the concepts and facts that comprise that body of knowledge. Such understandings can be assessed through paraphrasing, summarizing, or answering questions about the material and/or by performing a transfer task.

Situated and sociocultural theories are concerned with individuals participating in a community of learners. Thus, rather than acquiring behavior or knowledge, learners are seen as developing social practices appropriate for functioning in such communities, as well as the ability to use tools (such as computers and calculators) that enhance one's 'intelligence.'

3. *Traditional Approaches to Learning*

Traditional theories of learning view learning within a stimulus-response framework—that is, as something that happens to the learner from the outside in. A stimulus occurs in the environment (perhaps something done or said by another person), and the individual responds. Depending on what happens next (the occurrence of reinforcement or punishment), the probability that the learner will make the same response in the future either increases or decreases. For instance, the frequency of a student's hand raising either increases due to the teacher's positive statement following a correct response or decreases due to the teacher consistently calling on other students or the embarrassment that results from providing an incorrect answer.

These theories provide good explanations for certain kinds of behavior, especially the acquisition of factual information, skills, and behavior patterns. In these cases, the focus is on the performance of behavioral tasks rather than adding components to the learner's cognitive structure. Behavioral theories, however, provide poor explanations for the way individuals come to understand complex ideas and phenomena. The importance of classical conditioning is frequently dismissed as relevant only to dogs salivating (Pavlov's initial research paradigm). This type of learning, however, provides by far the best explanation of how and why humans respond emotionally to a large variety of stimuli and situations. Fear of the dark (or water), a strong dislike (or hatred) for a particular person or group of people, phobias of various kinds, and infatuation with another person are only a few examples of the types of emotional reactions acquired through classical conditioning.

4. *Contemporary Approaches to Learning*

Most contemporary theories of learning assume that learning arises out of the internal conditions or states of the learner (that is, from the inside out rather than the outside in). In general, these internal factors are considered more important than external environmental factors. The learner does not merely 'record' or remember the material to be learned. Rather, he or she constructs a unique mental representation of the material and the task to be performed, selects information perceived to be relevant, and interprets the information on the basis of his or her existing knowledge and current needs. During this process, the learner adds information not explicitly provided by an outside source, whenever he or she needs such information to make sense of the material being studied. Most of these theories, to varying degrees, share three sets of beliefs. First, meaningful learning (i.e., learning for understanding) is an active, self-regulated, constructive, cumulative, and goal-oriented process. Second, learning is dependent on (situated in) the

particular context in which it occurs. Third, learning is fundamentally a social, cultural, and interpersonal process; a process governed as much by social and situational factors as by cognitive factors. Each of these characteristics will be discussed.

4.1 Learning is Active and Self-regulated

It often is said that traditional theories of learning view the learner as passive, although it is more accurate to say they characterize the learner as reactive—i.e., the learner reacts to a stimulus in the environment, and that response is reinforced (or punished). Although behavioral psychologists usually recognize the need for the learner to be active in practicing associative bonds of various kinds, this type of activity is far different from the activity suggested by more recent theorists.

Current theories of learning view the learner as mentally active, even proactive, in his or her efforts to understand, for instance, the use of metaphors or the concept of photosynthesis. The learner carries out various cognitive and metacognitive operations on the information being learned, a process that results in the material being acquired in a meaningful manner.

During this process, the learner makes many decisions about what to do next (e.g., rehearse a particular piece of information, seek an answer to a question that comes to mind, look for similarities among various pieces of information). Effective learners also monitor the learning process, making periodic checks of how well the material is understood. As learning proceeds, the learner regulates his or her activities, making any adjustments that are needed. Among the factors involved in this process of self-regulated learning are metacognition, self-efficacy, and studying.

4.2 Learning is Constructive

The constructive, rather than reproductive, nature of learning is an integral part of most contemporary theories of learning. Understanding is achieved, according to these theories, through an active process of construction rather than by the passive assimilation of information or the memorization of facts. These theories discard the idea that knowledge is an entity that can be passed from one person (teacher, book, etc.) to another (the learner). Rather, each learner (individually or as a member of a group) perceives and interprets new information in a unique manner, based on factors such as prior knowledge, interest, motivation, and attitude toward self. The learner then elaborates this interpretation by relating it to his or her existing understanding of the topic and/or other aspects of the material being learned. As a result, the learner's understandings are reorganized and refined, and he or she may experience growth of general cognitive abilities such as problem solving and metacognitive processes.

Since no two people interpret the same information in the same way, no two people end up with the same understanding of the concepts and facts being studied. In the final analysis, the manner in which the learner processes new material and the type of cognitive processing in which he or she engages is the single most important determiner of what the individual learns.

There is not, however, a single constructivist theory of learning. Considerable differences exist among constructivist theories with regard to the relative influence of the mind versus the environment, private versus public knowledge, and individual versus social factors (Phillips 1995, 2000). Radical constructivism, cognitive constructivism, social constructivism, and situation cognition represent different types of constructivist theories that occupy different positions on these dimensions.

4.3 Learning is Cumulative

All learning builds upon the individual's prior knowledge and experiences, which can either facilitate or inhibit the new learning. Research on schema theory and the difficulties involved in overcoming one's prior conceptions (sometimes referred to as misconceptions when they differ from established conceptions in a field such as science) illustrate the potent influence that prior knowledge has on learning.

4.3.1 Schema Theory. Schema theory, an important aspect of cognitive theories of learning, suggests learners acquire complex, organized structures of information about a topic, such as eating in a restaurant or playing music (Derry 1996, Winn and Snyder 1996). When someone encounters information (perhaps by hearing a story), it is interpreted according to a schema considered appropriate by the learner. The learner will fill in details missing from the material by making inferences based on information contained in the schema.

For example, a person hears a story about four friends having dinner in a restaurant. Unless the story mentions that the group left an unusually small or large tip, the listener will assume with considerable confidence that a normal tip was left. Leaving a tip is part of the schema for eating in a restaurant, although the amount of the tip may vary, depending on the complexity of the person's schema with regard to tipping in different types of restaurants and different countries.

4.3.2 Prior Conceptions. When learners engage in a learning activity, they bring with them a set of prior

conceptions of the topic being studied (e.g., Rezaei and Katz 1998). These initial conceptions make sense to the learner, but frequently they are considered incorrect by the adult community. Because they are so well established, these prior conceptions are very difficult to change, probably far more difficult than most people realize.

In order to understand photosynthesis, for instance, many students must overcome erroneous conceptions about 'food' developed from their experiences with food for people. They 'must abandon their assumptions about the metabolic similarities between plants and humans and restructure their thinking about the nature of food … [In this regard, they must] learn that [certain of their] beliefs about food do not generalize from humans to plants while [other beliefs must] be clarified, expanded, and given new prominence' (Anderson and Roth 1989 p. 278).

Students who score well on classroom tests and receive high grades in a course often maintain inaccurate conceptions of key concepts they had before the topic was studied. These students' true level of understanding is often concealed by tests and assignments that permit them to do well without understanding the material (e.g., by memorizing information). Students must be asked to apply their understandings to a wide range of problems and situations before can one have confidence that they possess an appropriate and adequate understanding of the topic.

4.4 Learning is Goal-oriented

Instructional goals can facilitate learning, although the use of instructional objectives is rejected by most constructivist and social theories of learning. Narrowly defined objectives are reminiscent of behavioral theories and are seen by many as stifling of meaningful learning. Yet, meaningful learning is more likely to be successful if the learner has at least a general idea of the goal being pursued and holds appropriate expectations for achieving the desired understanding.

There are many ways in which learning goals can be established. In many instructional situations, it is appropriate for students to develop or discover their own goals. Identifying appropriate learning goals (which may change as learning progresses) can become an important part of self-regulated learning and metacognitive control. In any case, it is the student'*s* goals that are critical for learning. The statement of objectives or goals by a teacher is not sufficient. Unless the learner adopts the goals as his or her own, they will have little if any impact on the learning process.

4.5 Learning is Situated and Distributed

According to situated theories, knowledge and learning are situated in a particular social context and distributed across various individuals, artifacts and tools (books, calculators, etc.), and the norms and practices of the group in which the learner is participating. The interactive nature of these various systems is considerably broader and more complex than the behavior and cognitive processes of the individual learner (Greeno et al. 1998). As Greeno (1997) notes, 'the situative view [of learning] focuses on practices in which individuals have learned to participate, rather than on knowledge that they have acquired' (p. 6). The role of the individual learner, a hallmark of traditional theories, is no longer a central focus in many current theories.

The suggestion that knowledge and learning are distributed is readily apparent in many common situations. For instance, individuals in a class (or book club) studying 'To Kill a Mocking Bird' will have varying degrees of knowledge about (and understanding of?) the plot, the various characters, the issues addressed, etc. Discussing, analyzing, and critiquing these various perspectives increase each person's understanding of the book and the issues that are raised. But this understanding is partial and incomplete. The individual learner will never have the full understanding that is present in the group. In fact, some of the person's knowledge and understanding may depend on (be available only during) the interaction of various agents (people, artifacts, etc.) that are part of that particular situation.

4.6 Learning is Social, Cultural, and Interpersonal

One of the most important differences between traditional and contemporary theories of learning is the role 'participation' plays in most current theories. Learning is seen as a social, cultural, and interpersonal activity. A community of learners, however, does not refer only to students. Such a community might consist of professional practitioners, a religious organization, or a political enclave.

Many present-day theorists agree with Lev Vygotsky that cultural development and learning occur initially in the social (interpersonal) realm. Social interaction and language play critical roles during this phase. As ideas, understandings, and ways of interacting become established on the social plane, they begin to move to the psychological (intra-personal) plane. As Weade (1992) notes:

> The structure and meaning of an evolving academic discourse is embedded within an evolving social structure. Simply put, the social structure mediates who can talk to (or act toward) whom, when, where, in what ways, for what purposes, under what conditions, and with what tangible or imagined outcomes (p. 95).

5. Mechanisms for Learning

The various theoretical perspectives differ in the way they conceptualize the factors responsible for learning

to occur. Traditional theories suggest learning is the result of reinforcement or feedback. Practice also is important, although practice will not produce learning unless it is accompanied by reinforcement. In the case of classical conditioning, contiguity (proximity) of two stimuli is the primary cause of learning. Cognitive theories generally postulate that learning occurs as the result of elaboration, thinking, problem solving, and/or reflection. It is the mental processing of information, rather than external reinforcement, that produces learning. Shuell (1996) suggests that 12 'learning functions' need to be engaged for meaningful learning to occur: (a) establishing expectations; (b) establishing motivation; (c) activating prior knowledge; (d) focusing attention on relevant features of the material being studied; (e) encoding information; (f) comparing information; (g) generating hypotheses about possible relationships and solutions; (h) repetition of information until it is integrated into higher-level concepts; (i) receiving feedback on adequacy of one's understanding; (j) evaluating one's hypotheses and the feedback received; (k) monitoring the learning/understanding process; and (l) combining, integrating, and synthesizing available information to form a new (revised) understanding of the topic being studied.

Constructivist, situated, and sociocultural theories suggest that learning results from social interaction, discourse, negotiation, and activity (physical and/or mental) in the performance of 'authentic' activities. Presumably, different types of discourse and negotiation, for example, result in different types of learning, but very little research on these factors is presently available.

6. *Educational Paradigms*

Just as there is not a single type of learning, neither is there a single best educational paradigm or instructional practice. Schools and educational programs are far more likely to be based on philosophical presumptions than on empirical and theoretical foundations of learning. Schools differ in their philosophical beliefs about human nature, children, locus of authority, and knowledge, as well as beliefs about the nature of teaching and learning. Every educational system and instructional program contains a theory of learning, although this theoretical foundation usually is implicit.

Some of the philosophical and theoretical differences have endured for centuries, and the debate is likely to continue. For example, the 'factory model' of schooling, based on production and management procedures proven successful during the industrial revolution, dominated education in the USA for many years. This perspective on teaching and learning, however, stands in sharp contrast to the voices of Thoreau, Dewey, and others who advocate discovery, social reform, and freedom as the appropriate means of education (Shuell 1993).

These differences are evident in the various theories of learning discussed previously. Traditional classrooms, for example, are based on traditional theories of learning and knowledge. Knowledge is seen as an entity that can be passed from one person to another (in this case, from teacher to student). Consequently, the curriculum consists primarily of factual information. Since learning is viewed as a process of memorization and practice, an appropriate classroom is one in which the teacher tells students what they need to know through the use of expository and didactic methods. The consistency between the underlying theory of learning and instructional practices is quite apparent.

On the other hand, if one believes that knowledge is something created afresh by students and that learning occurs from working on authentic tasks in a social environment, a very different type of classroom emerges. A visit to this classroom would find students working in groups, very likely discussing how best to solve a problem in order to complete a task. Or they might be found negotiating the meaning of a particular concept in an effort to understand and perhaps apply it to the solution of some problem. Once again, consistency exists between a theory of learning and the instructional practices occurring in the classroom.

Schools and classrooms are organized in different ways, have different learning practices, and assess students in different ways. Students learn more than what they are explicitly taught. They 'also develop patterns of participation and identities that are shaped by these different practices in which they learn' (Greeno et al. 1998: 14). Classroom learning involves social, emotional, and participatory—as well as cognitive—factors. Several educational paradigms based on contemporary theories of learning are discussed.

6.1 *Cognitive Apprenticeship*

The cognitive apprenticeship model of teaching grew out of situated theories of learning. Apprenticeships (both formal and informal) are a common way of learning in non-school settings. Although there are differences between traditional models of apprenticeship and cognitive-apprenticeship models of teaching, the latter were proposed in a belief that the knowledge and skills learned in school have become too abstracted from their use in the world outside of school (Shuell 1996).

Generally, cognitive apprenticeship models of teaching involve a series of six teaching procedures. Students first observe an expert (usually the teacher) model the desired performance in an environment similar to the ones in which the performance is to occur. Second, coaching (hints, feedback, modeling, reminders, etc.) is provided. Next, conceptual scaffold-

ing is provided with the student performing as much of the task as possible, although this external support is gradually faded as the student gains proficiency. Fourth, students are asked to articulate their knowledge and understanding of the task, followed by a request for them to reflect upon their understanding and reasoning. Sixth, students are encouraged to explore new ways in which the knowledge or skill can be used. Cognitive apprenticeship programs have been developed in the areas of reading, writing, and mathematical problem solving.

7. *Reciprocal Teaching*

Reciprocal teaching is a cognitive-apprenticeship model for teaching reading comprehension. The procedure involves a structured dialogue in which the teacher and students take turns (hence the name) leading a discussion that includes four types of strategic activities: predicting, questioning (making up a question on the main idea), summarizing (self-review), and clarifying. Throughout the instructional session, the teacher provides guidance and feedback (scaffolding) tailored to the needs of the current student discussion leader in an attempt to improve the level of his or her performance. A more extensive summary of reciprocal teaching and a list of references are available in Shuell (1996).

7.1 *Conceptual Change Teaching*

A large body of literature, primarily in science and mathematics education, has evolved on overcoming the misconceptions that many students have prior to the start of classroom instruction. As noted previously, these pre-existing conceptions are difficult to change. Changing them involves more than students gaining 'insight,' and the process is a slow one. Four conditions are generally considered important for conceptual change to occur in students (Posner et al. 1982): (a) the student must become dissatisfied with his or her existing conceptions; (b) the new conception must be intelligible to the student; (c) the new conception must initially appear plausible and capable of solving the problems generated by its predecessor; and (d) the student must see the new conception as being useful for understanding a variety of situations.

8. *Summary*

New conceptions and theories have expanded our understanding of human learning by focusing on factors ignored in earlier research. As theories progressed from behavioral to cognitive to situated to sociocultural explanations of learning, the emphasis shifted from changes in behavior to acquisition of knowledge to social participation. The corresponding mechanisms for learning also changed from reinforcement and practice to thinking and other mental processes to participation in a community of learners. To a large extent, however, the various theories compliment one another, for each focus on a different aspect of the learning process or a different type of learning. Generally speaking, contemporary theories suggest that meaningful learning is an active, self-regulated, constructive, cumulative, goal-oriented, context-dependent, social, culturally, and interpersonal process. Various educational paradigms have emerged from these theories, including cognitive apprenticeships, reciprocal teaching, and teaching for conceptual change. With regard to education, these theories suggest that meaning does not reside in the material being learned or the manner in which it is presented to students. Information may possess a potential for being meaningful, but it is the learner who makes it meaningful by processing it in a meaningful manner. It is not sufficient for the teacher to explain or demonstrate how various concepts and facts are related. This activity can occur without the occurrence of meaningful learning on the part of the student.

Learning to Learn

The quest for understanding and harnessing an individual's ability to identify, reflect upon, improve, and control his or her learning processes and outcomes, began in ancient times with the study of mnemonics (memory aids) and Socratic teaching methods. However, it is only since around 1975 that incredible progress in understanding 'learning to learn' and the methods that can be used to improve it have occurred. This entry will present a definition of learning to learn followed by a brief history of the development of the study of learning to learn processes. A model summarizing much of the current research in this area will then be presented as well as a summary of the results of current research examining the effectiveness of methods for improving learning abilities and skills. The entry concludes with a discussion of suggestions for future research and conceptual development in the area of 'learning to learn.'

1. *Learning to Learn Strategies*

'Learning to learn' strategies include any thoughts, behaviors, beliefs, or emotions that facilitate the acquisition, understanding, or later application and transfer of new knowledge and skills in different performance contexts. They range from active rehearsal to help remember word lists, to the use of elaboration and organization to encode, integrate, and later recall or apply knowledge across several content areas. Learning to learn strategies help generate meaning for the new information that is to be learned. Repeating the names of the planets in order, organizing the discoveries of the great explorers by creating timelines and mind maps, comparing and contrasting the causes of World War I and World War II, are all examples of learning strategies. They all are designed to help the learner generate meaning and store the new information in memory in a manner that will facilitate integration with related knowledge and increase the probability of later recall and use, particularly in transfer contexts.

A learning strategy is also a plan for orchestrating cognitive resources to help reach a learning goal. 'Learning to learn' strategies have several characteristics in common. First, they are goal-directed. Learning strategies are used to help meet a standard of performance or to reach a learning goal. Second, learning strategies are intentionally invoked, which implies at least some level of active selection. The selection of one or more of these strategies is determined by a number of factors, such as a student's prior experience with the strategy, his or her prior experience with similar learning tasks, his or her ability to deal with distractions, and the student's commitment to his or her goals. Third, cognitive learning strategies are effortful; they require time and often involve using multiple, highly interactive steps. Because of the effort required, a student must be motivated to initiate and maintain strategy use (e.g., see *Motivation, Learning, and Instruction*). In addition, the student must believe that the strategy will be effective and that he or she can be successful using the strategy. Finally, cognitive learning strategies are not universally applicable—they are situation-specific. The student's goals, the task requirements, the context, and other factors all interact to help determine which strategy may be best. To be successful in selecting and using a strategy, a student must understand under what circumstances a given strategy is, or is not appropriate.

The following section will discuss the evolution of learning to learn as a field of study and a source of applications for many students experiencing difficulty in an educational setting.

2. *Historical Overview*

In ancient times the great Greek orators were known for giving long speeches that sometimes lasted more than two or three hours. They managed this task through the use of mnemonic, or memory devices that helped them to remember both the ideas and the order of the ideas for their presentations. The most famous of these techniques is the Method of Loci. Basically, using the Method of Loci involves remembering a series of locations in order. This could be the buildings and landmarks the orator passed on the way to the arena or the rooms in a large villa. As the ideas were

generated for the speech, the orator would 'store' an image of the idea at a specific location. When the time came to give the speech, the ideas would be recalled as the speaker 'went' from location to location.

For years the study of mnemonics lay dormant until interest renewed in the second half of the twentieth century. Psychology has gone through major upheavals in the twentieth century. The rejection of philosophy and introspection as primary tools for the study of psychology led to the rise of behaviorism and the rejection of 'mental' phenomena. In the rush to be scientific in developing theories and methods, researchers lost their focus on the mind and cognitive processes. It was not until the late 1960s and the 1970s that studies of perception, memory, and cognitive processes once again gained prominence (see *Educational Learning Theory*, *Learning Theories and Educational Paradigms*). Some of the earliest studies of memory re-examined the classical mnemonic systems in an attempt to identify and understand the cognitive processes involved in creating and using them. In the 1970s this literature was enriched by the work of Flavell and others on what he called 'metacognition' (Flavell 1971). Metacognition refers to thinking about thinking. It focuses on knowledge, reflection, and analyses of how an individual thinks and learns (see *Metacognitive Development*: *Educational Implications*). Building on both of these themes, researchers increasingly turned their attention to cognition, the variables that impact cognition, and the degree to which cognition can be influenced through educational interventions. This is the research that led most directly to the study of learning to learn.

3. *Types of Learning to Learn Strategies*

Weinstein and Mayer (1986) summarized much of the research and findings in 'learning to learn' and developed a taxonomy to describe the six major categories of learning strategies. The following is a summary of the categories in the taxonomy.

3.1 Rehearsal Strategies for Basic Learning Tasks

Many instructional tasks require simple recall. The acquisition of basic knowledge, however, is often just a first step in the creation of a more extensive and integrated knowledge base in an area. An example of a task in this category is memorizing the order of the colors in the spectrum. A useful strategy for this type of learning might be to repeat, in sequential order, the names of the colors.

3.2 Rehearsal Strategies for Complex Learning Tasks

Learning tasks in this category are more demanding and tend to involve knowledge and skills extending beyond the superficial learning of lists or unrelated bits of information. Examples of strategies in this category would include highlighting class notes or copying key ideas from the class readings. Like the rehearsal strategies for simple tasks, these methods are often most appropriate in the early stages of building a knowledge base in an area.

3.3 Elaboration Strategies for Basic Learning Tasks

Meaningful learning often involves building bridges between what is already known and what a student is trying to learn. Elaboration strategies help the student build these bridges by using previous knowledge or experiences to add to what he or she is trying to learn as a way to make the new information more meaningful and memorable. Examples of strategies in this area include generating a mental image of a scene described in a novel and relating a scientific principle to everyday experience. The facilitating effect of using these strategies is usually attributed to both the processing that is involved in creating the elaboration and the product itself.

3.4 Elaboration Strategies for Complex Learning Tasks

Strategies in this category help the learner to be more active in building bridges between prior knowledge or experience and more complex tasks. Examples of strategies in this category include paraphrasing and summarizing, applying a problem-solving strategy to a new problem, creating analogies, and using everyday experience to help understand a new concept.

3.5 Organization Strategies for Basic Learning Tasks

Organization strategies involve translating or transforming information into another form and creating some sort of scheme to provide structure for this new way of characterizing the information. Examples of organization strategies for basic tasks include grouping foreign language vocabulary words by their parts of speech and grouping the battles of World War II by their geographic location. Like elaboration strategies, the facilitating effect of organization strategies is usually attributed to both the processing that is involved in creating the organization and the product itself.

3.6 Organization Strategies for Complex Learning Tasks

Complex tasks can often be made more meaningful and more manageable by using organization strat-

Figure 1
Model of strategic learning.

egies. Examples of strategies in this category include creating a hierarchy of main ideas to use in writing a term paper, generating a force diagram in physics, or creating an outline for the class notes from a section of a course. Like all of the strategies in the elaboration and organization categories, it is both the process and the outcome that appear to help in both knowledge acquisition and later recall and performance.

4. *Model of Strategic Learning*

As research in 'learning to learn' expanded in the 1980s and 1990s, it became clear that a number of different factors contribute to, and influence both choice and type of strategy used by a student (see *Self-regulated Learning*). For example, it is not enough for a student to know about different types of learning strategies. He or she must also know how to use them and under what conditions it is appropriate to use them. Another factor that affects the strategies selected and used by a student is the social contexts of both the educational setting, in general, and the individual classroom. There are also support variables that affect a student's attitudes and beliefs about learning and his or her motivation to succeed. These variables help to generate a context in which effective learning can take place. For example, a student must be clear about his or her long-term and short-term academic goals in order to use them to aid his or her motivation to initiate and maintain use of effective learning strategies.

In the past researchers and educational program developers have usually focused on one or a subset of topics within learning to learn, such as cognitive elaboration strategies or student motivation. Current work is purposefully examining the interaction among two or more components related to the acquisition and use of learning strategies. This change is a result of the increasing understanding of the nature of student learning and school achievement at all educational levels. Researchers have found that it is the interaction

among varying factors that results in successful learning and transfer of new knowledge and skills. The components that seem to have the greatest impact on a student's acquisition and use of learning strategies are summarized in a model developed by Weinstein and her colleagues at the Cognitive Learning Strategies Project located at the University of Texas at Austin in the USA (see Fig. 1).

This model is an extension of the earlier model developed by Weinstein and Mayer (1986). It focuses on variables impacting strategic learning; learning that is goal driven. Briefly, the core of the model is the learner's long-term learning goals and self-system variables. Goals are considered to be critical components that provide direction for self-regulating thoughts and actions and for generating and sustaining the motivation necessary to carry out those thoughts and behaviors. A hallmark of a strategic learner is that he or she sets specific and challenging, yet realistic, learning goals and actively pursues them. These learning goals are outcomes to be achieved in and of themselves, but are also subsumed within larger and much longer-term goals and thereby have a future utility value. However, setting specific learning goals is necessary but not sufficient to ensure successful learning outcomes. A strategic learner must also have the skills, motivation and self-regulatory thoughts, beliefs, and behaviors necessary to successfully pursue such goals. The core of the model is surrounded by these three components: (a) the learner's 'skill' levels in relation to the learning task at hand; (b) the learner's 'will' or motivation to accomplish the desired outcome; and (c) the learner's 'self-regulating thoughts, beliefs, and actions' (sometimes referred to as executive control processes in earlier literature). It is the properties that emerge from the interactions among the learner and these components that are at the core of 'learning to learn.' For any given learning task, the student must take into account variables from each of these components.

5. *Current Research, Methodological Issues, and Directions for Future Research*

Much of the current research in learning to learn has focused on improving student learning outcomes, primarily in college or tertiary settings. Researchers have demonstrated the effectiveness of teaching learning to learn strategies to students, often with quite dramatic results. These results have also been robust across content domains, individual classes, and years of college.

Given the importance of learning to learn for student achievement and retention to graduation, additional research is needed to address some of the methodological and conceptual issues in this area. First, there is a need for the development of consistent terms for the various aspects of learning to learn. Currently, each individual or group of researchers uses somewhat different terms to often describe very similar ideas and processes. Second, there is a need for the further development of models of learning to learn at the global level and at more task-specific levels. Third, more knowledge is needed about the nature of transfer of 'learning to learn' strategies. Fourth, measurement of 'learning to learn' strategies and processes needs to be refined. Current instruments like the 'Learning and Study Strategies Questionnaire' and the 'Motivated Strategies for Learning Questionnaire' are good general diagnostic screening measures, but more precise measurements of the components of 'learning to learn' and how they interact in a given learning context are needed. Fifth, additional developmental work to create instructional paradigms to teach learning to learn in both traditional learning contexts and web-based applications is needed.

'Learning to learn' is crucial for success in any learning context. As society moves toward a world where lifelong learning is a fundamental reality, the importance of understanding and using learning to learn strategies will only increase.

Legal Culture and Legal Consciousness

The phrases 'legal culture' and 'legal consciousness' are used analytically to identify the understandings and meanings of law that circulate in social relations. The prefix *legal* characterizes an aspect of the general culture that is associated with law, legal institutions,

legal actors and behaviors. Legal *culture* refers to an aggregate level (macro or group) phenomenon; legal *consciousness* usually refers to micro level social action, specifically the ways in which individuals interpret and mobilize legal meanings and signs.

Culture and consciousness are constructs debated and contested regularly, and the adoption of these terms in legal scholarship has also been fraught with controversy. The meaning of these terms is unstable, both theoretically and empirically. This may be due to a long history in social science as well as common parlance, but it may also be, as Raymond Williams writes, because 'culture is one of the two or three most complicated words in the English language' (Williams 1983, p. 87). Some confusion derives from intermingling two common meanings of culture: as an analytic tool of social analysis referring to the meaningful semiotic aspects of human action, and as a concrete world of beliefs and practices, ways of doing and thinking that are associated with a particular group or society. In the latter use, referring to the distinctive customs, opinions and practices of a particular group or society, the term is often used in the plural, as in the legal cultures of Japan and China, or in reference to African or Latin cultures. In the former, analytic sense, the word is used in the singular, as in legal culture, or the culture of academia. These distinctions need to be specified clearly when using these terms.

Despite often theoretically abstruse debate, many scholars find the concepts of legal culture and consciousness hard to avoid when they attempt to focus on aspects of law that are not confined to formal legal materials (such as doctrines, statutes, cases, constitutions) or offices and institutions (such as lawyers, judges, courts). Legal culture and consciousness are terms used to emphasize analytically ways in which formal legal institutions and everyday social relations intersect and share cognitive resources.

1. *The Concept of Culture Generally*

The concept of culture as an aspect of social life has been invoked in numerous ways. Referring primarily to learned behavior as distinct from that which is given by nature, or biology, culture has been used to designate everything that is humanly produced (habits, beliefs, arts, and artifacts) and passed from one generation to another. In this formulation, culture is distinguished from nature, and distinguishes one society from another. A narrower conception of culture refers to a particular set of social institutions that is devoted specifically to the production of signs and meanings. In this usage, cultural institutions include, for example, art, music, theater, fashion, literature, religion, media, and education. While the first definition is overly broad, including just about all of human life, the second is too specific: the meanings produced and circulating through the other institutions and 'noncultural' spheres of life are ignored or devalued.

Contemporary cultural analyses have moved beyond these extreme conceptions of culture as either everything human or as only that which calls itself culture, to conceive of culture as a system of symbols and meanings and their associated social practices. This formulation of culture treats as inseparable signs and performances, meanings and actions. It highlights by abstracting 'the meaningful aspect of human action out of the flow of concrete interactions … [by disentangling], for the purpose of analysis, the semiotic influences on action from the other sorts of influences—demographic, geographical, biological, technological, economic, and so on—that they are necessarily mixed within any concrete sequence of behavior' (Sewell 1999, p. 44). This attention to linguistic and symbolic aspects of social action rejects any notion that culture is uniform, static, or shared ubiquitously. Moreover, this conception of culture goes beyond a focus on language alone. Drawing from sociological theories of action and practice (Bourdieu 1990), culture is conceived as an arena or field of practical daily interaction, competition, and struggle, deploying repertoires and strategies of action (Swidler 1986). Here, culture is not a coherent, logical and autonomous system of symbols, but a diverse collection of resources that are deployed in the performance of action. Variation and conflict concerning the meaning and use of these symbols and resources is expected. Although many of these cultural resources are discrete, local, and intended for specific purposes, it is possible to observe patterns so that we are able to speak of a culture, or cultural system.

> System and practice are complementary concepts: each presupposes the other … The employment of a symbol can be expected to accomplish a particular goal only because symbols have more or less determinate meanings—meanings specified by their systematically structured relations to other symbols. Hence practice implies a system. But it is equally true that the system has no existence apart from the succession of practices that instantiate, reproduce, or—most interestingly—transform it. Hence a system implies practice. System and practice constitute an indissoluble duality or dialectic: the important theoretical question is thus not whether culture should be conceptualized as practice or as a system of symbols and meanings, but how to conceptualize the articulation of system and practice. (Sewell 1999, p. 47)

2. *The Concept of Legal Culture Introduced and Debated*

Writing in 1975, Lawrence Friedman introduced the concept of 'legal' culture as a means of emphasizing the fact that law was best understood and described as a system, a product of social forces, and itself a conduit of those same forces. Although law is com-

monly understood as 'a set of rules or norms, written or unwritten, about right and wrong behavior, duties and rights,' (1975, p. 2) according to Friedman this conventional notion attributes too much independence and efficacy to the law on the books, effacing the power and predictability of legal practices. To advance a social scientific study of law in action, Friedman adopted the model of a system—a set of structures that processes inputs (demands and resources) from an environment to which it sends its outputs (functions) in an ongoing recursive feedback loop (see *Luhmann, Niklas* (1927–98)). He identified three central components of the legal system: (a) the social and legal forces that, in some way, press in and make 'the law'; (b) 'the law' itself—structures and rules; and (c) the impact of law on behavior in the outside world. 'Where the law comes from and what it accomplishes—the first and third terms—are essentially the *social* study of law' (Friedman 1975, p. 3).

Although the social scientific study of law was, with minor but notable exceptions, marginalized in American universities—law schools and social science departments—Friedman was working in a tradition that had strong European roots. In jurisprudence, for example, Friedrich Karl von Savigny (1831), a nineteenth-century German statesman and jurist, had described law as one of the most important expressions of the 'spirit of a people' (*Volksgeist*), a continuous thread in an evolving culture. Oliver Wendell Holmes (1881), the American judge and jurist, wrote from a very different, distinctly realist and pragmatic rather than romantic perspective, but nonetheless expressed a similar conviction that the law was a great anthropological document. Such notions of the cultural character and significance of law challenged positivist jurisprudence that defined law as an autonomous system of officially sanctioned and logically derived rules and procedures (e.g., see *Legal Scholarship*). Classical works of European sociology also placed law at the center of social life rather than at the margins. Both Durkheim and Weber offered analyses of law both as an expression of broader social forces in the transformations toward modernity, and as a channel for developing social sensibilities, interests, and actions (e.g., see *Durkheim, Emile (1858–1917)*; *Weber, Max (1864–1920)*).

Friedman chose the phrase legal culture to name the 'social forces … constantly at work on the law,' 'those parts of general culture—customs, opinions, ways of doing and thinking—that bend social forces toward or away from the law' (1975, p. 15). As an analytic term, legal culture emphasized the role of taken for granted and familiar actions that operated on and within the interactions of the legal system and its environment. As a descriptive term, it identified a number of related phenomena: public knowledge of and attitudes toward the legal system, as well as patterns of behavior with respect to the legal system. These included judgments about the law's fairness, legitimacy, and utility. To the extent that patterns of attitudes and behaviors are discernible within a population and vary from one group or state to another, it was possible, he said, to speak of the legal culture(s) of groups, organizations, or states (Friedman 1975, p. 194). As an example of variations within legal cultures, Friedman distinguished the internal legal culture of professionals working *in* the system from the external legal culture of citizens interacting *with* the system. As the 'ideas, values, expectations, and attitudes toward law and legal institutions, which some public or some part of the public holds,' legal culture was meant to name a range of phenomena that would be, in principle, measurable (Friedman 1997, p. 34). Although never theorized elaborately and reformulated several times over the years as a general concept more than a set of quantifiable indicators, the concept of legal culture was useful as a way of 'lining up a range of phenomena into one very general category' (1997, p. 33).

Following its introduction, researchers began using the concept of legal culture in a range of empirical projects including studies of: children's knowledge of and attitudes to law (Tapp and Levine 1974), rights consciousness among Americans (Scheingold 1974), the practices of criminal courts (Eisenstein et al. 1988; but see Kritzer and Zemans 1993), and comparative analysis of different groups and nations (Kidder and Hostetler 1990, Hamilton and Sanders 1992, Sanders and Hamilton 1992, Bierbrauer 1994, Chanock 2001). For those who attempt to measure variations in legal culture, the indicators include such diverse phenomena as litigation rates and institutional infrastructures (Blankenburg 1994, 1997); crime rates (Miyazawa 1987), or assumptions about who should use the legal system and when (Ferrarese 1997).

Predictably, debates have arisen among researchers who have attempted to use the concept in empirical projects (Nelken 1997). The most persistent divide seems to be among those who use culture as an analytic concept within a more developed theory of social relations, and those who view legal culture as concrete, measurable phenomena. Those who attempted to use the concept as a focus for comparative research moved quickly toward measurement and a more limited concept. For some of these researchers, when the concept of legal culture is used with insufficient specificity, the distinction between all of culture and legal culture is unclear, and what constitutes the legal seems too often assumed and undefined (Blankenburg 1997). Some researchers insist that legal culture is that which is produced and studied most effectively among professional legal actors, while others insist that such a narrow definition belies the theoretical utility of the concept of legal culture as a way of marking the inescapable connection between law and everyday life, the feedback loop that Friedman posited in his notion of a legal system.

Cotterrell has produced one of the most sustained critiques of the concept (1997). He insists that 'every-

thing about law's institutions and conceptual character needs to be understood in relation to the social conditions which have given rise to it. In this sense law is indeed an expression of culture.' Nonetheless, Cotterrell is unwilling to accept a concept of legal culture that makes it indistinguishable from other forms of social control or normative ordering; instead, he seeks a middle ground that recognizes the cultural influences on and from law but yet retains a recognition of the distinctiveness of legal forms and doctrines.

To some extent, the sociolegal debates reproduce the controversies among anthropologists and sociologists concerning the concept of culture generally. The most important issues are less empirical than theoretical. The measurement problems derive from the theoretical arguments. How is legal culture evident and measurable, and yet diffuse and abstract; what is the relative importance of causal explanation as against description and interpretive understanding in producing a social scientific study of law; how central is formal legal doctrine in understanding participation in, support for, and consequences of law? Contemporary research on legal consciousness addresses these questions.

3. *Legal Consciousness*

If research on legal culture focuses attention on the myriad ways in which law exists within society generally, the study of legal consciousness traces the ways in which law is experienced and interpreted by specific individuals as they engage, avoid, or resist the law and legal meanings. This empirical attention to popular understandings of law reformulates some of the theoretical debates expressed in the study of legal culture.

3.1 *Legal Consciousness as Attitude*

Some scholars conceptualize consciousness as the ideas and attitudes of individuals that, when taken together, determine the form and texture of social life. An expression of the liberal tradition in political and legal theory, this conception of consciousness suggests that social groups of all sizes and types (e.g., families, peer groups, corporations, communities, nation states and societies) emerge out of the aggregated actions of individuals. In this individualist conception, consciousness consists of both reason and desire. According to liberal ideology, inevitable human variation will always assure that humans will desire different things, even if they reason similarly.

Relying on this attitudinal conception of legal consciousness, researchers have attempted to document the variation in beliefs, attitudes, and actions of individuals as a means of explaining the shape of legal institutions and practices. Some assess the degree to which the rule of law is part of the socialization and habits of population (Stalans and Kinsey 1994). Others, Lind and Tyler (1988) for example, document Americans' attachment to ideas of fairness and due process, describing a deep normative consensus on what they call procedural justice (cf. Thibault and Walker 1975, Tyler 1990). The research suggests that Americans commonly evaluate their legal experiences in terms of the processes and forms of interaction rather than the outcomes of those interactions (see *Compliance and Obedience*: *Legal*). In contrast, a study of legal attitudes among Europeans observes considerable variability in citizens' commitments to, and alienation from, law and legal values (Gibson and Caldeira 1997). Studies in states transitioning from authoritarian rule to democracy also report notable intra-nation as well as international variation (Kourilsky-Augeven 1997).

3.2 *Legal Consciousness as Epiphenomenon*

In other formulations, some scholars regard consciousness as a by-product of the operations of social structures rather than the formative agent in shaping institutions and history. Structural anthropology, for instance, describes social actors located in complex webs of patterned social relationships that determine their perceptions and actions. Similarly, some Marxist structuralism treats ideas, including cultural symbols and narratives, as a superstructural residue of material conditions that serve the interests of elites. Following this perspective, legal consciousness is an epiphenomenon, because a particular social and economic structure is understood to produce a corresponding legal order with similarly constituted legal subjects. Individuals seem to lack agency, portrayed as the bearers rather than authors of social relations. Work in this tradition often describes how the needs of capitalist production and reproduction mold legal behavior and consciousness. Studies focus on the production and practice of law, its accommodation to class interests, and the inequities that result.

Some research from this structuralist perspective complicates the proposed relationship between law and institutional structures by suggesting that the legal order develops in response to conflicts and inconsistencies generated by the capitalist mode of production rather than as a direct instrument of particular class interests. 'To legitimize the inconsistencies and irrationalities born of the contradictions of the economy, the legal order constitutes myths, creates institutions of repression, and tries to harmonize exploitation with freedom, expropriation with choice, inherently unequal contractual agreements with an ideology of free will' (Chambliss and Seidman 1982, p. 70). By focusing on the legitimating functions of law, research describes the ways in which law helps people see their worlds, private and public, as both natural and right.

Balbus, for example, argues that certain features of liberal law, such as the highly prized claims to formal equality, what others describe as procedural justice (see *Compliance and Obedience*: *Legal*, buttress and legitimate the inequality of the existing economic order. Due process and formal equality help convince 'the "propertyless" that they have the legal right and, hence, the real opportunity of rising into the bourgeoisie' (Balbus 1973, p. 6). Some of this literature has focused on 'false consciousness,' or the inability of subjects, especially members of the working class, to perceive their true interests or to recognize opposing interests.

Other structuralist and Marxist theorists, however, do not treat cultural symbols as superstructural residues. Althusser (1971), for example, suggests that cultural symbols, or ideologies, are themselves material practices and relatively autonomous; hence culture and ideology are more than just residues. In this sense, the distinction between structure and consciousness is overdrawn. Rather than by-products of material practices, culture and consciousness participate actively in the production of material practices and social realities (see *Structuralism*; *Marxist Social Thought*, *History of*).

4. *Constitutive Theories of Legal Culture and Consciousness*

Constitutive analyses work to resolve these debates concerning causality, determinism, structure, and agency in studies of culture and legal consciousness. Research from a constitutive perspective emphasizes the roles of consciousness and cultural practice as communicating factors between individual agency and social structure rather than expressions of one or the other. Defining legal consciousness as participation in the processes of social construction, research has focused on the ways in which local, concrete action accumulates into systemic institutions and structures (Ewick and Silbey 1998).

Working within a Gramscian framework (e.g., see *Gramsci*, *Antonio* (1891–1937)), analysts try to describe how the taken-for-granted aspects of social relations, including the legal aspects, are produced, enacted, and reproduced. They document situations in which local processes reproduce macro social structures and institutions recursively, and at the same time provide openings for creativity in reshaping those structures. In particular these constitutive/cultural analyses of legal consciousness describe the processes by which law contributes to the articulation of meanings and values in daily life. Attention is directed to the local contests to create controlling meanings from competing discourses within most aspects of ordinary life including families (Merry 1990, Yngvesson 1993), religious communities (Greenhouse 1986), medical care (Heimer and Stassen 1998, Heimer 1999), engineering (Espeland 1998), gender, race or age discrimination (Bumiller 1988), management of handicapped identities (Munger and Engel 1996) or poverty and public welfare (Sarat 1990, Munger 1999) (e.g., see *Law and Everyday Life*). In these analyses, researchers observe both the orchestration of the local contest and the systematic outcome, in this way mediating micro and macro perspectives. Within this framework, consciousness is understood to be part of a reciprocal process in which the meanings given by individuals to their world become patterned, stabilized and objectified. These meanings, once institutionalized, become part of the material and discursive systems that limit and constrain future meaning-making. In this constitutive conception of legal consciousness, law does more than reflect or encode what is otherwise normatively constructed. Law enables as well as constrains the possibilities of social interaction.

In one study, Conley and O'Barr observed litigants in small claims courts to determine how ordinary 'people identify and analyze legal problems, how they decide when and in what form to bring a problem to the legal system, and how they respond to the demands that the system makes of them' (1990, p. ix). The authors observed two distinct discursive styles. One style is rule oriented, adopted primarily by experienced players who see law as a system for assessing and distributing responsibility; this style is valued by the judges and court personnel. The second style focuses on and emphasizes relationships, sequences of events, and the temporal unfolding of a narrative; this style is preferred by minority and group litigants as well as women and poorer citizens. Although having one's day in court is an American ritual, highly prized as an essential human right, many citizens end up frustrated, the researchers claim, because legal authorities prefer and often demand something other than a heart-rending narration of pain or an impassioned moral claim (Merry 1990).

In a recent study of the legal consciousness of ordinary Americans, Ewick and Silbey (1998) construct three accounts of law that encompass the range of cultural materials with which people produce and experience legality as a structure of social action. The stories incorporate alternative normative bases for legal claims to authority, varying constraints that define action as legal, varying sources for legal capacities, as well as varying temporal and spatial locations for law. In one account, the law is remote, impartial and objective, something to be invoked for solemn and collective purposes that transcend the messiness and partiality of individual lives. The law itself resides in times and spaces separate from everyday places and, while enacted by legal functionaries, exists apart from the words or deeds of particular persons. In a second account, legality is understood to be a game of skill, resource, and negotiation, where persons can seek their own interests

legitimately against others. Law in this rendering appears as a defined arena for strategic interactions, sometimes engaged playfully and sometimes with deadly seriousness, but always simultaneously alongside and within everyday life. A third story describes the law as an arbitrary power against which people feel virtually incapacitated. Often the only means of deflecting the legal power is to employ various subterfuges and evasions. These minor forms of resistance typically leave the law unchallenged and unchanged. Their employment and effectiveness is premised, however, upon a potentially subversive recognition of the structure and organization of legality in everyday life.

Ewick and Silbey demonstrate the connection between the micro phenomenon of legal consciousness and the macro institutions of law by showing how the multiple forms of legal consciousness expressed in the three stories of law exist simultaneously, and together sustain legality as a durable structure of social action. Although the dual depictions of law as god-like (remote, transcendent, objective and magisterial) and game-like (legitimate, rule bound, and resource dependent) seem to challenge one another, they are actually complementary. Although each view emphasizes different normative values and provides a different account of the social organization of law, as an ensemble they cover the range of conventional experiences of legality. Any particular experience can find expression within the heterogeneity of the whole. The law is neither rendered irrelevant for everyday life (by virtue of being remote) nor subsumed by it (by virtue of being familiar).

These constitutive studies reject the dualisms in recurrent debates about the relative roles of structure and agency in shaping the world and focus instead on the role of consciousness (participation in social interaction) in (re)producing the social world (e.g., see *Law as Constitutive*). Moreover, these constitutive analyses of culture and consciousness specify how myriad discrete actions accumulate into institutional forms through processes of reification in which the contingent human production of social life is effaced by attending to its continuous, durable features. This attention to systematic aspects make the social interactions and practices appear to be independent of just that human action of which it is composed. Thus, studies of legal culture and consciousness try to emphasize the daily, locally repeated enactment or practice of social structure. Some cultural accounts, however, go so far as to reject explicitly any distinction between structure and agency, insisting that the analytic distinction itself contributes to the ongoing processes of reification constituting social reality. Finally, in these constitutive studies of legal culture and consciousness, law is understood to be part of a complex totality in which 'it constitutes as well is constituted, shapes as well as is shaped' (Kairys 1982, p. 5).

Legal Education

Legal education, in any systematic sense, is a relatively new phenomenon in most jurisdictions. In ancient Greece and Rome there was some formal training in advocacy (moral and legal) supporting the establishment of a professional class of persons with legal expertise, but this class was not a profession. Early forms of legal education were delivered primarily through observation and training acquired by serving as an apprentice to a legal consultant (*jurisprudent*) rather than through formal academic study. For many centuries legal texts were quite rare, which meant that the art of rhetoric inevitably formed the 'core' of early legal education. Gradually, however, as texts on both law and custom became more common and records of court decisions were kept, this dominant oral tradition was supplanted with a new written tradition created by full-time law teachers dedicated to establishing and communicating a literature on, about, and for law. Whether this literature was written to serve the goals of the academy or the professional bodies has never been clear. To the present day, the ultimate goals of legal education have been strongly contested by its various stakeholders.

1. The Establishment of Organized Legal Education

Legal education began by asking universal questions linking legal rules, morals, and justice. Only much later were these elements separated, and some were discarded altogether. The focus on national legal systems correlates with the rise of nation states and legal professions. Early legalists were certainly not parochial in their outlook and did not draw sharp distinctions between law and morality, nor did they fail to consider the relationship with other professions and disciplines. If one draws a distinction between legal *education* and *training*, it could be said that, with the passage of time, the latter has steadily displaced

the former. As a result, the boundaries of legal thought have been shrinking and the legal mind has become more introverted and absorbed with technical ephemeral rules rather than fundamental values.

Roman law, canon law, and international law were the focal points of legal study in the medieval universities on the continent of Europe, and these legal sources formed the basis of a common transnational legal language facilitating trade between commercial classes (see *International Law and Treaties*). The English common law was an exception to this trend where the impact of this triad was greatly reduced by the relatively early development of an indigenous and quite sophisticated legal culture insulated from Roman law. Legal education in medieval England was provided by the Inns of Court, which organized apprenticeships involving both shadowing practitioners and practical exercises within a closed, and almost monastic, community. With the advent of printing, legal texts started to supplant, but not to replace, these informal methods of socialization. Organized legal education for solicitors did not commence until Sir William Blackstone started to give his famous lectures on English law at Oxford in the 1750s. It was not until the Victorian era, with visionaries such as John Austin, Jeremy Bentham, and Sir Henry Maine, that university liberal legal education became established at University College London and beyond, including the Council of Legal Education which was set up in 1852 (see Cocks 1983, 1988). In the United States, legal education is generally seen to have begun with the foundation of Harvard Law School in 1817 (Sutherland 1967, Stevens 1983).

2. *The Aims of Legal Education*

Throughout the world toward the close of the last century, several national reviews were set up to report on the state of legal education (Ormrod 1971, Arthurs 1984, Pearce 1987, MacCrate 1992, Franken 1995 ACLEC 1996). From these national reviews, it is apparent that legal education has increasingly diverse aims serving concurrently both academic and professional goals. The precise mix balancing scholarship and practice varies between, and within, particular jurisdictions. And even within particular institutions there are heated debates about theory, substance, and method. Scholarly approaches have become pluralistic and fall into a number of subcategories: doctrinal ('black letter'); sociolegal; contextual; critical; jurisprudential; interdisciplinary ('law and'); comparative; clinical; and skills-oriented (see Twining 1994). At the most general level almost all would agree that legal education should introduce students to what it means to 'think like a lawyer' (Ormrod 1971, p. 102). Law is an intellectual discipline with distinctive concepts, institutions, and methods of reasoning, and a primary responsibility of all law schools is to create, develop, and transmit this 'core' knowledge. In England and Wales, as elsewhere, the professional bodies take an active interest in defining this core but their involvement is often resented, or resisted, by the academy which claims jurisdiction over the academic stage. The ACLEC Report sought to balance the interests of various stakeholders by concentrating on articulating an 'outcome statement' which specified the broad skills, knowledge, and values law students should possess by the time they graduate without dictating to law teachers precisely how their students should be taught (ACLEC 1996, p. 72).

Interdisciplinary approaches, initially on the periphery of the curriculum, have become increasingly part of the mainstream. Anglo-American legal education has embraced the study of 'law and society,' while law schools in continental Europe have often made non-law subjects, such as legal history, economics, philosophy, or sociology, compulsory for undergraduate law students. In the civil law world, legal education continues to be dominated by the study of codes that can be traced back to Roman law. Codes provide the focal point for formal instruction, which tends to discourage or displace critical reflection. Within the common law systems doctrinal analysis still prevails, although it is now generally accepted that law students should also be exposed to ideas about the context of law.

By the time of their graduation, law students are expected to have laid the foundation for a career which is law-related but not necessarily within the legal profession. Although the majority of law students in England and Wales still expect to qualify as either a solicitor or barrister, this is not true in continental Europe, the United States, or Japan, where the emphasis is on producing lawyers who will disperse into a range of occupations in the public and private sectors. Increasingly it is being recognized that law schools not only prepare students for a career in law but also enable people who can handle legal sources to cope with change in a wide variety of working environments, which could be described as the legal services industry. This industry is being transformed by globalization, new technology, and interdisciplinary tendencies common to all modern professions. Legal education continues to teach students how to 'think like a lawyer,' but today this thinking requires much more than a passive understanding of primary sources, principles, and concepts. It must include a critical awareness of what is happening outside the world of law. Because so much law has a built-in obsolescence, it is vital that law students possess the skills and confidence to interpret new rules and situations. University legal education must therefore provide a solid foundation for the education taking place at the vocational stage and during continuing professional development, as well as a framework for understanding the uncertainties which lie ahead.

3. Trends in Legal Education

In demographic terms, university legal education has been steadily expanding in most jurisdictions since World War II. This has created a mismatch between the supply of law graduates and their demand from prospective employers, at least from within the legal profession. Today most lawyers are middle class university graduates, though they are no longer necessarily law school graduates, or male, or Caucasian. Methods of delivering legal education are constantly evolving, but a university degree which acts as a qualifying examination recognized by the profession has replaced apprenticeship, which was for centuries the normal entry route to a legal career. Women have become increasingly visible in law schools and the profession, and their presence is challenging traditional male-dominated attitudes toward both the law and legal work (see *Feminist Legal Theory*). Moreover, it is possible to enter the profession having studied another degree, and indeed some law firms express a clear preference for those with non-law or mixed degrees (Economides 1999, p. 400).

The professions have always sought to control entry, partly to maintain standards and to protect what they see as a finite amount of legal work that can be shared (Abel 1999). On the other hand, because universities (and to some extent government policy) decide who enters law school—and in most countries these have been expanding in both size and number—law students continue to flood the market. In Japan, which produces 40,000 law graduates a year, recent reforms have increased the total number of places on the professional training course to still only around 1,000 places. What some may describe as the overproduction of law graduates who fail to gain full professional qualifications has also brought about new forms of legal service delivery through so-called 'para-legals.'

The increase in the numbers of those entering law school has not always been matched by a corresponding increase in resources, resulting in adverse staff–student ratios or an imbalance in the social and ethnic composition of the law student population. In order to cope with this expansion in numbers, new teaching methods have evolved, whereby students participate in more independent, active learning, and teachers are under pressure to explore the potential of computer-assisted learning (CAL). Distance-learning in legal education remains uncommon, though is not unknown, and could have significant implications not only for citizens, access to legal education but also for citizen access to legal services more generally. Progress with the notion of community legal education (Cooper and Trubek 1997, p. 233) could be accelerated with increasing access to the Internet and the development of expert systems in law. However, these developments threaten the power base of the legal profession and its exclusive control over legal knowledge and expertise (Susskind 1998).

Law schools tend to deploy a variety of methods to deliver teaching and these are determined by national traditions and available resources. Perhaps as a consequence of increased communication and awareness of different approaches, there is convergence resulting from the exchange of ideas and experimentation. The casebook approach, which was pioneered by Christopher Columbus Langdell at Harvard over a century ago, and the Socratic method in which students are forced to explain the logic of legal argument through a question and answer session conducted in a large classroom, have been exported to other common law countries. Most undergraduate law teaching is delivered through a combination of formal lectures (normally optional) backed up by tutorials, workshops, and/or seminars. Postgraduate legal studies is more library and seminar based. Teaching legal skills has now become an important part of the informal law curriculum in Anglo-American law schools, which have moved beyond mooting (mock trails) to include client-interviewing and clinical approaches sometimes involving live clients. However, the fact that European Union law is now part of the mainstream of the curriculum means that both civilian and common law methodologies are understood by law students throughout Europe (East and West) and European law students can observe the synthesis of these hitherto contrasting legal methodologies in the courts of Luxembourg and Strasbourg.

A further recent trend in legal education common to many modern law schools concerns the revival of interest in the ethics and morality of law. In the United States, the Watergate scandal led to compulsory courses in professional responsibility. In many continental legal systems, deontology is taught, but usually in a highly formal, uncritical manner which does not depart far from the code of professional conduct. For most of the past two centuries positivism has prevailed in the teaching of law, with law students being taught to focus almost exclusively on studying legal rules divorced from their moral, political, or social context. Contextual and critical tendencies in legal scholarship have challenged legal formalism since the 1970s, but most recently there has been an attempt to (re)introduce into the undergraduate curriculum ethical perspectives in order to enrich and deepen the education of law students (Economides 1998). By exposing law students to ethics and values, educators seek to promote a more responsible and less cynical approach to both legal study and practice. Evidence from several jurisdictions in both the common law and civilian legal systems suggests that the modern law school inculcates egotistical cynicism rather than an altruistic sense of public duty or any strong commitment to justice (Cooper and Trubek 1997, 1999, Economides 1998, 1999, Junqueira 1999, Erlanger et al. 1996, Granfield 1992). The need to introduce the

teaching of legal ethics arises not only at the initial stage of legal education but is also necessary at other stages of the educational continuum (see *Legal Positivism*; *Legal Formalism*; *Law in Latin America*).

4. The Educational Continuum

Legal education should be seen as part of lifelong learning and need not be confined to what happens inside law schools or preparation for legal practice. The fact that law schools are expected to deliver lawyers ready for practice often results in narrow, cramped, and overcrowded curricula with an unhealthy obsession with examination grades. This obsession with grades (which determine entry and status within the job market) arguably undermines the educational experience and substitutes competitiveness for collegiality. It also inhibits intellectual freedom by forcing the law student to memorize rules rather than explore ideas, with the result that legal education tends toward 'training for hierarchy' (Kennedy 1982). While the education of lawyers clearly falls into distinct phases, it is perhaps preferable to regard the acquisition of legal skills and knowledge as part of ongoing processes, which are continually refined throughout a legal career, and in this way to reduce some of the pressure and expectations invested in particular rites of passage such as graduation and professional qualification. Ideally each stage should prepare the student for what follows next without being too prescriptive about the content or methods deployed at any particular stage.

4.1 The Initial Stage

Legal education normally commences with an undergraduate degree, though in some countries law may be taught in secondary schools along with instruction in civics or citizenship. In the United States most law schools require graduate entry and this is also the case in India and Pakistan. The undergraduate law degree—in which the foundations of legal knowledge are laid—is thus the normal initial or academic stage of legal education, though most countries permit a measure of flexibility with regard to entry to (and exit from) professional qualification. Postgraduate degrees serve to prepare students for specialist areas of legal work or a career in academic law; students may follow a Masters course or read for a higher degree leading to an MPhil or PhD.

In the Anglo-American system, and in many other countries in the common law world, students are expected to pass examinations in four or five subjects at the end of each year. It is also increasingly common for law schools themselves to be ranked according to their research and teaching quality; such rankings are organized and publicized by government or leading newspapers. The US *News and World Report*, for example, ranks law schools in the United States; in the United Kingdom, the Higher Education Funding Council (HEFCE) administers the Research Assessment Exercise (RAE). Examinations also feature in many continental European countries, but here the university law degree invariably takes much longer; in Germany, the norm is five years (though this is currently under review) and concludes with a single comprehensive examination (the First State Examination) at the end of those five years. Other European countries combine the system of yearly examinations in each course with a comprehensive examination at the end of the five-year period of study (Lonbay, 1990). The examination system has been accused of producing compartmentalized thinking, in which students are unable to think across subject boundaries; for this reason, it has become common to introduce general topics such as Public Law and Private Law which are spread over two years. Apart from the written examination, most law schools offer students the opportunity to write a long essay or dissertation, sometimes in lieu of a written examination; and continental law schools in Italy and France make use of oral examinations and a thesis to be written in the students' final year. In English law schools, the oral examination is usually confined to resolving problematic or borderline results, but increasing use is made of various forms of continual assessment. Students can sometimes also gain credit for working on law reviews, but this is quite rare outside the United States.

4.2 The Vocational Stage

In England and Wales lawyers qualify as barristers or solicitors by taking either the Bar Vocational Course (BVC) or the Legal Practice Course (LPC) (see Economides and Smallcombe 1991). Both courses have introduced a new skills element and can now be taken at various franchised institutions including some university law schools. Following the Courts and Legal Services Act 1990, which blurred the distinction between barristers and solicitors by allowing certain of the latter to gain higher courts rights of audience, the arguments in favor of common training for both branches have become much stronger (see ACLEC 1996, Chap. 5). Currently, barristers' training is focused on the four Inns of Court (Lincoln's Inn, Inner Temple, Middle Temple, Gray's Inn) and falls under the jurisdiction of the Senate of the Inns of Court and the Council on Legal Education, while solicitors' training is governed by the Law Society. University graduates may obtain partial or total exemption from the first part, depending on their degree, provided it satisfies the Joint Announcement on Qualifying Law Degrees. To qualify as a barrister, one must pass the BVC and serve a period of

apprenticeship (pupilage) which involves six months in chambers attached to a barrister. The pupil barrister cannot practice unsupervised until s/he has been a pupil for one year. A major obstacle for students coming from poorer backgrounds has been finding a place in chambers, but the profession has initiated reforms to assist the fair distribution of the limited training places which become available. To qualify as a solicitor, one must pass the LPC and get a training contract in which one serves an apprenticeship as a trainee solicitor, normally attached to a firm of solicitors, for two years. Scotland and Ireland have similar arrangements, though both jurisdictions have progressed farther with the notion of common training. Judicial training, which usually follows a successful career at the Bar, is now overseen by the Judicial Studies Board, while employed lawyers, for example in the Crown Prosecution Service, are subject to further training in-house. Vocational legal education in recent years has been dominated by the large city firms which have invested heavily in in-house training (and toyed with the idea of setting up their own vocational course provider), while many small firms in the provinces and rural areas, even though willing, have been unable to afford to take on trainee solicitors. Common training exists in the United States in that passing the state bar examination (which do vary) both grants admission to the bar and qualifies one for all categories of legal work.

In civil law countries, specialization takes place following graduation. In Japan, Spain, and France there are special national schools to train judges, entry to which is highly competitive and based on performance in an examination. In Germany and Scandinavia law graduates intending to pursue a judicial career also take further vocational examinations and are then attached to a court while serving a probationary period, at the end of which tenure for life is granted. Those wishing to qualify as lawyers follow training geared to particular forms of legal practice. In France, the choice is between qualifying as an advocate, an *avoué*, or a notary. In Germany, law graduates wishing to practice follow a program of practical training as a *Referendar* in diverse legal settings across the public and private sectors at the end of which they must pass the state bar examination (*Assessorexamen*) (see further Lonbay 1990).

4.3 Continuing Professional Development

Most modern professions prefer lawyers to follow practical courses post-qualification in order to refresh their knowledge of law and keep abreast of new developments, but few have gone so far as to make continuing professional development (CPD) compulsory. In the United States CPD is mandatory in only 16 states; in Australia, only New South Wales requires general mandatory CPD (Nelson 1993). There is no CPD in Austria, Belgium, France, the Nordic countries, Germany, Greece, Ireland, Italy, or Luxembourg, although a compulsory CPD regime has been operative in the Netherlands since 1996 for all Dutch lawyers (*advocaten*). Spain and Portugal have been reviewing CPD and increasing the provision of voluntary courses. In England and Wales both branches of the profession now require CPD (see ACLEC 1997).

Legal Formalism

'Legal formalism' is an important category in the history of law, the sociology of law, comparative law, and the cultural study of law, as well as in the philosophy of law and the interdisciplinary field currently called 'legal theory.' It is used in different senses in these different fields, and within each field it is a contested concept, rather than a well-established term with a clear meaning. This entry presents a catalogue of different usages and a brief introduction to the modes of contestation of the meaning of the term.

The modern usages of the word derive from the work of leading legal theorists of the late nineteenth and early twentieth centuries who were much concerned with two historical phenomena that play little role in the late twentieth-century discussion. One of these was 'primitive formalism,' meaning the practice of deciding disputes through devices such as oracles and trial by battle, regarded as 'irrational.' The other was the ancient Roman and medieval English system of 'formulary justice' or 'strict law,' in which a claimant could get redress through the legal system only by fitting his case into a closed class of 'actions.' No overarching principles were available, at least according to the theory, to deal with cases that fell outside the class, but within generally held ideas of moral responsibility. Modern law, in the nineteenth-century view, was characterized by its movement beyond both primitive formalism and formulary justice, but had to find a way to preserve some of the virtues of these earlier systems. (Maine 1917, von Jhering 1869, Holmes 1881, Pollock and Maitland 1898, Weber 1954).

1. *Formalism as a Descriptive Category*

Greater or lesser formalism is one of the dimensions along which we compare legal regimes and assess internal change, whether at the level of detail, of a large ensemble of rules, or of a system as a whole. One might also just say 'more or less formal,' or call it the dimension of 'formality.' In this usage, no positive or negative evaluation is indicated by categorizing a body of legal rules as more or less formal or formalist. A system is procedurally formalist to the extent that it makes the success of a substantive legal claim depend on following procedural rules (Schauer 1988). It is transactionally formalist to the extent that it requires specific formalities for transactions such as contracts or marriages (von Jhering 1869, Demogue 1911, Fuller 1941). It is administratively formalist to the extent that it surrounds the exercise of state power with procedural and transactional formalities. Rule formalism is a general preference for rules over standards.

Two important dimensions of formality are the degree of insistence on compliance with formalities (what exceptions are permitted?), and the degree of absoluteness of the sanction of nullity for failure to comply (what remedies, if any, for a person who fails to comply?). The degree of formality in each dimension varies within systems, between systems, and over time. What binds the types together is the willingness of the formalist to sacrifice substantive justice (or 'equity') in the particular case. Western legal discourse provides a highly developed set of arguments in favor of and against adopting more or less formal rule systems, and a rich literature on the moral and political meaning and practical consequences of the choice. Every argument for greater formality has a symmetrical opposite urging less formality (Kennedy 1976).

A different descriptive use of the term legal formalism refers to a range of techniques of legal interpretation based on the meaning of norms (whether established privately, as in contracts, or publicly, as in statutes), and refusing reference to the norms' purposes, the general policies underlying the legal order, or the extrajuristic preferences of the interpreter. Textual interpretive formalism decides by identifying a valid norm applicable to the case and then applying it by parsing the meanings of the words that compose it. Textual formalism is literalist to the extent that it refuses to vary meaning according to context, and originalist to the extent that it finds meaning only through the context at the time of enactment (Schauer 1988).

Conceptual interpretive formalism 'constructs' general principles thought necessary if the legal system is to be understood as coherent. It uses the principles to resolve uncertainty about the meaning of extant valid norms, and applies the principles according to their meaning to fill apparent gaps (Geny 1899). Precedential interpretive formalism interprets according to the meaning of norms derived as the holdings of prior cases (Grey 1983).

Interpretation positing gaplessness requires the interpreter to apply in every case, according to their meanings, the legal norms he or she can derive textually, conceptually, or through precedent; it categorically forbids reference to purposes and policies (Weber 1954). A final descriptive use of the term formalism in legal discourse refers to theories that purport to derive particular rules of law, or prohibitions on adopting particular rules, from a small group of internally consistent abstract principles and concepts (e.g., corrective justice, fault) understood as morally binding on legal actors (Weinrib 1988).

As with the discourse of the appropriate degree of formality of norm systems, there is a wide range of arguments for and against the adoption of each of these types of interpretive formalism. There is also disagreement as to their conceptual coherence and practicability (Kennedy 1997).

2. *Formalism as a Critical Category*

The critical use of the category of formalism was developed by the sociological jurists around the turn of the twentieth century, in their attack on mainstream late nineteenth-century legal thought. According to the critics, the mainstream saw law as having a strong internal structural coherence based on the two traits of 'individualism' and commitment to legal interpretive formalism. These traits combined in 'the will theory.'

In the sociological jurists' version, the will theory was that the private law rules of the 'advanced' Western nation states were well understood as a set of rational derivations from the notion that government should help individuals realize their wills, restrained only as necessary to permit others to do the same. In its more ambitious versions, the will theory made public as well as private law norms follow from this foundational commitment (for example, by generating theories of the separation of powers from the nature of rights).

The will theory presupposed consensus in favor of the goal of individual self-realization. It was not a political or moral philosophy justifying this goal; nor was it a positive historical or sociological theory about how this had come to be the goal. Rather, the theory offered a specific, will-based, and deductive interpretation of the interrelationship of the dozens or hundreds of relatively concrete norms of the extant national legal orders, and of the legislative and adjudicative institutions that generated and applied the norms (Pound 1917, Kennedy 2000).

The sociological jurists critiqued the individualist premises of the will theory in the name of 'social law' (Gurvitch 1932). They also critiqued its methodology, on two grounds. First, they argued that in practice it involved the widespread abuse of deduction, meaning that jurists habitually offered deductive justifications for interpretations that were in fact logically underdetermined (von Jhering 1877–83, Holmes 1897, Geny 1899).

Second, they argued that the will theory falsely assumed the possibility of constructing the legal order in such a way that it would be gapless in fact, and therefore susceptible to exclusively meaning-based interpretation. The sociological jurists claimed that particular instances of the abuse of deduction, and the theory of meaning-based gaplessness generally, disguised the biases of interpreters, and prevented the consideration of the 'legislative' element in interpretation. They advocated interpretation on the basis of 'scientifically' established social desiderata, as well as or instead of according to meaning (von Jhering 1877–83, Geny 1899, Cardozo 1921).

It is a matter of dispute in legal historiography to what extent late nineteenth-century legal thought was well characterized by its critics, and to what extent the will theory and formal methods caused it to have a politically conservative substantive content (contrast Kennedy 1980, Grey 1983, Horwitz 1992). It is nonetheless clear that sociological jurisprudence dramatically changed mainstream legal academic discourse through its critiques of the abuse of deduction and of the possibility of meaning-based gaplessness. However, structurally analogous conflicts, involving the same elements, preoccupied legal thinkers throughout the twentieth century. These reflect a historical dialectic of critique and reconstruction, in which new positions are only uncannily similar to, not identical with, previous ones.

Whether in the form of Geny's '*libre recherche scientifique*' (Geny 1899) or Cardozo's 'method of sociology' (Cardozo 1921), the sociological jurists' proposed alternative method was rejected during the 1930s by a new legal theoretical avant-garde, including both the American legal realists and Kelsenian neopositivists on the Continent, on the ground that its proponents confused facts and values, scientific and normative judgments. The critics argued that the social purposes or functions the sociological jurists used to base their means/ends rational derivations of legal rules were either vague or conflicted in particular cases, so that the claim to a scientific method was no more than a screen for a new form of politically progressive natural law (Llewellyn 1930, Kelsen 1934). In the US, the progressive academic elite abandoned sociology in favor of two (arguably contradictory) normative projects: in private and administrative law, 'policy analysis,' understood as the process of reconcil-

ing or balancing diverse legal desiderata on the basis of information about the social context (Fuller 1941, Kennedy 2000); and in constitutional law, civil libertarianism.

Critics of the Warren Court's progressive civil libertarian reform of American public law charged the Court with formalism, that is, with an abuse of deduction from personal rights exactly analogous to the earlier conservative abuse of deduction from property and contract rights (Hand 1958). Critical legal scholars critiqued the policy-based post-New Deal technique of private and administrative law as 'social conceptualism' or 'policy formalism,' because it selected policies arbitrarily, underestimated the conflicts among them, and offered no defense of balancing as a rationally determinate procedure. (Klare 1978). The post-1960s reconstruction projects that grounded adjudication either in the efficiency norm or in concepts like autonomy or commutative justice were vulnerable to similar critiques.

Modern legal theory (with the exception of natural law theorists) is antiformalist, in the sense of denying the possibility of strictly meaning based gaplessness. Positivism, whether in its Hart or its Kelsen variant, affirms that discretion in adjudication is inevitable, while limiting it to the 'penumbra' or to the area inside the 'frame' provided by the norm in question (Hart 1994, Kelsen 1934). American legal theory, from Cardozo to Dworkin, is antipositivist, and affirms gaplessness, but on the basis of policy, purpose, rights, or principles, rather than on the basis of textual, conceptual, or precedential formalism (Kennedy 1997). In the debate between H. L. A. Hart and Lon Fuller, Hart charged Fuller with formalism because Fuller believed in a gapless order, and Fuller charged Hart with formalism because Hart believed there were easy cases where norm application was truly meaning-based.

Since World War II, there have been a variety of theories that challenge not meaning-based gaplessness, but all meaning-based interpretation, in so much as it claims to be a matter of legal 'truth.' In the common law world, a first critique of precedential interpretive formalism is that policy argument is always necessary in order to determine the relevance of a precedent for a new case (Brewer 1996). A second is that common law theory, if it is to be coherent, must authorize the creation of an exception to a precedentially established rule in any case where an exception would serve the policies animating the system as a whole (Schauer 1991).

On the Continent, rhetorical and hermeneutic theories of legal interpretation assert that outcomes are always relative to horizons, no matter how superficially deductive (and then reground interpretation in the supposedly shared horizon of liberal faith) (Herget 1996). Postmodern theorists take it for granted that there are critiques of meaning-based and policy-based legal reasoning sufficiently conclusive that the interesting questions concern the interpretation of the subjective experience of legal certainty and the juristic status of concepts like 'justice' (Goodrich and Carlson 1998). Skeptical theories gain support from comparative law scholarship showing diametrically opposed interpretations of identical code provisions, and identical case law derived from contradictory code provisions (Sacco 1991).

3. *Formalism as a Category in the Sociology of Law*

Treves usefully distinguishes between sociologies that include law as one of the elements in an integrated representation of society, and sociologies that take law as their object, bringing to bear on it the variety of instruments of sociological investigation (Treves 1995). The concept of legal formalism has been deployed critically against the first type of theory and descriptively within the second type.

In both descriptive sociologies of modernity and prescriptive political philosophical accounts, it is common for law to figure as an important, sometimes an essential, building block. The theory is not about law, but if its representation of law is inaccurate, the theory fails. The charge of formalism, in this context, means that the general theory represents law as having a gapless, meaning-based internal structure, responsive to outside imperatives of some kind. In fact, according to the critics, the contradictory internal structure of Western legal systems leaves adjudicators and other legal administrators great discretion in the interpretation of norms. It follows that neither the legitimacy of the legal order, nor its content, nor the effects of legal institutions, can be inferred from the external imperatives the theorist imagines animate them.

In this vein, critical legal scholars attacked the Marxist sociology of law as no more than the will theory, with the 'logic of the commodity' in place of natural rights (Kennedy 1997), and then turned the same critique on American functionalist legal sociology (Gordon 1984), and finally against the Habermasian attempt to distinguish between discourses of justification and application (Michelman 1996). In each case, a formalist treatment of law was the weak link in the general sociological construction.

The field-defining work in Treves's second mode—the multifaceted investigation of law as a social phenomenon—has been Max Weber's *Economy and Society*. Weber there offers a descriptive typology of forms of legal rationality. The 'highest' type—a logically formal rational system—is a collection of norms that are internally consistent and that officials apply to particular fact situations according to textual and conceptual formalism premised on gaplessness, as described above. In Weber's phrase, interpretation is

the 'logical analysis of meaning.' Despite the superficial resemblance, this ideal type is not just the late nineteenth-century will theory under another name, because it is not intrinsically associated with either the concept or the social reality of individual freedom, and because it is a contingent product of Continental legal history, rather than implicit in a larger normative conception. Weber dismissed the critiques formulated by the sociological jurists, described above, as self-serving resistance to the inevitable rationalizing trend of modernity (Weber 1954).

For this reason, his ideal type today defines a problematic rather than offering a powerful description. First, it is a matter for investigation how an order claiming any of Weber's types of legal rationality operates through officials at the level of practice (Sarat 1985), how state law interacts with other normative orders, and what effects are plausibly linked to a type (Trubek 1972). Second, it is a question for further study whether it is ever plausible, given the critique of gaplessness and the ever-present possibility of the abuse of deduction, that a legal order operates in practice in a way usefully described as logically formal rationality. Third, as the above discussion shows, the legal/bureaucratic mode of legitimation no longer relies on the claim of logically formal rationality, but rather on a complex mixture of claims of local meaning-based closure, claims of policy rationality (substantively rational, in Weber's terminology), and claims of democratic procedural legitimacy. These have not precluded a 'legitimation crisis.'

Paradoxically, given Weber's starting point, the modern sociology of law typically takes claims of closure in interpretation as motivated errors requiring explanation, rather than as the accurate self-description of legal modernity. Since 1900 critics have argued that the claim of closure masks conscious or unconscious 'legislative' or ideological agendas, and, since the 1930s, that the same claim is in one way or another linked to the Freudian superego and the Father (Holmes 1897, Frank 1949, Kennedy 1997, Goodrich and Carlson 1998).

4. Conclusion

Formalism, in its various senses, has been an epithet for so long that it is a plausible act of rebellion to embrace it (Scalia 1989), and many of the doctrines of the late nineteenth-century US Supreme Court that provoked the sociological jurists' critique have been revived in recent American constitutional law. These developments have produced interesting new critiques, but have not revised the terms of the discussion. Toward the end of Karl Llewellyn's classic article, 'What price contract?' (1931), he writes: 'One turns from contemplation of the work of contract as from the experience of Greek tragedy. Life struggling against form, or through form to its will—"pity and terror".' One might respond, against Llewellyn's romanticism, that descriptively formal law—both formal rule systems and formal techniques of interpretation—involves the morally delicate refusal to respond to the call for justice in the particular case, for reasons that may be good or bad according to the circumstances. Formal law is part of the drama of governance, the trivial or murderous drama of breaking eggs to make omelettes. The critical use of the term formalism, against the abuse of deduction and the fantasy of gaplessness in legal discourse, is part of the twentieth-century battle between those who have wanted to depoliticize the drama as much as possible, through reason, and those who have seen it as inevitably a dangerous improvisation.

Legal Insurance

1. The Term 'Legal Insurance'

Legal insurance is a voluntary private insurance which covers the costs of lawsuits. It may also be called *legal cost insurance*, *legal expenses insurance*, or *legal protection insurance*. The German expression is *Rechtsschutzversicherung*, the French *l'assurance de défense*. The European Union directive EU 87/344/EWG uses the term *legal expenses insurance*, which is defined in Art. 2 as follows: 'Such consists in undertaking, against the payment of a premium, to bear the costs of legal proceedings and to provide other services directly linked to insurance cover, in particular with a view to:

(a) securing compensation for the loss, damage or injury suffered by the insured person, by settlement out of court or through civil or criminal proceedings,

(b) defending or representing the insured person in civil, criminal, administrative or other proceedings or in respect of any claim made against him.'

The expressions *Prepaid Legal Service* and *Group Legal Plan*, which are used in the USA, illustrate the particular economic context and judicial functions of the service in this country. In Asian and African countries, legal insurance is practically unknown.

2. Development and Actual Situation

Although the origins of legal insurance can be found in the nineteenth century, it grew into an economically and politically relevant insurance branch in Western Europe only after World War II, albeit with regional differences. In Great Britain, for example, until 1967 it was forbidden and punishable to financially support another party in litigation if one had no personal interest in the outcome of the trial ('champerty'). Thus, the first legal insurance policy entered the British market as late as 1974. The spread of legal insurance has since been hindered by the high costs of litigation in Great Britain and the resulting low tendency of the general population to go to court (Prais 1995, p. 433). The French have also shown little interest in legal insurance policies. Legal insurance has, in contrast, achieved its greatest importance in German-speaking countries. In 1989 average per capita spending on legal insurance was 23.5 ECU in Germany, 10.8 ECU in Switzerland, and 17.4 ECU in Austria. Other countries follow at some distance. Average spending in Belgium was 8.9 ECU, in the Netherlands 5.3 ECU, in France 1.7 ECU, and in Great Britain a mere 1.1 ECU per capita (Blankenburg 1994, p. 295). Since 1989 this branch of insurance has expanded rapidly in all above-mentioned countries, although at different rates. In 1997 the total revenues from legal insurance amounted in Germany to 2.44 billion ECU, or an average 28.4 ECU spent per capita. Swiss revenues reached a level of 17.16 ECU, Austria 30.6 ECU, Belgium 18.9 ECU, the Netherlands 11.9 ECU, and France 5.8 ECU (Comité Européen des Assurances 1999). Over 50 percent of all German

households are covered by at least one legal insurance policy.

Several factors are responsible for the different development of legal insurance coverage in European countries. Most important is the difference in national systems of calculating legal counseling and court costs, in particular because contingency fees for lawyers are illegal in many countries. In calculating the risks of this type of insurance, the insurance company must be able to estimate the future costs of counsel and litigation. The German method of calculating legal counseling fees for both parties according to the sum in dispute (including legal counseling, paid by the party that loses the case), facilitates these estimates.

3. *Types of Insurance*

Insurance for motoring and traffic accidents has been the main factor behind the expansion. The second important field for legal insurance is family insurance, which covers claims arising out of the private sphere of the insured party, his or her spouse, and underaged children. The most common insurance package includes protection from claims arising out of diverse types of contracts, social insurance, and defense in criminal and misdemeanor cases. It is often combined with automobile and traffic insurance. Generally excluded are counseling for legal matters concerning divorce and inheritance, as well as for the stipulation of contract such as real estate purchases and testaments, since the latter are deliberately chosen legal interactions. In this sense, the insurers remain true to the concept of insurance as protection from unattended and unforeseeable risks.

A third field of legal insurance offers commercial legal protection, a policy for businesses and professionals. The coverage includes labor litigation for the employer on the one side, defense in misdemeanor cases and criminal procedures on the other. Some cover taxation matters as well. Generally, coverage also includes insurance for the company's motorized vehicles.

Legal insurance for real estate matters or for commercial leasing are often offered as special policies. A further policy insures farmers.

Legal insurance policies are offered both by specialized companies and by normal insurance companies, for which it is only one, often minor, business area. In some countries, legal counseling is offered by employees of the insurance company, who may not necessarily have legal training; in others the insured party is given complete freedom in the choice of attorney. In Germany, legal counseling by a lawyer is mandatory. Insurance companies allow free choice of attorney, but may offer recommendations. The EU directive 87/344/EWG has brought a certain degree of standardization to Europe, regulating conflicts between insured and insurer and protecting freedom in the choice of legal counsel.

4. *The Situation in the United States*

The American *prepaid legal services* began as a service offered by trade unions and professional groups to their members. These organizations employ attorneys, who advise members not only on labor law, but on all types of legal matters, and represent them in court. This service was suppressed in several states until the US Supreme Court ruled in 1971 that the fundamental constitutional right of 'meaningful access to the courts' would be denied 'if courts could deny associations of workers or others the means of enabling their members to meet the cost of legal representation' (US Transportations Union vs. State Bar of Michigan, 401 US 576 (1971), 585).

The steady development of welfare policies then led to a liberalization of laws regarding legal counsel. Labor unions, employers' associations, and the American Bar Association agreed that legal protection can legally be the subject of a wage settlement. Since this agreement, many funds have been established and financed by workers, unions, and employers. These funds are favorably taxed for nonprofit-organizations, which usually do not cooperate with commercial insurance companies (Pfennigstorf and Schwartz 1986, p. 52). The most common type is the 'group legal service plan,' which covers workers in a particular branch and is financed substantially by the employers.

Through these legal service plans, workers and their families have gained access to legal counseling and, when necessary, to legal support in court. The services extend to all types of legal matters including consultations with and financing of counsel in private concerns (such as real-estate transactions, rental contract, divorce proceedings, and the writing of testaments). These funds thus cover legal counsel needs which are excluded from the European legal insurance policies.

The differences are due to the noncommercial character and socially motivated goals of the US programs. These intend to raise the awareness of legal rights, especially in a population with modest financial means, and to offer them the possibility of asserting these rights (Pfennigstorf and Schwartz 1986, p. 47, see also *Law, Mobilization of*). In order to control the costs and the quality of the rendered legal services, prepaid legal service plans offer counseling only through their own employees, who may be attorneys bound by exclusive contract but in many cases have little or no official legal training. Alternative dispute regulation (ADR) is one very important field of action for these plans.

With this background, commercial legal insurance has only developed slowly. A few insurance companies succeeded with special programs such as consultation by telephone or a limited number of hours of legal

consultation (Pfennigstorf and Schwartz 1986). Since the premium must be relatively low to attract clients, legal insurance tends not to be a profitable commercial venture in the US.

5. *Consequences and the Success of Legal Insurance*

The effects of the expansion of legal insurance have been considered primarily from two perspectives. For some, the growing number of covered persons is itself a success, since ideally everyone, including the financially weaker members of a population, should have access to legal counseling and protection. Others focus on the readiness to litigate, which is facilitated by legal insurance, and the growing burden placed on the courts.

This conflict forms the basis of many discussions of legal insurance in sociological literature and in the public arena, especially in Germany. While most agree that equal access to the courts is a fundamental right under the rule of law, there is also a consensus that unnecessary litigation should be avoided. Critics of legal insurance claim that insured parties will be more likely to use the courts to pursue their rights or presumed rights, since their own financial risks have been minimized, in order to profit from their insurance coverage and the paid premium. Attorneys are purported to recommend more often that a client go to court if that client is insured. This not only increases the growing numbers of lawsuits but also the financial opportunities for the legal professions.

Rational choice theorists argue that legal insurance results in a 'torrent of lawsuits,' 'wasting a huge amount of resources,' and thereby leads to an 'inefficient allocation in civil law procedures' (Adams 1981, p. 125, 1986). According to this analysis, legal insurance must necessarily lead to an increase in the number of lawsuits, since there is no force to counter this expansion. Attorneys have no economic interest in reducing the costs and numbers of lawsuits, since this directly affects their income. Insurance companies are also interested in an increase in lawsuits, since this expands their markets, providing, of course, that they can pass the increase in costs on to their policy holders. Courts, on the other hand, are obliged by law to accept and to decide on every claim and have therefore no means of controlling the number of cases. Meanwhile, the general population seems to react to the increasing complexity of social relationships and the legal system by looking to legal insurance policies as a form of protection against possible future lawsuits (Blankenburg 1994).

Empirical research has, in contrast, shown that legal insurance has caused only a mild increase in lawsuits in Germany (Blankenburg and Fiedler 1981, Jagodzinski et al. 1994). Insured plaintiffs litigate only 5–10 percent more often and more persistently than uninsured plaintiffs. In some fields of litigation, the difference is even smaller. Considerable differences of 10 percent to 27 percent between the two groups have been observed only in the contestation of traffic misdemeanors. In these particular cases, the insured tend to be less successful than the uninsured, since insured plaintiffs are more willing to go to court in less promising cases or to claim excessive sums which can not be awarded by the court (Jagodzinski et al. 1994, p. 141).

These empirical studies show that it is incorrect to assume that a 'torrent of lawsuits' have been caused by legal insurance. Legal insurance does not lead to a significant amount of abuse or negative developments. The research suggests that attorneys adequately differentiate between founded and unfounded claims before beginning litigation. Statistics show that when insured plaintiffs litigate more persistently than uninsured plaintiffs, they tend to achieve favorable verdicts (Jagodzinski et al. 1994, p. 143).

Legal insurance has had a definite financial effect on the legal profession, particularly in Germany, where 70 percent of the turnover goes to attorneys. Every attorney received an average of 44,000 DM from legal insurance in 1989. In other countries, it has proved to be far less important for the bar (Blankenburg 1994).

According to Blankenburg, different national regulations concerning legal counseling are the main reason for these discrepancies. While only lawyers are allowed to give legal advice in Germany, insurance companies in the Netherlands rely on the less expensive alternative of legal counseling through company employees. Attorneys are only consulted in complicated cases. The existing competition for clients between legal insurance and lawyers has led to a downward trend in legal counseling fees in this country, and has also resulted in lower premiums for the insurance policies. In Germany, legal insurance counseling and services quickly become unaffordable for the financially weak members of the population. For this reason, legal insurance has not replaced state financed legal aid programs (Blankenburg 1994, p. 296). This observation is also true for GB (Prais 1995, p. 444).

As these discussions show, the effects of legal insurance are varied. It is useful to protect clients' rights but tends to become more and more expensive, since neither lawyers nor the insurance companies have an interest in limiting the costs of legal counseling. As long as there is no effective competition on the market, premiums will continually rise. In this respect, the US system of prepaid legal services is more economical, but it also closes the market for commercial legal insurance, thereby hindering competition. According to European experiences, such a system of legal counseling tends in the long run to increase costs, as long as there is no counteracting force.

Legal Issues: Public Opinion

Two guiding principles of Western democratic thought are that effective government requires the consent of the governed, and public consent requires the fair and just rule of law. Thus research on public opinion toward the law and the legal system has preoccupied mainstream social science for much of its history, reappearing in various guises, including the 'fair press vs. free trial' debate, seemingly paradoxical links between actual crime and fear of crime, public disdain for 'judicial leniency,' and theories of perceptual deterrence.

This short review will of necessity be selective in its coverage. With respect to substantive legal issues, it will emphasize criminal justice, providing only passing references to tort litigation and no coverage of public opinion in the domains of contract law, family law, intellectual property law, and so on. With respect to methodology, it will emphasize quantitative public opinion surveys, statistical modeling of field data, and laboratory experiments, neglecting the rich but idiosyncratic literature using qualitative interviews and qualitative analyses of textual sources. Finally, the article—like the English-language empirical literature—gives disproportionate emphasis to North American and British research, though some lines of cross-cultural research are noted.

1. Public Evaluations of the Legal System: An Overview

1.1 Evaluating the Police

In the aggregate, Americans and Europeans evaluate the police favorably. For example, most Americans report confidence in the police as an institution, and about half have confidence in the ability of the police to protect them from violent crime (Bureau of Justice Statistics 2000). Such confidence is not inevitable. For example, in 1993, positive views of the police were expressed by a majority of French, Belgian, Dutch, and West German citizens but by fewer than half of East Germans (Reif and Melich 1996), and within the United States, African Americans consistently report more negative views of police conduct than the white majority; they are about twice as likely to report low confidence in the police or to express the view that the police have low ethical standards.

1.2 Evaluating Attorneys

Most adults know, or at least recognize, a few of the multitude of 'lawyer jokes' long in circulation (see Galanter 1998). We rarely tell jokes about physicians, whom we hold in high regard, or molesters, whom we loathe. This suggests that we are ambivalent about lawyers; we decry their ruthless mercenary adversarialism—except when they are representing us in a conflict. Thibaut and Walker (1975) asked Americans to imagine various hypothetical conflicts and various mechanisms for resolving them—including two-party mediation, third-party investigation and resolution by a neutral inquisitor, and a third-party decision based on investigation and arguments presented by advocates for each side. Importantly, the descriptions were stripped of labels like 'lawyer' or 'judge' and other overt references to actual legal systems. A strong majority identified the adversarial system as the fairest mechanism. Subsequent studies (see Lind and Tyler 1988) have

replicated this finding in European nations with inquisitorial systems, suggesting that it is not an artifact of American socialization or familiarity with adversarial justice. (However, respondents in Asian countries tend to divide their support between the adversarial model and two-party mediation.)

1.3 Evaluating the Courts

A majority of Americans—of all ethnicities—rate the honesty and ethical standards of judges as high or very high (Bureau of Justice Statistics 2000). But this high regard does not translate into satisfaction with judges' decisions. For several decades in the twentieth century, American public opinion polls showed consistent majority support for the view that the courts are too lenient in their treatment of criminal defendants, (Bureau of Justice Statistics 2000). Interestingly, African Americans are only slightly less likely to endorse this view, and the gap between racial groups has been closing.

Taken at face value, these statistics imply that the courts are either 'out of touch' with public views, or intentionally ignoring them. There is some basis for the latter interpretation, of course; Western systems of rights and protections evolved in large part to protect individuals from group tyranny. But a number of clever experiments reveal these citizen complaints are largely based on distorted perceptions of the justice system and its caseload (see Roberts and Stalans 1998). Citizens who view courts as lenient in the abstract have been found to recommend criminal sentences that fall *below* statutory mandatory minimum sentences or the discretionary sentences of judges. And citizens' views in actual cases become significantly more lenient when they read lengthy trial descriptions rather than short trial summaries.

Most available survey evidence indicates that Americans hold much more favorable opinions of the jury system than of the courts more generally (Hans 1993). MacCoun and Tyler (1988) found that citizens strongly preferred trial by jury to trial by judge, and the traditional 12-person unanimous jury to smaller or nonunanimous juries. Relative to trial by judge and to smaller or nonunanimous juries, the traditional jury structure was seen as fairer, more accurate, more thorough, and more representative of community viewpoints. This was not blind enthusiasm; citizens preferred more efficient approaches (trial by judge or small nonunanimous juries) for trivial cases like shoplifting.

Proponents of alternative dispute resolution (ADR) mechanisms such as arbitration and mediation argue that traditional trials are too costly, too time-consuming, too complex, and too alienating. Indeed, many (but not all) ADR programs receive high marks from all parties (plaintiffs, defendants, and attorneys), but contrary to the ADR movement's rhetoric, disputants who actually participate in trials tend to view the trial process favorably, and to a surprising extent, this is true of 'losers' as well as those who prevail at trial (MacCoun et al. 1992).

2. Sources and Mechanisms of Influence on Public Views

2.1 Direct Experience

The procedural justice literature documents the importance of direct personal experience in shaping the public's views of law and legal authorities. Most citizens have had direct contact with the police; some have had contact with lawyers; fewer have participated in trials; and only a minority have direct experience with the penal system.

For many citizens, jury service is their major (or only) direct experience with the court system. Diamond (1993) has reviewed survey evidence on the effects of jury service on public attitudes, finding that a majority of jurors provide positive evaluations of the jury system, and of the legal system, after their service. Most jurors say their attitudes became more favorable than before their service, and attitudes are more favorable among those who are selected for a jury than among those who serve but are not seated.

2.2 Mass Media Effects

Clearly, citizens without direct contact with the legal system must base their views on other sources. But even those with direct experience are routinely bombarded with indirect, vicarious information. There is an enormous literature demonstrating that the mass media promote distorted views of crime, and the process and outcomes of the justice system (e.g., Roberts and Stalans 1998, Warr 1994). The presumed causal chain is ACTUAL EVENTS → MEDIA FILTERING AND DISTORTION → BIASED PUBLIC BELIEFS AND OPINIONS, with these public views feeding back to the media via consumer choices.

The first part of the chain is well supported. Numerous content analyses over several decades show a consistent pattern: Media coverage provides a highly skewed picture of crime and the legal system, and this is true of newspapers, television news, 'reality-based' police shows, and fictional portrayals on television and in movies. In the criminal domain, reported offenses are disproportionately violent, defendants are disproportionately African American, police officers are disproportionately European American, victims are disproportionately female, and offenses disproportionately involve strangers (see Warr 1994). In the personal injury domain, reported lawsuits are

much more likely to result in a jury trials and to produce a plaintiff victory than the typical or average lawsuits, and reported jury awards are 14 times larger than the average award in state courts, and 34 times the size of the median award (Bailis and MacCoun 1996).

There is also evidence for the second half of the causal chain. The prejudicial effects of pretrial publicity on criminal juror judgments are well documented (see Steblay et al. 1999). And numerous studies indicate that citizens' views of court leniency are shaped by the mass media (see Warr 1994). Citizens tend to overestimate the severity of typical crimes and criminals (relative to official statistics), and these misperceptions reliably predict the propensity to see the courts as excessively lenient; e.g., citizens given actual newspaper accounts of trials supported harsher criminal sentences than citizens who read actual court documents from the same cases (see Roberts and Stalans 1998).

2.3 Hindsight Bias

Hindsight bias is the *ex post* tendency to overestimate the *ex ante* likelihood of an outcome, relative to what one would have actually guessed before the event. Because most legal judgments are made *ex post*, they are vulnerable to this bias, as documented in a variety of experimental studies (Rachlinski 1998). Hindsight bias also influences citizens' *ex post* reactions to newsworthy legal decisions. Trial evidence appears more incriminating to people who believe a defendant has been convicted than for those who believe the defendant was acquitted (Bodenhausen 1990).

A pernicious example of this phenomena was the elite and popular reaction to the acquittal of actor/athlete O. J. Simpson at his criminal homicide trial in the USA. Because 9 of the 12 jurors were African American, a large number of commentators, including the lead prosecutor, 'explained' the verdict as a case of 'racial nullification'—the notion that African Americans are more lenient when judging other African Americans. In an October 1995 Gallup poll, 48 percent of whites vs. 18 percent of African Americans said they had 'less confidence' that 'jurors can reach a verdict in a trial without letting their racial attitudes affect their judgment' (Moore and Saad 1995). In fact, the jury literature provides little support for 'racial nullification' as a general phenomenon (Kerr et al. 1995). The reasons for the acquittal will never be known with certainty, but it seems clear that pronouncements of 'racial nullification' reflected hindsight bias. Despite widespread knowledge of the composition of the jury, surveys during the trial showed that few trial attorneys and citizens expected an acquittal; indeed *Sporting Index* reported that most American gamblers were betting on a conviction (*Los Angeles Times* 1995).

2.4 Victim Blaming

Cognitive accessibility and hindsight effects are 'cold' cognitive mechanisms, but there is little doubt that 'hot' emotional and motivational factors influence public opinion as well. According to the just world theory (see Montada and Lerner 1998), it is psychologically threatening to believe that undeserving victims can suffer a horrible fate. Experiments show that we often alleviate this distress by searching for reasons why victims 'got what they deserved.'

3. Underlying Dimensions of Public Evaluations of the Legal System

The history of theory and research on lay justice judgments involves a continuous branching process in which simple, unidimensional models have given way to more complex multidimensional models (see Tyler et al. 1997).

3.1 Outcome Satisfaction, Relative Deprivation, and Distributive Justice

Economics, behaviorist psychology, the social exchange tradition of sociology, and the public choice tradition of political science share a common emphasis on the explanatory power of outcomes and incentives. The mass media and the legal literature tend to perpetuate the view that outcomes—especially monetary outcomes—drive legal behavior, legal judgments, and evaluations of the legal system. An early refinement of this view was relative deprivation theory (see Tyler et al. 1997)—the notion that what matters to citizens are relative outcomes (mine vs. yours or theirs), rather than absolute outcomes. As a predictive theory, the relative deprivation approach has had only mixed success, in large part because the theory *overpredicts* resentment and rebellion. One problem is that the theory fails to predict which of many possible comparison standards the citizen will use; citizens do not invariably choose the source that provides the most invidious comparisons. Another weakness is the failure to predict whether outcome discrepancies will be seen as justified or not.

Descriptive (rather than normative) theories of distributive justice address this latter gap. In the 1970s, the most influential model was equity theory (e.g., Walster and Walster 1975), which models justice judgments as a function of the relative ratio of inputs to outcomes for each actor in a relationship. Indeed, in reactions to job-related conflicts, citizens in Eastern and Central Europe (Bulgaria, Hungary, Poland, Russia) are at least as likely to apply this equity standard as are citizens in traditional Western market democracies (France, Spain, the United States) (Cohn

et al. 2000). But it has become clear that this model works less well in nonmarket contexts and relationships (Fiske 1992). Across various settings, studies have found support for allocation by equality, by need, or by more complex multidimensional decision rules (see Mellers and Baron 1993). In addition, judgments of distributive justice (and their behavioral consequences) vary by social level of analysis; for example, perceiving that one's group has received unfair outcomes is more likely than purely individual deprivation to motivate anger and political action (see Tyler et al. 1997).

3.2 Procedural Justice

Outcomes are clearly linked to public evaluations of justice, but there is growing evidence that scholars have overestimated the importance of this linkage. Thibaut and Walker's (1975) influential experimental research program provided considerable evidence that the processes by which outcomes are reached matter profoundly to citizens. Since the 1970s, this 'fair process effect' has been replicated across a wide variety of nations (in North America, Europe, and Asia), domains (criminal justice settings, tort litigation, private organizations, and the political sphere) and dependent variables (satisfaction with the legal system, acceptance of third-party decisions, compliance with legal authorities, and decisions to file lawsuits) (see Lind and Tyler 1986, MacCoun et al. 1992, Tyler et al. 1997). In a surprising number of studies, procedural justice judgments emerge as a stronger independent predictors than either objective or subjective measures of the outcomes citizens received.

Thibaut and Walker (1975) contended that procedures matter to citizens because fair procedures produce fair outcomes. The key parameters of their model were decision control and process control; the latter is important because it is rarely possible to resolve conflicts without relinquishing some decision control. The predominant determinant of process control in the Thibaut–Walker program was 'voice'—the opportunity to control the presentation of one's arguments to a third-party decision-maker. Even among tort litigants, popularly portrayed by the media as greedy plaintiffs and stingy defendants, the 'opportunity to tell my story' is the most commonly cited goal of both sides. Indeed, this voice motive helps to explain why ADR mechanisms have generally failed to streamline court dockets; because ADR provides a relatively cheap way to 'tell my story,' it diverts more cases from private settlement than from trial (see MacCoun et al. 1992).

Thibaut and Walker's control-based account of voice effects has fared less well. Lind and Tyler (1988) have provided the most empirically successful account of voice effects. Their group value theory argues that voice effects are 'relational' rather than instrumental; they reflect citizens' motivation to achieve a favorable and secure social identity. In numerous studies, relational concerns—the sense that authorities acted with benevolent and impartial motives, and that one was treated with dignity and respect—emerge as more important determinants than either outcome evaluations or perceptions of control (Lind and Tyler 1988, Tyler 1990, Tyler et al. 1997). Within the United States, these relational factors are found in judgments across gender, ethnic, educational, and occupational categories, and these findings have been replicated in Europe and even in more collectivist Asian societies (Tyler et al. 1997).

There are moderators and boundary conditions on the model. Procedural justice effects are weaker for citizens who identify strongly with a subordinate group, but weakly with a superordinate group (e.g., minority 'separatists' as opposed to 'assimilationists'). Another is that procedures matter more when citizens lack clear objective criteria for evaluating outcomes (van den Bos et al. 1997).

Nevertheless, fair process effects are so robust that scholars fear they pose a threat of 'false consciousness'—the notion that authorities can use the appearance of fair procedure (dignity, respect, voice) as an inexpensive way to coopt citizens and to distract them from outcomes that by normative criteria might be considered substantively unfair or biased (e.g., MacCoun et al. 1992). For example, an insurance executive requested a meeting with two procedural justice researchers to ask how he might increase the formality of meetings between clients and insurance adjustors, in order to reduce the rate of contested claims.

3.3 Retributive Justice

It is important to note that citizens' departures from pure economic self-interest are not merely warm, sentimental, and benevolent. The behavioral game theory literature has provided ample evidence that people will often forgo personal gain in a spiteful attempt to harm others, and it is tempting to interpret the strong retributive streak in American public opinion in a similar way. During the 1990s, the USA has seen a dramatic escalation in the size of the prison population, especially relative to that of other industrialized nations. In an era when even liberal politicians decry 'big government,' the American public seems blithely unconcerned by staggering increases in the total share of the state and federal budgets accounted for by the prison complex.

Public misperception of crime rates is surely a partial explanation, but several lines of evidence implicate retributive motives, rather than an instrumental attempt at crime control. For example, many citizens overtly endorse a deterrence rationale for the death

penalty, believing that 'it will prevent crimes.' Yet most do not change their views when asked how they would feel if there were unequivocal evidence that execution provided no marginal deterrence above and beyond life imprisonment (Ellsworth and Gross 1994). Indeed, attitudes toward capital punishment are relatively impervious to research evidence, showing little or no deterrent effect; proponents and opponents each interpret the evidence in a manner that preserves their pre-existing opinion (Lord et al. 1979) (see *Death Penalty*).

3.4 Fear of Crime

It is a cliché among academicians that fear of crime bears no relation to actual crime rates. In fact, between 1973 and 1987, American fear ratings moved in tandem with the violent crime rate (Warr 1994). But perceptions of crime trends are not very accurate; a growing minority (from 4 percent in 1993 to 35 percent in 1998) recognize that US crime fell in the late 1990s, but throughout that period, a majority (from 87 percent in 1993 to 52 percent in 1998) contended that 'there is more crime in the US than a year ago' (Bureau of Justice Statistics 2000).

In many surveys, the elderly and women express the most fear of crime; these patterns are called 'paradoxical' (because young males are the group at greatest risk of victimization) but only under the peculiar notion that fear should solely reflect relative statistical risk. It appears that these patterns reflect differences in the way women and the elderly conceptualize the question (Ferraro 1995, Warr 1994), but also the influence of media depictions that exaggerate the proportion of crimes in which the victims are white females (Chiricos et al. 1997). But the fear literature is plagued by inconsistent findings, perhaps due to a frequent reliance on crude, single-item 'fear' measures that may not measure the experience of fear (i.e., events in the amygdala and autonomic nervous system) and that surely tap other constructs, like perceived risk, attitudes toward the police and the courts, attitudes toward stereotypic offender groups (youth, males, ethnic minorities), and so on.

3.5 Fear of Legal Sanctions

The general public tends to exaggerate the risks of arrest and punishment for many crimes, relative to actual risks and to the more accurate risk perceptions of active criminal offenders (see Paternoster 1987). These facts are consistent with either a deterrence interpretation (perceived legal risk deters crime) or a learning interpretation (offenders learn that legal risks are low). But quasi-experimental studies of legal interventions and panel self-report surveys suggest that the certainty of sanctions does deter crime, and that the effects of sanction severity are weak and unreliable (Paternoster 1987) (see *Deterrence*).

3.6 Legitimacy

In a series of experiments, Robinson and Darley (1997) identified numerous discrepancies between the Model Penal Code and lay intuitions about legal liability. They hypothesize that a congruence between lay views and the formal law enhances both legitimacy and compliance. Tyler's (1990) panel survey of Chicago citizens suggested that those who perceived laws and legal authorities to be fair were less likely to report having committed criminal offenses when surveyed at a later point in time. A re-analysis of data from the Milwaukee Domestic Violence Experiment found that the perceived unfairness of police interventions was a stronger predictor of subsequent domestic violence than was the initial decision to arrest or not to arrest the offender (Paternoster et al. 1997).

4. Conclusion

Public opinion research on legal issues has benefitted enormously from the increasing use of advanced multivariate analyses, panel surveys tracking individuals' views over time, and factorial experiments. But there are far too few cross-national studies. The bulk of the English language literature describes the views of North American and British citizens in the late twentieth-century. Thus we still know far too little about how people judge laws and legal authorities outside of common-law systems in wealthy, advanced industrial nations. We do not know whether these Anglo-American views reflect fundamental psychological principles or simply the particular context in which they were expressed.

R. MacCoun

Legal Personality

In order to be able to participate in any legal or political system an actor must have a legal personality, that is, a set of rights and duties recognized by that system. In theory a legal system may be premised on the belief that certain actors have an inherent legal personality, or that legal personality is entirely a matter of the grant of rights and placement of duties by the sovereign, or that some actors have inherent legal personalities and some are granted a personality. In practice, however, every legal system both recognizes rights and duties in certain actors and insists that certain legal personalities are a matter of positive law. As a historical matter, the content of an actor's legal personality has waxed and waned depending on the legal system in question, instrumental questions about the utility of legal personality, and cultural presuppositions about who and what might have the benefit of rights or the burden of duties. Especially because a legal actor may be neither human nor animate, as when a corporate body has a legal personality, discussions of both the legitimacy and the content of the actor's legal personality may become quite controversial. Thus, the jurisprudential basis for an actor's legal personality is a matter of theoretical and historical concern.

Every legal system must decide which individuals and collectivities, whether formally or informally constituted, or anything else, have legal personalities and what the content of those legal personalities might be. Some legal systems assume that certain actors have

rights (see *Rights*) within the system based on inherent features of the actors, such as their humanity. Every legal system also grants certain actors not assumed to be able to act within the system the right, sometimes limited, to pursue their legal aims. This ascription of rights and duties upon an entity not presumed to be able to act within the system is its legal personality. Some legal systems, notably those premised on natural law (see *Natural Law*), but certainly not limited to such systems, have recognized that some actors have inherent legal personalities. In systems of positive law (see *Legal Positivism*), however, no quantum of rights inheres in any actor, at least in theory. Nonetheless, the history of legal personality is replete with examples of legal systems recognizing inherent rights in individuals, groups, and entities, whether their right to participate in the system is presupposed or granted as a matter of positive law.

The most prominent twentieth century example of an entity granted legal personality is the business corporation, though the history and theory of legal personality long antedate the business corporation. Religious, charitable, and governmental bodies are among the entities that have historically been granted legal personalities, especially insofar as legal systems have recognized distinctions between the rights of an office as distinct from the rights of the person occupying the office. Moreover, in legal systems characterized by hierarchies of actors not all human beings have been assumed to have full legal personalities. Therefore, women (see *Gender and the Law*), children (see *Children and the Law*), slaves (see *Slaves/Slavery, History of*), and foreigners, among others, have had to have their legal personality defined. Recently, the possibility of ascribing legal personality to animals and other entities has entered jurisprudential debates, largely in the hope that in doing so the legal system would necessarily find that they have rights that might be vindicated.

1. Legal Personality, Inherent Rights, and Positive Law

Two theoretical difficulties attend the concept of legal personality. The first is the class or classes of entities which have personality in the eyes of the law. The second is whether legal personality inheres in any entity and what the content of inherent legal personality might be. Systems premised in natural law of some variety, for example, assume both that individual human beings have an irreducible quantum of legal personality and that the content of that personality provides each individual with a certain level of protection and dignity. Such systems need not, however, treat all human beings as having equivalent legal personality. An aristocrat and a slave may each possess a legal personality, but they need not be equal. Nor do political systems have to limit their vision to an individualist conception of personality. Theories of organic polities, for example those premised in republican (see *Republicanism: Philosophical Aspects*) or communitarian ideologies, maintain that group identity is fundamental to social organization and should be recognized at law. Even societies with a largely individualist politics recognize the legitimacy of some group activity. Legal personality may therefore be presumed to inhere in collectivities within society, such as tribes, governments, churches, and even offices, such as governmental or religious offices. The difficulty in any such system is, of course, that human beings are required to discover both who and what might have a legal personality and then to discover the content of that personality.

Systems of positive law appear to solve the problem of legal personality present in systems which maintain beliefs in inherent legal personality. Under positive law legal personality does not inhere in anything or anybody but is rather the result of a grant by the sovereign authority. Hence, legal personality is a fiction created by the sovereign for instrumental purposes. The sovereign may decide to grant the right to act within the legal system to a person, to a class of persons, or to groups of people, constituted either formally or informally within the social structure. Indeed, the sovereign may grant the right to act to inanimate objects or to entities which are themselves the creation of the sovereign, such as corporate or subsidiary political entities. The difficulty presented by systems of positive law is, however, one of rights consciousness within a culture. That is, cultural conceptions of the dignity of human beings, either individually or collectively, the naturalness of human associations, or even conceptions of the inherent rights of, for example, animals, may war with the sovereign's willingness to grant legal personality, no matter how minimal.

In practice virtually no system is either purely one in which legal personality inheres in people or things or in which the sovereign jealously guards the prerogative of the grant of personality. Systems premised on an understanding of inherent legal personality find themselves constantly revising the classes of individuals and entities covered and constantly discovering new aspects of their legal personalities. Moreover, sovereigns within such systems also indulge in the power to grant legal personality. Systems of positive law regularly discover that they must recognise aspects of legal personality that are not spelled out within the grant of personality. Couched sometimes as inferences from the grant and sometimes as necessary components of any grant of personality, these redefinitions of legal personality depend upon changing cultural, especially changing political and economic, circumstances for their content, even though the content of the changes must be recognized by some arm of the sovereign, for example, the courts. The history of legal personality demonstrates, moreover, that conceptions of legal

personality have not neatly evolved from concepts of inherent personality to positive grants of personality. Instead, concepts of legal personality both depend upon and in turn influence surrounding circumstance.

2. Legal Personality in Jurisprudential History

The conflict between inherent and fictive conceptions of legal personality has a long history. Among the first instances in which the distinction between inherent and fictive legal personalities arose in western culture came during the thirteenth century during the papacy of Innocent IV. The Pope, attempting to consolidate the power of the Church and to harmonize society under its auspices, used the concept to delegitimate the authority of institutions inferior to the Church. As the Church was the agent of God, all collective human activity was subordinate to it. Thus, other institutions were inferior to the Church and owed their existence not to their independent authority but existed at the behest of the Church or by its grace. They were, therefore, legal fictions. The Church was not alone in its attempt to subordinate other human institutions by fictionalizing their existence.

The early modern state and its successors have also tried to centralize power by subordinating other human institutions in the name of sovereignty. For example, guilds could only be legitimate to the extent that they acknowledged their derivative status. Similarly, corporate bodies could maintain corporate status only by virtue of charters. Under the Bubble Act collective corporate activity in England could be prosecuted unless done under charter, though such prosecutions were evidently quite rare. In the United States the power of cities, towns, and other local entities derives from the individual states. Indeed, even the sovereign authority of the states and the other sovereignty recognized within the United States, that of the Indian nations, have their own tortured histories. The reason they are tortured, of course, is that modern political consciousness accepts Innocent's positivist precept, that authority to act within a legal system depends on a grant from the sovereign authority, turning the concept of a sovereign existing within another sovereign into a first-rank problem of political logic.

By way of contrast, the concept that legal personality is inherent stems both from aspects of natural law and political conceptions of an organic society. The religious traditions that informed natural law suggested that individuals possessed a minimum of dignity that others, the sovereign included, were bound to respect. Failure to respect human dignity imperilled one's soul. The history of the law of slavery is, for example, in many ways dependent on the distinction between the recognition of a slave's human dignity and the consideration of the slave's status as mere property. Parallel considerations animating organic politics legitimate recognition of groups and group activity. Some political theorists have long argued that social groups and collective activity are fundamental aspects of human life and therefore the recognition by a legal system of collective identity and the legal right of collective activity is not a function of sovereign grace but rather a function of the human condition. Such recognition has taken a variety of forms throughout history. Recognition of social and political class divided parliamentary bodies in England and France, whereas, at least in the pre-Civil War United States, one's loyalty to a state, defined formally as a geographic matter and informally as a matter of culture and politics, in part grounded the legitimacy of the federal system. Belief in the inherent legitimacy of group activity has informed spirited intellectual and political activity, such as Frederic Maitland's late nineteenth- and early twentieth-century desire to undermine certain individualist premises in the common law and to personify at law labor unions in an attempt to protect concerted activity by the working class in England.

In modern jurisprudence, however, no form of collective activity has caused more ink to be spilled in the debate over the nature of legal personality than the business corporation. Nowhere was the debate over the meaning of corporate personality as keenly debated in such a concentrated period as in the United States from the end of the second decade of the nineteenth century through the first third of the twentieth century. No mere academic dispute, the debate over corporate personality was framed by the twin considerations of society's power to promote and regulate economic activity on the one hand and the nature of collective activity, in this case entrepreneurial activity, on the other.

While English and American discussions of corporate personality existed before the nineteenth century, both in the common law and elsewhere, the first definitive exploration of the American position came in the Supreme Court's decision in *Dartmouth College vs. Woodward*, 17 US 518 (1819). In that case Chief Justice John Marshall wrote that a corporation 'is an artificial being, invisible, intangible, … possess[ing] only those properties which the charter of its creation confers upon it, either expressly, or as incidental to its very existence. These are such as are supposed best calculated to effect the object for which it was created.' The declaration of the Chief Justice appeared to put the United States squarely in the camp of positive law insofar as corporate personality was concerned. Considering that elsewhere in American jurisprudence the legal personality of white male property-owning citizens was assumed, it is, however, quite clear that neither a belief in inherent legal personality nor a purely positivist vision animated overall American legal thought. Indeed, even within the realm of corporate personality both the case generally and Marshall's own opinion left room for both visions.

Despite the clear import of Marshall's language, the case held that the sovereign could not unilaterally alter the charter of its own creation when that creation was a private entity, which the college was. Even within the realm of positive law, therefore, Innocent's vision was subtly altered. The sovereign could, of course, reserve the power to alter charters it granted, and the chartering states quickly proceeded in that direction by legislative act. Nevertheless, even without recourse to the legislature, Marshall had left open the potential expansion of corporate personality by recognition of the necessary incidents of corporate existence.

Dartmouth itself was, of course, an educational and not a business institution. In the United States, however, the expansion of the economy and the entrepreneurial fervor of the citizenry meant that individuals looking for vehicles under which to organize their capital for business purposes quickly adopted the corporate form as their preferred mode. States, eager to accommodate, granted corporate charters in ever greater numbers. As the corporate form grew to be the natural mode for organizing capital, Marshall's supposition that corporations were 'artificial being[s]' grew ever more suspect. Rather than beings created by the state, they seemed creations of entrepreneurs. These creations, moreover, did not have simply the rights granted by the sovereign, but had whatever properties necessary to accomplish their object. Business existed in environments which required properties of great flexibility in order to operate and to achieve their object. They needed, among many other things for example, the right to own property, both real and personal, including intellectual property; they needed the right to operate across jurisdictional lines in order to better exploit markets for their products; they needed to be able to exploit resources in different jurisdictions, be they natural resources, pools of labor, sources of power or transport, or even pockets of capital. In addition to finding the elementary aspects of legal personality, such as the right to sue and to be sued, courts began to find other rights incidental to corporate existence. What is equally interesting is the tension between the legislature, which had the right to set the terms of a corporation's legal personality, and the courts, upon which fell the interpretive burden of discovering rights which were incidental and through their discovery legitimating those rights. To be sure, legislatures often resisted granting certain rights and American courts moved in fits and starts in recognizing incidental rights, but the direction was clear. Marshall's qualification was, therefore, one of the ways in which the American jurisprudential image of the corporation reversed itself.

Well before the end of the nineteenth century, corporations asserted and courts recognized their changing legal personality. Though the object was clear, the protection of the property interests of the owners of corporations, the corporation's malleable legal personality was deployed as a jurisprudential weapon. At the time of the Dartmouth College judgment, corporations were rare, the state's imprimatur was thought to be useful in aggregating capital for risky and large ventures, and legislative consideration of corporate charters was real. A fictional understanding of the corporation's legal personality made sense, both to the state and to the individuals who sought a charter. By the last quarter of the nineteenth century, however, none of those conditions obtained. Corporations, especially business corporations, were common. Organizing entrepreneurial activity under corporate auspices was increasingly the norm. Capital markets had advanced to the point where the state's grant was largely irrelevant to the capacity to obtain capital and, as important, the state's stamp of approval was no longer felt to be necessary. Regulation of the behavior of corporations through their charters was largely nominal and the granting of charters was becoming an administrative rather than a legislative process. Indeed, the politics of regulation, always present, grew more contentious as the century progressed, especially as corporate activity made state and local regulation problematic. Regulation of behavior, regardless of legal form, increasingly became the norm and owners of corporations, in turn, sought to protect their property through new conceptions of corporate legal personality.

American legal treatises concerned with corporate law at first edged in the direction of abandoning the conception of the corporation as an entity with a legal personality of its own and instead made a brief attempt to see the corporation as the aggregation of the property of individuals and protected as would be the individual property of those individuals. Decades of jurisprudence dealing with corporate personality, the separation of owner and entity powerfully reinforced by the limited liability of corporate shareholders, and the willingness of courts to find an ever greater sphere of corporate rights suggested a different path. By the end of the century American jurisprudence, while still paying verbal homage to Marshall's understanding, had, in fact, begun to assume that many aspects of a corporation's legal personality were inherent. Ironically, the American jurisprudence of corporate personality, which proved to be politically conservative, fed on many aspects of progressive jurisprudence. Maitland's writings on personification of the corporation, for example, though designed to help the aspirations of English labor as part of a larger jurisprudential vision, abetted an understanding of the naturalness of corporate rights in the United States. Indeed, the use of the term legal person to describe the corporation carried with it strong implications of a legal personality the equivalent of other persons.

In American jurisprudence the debate over the personification of the corporation exhausted itself in the years immediately prior to the Second World War. In part the business corporation had achieved a legal

personality sufficient for its needs and the needs of its owners. Further dispute on the reality and inherent content of a corporation's legal personality seemed irrelevant. Corporations existed and their legal rights and duties gave them sufficient flexibility to operate, flourish, and protect themselves. Simultaneously, attacks on general conceptions of rights by legal realists and others in favor of concepts of legal interests that society ought to recognize turned out to be just as hospitable to corporations in an environment that valued economic productivity more highly than much else. Nonetheless, the instrumental value of asserting an inherent legal personality was far from lost. In the last 1980s, for example, the United States Supreme Court recognized free speech rights of corporate bodies premised on the First Amendment of the Constitution, going so far as to characterize as 'extreme' the position that corporations have only the rights granted to them by states.

Legal personality, as the history of corporate personality demonstrates, is a jurisprudential tool with an independent significance. Without a legal personality, no person, entity, or thing may actively participate in a legal system. Once having obtained a legal personality, either by the assertion of an inherent personality and the recognition of that personality by the appropriate political bodies, or by the grant of personality from the sovereign, the content of the personality is plastic but the capacity to participate, even if limited, is clear. By right of participation, the avenue to enlarging the content of that personality opens itself up to assertions of right and instrumental value.

Legal Pluralism

The concept of legal pluralism refers in the most general sense to the situation in which the 'law' that obtains in a social field consists of more than one set of binding rules, whose behavioral requirements are different and sometimes conflicting. The concept plays a key role in modern sociology and anthropology of law (and to a lesser degree in related disciplines such as the economic analysis of law). It is one of the most important contributions that the sociology and anthropology of law have made to legal theory, demanding attention to unresolved questions concerning the concept of law itself and its relation to the nation-state, and affording an analytic link between 'sociological jurisprudence' (a recurrent theme in legal scholarship) and sociological analysis of the place of rules and social control in social life. It is also an important although marginal (because of the limitations of Western legal scholarship) concept in legal analysis (e.g., in connection with the role of 'custom' in liability in tort and contract).

The concept has two related but distinct meanings (Griffiths 1986); 'Juridical legal pluralism,' refers to a particular sort of legal arrangement, a way in which a legal system that is in principle unitary can deal with cultural and other sorts of diversity in its population by providing (or recognizing) distinct rules and procedures for specific groups (indigenous peoples, ethnic and religious groups, local communities, merchants and other economic groups, etc.). 'Empirical legal pluralism' refers to a social state of affairs in which an actor is confronted by different and possibly conflicting behavioral expectations (as when the norms among the participants in a particular economic activity differ from the applicable legal norms). Since in the case of juridical legal pluralism there are different legal rules for different situations, but only one rule for a given actor in a particular situation, empirical legal pluralism is not entailed; nor does empirical legal pluralism entail juridical legal pluralism, since the competing systems may themselves be monistic. The remainder of this article is devoted largely to legal pluralism in the empirical sense.

1. History of the Concept

Part of the ideological baggage of the modern nation-state is the idea that the state is the source of all law, properly so-called, and that law is (or at least ought to

be) exclusive of other forms of regulation and is uniform for all persons. When Western European expansion began to take the form of colonization, this conception of law confronted the existence of indigenous peoples whose existing law could not be ignored. Whether for reasons of international law (the right of conquered peoples to retain their own law) or of administrative convenience ('indirect rule'), the idea of legal pluralism as a form of governance was born: colonial law (q.v.) incorporated by reference (some parts of) the pre-existing 'laws and customs' of subjected peoples, rejecting others as 'repugnant' to morality and public order. Colonial legal pluralism brought forth a considerable body of law (legislation, case law, legal doctrine) and an extensive legal literature (Hooker 1975). See Van den Bergh (1986) for the prehistory of the concept of legal pluralism in Roman law, medieval and canon law, and early colonial law.

Attention to legal pluralism in the empirical sense was for a long time restricted largely to legal anthropologists. Anthropology of law (q.v.) arose under the wings of colonial administrations, producing a number of early classics on 'the law of the …,' conceived of in the first place as contributions to colonial administration. On the whole, until the second half of the twentieth century legal anthropology treated the 'law' of the societies with which it dealt as an autarkic phenomenon, 'recognized' but not influenced by, or interacting with, the colonial state and its 'law.' The emancipation of legal anthropology from its subservience to the concerns of colonial administration led to a fresh start in which the legal order of a society, at all levels, is seen as a dynamic and complex whole.

The intellectual roots of modern, empirical legal pluralism can be traced back to Ehrlich (1913) who insisted that the 'rules for behavior' that actually govern social interaction are the norms that constitute the 'inner order of the associations' of which a society consists, whereas the law of the state consists of 'rules for decisions' addressed to courts and other legal decision-makers. But it was only in the second half of the twentieth century that the fact that the behavior of social actors is generally subject not just to one set of more or less binding rules ('law'), but to a variety of them, came to be generally accepted among sociolegal scholars as an essential theoretical and methodological insight. Scholars made sensitive by the colonial experience and the process of decolonization to the possibility of legal diversity began to treat the idea as fundamental in sociolegal theory and research.

In the 1960s, the concept of legal pluralism served as the rallying cry for a new approach to the study of law in society. Vanderlinden's essay '*Le pluralisme juridique: essai de synthèse*' marked the transition from preoccupation with the relationship between colonial law and local customary law to the realization that legal pluralism is characteristic of modern, industrialized societies too. Vanderlinden defined legal pluralism as '*L'éxistence, au sein d'une société déterminée, de méchanismes juridiques différents s'appliquant a des situations identiques*' (1971, p. 19). Armed with such a definition, and with an increasingly loose, encompassing conception of 'law,' legal pluralism came to seem ubiquitous. If one looked carefully it could be found in the business world, bureaucratic organizations, schools, neighborhoods, and so forth. Recently, the supranational arena (the European Union, international organizations, international trade and economic globalization) has also come to be recognized as an important locus of legal pluralism.

In the 1980s, scholarly interest in legal pluralism became institutionalized. The Commission on Folk Law and Legal Pluralism of the International Union of Anthropological and Ethnological Sciences was founded in 1978. It organizes regular international symposia, and publishes books, proceedings, and a *Newsletter*. There are two international scholarly journals devoted to the field: the *Journal of Legal Pluralism and Unofficial Law*, founded in 1981 as a continuation of *African Law Studies*, and *Law and Anthropology*.

The usual variety of approaches can be found among those who use the concept of legal pluralism in the empirical sense. These include Marxism (e.g., Fitzpatrick 1980, Santos 1977, Snyder 1981a), feminism (e.g., Griffiths 1997), interpretive, constructivist and 'postmodern' approaches, and eclecticism that straddles the line between social science and a normative, legal approach. Historians have made some important contributions (e.g., Thompson 1991). Most writing on legal pluralism has been from a Western perspective, but Chiba (1989) is a notable exception.

2. *Critique of the Empirical Concept of Legal Pluralism*

The juridical concept of legal pluralism is generally accepted and has never given rise to any significant disagreement. The empirical concept, by contrast, despite the fruitful role it has played in social scientific research and theory, has given rise to some controversy (Tamanaha 1993, Woodman 1998). The objection is in particular to use of the word 'legal,' which, it has been argued, is irredeemably normative, carrying with it etymological associations (with 'legality' and, in languages such as German and Dutch, with the idea of justice) that inevitably give rise to confusion.

While well-taken as far as it goes, the criticism seems to require us to formulate the interaction captured in the concept of legal pluralism as one between two different things: 'law' and non-'legal' social control. Such an opposition entails just the misleading legal-positivist (q.v.) assumption that invention of the unifying concept of legal pluralism was intended to overcome: that 'law' can be considered as theoretically

and empirically distinct from other forms of social control. Use of the concept of legal pluralism reflects the conviction that the differences between 'legal' and other forms of social control are matters of continuous variation and that the factors that affect the impact of rules on behavior are the same in both cases. To accomodate the criticism of the concept of legal pluralism without returning to a sterile opposition between 'law' and other social control, one could choose, for empirical purposes, to speak of normative pluralism or 'rule-system pluralism' (Tamanaha 2000, p. 306). Another line of criticism, that the concept of legal pluralism ignores the importance of differences in power (see Starr and Collier 1989), seems in light of the literature plainly mistaken.

3. *Use of the Empirical Concept in Empirical Theory and Research*

From the outset, the most active area of empirical research and theory in which legal pluralism plays a central role has concerned dispute processes. Holleman's (1973) insistence that the social scientific study of law must concern itself not only with 'trouble cases' but also with 'trouble-less cases' of law use, together with the interest in the 1970s in 'law and development' (q.v.), led to the growth of a second major area of interest: the social working of law under circumstances of legal pluralism. The effects of a situation of legal pluralism on the functioning of state and nonstate institutions such as courts, is a third area of interest. Finally, attention had been paid to the ecclectic and opportunistic way that people make use of a situation of plural legal resources in constructing relationships and complex social institutions such as 'property,' 'social security,' and 'international trade.'

3.1 *Dispute Processes (Litigation and Adjudication)*

Legal pluralism is an important factor in understanding what people have disputes about, how disputes emerge in social life, what choices are made about how to deal with them, how they progress, what ultimately happens with them, and how the disposition of a particular dispute affects the way other people deal with similar problems. At all stages of a (potentially) 'legal' dispute, the existence of non-'legal' norms, procedures, and institutions profoundly influences what happens. Building on the general literature on dispute processes, or litigation (q.v.), a number of scholars have devoted particular attention to the normatively plural context in which disputes often take place. Exemplary studies are Ellickson (1991) on cattle-trespass disputes between neighbors in rural California; Todd 1978, on disputing relationships and social status in a Bavarian village; Santos (1977) on informal law and disputing in a Brazilian squatter settlement; and Abel (1979) on the introduction of Western courts in the non-Western setting of British Africa. The ways in which adjudicatory institutions adjust to the choices their clientele make has attracted particular interest K. von Benda-Beckmann (1984), in particular, has used the 'extended case' method of legal anthropology to good effect, showing how 'forum-shopping' litigants make differential use of state and nonstate law in different phases of a dispute, so that the execution of a court judgment, for example, may be regulated in practice by nonstate norms. Galanter (1981) and Griffiths (1983) have sought to integrate the perspective of legal pluralism into general formulations of litigation theory.

3.2 *Social Working*

Research, in both Western and non-Western settings has shown repeatedly that legal pluralism can be the key to understanding the effectiveness of a legal rule. Moore (1973) argued that the ways in which legal rules do or do not influence behavior can only be understood if one considers them from the perspective of the actors to whom they are addressed. These actors are generally exposed not only to the behavioral expectations expressed in legal rules but also to the often quite different expectations of more immediate sources of regulation to which they are exposed ('semi-autonomous social fields').

The idea that the relationship between local law and state law is that the former frustrates the effectiveness of the latter is, however, too simple. In the first place, as Moore observes, when external law is effective in a social field this is often thanks not to the enforcement capacities of the state but to the support legal rules receive from local social control (see Kagan and Skolnick 1993 for the example of rules regulating smoking). In the second place, state law often adapts and builds upon forms of regulation that have earlier emerged in, and are enforced by, local social fields. The Dutch experience with regulation of medical practice surrounding death (Griffiths 2000) is a good example of the process by which such self-regulation (in this case, by the medical profession) can later be adopted by legal institutions and enforced as 'law.'

3.3 *Interaction of State and Nonstate Law and Institutions*

A phenomenon of special interest concerns the 'creation of customary law': the fact that when local law is 'recognized' by state law (as in the case of colonial legal pluralism), it must be ascertained and applied by noncustomary tribunals. In the process, a great deal of transformation takes place, so that the 'customary law' applied in state courts may have only a distant relationship to its supposed sources (Snyder 1981a, Woodman 1988).

A related phenomenon is the effect on local political authority when it is incorporated into a (post) colonial system of government. Such incorporation brings with it notorious errors in the identification of indigenous authorities, the witting or unwitting attribution to them of various nonindigenous powers, the manipulation of indigenous processes of succession to high office, and so forth. The fundamental bases of legitimacy tend to be corrupted and indigenous mechanisms of control over political authority eroded. This is a central theme in a number of studies of local political authority (e.g., Holleman 1969, Owusu 1970). The more recent literature emphasizes that legal pluralism can be the idiom in terms of which political struggles are fought. Asserting or rejecting the validity of a rule of particular provenance, or attributing particular virtues or defects to particular sorts of law (customary, religious, or state law), can be ways of claiming political authority (e.g., Benda-Beckmann 1989).

3.4 Eclectic Use of Normative Resources

Colonial legal pluralism was characterized by a 'choice of law' approach: either state law or customary law applied to a given case, and if customary law was applicable, then it was either the law of group A or that of group B. It took some time before scholars working with the newer empirical conception of legal pluralism came to appreciate that social reality is generally not either/or but both/and: actors with access to multiple sources of law construct legal relationships ecclectically, fashioning a patchwork composed of bits and pieces of local law, religious law, state law, and international law. Thus property and inheritance relationships in Minangkabau combine elements of Indonesian law, local adat law, and Islamic law (cf. Benda-Beckman 1979).

Eclecticism in the choice and promotion of legal sources is a well-known phenomenon in the case of dispute processes (see Sect. 3.1 above). A good example of eclecticism in the structuring of relationships concerns social security. The social security arrangements that people in developing countries construct for themselves include elements of state law and elements of customary and religious law, and if they migrate to a Western country its formal social security arrangements get included in the mixture (Benda-Beckman et al. 1988). Since intra-family income transfers continue to be very important in industrialized countries, it seems safe to assume that here, too, normative eclecticism is a crucial feature of the actual social security many people depend on.

In the area of economic globalization, Snyder has argued that 'global economic networks are governed by the totality of strategically determined, situationally specific, and often episodic conjunctions of a multiplicity of institutional, normative, and processual sites throughout the world.' A patchwork of what he calls 'global legal pluralism' results from the behavior of 'strategic actors [whose choices have] been absolutely fundamental in determining which … sites have seen the light of day, which have flourished and developed, and which have withered and even died for lack of clients' (Snyder 1999, p. 371).

Legal Positivism

Legal positivism is the label attached to a widely accepted, though hotly disputed, theory about the nature of law. Within jurisprudence, legal positivism is most often discussed by way of contrast to natural law theories of law. The contest between these rival traditions has long dominated the discussion in legal philosophy, though there are signs that the debate may have run its course. Because legal positivism originated as a reaction to natural law theories about law, the best way to understand legal positivism is through this debate. The following section will describe the nature of the debate; the section thereafter will set out the core elements of legal positivism; the final section will discuss the reaction to, and significance of, legal positivism, from the standpoint of social scientific approaches to law.

1. The Debate between Legal Positivism and Natural Law

Ironically, Hobbes, who is widely credited to be the early progenitor of legal positivism, built his positivistic theory of law on a natural law base (Bobbio 1993, Fuller 1940). According to Hobbes, the necessity for peace and order is the fundamental precept of natural law. Given that the state of nature is, in his immortal phrase, 'solitary, poore, nasty, brutish, and short,' people join together and give over law-making and enforcing power to a Sovereign for the purpose of maintaining peace and order (Hobbes 1946, Chaps. XIV, XV). Thereafter, law consists of the commands of the Sovereign. Although the Sovereign is to be guided by reason in the establishment of law, even unjust commands are valid laws; to suggest otherwise would invite the disorder that will result if people were

allowed to apply their own judgment to evaluate the law. Under Hobbes' formulation, while natural law provides the initial foundation for positive law, once that foundation is established, natural law becomes irrelevant. It does not provide a continuing standard or test for the validity of the law. (See *Natural Law*; *Justice and Law*; *Injustice: Legal Aspects*.)

This conclusion raises the issue that has long set legal positivists and natural law theorists at odds. Thomas Aquinas, citing Augustine, asserted that 'A law that is not just, seems to be no law at all' (Q. 96, A. 4, Obj. 3). 'Consequently every human law has just so much of the nature of law, as it is derived from the law of nature. But if in any point it deflects from the law of nature, it is no longer a law but a perversion of law' (Q. 95, A. 2, Obj. 4). A similar statement was made by William Blackstone. '[N]o human laws are of any validity, if contrary to this [law of nature]' (Boorstin 1996, p. 49). More recently, Lon Fuller asserted that there is a minimum moral element to law, without which it is 'not simply bad law, but not law at all.' (Boorstin 1999, p. 197).

Legal positivists are adamantly opposed to this position. Austin, who produced the first widely influential articulation of the legal positivist position, wrote a scathing response to Blackstone. 'Now, to say that human laws which conflict with the Divine law are not binding, that is to say, are not laws, is to talk stark nonsense. The most pernicious laws, and therefore those which are most opposed to the will of God, have been and continually are enforced as laws by judicial tribunals' (Austin, 1995, p. 158). 'The existence of law is one thing; its merit or demerit is another.' What law *is*, and what law *ought* to be, legal positivists insist, are separate questions.

Aside from the general confusion it engenders, the failure to maintain the separation between *is* and *ought* raises two particular political concerns for legal positivists (Hart, 1958, pp. 597–98). The first concern involves the persons who conclude, based upon his or her understanding of natural law, that the offensive positive law is invalid and, therefore, can be freely disregarded. An example of this is the radical anti-abortionist who invokes natural law to justify illegal actions—including the execution of doctors who perform abortions—on the grounds that laws allowing abortion are invalid because they condone the killing of innocent lives. The second concern is that the identification of law with morality will lead people to be less critical of the law, their vigilance against it softened by the seductive assumption that the law *is* what it *ought* to be. Many legal positivists believe that the fact that a norm happens to have the status of 'law' does not of itself give rise to an obligation of fidelity (Schauer 1996). An obligation arises only after the law passes moral muster. Thus, legal positivists assert, maintaining the *is*/*ought* distinction allows us to more critically evaluate the law from a moral standpoint. These two concerns, it should be observed, while not contradictory, are not entirely consistent, in so far as the first worries about people choosing to disregard the law on the grounds that it is invalid, while the second worries about people slavishly following the law because they assume it is necessarily morally worthy. These two concerns, pointing as they do in different directions, simultaneously expose legal positivism to the charge of being excessively conservative as well as the charge of being excessively radical.

The second concern, more so than the first, animates many legal positivists in their dispute with natural law theorists, and their concern is not a purely abstract one. In the aftermath of World War II, some natural law theorists blamed the legal positivist separation of law and morality for the failure of the German legal establishment to resist atrocities committed by the Nazi government through law (Hart 1958, pp. 615–21, Rommen 1998). The view that 'law is law' regardless of its immorality, according to Gustav Radbruch, led the German legal profession to be completely subservient to state legal power. The legal positivist response, besides questioning whether there is any empirical support for the asserted causal connection, is that this view fails to appreciate that the separation of law from morality has the effect of reducing the prestige of law and thereby exposing it to greater moral critique. Under this view, the fact that a pronouncement is valid law carries little weight, and an immoral law (valid as it may be) should be resisted.

When viewed in these terms, the longstanding debate between legal positivists and natural law theorists is a narrow one. Legal positivists argue that a positive law is law, regardless of whether it is inconsistent with morality. Nevertheless, they immediately assert, a valid law can and should be evaluated from a moral standpoint, and not considered obligatory if found wanting. Many natural law theorists have asserted that consistency with natural law is a condition of the validity of positive law. An immoral law is, therefore, not 'law' at all, and carries no obligation (except perhaps is instances when a greater good might still be served by adherence to a bad law). However, anything that qualifies as law pursuant to this understanding automatically generates an obligation to comply. Whichever direction one approaches from, in the end both sides agree that an immoral positive law (whether or not characterized as 'law') generally does not give rise to any obligation to obey.

After generations of disagreement, there are now signs of a rapprochement. Finnis, the most influential modern exponent of natural law theory, argued that Aquinas was actually an early legal positivist, in the sense that he recognized that immoral laws were still in fact 'laws,' albeit deviant or deficient forms of law (Finnis 1980, 1996). A leading legal positivist, MacCormick (1992), has acknowledged that there are certain respects in which law or legality contains moral qualities, though he emphasized that this does not

vitiate the separation thesis. Indeed, at base, only the separation thesis separates these two schools. If natural law theorists, like Finnis, are willing to acknowledge that an immoral law is still 'law' in positive law terms—a point that a number of natural law theorists have not actually contested—there are few reasons to maintain the mutual opposition. There is no inherent incompatibility between these two approaches. A legal positivist may, without contradiction, believe in natural law moral theory, and apply the moral precepts produced by this theory to evaluate the law.

To be sure, not everyone agrees that the debate is over, but the bulk of the discussion of late has shifted to other matters, away from the issue of validity. One aspect of this classical debate remains unresolved, however. Although it has attracted relatively little attention, it is of continuing relevance and bears mention. The primary focus of the debate has been on whether immoral laws are invalid; the reverse question this raises is whether natural law principles have the status of law even if not affirmatively recognized by the positive law. If the answer is yes, then the Nuremberg Trials, and more recently the trials of the German border guards prosecuted for shooting people attempting to escape former East Germany, were routine applications of pre-existing natural law principles with direct effect. If the answer is no, then (ignoring weak arguments that there were pre-existing applicable positive law prohibitions based upon general declarations of human rights) these trials can be condemned as extralegal impositions of power by the ultimate victors in a political battle. Furthermore, if the answer is no, a strong argument can be made that these trials themselves violated the natural law prohibition against the *ex post facto* imposition of law, criminalizing and punishing behavior that was not illegal at the time it was committed. The issue of the legitimacy and legality of these kinds of actions, with serious unresolved moral as well as practical implications, will continue to arise as long as there is an attempt to hold government officials responsible for putatively legal conduct committed while in office.

2. *The Core Elements of Legal Positivism*

Awareness of the context within which legal positivism arose and developed is essential to an understanding of the theory, but it does not capture nor exhaust the insights contained within the theory. As with every theoretical tradition, there are many varieties of legal positivism. Of late, as the dispute between legal positivism and natural law has moderated, internal divisions within legal positivism have taken center stage in the theoretical discussion. The nuances of the internal debate need not be explored. It takes place within shared parameters that characterize most legal positivists, and these parameters are what matter. Before describing these parameters, it should be noted that there have been two dominant versions of legal positivism in the twentieth century, the first by Kelsen and the second by Hart. The essential difference between the theories lies in their orientation (Bix 1996, Chap. 6): Hart had an empirical bent, whereas Kelsen constructed an abstract system consisting of a hierarchy of norms (Kelsen 1967). The focus in this discussion will be on Hart's version, because, owing to its greater clarity and persuasiveness, it has eclipsed Kelsen's version substantially.

Hart's *The Concept of Law* (1961) is without question the most important legal positivist text, and probably the most influential book in the field of jurisprudence in the second half of the twentieth century. Hart's project was to produce 'a theory of what law is which is both general and descriptive' (Hart 1994, p. 239). His theory was 'general' in the sense that he intended to clarify the nature of law as a social phenomenon found in many different cultures and societies, by way of contrast to a 'particular' jurisprudence, which is focused on a specific legal system. His text was 'descriptive' in the sense that he eschewed evaluative analysis, limiting himself to describing practices and clarifying concepts related to law. He characterized his standpoint as that of an external observer describing the ways participants engage in and understand law from an internal point of view. To emphasize his empirical orientation, Hart described his book as 'an essay in descriptive sociology' (Hart 1961, p. v).

According to Hart, a legal system consists of the union of what he called primary and secondary rules. Primary rules are the rules that govern relations within society. Secondary rules are the rules legal officials follow to identify, apply, and change the primary rules. Hart famously labeled the core secondary rules the 'rules of recognition,' 'which specify some feature or features possession of which by a suggested rule is taken as conclusive affirmative indication that it is a rule of the group to be supported by the social pressure it exerts' (Hart 1961, p. 92). According to Hart, the emergence of secondary rules is what separates prelegal (or primitive) societies from societies with law. Although simple societies with only primary rules can exist, they are static and inefficient in responding to new situations or bringing about desired change. The availability of secondary rules cures these defects.

Thus, secondary rules identify the primary rules; the question that remains is how to identify the secondary rules. Hart's answer to this—in contrast to Kelsen's abstract identification of the ultimate *Grundnorm* as the source of all other norms—is that the rules of recognition can be identified by observing the *actual social practices* of the legal officials when they identify law. The existence and nature of the rules of recognition in a given legal system is thus 'a matter of

fact.' Based upon this resort to existing social practices, theorists have labeled Hart's approach to law as 'conventionalist.' Law is whatever the legal officials indicate by their social behavior they recognize as law, with no content restrictions on what that might be. Hart added one further requirement to the secondary rules. He was concerned to distinguish law from mere habits of obedience, and from the 'Gunman Writ Law,' which was the impression left by Austin's command theory of law. Hart felt that Austin's coercive view of law failed to recognize that law contains a normative aspect. This normative aspect, according to Hart, can be recognized only if one takes into consideration the internal point of view of legal officials. From this perspective, it is evident that legal officials *accept* the secondary rules as 'common standards of official behavior and appraise critically their own and each other's deviations as lapses' (Hart 1961, p. 113). Consistent with his nonevaluative stance, Hart specifies the necessity for the officials' acceptance of the secondary rules without suggesting whether this acceptance is merited (which can only be determined by examining particular legal regimes).

Hart concluded that there are two minimum conditions necessary and sufficient for the existence of a legal system. The first condition is that the primary rules must be generally obeyed by the populace, though it is not essential that the populace normatively accept the primary rules. It does not appear to make much sense to say that a legal system exists if the bulk of the populace generally disregards it. The second condition is that the legal officials accept the secondary rules as critical standards for their behavior. Whenever these two conditions obtain, a legal system will exist.

With its simplicity, clarity, elegance, and scope, Hart's reconstruction revitalized legal positivism, and spawned an enormous response, in support and against. As a consequence of his work, virtually all legal positivists (in the Hartian tradition) adhere to two core theses about the nature of law: the Separation Thesis and the Social Sources Thesis. The Separation Thesis holds that there is no necessary relation between law and morality (Coleman 1982, Coleman 1996). The genesis of this thesis has already been identified in the earlier described insistence of legal positivists that the fact of legality alone does not carry with it the imprimatur of moral rectitude. It is important to recognize that this is a limited, negative thesis, a denial of the natural law position, rather than an affirmative statement of the relationship between law and morality. Legal positivists are not insisting that there are no connections between law and morality, only that there is no *necessary* connection. They recognize that the 'law of every modern state shows at a thousand points the influence of both the accepted social morality and wider moral ideals.' (Hart 1961, p. 199). This influence comes in a myriad of ways. Law and legal norms often reflect (or claim to reflect) the morality of its community. Legal norms often expressly refer to and incorporate moral principles like justice, fairness, reasonableness, and due process. Law often has positive moral consequences, especially in its role in maintaining order in society. Law also often helps perpetuate moral norms, and participates in the moral education of members of the community, when it adds a legal sanction to support moral norms that have been recognized by law. Recognition of these intimate connections between law and morality is consistent with the Separation Thesis. The key qualifier in the above list is *often*. The Separation Thesis insists only that it is not necessarily the case that a moral norm, by virtue of that fact, automatically becomes a legal norm, and that it is not necessarily the case that an immoral law is, by virtue of that fact, not valid law, although both possibilities may be the case in a given legal system if the positive law of that system so determines.

The Social Sources Thesis holds that what is or isn't valid law in a given system, as determined by the rules of recognition, is a social fact. By observing the practices of the legal officials within a legal system, it will be possible to identify the criteria applied by the legal officials to determine what is valid law. These practices often include, for example, treating legislative enactments and judicial precedents as valid sources of law.

Although these two theses are shared by legal positivists, the broad consensus in support of them conceals a substantial internal divergence among legal positivists about what these theses represent and allow or disallow. Much of the internal disagreement has been generated by attempts by Hart and other legal positivists to respond to the sustained critique of legal positivism by Dworkin. This complex internal and external debate cannot be recounted here, though its core themes can be articulated summarily.

Dworkin has attacked Hart at several different levels and points (Dworkin 1977, Dworkin 1985, Dworkin 1986). He denies the very possibility or value of general, external, purely descriptive jurisprudence. Dworkin insists that jurisprudence itself is an aspect or extension of the law of a particular legal system and must, therefore, be conducted from the particular, internal perspective, which is inherently evaluative in orientation. Against the substance of Hart's argument, Dworkin denies the Separation Thesis by arguing that law and morality are inextricably intertwined, with moral principles providing the unseverable backdrop for the interpretation and application of legal rules. Based upon this view of the intimate connection between morality and law, Dworkin also denies Hart's assertion that there are points at which the law runs out. According to Dworkin, law incorporates a large body of moral norms and principles, and, understood as such, law always provides, a single correct answer to legal problems. Dworkin further argues that the social practice aspect of Hart's rules of recognition fails to accurately describe our own legal system, which

expressly incorporates moral norms (like due process and fairness) in a manner that renders the identification of the primary rules dependent upon difficult and controversial questions about the truth of moral norms. He identifies two specific problems with Hart's notion of rules of recognition. First, rules of recognition are incapable of identifying all of the many and varied moral norms and principles incorporated into the law. Second, Dworkin insists that legal positivists cannot, consistent with their theory of law, allow the incorporation of such norms and principles because the uncertainty which would result—making the identification of law contingent upon the resolution of complex moral questions—defeats legal positivists' claim that the value of secondary rules is their ability to identify primary rules in a way that provides guidance to the populace.

This abbreviated recitation is a partial selection of Dworkin's criticisms of Hart and legal positivism, focusing on the themes described earlier, and inevitably does not do justice to his arguments. A number of the issues separating Hart and Dworkin can be resolved by the acknowledgment on both sides that general (Hart) and particular (Dworkin) jurisprudence are two different enterprises which need not necessarily conflict. The most significant remaining controversy relates to the extent to which the rules of recognition can refer to open-ended moral questions that turn the issue of what law is on questions of content (rather than just social practices). Hart insists that there are no restrictions on the rules of recognition that would prohibit a particular legal system from turning the identification of law on the resolution of moral questions, as long as that is what the actual social practice constituted by the applicable rules of recognition requires. Hart labels his view 'soft positivism' (Hart 1994, pp. 250–4, Coleman 1998). With regard to whether this defeats the point of legal positivism, Hart (1994, p. 251) responds that positivism tolerates a certain degree of uncertainty in the identification of the primary rules, and furthermore that the resort to moral standards would not necessarily result in an excessive amount of uncertainty.

In theory, soft positivism would still be a correct description of a legal system that has only a single rule of recognition which says: do justice (Coleman 1998). Once this 'inclusive' view of legal positivism is taken, it is no longer evident that, as with the debate between natural law and legal positivism, anything of great moment rests upon the resolution of the debate over legal positivism between Hart and Dworkin. However, contrary to Hart, there are 'hard' or 'exclusive' legal positivists, led by Raz, who do not concede Dworkin's position about the inclusion of open questions of morality within law (Raz 1979). Now much of the debate is an internal one between hard and soft legal positivists (Bix 1999, Leiter 1998, Coleman 1998). Although hard positivists recognize that the law often refers to such norms, they assert that at that moment the law runs out and the judge's decision is based on extralegal considerations. The moral considerations to be resolved are not a part of the pre-existing law before the issue is decided, though they can thereafter become law if recognized and treated as legal precedent (consistent with the applicable rules of recognition). Hard positivists believe it is essential to take this position if legal positivism is to satisfy its claims that the function of law is to provide guidance to the public on the rules of conduct, and if law is to claim independent authority, apart from morality.

Once again, it would appear that the issue that divides the disputants is a relatively narrow one. Neither side denies that often the law refers to moral norms (like justice and fairness) which turn on the resolution of issues of substance or content. At that point the soft legal positivist says the judge is still doing law, while the hard legal positivist says that the law has run out. This is not to suggest that the debate is insignificant. When considering these issues, legal philosophers are attempting to come to an understanding of the nature of law. It is important to recognize that, as with several of the debates discussed above, the resolution will not be found in resort to the facts, since there is not substantial disagreement about the facts, but rather over how these facts are to be described from a theoretical standpoint. Despite the avowedly nonnormative stance of legal positivists, it would appear that the resolution of many of these debates is contingent on the outcome of evaluative questions, like which concept of law and its relation to morality is not just descriptively accurate but also morally optimal.

3. *Legal Positivism and Social Science*

Legal positivism generally, and Hart's theory in particular, has an ambivalent relationship with the social sciences. Even what might seem like an obvious connection—use of the label 'positivism'—is not free of ambiguity. The term positivism literally refers to the fact that law is 'posited,' a human social creation. Some legal theorists assert that there is no direct connection between legal positivism and scientific positivism (Patterson 1953, p. 15, Posner 1990, p. 20); others suggest that the connection is a general one which lies in the shared insistence on the *is/ought* distinction (Schauer 1996, p. 49). Still others insist that there is a strong connection, grounded in a shared empiricist narrowing of reality, need for certainty (Rommen 1998, pp. 109–13), and a shared opposition to theological and metaphysical modes of thought (Lee 1989, pp. 16–18). Hart himself invoked connections to social science. As noted earlier, he described his book as an essay in descriptive sociology, though this claim did not endear him to social scientists. Furthermore, in his discussion of the internal aspect of

rules, Hart acknowledged Winch's *The Idea of a Social Science* (1958), and he has been lauded for importing the hermeneutic perspective from social science into jurisprudence.

These connections aside, Hart's theory has been criticized by many social scientists who study law. A standard social scientific criticism is that Hart made a host of putatively descriptive sociological claims without having first done the requisite sociological investigation (Cotterrell 1989, pp. 94–106). An anthropological critique of Hart focuses on the fact that his concept of law was abstracted from state legal systems, which consequently leads to the conclusion that certain societies—those lacking in secondary rules—did not have law, suggesting that they are primitive or less civilized (Roberts 1979, pp. 23–5). This smacks of ethnocentric privileging of Western legal systems. Social scientists who hold the belief that 'no society is without law' (Moore 1978, p. 215) must reject Hart's concept of law. A third common criticism, though one aimed at legal positivism more generally, is that legal positivist views of law tend to have the effect of masking the social reality that there are a plurality of 'legal' systems operative in society, not just the state legal system that legal positivism emphasizes (Griffiths 1986).

Despite these criticisms, Hart's concept of law has had a significant, if mostly underground, influence in social scientific approaches to the concept of law. Bohannan's widely followed anthropological definition of law as the reinstitutionalization of norms bears a strong resemblance to Hart's notion of primary and secondary rules (Bohannan 1965). Galanter, one of the leading theorists of legal pluralism, adopts Hart's concept of law to distinguish legal from non-legal forms of social regulation (Galanter 1981, pp. 18–19, n. 26). Hart's concept of law is attractive because it comports with our intuitions about law; it comports with our intuitions because, in the modern world, it is the form of law with which we are most familiar. Since law is a social institution, it is inevitable that, whichever concept of law one formulates, it will be derived from a preconception about the nature of law (Tamanaha 1993, 1995).

Legal positivism, especially Hart's version of it, regardless of its limitations, holds a great deal of promise for the social scientific study of law, though that promise has yet to be fully realized. The legal positivist ambition to construct a general and descriptive approach to law is one the social sciences should embrace. Social scientists can conduct the sociological studies Hart failed to complete, using his model of law as the union of primary and secondary rules to guide their research, without necessarily accepting the separate propositions that this is the best or only way to characterize and understand law. Hart's primary mistake from the standpoint of a descriptive sociology came when he built normative acceptance by legal officials into his concept of law. Whether or not legal officials accept the secondary rules is an open question that can only be resolved following investigation (Tamanaha 1997, pp. 131–7). With these and other adjustments, a social scientific effort to continue and extend Hart's project could apply his conventionalist approach to identify, abstract from, and describe other forms of law operative in society. This sociological or 'sociolegal' version of positivism has the potential to provide information about the relationship between law and society and to establish a bridge between jurisprudence and the social scientific study of law (Tamanaha 2001).

Legal Process and Social Science: United States

Introduction

There are two complementary orientations in the field of 'law and social science.' One is usually termed 'law and society' and addresses theories of how law comes into being and changes in a culture, and how law relates to other cultural forces, such as religion, or the family. The second is called 'social science in law' and deals with more applied questions of how courts and lawyers make use of social science information in reaching decisions in actual legal cases. This article is concerned with the latter orientation.

1. Legal Realism

Since the rise of American legal realism, early in the twentieth century, courts have, to varying extents, been open to using social science research when that research could help resolve an empirical issue that arose in litigation. Social science research was first urged upon a court in 1908 by Louis Brandeis in *Muller vs. Oregon* (208 US 412), a landmark case dealing with the constitutionality of social welfare legislation limiting to 10 hours the work day of any woman or girl employed in a factory or laundry. Brandeis assembled a substantial body of social science research tending to show the debilitating effect on women and girls of working long hours, and presented this material to the United States Supreme Court in a brief defending Oregon's statute. In the opinion in *Muller* upholding the legislation, after referring to the social science materials in a footnote, the Court stated that although they 'may not be, technically speaking, authorities,' the studies would nonetheless receive 'judicial cognizance.'

2. Three Uses of Social Science in Law

Although the use of what came to be known as 'Brandeis briefs' became common in the years after *Muller*, legal commentators were hard pressed to explain an apparent anomaly: How was it that Brandeis could present research to an appellate court in a written brief, when 'facts' were supposed to be introduced at the trial level by the oral testimony of witnesses? This conundrum persisted until Kenneth Culp Davis, in a seminal article published in 1942, distinguished two types of 'fact.' The first type, legislative fact, referred to facts that were used by courts to help decide broad questions of law or policy, as Brandeis had used research to help decide the constitutionality of social welfare legislation. The second type, adjudicative fact, referred to facts that were used to decide questions of interest only to the specific parties to a lawsuit, such as whether a particular traffic light was red or green. Davis' distinction soon became widely accepted and now forms the traditional scheme used by courts and commentators to describe the judicial uses of social science. There are indications that a third use of social science in law has developed, however, and that Davis' distinction between different types of 'fact' may have outlived its usefulness.

2.1 Social Science Used to Make Law

Legislative facts are facts that courts use when they make law (or 'legislate'), rather than simply apply settled doctrine to resolve a dispute between particular parties to a case. While the determination of adjudicative facts affects only the litigants before the court, the determination of legislative facts influences the content of legal doctrine itself, and therefore affects many parties in addition to those who brought the case. It was Davis' position in 1942 that '[t]he rules of evidence for finding facts which form the basis for creation of law and determination of policy should differ from the rules for finding facts which concern only the parties to a particular case.' In this manner, Davis justified the Supreme Court's practice in *Muller* of disregarding the rules of evidence by accepting 'facts' on appeal and in a brief. The rules of evidence did not apply to Brandeis' social science materials: they were 'legislative' facts.

Judicial acceptance of social science research as a form of legislative fact became commonplace throughout American law after *Brown* vs. *Board of Education* (347 US 483 (1954)). In that case, the United States Supreme Court cited the published research of numerous social scientists to support its empirical assertion that the segregation of public schools instills in an African American child 'a sense of inferiority [that] affects the motivation of a child to learn.' In the five decades since *Brown*, research has frequently been invoked by courts to demonstrate the validity of empirical assumptions made in the process of modifying existing law or creating new law. In *United States* vs. *Leon* (468 US 897 (1984)), for example, the United States Supreme Court considered the question of whether the rule excluding evidenced produced by an illegal search should be modified to admit evidence that the police seized while they were relying in good faith on a search warrant that later proved to be defective. The Court held that whether the rule should be modified to allow such evidence 'must be resolved by weighing the costs and benefits' of creating an exception to the rule when the police act in good faith. In the process of weighing these costs and benefits, the Court reviewed six social science studies concerning the effects of the exclusionary rule on the disposition of felony arrests and concluded that the benefits of creating an exception, in terms of increasing the number of guilty criminals brought to justice, outweighed any costs involved.

Criticism of the concept of legislative fact has been intense. It has been claimed to be largely a negative concept: the usual rules of evidence should not apply to facts introduced for the purpose of making new law. The concept provides little positive guidance for courts as to how they should deal with this type of social science information. Improvements in the manner that courts use social science information to create rules of law may be possible only by abandoning the notion of 'legislative fact' and developing a new concept that alters the way in which courts view social science materials. 'Social authority' has been proposed by Monahan and Walker (1986) as one alternative to legislative fact as an organizing principle for courts' use of social science to create or modify a rule of law. Under this rubric, courts would treat social science research relevant to creating or modifying a rule of law as a source of 'authority' rather than a source of 'facts.' More specifically, courts would treat social science research much as they treat legal precedent under the common law.

2.2 Social Science Used to Determine Facts

Adjudicative facts—also called 'social facts'—are facts that apply only to the particular parties before the court. They are used to determine (or 'adjudicate') what happened in a specific case, and not for some larger purpose, such as to argue that the law should be changed.

One of the most frequent uses of social science research as adjudicative fact involves trademarks. The Lanham Trademark Act (15 USCA Sec. 1127) states that a new trademark will not be registered if it so resembles a trademark already registered to another person 'as to be likely … to cause confusion.' A person who sells a product that is likely to cause confusion with an already trademarked product is liable for trademark infringement. Social science research in the form of surveys of consumers or potential consumers to ascertain the degree of confusion between products has been admitted in court for many decades. Initially, such evidence was often successfully challenged as contravening the prohibition against 'hearsay' evidence, since the respondents to the surveys were not present in court to testify. In *Zippo Manufacturing Co.* vs. *Rogers Imports* (216 F. Supp. 670 (1963)), however, the hearsay objection was definitely laid to rest: 'The weight of case authority, the consensus of legal writers, and reasoned policy considerations all indicate that the hearsay rule should not bar the admission of properly conducted public surveys.'

A wide variety of social science methodologies are now routinely used by both plaintiffs and defendants in trademark cases to determine the presence of consumer confusion. *In Processed Plastic* vs. *Warner Communications* (675 F.2d 852 (7th Cir. 1982)), for example, Warner licenced several toy companies to produce replicas of a unique automobile that figured prominently in a television series that it owned. The Processed Plastic Company, which had no agreement with Warner, began to sell a toy car that Warner claimed looked like the car in its television series. To demonstrate this fact, Warner introduced in court a social science survey of random groups of children questioned at shopping malls that found that 82 percent of the children shown a Processed Plastic car

identified it as the car that appeared in Warner's television series. The court decided that these data showed that Processed Plastic has likely infringed Warner's trademark rights by creating consumer confusion.

The key to understanding how courts deal with social science research used to determine an adjudicative fact is that, unlike 'legislative' facts, adjudicative facts are susceptible to proof by the usual rules of evidence. Evaluating the research for the purpose of admissibility is limited to determining whether it is material, whether it has any probative value, and whether its admission violates any other evidentiary rule. The ultimate weight to be placed on the social science evidence is a matter for the fact-finder.

2.3 Social Science Used to Provide Context

Most of the judicial uses of social sciences fall into one of the two categories originally described by Davis. In recent decades, however, courts have begun to confront uses of social science research that do not conform to the established classification. There are increasing indications that a new, third use of social science in law is emerging. Examples can be found in cases concerning eyewitness identification and sexual victimization.

In *State* vs. *Chapple* (660 P.2d 1208 (1983)), the only evidence that the defendant had committed murder was the word of two eyewitnesses. At trial, the expert testimony of a research psychologist was offered by the defendant to counter the testimony of the eyewitnesses. In a proffer of the evidence, the psychologist described published studies on factors such as the speed with which memory decays over time, the effects of stress on eyewitness accuracy, and the relationship between the confidence of a witness and the accuracy of identification. The trial court held the research on the accuracy of eyewitness identification was not a 'proper subject' for expert testimony and excluded the expert. However, the Arizona Supreme Court reversed and remanded the case for a new trial, stating that 'there were a number of substantive issues of ultimate fact on which the expert's testimony would have been of significant assistance.'

Similarly, the defendant in *State* vs. *Myers* (359 N.W.2d 604 (Minn, 1984)) was found guilty of criminal sexual conduct involving a child. The trial court had allowed the prosecution to introduce a social scientist as an expert witness to describe the behavioral traits 'typically' observed in abused children, traits that were also seen in the child complainant. The defense objected to this evidence at trial and appealed. The Minnesota Supreme Court upheld the conviction, however, stating that 'background data providing a relevant insight into the puzzling aspects of the child's conduct and demeanor which the jury could not otherwise bring to its evaluation is helpful and appropriate.'

In neither of these cases was social science research being used to provide legislative facts. No creation or modification of a rule of law was sought. Rather, in both cases the parties offering the research accepted the applicable legal rules and sought to show that the research would help the jury to decide the specific factual issues being litigated. Yet in neither of these cases was social science research being used to provide adjudicative facts either. The parties to the cases were not involved in the research at all: the experts relied on research studies published before the events that gave rise to the litigation took place.

The way social science was used in *Chapple* and *Myers*, however, reflects the defining characteristics of both legislative fact and adjudicative fact. In each case, the research demonstrated the critical component of legislative fact—generality. Just as the research used in *Leon* focused on the 'collective' costs and benefits of changing the exclusionary rule, the research used in *Chapple* focused on 'general factors' affecting all eyewitnesses. Similarly, the research in *Myers* concerned 'general characteristics' that were 'typically observed' in groups of abused children. In each case, the research used also possessed the critical component of adjudicative fact—specificity. Just as the research used in *Processed Plastic* spoke only to whether consumers were confused between two given products, the studies in *Chapple* were used only to challenge the testimony of eyewitnesses to a particular crime, and the research in *Myers* was used only to show that the named victim was, in fact, abused.

The research used in these cases and many like them is thus neither wholly legislative nor wholly adjudicative fact but has the essential elements of both of the conventional categories. Walker and Monahan (1987) have proposed a third category, termed social framework, to denote the use of general conclusions from social science research to determine factual issues in a specific case.

3. Future Directions

At the end of beginning of the twenty-first century, social science in the legal process is being transformed in two ways. First, the law of scientific evidence is very rapidly developing. In 1993, the United States Supreme Court, in *Daubert* vs. *Merrell Dow Pharmaceuticals* (509 US 579), for the first time decided the legal standard for the admissibility of scientific evidence.

The Rules of Evidence … assign to the trial judge the task of ensuring that an expert's testimony both rests on a reliable foundation and is relevant to the task at hand. Pertinent evidence based on scientifically valid principles will satisfy those demands.

The Court offered 'some general observations' on how judges should evaluate the validity of scientific research. Among other things, judges should consider whether a scientific theory or technique has been 'tested,' whether it has been 'subjected to peer review and publication,' whether it has a 'known or potential rate of error,' and whether it is 'generally accepted' in the scientific community. In a subsequent case, *Kumho Tire Company* vs. *Carmichael* (119 S. Ct. 1167 (1999)), the Court held that these concerns apply not just to 'scientific' expert testimony, but to all forms of expert testimony.

The second development in this area is the rapid rise in the availability of material to train lawyers and judges in the uses of scientific evidence, including social science evidence. Shortly after *Daubert*, the Federal Judicial Center (1994) published a *Reference Manual* that provided guidance for the admissibility of statistical evidence and the findings from social surveys. Subsequently, a three-volume work, *Modern Scientific Evidence* (Faigman et al. 1997), offered detailed analyses, from both legal and social scientific perspectives, of all of the issues discussed above. As the authors of this latter work note, '*Daubert*, perhaps represents nothing more, or less, than that henceforth the legal culture must assimilate the scientific culture.'

Legal Professionalism

The elaborate body of law that governs public and private life in most states today is not self-executing. Legal personnel and institutions must give it effect, as when judges adjudicate cases in the courts. Since ancient Rome, experts have represented or advised clients in legal matters (Pound 1953). They now exist in ratios of up to one per 300 citizens, the rate in the United States (Abel 1989). Most represent clients before tribunals, advise them about the legal consequences of their actions, draft their wills and contracts, or negotiate the terms of their transactions with others. Some do all these things; others specialize by task or field of law.

In the United States, the experts authorized to do this work are called lawyers or attorneys. (But legal tasks often overlap with tasks that non-lawyers perform, as where lawyers and accountants alike may prepare clients' tax returns.) They are trained, licensed, and regulated as a unitary profession, though many specialize. Comparable experts in other states may be divided into several legal professions, but the distinctions may change over time (Abbott 1988). In France, *avocats* go to court, *conseils juridiques* advise, and *notaires* draft documents. In England, barristers once held exclusive 'rights of audience' in the courts while solicitors provided other services, but the lines are now blurring. For brevity's sake, this article refers to all authorized legal service providers as lawyers and members of the legal profession or bar.

'Legal professionalism' refers to a cluster of values (see Sect. 1)—an ethic or ideology—that lawyers arguably share and that arguably influences their conduct. The concept has led two lives: as a folk concept for lawyers and as an analytic tool for sociologists. Lawyers find the concept normatively attractive as well as rhetorically useful, where they are politically diverse, for reaching a consensus in intra-professional policy debates. Bar leaders *ascribe* the ethic to lawyers, hoping to justify the profession to the laity, or foster professional solidarity, or avoid external regulation (see Sect. 1.7). They also *prescribe* the ethic for lawyers, hoping to inspire them to serve clients well while also promoting legality or the rule of law. Sociologists, for their part, have cited professionalism to explain or predict lawyers' conduct, to compare law practice in different times or places, or to compare lawyers with other occupational groups. They emphasize what legal professionalism has in common with the prevailing ethic or ideology in other professions (Friedson 1986), while lawyers see it as a 'learned' distinguishing characteristic.

Professionals, as opposed to amateurs, work to make money. Yet legal professionalism, according to *scholarly* defenders, implies pursuing a learned art as a common calling in the spirit of public service—'no less a public service because it may incidentally be a means of livelihood' (Pound 1953). So understood, the ethic appears to have precapitalist roots and might be expected to lose sway in today's entrepreneurial world (Krause 1996, but see Larson 1977).

Just as lawyers' work, clientele, and status vary from one legal system to another (Rueschemeyer 1973), so professionalism's impact on lawyers appears

to vary. Political or religious ideology can diminish its influence, as happened in the former Soviet Union. And yet, since its values are only weakly specified, professionalism may spur lawyers in dictatorships to resist state intrusions into lawyer–client relations even as it inspires lawyers in constitutional democracies to avoid such intrusions by forbearing to help clients commit illegalities (Friedman and Zile 1964).

1. *Core Values of Legal Professionalism as Lawyers Understand It*

Legal professionalism urges lawyers, individually and collectively, to pursue or maintain these conditions: competence, client trust, independent judgment, a just distribution of legal services, the legitimacy of the legal process, a professional community, and self-regulation.

1.1 *Professional Competence*

Seen through the lens of professionalism, lawyer competence takes on a distinctive gloss. Lawyers must be learned in law and skilled in applying it. Since their knowledge and skills are esoteric, the quality of their work is to be judged by professional, not lay, standards. Of course, craftsmen also possess esoteric knowledge, viewed in their case as competence gained through experience. Lawyers in some states view their expertise in this way; lawyers elsewhere consider it grounded on theory, a 'science' to be studied at university (Weber 1954). Either way, incompetence so threatens vital interests that would-be lawyers should not practice law, or call themselves lawyers, without obtaining a license, which usually entails long study, exams, and/or apprenticeship. Once licensed, lawyers should continue to hone their skills. They do not simply work, they practice.

Lawyer competence exalts quality over cost. Lawyers should not so limit the scope of their engagements that clients must give up their right to competent service, even if the limits make services more affordable. In the name of ensuring competence, some bars have even forbidden lawyers to charge fees below floors promulgated in minimum-fee schedules. Recent attacks on these schedules illustrate the tensions between professionalism and market values. Doubting that the floors ensure quality, and suspicious of restrictions on price competition, some states have removed a 'learned-profession' exemption from antitrust laws and now treat the schedules as illegal restraints on *trade* or *commerce*. More generally, critics disparage many bar policies that pit professionalism against market values. They see professionalism as a policy-making bias, if not a mask for lawyer self-interest. Scholars fuel the fire by likening minimum fees to the practices of medieval guilds (Krause 1996). In return for setting and enforcing just prices and quality standards, princes gave guilds exclusive rights to make and sell their goods.

1.2 *Promoting Client Trust Through Ethical and Fiduciary Duties*

Competence is a cognitive achievement. But effective lawyering also depends on maintaining client trust, which is more a function of ethical commitment than of cognition. Professionalism urges lawyers to shoulder fiduciary duties to clients that exceed other service providers' duties to customers. Consider the duty of confidentiality. Clients must reveal sensitive or compromising facts to their lawyers but they fear that such disclosures could be used against them. The duty of confidentiality and the related attorney–client 'privilege' counter this fear. If lawyer or client is summoned to testify in court about their private communications, the client may be privileged to suppress the testimony. Believing that clients need such protection in order to be candid, lawyers see no tension between keeping clients' secrets and the societal goal of getting at the truth through adjudication.

Since information disparities enable lawyers to manipulate client demand, lawyers should also promote trust by giving clients disinterested advice about the services they need and not soliciting clients so aggressively that disinterestedness is put at risk. Lawyers, moreover, owe each client undivided loyalty. Ethical norms discourage engagements in which personal or third-party interests may conflict with client interests and thereby cloud a lawyer's judgment on the client's behalf.

Lawyers often enjoy considerable social status. Max Weber (1954) found the source of lawyers' status in their knowledge base, while Emile Durkheim (1958) stressed their ethical or fiduciary commitments, which he saw as a product of professional socialization. But how well professionalization instills these commitments is unknown and in the past states relied instead on class, ethnicity, or family prominence to ensure lawyer trustworthiness. Before World War II, for example, only aristocrats and gentlemen became English barristers.

1.3 *Independent Professional Judgment*

Most engineers are not partners in engineering firms; they are employees in public or private entities run by others. Engineers are thus a learned, but not a 'free,' profession as lawyers aspire to be. Legal professionalism exhorts lawyers to remain free to exercise independent professional judgment, both in public life and in law practice. Yet, with 20 percent of the bar in North America and Western Europe now employed

by businesses, public agencies, or state-subsidized offices serving low-income clients (Spangler 1986), lawyers worry that independent judgment is becoming unsustainable.

Like Edmund Burke, legal professionalism views public policy-making as a process of reasoned deliberation, not a mere reflection of power or toting up of preferences. On this view, the bar can facilitate policy-making in states prone to political gridlock by recasting some issues as apolitical questions of law reform and debating them in the idiom of legalism, which focuses less on substantive aims than on whether proposals are constitutional and cohere with existing legal principles (Halliday 1987). Professionalism also urges the organized bar to address lawmakers on behalf of a palpable public interest, not the parochial interests of lawyers or powerful clients.

In law practice itself, independence implies sufficient discretion to exercise sound judgment on behalf of clients. Professional norms warn lawyers not to defer to the wishes of third-party payers in deciding how to serve clients and, in a dwindling number of states, also forbid lawyers to take non-lawyers such as accountants as partners. English barristers and French *avocats* have even been forbidden to form partnerships with others of their own kind lest their own capacity to exercise independent judgment be impaired.

But independence is not valued solely for the client's sake. Lawyers must also withstand clients' pressures to disregard third-party rights or the legal system's institutional needs. Lawyers call themselves 'officers of the court' or 'ministers of justice' to stress this reason for maintaining independent judgment. Fearing that lawyers who work solely for one client (often a company) will be too client-dependent, some European bars forbid them to designate themselves publicly as lawyers, or represent their client in court, or shelter client secrets under the attorney–client privilege. On similar grounds, English barristers are not retained and instructed by their clients, but by their clients' solicitors, who, as go-betweens, may shield barristers from overbearing clients.

1.4 Maintaining a Legitimate Legal Order Through a Just Distribution of Legal Services

State licensing gives lawyers market power, while professionalism urges them not to leave the distribution of legal services solely to market forces, even as tempered by state subsidies for clients of modest means. Because legal services often affect non-clients as well as clients, client ability to pay is not a valid measure of the resources that a just legal order would devote to those services. For example, since the public has a general interest in the integrity of the criminal justice system, access to criminal defense lawyers should not turn on a defendant's ability to pay, for indigents would then have no one to defend them and the validity of the state's charges would be left in doubt. Subsidies are an imperfect solution, not just because they are often minimal, but because the state may so restrict the ways in which lawyers may use the funds that lawyers think they can no longer exercise independent judgment. Professionalism therefore urges lawyers to accept some engagements *pro bono publico*, i.e., for little or no pay.

1.5 Maintaining the Procedural Legitimacy of the Legal System

Professionalism encourages lawyers to promote a legitimate legal order by preserving the integrity and rationality of legal processes. Lawyers should support the bar's campaigns for law reforms that rationalize procedures, and should not abuse procedures in order to pursue clients' aims. The tension between client interests and system-maintenance is a central theme in bar discourse.

1.6 Maintaining a Professional Community Through Bar Associations

As noted in Sect. 1.2, Durkheim thought professional associations could have a positive influence on their members. This is also a tenet of legal professionalism as lawyers understand it. Julius Henry Cohen, an American bar leader who was Durkheim's contemporary, argued that

> Lawyers must subordinat[e their] inclination, appetites, and ambitions to an organization which has as its object to promote the performance of a social function (Cohen 1924, quoting R. H. Tawney).

Since the bar must play superego to the lawyer's instincts, Cohen believed unaffiliated lawyers cannot be wholly professionalized. He saw no risk that greater bar solidarity might lead to harmful restrictions on professional competition.

1.7 The Elaboration and Promotion of a Professional Ethic Through Self-regulation

'Self-regulation' can refer to the ideas that lawyers should be governed by internalized values rather than external rules, or regulated by the judiciary rather than the 'political' branches of government. More often it refers to the idea that the bar itself should provide regulatory oversight by formulating ethical norms to govern lawyers and maintaining a disciplinary system to censure, fine, or disbar violators. Formal sanctions become important once lawyers become so numerous, diverse, and unknown to one another that concern for their reputations no longer ensures compliance. Legal

professionalism favors self-regulation largely as a way to obviate any need for regulation by the 'political' branches of government, which might not grasp or accept the lawyer's role in society and might be too quick to sanction those who challenge the legality of state action.

2. *The Uses and Contested Value of Legal Professionalism in Sociology*

Since the late-nineteenth century, scholars, notably sociologists, have found professionalism a useful analytic concept, though few have used it exclusively in studying lawyers. They have invoked professionalism, often as a variable, to (a) characterize an occupational mentality, (b) account for the conduct or relative status of occupations, (c) explain how occupations avoid outside regulation, (d) construct occupational taxonomies, or (e) trace the evolution of occupation toward an ideal type (Pound 1953). Until 1970, most scholars who deployed the concept were functionalists, such as Durkheim or Talcott Parsons (1954), who stressed the societal benefits of training lawyers to embrace the communal and anticommercial values of professionalism-as-ethic. But since then, critical theorists have questioned its analytic value or validity, at least as used by the functionalists. The critical school views professionalism as a modern conceit or ideology that occupational groups use, wittingly or not, to mobilize themselves or to justify their autonomy, status, and market power to the laity (see, e.g., Larson 1977).

3. *The Murky Prospects for Legal Professionalism as Ethic and as Ideology*

Whether one views legal professionalism as ethic or ideology, it is clear that powerful forces are arrayed against its continued vitality (Krause 1996). Lawyers, especially those with business clients, cannot be insulated from the entrepreneurial values ascendant in much of the world today. Clients press them to form practice alliances with accountants and consultants, alliances that may be cost-effective but undermine intra-professional solidarity. Relentless specialization in response to law's penetration into all aspects of life is generating specialty bars that threaten the viability of more inclusive bar associations. Specialization is also turning lawyers into technicians whose narrow skills lay competitors can often match (Kritzer 1998). In dynamic economies, moreover, lawyers cannot quench the demand for legal services; again inviting lay competition (Abbott 1988). Cost-cutting efforts to 'unbundle' or fragment traditional legal tasks, coupled with the transformation of some legal services into standardized products, are also eroding the distinctiveness of legal work. Finally, the proliferation of large, bureaucratically-controlled worksites for lawyers—mega-law firms, corporate law departments, public agencies, and subsidized legal aid offices—is in obvious tension with professional independence.

However, the cluster of ill-specified values summed up in the term 'legal professionalism' is not necessarily doomed to extinction. One can imagine counter forces that might sustain professionalism as ethic or ideology. Renewed respect for the rule of law and for legal dispute resolution techniques may accompany the ascendancy of commercial values, and specialization may be tempered by renewed demand for ethically committed lawyers who provide wise counsel based on wide understanding of law, legal traditions, and the virtues of legality.

Legal Realism

'Legal Realism' is the name generally given to a movement in American legal thought between World War I and World War II. However, any attempt to identify precisely the intellectual content of the Realist movement is made difficult by the fact that its salient tenets, and thus its meaning, were widely contested during its heyday and are still widely contested.

1. *Difficulties in Defining 'Legal Realism'*

The Realist movement has been seen as an outgrowth of the Sociological Jurisprudence of Rudolf von Jhering as expounded by Roscoe Pound (1911–12), as well as a reaction to Pound's work. In addition, many have understood Realism as an outgrowth of the thought of Oliver Wendell Holmes, Jr. (1897), although it is not clear that such an identification is warranted, given Holmes' relentless pessimism and lack of faith in democracy. Also, while all agree that Realism was a reaction to legal formalism, sometimes referred to as 'conceptualism'—the notion that legal rules can be correctly deduced from a proper understanding of the nature of a limited set of important, narrowly legal premises—there nevertheless is disagreement as to whether any significant American legal thinker held such a position and thus what an opposition to formalism might signify (see *Legal Formalism*). The most that can be said is that all scholars agree that some portion of the activities of individuals commonly called Realists was directed at critique of the doctrinal results of legal formalism, at understanding judicial decision-making, at empirical research in law, at reform of legal education, and at participation in the activities of the New Deal administration of Franklin D. Roosevelt.

There is, however, nothing like agreement among scholars about the relative importance of these various activities for understanding Realism; moreover the weighing of relative importance in part determines who is included in a list of The Realists. Thus, while it is likely that most scholars would agree that Thurman Arnold, Charles E. Clark, Walter Wheeler Cook, William O. Douglas, Jerome N. Frank, Walton H. Hamilton, Karl N. Llewellyn, Underhill Moore, Herman Oliphant, and Hessel Yntema belong on the list, the inclusion or exclusion of men such as Adolph A. Berle, Walter Bingham, Felix Cohen, Morris R. Cohen, Arthur L. Corbin, John Dewey, Leon Green, Robert L. Hale, Robert M. Hutchins, Edwin Patterson, Thomas Reed Powell, Edward S. Robinson, Max Radin, Fred Rodell, Wesley Sturges, and Leon Tulin, all plausible figures, will change one's understanding of Realism, as well as be dictated by that understanding. What follows, therefore, is only one of several possible expositions of American Legal Realism. Other expositions can be found in the works of Duxbury (1995), Horwitz (1992), Hull (1997), Kalman (1986), Purcell (1973), Rumble (1968), Stevens (1983), Twining (1973) and Verdun-Jones (1979).

2. *A Contestable Definition*

'Legal Realism' is best understood as the reaction of a group of individuals within the American legal academy to the collapse of the Progressive movement after World War I, the decisions of the United States Supreme Court invalidating economic regulation on grounds either of substantive due process or of interference with vested contractual rights, and the general shift of the USA to the political right in the Harding, Coolidge, and Hoover administrations. The important words in this definition are 'within the American legal academy,' for the movement largely took place at three schools—Columbia, Johns Hopkins, and Yale. Obviously, this definition does not succinctly describe the political orientation of the Realist movement. On this topic the best that can be said is that, taken as a whole, the Realists were hardly radicals. It would be astonishing to learn belatedly that any of these men were members of the Communist Party, and it is doubtful whether any even voted Socialist. Many served in the Roosevelt administration, but doing was an indication of socialist leanings only to the most reactionary members of the business elite and their Republican Party allies. Thus, Realists are better seen as mainstream liberals caught in a very conservative time.

The relationship of the Realist movement to the Progressive movement can be seen both positively and negatively. Positively, there is the similarity in the political causes supported (organized labor), and opposed (big business). Also, the empirical research engaged in by many of the Realist scholars is similar to research undertaken by Progressive reformers (although not progressive law professors) before World War I. Indeed, both groups shared an 'all men of good will' ethics, as is evident from the notion underlying their empirical research that once the facts about a social problem are known, then reform will follow. In this sense neither group was committed to what we would now see as an ideological view of law that, in contrast, would suggest that exposure of the 'facts' about a social practice might bring embarrassment, but would also bring denial and resistance

to change. For both the Progressives and the Realists evil existed in the world, but it existed in individuals, not in classes or other affinity groups.

The Realists' relationship to the Progressive movement can be seen negatively in the reaction of the members of the movement to Pound as Dean of the Harvard Law School. Pound was a mainstay of the legal wing of Progressive reform movements before World War I. His condemnation of 'Mechanical Jurisprudence' (Pound 1908) was a rallying cry for Progressives, as was his exposition of 'Sociological Jurisprudence' (Pound 1911–12). Pound's jurisprudence was designed to be a response to the first wave of antiprogressive constitutional decision-making by the Supreme Court. It seemingly encouraged empirical research by emphasizing the difference between 'the law on the books and the law in action' (Pound 1910), in order to urge courts to avoid a formal, mechanical application of law, and instead to recognize, balance, and thus adjust the interests of the parties in the light of contemporary social and economic conditions.

Yet, for the Realists, Pound was also part of the problem that their activities were designed to address. For them, all of Pound's talk about the gap between the law on the books and the law in action and about the need for balancing of interests had never translated into the activity of exploring these gaps or identifying the interests in question through empirical research, or into actually suggesting how particular interests might be balanced. Moreover, Pound's law school was little changed from the school of Langdell and Ames, seen by Realist scholars to be among the arch formalists. It reflected none of what they saw as the implications of Progressivism and Sociological Jurisprudence for legal education—a revision of category systems, an emphasis on factual investigation, and explicit work on social policy.

3. *What Realists Did*

What the above definition pointedly lacks is some explicit statement of what the Realists believed, and therefore what Realism is. This omission is intentional. Realism is what Realists did and it is only with that aphorism in mind that one can make sense of the disparate materials that were published by what must be seen as a network of friends, not a coherent intellectual position. Start, then, at the beginning.

Although some pre-War work by Bingham has a particularly Realist cast, Realism largely started at Columbia with pieces by Cook and Moore, who respectively argued for a more empirically based understanding of the real, as opposed to verbal, activities of appellate courts in the field of conflict of laws and of the real, as opposed to verbal, activities that made up the institutional practices that the law defined, such as property and contract. From their work, one can see that Legal Realism is not even a distant relative of philosophical realism, the doctrine that the concepts of daily life are ontologically real, but, as Leiter (1997) has suggested, is much closer to naturalism in art or literature, a commitment to see and describe the realities of daily life scientifically, that is without idealization or the avoidance of the ugly, although in Legal Realism's concern with democracy and the activities of the middle class, there is some affinity with literary and artistic realism as well.

Curiously, the group of Realists who taught at Columbia, including Oliphant, Llewellyn, and Douglas, was not particularly interested in constitutional law, as might have been expected given the group's affinities to Progressivism, but in corporate and commercial law. These men argued that, because of antiquated ideas about judicial decision making, in areas of law related to business, just as in constitutional law, the law was lagging behind changes in commercial life, particularly the growth of the large corporation employing thousands of workers and the change in methods of production and distribution of goods that had broken older patterns of finance and trade. This focus had much in common with the Institutional Economics of John Commons, Richard T. Ely, and Thorstein Veblen that emphasized the way that the institutional, by which they meant regular, patterns of economic behavior determined the growth or decline of industries, attitudes toward labor, and practices in the pricing of goods. Thus, Moore worked on the law of banking, Oliphant on labor and antitrust, Llewellyn on the sale of goods, and Douglas on corporations and commercial bankruptcy (see *Markets and the Law*).

Even more curiously, the empirical research that was implied by the work at Columbia was not undertaken there, but rather at Yale and Johns Hopkins, mostly in the years after the Columbia law faculty blew up over the results of a Dean search. At Yale, pioneering empirical work, superintended by Clark, Douglas, and Moore, focused on the activities of the federal courts in civil, criminal, and bankruptcy cases, on the activities of bankers in handling negotiable instruments, on the operation of the tort system in auto accidents, on the effect of parking regulations in altering the behavior of parkers, and on the legal needs of citizens of modest means. At Johns Hopkins, equally pioneering work, superintended by Oliphant, Yntema, and their colleague at Columbia, Leon C. Marshall, was done on the operation of state courts in civil, criminal, divorce, and justice of the peace cases.

Much of the rest of the scholarship of the Realists, though not empirical in the narrowest sense, was still within artistic and literary naturalism's desire to describe the realities of daily activities. Cook's continuing work on what courts were really doing in conflict of laws doctrine and Green's parallel work on torts doctrine, fit this mold, as does the work of Arnold and Robinson on the symbolic uses of law, Llewellyn's work on commercial practice, Hutchins'

work on the psychological underpinnings of evidence law, and Berle's work on corporate governance. All of this work, and most of the more narrowly empirical work as well, was directed at critiquing legal, particularly judge-made rules, but Realism is more famous for its related, but more frontal assault on contemporary understandings of judicial decision-making.

Realists attacked formalist understandings of judicial decision-making in three ways: logically, psychologically, and sociologically. The logical attack argued that legal concepts that the formalists, especially the formalists on the Supreme Court, saw as necessarily determining decisions were not in fact determinative. Here Realists relied on Wesley N. Hohfeld, who argued that legal concepts inappropriately treated as unitary various discrete legal relationships, any one of which could not be implied from the existence of another; on Judge Benjamin N. Cardozo, who asserted that there were four different methods for deciding a case and so allowed the judge the 'sovereign prerogative of choice'; on Cook, who claimed that legal rules 'hunt in pairs,' so that for every rule there is an exception or counter rule whose application would lead to a different result; and on Llewellyn, who eventually demonstrated that there is a great range of acceptable techniques for dealing with a legal precedent. Together, these observations suggested that legal concepts did not produce necessary results by the use of logic alone, but rather permitted judges a choice of results, a choice that was made surreptitiously, as it were, without explicitly considering the function that the rules played in society or the policy behind those rules.

The psychological attack argued that judicial opinions, traditionally presented in a seemingly syllogistic form, hid a decision that was reached in very different ways. Here Realists relied on the work of another judge, Joseph Hutchinson, who argued that most decisions were decided on the basis of a 'hunch' about the appropriate result, and of Frank, who argued strenuously that a judicial opinion was but a rationalization of a decision reached in another way, that formalism was motivated by an infantile search for paternal authority and that a truly adult judge would recognize and expose the many factors, particularly the idiosyncrasies of his response to the facts proven at trial, that lead to the choice that was made in an individual case. Together these observations suggested that judicial decisions obscured behind a web of false necessity the real factors that operated to generate results in particular cases.

The sociological attack, which was more muted than either of the other two, attempted to identify the factors at work behind the facade of the judicial opinion. Here the most common argument implicitly drew on the work of William J. Ogburn, who argued that the structure of social understandings of the world commonly lagged behind the practices that these understandings purported to describe. Versions of this concept of 'cultural lag' were offered by the Realists to explain how it was that judges utilized an 'outdated' economic theory to understand labor conditions or commercial transactions, an 'outdated' psychological theory to understand witness testimony, or an 'outdated' political theory to limit governmental action to address the conditions of modern life. It was here that the Realists' jurisprudence, as that word is traditionally used, met up with their interest in empirical research. Faced with the facts gathered from empirical research, it was assumed that judges and other legal actors would come to abandon their outdated theories.

The Realists' remedy for the inadequacies of formalism was functionalism. The problems with formalism were seen to be the lack of relationship between the concepts and categories of the law and the 'realities' of modern life. Closer attention to these realities would allow one to focus the law's attention on institutions, such as the organized activities of businessmen in a trade association, and on the functions that these activities represented, and so see to it that the law addressed directly the problems in that trade as a matter of effective and appropriate social policy. Such an analysis would disclose just when the law needed to be updated because of its lag behind social practice and also would expose circumstances where law was dysfunctional, where a body of doctrine was ineffective, as, for example, when Arnold argued that the antitrust laws provided the comfort of a myth that law was doing something to address public fears about big business, while ignoring the anticompetitive practices that made for monopoly.

For all the talk about functionalism as an antidote to formalism as a jurisprudence, indeed for all that Realism is taken to be a jurisprudence, it is important to understand that much of the impetus behind realism was educational. The Realists were mostly law professors for whom the question of how to present the materials of law study was a daily concern. It is with respect to legal education that functionalism and empirical research might have been expected to have some real bite. Functionalism raised questions about what were the appropriate categories under which to group the legal materials, and a study of the entire curriculum at Columbia was undertaken to examine how the curriculum could be organized more functionally. Similarly, empirical research was designed to answer the questions about the efficacy of the institutions and rules of law in the aid of understanding what social policy was appropriate in each functionally defined area.

Although almost no part of the curriculum was rearranged functionally, indeed, for example, the course in trusts is still taught despite the absolutely withering critique that Arnold leveled against it, and though law professors do little more empirical research today than was the case before World War I, it is in

the area of education that Legal Realism had its greatest impact. The critique of formalism utterly changed the way that law was justified in the law school classroom. From a formalism based on assertedly logical derivation from the nature of a given legal category the justification of legal rules has shifted to a realism based on assumed knowledge of social conditions to which law is applied in the pursuit of supposedly agreed upon social policy. The law professors now talk the language of the early twentieth century political science professors, as well as of the bureaucrats in Washington and in scattered state capitals. Whether this is an advance is for others to say (see *Legal Education*).

Legal Reasoning and Argumentation

1. Reasoning in Adjudication

It is sometimes said that the main aim of legal education is to develop skills of 'thinking like a lawyer,' including skills of legal reasoning. This phrase is often taken to imply that all lawyers think alike, that they only think about questions of law in the context of adjudication; that there is a single correct way of thinking about such questions; and that this way of thinking is unique or special to lawyers. An alternative view is that lawyers' reasoning extends far beyond binary questions of law in adjudication to a wide variety of legal contexts and operations; that what constitute valid, cogent, and appropriate modes of reasoning in each kind of context, and how far rationality is attainable, is contested; and that the relevant skills of reasoning involved are not a lawyers' monopoly. Special considerations apply in particular legal contexts, such as rules of precedent or evidence or procedure, but the basic criteria of validity and cogency for all of these operations can be subsumed under one or other general theory of practical reasoning. This article proceeds on assumptions that are closer to the second view but, solely for reasons of space, it focuses on reasoning about questions of law and questions of fact in adjudication. It does not deal with the psychological processes by which adjudicators reach decisions.

Reasoning in adjudication is a focal point for some perennial problems of legal philosophy, including contested questions about epistemology, rationality, and skepticism; differing conceptions of law and justice; the relations between law and morality; formalism; the role of judges in a democracy; official discretion; and transparency in decision-making.

According to one view, a question of law is easy or straightforward if a justification for a decision can be rationally reconstructed in the form of a simple syllogism:

Major premise: Whenever X happens, then Y ought to happen (Rule (R)).

Minor premise: X happened (Facts (F)).

Conclusion: Therefore Y ought to happen (Judgment of guilt, liability etc.).

This model of legal reasoning has often been dismissed as 'mechanical' jurisprudence, because most problems of interpretation arise in relation to doubts about the formulation and precise interpretation of the major premise (R) and the categorization of the facts in the minor premise (F). However, this is precisely the form in which justifications for decisions in 'easy' or 'clear' cases can be rationally reconstructed.

What if the major premise or the minor premise requires justification? There is quite widespread, but not universal, agreement among jurists that deduction has only a limited role in such second order justifi-

cation of R (legal propositions) and in inferential reasoning from evidence about disputed issues of fact (F). For example, the standard alibi defense can be reconstructed in the form of two linked syllogisms:

No person can be in two different places at the same moment of time.

A was in a different place when this crime was committed.

Therefore A was not physically present when this crime was committed.

It is necessary for a person to be physically present to be guilty of this crime.

A was not physically present when this crime was committed.

Therefore A is not guilty of X.

Insofar as deduction plays a limited role in justifying R or F, the reasoning involved does not lead to necessary conclusions ('open system reasoning').

2. *A Rationalist Model of Reasoning in Adjudication*

Orthodox rationalist views about reasoning in adjudication can be reconstructed as a model or 'ideal type,' which the views of many leading jurists approximate. This model represents a set of basic assumptions about the aims and nature of adjudication and what is involved in valid reasoning about disputed questions of law and of fact in this context.

Aim and Nature of Adjudication

(a) The direct end of adjudication is rectitude of decision, that is the correct application of valid laws to true material facts (facts in issue).

(b) The logic of justification of judicial decisions involves an application of general principles of practical reasoning in a specific context.

(c) A judicial decision is legitimate if and only if it is justified by sound arguments that satisfy the moral requirement of formal justice that like cases should be treated alike.

(d) In clear cases a sound justification satisfies the deductive form: if R, then C; F is a case of R; therefore C.

(e) Doubts can arise about R (e.g., about its validity, its identity, its scope) or about its application to F, or about whether F has been established to the relevant standard of proof, or a combination of these.

(f) Doubts about R give rise to questions of law; doubts about F give rise to questions of fact.

(g) In adjudication both questions of law and questions of fact are typically binary (e.g., liable/not liable; guilty/not guilty).

Questions of Law

(h) Resolution of questions of law in hard cases requires second-order justification, which may involve different forms of reasoning, notably deduction, induction, reasoning by analogy, or a combination of these.

(i) A number of independent material reasons may be advanced in a single argument for or against a decision of a question of interpretation or application of R. These reasons may be of different kinds.

(j) The validity and cogency of different kinds of material reasons are system-specific; they depend on the rules and conventions of a given system with respect to authoritative sources of law and appropriate modes of argumentation.

(k) Second order justification of R may involve two kinds of reasons: (a) authority reasons which relate to the compatibility or fit of a line of argument with the rules and principles of the system and the authoritative sources recognized by that system (arguments about validity, consistency, and coherence); (b) substantive reasons, which relate to values, goals, or institutional requirements of the system (Summers 1992).

Questions of Fact

(l) Rational determination of the truth of alleged facts (F) in adjudication is typically a matter of probabilities, falling short of absolute certainty.

(m) Judgments about the probabilities of allegations about particular past events can and should be justified by reasoning from relevant and admissible evidence considered by the decision-maker.

(n) Judgments about probabilities, generally speaking, have to be based on the available stock of knowledge about the common course of events.

(o) Rational determination of F is a matter of ordinary common-sense reasoning, as modified by the rules of evidence and procedure of a given system.

2.1 *Questions of Law*

Theorists of reasoning about questions of law can be roughly categorized into *rationalists* and *critics*. A reasonably representative sample of leading rationalists might include Aulis Aarnio (Finland), Robert Alexy (Germany), Ronald Dworkin (USA/Britain), Torstein Eckhoff (Norway), Neil MacCormick (Scotland), Joseph Raz (Israel/Britain) and Robert Summers (USA). Although they come from different legal traditions and quite varied intellectual backgrounds, rationalists are in broad agreement on most of the first ten points in the model. Most focus mainly on second-order justification of adjudicative decisions on questions of law in hard cases, because these are perceived to be the most interesting theoretically. These theorists may differ about which kinds of substantive reasons are valid, about their relative weight or cogency, and whether substantive reasons are an integral part of the law or are extraneous to it. Some jurists in the civil law tradition maintain that all second-order justification

can be reconstructed in deductive form, but the predominant view among common lawyers is that this kind of justification involves mainly open system reasoning.

Among rationalists there is a variety of views on material reasons in second-order justification (k). Some differences are matters of emphasis or detail or conceptual refinements, but others are seen as significant. For example, Ronald Dworkin (1977, 1986) has advanced three theses that are regularly disputed: (a) that there is a single right answer to almost every question of law even in very hard cases; (b) that principles of political morality underlying a legal system are an integral part of the law, and are not external to it; (c) that principles of political morality are the only valid substantive reasons for justification in adjudication; policy reasons and other arguments external to the law are not valid. These theses are part of a general theory of adjudication that maintains that legal reasoning is essentially a moral enterprise; the duty of judges in a liberal democracy is to uphold the law and to vindicate rights on the basis of interpretations that make 'it the best it can be.'

At first glance, Dworkin's theory is in conflict with standard tenets of legal positivism, especially that (a) a sharp distinction must be drawn between law as it is and law as it ought to be; (b) when the law 'runs out,' judges may invoke non-legal reasons, including consequentialist reasons; and (c) in such circumstances judges can, may, and do make law interstitially. However, the differences between Dworkin and other rationalists are narrow. Most rationalists agree that moral arguments play a valid role in legal justifications. If 'one right answer' means a solution justified by the strongest conceivable argument, most would accept that it is meaningful to talk of stronger and weaker arguments, and that *ties* are a rarity even with respect to open-system reasoning (see *Legal Positivism*).

The rationalist model has been subject to several challenges. First, it is narrow. It does not address modes of reasoning in earlier times or in non-western cultures or in the variety of other legal contexts in which practical reasoning is involved. Interpretation by an upright judge may provide a general model of correct interpretation for other officials and for good citizens, but what constitutes valid, cogent, and appropriate reasoning in adjudication will not be exactly the same for other interpreters. For example, a factory or a tax inspector may appropriately take into account different considerations, and interpret the same law differently from a judge.

Second, skeptics may doubt the possibility of rationality in adjudication or challenge the idea that this represents the only possible, or the most appropriate, model of rationality or that a single model is applicable across cultures. Suggestions that judicial opinions are merely *ex post facto* rationalizations have been shown to be based on confusion between the logic of justification and the psychology of decision (Wasserstrom 1961). The requirement or expectation that decision-makers should justify their decisions publicly may serve as an institutional constraint or steadying factor that limits arbitrariness or corruption or pure subjectivity (Llewellyn 1962, Raz 1978). Recently, critical and postmodern challengers have argued that rationalist models conceal the fundamental indeterminacy of legal decision-making. For example:

> In all the Western systems, the discourse that judges, legal authorities, and political theorists use to legitimate the application of state power denies (suppresses, mystifies, distorts, conceals, evades) two key phenomena: (a) the degree to which the settled rules (whether contained in a Code or in common law) structure public and private life so as to empower some groups at the expense of others, and in general function to reproduce the systems of hierarchy that characterize the society in question; (b) the degree to which the system of legal rules contains gaps, conflicts, and ambiguities that get resolved by judges pursuing conscious, half-conscious, and unconscious ideological projects with respect to these issues of hierarchy. (Kennedy 1997) (see *Critical Legal Studies*)

The scope of disagreement between rationalists and their critics is easily exaggerated, for few jurists subscribe to extremes of strong philosophical skepticism or of radical indeterminacy on the one hand or of strict rationalism and objectivity on the other.

A third challenge suggests that the distinction between clear and hard cases is problematic. Are cases inherently hard or easy? Or is it that some cases are merely perceived or treated as easy and others as hard? Cannot a creative lawyer construct arguments that raise doubts about what was previously perceived to be settled? Such skepticism receives *prima facie* support from a consideration of the many different kinds of doubt that can arise in relation to the interpretation of both legal and non-legal rules (Twining and Miers 1999, Chap. 6). Even in a seemingly simple situation, a single factor can be a starting-point for an argument that raises a doubt about what previously may have been treated as clear or settled or simple; but it does not follow from such indications of *potential* complexity that in practice every routine or seemingly clear case can easily be treated as hard. There are indeed cases in which a significant development of the law took place because what was previously taken as settled was successfully challenged. But these are 'leading cases' just because they were exceptional.

A fourth type of challenge suggests that normative theories of legal reasoning tend to be too abstract and simplistic to catch the complexities and subtleties of actual legal arguments. Judicial opinions that run to many pages are 'reconstructed' in just a few propositions. Furthermore, it is often unclear whether the reconstruction is of *actual* or of *possible* arguments. Is a reconstruction of a formalistic, ambiguous, or opaque judicial opinion, or of a decision not backed

by any public justification (such as jury verdicts at common law), to be regarded as a reconstruction of the actual justification presented, or of the best justification that might have been advanced, or of something else? For example, the discursive style of appellate judges at common law is often contrasted with the more succinct style of French judgments which, it is said, are typically expressed in deductive form. If hard cases require a second order justification that can only exceptionally be deductive, this suggests that French courts typically do not indulge in explicit second order justification.

2.2 *Questions of Fact*

The study of evidence and inference has roots in the long history of rhetoric and of probabilities, but interest in reasoning about questions of fact in adjudication has been intermittent. Evidence has received more sustained attention in common law countries than in the tradition of civil law, but there the main focus has been on the Law of Evidence. Notable exceptions include Bentham's *Rationale of Judicial Evidence* (1826) and Wigmore's *Science of Judicial Proof* (1937). Since 1970 'The New Evidence Scholarship' has been the forum for lively debates about the competing claims of different theories of probability; the thesis that the paradigm case of probabilistic reasoning in adjudication is in principle inductive (Baconian) rather than mathematical (Pascalian) (Cohen 1977); and whether 'atomistic' models of rationality can accommodate 'holistic' ideas of narrative coherence on which, according to psychological research, decision-making by jurors is predominantly based (e.g., Pennington and Hastie 1991). Such legal concerns are relevant to the study of evidence and inference in other disciplines (Schum 1994).

Here, three points deserve emphasis. First, Anglo-American ideas in this area have recently spread to Continental Europe (e.g., Malsch and Nijboer 1999), but there has been almost no sustained comparison between conceptions of evidence and inference in law in modern Western and other traditions. Second, as with reasoning about questions of law, a high proportion of legal scholarship about evidence and inference in law shares a set of assumptions that approximates to the rationalist model of reasoning in adjudication. Third, these assumptions are similarly open to various skeptical or critical challenges including (a) strong philosophical skepticism about the possibility of knowledge or of rational argument or of objectivity in this context; (b) ideological skepticism about the coherence and tenability of 'liberal legalist' ideas about adjudication; (c) skepticism about claims that the main end of adjudication is implementation of law and vindication of rights; (d) legal fact-skepticism about the feasibility of designing institutions, procedures and rules that will, in practice, regularly maximize the probability of achieving correct decisions (Frank 1949); and (e) contextual skepticism about the sense of studying adjudicative decisions outside the broader context of total legal processes and broader social processes. To these might be added further challenges associated with post-modernism, feminism, cultural relativism, and developments in the philosophy of science (Twining 1994).

3. *Law and Fact*

At first sight, the distinction between law and fact seems simple. 'What is the scope of this statutory provision?' is a question of law; 'What happened on that particular occasion?' is a question if fact. However, the line is often difficult to draw, especially with regard to the application of rules and the appropriate categorization of a particular fact situation. 'Was X dishonest?' or 'Is this a case of murder?' could be interpreted as a question of law or a question of fact, or a mixed question of law and fact. How such questions are treated in particular cases varies between systems and among different contexts within the same system for different practical purposes. For example, in English jury cases, questions of law are for the judge while questions of fact are for the jury; decisions on questions of law can have precedent value, but findings of fact do not. Questions relating to appeals, mistake in contract, or the obligation to give reasoned justifications turn on the distinction between law and fact, but where exactly the line is drawn varies according to context. Furthermore, legal cultures differ significantly in the framing of issues in particular disputes as questions of law or of fact (e.g., Dezalay and Garth 1996).

Reasoning about issues of law and of fact have stimulated two largely separate bodies of literature, despite the intimate connection and similarities between them. Both are perceived to be species of practical reasoning with structures that are binary (guilty/not guilty, liable/not liable) and dialectical (all reasons tend to support or to negate an ultimate proposition or conclusion). The ultimate decision is a normative judgment (e.g., liable/not liable). Many questions of fact have normative elements: for example, 'did X behave reasonably in the circumstances?' is a question of fact, which involves both evaluative and empirical elements. Categorization of an issue as being of fact or of law can have important practical consequences, and the kinds of reasoning that are deemed appropriate differ; for example, no one has seriously suggested that Bayes' theorem applies to questions of law, but nevertheless it might be interpreted as providing a suggestive metaphor regarding the combination of judgments based on different kinds

of reasons within a single argument. Where decisions on fact, law, and sanctions are the responsibility of a single tribunal, there may be some freedom to consider what is a good solution to the problem of the case as a whole, an option not generally available where responsibility for decisions is divided between judge and jury.

4. Argumentation

Theories of legal reasoning are primarily normative theories. 'Argumentation' here refers to the actual discourses used in advancing arguments, including reasonings that are explicitly or implicitly embodied in such discourses, nonrational means of persuasion, and the strategy, tactics and styles of argument. Argumentation can be studied from a wide range of empirical, interpretive, and critical perspectives that apply to social discourse generally including rhetoric, conversation analysis, semantics, and semiotics. See *Ethnomethodology: General*; *Logic and Linguistics*; *Rhetoric*. There has been little sustained research into actual discursive practices of legal actors and, as with the normative literature, most studies have focused on argumentation in adjudication and advocacy.

Most normative theorists claim that their accounts have a more or less close relation to how judges and advocates actually argue. For example, Ronald Dworkin (1986) boldly claims that his theory not only prescribes an ideal, but also describes 'best practice' in common-law courts; however this claim is not backed by evidence. MacCormick (1978) uses actual cases from several jurisdictions as illustrations, but his sample is not representative. Some analysis of judicial styles has been based on fairly extensive random samples (e.g., Llewellyn 1962, Wetter 1960), but these studies have not been replicated.

Explicit links between normative theories of reasoning and actual discourses have been both diverse and intermittent. In social theory the most important connection has been Max Weber's thesis that formal rationalization of law is a concomitant of the rise of capitalism and modernity (see *Weber, Max* (1864–1920)). Critiques of rationalist theories of adjudication are often part of a more general critique of 'liberal legalism' and the Rule of Law (e.g., Kennedy 1997). Closest to the orthodox juristic literature is the neo-Aristotelian 'New Rhetoric' of the Brussels School (e.g., Perelman and Olbrechts-Tyteka 1969, and in Germany, Viehweg [1953] 1993), whose central concern is to describe the starting-points (*topoi*), argumentation schemes, and material factors that can be deployed to try to convince a specific audience (such as a court) or, more speculatively, a universal audience, to do or to decide something. Sharing some intellectual ancestors with the New Rhetoric but being more empirically oriented, the Amsterdam School of Pragma-dialectics aims to develop a model for the rational analysis and evaluation of legal argumentation as a specific, institutionalized form of argumentation in general (e.g., van Eemeren et al. 1996). This is part of a general effort to develop a model and code of conduct for rational discussants in a conversation intended to resolve disputes. Applied to law, this model sits somewhat awkwardly with robust adversarial argument. The self-imposed limitation of analyzing what is actually said ensures that the approach is quite concrete, but makes it difficult to catch unspoken conventions.

5. Conclusion

There is a rich body of normative theories about reasoning in modern Western adjudication, but more work is needed to integrate the literature on reasoning about questions of law and questions of fact and to extend the focus of attention to other legal operations and other legal traditions. With respect to argumentation, one can agree with two leading theorists that 'what is needed are reflective hermeneutic studies of the current actuality of reasoning practice in modern legal systems' (Aarnio and MacCormick 1992).

Legal Reasoning Models

1. Introduction

Research in legal reasoning models investigates formal and computational theories of how legal experts analyze problems, create arguments, and make decisions. The formalization of law and legal reasoning is not a new enterprise, but rather one that has challenged philosophers of law throughout the twentieth century. Wesley Hohfeld (1913), a legal positivist, proposed that all legal states of affairs can be described in terms of four fundamental relations: rights, duties, powers, and liabilities (with inverse relations: no-rights, privileges, disabilities, and immunities). In contrast, legal realists such as Jerome Frank (1931) argued that law cannot be characterized as a formal system, because the infinite variety of particular facts on which legal decisions turn make legal reasoning inherently unpredictable. The problem of open-textured concepts (i.e., legal concepts that do not have clear definitions to determine their applicability, but which depend on experience and common sense, such as the concept of recklessness) is the focus of a famous debate between H. L. A. Hart and Lon Fuller (Hart 1958, Fuller 1958), in which a legal rule stating 'No vehicles are permitted in the park' is used to demonstrate that even an apparently clear concept such as 'vehicle' can be legally indeterminate, as in the case where a veterans group wants to drive a tank through the park as part of a Memorial Day parade.

With the advent of computers and artificial intelligence, both the range of techniques available and the practical motivation for creating legal reasoning models have grown. Rule-based systems using logical inference techniques have been developed and used successfully in a number of legal domains, especially those dominated by complex regulations such as taxation and social benefits administration (Johnson and Mead 1991). A unique challenge in developing legal rule-based systems is the need to model the relationship between the logical representation and its textual sources (Bench-Capon and Coenen 1992). This need arises first, because legal experts (and legal expert systems) must be able to cite the authoritative texts on which their conclusions are based, and second, to enable legal knowledge bases to be efficiently updated when laws and regulations are amended.

Despite the successful adaptation of rule-based reasoning models to the legal domain, it is the view of most researchers that the essence of legal reasoning is its open-textured and indeterminate nature (Berman and Hafner 1987). Two essential cognitive abilities for legal reasoning models include:

(a) reasoning with cases to interpret open-textured or conflicting legal rules and concepts

(b) adversarial reasoning: the ability to create persuasive arguments for both sides of an issue.

2. Case-based Legal Reasoning Models

Case-based reasoning (CBR) research in artificial intelligence (see also *Problem Solving and Reasoning: Case-based*) is concerned with the use of remembered prior experiences in analyzing new situations and solving problems. The distinguishing characteristic of case-based reasoning is that prior experiences are stored as distinct histories or 'cases,' in contrast to other AI reasoning frameworks where knowledge (however acquired) is integrated into a unified structure of logical rules, frames, neural nets, or combinations of these.

Research in case-based legal reasoning has a more restricted meaning: formal judicial decisions (i.e., legal cases) play the role of remembered experiences, and the problem-solving goal is the application of a prior case to answer legal questions about a new case. In legal CBR models, a set of domain-dependent, legally-relevant features is defined, and a prior case is considered more or less *on point* depending on the degree of match between the features of the prior case and those of the new case. Computational models of legal CBR are concerned with the following problems: representation of cases, including their facts, issues, *holdings* (the judicial conclusions they contain), and results; organization of the case database, including the indexing structure and retrieval algorithms; ranking of retrieved cases by their similarity to a new case; and creation of case-based legal arguments.

The first legal CBR model that addressed all of these problems was embodied in HYPO (Rissland and Ashley 1987, Ashley 1990), a computer program for analyzing cases and constructing legal arguments in

the domain of trade secrets law. In HYPO, legally relevant features called *dimensions* are used to index and retrieve cases. HYPO's legal domain knowledge includes, for each feature, which side of a dispute would be favored by the feature's having particular values (e.g., a *true* value for predicates, or a larger value for number-valued features), and how the feature's value is related to a case's underlying facts. For example, in the trade secret domain, one such feature is *Generally-Known*, indicating that the alleged secret information is generally known within the industry. When a new case is presented to HYPO, the features applicable to the new case are computed. Then, HYPO constructs a 'claim lattice'—a similarity network that has the new case as its root node, and prior cases that share a maximal set of feature-values with the new case as its immediate successors. These immediate successors are taken to be the *most-on-point cases*.

Later research extended the use of HYPO-style CBR in several ways. In the GREBE system (Branting 1991), a representation of the *ratio decidendi* (the rationale or justification) of cases was used to identify portions of a prior case's holdings that were relevant to a new case, even when other portions of the prior case were not on-point. Branting's model addressed a well-known weakness of the pure feature-based approach to CBR: its failure to represent the reasoning that connects the features with the results of a case. The logic underlying a legal decision is implicitly encoded in GREBE by grouping the features of a precedent according to the holdings they influence. Berman and Hafner (1993) addressed another aspect of legal CBR: the need for legal reasoning models to include the societal goals and policies that motivate legal rules and decisions. They proposed an extended representation of cases which incorporates knowledge about legal purposes.

Several researchers have developed models of legal reasoning in which rules and cases are used in combination. Gardner (1987) used a logic tree to model the top-down, rule-based analysis of a legal situation. At the leaves of the tree are undefined concepts, linked to cases providing positive and negative examples. In the CABARET system, Skalak and Rissland (1991) described a mixed strategy for legal argumentation using both rules and cases. When a rule-based strategy produces a result favoring the opposing side, CABARET uses precedents to support argument moves such as the broadening of a rule's interpretation or the discrediting of a rule.

3. Models of Legal Argumentation

Argumentation is considered by many law teachers and legal scholars to be the quintessential element of a lawyer's cognitive skill. Thus, many models of legal argumentation have been developed, falling into three broad categories: case-based, logic-based, and legal discourse models.

Case-based models of legal argumentation focus on the process of arguing with precedents, using techniques such as analogizing, distinguishing, and trumping. A case-based model of legal argumentation was developed as part of the HYPO system described above. In HYPO, after the claim lattice is created to determine the most-on-point precedents, HYPO constructs a three-ply argument for the new case. Letting Side 1 represent the party on whose behalf HYPO is arguing, first a *Point for Side 1* is produced making a claim that Side 1 should win, next a *Response for Side 2* is produced, countering the claim, and then a *Rebuttal for Side 1* is produced to answer the response. To create the initial point for Side 1, HYPO identifies the most on point case whose result favored Side 1, and makes an argument by analogy, noting the similarity between the new case and the prior case. Responses and rebuttals use the legal argument techniques of *distinguishing* by focusing on differences rather than similarities, and *trumping* by presenting more on-point counterexamples (Ashley 1990, p. 71).

Logic-based models of legal argumentation begin by expressing arguments as formal proofs within a system of logic, and then focus on the common situation in law where two logical arguments exist which reach contradictory results. In order to resolve such contradictions, it is necessary to adopt a framework of defeasible logic (Reiter 1980), where rules may have exceptions, and beliefs may be defeated by the acquisition of new, conflicting knowledge. For example, a legal rule 'No vehicles are permitted in the park' may co-exist with another legal rule 'Emergency vehicles are permitted to violate traffic laws.' Two logical arguments can then be constructed regarding an ambulance that entered the park: one concluding that the ambulance violated the law, the other concluding that the ambulance acted legally.

A logical argumentation framework is described in Prakken (1993), where two conflicting arguments, represented as formal proofs, can be compared using one or more ordering principles applied to the legal premises of the two arguments. (Traditional ordering principles found in legal texts include *Lex Superior* (e.g., federal laws trump state laws), *Lex Specialis* (more specific laws trump more general laws), and *Lex posterior* (newer laws trump older laws); however, Prakken's framework allows for any criterion whatsoever that can prefer one argument to another.) Given a set of ordering principles, Prakken's framework classifies legal arguments into three categories: justified arguments (which cannot be defeated), defeated arguments, and defensible arguments (which are neither justified nor defeated).

Legal discourse models are concerned with the structural and semantic characteristics that give a legal argument legitimacy. A number of argumentation models have been developed based on Toulmin's

(1958) theory of justified arguments. In Toulmin's theory, an argument's conclusion is called the *claim*; the *grounds* are the facts asserted to support the claim; the *warrant* is a bridge-like statement (e.g., a legal rule) that provides the logical connection between the grounds and the claim; and the *backing* is the authority for the warrant (e.g., a statute or regulation).

Loui and Norman (1995) have developed a discourse-based model of legal argumentation that focuses on defining categories of rationales (i.e., warrants) used in adversarial legal arguments, and the forms of attack appropriate for each. They identify several types of legal rationales: for example, the *compression* rationale justifies a simple and general rule as a normal-case simplification of a more complex and specific one. An example of a compression rationale described by Loui and Norman (p. 161) is the rule 'vehicles are not allowed in the park,' which (one might argue) is a normal-case simplification of the more complex rule: 'vehicles used for private transportation are not allowed in the park,' since normally vehicles are used for private transportation. A straightforward strategy for attacking the 'no-vehicles' rule (as in the case of the Memorial Day tank display) is to restate the rule in its uncompressed form, and argue that the case at hand falls outside the normal category of private transportation.

4. Conclusions and Future Directions

The field of law offers a fertile domain for the study of important problems in artificial intelligence and cognitive modeling, such as using prior experiences to solve new problems, reasoning with open-textured concepts, and making persuasive arguments. Promising new directions for research include the development of formal legal ontologies and their use in knowledge-based systems (Visser and Bench-Capon 1998) and the use of explicit legal concepts and models (such as contracts) to govern the behavior of systems for electronic commerce.

Legal Scholarship

Legal scholarship can be distinguished from scholarship about law, such as the history of law or the sociology of law, by virtue of its internal perspective (Dworkin 1986, Hart 1961). This means that it treats law as a set of norms that can be analyzed according to their internal coherence and moral significance, rather than as one component of a social system whose contours and content are determined by the same forces that affect other aspects of the society. Within the boundaries of this internal approach, there has traditionally been a division between jurisprudence, which concerns the theory of law, and doctrinal studies, which concern specific legal provisions. In recent years, however, both the distinction between internal and external perspectives, and between jurisprudence and doctrinal studies, have been significantly eroded by intellectual developments such as law and economics, critical legal studies, critical race theory,

feminist legal theory, gay legal studies and sociolegal studies. These developments have deployed the methodologies of other disciplines in the analysis of the internal structure and moral significance of law. At the same time, they have made the study of particular legal doctrines more theoretical and rendered legal theory less unified and more subject-specific. While the distinctions between legal scholarship and scholarship about law, and between jurisprudence and doctrinal studies, remain useful, they now refer to bodies of scholarship with generalized family resemblances, rather than distinct methodologies with clearly-defined boundaries.

1. *Jurisprudence and Doctrinal Studies Between 1900 and 1970*

1.1 *The Attack on Formalism*

In the early years of the twentieth century, doctrinal studies in both the continental and Anglo-American worlds were dominated by an approach that can be described as legal formalism, or conceptualism (see *Legal Formalism*). Its essential premise was that the law is an autonomous system, based on general principles, that is accessible to reason and that enables judges to reach uniform and definitive decisions in contested cases (Schauer 1988). Formalism did not necessarily advance the natural law idea that this system represented transcendental truth (see *Natural Law*), but it did claim that law was animated by general principles of justice that transcended particular political or policy positions. In continental Europe, the source of this autonomous system was regarded as each nation's legal code; in Great Britain and the United States, it was the common law. By virtue of the claim that law is autonomous, and the rather close focus on judicial decisions, both versions of formalism were somewhat insulated from major jurisprudential movements such as Marxism (see *Marxism and Law*) and sociological jurisprudence.

The attack on formalism came from two sources. The first, generally described as legal realism, asserted that judicial decisions and legal concepts are indeterminate or contextual, that they are the product of social attitudes, rather than reasoned analysis, and that they are subordinated to the political process, rather than transcending it (see *Legal Realism*). American legal realism emphasized the indeterminacy of judicial decisions and their dependence upon the particular views of the judge. Continental realism, which was centered in Scandinavia, emphasized the contextual nature of legal concepts and their dependence upon more general social attitudes. The second source of the attack was sociological jurisprudence, which often did not attack formalism *per se*, but rather attempted to develop an alternative conception of law as determined by, and contributing to, more general social forces (Ehrlich 1975). This was connected with the work of anthropologists and sociologists who treated law as an aspect of social systems, particularly those without formal legal institutions. A number of leading American realists saw the sociological approach as an alternative to doctrine, and a few tried to study legal behavior as a sociological phenomenon (see Schlegel 1995).

Apart from this sociological approach, the dominant theme in early twentieth-century jurisprudence was legal positivism (see *Legal Positivism*). According to Kelsen, law is simply the set of threats promulgated by public officials whose authority is established by a single, agreed upon principle, or *Grundnorm* (Kelsen 1967) As such, it is completely separate from morality; a particular normative statement is a law if, and only if, it has been duly promulgated by a recognized public official, or by a private party who has been delegated to act by such a recognized official. Legal positivism was motivated partially by larger philosophic trends (such as logical positivism) and partially by the effort to refute natural law jurisprudence. While its connection with doctrinal studies is not immediately self evident, it seems consistent with American realists' rejection of general common law, that is, the idea that legal rules can be derived from general principles and need not correspond to the decisional law of any specific jurisdiction, and with the Scandinavian realists' insistence that there are no overarching legal concepts, but only concepts specific to particular societies.

1.2 *The Rehabilitation of Law*

The years following World War II saw renewed interest in the concept of law in both jurisprudence and doctrinal studies. In jurisprudence, scholars began searching for a way to re-infuse some sense of social morality into the term law, so that one would not be required to apply that term to the rules promulgated by a generally immoral regime such as Nazi Germany. This led to a revival of natural law (Finnis 1980), but the appeal of this work was limited by its continuing religious overtones (see *Natural Law*). More influential was Fuller's effort to articulate a purely procedural version of natural law (Fuller 1964), which asserted that any declarations that we would be willing to regard as law must have certain universal characteristics such as generality, constancy, and nonretroactivity. Still more influential was Hart's recharacterization of legal positivism in light of Wittgenstein's linguistic theory (Hart 1961). Law, in Hart's view, is a complex set of social rules that not only states the sanctions that public officials will impose, but also the manner in which: (a) they impose these sanctions; (b) new sanctions are developed; (c) private parties are empowered to take actions that will be enforced by public authorities; and (d) the authorities who carry out these various functions are identified.

Doctrinal scholarship rejected legal realism more definitively than jurisprudence rejected legal positivism. In the United States, the legal process school conceded that the legal system was subordinate to politics, thus acknowledging positivism's essential claim, but insisted that the concept of law retained an important role within this more limited sphere of action. Fuller argued that reasoned decision making according to rules established in advance is the best way to adjudicate disputes between parties, although a poor way to formulate new social policy (Fuller 1978). Other members of this school explored the rationales by which the courts could use the US Constitution to evaluate, and, if necessary, strike down legislation, without substituting its political judgment for that of the legislature (Bickel 1962, Wechsler 1959). Central to this inquiry was the belief that doctrine possessed an inherent logic or coherence, so that judges could reach generally accepted conclusions by means of reasoned argument. Implicit in this belief was that public officials, particularly judges, generally acted in the public interest, and that their decisions harmed social welfare only when they strayed beyond the limits of their institutional competence.

In Europe, theories of judicial decision making focused on statutory interpretation, which generally (although not in Britain) meant the interpretation of a comprehensive civil or criminal code. Many scholars asserted, or assumed, that judges could reach generally accepted conclusions by means of reasoned argument if they followed and extrapolated the inherent logic of the code (MacCormick and Summers 1991). As in the case of the American legal process school, this work was premised on the idea that doctrine was coherent within a politically defined area of proper operation. Because it concerned interpretation of a legal code, rather than common law or a vaguely worded constitution, it was more closely allied to legal positivism than its American equivalent. Both the American and European versions of this postwar approach were sufficiently focused upon law's internal rules to minimize the influence of social science studies of law.

2. *The Critique of Law, 1970 to 1985*

2.1 *Law and Economics*

The attack on this rehabilitated concept of law was initiated primarily in the United States, and came from two sources that were associated with opposite ends of the American political spectrum. The first was the Law and Economics Movement, which was derived from the Chicago School of microeconomics and shared its basic premise that all social action is a rational effort to maximize the actor's material self-interest (see *Law and Economics*). According to this analysis, legislators are motivated solely by their desire to be re-elected (assuming that effective sanctions exist against outright bribery); thus, the laws they produce have no inherent logic, and no necessary relation to the public interest. While these laws might correspond to the preferences of voting citizens, they are more likely to reflect the distorting influence of special interest groups that can organize and fundraise more effectively than the general public (Olson 1965). A judge who is interpreting such laws cannot be guided by their internal logic; all she can do is enforce the bargain that the interest groups reached, or interpret the law narrowly in deference to public values (Easterbrook 1983, Macey 1986). Posner originally asserted that the common law, as opposed to statutory law, represented a coherent body of doctrine that implemented the social policy of efficiency (Posner 1972). Other law and economics writers soon abandoned this implausible contention and devoted their efforts to analyzing the self-interested motivations that lead private parties to engage in or to avoid litigation, and that lead lawyers to encourage or discourage them from doing so, to settle cases, or to adopt specific trial strategies (Priest and Klein 1984). This work suggests that common law, like statutory law, lacks any conceptual coherence, and is merely the product of economic forces.

In addition to its analysis of doctrine, the Law and Economics Movement advances the jurisprudential position that the only proper purpose of law, or of government in general, is to achieve economic efficiency, that is, to maximize the nation's wealth (Posner 1972). When combined with the economic analysis of law, this leads to the conclusion that regulatory law is generally undesirable, and that the social control of economic relations should be left to the market. The argument seems more political than legal, in that it addresses the purpose of law rather than its nature, and it is clearly related to the conservative politics of most of the early law and economics scholars. But it also represents a theory of law, in that it advances a general rule that identifies improper laws and improper roles for legal actors.

2.2 *Critical Legal Studies*

The Critical Legal Studies Movement was derived, albeit rather loosely, from the critical theory of the Frankfurt School. It revives the realist claim that law, both statutory and decisional, is not an internally coherent system but a collection of unrelated rules. Unlike legal realism, however, critical legal studies asserts that the reason for this lack of coherence is that law is a device by which the political elite maintains its hegemony, or social control (Horwitz 1977, Unger 1975). It is a particularly effective device, moreover, because the widely-accepted claim that law is coherent or logical masks its class-oriented character; in effect, it creates a false consciousness among the disadvantaged that leads them to accept their subordinated status (see *Critical Legal Studies*). By means of doctrinal analysis, critical legal studies scholars seek

to disprove the claim that legal decisions are logical or coherent, and thereby to reveal the hegemonic purposes of these decisions. In undertaking this analysis, they went beyond the legal realists' demonstration of the internal inconsistencies of doctrine, invoking various aspects of continental thought such as deconstruction and postmodernism to demonstrate that any claim to linguistic coherence is essentially fraudulent.

This analysis of doctrine is linked to the jurisprudential position that the social dominance of the elite, and its use of law to secure its position, is profoundly immoral. A just society achieves equality among its members—if not complete equality, then certainly a much higher degree of equality than contemporary society displays. Thus, modern society needs to be emancipated from its existing social structures and from ideologies, including law, that maintain those structures and preach the legitimacy of those structures to the disadvantaged. Again, this is essentially a political argument, with an obvious connection to the progressive or radical politics of critical legal studies scholars. But again, it constitutes a general theory of law by distinguishing between the improper, hegemonic purposes of law and its proper, emancipatory purposes.

Despite their obvious differences in political orientation, law and economics and critical legal studies rest on closely related insights, and exercise similar impacts on the character of legal scholarship. Both movements renew the realist attack on law's doctrinal coherence, and go beyond realism by grounding this attack on a political analysis. In both cases, moreover, that analysis asserts that law is produced by political and economic elites for the purposes of securing their positions. By thus attributing the incoherence of doctrine to political causes, both law and economics and critical legal studies join doctrinal analysis to larger jurisprudential questions in a manner that was not true for legal formalism, legal realism, or the legal process school. The two movements are further allied in their heavy dependence upon nonlegal methodologies. For the first time, two large groups of legal scholars were prepared to abandon the idea that law is an autonomous or quasi-autonomous system that provides its own analytic tools, and look to other disciplines for the main elements of their analytic framework.

3. *The Topography of Legal Scholarship at the Beginning of the Twenty-first Century*

3.1 *Late Twentieth-century Law and Economics*

Law and economics remains a robust tradition within legal scholarship, and much work continues to be done according to the Chicago School model that assumes rational, self-interested actors and smoothly functioning markets. But the criticisms of this approach by legal scholars, combined with the internal evolution of the field, have led to an increasing body of post-Chicago Law and Economics scholarship. One theme of this work, reflecting developments in economics itself (Williamson 1985), is that institutional arrangements exercise powerful effects in structuring behavior. Since legal actors generally function in an institutional context, this has proven to be a productive line of inquiry. Positive political theory, which treats institutions themselves as rational actors, has also been utilized in current legal scholarship to take institutional factors into account (Eskridge and Frickey 1994, Georgetown Law Journal 1992). A second, and related, theme is that internalized norms exercise powerful effects that conflict with the self-interest, or at least the immediate self-interest, of the actor. Some scholars argue that legal rules can be regarded as internalized norms that reflect varying degrees of long-term rational self-interest (University of Pennsylvania Law Review 1996); others assert that particular communities, such as merchants in a given trade (Bernstein 1996), or farmers in a given area (Ellickson 1991), engage in heavily norm-determined behavior that strongly affects the impact of official law on these communities. The combined effect of focusing on institutions and on norms has been to modify, without eliminating, the external perspective that law and economics generally adopts. Law is not being treated as presumptively coherent, but its internal structure is being given a role that followers of the Chicago School tend to deny.

Still another influence on law and economics has been the attack on human rationality by cognitive psychologists (Kahneman et al. 1982). This work, which is heavily empirical, has revealed that people, at least in laboratory settings, are irrationally optimistic, irrationally attached to the status quo, or irrationally influenced by the way that choices are presented. Legal scholars have applied these results to a variety of settings, such as jury decisions, contracting behavior, and policy making, and have also begun conducting their own empirical research to study behavior that is relevant to specific legal situations (Jolls et al. 1998, Vanderbilt Law Review 1998). Thus, the effort to develop an account of human behavior that is more realistic and more modulated that the rational actor model of law and economics has lead to the extensive incorporation of a second discipline, psychology, into legal scholarship.

3.2 *Outsider Scholarship*

Critical legal studies has been succeeded by a series of movements that tend to refer to themselves as Outsider Scholarship. They include critical race theory, feminist theory, and gay legal studies (see *Critical Race Theory*; *Feminist Legal Theory*; *Sexual Orientation and the Law*). While it cannot be said that critical legal studies itself is entirely moribund, its role within the academy

has been largely replaced by these latter movements, which share its critical approach but contest its particular conclusions. Outsider scholarship, like critical legal studies, asserts that law is an instrumentality of hierarchy and social domination, but it rejects economic class analysis as an explanation for this phenomenon. Instead, it argues that more specific prejudices are involved, namely, the prejudice of the racial majority against minorities like African-Americans, Latinos, and Native Americans, the prejudice of men against women, and the prejudices of heterosexuals against gays and lesbians (Bell 1987, MacKinnon 1989, Eskridge 1994).

One result of this approach is to create a critical scholarship with a more direct connection to American politics; while class has never been a salient political issue in the United States, race, gender, and sexual orientation are all subjects of active political movements. Another, and not unrelated result, has been to decrease the breadth of the critical attack on law. Critical legal studies tends to regard law in its entirety as an oppressive device that hides its true effect behind a facade of objectivity. Outsider scholarship, because it concerns social phenomena that are less comprehensive than class, views law as oppressive because it has denied outsiders the benefits it grants to the dominant group. Its prescription, therefore, is not to abandon or even transform law, but to provide law's benefits to the outsiders, fulfilling the promise that it has thus far denied.

The effect of this outsider scholarship is thus to modify the external perspective of its predecessor. Law is still viewed with suspicion, but its role as a system with internal values is affirmed. For example, instead of arguing that rights are illusory, or an impediment to genuine equality because they can only be validated through litigation, outsider scholarship tends to argue that the disadvantaged cannot afford to wait for such comprehensive transformations, but should use the concept of rights to achieve a more limited but more accessible equality within the existing system (Williams 1991).

Outsider scholarship shares the critical legal studies view that legal concepts are social constructions that serve specific purposes, often those of dominant elites, and that these concepts are radically indeterminate. But it has not relied as heavily on the indeterminacy argument. As many scholars have pointed out, the argument is itself too indeterminate, since it lacks the criteria to judge how determinate the law could be, and how much determinacy is desirable (Kress 1989). In addition, most legal scholars recognize that the indeterminacy argument does not necessarily lead to the political conclusions that critical legal studies advanced. Thus, outsider scholarship analyzes legal rules in fairly traditional terms. Its methodological innovation has been its extensive use of narrative, or story telling, as a means of communicating the personal experience of oppression that racial minorities, women, or gays and lesbians have experienced (e.g., Bell 1987, Eskridge 1994). While this has a literary quality (when done well, at least), it is not related to literary criticism or to the methodology of any other discipline. Rather, it is a technique that is intended to appeal to the values of the reader within the framework of legal scholarship and the legal system.

3.3 Standard Legal Scholarship

Throughout the period when law and economics and critical legal studies were articulating their critique of law and of the legal process school, standard legal scholarship continued to be written. At that time, and at present, it constituted the largest proportion of the legal scholarship being produced. It is standard because of its quantity, but also because it is not explicitly identified with any particular school of thought or methodology. In fact, this scholarship can be loosely regarded as a continuation of the legal process school. Like legal process, it acknowledges that law is subordinate to politics, but treats legal rules as a body of doctrine that has enough coherence to generate analytic standards. In addition, it shares the legal process view that the participants in the legal system, particularly judges, but also legislators and administrators, are public-oriented enough so that scholarly prescriptions for improving their decisions can be addressed to them (e.g., Choper 1980, Dworkin 1986, Ely 1980). The standard scholarship that is currently being produced differs from its predecessors because it has at least partially absorbed the lessons of both law and economics and critical legal studies, although without accepting their critique of law's legitimacy (Rubin 1996).

Most legal scholars now acknowledge that viewing legal actors as public-oriented is problematic. They recognize that these actors are sometimes motivated by their material self-interest, and sometimes intent on preserving existing hierarchies and class relations. Thus, they do not see the legal system as a realm of reasoned, public-oriented decision making that transcends politics, as legal formalism did, nor as a realm of reasoned, public-oriented decision making that is circumscribed by politics but insulated from it, as legal process did. Rather, politics both sets the limits of the legal system and intercalates itself into particular legal decisions. But standard scholarship rejects the notion that decision makers are motivated by any uniform value system, whether it is self-interest, prejudice or public orientation; the prevailing attitude seems to be that some degree of conscientiousness can be assumed, but that the actual motivations must be sorted out in particular situations.

Methodologically, standard scholarship has assimilated the idea that law is not a quasi-autonomous system that provides its own analytic tools. Scholars

regularly rely on informal law and economics or public choice insights in analyzing the behavior of public officials, and, to a lesser extent, on the insights of critical theory. More importantly, these scholars regularly incorporate data from other fields, such as political science, sociology, economics, and psychology, in framing recommendations. The criterion for stating that a particular legal decision, whether by a judge, legislator, or administrator, is incorrect, or could be improved, is less likely to be the internal coherence of legal doctrine, and more likely to be some judgment about social welfare. Such judgments will frequently involve empirical information generated by another discipline and will almost always acknowledge, implicitly if not explicitly, that such information is relevant to the conclusion.

3.4 Contemporary Sociolegal Studies and Legal Knowledge

These developments in law and economics, outsider scholarship, and standard legal scholarship represent a process, extending over the entire course of the twentieth century, by which the distinctions between internal and external scholarship, and between jurisprudence and doctrinal studies, have been partially effaced. This process has important implications for the prevailing conception of legal knowledge, implications which can be illustrated by considering a fourth aspect of contemporary scholarship, namely, sociolegal studies.

The sociology of law, as developed by nineteenth-century scholars such as Maine and Savigny, was originally a jurisprudential position, articulated in opposition to the universalist claims of both natural law and the Napoleonic Code. Its basic insight was that law is the product of particular cultures. With the growth of academic sociology and anthropology, this became translated into detailed studies of legal behavior that were more specific, but also more external to the legal system that they studied. Rather than focusing on the internal coherence of the system, or the experience of its participants, sociolegal work treated law as a phenomenon to be determined by examining the behavior of relevant actors. Legal scholars typically ignored such studies because they regarded law as a self-contained, meaningful system that generated its own criteria of analysis.

In response to the attack on the entire concept of law by law and economics and critical legal studies, most legal scholars now recognize that law possesses only a provisional coherence. Its value is no longer determined by its internal logic, but by its ability to achieve political and social goals. For most scholars, however, law is not simply a set of unrelated provisions that achieve these goals, but a system with both institutional and conceptual features. To have legal knowledge, one must be familiar with the features of this system; to use this knowledge, one must make predictions, or prescriptions, about the way this system achieves independently determined goals. Thus, data from fields such as economics, sociology, political science, anthropology, and psychology becomes directly relevant to legal scholarship. Some of this data comes from work that is not specifically concerned with law, such as organization theory or cognitive psychology, but a good deal comes from modern sociolegal studies, where law is the social scientist's explicit concern. But this work, however useful, does not displace legal scholarship. The legal scholar still has a crucial role in determining how such data will be used by the institutional and conceptual elements of the legal system. In fact, legal scholars have recently begun to re-emphasize these conceptual elements, arguing that, within a richly described social context, law possesses a wide range of symbolic and constitutive roles (Habermas 1996, Lessig 1995, Luhmann 1995) (see *Law, Autopoiesis in*; *Law as Constitutive*). Sociolegal scholars have come to recognize this as an empirical fact, and have thus taken advantage of legal scholarship's greater receptivity to social science data by engaging more fully with the internal features of the legal system. The result is a partial effacement of the distinction between external and internal scholarship, without its complete elimination.

The challenge to the concept of law, the multiplicity of responses, and the greater methodological range of the resulting scholarship has also partially effaced the distinction between jurisprudence and doctrinal studies. Basic questions about the nature and purpose of law, and the nature of legal knowledge, must now be resolved by scholars engaged in detailed doctrinal analysis. Such questions can be ignored, of course, in the interest of simplicity, but the work will be open to challenge by those who question its basic premises. Again, the distinction has not been entirely eliminated; as a practical matter, many scholars content themselves with an analysis of doctrine within one or another subdisciplines of legal scholarship, and let others fight the more theoretical battles on their behalf. But most recognize that the status of their work as legal knowledge depends on theoretical arguments in a more immediate way than was true a century before.

These developments can be illustrated by considering some of the principal topics of modern sociolegal studies. One notable social science approach to judicial decision making in the early postwar era were the judicial attitude studies that treated court decisions as a pure reflection of the judge's ideology, uninfluenced by legal doctrine (Schubert 1959, Ulmer 1960). While work of this sort continues to be produced, often by the same authors, more recent social science studies of judicial decisions tend to emphasize the interplay between ideology and doctrine (Perry 1991, Shapiro 1981), a process which enables legal scholars to utilize

their findings and extend them into jurisprudential areas (Feeley and Rubin 1999, Kennedy 1997, Tamanaha 1997). A second distinctive strand during the early postwar period emphasized the discontinuity between the law on the books and the law in action. Modern sociolegal studies often recharacterize this issue in terms of the implementation process, which involves an analysis of the interplay between statutory or regulatory language and the realities of administrative enforcement (Bardach and Kagan 1982, Coglianese 1997). Once again, such an approach yields jurisprudential implications more readily than its predecessor, since it replaces an inevitable abyss between written and practiced law with a dynamic interchange where the practice suggests a reconsideration of the legal structure (Ayres and Braithwaite 1992, Kagan 2000).

A related development is the sociolegal analysis of contracts. The seminal work in the field emphasized that contract law, as reflected in the decided cases that were the exclusive focus of most law school courses, did not exercise the dominant effect on contractual practices; rather, the relationship between the parties and their underlying cultural understandings were the primary determinants (Macaulay 1963, MacNeil 1980). Building on this insight, and incorporating the lessons of contemporary law and economics, legal scholars have been able to analyze the practical operation and effect of specific contractual terms (Gilson 1984, Hadfield 1990). In effect, modern sociolegal scholars are now engaging with the specific contractual language, just as they are engaging with the internal aspects of legal doctrine and statutory provisions.

Legal Systems, Classification of

'Law' and 'legal systems' as concepts are closely related. Since there have been innumerable definitions of law, ideas about legal systems have been similarly diverse. A system involves regular interactions among elements that together make up an entity with boundaries. Thus, lawyers, judges, legislators, administrators, the police, and legal scholars all work with rules in regularized ways that involve cultural expectations about their roles and the legal institutions with which they interact. In this view a legal system is greater than the rules themselves (Merryman et al. 1994). But a legal system may also refer to only the rules of a tribe, city, nation, or the international order, or to the natural rules for humankind itself. The question of classification then consists of looking for similarities and differences among the relevant legal systems.

1. *The History of Legal System Classifications*

The task of classifying legal systems has been tied to the development of comparative law as a practical and scholarly discipline. More recently, the differentiation of the behavioral and social sciences into discrete subjects has added diverse perspectives on the nature of law and legal systems.

1.1 *Classical Classifications*

Classical Greeks made the earliest recorded efforts explicitly classifying legal systems as a result of their philosophical speculation based on the comparative study of law. For instance, Plato (429–348 BC) in his *Laws* discussed the rules of several Greek and other *poleis* in formulating his ideal code and legal institutions for Magnesia. Aristotle (384–322 BC) examined many legal structures in his *Politics* before settling on the three preferred categories of kingship, aristocracy, and constitutional government (*politeia*) with their deviant siblings tyranny, oligarchy, and democracy.

In Rome, jurists' interest in foreign law was more practical, particularly with the creation of the office of *praetor peregrinus* in 242 BC. This praetor supervised jurisdiction over disputes involving non-Romans. It was here that the mixture of a less formalistic Roman *ius civile*, Greek law, and other foreign legal norms led to an internationalized *ius gentium*. Roman jurists did not have a philosophical interest in studying and classifying foreign legal systems, since they believed in the superiority of their own law. An exception that makes the point was the fourth-century *Collatio legum Mosaicarum et Romanarum*, in which excerpts from Roman jurists were paired with the laws of Moses to improve the stature of Christianity (Zweigert and Kötz 1996, p. 48).

1.2 *Early Modern Classifications*

In the early modern era some natural law jurists such as Hugo Grotius (1583–1645), Samuel Pufendorf (1632–1694), and Baron Charles Louis de Montesquieu (1689–1755) used the comparative law method to provide empirical backing for natural law principles. Others such as William Blackstone (1723–1780) had the additional objective of providing prestige for their national law: Blackstone's four-volume *Commentaries on the Laws of England* (1765–1769) (Blackstone 2001) emphasized the similarities in English common law, Roman law, and natural law.

Montesquieu's extensive speculation about the relation of law to natural and social forces and explicit classification of legal systems emphasized the distinct

manners (*moeurs*) of a particular people in a particular era. His *Lettres Persanes* (1721) (Montesquieu 1964), published anonymously, used the device of two Persians traveling in Europe who satirized the customs of French and European society. They pointed to the abuses and cruelties of criminal justice systems and argued for a rational theory of punishment adjusted to the settled sensibilities of the people. Letter 80 could have been written to critique the turn-of-the-millennium criminal sentencing and prison policy of the USA:

> [O]bedience to the laws of a state does not correspond with the greater or lesser degrees of cruelty in punishment. In countries where penalties are moderate, they are as much feared as those in which they are tyrannical and dreadful … . Our imagination adapts itself to the customs of the country in which we live (Montesquieu 1964, p. 136).

Montesquieu's relativist view of humans' ability to achieve justice was further developed in *De l'esprit des lois* (1748) (Montesquieu 1989), which drew upon causative factors such as climate, soil, population size, a people's morals and customs, religion, and commerce. He classified governments along with the appropriate principle for their constitutive societies. Thus democracy required civic virtue; aristocracy, moderation against the people; monarchy, honor for the law and intermediate institutions; and despotism, fear to maintain order. He found different mechanisms for lawmaking and adjudication in the first three types of legal system, but pointed out that law was not necessary for despotism.

1.3 Nineteenth- and Twentieth-century Classifications

This set the stage for much more elaborate classifications of local and national legal systems beginning with nineteenth-century evolutionary theorists. Law in these schemes was part of the larger social system that changed over time. For instance, Sir Henry Maine (1822–1888), interested in the striking parallels between the development of English common law and classical Roman law, posited in *Ancient Law* (1861) (Maine 1977) stages of social development common to different peoples that could be correlated with particular instruments of legal growth. Legal systems could be characterized by whether social change was primarily dealt with by legal fictions, equity or natural law, or conscious creative legislation.

Max Weber (1864–1920) (Weber 1968) used many of the same historical sources as legal evolutionists, but in *Wirtschaft und Gesellschaft* (1922) constructed ideal types to facilitate the comparison of actual social and legal systems in trying to explain the rise of industrial capitalism. His four-cell typology for lawmaking and law application considered the rationality or irrationality of legal thought, as well as whether the legal norms and decision making were highly differentiated from religion, ideology, or emotion. He argued that the category of formal (autonomous) rationality with a consistent body of general legal norms provided the predictability facilitating modern capitalism.

In an effort to make US lawyers and political scientists less parochial, John Henry Wigmore in 1928 published the three volume *A Panorama of the World's Legal Systems* (Wigmore 1928). He covered 16 historic and contemporary legal systems by the pictorial method, using between 20 and 50 pictures accompanied by text for each legal system to enliven its justice buildings, principal legal actors, and characteristic legal materials. Organized historically, these systems included the Egyptian, Mesopotamian, Chinese, Hindu, Hebrew, Greek, maritime, Roman, Celtic, Germanic, canon, Japanese, Mohammedan (Islam), Slavic, Romanesque (civil law), and Anglican.

2. Legal System Classifications by Disciplines Related to Law

Drawing on these earlier studies and with a common concern for the relationship between law and society, anthropologists, sociologists, and political scientists generally believe that formal legal rules should be deemphasized when classifying legal systems.

2.1 Legal Anthropology

Anthropologists have also observed that some societies operate without government but nevertheless have social order and law-like institutions. In modern nations there may be distinct societies, so that it becomes appropriate to speak of legal pluralism. Classification of legal systems then depends on the characteristics of different societies or their subgroups. Leopold Pospíšil (1974, pp. 106–26), for example, described this situation as a patterned mosaic of subgroups that belong to certain identifiable types with different memberships. Each subgroup owes its existence to a legal system that regulates the behavior of its members. These legal systems then form a hierarchy reflecting the degree of inclusiveness of the corresponding subgroups, and can be categorized by legal level such as the family, lineage, community, state, or nation. People are simultaneously members of several subgroups of different inclusiveness, which may lead to contradictory legal loyalties.

2.2 Legal Sociology

Lawrence Friedman (1977, pp. 78–86), a legal sociologist, argued that legal systems can be classified

according to their internal legal culture, which includes the attitudes and values of judges, lawyers, and other legal actors toward a task such as lawmaking or adjudication that relies on reasoning or some other basis of legitimacy. He considered two variables. First, when a legal system requires reasoning to be premised on legal propositions it is a closed system; when propositions may be nonlegal the system is open. Second, some systems regard legal propositions as fixed and timeless; others accept change as normal.

Using these two variables, Friedman derived four types of reasoning associated with law. First, some systems such as those based on sacred law are closed and reject the idea of change. What change does occur must be based on legal fictions. Second, a legal science system such as that in Germany is closed, but it permits change by simply adding legal rules or deriving new legal principles. Third, traditional or customary law systems do not accept explicit change but are open to new norms based on shifting behavioral patterns. Fourth, a system permitting change by looking outside the stock of legal propositions includes what Weber called substantive rationality. This could be revolutionary legality such as that in socialist Russia, or welfare legality that looks to ethical imperatives or utilitarian principles.

2.3 Political Science

The 1950s comparative politics revolution shifted that field from one that tended to emphasize public law and to describe the legal institutions of foreign governments to the explanation of political behavior in structural and functional terms. Gabriel Almond and Bingham Powell (1978), for instance, used the developmental variables of cultural secularization and structural differentiation, together with the low or high level of political subsystem autonomy associated with interest groups and political parties, to classify political systems. Modern systems could be premobilized, mobilizing, or penetrative, and within each of these categories either authoritarian or democratic.

3. Current Classifications in Comparative Law

A useful classification of legal systems should make the criteria of division clear and allow scholars to assimilate, simplify, and comprehend the great wealth of legal detail existing in individual systems. The dominant approach to classifying national legal systems in contemporary comparative law is to identify families, styles, or traditions. Beyond the aim of simplification, this idea could permit one to understand more clearly pluralistic legal systems with an official, dominant legal tradition, but including indigenous communities with their own law or communities lacking a sovereign political organization that use canon law, Muslim law, Hindu law, or Jewish law.

3.1 The Influence of René David

Comparative lawyers have disagreed about the criteria to use for classification but the results have been surprisingly similar, differing primarily in the number of categories emerging. René David, in *Traité élémentaire de droit civil comparé* (1950), used two criteria that were further refined in his 1964 *Les grands systèmes de droit contemporains* (David and Brierley 1985). He believed that the primary criterion should be the legal system's ideology, its 'philosophical, political or economic principles,' the 'social objectives to be achieved,' and 'the place of law itself within the social order.' A secondary criterion should be a system's legal technique, 'the law's conceptual structure or … the theory of sources of the law.' On the basis of these guides, David found three prominent legal families: Romano-Germanic, common law, and socialist law. Some elements from one or more of these families have influenced all national legal systems. In addition, there are lesser legal systems, such as those for religious law (Muslim and Hindu) and for East Asia and sub-Saharan Africa (David and Brierley 1985, pp. 20–31).

This typology controlled the organization of the *International Encyclopedia of Comparative Law*'s volume two (1984), entitled 'The Legal Systems of the World: Their Comparison and Unification,' of which René David was the chief editor (David 1984). The only variation from David's earlier formulation occurred in Chap. 1, where Romano-Germanic (civil) law and common law were combined into the Western conception of law (see Clark 1990).

3.2 Legal Traditions

David argued that it

> is a superficial and indeed false view to see law as being composed of the totality of [legal] rules … [T]he juridical phenomenon which they represent … constitutes a *system*: it has a vocabulary used to express concepts, its rules are arranged into categories, it has techniques for expressing rules and interpreting them, it is linked to a view of the social order itself which determines the way in which the law is applied and shapes the very function of law in that society (David and Brierley 1985, p. 19).

John Henry Merryman in 1969 proposed a similar idea of legal traditions, of which three were most influential in the modern world: civil law, common law, and socialist law:

> A legal tradition … is not a set of rules … . Rather it is a set of deeply rooted, historically conditioned attitudes about the nature of law, about the role of law in the society and the polity, about the proper organization and operation of a legal system, and about the way law is or should be made, applied, studied, perfected, and taught. The legal tradition relates the legal system to the culture of which it is a partial expression (Merryman 1985, pp. 1–2).

In teaching and research on comparative law in the USA, scholars have invoked considerations of geography, history, and legal culture as secondary criteria to legal traditions. This enlarges on the concentration on German and French examples by adding attention to Mediterranean European, Latin American, and East Asian legal systems (Merryman et al. 1994). Even at the end of the twentieth century David's tripartite division of families, including socialist law and other categories for East Asia and sub-Saharan Africa, still seemed to hold substantial validity for some research topics, such as the role and importance of the legal profession in society (Clark 1999).

3.3 Legal Styles

About the time of David's revised formulation of legal families Konrad Zweigert (1961) wrote about his theory of *Rechtskreisen*. It looked at the styles (*Stile*) of legal systems to divide them into legal spheres or families. He critiqued earlier attempts at classification as too one-dimensional, turning primarily on one criterion. Zweigert, as updated by Hein Kötz, found five factors to be crucial to classify the style of a legal system or family: (a) historical background and development; (b) predominant mode of legal thought; (c) distinctive legal doctrine or institutions; (d) sources of law; and (e) ideology. Using these factors, Zweigert and Kötz settled on eight categories: Romanistic family, Germanic family, Nordic family, common law family, Peoples Republic of China (replacing the earlier socialist family), Japan, Islamic law, and Hindu law (Zweigert and Kötz 1996, pp. 62–73).

3.4 Critique of Current Classifications

There are a number of problems with these classification schemes, which their proponents often recognize. First, a classification is intended for a specific purpose, which may make it unsuitable for another purpose. Thus Zweigert and Kötz intended their divisions to serve as chapters in their comparative law treatise for students and jurists. An African legal family was omitted because it is still in the process of emerging (1996, pp. 65–6).

In addition, almost all comparative law classifications are based on a private law emphasis, which weakens their utility for public law comparisons. For instance, a study of the judicial review of legislation as an aspect of constitutionalism could put England and France in one category, but Germany and the USA in another, confounding the civil law–common law dichotomy. Mirjan Damaška (1986) rejected the usual classification of legal families in his comparative study of procedure and the administration of justice. He formed a Weberian four-cell model that considered the structure of state authority on one axis (hierarchy or coordinate) and the type of proceeding on the other (conflict solving or policy implementing). Illustrations include the active judge in continental European civil procedure in the conflict-solving hierarchy cell, English and USA's civil and criminal procedure in the conflict-solving coordinate cell, Soviet civil and criminal procedure in the policy-implementing hierarchy cell, and USA's public interest litigation in the policy-implementing coordinate cell.

Second, no matter how logical a classification, there will always be hybrid legal systems that do not fit easily within one category or another. Well-known hybrids in legal family classifications include, for example, Scotland, Louisiana, Puerto Rico, Québec, Israel, South Africa, Sri Lanka, and the Philippines that share civil law and common law elements; the People's Republic of China with East Asian and socialist elements; India with Hindu and Islamic law for family and inheritance matters but common law for obligations and commercial issues; and Arabian countries with Islamic law for family and inheritance issues but French-influenced law for the commercial sector (Schlesinger et al. 1998, pp. 291–304, Zweigert and Kötz 1996, pp. 64, 72–3).

Third, related to the problem of hybrid systems is the situation of legal pluralism, associated with the personality principle for choice of law, where an official, dominant legal tradition coexists with an indigenous or religious community that de facto regulates itself according to its own norms (Merryman et al. 1994, pp. 656–703).

Fourth, Ugo Mattei (1997) suggested a new tripartite classification to reduce the Eurocentricism of earlier approaches. His families depend on the dominant pattern of legal decision-making in a system, which can be characterized as professional law, political law, or traditional law. In the professional law family (including west European civil law nations and the common law United Kingdom, Oceania, United States, and Canada), the idea of law autonomous from politics and religion predominates. The political law family includes ex-socialist and developing countries (eastern Europe, sub-Saharan Africa, and Latin America) in which the notion of autonomous law is not strong enough to prevent politics from supplanting legal rules for important legal decisions. Finally, the traditional law family consists of those legal systems that may have absorbed substantial elements from the civil law or common law (Asia and northern Africa), but in which the dominant culture controlling legal

decision-making is rooted in Confucianism, Hinduism, or Islam.

4. Convergence or Divergence of Legal Traditions

John Merryman et al. (1994, pp. 16–25) identified three strategies of convergence that could bring the civil law and common law traditions closer together. First, programs for the unification of law are gaining support. These include the Hague Conference on Private International Law, the International Institute for the Unification of Private Law (UNIDROIT), and the United Nations Commission on International Trade Law (UNCITRAL). Within Europe, working groups of jurists from both common law and civil law countries are drafting rules with the hope to return to a kind of Roman-canonic *jus commune*.

A second strategy is legal transplantation, which can follow military conquest or occur by conscious choice. Developing countries often select legal rules and institutions as evidence of modernization. Japan in the late nineteenth century provides an interesting example of explicit legal Europeanization. Countries interested in law reform may also look abroad for inspiration.

Third, the tendency for countries with similar social and economic conditions to develop similar legal systems is part of what may be called natural convergence. This similarity is encouraged by greater international communication, travel, and business. In response to the notion that focusing on convergence of the civil law and common law is too Eurocentric, one could respond that developing nations and East Asian countries have themselves been consciously involved in a process of convergence by supporting rules and institutions associated with either of these two worldwide legal traditions.

Although the beginning of the twenty-first century seems to be characterized by an overarching process of globalization in political, economic, and social life, there are in fact two opposing forces in international society. One is the universalizing force expressed in the increased importance of the United Nations, the World Trade Organization, and regional supranational legal systems such as the European Union and NAFTA.

Besides universalizing pressures there are particularizing forces within some nations that reflect elements of diversity such as religion, ethnicity, language, and social class. Everywhere there are movements for political decentralization, economic privatization, and social recognition that seem to complicate the legal universe. Examples include the Scottish and Welsh in the UK, the Basques and Catalans in Spain, the Kosovars in Yugoslavia, and the Québecois in Canada. Thus while it is true that the principal legal traditions are converging, they are also at the same time on some levels diverging.

Legal Systems: Private

Private legal systems are nonstate institutionalized means for obtaining compliance with the norms or rules of a social order. They comprise the numerous forms of social control that are part of group or organizational life, but that are not formally part of state law. They include, for example, the practices of disciplinary bodies, boards and councils of industrial organizations, the tribunals of professional or trade associations and labor unions, and the disciplinary committees of universities and colleges. They also include the peer sanctioning of relatively amorphous voluntary associations, such as self-help and mutual aid groups.

1. *Mechanisms of Control*

Private legal systems bring about conformity to the normative expectations of their collective setting through one of three mechanisms for administering either positive or negative sanctions: (a) coercion, being the threat or use of negative sanctions that reduces a person's social standing; (b) persuasion or ideological control that uses positive inducements to conformity; and (c) suggestion, that reminds people of their obligations, responsibilities and duties in relations with one another.

In some private forms, such as the disciplinary bodies of universities or professional associations, the administration of justice is elaborate, formalized and with considerable history and established precedent, and whose sanctions may involve fines, loss of privileges, or suspension of licensure. In other cases, such as the community or neighborhood association or the local meeting of Alcoholics Anonymous, the administration of justice may be minimal, implicit, or nonexistent, comprising simply of the exercise of sanctions such as ostracism, shaming, gossip, or ridicule. For discussion of related concepts readers should see *African Legal Systems*; *Legal Pluralism*; *Folk/Indigenous/Customary Law*; *Conflict of Laws*.

2. *Significance*

Nonstate private legal systems and their administration of justice are important because more people are directly governed by and controlled through them on a daily basis than they are by state law, which remains relatively distant from most people's day-to-day life. However, while state law and its various agencies and operations are publicly accountable, private systems of justice often escape accountability. While numerous refinements and endless energy are invested in public systems of law to protect the individual's right to due process, to guard against excessive or abusive use of state power, and to minimize arbitrary decisions, rarely are such limitations to potential abuse exercised on the day-to-day working of private legal systems and their forms of justice. Insofar as the ideal of reducing arbitrariness is the hallmark of legality, this is 'a variable achievement' (Selznick 1969).

3. *Private Legal Systems as Types of Law*

Consistent with Weberian analysis, private legal systems are types of law insofar as they are guaranteed by the probability that physical or psychological coercion to bring about conformity to the order or avenge violation is applied by a staff of people holding themselves especially ready for that purpose. Yet, Selznick (1969) argued that if law is seen only in terms of coercive rules, its moral idealism, its progressive striving to reduce arbitrariness in the administration of justice, is overlooked. For Selznick (1969, p. 7) law is 'generic' in that it is 'endemic in all institutions that rely for social control on formal authority and rule making.' This means that the norm of legality is not confined to the state, but occurs in every group that develops rational rules to administer justice. However, while this approach accommodates the concept of private legal systems, it restricts legality to the formal rational, and discounts the informal, which in Weber's terms may be both substantive and irrational, but nonetheless is a form of legal authority over those whom it exercises control.

Building on Gurvitch's (1947) more inclusive analysis, all legal systems, whether rational or irrational, can be considered as existing in two planes. On the horizontal plane is the range of legal systems differentiated by the scale of organizational complexity within which they are constituted and through which they primarily function. This horizontal continuum would range from the global to the group, with a variety of intermediate organizational fields including society, community, and organization. Within any organizational field there are many different types of organization and many types of groups. Moreover, each type of organization may exist in a wider context, but each also has a degree of separation from its

Table 1
Law, private legal systems and levels of formality

	Global	Societal	Communal	Organizational	Group
Type of legal system	International law	Different national state legal systems; Different kinds of state law	Private legal systems; Norms and controls established by communities	Private legal Systems; Rules and controls established by corporations and organizations	Private group norms
Formal (examples)	International law on human rights; Law on genocide	US statutory law; US common law, e.g., criminal law	Neighborhood rules and ordinances affecting housing, noise, pollution	Rules on gross misconduct, cheating, employee theft, absenteeism, property damage	Norms of Alcoholics Anonymous
Informal (examples)	Norms governing smuggling	Police discretion; Plea bargaining	Neighborhood norms on street crime gay rights racial tolerance	Norms of indulgence; Levels of acceptable violation	Norms of employee work team; Norms of street drug gangs

encompassing social form, based on its own semi-autonomous existence in relation to the whole, of which it is a part. Then, for analytical purposes, consider the degree of formality of the legal system in a vertical plane, as ranging from formal to informal. For Gurvitch, the formal is characterized by being organized, written, fixed, and planned in advance, whereas the informal is unorganized, flexible, spontaneous, and intuitive (see Table 1.) Clearly it is not necessary for informal systems of private law to be spontaneous, since they can be established over time and build up considerable institutionalized history as in the case of street gang initiation rituals.

This schema is helpful in that it shows us that informal social control is not the exclusive control mechanism of the group. While developed organizational forms, such as the state in capitalist industrial society, appear to be dominated by formal social control, such as criminal law, within law's organization, and reflective of the groups that make it up, exist numerous levels of informal private justice working within, and often against the explicit principles of its wider system. Examples would include police discretion and plea-bargaining. Conversely, formal social control is not the exclusive mechanism of the state or formal organization. While levels of organizational development often preclude small groups from having highly formal private legal systems, they sometimes develop rudimentary formal controls (Henry 1983). Thus, each type of collectivity has depths of formal and informal operation. For example, an organization, such as a manufacturing company is governed by the regulations of formal state law, but also has its own non-state private legal system for administering internal discipline. Insofar as this relies on written formal rules, procedures, and penalties, it would be considered a type of formal private law. However, within the same company there may exist a range of groups of employees, of different professions, skills or trades, different unions, work teams and social cliques, etc. Each may exercise its own private collective control over its members. Arguably, the most effective system of control is that where the multiple kinds of social control, and each of their levels of operation from formal to informal, complement each other in bringing about conformity. Indeed, rather than using only one type of legal system, a collectivity typically uses a combination of types and of levels of legal system, simultaneously (Henry 1983).

4. The Interrelationship Between Private Legal Systems and State Law

Although private legal systems by definition, exist outside the state, they have a semi-autonomous relationship with state law (Moore 1978), being subject to its broad framework, yet within these constraints being free to create and enforce their own rules. That they exercise control consistent with the broad requirements of the state means that they can reaffirm state law, and so function as state surrogates. As such, private legal systems are a subset of the more generic notion of social control, which refers to broad societal, community, or organizational level processes such as socialization, education, social welfare, etc., that bring

about conformity to societal social order. In this broader sense, private legal systems are a reaffirmation of the relations of order, part of the ongoing construction of a collectivity's social reality. It is in this sense that private legal systems merge with ongoing daily interaction as an integral part of the constitution of group process to develop the appearance of stability, predictability, and order. This point is at the heart of Ehrlich's (1913) observation that 'living law' is that which dominates life itself even though it has not been posited in legal propositions. Yet the semi-autonomy of private legal systems also allows for a contradictory and subversive role in relation to the state. This web of 'legal pluralism' (Pospisil 1971) may exist in harmony or conflict, reinforcing or undermining the social control of other private legal systems and even the formal law of the state, such that they may condone and even approve of behaviors that the overarching state system would condemn. For example, consider the toleration of some level of pilfering (theft) by employees in a food manufacturing company.

Clearly, any consideration of nonstate private legal systems, therefore, must also involve an examination of the theory of 'legal pluralism' and must address the varying interrelationships between the different types of social control and between their varying levels of formality. Further, insofar as private legal systems exist in an ambivalent relationship to state law, sometimes supporting it, at other times contradicting it, and even undermining it, consideration must also be given to how these forms relate to, and even constitute, the totality of control in a society.

4.1 The Limits of Traditional Legal Pluralism

Recognition of the significance of nonstate forms of law has led sociolegal theorists to revise their thinking about the law and society relationship. The suggestion that state law and its institutions for administering justice are but one form of social control has been a core feature of legal pluralism from the foundations of theorizing about law. However, the legal pluralist tradition has focused on the character, source, and hierarchical place of nonstate normative orders in relation to state law. Until the mid-1970s, much of their argument explored the relationship between indigenous tribal custom and European colonial law (Pospisil 1971). This tradition saw indigenous orders as autonomous, independent, yet subordinate to colonial law. By the mid-1980s, the emphasis had shifted to non-colonial societies but retained its concern with the hierarchical power relations between dominant and subordinate law forms. Thus, many critical theorists take 'informal justice institutions' as the subordinate normative order and examine how they serve the ideological function of blurring the power of the state so that it appears to be a benign part of the social fabric. They have shown that this ideological subordination is accomplished by the co-optation and exploitation of a human desire for informal, localized, community justice, and that the episodic tendency toward an 'informal,' decentralized state control serves a dual legitimating and net-widening control function for the state (Cohen 1985). However, these criticisms seem more applicable to the growth of state sponsored dispute settlement institutions, community policing, and restorative justice, than to explaining the state's interrelationship with other, established, private legal systems, which have largely been ignored. During the late-1980s, attention turned to the contribution that the social relations of these nonstate systems of law make in constituting state law.

4.2 Private Legal Systems and Constitutive Legal Theory

Critical contributions to the legal pluralist debate argued that recognition of the interpenetrating role of non-state normative orders requires a new conception of law in society. This has been variously referred to as the 'relational theory of law,' 'constitutive theory,' and 'postmodernist' or 'deconstructionist' theory.

Constitutive theory is based on the idea that law is, in part, social relations and social relations are, in part, law (Moore 1978, Fitzpatrick 1984, Henry and Milovanovic 1996). It is the movement and tension whereby these are socially constituted, 'the way "society" is produced *within* "law"' as David Nelken has described it and how law is produced within society, rather than how they interact, that is crucial to understanding the law–society interface. Thus, instead of assuming that state law is the hub of social control whose spokes radiate as unidirectional pathways of influence to other social and normative orders, constitutive theory also directs our attention to the reverse process: forms and mechanisms whereby legal-relations are penetrated by extra-legal social relations, often constituted as non-state private legal systems. A constitutive approach examines both the presence and the source of other social forms, which as Alan Hunt says, 'are not simply variant forms of legal reasoning but derive their significance and their legitimating capacity from the forms of social relations from which they originate' (see Hunt 1993).

It is not, then, just that law is created by classes or interest groups, whether instrumentally or symbolically, to maintain or increase their power. Rather, some of the relations of these groups, particularly their rules and procedures are, and indeed become, the relations of law, as relations of law similarly become social relations. This dialectical analysis suggests that 'any site of social relations is likely to be traversed by a variety of state and non-state legal networks' and that 'what constitutes "the law" in any specific context will depend upon which legal networks (or more

precisely which parts of which networks) intersect in that context, how these orders are mobilized, and how they interact' (O'Malley 1991, p. 172).

Thus, instead of treating law as an autonomous field of inquiry linked only by external relations to the rest of society, or investigating the way 'law' and 'society' as concrete entities 'influence' or 'affect' each other, constitutive legal theory takes law as its subject of inquiry, but pursues it by exploring the interrelations between legal relations and other social forms. As Hunt has observed, constitutive theory explores how law or legal relations are generated within non-legal social relations and how legal relations and social relations interpenetrate (Hunt 1993).

Peter Fitzpatrick (1984, 1992) incorporated several contributions (Foucault 1977, Moore 1978, Macaulay 1963) about the notion of interrelationships between law and the larger social matrix within which it is set, into the concept of 'integral plurality.' He says that the reason state law is, in part, shaped by the plurality of other social forms, while these forms are simultaneously being shaped by it, is because 'elements of law are elements of other forms and vice versa.' While law incorporates other forms, transforming them into its own image and likeness, the process is not unilateral but mutual, such that 'law in turn supports the other forms but becomes in the process, part of the other forms.' As such, 'state law is integrally constituted in relation to a plurality of other social forms' and 'depends on social forms that tend to undermine it' (Fitzpatrick 1984).

Fitzpatrick's theory of integral plurality is a considerable advance, both over earlier legal pluralism, and over critical legal theory, for it demonstrates that there is not so much a unilinear relationship with other social forms but rather that 'law is the unsettled product of relations with a plurality of other social forms. As such, law's identity is constantly and inherently subject to challenge and change.' Fitzpatrick's fundamental insight was to recognize that state law obtains some of its identity from its interrelationship with non-state forms and vice versa; that without this connection each would be constitutively different.

Fitzpatrick (1988, 1992) argues that the interrelations between state law and nonstate normative orders forms new entities, as a common discourse and set of practices is worked out between participating arenas of power. This is particularly evident in the context where law is being synthesized from other existing sets of rules and norms. He says that in the process of synopsis of existing rules and practices, the participating networks retain their own relative autonomy, but corresponding structures are formed which merge selected elements of the component networks into an emergent whole that becomes the new law. Pat O'Malley, developing this idea further, describes these attempts at legal synthesis as 'synoptic projects' which, are characterized by the emergence of a common and integrating discourse and set of practices worked out between interacting agencies. Such negotiation involves suppression of incompatible elements of the different participating agencies, knowledges and practices, translation of other elements into more compatible forms, and the integration of all into a workable whole, albeit often inconsistent, labile, and conflicting. In this process emergent, synthetic, or synoptic social practices and knowledges may appear (O'Malley 1991, pp. 172–3)

O'Malley claims that such 'synoptic projects' are most likely to occur where changing conditions, such as the emergence of obstacles to the continued effectiveness of existing arrangements, make their continued operation problematic. For others, such as Santos (1987) and Teubner (1992, pp. 1453–4), the process is one of 'interdiscursivity' where intra-organizational legal discourse 'productively misunderstands,' and misread (through their rereading, reinterpreting, reconstructing, and reobservation) 'organizational self-production as norm production and thus invents a new and rich "source" of law.' A similar misreading occurs, says Teubner, when the organization reincorporates legal rules developed and refined in disciplinary proceedings and makes use of them to restructure its organizational decision making.

In summary, developments during the 1990s in constitutive legal theory have taken a postmodernist stance arguing that law is mutually constituted through social relations and discursive misreading. The discursive processes of nonstate private legal systems with which state law is interrelated and interwoven provides a significant context of synoptic projects wherein old power is molded into new forms. Although critical of this new legal pluralism from the perspective of legal autopoiesis, Teubner (1992, p. 1443) accurately observes, that the relations between the legal and the social are characterized by 'discursive interwovenness,' 'are highly ambiguous, almost paradoxical: separate but intertwined, closed but open.' He argues that this new legal pluralism is 'no longer defined as a set of conflicting social norms in a given social field but as a multiplicity of diverse communicative processes that observe social action under the binary code of legal/illegal' (Teubner 1992, p. 1451). It follows, as O'Malley (1991), Hunt (1993), and Santos (1987) have argued, that to understand the form and process of state law, it is crucial to establish the social sources of the nonstate forms and private legal systems with which it is interrelated and thereby partially constituted.

Although much has been said about how law shapes social forms, and about how interests shape law, until mid-1980s, little research had been done on the way that semi-autonomous non-state private legal systems interrelate with and constitute state law while also being constituted by it. However, as Sally Merry has observed, the study of the way nonstate normative orders constitute state law is in its infancy. Import-

antly, the few studies exploring this interrelationship tend to show how the human agents who penetrate state law through introducing normative content from private non-state arenas, are drawn to reproduce state law more than they are to transform it. Neglected is the extent to which their agency contributions, as carriers for the private normative systems, transform that law in the process of constituting it. A critical research question becomes how private legal systems, such as professional self-regulatory bodies, industrial discipline and dismissals rules and procedures, and the variety of other nonstate forms of social control are constitutive of state law.

In considering the theoretical significance of constitutive legal theory to understanding the relationship between law and private legal systems it is worth stating the obvious. Law and particularly statutory law creation, is often a deliberate effort to incorporate and synthesize custom and practice, norms and rules prevailing in other settings into a general legal framework. The point, however, is that by recognizing the relative autonomy of these nonstate systems of private law, and simultaneously recognizing their ability to interrelate with state law, constitutive theory allows for the possibility that law creation will have an unpredictable outcome. In this process the eventual product is always unintentionally different from what its drafters will have intended. This is so, precisely because of the relative autonomy of the relations of non-state private legal systems.

Legalization

Legalization is a Janus-faced concept that betokens both freedom to act and subjection to law. In the first sense, it means being freed by law to act in ways formerly forbidden—for example, the repeal of Prohibition by the US Constitution's Twenty-first Amendment that legalized drinking, and the 'decriminalization' of so-called 'victimless' crimes such as prostitution, and use and possession of certain drugs. In earlier ages in Western Europe (and in claims being pressed in other parts of the globe in the early twenty-first century) legalization in this sense is exemplified in acts of tolerance that freed worshipers from the straits of official religion. In the second sense, legalization signifies transferring control of an action or behavior to the legal system. It is this second sense that constitutes the subject of this article. (Acts of legalization may embrace both senses of the term—for example, the enactment of divorce laws in some countries has served, on the one hand, to make divorce possible, while on the other hand, subjecting the divorcing parties to legal requirements.)

1. Legalization Generally

Taken over long periods, legalization as a process has been part of the development of all but the smallest of human societies. Placing responsibility for the control of many aspects of human behavior in the legal system is central to civilization itself. In the long run, legalization replaces the unfettered decision of rulers, the bonds of custom, and religious authority with the rule of law, at least considering the rule of law in its broadest constitutional sense of applying predictable and stable legal rules to the citizenry equally, and avoiding the imposition of arbitrary power. A familiar example is the growth of the common law in England

over several centuries, as legal principles and policies absorbed rules and traditions of various institutions that once held sway over most aspects of life, including family, work, property, religions, and political relations.

But legalization can be understood in narrower senses in which the spread of law and law-like institutions need not be synonymous with the rule of law or constitutional order. Throughout the twentieth century, communist societies and certain others, most notably fascist Germany, dispensed with constitutionalism in fact while pretending to it in theory, even as legal decrees and rules infiltrated numerous activities, including the economy and social relations, that had been much freer of control under the prior regime.

Nor does legalization necessarily imply any particular content to laws, which may be as liberal or repressive as the regimes that promulgate them. Laws regulating travel across political borders, which were instituted as early as the sixteenth century, have varied considerably over the centuries, and from country to country, in the strictness of the compulsory passport system that most nations have created. Except during the American civil war, no passports were required to enter or stay in the United States until World War I. Quite the opposite prevailed in France, beginning in the 1790s, and until the middle of the nineteenth century in much of Europe. Likewise, as a means of regulating internal travel, many countries adopted internal passport requirements, while others, notably the United States, have maintained steadfastly a constitutional right to travel without hindrance or papers.

In modern times, the process of legalization can be discerned most clearly in three primary developments: (a) the increasing legal regulation of activities and behaviors previously unregulated or regulated by other means; (b) the growth of private rights of action by which individuals may press legal claims against other individuals and the state; and (c) the spread of legal relations into the international sphere. The first two developments are closely connected, most especially in the United States.

2. *Increasing Legal Regulation*

In 1881, Oliver Wendell Holms Jr, the future US Supreme Court justice, declared in his classic book *The Common Law* that 'the general principle of our law is that loss from accident must lie where it falls, and this principle is not affected by the fact that a human being is the instrument of misfortune' (Holmes 1963, p. 76). But at that very time, American law was undergoing a sea change: the law of negligence would transform many accidents into legally compensable events, and the courts were pulling down a barricade of rules that they had constructed laboriously during much of the nineteenth century against defendants' liability. The growth in American law followed closely on the rise of industrialization, the explosion of technological development, and the spread of the market economy. Not all increase in the number of statutes and judicial decisions can be counted as legalization, since refinement and improvement in law is not necessarily the same as the spread of law and legal relations to new areas. Nevertheless, much of the outpouring of new law was part of the legalization of the country, a fitful though eventually sweeping movement toward 'total redress' (Lieberman 1981, p. 31) or 'total justice' (Friedman 1985). Throughout the twentieth century, the state has endeavored to refashion the theory of harm, and to encompass innovative ways of deterring and redressing the manifold injuries that came to be recognized as products of changing economic and social relations. This legalization of harm has unfolded in four principal ways.

First, from the 1880s to the time of writing, the legislatures of the states and the US Congress have enacted a tidal wave of statutes, dwarfing all previous eras of legislative enactment in all other countries. Since this is not a history of law-making, the list that follows is not intended as a chronology but rather as a snapshot of the kinds of activities that have been enveloped by law during the twentieth century: labor and employee relations (including working conditions, pay, health, safety), environmental pollution, consumer concerns (including banking and credit, housing, product safety, and advertising), the market mechanism (including antitrust, corporate structure, securities regulation, and the like), communications, elections, transportation, education, discrimination (by a host of institutions, public and private, on a variety of bases, including race, sex, ethnicity, religion, and disability), family relations (including marriage and divorce, child custody, and welfare), public assistance (including unemployment insurance, welfare benefits, and old-age security), and personal relations (including sexual relations and procreation), to name only the most prominent of the areas that have come under legal sway. Statutes operate in four ways: (a) they occasionally declare specific rules that require changes in behavior (e.g., a reduction of pollution by a certain percentage no later than a specific year); (b) even when they are not specific, statutes put decisions formerly private at risk of being second-guessed by public decision makers, including courts, prosecutors, administrators, and adversaries; (c) statutes aimed at altering complex business and other practices almost invariably wind up being enforced by bureaucracies with considerable discretion to define the law on their own terms: and (d) frequently, legislators empower individual private litigants, as well as public prosecutors, to enforce statutes in court.

Second, as just noted, legalization has been enshrined in administrative bureaucracies created to manage a host of private relations. Although some statutes spell out bright-line rules (for instance, setting the drinking age at 21 years, or placing a ceiling on interest rates that may be charged), legislatures routinely delegate not merely enforcement power to administrative agencies to carry out major regulatory programs but also the very power to define the law. One measure of the scope of administrative law in the United States at the close of the twentieth century is contained in the pages of the *Federal Register*, the US government's official digest of proposed and promulgated federal regulations; it runs to around 60,000 pages annually. The impulse to legalize has thus created a vast bureaucracy and undercut the rule of law as understood by one of its leading proponents, A. V. Dicey, who, speaking of the British legal system in the nineteenth century, said 'there can be with us nothing really corresponding to the 'administrative law' (Dicey, 1959, p. 203).

Third, alongside the legislatures and administrative agencies courts themselves have multiplied legal rights. The common-law understanding of harmful activity has expanded to encompass, for example, strict liability in tort, so that manufacturing operations that were once legally unapproachable in the absence of statutes have been regular fare at the judicial feast. Likewise, the courts in the United States have expanded vastly the panoply of public rights, particularly in the arena of the Fourteenth Amendment's command that the states provide due process and equal protection of the laws.

Fourth, as a direct consequence of the preceding three developments, individual litigants have gained the right to take their multiplying grievances to court, as discussed in the next section.

3. *Growth of Private Rights of Action*

The widely observed penchant of Americans to sue springs from a rich tradition. As long ago as 1835, Alexis de Tocqueville observed, in an often quoted passage in *Democracy in America*, that 'there is hardly a political question in the United States which does not sooner or later turn into a judicial one' (de Tocqueville 1966, p. 248). Nevertheless, during the last quarter of the twentieth century, it became the conventional wisdom of many observers that the United States was suffering from something new: a 'litigation explosion' (Olson 1991). Though the term is obscure, and such statistics as are available are subject to different interpretations (Galanter 1983, 1993, 1996, 1998), it is clear that the *types* of actions that plaintiffs may bring to court were greatly extended during the twentieth century. Many activities once entrusted to other domains—for example, politics—or left wholly unregulated and open to the whims of individuals, have become objects of legal oversight.

The most notorious example of the trend toward legalizing what was once purely political was the investigation of US presidents and high-ranking executive officials by so-called 'independent counsel.' Although in form a public prosecutor, the independent counsel was in effect a combination of a private lawyer and a client, since the executive branch was precluded from effective oversight of the prosecution. The independent counsel movement had its origins in the Watergate scandal in 1973, when the US attorney general authorized the appointment of a private lawyer as a special prosecutor, and promised to keep the government's hands off the investigation. President Nixon's discharging of Archibald Cox, the first Watergate special prosecutor, led to a federal statute providing for the appointment of independent counsel by the federal court. Ultimately, the independent counsel system ensnared President Bill Clinton in a series of investigations, culminating in the squalid inquiry into his sex life and subsequent impeachment in 1998. The independent counsel law was allowed to lapse in 1999, stemming from widespread revulsion against the legalization of such questions, and the inept tactics of Kenneth Starr, the independent counsel.

Other notable examples: The overthrow of racial segregation laws in the United States primarily began with cases filed in individual courtrooms in the 1950s. Apportionment of legislative districts, once solely a matter for political resolution (even in the face of constitutional commands widely disregarded by the legislators themselves), has become a cottage industry of litigation in the United States since the 1960s. In the 1970s, manufacturing and other practices were subject to sweeping oversight in court efforts to clean up the environment. Sexual harassment, a still evolving concept, became justiciable as the result of statutes and court decisions in the 1980s, overturning a centuries-long practice of remitting women to their private suffering in the face of it. In the 1990s, the tobacco industry was forced to agree to pay hundreds of billions of dollars in health-related claims, largely through settlements in the wake of legal claims, and a similar effort to control the distribution and sale of guns was mounted in the late 1990s. At the beginning of the twenty-first century, animal rights activists are attempting to prevent medical experimentation on animals by seeking to persuade courts to declare animals not merely property but possessors of rights.

Less generally remarked are the legal devices that serve as a spur to further legalization. In the Sherman Antitrust Act, a federal law enacted in 1890, Congress authorized private individuals to sue for restraints of trade and monopolization by business interests, and the act permitted winning plaintiffs to recover both treble damages and their lawyers' fees from losing defendants. Other devices include contingent fees in

personal injury suits; the class action, which permits the consolidation of small claims arising from the same event into a single suit, thus giving the plaintiffs' lawyers a financial incentive to proceed with the case; and the relaxation of so-called 'standing' rules that determine who is the proper party to file a suit—The US courts have occasionally been receptive, for example, to members of Congress who file suits against the President and the executive branch to try to reclaim in court what they lost in the give-and-take of legislative voting.

Legalization through private rights of action is not limited to the lawsuit itself. Understanding that lawsuits are always possible as the final outcome of legal relationships has led people to redefine personal relationships as legal ones. Since innumerable examples are possible, this one will serve as emblematic: a magazine report in 1999 declared that 'some celebrities have asked wedding guests to sign nondisclosure agreements as a condition of attending a ceremony that might attract the interest of the tab[loid]s' (Beam 1999, p. 64).

4. *Legalization in and of the International Arena*

Historically, legalization is an internal affair of each nation. Relations between nations have been governed by diplomatic and political process and, failing that, by war. But following World War II, the prosecutions of Nazi war criminals laid the groundwork for the principle that government officials are not legally free to do whatever they wish as leaders of sovereign nations, and may not always claim immunity when finally caught. The Nuremberg trials established the concept that war crimes and crimes against humanity are justiciable, and in modern times have promoted the increasingly popular notion that the shield of diplomatic immunity may be penetrated by the courts under certain circumstances. Although large numbers of war crimes since then have doubtless gone unpunished (only one major Vietnam war crimes case, concerning the massacre at My Lai, was prosecuted in the United States), by the 1990s a new sentiment led to the tentative creation of the International Criminal Tribunal, situated in the Hague, with jurisdiction to investigate and prosecute acts of genocide and other war crimes in the former Yugoslavia and Rwanda. In 1999, it indicted then President Slobodan Milosevic of Serbia, the first sitting president to be indicted by an international tribunal, and other high officials of the regime, and in 2000 it began a series of prosecutions that garnered international attention.

Other portents include successful civil suits against the estate of Ferdinand Marcos, the Philippine dictator, for human rights violations, and the British proceedings, in 1998, against former Chilean dictator Augusto Pinochet, who was arrested in London on a warrant issued by Spain, charging him with numerous civil rights violations during his 17-year rule in Chile, including murder, torture, and kidnapping. The British courts denied his claim to diplomatic immunity, although he was released in 2000 for health reasons. In the United States, the courts have been amenable increasingly to civil suits by victims of terrorism against their attackers. In 1998, US federal courts awarded more than $300 million in two suits against Iran for its involvement in supporting terrorists involved in killing and kidnapping, and in 2000 Iran was ordered to pay $300 million in damages to one of the hostages taken in Teheran in 1980. Also in 2000, thousands of Filipino slave laborers conscripted by the Japanese Army during World War II filed a class action under California law against Japanese companies or their successors that forced them to labor in mines and plantations. In that same year, Congress enacted legislation enabling victims to collect damage awards from assets in the United States of nations that sponsor terrorism.

5. *Legalization outside the United States*

Although the trend toward legalization is more advanced in the United States than in other countries, there is evidence that the direction of legal change is toward more law, not less; the increase in law is occurring in both industrialized Western nations and less developed nations worldwide, and for the same reasons that the rule of law emerged in the West. A globalized economy demands stability, and globalized communications demonstrate to peoples everywhere the gap between stable and unstable legal systems. Not every nation fits this abstraction: despite its emerging markets, communist China maintains a strong political hold on its courts, just as religiously fundamentalist countries prefer clerical decrees to secular legal rules. In the West, what few comparative studies exist suggest that litigation rates in certain European countries, adjusted for differences in costs, are not appreciably different from rates in the United States (Galanter 1992, p. 10). Two articles from the *New York Times* in 2000, chosen at random, suggest that the impulse toward legalization may be growing in radically different societies. A Chinese citizen sued Canon, Inc., a Japanese company, for $12 million for mental distress, because a computer disk promoting Canon's ink-jet printers said that China, Hong Kong, and Taiwan are separate countries, thus allegedly undermining China's sovereignty (Smith 2000). In Canada, the four major Christian Churches (Anglican, Roman Catholic, Presbyterian, and United Church) may be bankrupted by thousands of suits filed against them for sexual, physical, and 'cultural' abuse by Indian former boarding school students (Brooke 2000) .

6. Measuring Legalization

No good measures of legalization exist, in part because the topic is not studied conventionally, and in part because legal data particular to individual countries and cross-national comparative data are compiled only haphazardly. Even in the United States, a well-defined measure of litigation rates does not exist. One measure sometimes propounded is the gross number of lawyers or lawyers per capita. In the United States, lawyers numbered about 285,000 in 1960, and more than tripled to nearly one million in 2000; per capita, the ratio rose from one lawyer for every 631 Americans in 1960 to one lawyer for every 272 in 2000. By comparison, in Japan, lawyers number around 100,000, for a per capita ratio of one lawyer for every 1260 Japanese. Whether these differences are meaningful, and if so, in what way, remains controversial. The number of lawyers may be explained at least as convincingly by the number and nature of transactions and interpersonal contacts as by some tendency to greater legalization. Quantifying legalization is a research task that remains to be undertaken.

Legislatures: United States

Legislatures are key governmental institutions performing the function of representation and lawmaking in the political system. Legislatures vary enormously in governmental power, from the weakest in parliamentary systems where principal power resides with the executive, to the strongest in separation-of-power systems, where the legislative and executive branches of government have roughly coequal status. Most of the world's democratic systems have parliamentary governments (see *Parliamentary Government*). Among separation-of-power systems, legislative bodies at the national (see *Congress: United States*) and state levels in the United States are the most highly developed. The present discussion deals with the legislatures of the 50 American states, in terms of the many functions they perform and the main elements that characterize them.

1. What Functions Do Legislatures Perform?

Legislatures perform three major functions in the political systems of their states: representing constituencies, lawmaking, and balancing power.

1.1 Representing Constituencies

The predominant responsibility of legislatures is that of representation, primarily of individuals and groups within the states. Individual legislators see themselves as representatives of their districts. While districts within states have the same number of people, districts vary in size among the 50 states. Legislators may represent as many as 796,956 people, as the 40 senators in California do, or as few as 3,924 as some of the 150 representatives in Vermont do.

One of the important jobs of senators and representatives is to provide service to constituencies and constituents—responding to people's requests for help, doing case work, and taking care of the district's interests with respect to state-aid formulas and local projects. Representation requires that organized groups and individual citizens have access to members, to committees, and to the legislative process generally to make known their views. The legislature is attentive, and on major issues, responsive to what people in a district and in the state want. On very few issues do a majority of constituents feel strongly on one side or the other. On those issues it is likely that the legislator feels similarly. Whatever the legislator's views, where there seems to be a mandate in the constituency, legislators will be inclined to go along with it as 'delegates' elected to carry out the will of the people. On the large majority of issues, however, relatively few

constituents have views and legislators respond mainly to organized interest groups in the constituency as well as to other influences. On such issues legislators can act as 'trustees,' according to their own views of the issue and political situation.

1.2 Lawmaking

Overlapping representation are a number of activities the focus of which is primarily internal. The legislative role in formulating, reviewing, and adopting a state budget has special significance in the process of making laws, since the budget is probably the most important bill (or bills) that a legislature passes. The lawmaking process itself is characterized by organized interest groups and their lobbyists and by scattered individuals, who offer diverse perspectives and positions on the issues in question.

Deliberation is an important feature of lawmaking in legislatures. It involves a give-and-take and an exchange of information and ideas. It is a vital element of committee activity, but it also goes on in leadership conferences, and informal exchanges among members. Building consensus on a bill requires more than the efficacy of deliberation; it also requires the willingness of opposing sides to enter into a bargaining process whereby they try to resolve their differences—through dealing, trading, and compromise. Sometimes one side wins decisively and the other loses decisively, but the overwhelming majority of laws enacted by a legislature are settled by means of building consensus—within a legislative party, within a legislative chamber and with the other legislative house.

1.3 Balancing Power

Constitutionally, legislatures are designated as the first branch of government and the executive as the second branch. American state legislatures, unlike parliamentary bodies or many American city councils, are relatively independent of executives and participate coequally in lawmaking for the state. Although most budgets are formulated by the executive branch and nearly all governors can veto line-item appropriations, legislatures are instrumental in deciding on spending priorities for the state and allocating funds for state agencies and state programs. Governors have a lot to say over the legislature's agenda of major issues and can veto legislative enactments; yet, the legislature's cooperation is necessary if a major law is to be adopted.

2. What Factors Play a Role in the Performance of Legislatures?

American state legislatures can be differentiated on a number of dimensions, each of which helps shape the legislature's performance of its three major functions.

2.1 Legislative Structures

With the exception of Nebraska, each state legislature is bicameral, with a senate and a house. Bills must be enacted by both bodies before they are sent to the governor for signature, or possibly veto. Senates are smaller in size than houses, normally with only one-third to one-half as many members. Senates range from Minnesota's 67-member body to Alaska's 20-member body. The largest house, in New Hampshire, has 400 members, while the smallest, in Alaska, has 40. The principal working groups of state legislatures are standing committees, which have responsibility for particular policy domains—such as education, health, welfare, and transportation—and for revenues and expenditures. Committees enable a senate or house to divide labor, allow members to specialize, and provide for a more thorough review of legislative proposals than could be done on the floor of the chamber.

2.2 Legislative Capacity

The quantity and quality of resources available to the legislature to perform its functions are important. A number of elements signify a legislature's capacity. The amount of time, both during the formal session and during the period between sessions (the interim), matters. With 44 of the 50 state legislatures meeting annually, sessions vary in length from those that run only 20 or 30 days to those that run for most of the year. California, Illinois, Massachusetts, Michigan, New York, and Pennsylvania are virtually full time, while Arkansas, North Dakota, and Wyoming are very part time. Another aspect of capacity is professional staff. The organization and size of legislative staffs range greatly. In some states staff tend to be centralized in one non-partisan agency (as in Kentucky and Ohio); in other states staff is decentralized—divided between the senate and house and among legislative parties and standing committees. The most populous states with full-time legislatures (like California and New York) have the largest staffs, while the least populous states with very part-time legislatures (like Delaware and Wyoming) have the smallest staffs. Additional resources employed by legislatures include facilities, technology, and the amount of money budgeted for the legislative operation as a whole. Whether a legislature is more or less professional depends largely on its capacity to do its job.

2.3 Legislative Members

The total number of legislators in the 50 states is 7,425. Members of senates generally serve four-year terms, while members of houses generally serve two-year terms. In 19 states legislators are limited to six, eight, or twelve years of service in the senate or house. Term

limits were adopted by the initiative process (or by threat of the initiative) in 20 states and by the legislature itself in another state, but were thrown out by the courts in three. Most members in most states are 'citizen' legislators, who supplement modest public salaries with income earned in private employment—as attorneys, business persons, teachers, farmers, etc. Large proportions of legislators aspire to careers in politics, working their way through leadership chairs in the state senate or house or running for Congress or statewide office. Relatively few incumbents leave voluntarily (excluding those who run for higher office) and relatively few who stand for re-election are defeated.

2.4 Legislative Parties

Parties are of little importance in the Nebraska legislature, which is not only unicameral but is also officially nonpartisan, and in legislatures that are controlled overwhelmingly by one party or the other. Otherwise, parties play a significant role. About two-thirds of the 99 legislative chambers are competitive, in that both the Democrats and the Republicans have held the majority in recent years and/or have a prospect of winning a majority in the near future. (This competition at the chamber level exists despite the fact that anywhere from two to four out of five senate and house districts are reasonably safe for either Democrats or Republicans.) The majority party in a legislative body normally exercises predominant control. In the lawmaking process, the minority can choose either to work with the majority in an effort to shape the legislative product or challenge the majority in an effort to create issues on which to contest the forthcoming election. Where the legislative parties are most competitive partisanship is likely to be strongest. The legislative parties employ caucuses or conferences of members, which meet during the session on an occasional basis, weekly, or every day just before the senate or house convenes.

In about three-quarters of the states the legislative parties are not only involved in governance through their influence on the lawmaking process, but are also involved in campaigns for the election of candidates to the legislature. The parties and legislative party leaders raise funds and allocate them to incumbents and challengers, who face contests in the most competitive districts. Although campaigns remain candidate-centered and local, the legislative parties exercise a centralizing influence. All of this increases partisanship in the legislature.

2.5 Legislative Leaders

The top leaders in a legislative body are the speaker of the house and the president, president pro tem, or in a few cases majority leader of the senate. The presiding officers of the body are elected by the entire membership, although the majority party candidate normally wins. Other leaders are appointed by top leaders or are selected by the party caucuses.

Legislative leaders have a number of responsibilities. First, they build consensus within their party or in the chamber as a whole in order to pass legislation and serve the interests of their partisan or chamber members. Second, they negotiate with the other house and with the executive so that legislation can proceed from passage in one chamber to enactment in law. Third, they organize their chamber, appointing members to committees and designating committee chairs. Fourth, they exercise control of the agenda and the flow of bills to the floor. Fifth, they preside over floor sessions. Sixth, they manage, or oversee the management of, the senate or house and of joint facilities. Seventh, they minister to members who need help with their bills, assistance for their districts, appointments for constituents, or other kinds of assistance. Eighth, they represent the chamber in dealings with the media. Ninth, they help their party's incumbents get re-elected and support their party's challengers to the opposition.

Today few leaders exercise the power of their predecessors. Leaders no longer have a monopoly on information or staff and members are less willing to follow leadership. Legislative leadership nowadays is more a matter of helping the membership develop consensus on where it wants to go than of getting the membership to go where their leaders want to go.

2.6 Legislative Institutionalism

A combination of factors define the institutionalism of legislatures. First is concern, which has to do with a sense of, identification with, or dedication to the legislature. Members who care about the legislature's well being and who engage in institution-building activities (and do not engage in activities that are institutionally harmful) foster institutionalism. Second is community, which encompasses the culture and norms of the legislature and requires some level of agreement on the need for civility and some manifestation of collegiality. Third is continuity, which not only provides for greater knowledge and skill on the parts of lawmakers but also promotes institutional values. Fourth is autonomy, which requires that legislatures be insulated, at least to some extent, from the environment and that they have substantial control over essentially internal processes.

Legitimacy

How legal order and change are produced is a central question of law and social science inquiry. Similar questions about how social and political order—or conversely, change—come about are central to sociology and political science. Max Weber designed his concept of legitimacy in part to answer these questions. Broader discussions of legitimacy remain motivated by these themes.

Weber (1978) distinguished between obedience to commands achieved by applying force and obedience to commands achieved through legitimation. When domination is legitimated, that is, when power becomes transformed into authority, by definition subordinates consider the exercise of authority valid. Commands are obeyed because subordinates believe they are appropriate. Force, which Weber regards as an ineffective guarantor of order in the longer term, becomes unnecessary. Social order is assured through voluntary compliance.

According to Weber, there are three general types of legitimated social orders. Traditional authority stems from 'an established belief in the sanctity of immemorial traditions and the legitimacy of those exercising authority under them' (Weber 1978, p. 215). Charismatic authority stems from subordinates' belief in the singular and exceptional personal qualities of the leader. Since it inheres in attribution of extraordinary, magical qualities to an authority, it does *not* depend on any particular institutional arrangements.

In contrast, rational–legal authority is exercised in bureaucratic settings. Bureaucracy is characterized by general, written rules, a hierarchy of positions constituting both a chain of command and a career ladder, universalistic allocation of positions based on certified expertise, and rule-application in an impartial manner by bureaucratic officials. In rational–legal authority, strictly personal characteristics of leaders are irrelevant to subordinates' belief in the validity of leaders' commands. Instead, rational–legal authority stems from 'a belief in the *legality* of enacted rules and the right of those elevated to authority under such rules to issue commands' (Weber 1978, p. 215). A rational–legal system is made up of an inter-related set of formal rules specifying what must, may, or must not be done—and where relevant, by whom and under what conditions. Included are formal procedural rules that authorities must follow so that any substantive commands they issue will be valid. Under principles of legality, there also are rules that specify how authority figures come to occupy their positions, and thus to have the right and duty to issue any commands at all. Under conditions of legality, authorities are subject to the rules just as are those they command. Behavior of subordinates and superordinates alike is circumscribed, taking place according to rules.

In this view, *legal* rules are self-legitimating by definition. To better understand what characteristics of rules or rule-production can legitimate law, and what are the further consequences of law's legitimation or delegitimation, inquiry must be broadened and deepened. Nonetheless, Weber's discussion of legitimacy has been seminal for three reasons.

First, conflicts based on the divergent instrumental interests of haves and have nots are endemic in stratified social orders. Weber's concept of legitimacy suggests that people's *cognitive* and *normative* orientations to some legitimacy source—whether tradition, charisma, or legality—can counteract the tendency of interest-based conflicts to undermine social order. When legitimacy results from collective orientation to, and belief in, a particular set of 'rules of the game,' people will support and comply with decisions that run counter to their socioeconomic, political, or legal interests. Even those who consistently are disadvantaged will not rebel (Della Fave 1986, Scharpf 1999, Stryker 1994, Walker et al. 1991). Viewed this way, legitimacy may be immensely powerful in maintaining social order. Theorists and empirical researchers alike are encouraged to inquire into mechanisms producing legitimation and delegitimation of decisions, decision-making authorities, and decision-making institutions.

Second, Weber's discussion is seminal because it points toward the potential centrality of *legal order* for the legitimacy, and hence stability, of the broader

political system. Based on Weber's concept of rational–legal authority, law should play a central role in legitimating any political system that is organized bureaucratically with rules formally enacted and applied by a specialized administrative staff. As Weber's (Weber 1946, 1978) own notion of the historically increasing rationalization of modern life suggests, political systems meeting these criteria encompass much of the globe at the start of the twenty-first century. Code law and common law systems both meet the basic criteria. We most often associate democracy with law-based legitimation, but many nondemocratic systems also meet basic criteria for law to help produce political legitimacy.

Third, consistent with Weberian premises, pervasive *legalization* is a well-documented fact of contemporary economic and social life. New institutionalist research on organizations shows how *state law* penetrates the workplace (Edelman 1992, Dobbin and Sutton 1998). These scholars also document increasing organizational diffusion of *nonstate*, *but law-like* formal-rational governance systems characterized by written company rules and quasijudicial, due process-oriented grievance mechanisms (e.g., Sutton et al. 1994). Such diffusion stems in part from organizations' search for legitimacy among diverse constituencies (Stryker 2000).

In short, whether scholars focus on the formal polity or on other institutional arenas, they gain by inquiring about causes and consequences of law's legitimacy. They also should inquire about the nature and impact for the political-economy and society of any collective 'belief in legality.' Such issues are related, but not identical to, those addressed in the voluminous literature on the *rule of law* (Walker 1988, Dworkin 1985). The rest of this article reviews current concepts of legitimacy. It then discusses causes and consequences of legitimation or delegitimation.

1. Legitimacy: Conceptual Debates and Clarifications

Contemporary approaches to legitimacy contain three major themes: legitimacy as cognitive orientation to a set of binding rules of the game for political and legal acts, authorities and institutions; legitimacy as attitudinal approval of those rules; and legitimacy as behavioral consent to those rules (Stryker 1994, 2000). Implicit in each definition is a different explanation for legitimacy. A normative mechanism—internalized belief in the rightness of political or legal acts, authorities, or institutions, and a consequent internalized obligation to obey their commands—predominates for scholars who view legitimacy as attitudinal approval (e.g., Tyler 1990, Della Fave 1986, Lipset and Schneider 1983). An instrumental mechanism—ordinarily provision of material resources and rewards—predominates for scholars who view legitimacy as behavioral consent. Consent can vary along a continuum from active participation to passive acceptance to sullen obedience (compare, e.g., Habermas 1975 with Przeworski 1980). A constitutive mechanism—cognitive recognition of '*the* way things are'—predominates for scholars who view legitimacy as cognitive orientation (e.g., Walker et al. 1986), Walker et al. 1991, p. 6: emphasis in original). The research on legitimacy processes by Thomas et al. (1986, p. 378) distinguished between *validity*—'collective approval of a binding rule'—and *propriety*—'an individual's approval of the rule.' Validity does not require consensus or uniformity of belief, but only that there is 'a known institutionalized order within the collective' (Thomas et al. 1986, p. 380). Valid rules have constitutive effects when actors conform because they view the rule as binding, even and perhaps especially if they do not personally approve of the rule or if they receive adverse outcomes when the rule is applied.

Adding to the proliferation of diverse concepts and explanations for legitimacy, some scholars emphasize the formal or procedural basis for producing cognitive orientations or internalized beliefs in legal or political acts or in entire legal or political orders, such as constitutional democracy. Other scholars suggest that unless the content of legal and political commands reflects a population's substantive values, the commands will not be perceived as legitimate (see, e.g., Friedman 1981, Hyde 1983). The sum total of empirical research suggests that no matter what one's definitional starting point, all the extant approaches to legitimacy processes have produced useful insights and findings (Tyler 1990, Stryker 1994, 2000). Now these insights must be put together. As Stryker (1994, p. 85, citations omitted) noted:

> [Theory and research] [s]eparating recognition of binding rules from their approval is important because it suggests how cognitive awareness of a set of institutionalized rules can reproduce these rules by causing behavioral consent and attitudinal approval. Existence of valid rules logically presupposes that people presume peer and authority figures will behave according to, and in support of, those rules. Peer support feeds back to reinforce a person's orientation to the rules, as does that person's expectation that sanctions can be applied effectively and with peer support. Empirical findings suggest that increased collective orientation to rules lessens the mobilization of collective action against rules that are detrimental to actors' material interests. Conversely, if peers or authority figures do not play by and support the rules, collective orientation to those rules should weaken and diminished behavioral consent should follow.

2. Legitimacy: Causes and Consequences

Attitudinal support for political or legal authorities or institutions has been a more frequent operationalization of the concept of legitimacy than has been perceived obligation to comply with the decisions of

these authorities or institutions (Tyler 1990). One important line of research focusing on both types of concepts and indicators is that of Tom Tyler and diverse colleagues (Tyler 1990, 1994, et al. 1989; Lind et al. 1993).

To study the relationship between legitimacy and lawbreaking in 'the range of laws people deal with in their everyday lives,' for example, drunk driving, speeding, littering, and minor shoplifting. Tyler (1990, p. 30) conducted research on a random sample of Chicago residents. To test the hypothesis that the legitimacy of law leads to voluntary compliance, creating either an internalized obligation to obey and/or affective support for legal authorities, Tyler analyzed data from a subsample that had recent personal experiences with the courts or police. Perceived obligation to obey the courts and police was higher than was attitudinal support for the courts and police. Both perceived obligation to obey and attitudinal support directly and statistically significantly influenced reported behavioral compliance. In an earlier study focused on political legitimacy, Rasinski et al. (1985) measured institutional legitimacy by the degree to which respondents perceived that a political official's right to make decisions depended on his/her position or legal authority. Higher institutional legitimacy lessened the degree to which negative evaluations of former US President Reagan's policy performance translated into a generalized lack of support for the entire US political system. Clearly, political and legal legitimacy are both consequential and inter-related (see also Lipset 1994, Somers 1994).

As to sources or causes, as well as consequences, of legitimacy, Tyler (1990) found that a 'process perspective' on procedural justice was a more powerful predictor of law's legitimacy than was an 'outcome perspective.' The outcome perspective presumes that people assess the fairness of procedures based on the degree to which they feel they can control the *content* of the decision. The process perspective presumes that people focus on more formal criteria like neutrality, impartiality or lack of bias. To some extent Tyler's (1990) findings echo Weber's assumptions about how rational–legal authority is legitimated, since in Tyler's data, people who perceived they had been treated neutrally, impartially, honestly, politely, and with respect exhibited enhanced support for police and courts. Perceived control over outcomes also contributed to enhanced support for police and courts, but the effect of process control was greater than that of decision control. An important caveat is that neither perceived process control nor outcome control was directly related to the measure of legitimacy with the most impact on compliance with law: perceived obligation to obey.

Subsequent studies by Tyler and others continue to stress the formal procedural bases for legitimacy, whether assessed for legal or political referents. These studies investigate a wider range of legal and political acts, authorities or institutions. Tyler (1994) empirically examined the effect that evaluations of the fairness of government law-making procedures had on subjective assessments of the legitimacy of the US Congress. Evaluations of procedural fairness proved much more important for legitimacy than whether or not policies adopted by Congress matched respondents' self-interested preferences. Tyler (1994) viewed this as strong support for the role formal procedures play in maintaining public support for political institutions, and hence political stability, even and especially when citizens do not agree with the policies adopted.

Lind et al. (1993) extended empirical research from the more everyday criminal law matters investigated by Tyler (1990) to monetarily consequential federal contract and tort litigation involving both individual and corporate litigants. These lawsuits required that litigants use arbitration, but litigants could reject the arbitrator's decision, in which case the lawsuit went to trial. The authors found that litigants' acceptance of the nonbinding arbitration awards was higher for both corporate and individual actors who positively evaluated the procedural justice they received.

As in Tyler's (1990) study, positive evaluations of arbitration outcomes and of arbitration processes both significantly and positively affected perceived procedural justice, but the impact of the process evaluations was greater than that of the outcome evaluations. This points again to the role of formal procedures as a basis for legitimation. However, Lind et al. (1993) also constructed an objective indicator of how favorable or unfavorable were the outcomes their litigants received through arbitration awards. The authors assessed the direct effect of this measure and also of litigants' subjective evaluations of their outcomes on litigants' acceptance of arbitration awards, controlling for perceived procedural justice. Since a significant positive effect of favorable outcomes on voluntary award acceptance remained, instrumental mechanisms were, in part, at work. Similarly, an instrumental mechanism is suggested by Tyler et al. (1989) who found that felony defendants' evaluation of judges was affected not only by defendants' perceptions of procedural justice, but also by their perceptions of distributive justice and (negatively) by the length of sentence they received.

Finally, with respect to the role of constitutive mechanisms in producing legitimacy, researchers who distinguished conceptually between recognition of a valid rule and affective support for that rule have shown that, over time, a process of rule internationalization *does* occur. In laboratory experiments conducted by Walker and co-workers (Thomas et al. 1986; Walker et al. 1986; Walker et al. 1991), collective orientation to a set of rules produced, over time, approval of those rules by many individuals in the collective. In addition to this internalization effect, the researchers found that the constitutive aspect of

legitimacy *directly* affected mobilization of collective action. In an experiment in which an experimenter-established reward structure that disadvantaged subjects was *not* meaningfully justified by reference to some group purpose, about 80 percent of subjects tried to initiate collective action to change that structure. When the experimenters legitimated the reward structure by clearly and explicitly linking it to the purpose of the investigation, a much smaller percentage of subjects initiated collective action, even though it remained in their material interests to do so (Walker et al. 1991).

Also inspired by Weber are inquiries into the impact that scientific–technical rationalization may have on the legitimacy of government and law. For Weber, both legal and scientific rationalization are key aspects of a broader societal rationalization trend. Weber did not always distinguish clearly between legal and scientific rationalization, but later scholars analytically distinguished between formal–legal and scientific–technical rationality (Offe 1975, Therborn 1977, Stryker 1994). This makes it possible to ask how law's increasing reliance on cause-effect reasoning in place of formal, rule-oriented reasoning and law's increasing incorporation of scientific expertise will affect its legitimacy (Stryker 1994, 2000). Neo-Marxist critical scholarship presumed that increasing governmental reliance on science would legitimate government by converting political issues to be resolved by popular debate into technical issues removed from popular control (Habermas 1970, 1975). The empirical literature is mixed. Political and legal authorities do adopt scientific–technical expertise intending to increase their legitimacy (Eisner 1991, Stryker 1990). But as Stryker (1994, citations omitted) noted: 'empirical work also shows that, no matter what proponents of increased reliance on science intend, under some conditions, scientific–technical rationality increases politicization and delegitimates processes and outcomes of welfare state [political and] legal institutions.'

By analytically separating constitutive, normative, and instrumental mechanisms linking law's enhanced reliance on science to law's legitimacy, Stryker (1994, p. 853) deduced the consequences of each mechanism for 'legitimacy processes, including mobilization and conflict over legal acts, authorities and institutions; and [she theorized] the conditions under which and groups for whom the three mechanisms reinfor[ced] or, conversely undercut each other in legitimating or deligitimating law.' Stryker's (1994) theory is consistent with diverse illustrative evidence, but the theory has not been tested directly. Still, it specifies exactly how the stability-threatening 'legitimacy crises' that are the focus of so much writing on government legitimacy may get created and diffused. At the same time, and consistent with conflict theory's focus on order *through* change, Stryker (1994, pp. 890–1) suggests:

> [The] dynamics of legitimation, delegitimation, mobilization, countermobilization and conflict are an integral part of the everyday, ordinary workings of legal institutions … Democratic politics of welfare states provide institutionalized political and legal rules for changing legal acts, authorities and institutions. Individual and collective protest can and does take place through such institutionalized channels as voting, political advertising, electoral fund-raising and campaigning, organized interest group lobbying, litigation and threatened litigation. Legally circumscribed strikes, pickets, marches, boycotts, and rallies provide potentially more disruptive but still legally institutionalized methods of collective protest … when the dynamics of legitimation and delegitimation play themselves out through these institutionalized means, they help achieve political order through legally and politically induced legal change.

Legitimacy: Political

Legitimacy is a critical but often vexing concept in politics and political science. It is critical because it goes to the very heart of any normative claim made by a government, a state, or a power that it should be willingly obeyed or respected. As such, the concept of legitimacy is closely interwined with a network of other normative and empirical concepts in political science—power, authority, rights, obligation, sovereignty, consent, institution, and the state. Legitimacy is vexing because of the difficulty of disentangling the normative bases of compliance or respect from any number of other possible motivations for obedience or deference. As with most critical and vexing concepts, the definition of legitimacy has itself been the subject of extensive debate and discussion. No single and universally acceptable definition of legitimacy exists. However, it is possible and useful to provide a discussion of its various meanings and the consequences of adopting one of them.

Perhaps the most fundamental divergence over the meaning of legitimacy is between a normative and an empirical approach to the concept. The normative approach is used by political philosophers to identify the standards by which a regime or action must be judged if it is to be regarded as legitimate. Political philosophers and the general public, for instance, might be interested in trying to answer the question: Why should the government be obeyed? And thus they might want to identify those conditions under which an authority is legitimate—the reasons why citizens *ought* to obey. A Lockean would argue, for instance, that consent is the central criterion that makes government authority legitimate (Simmons 1979). Without consent, there is no moral compulsion for citizens to obey.

In contrast, the empirical approach to legitimacy is not concerned with normative standards *per se*. Instead, it wants to explain why or when people do obey, respect, or show allegiance to a particular government, regime, state, policy, or institution. Or, conversely, why or when do they revolt, disobey, or act disloyally? Thus, the empirical approach is more concerned about whether the normative standards people hold—however defined—are met, than in debating what standards should hold. Political philosophers have sometimes criticized the social scientific approach to legitimacy as relativistic, and consequently, as potentially complicit in tyranny (Schaar 1981). The Nazi regime, so the argument might go, is deemed legitimate as long as its subjects regard it as such. As both Rodney Barker and David Beetham argue, however, the normative and the empirical approaches to legitimacy simply have different purposes and should not be regarded as antithetical (Barker 1990, Beetham 1991).

1. *Max Weber's View of Legitimacy and its Legacy*

The German sociologist Max Weber provided social science with its most enduring empirical approach to legitimacy. Weber linked legitimacy to the willingness to comply with a system of rule ('legitimacy orders') or

to obey commands ('imperative control'). An administrative staff, for instance, may obey commands because of custom, affectual ties, or material incentives. He argued, however, that compliance or obedience also typically requires a belief in the legitimacy of the system of rule or command. Every 'system of authority,' he argued, 'attempts to establish and to cultivate the belief in its 'legitimacy' (Weber 1947, p. 325). Compliance or obedience based on custom or expediency are unlikely, according to Weber, to be stable. It is worth noting here the similarity between Weber's concept of legitimacy and Marx's notion of ideology (Barker 1990, p. 59).

Weber identifies three types of 'pure' legitimate authority: *rational-legal authority* rests 'on a belief in the "legality" of patterns of normative rules and the right of those elevated to authority under such rules to issue commands'; *traditional authority* rests 'on an established belief in the sanctity of immemorial traditions and the legitimacy of the status of those excercising authority under them'; and *charismatic authority* rests 'on devotion to the specific and exceptional sanctity, heroism, or exemplary character of an individual person, and of the normative patterns or order revealed or ordained by him' (Weber 1947, p. 328). At other points in his analysis, Weber also describes a *value-rational* legitimacy, which holds 'by virtue of a rational belief in its absolute value' (Weber 1947, p. 130). Barker argues that value rationality ought to be included as a fourth type of legitimacy (Barker 1990, p. 49).

Legitimacy is at the heart of Weber's sociology of domination. Its centrality grows out of his fundamental claim that social scientific explanation ought to be based on the way in which individual action is subjectively and meaningfully oriented towards the actions of others. By arguing that different modes of domination depend on different patterns of authority, and that authority depends on whether people believe it to be justified (i.e., legitimacy), Weber sought to make legitimacy central to our understanding of social institutions and political order. This is readily apparent in his famous definition of the state, which Weber argued was 'a human community that (successfully) claims the *monopoly of the legitimate use of physical force* within a given territory' (Weber 1946, p. 78). Moreover, the concept of legitimacy is central to Weber's broader analysis of social and political change. His well-known argument about the emergence of modernity in the West claims that traditional and charismatic authority is progressively replaced by rational-legal authority.

Those following in the Weberian tradition have continued to emphasize the importance of legitimacy while refining it as an empirical tool. David Beetham has sought to reformulate Weber's description of legitimacy while maintaining its role at the heart of social scientific inquiry. The problem with Weber's definition of legitimacy, Beetham argues, is that Weber conflated belief and legitimacy. 'A given power relationship,' he writes, 'is not legitimate because people believe in its legitimacy, but because it can be justified in terms of their beliefs' (Beetham 1991, p. 11). Consequently, argues Beetham, we can analyze the legitimation of power in terms of three criteria. Power can be said to be legitmate to the extent that: (a) it conforms to established rules, (b) the rules can be justified by reference to beliefs shared by both dominant and subordinate actors, and (c) there is evidence of consent by the subordinate to the particular power relation. Conversely, a breach of rules leads to *illegitimacy*, a discrepancy between rules and supporting beliefs or the absence of shared beliefs leads to a *legitimacy deficit*, and a withdrawal of consent leads to *delegitimation*. (Beetham 1991, pp. 18–20). Beetham argues that legitimacy, by helping to promote compliance and cooperation, can enhance the order, stability and effectiveness of regimes (Beetham 1991, p. 35).

Rosemary O'Kane has challenged Beetham's claim that legitimacy is a critical concept in explaining regimes and regime change. While she approves of Beetham's attempt to refine Weber, she poses three general kinds of objections to his reformulation: (a) the definition of legitimacy in terms of moral beliefs is circular, (b) it is difficult in practice to disentangle acquiescence or compliance attributable to belief from that deriving from other factors, and (c) the focus on legitimacy leads to misleading assessments of the direction of causality (O'Kane 1993). She suggests that we limit criteria for judging legitimacy to 'legal validity' (the easiest criterion to evaluate empirically) and otherwise shift our focus from legitimacy to support. 'Investigation directly into the nature of support,' she argues, 'might prove the more rewarding for an understanding of the workings of political systems' (O'Kane 1993, p. 476). In fact, 'support' approximates a rational choice conception of legitimacy put forward by Ronald Rogowski, who defines a 'rationally legitimate' government as one that maximizes the expected utility of its citizens (Rogowski 1974, p. 43).

Beetham has replied to O'Kane that the distinction between legitimacy and support is essential if we are to grasp different logics of regime crisis and transformation (Beetham 1993). Thus, a military regime might enjoy temporary support based upon its performance, but it might have a high probability for instability in the longer term because of its lack of legitimacy. Beetham's argument recalls Seymour Martin Lipset's distinction between legitimacy and effectiveness. Legitimacy, according to Lipset, is 'the capacity of the system to engender and maintain the belief that the existing political institutions are the most appropriate ones for the society.' Effectiveness, in contrast, 'means actual peformance, the extent to which the system satisfies the basic functions of government as most of the population and such powerful groups within it as

big business or the armed forces see them' (Lipset 1963, p. 64). While legitimacy is an 'evaluative' concept, he argues, effectiveness is an 'instrumental' one.

2. From Legitimacy to Legitimation

Part of the problem with the term 'legitimacy' is that it suggests a static property of a regime or institution. Yet, it is obvious that many regimes and institutions are constantly striving to shore up their claims to legitimacy. In this sense, the terms 'legitimation' and 'delegitimation' imply the more active processes by which legitimacy is created and maintained or eroded and lost. Focusing on the process calls attention to the two-sided nature of legitimacy. On one side, legitimacy is about beliefs in the moral rightness or goodness of a regime or institution. On the other side, regimes or institutions make claims about their moral rightness or goodness. Barker has emphasized this two-sidedness, arguing that legitimacy '… is both a belief held by subjects, or by some subjects, and a claim made by rulers' (Barker 1990, p. 59).

In their treatise on the sociology of knowledge, Peter Berger and Thomas Luckmann have emphasized that legitimation is a process of explaining and justifying the validity of an institutional order. They argue that four different levels of legitimation can be distinguished. The first ('incipient') level of legitimation is the creation of language that is implicitly legitimating. The second level of legitimation entails the articulation of a set of rudimentary claims or maxims. At a third level of legitimation, an explicit 'theory' based on an autonomous body of knowledge is developed. Finally, a 'symbolic universe' develops that integrates disparate symbolic meanings into a 'totality' (Berger and Luckmann 1967, p. 96). Thus, legitimacy claims can be seen as varying in terms of their explicitness and integration.

Obviously, regimes and institutions may make highly explicit and integrated claims and still be regarded as illegitimate. Yet it is also plausible that the justificatory claims of a regime will significantly influence the beliefs of the regime's subjects, particularly if coercion or instrumental incentives are effectively used to transform these beliefs. This point brings us back to the political philosopher's fear that power might be regarded as legitimate because it is powerful. While this article has only briefly explored the concept of legitimacy, the tour has hopefully been sufficient to convince the reader that legitimacy is indeed a critical but vexing concept.

Legitimacy, Sociology of

Legitimacy may be defined as the formula by which individuals accept a power and consider their obedience as a just commitment. Thus, it implies consent and stresses the sociological dimension of the free acceptance of a power. As such, legitimacy emphasizes the symbolical aspect of obedience. Power is not exclusively based on coercion, even in the most authoritarian systems; totalitarianism itself includes an adherence which is conceived of as justified by the people. So, the sociology of legitimacy would argue that (a) power is a social relation, (b) this social relation should be at least partly meaningful for people who are involved in it, (c) this system of meanings justifies the power and its ability to make use of violence, and (d) this symbolic relation will be manipulated by the power-holders. Thus, free acceptance does not postulate the liberty of social actors but the social construction of a free adherence to a political order.

1. The Components of Legitimacy

Therefore legitimacy is one of the main topics of every research in political science. In a Weberian perspective, legitimacy is cosubstantial to politics. As Max Weber said, 'like the political institution his-

torically preceding it, the state is a relation of men dominating men, a relation supported by means of legitimate (i.e., considered to be legitimate) violence' (Weber 1970, p. 78). Reinhard Bendix (1977, p. 294) pointed out that this 'study of domination stresses the importance of group formation and of beliefs.' Thus legitimacy should be analyzed by taking into account the formation of the social structure (i.e., social history, social stratification, divisions, etc) and the nature of the beliefs which are used in a given sequence of history. Consequently, legitimacy is concretely made of various historical and cultural references and is currently analyzed by Weber as a specific and volatile combination of types of legitimization.

Thus, beliefs in the legitimacy of a system of domination are a philosophical, a political, and a cultural matter. In a philosophical perspective, it is clearly implied by the social contract philosophy. The obedience to the law stems from the adherence of everyone to the social order which is contractually defined. In a political perspective, 'men in power want to see their position as "legitimate" and their advantages as "deserved," and to interpret the subordination of the many as the "just fate" of those upon whom it falls' (Bendix 1977, p. 294). In a cultural perspective, the political relations of subordination would be conceived as 'politics of meanings' (Geertz 1973): The intensity and the efficiency of the subordination will depend on the appropriateness of the political myths that the rulers tend to promote. 'For a state to do more than administer privilege and defend itself against its own population, its acts must seem continuous with the selves of those whose states it pretends it is' (Geertz 1973, p. 317). In other words, a sociology of legitimacy must combine the analysis of the sources of legitimacy, of its political manipulation, and of its cultural congruence.

In his famous typology, Max Weber listed three sources of legitimization used to justify the power of command. Traditional domination is the authority of the 'eternal yesterday,' that is, 'the mores sanctified through the unimaginably ancient recognition and habitual orientation to conform' (Weber 1970, pp. 78–9). In this construction a command will be obeyed, and conceived as just, only if it is strictly in accordance with a learnt tradition. Charismatic domination is legitimated by 'the extraordinary and personal gift of grace (charisma), the absolutely personal devotion and personal confidence in revelation, heroism, or other qualities of individual leadership' (Weber 1970, pp. 78–9). This is the legitimacy of the prophet, the hero, the warlord, the plebiscitary ruler, but also the demagog. Charismatic leaders have to prove that they possess charisma and thus gain the privilege to break with tradition and free their command from accordance with tradition. From this point of view, this kind of legitimacy inserts a dynamic of change since it makes it possible to get the people's support without reproducing the traditional order. However, this source of legitimacy is particularly fragile and volatile since it may be called into question by a failure or a decreasing performance of the leader. In legal domination, people obey the law rather than a person. The command has to be in accordance with the legal system and those who hold power get their authority from their institutional role. As such, they are also subject to rules which determine their competence.

This Weberian typology has an evolutionist propensity. Legal domination is conceived as rational and superior to the others, on account of its universal orientation. The law is supposed to be equal for everybody, it is clearly differentiated from the person, and has to be written in order to be valid. As such, legal domination is not only fairer than the others, it is also supposed to be more efficient. Moreover, it tends to a homogeneous vision of legitimacy throughout the world and is supposed to transcend the cultural pluralism affecting humankind. Weber has usefully nuanced this construction by conceiving three types of legitimacy as 'pure types,' contrasting with a reality made of a complex combination of all of them. The sources of legitimacy have to be found in the propensity of social relations to be based on loyalty to tradition, the attachment to a charismatic leader, and respect for the law.

2. *Strategies of Legitimization*

This complexity stresses one of the strategic dimensions of legitimization, that is to say the process by which those who hold power strive to make their commands accepted as such. The strategy implies an optimal combination of the three sources of legitimacy and a skillful attempt at persuasion toward the ruled people. The use of traditional legitimacy is a major method for mobilizing different kinds of structures, like communitarian groups, family, tribes, and clans, or for fueling social relations, like clientelism or kinship. Therefore, it is one of the main components of patrimonial domination and is an important device for balancing weakness, crisis, or even the collapse of the state. This is one of the major factors of tribalization where the state is less developed, just as it contributes to explain religious fundamentalism where the political institutions are less efficient. On the other hand, when traditional legitimacy dominates in a political action, the autonomy of power holders tends to be limited, like their capacity to innovate and to create new kinds of commitment.

Charismatic legitimization, however, creates opportunity for innovation, inventing new ideologies, producing new kinds of institution, as it does with prophetic mobilization or during revolutions. Instead of traditional institutions, charismatic legitimacy mobilizes followers and disciples who are swift to trust

in their leader. However, the more domination is purely charismatic, the more it risks being fragile, threatened by a failure or a defeat, the more it lacks permanent structure and institutional order. That is why this kind of legitimacy is relieved by a 'routinization of charisma,' by which the new order turns to a new tradition which hampers the free initiative of the leader.

In the same way, legally sanctioned procedures will limit and even encapsulate political action. Even in modern states, the power holders strive to circumvent these hindrances by reviving traditional legitimacy and by making use of their own charisma. This practice is one of the main ways of by-passing institutional rationality in modern political systems, and is also a source of differentiation among the Western democracies.

The power holder manipulates the legitimizing formulas by achieving a persuasive power on those ruled and striving to create the conditions of a consensus mobilization, that is, a downward process that increases congruence within a society. This consensus mobilization implies a socializing process by which the myths on which legitimacy is based are shared among the member-units. It implies also a propaganda by which political practices are described as conforming to these myths (Etzioni 1968, pp. 361, 470). The myths that are learnt include a world vision and a system of values on which legitimacy is built. Universalism, equality, democracy, human rights, social contract, but also modernity, progress, and rationality are the main components of legal legitimacy which reflects the evolutionist postulate of the convergence among modernizing societies.

3. *Legitimacy and History*

This is the main point stressing the cultural dimension characterizing the sociology of legitimacy. Since it is value-oriented, legitimacy obviously has a cultural orientation, implied by its own history and by the social context of its construction. Historical sociology has shown how legal domination, as it is described by Max Weber, was strongly bound to a religious and cultural situation. Joseph Strayer (1970) pointed out how the Western nation-state authority was transferred from the Roman Church's vision of authority. Reinhard Bendix (1978, p. 247ff.) showed the religious bases of royal authority in Western, Islamic, and Chinese civilization, while he emphasized that the transformation from the rule of king to the government in the name of people supposed an 'intellectual mobilization' which is itself rooted in the social structure and the cultural background of each society. Therefore, the intellectual mobilization has varied from one country to another, both for strategic reasons and according to cultural factors. These differences are real gaps in societies which are clearly far from the Western model of legal authority as the model is built in the cultural context of securalism, Christian delegation of authority and representation, Roman pre-eminence of law and institution.

In this perspective, the sociology of legitimacy should be strongly comparative. It will mobilize close comparison in order to interpret the different ways of legitimization of similar institutions, as de Tocqueville did between France and the USA (Tocqueville 1981). It will also use 'huge comparisons' and stress 'dramatic contrast' for evaluating how the Western legitimacy formulas are able to be imported into Islamic, Asiatic, or African countries (Bendix 1978, Eisenstadt and Rokkan 1973, Badie 1992). The crisis stemming from the impossible transfer and pressure of globalization and homogenization results in a chronic deficit of legitimacy in non-Western countries but also in a dangerous inversion by which power holders are constantly less legitimate than the antisystem political entrepreneurs, who are mobilizing on behalf of revivalism and a true return to endogenuous values. That is why religious fundamentalism or ethnic identity have the monopoly of protest in many developing countries while they tend to embody a strong legitimacy. Consequently, this rift between state power and legitimacy and this dramatic weakening of the consensus mobilization results in a split inside the society, promoting either a quasi-state (Jackson 1990), a 'lame Leviathan' (Callaghy 1987), or a plural society in which legitimacy is entirely encapsulated in the subnational communities (Young 1976).

Thus the sociology of legitimacy also encompasses a sociology of change and a sociology of crisis. Values do not perpetuate themselves without any change among the different social groups. For instance, the increasing influence of postindustrial or postmaterial values implies transformations in the ways of legitimating social institutions (Bell 1960, Inglehart 1977). It will also result in new kinds of social movement (Offe 1985). This intermingling of value systems and mobilizations tends to weaken the consensual formation of legitimacy in modern and postmodern societies. It implies, in them, a competition of visions which are promoting new divisions, instead of furthering a convergence toward a homogeneous modern society; thus legitimacy is nowadays jeopardized by increasing structural oppositions between different kinds of culture: materialism vs. postmaterialism, nationalism vs. transnationalism, liberalism vs. statecentrism, open society vs. closed society. These new changes are cutting across traditional ones and are directly staking out the consensual basis of modern societies in which different collective imaginations of what power should be and how it can be accepted are competing.

In the meantime, turbulence in world politics (Rosenau 1990) is destabilizing the main references of nation-state legitimacy: By promoting transnational relations, it challenges the territorial dimension of

politics and the sovereignty claim of the nation (Biersteker and Weber 1996); by encouraging globalization, it promotes common goods and common global interests and redefines the postulates of democracy (Held 1995). In short, the new dimensions of international relations emancipate legitimacy issues from the nation-state structure and transfer them to broader references: humanity, the global world, world integration, human responsibility (Deng 1997). Therefore, this renewal of the sociology of legitimacy entails new reflections on ethics and international politics (Hassner 1998), on human rights (Mullerson 1997, Sellers 1996), on intervention (Mayall 1996), and on the transformation of international law and the creation of an international criminal court.

At the same time, the discovery and the rise of these new legitimacy issues are balanced by the development of a more positivistic vision of the public policies issues which are understood through the governance paradigm (Rosenau and Czempiel 1992). According to this, the functions of government are monopolized by the state and do not exclusively come within a vertical and hierarchical construction of authority. This last point tends to take political action away from the legitimacy debate: Political action should be appreciated more and more as a technical rather than as a just action. This trend can be analyzed as an ideological attempt at depoliticization and a striving to understate the importance of legitimacy issues in modern societies (Habermas 1975).

Actually, the sociology of legitimacy has also to take into account the intensity of the conscious and willful adherence of each individual to the political and social order. Legitimacy is not only the opposite of coercion, but has also to be distinguished from the passive agreement that political obedience is currently based on. As such, legitimacy is also one of the major components of civic culture.

Leisure and Cultural Consumption

Most definitions of leisure treat it as activity (or inactivity) opposite to or the counterpoint of work. Leisure can be considered as a reward for work, as the purpose for work or as 're-creation' to recover from work. In a postmodern society in which opposites are

increasingly blended, we see attempts by individuals and institutions both to make work more leisurely and to make leisure more work-like. Thus, in their work time, people dress more casually, take sabbaticals or attend retreats; while in their 'harried leisure' away from work they 'work out,' act as purchasing agents for their households, carry laptops into the wilderness or master new work skills.

A classic definition of leisure speaks of it as 'freedom from the necessity of labor.' In the economic sense of that definition, America has become a leisure society *par excellence*, since unprecedented proportions of its citizens no longer need to earn money from their work labors to obtain adequate provisions of food, clothing and shelter. While no one has come forward with a satisfactory estimate of the proportion of the population at that level of economic comfort, it is hard to imagine that it has not increased significantly since the 1950s—probably to include a healthy majority of the US adult population (not to deny the significant minorities who remain below the poverty line and need to work to make ends meet, allowing them minimal opportunity for leisure). Yet, those Americans who have no need to care for minimal creature comforts continue to be drawn to work despite any lack of its necessity for many of them.

Indeed, economists like Schor (1991) argue that 'overworked' Americans are working longer hours and enjoying less leisure than earlier generations—at a time when their counterparts in Europe have much longer vacations and shorter working weeks. Some recent economic reports proclaim that Americans now work even longer hours per year than Japanese workers.

1. Measurement of Work and Free Time

Such arguments are limited methodologically by the data sources involved, in that they are based on estimates made by workers of their work hours rather than more detailed measurement procedures, using on-site observation, electronic pagers or time diaries. One value of time diaries is that workers report on *all* their daily activities, and not just their work time. In accounting for all time, diary figures are less prone than estimates to problems of respondent memory loss, self-projection and double counting of time.

Time-diary figures compiled over the last 35 years show a surprisingly opposite trend from figures from government surveys that ask workers to estimate their working hours (see Sect. 5.4 for some telling biases in these estimates). In diaries, notable declines in time spent at work are recorded rather than the increases or constancies in workers' estimated work hours (Robinson and Godbey 1999). Nor do the diary figures support arguments that there has been increasing variance in work (or free time).

Declines in diary work hours mean that there is more opportunity to use such freed time for 'free time' activities like socializing, fitness activity and mass media use. That opportunity could be lost, however, should the workers in question use that reduced work time for family care or personal care activities.

However, these same diary studies indicate that family care activities have also declined and that personal care has stayed about the same since the 1950s. The surprising result from detailed diary data, then, is that Americans during their prime working years (ages 18–64) now have more free time than in the 1950s or 1960s (Robinson and Godbey 1999).

To some extent, that increased free time has come about because of structural changes in the workforce and population, in that:

(a) workers enter the workforce later in life, mainly because they receive more years of college education;

(b) workers retire at age 62 or earlier, largely due to increased benefits; and

(c) workers past age 65 live longer and thus can enjoy more free time during those retirement years—when most of them are truly freed from the necessity of labor.

The end result is that, when aggregated across a lifetime, a typical person's free time hours will notably outweigh time spent at the workplace (Ausubel and Grubler 1994).

The diary studies suggest that further gains in Americans' free time are also being made during work years in the form of unofficially shorter working weeks, increased holidays and longer vacations. Nonetheless, there remains the question of why Americans continue to work more (and thus forego free time) than they need to, and whether they are incapable of appreciating leisure, as Riesman (1958) worried in the late 1950s.

2. Cultural Consumption

One answer lies in Rainwater's (1979) argument that the costs of the 'survival market basket' keep increasing as community norms and expectations about possessions keep rising. Another is the increased media emphasis on the consumption of goods and services, as characterized by Schor's (1999) 'Overspent American' and by Ritzer's (1999) depiction of 'Cathedrals of Consumption'—the ever-more elegant shopping malls, vacation cruises and home entertainment systems on which Americans spend the incomes they make from their hours at work. The hours invested in these goods and locales suggest that the 'culture' being consumed with these work dollars is rather superficial, redundant and spiritually uninspiring in contrast to classic leisure. On the other hand are arguments from some postmodernists who accept people's 'commodified' popular culture standards as more suitable

Figure 1
Trends in free time in America: 1965–95

for them than those of elitist intellectuals (as argued further below).

Similar arguments arise from examination of the free-time activities chosen by Americans during the hours they are not working. As shown in Fig. 1, close to half of their free time is spent watching television programs that are undemanding and/or uncritical mainly of materialism or environmental degradation. Television hours dwarf time spent reading, and even that reading is rather undemanding (Zill and Winglee 1990). Further concern has arisen over the decreased time spent on 'social capital' free-time activities that provide the important social 'glue' that allows societies to flourish (Putnam 2000). The optimistic finding that fitness activity has almost tripled since the 1970s (as part of other 'healthier' life-style changes, such as decreased smoking or red meat consumption) is offset by suggestions that even these activities are governed by values from work and efficiency experts.

3. *Free Time vs. Leisure*

One political philosopher who foresaw many of these developments was Sebastian DeGrazia (1962). He lamented how modern democracies had overcome the 'tyranny of man' only to submit to the 'tyranny of the clock,' exemplified by the giving of gold watches to retiring employees for whom structured time was now meaningless. DeGrazia made a sharp distinction between free time, which can be quantified, and leisure, which cannot (although if DeGrazia could reliably 'know it when he saw it,' it was measurable in the social science sense). In ancient societies, the purest leisure emerged when individuals pursued activities (music, poetry, literature) from a personal sense of commitment, quality and fulfillment. In modern societies, DeGrazia saw such leisure in decline, even as free time continued to increase.

Perhaps the closest modern equivalent to classic leisure is evident in Csikszentmihalayi's (1990) studies of 'flow,' except that here individuals seek optimal experience and joy in doing. Two ironic features of flow episodes are that (a) the sense of time in a time-oriented society largely disappears and (b) most flow episodes the author cites occur during work time rather than free time.

Like leisure, flow remains unquantified, so it is not clear whether such deep cultural experiences are more or less prevalent. One set of 'high culture' indicators that has been monitored since the 1980s concerns Americans' participation in the arts. Table 1 shows the extent to which these arts activities are engaged in as spectators vs. producers in the most recent national study (Bradshaw 1998). Although level of respondent education is the best predictor of arts participation, and these levels have been rising, trend studies indicate no notable increase in arts participation across time. (The same conclusion emerges from trend studies of other cultural indicators, such as information levels, political participation and of community participation/social capital. Delli Carpini and Keeter 1997; Putnam 2000). At the same time, some scholars have argued that it is remarkable that participation in live arts events has not declined, given the competition from easily accessible media. What is to be gained from attending a live performance of a Beethoven symphony one has heard hundreds of times on the radio, or a live performance of a Shakespeare play, when an episode of *Hill Street Blues* is easier to view and understand? Why visit an art museum when the paintings can be arrayed more meaningfully on an Internet site?

Table 1
Proportions of Americans engaging in various arts activity in prior year (1998 data; ages 18 and older)

	Attend performance	Perform	Perform publicly	Mass media		
				TV	Radio	Records
Jazz	12%	2%	1%	31%	39%	29%
Classical	16	11	1	32	41	34
Opera	5	2	0.3	15	11	11
Musical	25	8	2	25	5	12
Plays	16	N/A	N/A	23	N/A	6
Ballet	6	0.5	0.3	39	N/A	N/A
Other dance	12	13	2	N/A	N/A	N/A
Art museum	35	16	3	45	N/A	N/A
Literature	63 (Read)	12 (Write)	1	N/A	N/A	N/A

N/A Question not asked

The time-diary studies indicate that less than one percent of Americans' free time is devoted to such arts participation activities, too small to be detectable in the 'recreation' block in Fig. 1. Even the Table 1 entries total less than five episodes, or less than 20 hours, of high culture participation per year.

Nonetheless, these data sources do point to several important conclusions about the nature of such high culture activities, in that they are engaged in more by (a) better-educated individuals (also true for many popular culture activities), and (b) busy individuals who have a long working week and are heavily involved in other activities.

Both findings fit in to a larger 'Newtonian' pattern of behavior, in which 'Bodies in motion stay in motion' that applies to other leisure behavior (a corollary to Parkinson's Law that 'If you want something done, give it to a busy person').

4. *Correlates of Free Time*

Who, then, has more of the resource of free time, which at least affords the opportunity or leisure, even if rarely used for that purpose?

4.1 *Gender*

While American women are generally thought to have much less free time than men, that is only true for women who are employed (Robinson and Godbey 1999). Because many women (aged 18–64) remain out of the labor force, however, the free time of women and men is surprisingly similar (as well as what they do in that free time). The gender inequality that is found is between working and non-working women, and that gap has been increasing over time. Much the same gender patterns have been found in most other Western countries (Goldschmidt-Claremont and Pagnossin-Aligisakis 1995).

4.2 *Age*

As expected, free time is U-shaped across the life-cycle, reaching more than 40 hours a week for teens and young adults, dropping to 30 hours or less for those raising families during the peak career years of their 30s and 40s, then rising to 40 hours again in the 'empty nest' years and approaching 50 hours in the retirement years.

The main reason for this curve is not age *per se* but the various role obligations that peak in middle age—namely work, marriage, and children. The more hours of work, obviously the less free time; however, as noted above, there is far from a 1:1 correspondence. Moreover, workers who put in long hours are more active in the arts, in fitness activity, in civic participation, and in sexual activity (Robinson and Godbey 1999; Putnam 2000). Getting married usually means less free time as well, as does having children, so that married women with children have 10–15 hours less free time a week than single childless women of equivalent work status.

4.3 *Status*

While social status may be a most powerful predictor of one's power, resources, attitudes or behavior, it has little to do with how much free time people have. Part of that is due to the greater enjoyment of work (and other leisurely features) among higher status workers and the need for lower status workers to work longer hours to offset their lower wages. The rich 'leisure class' of which Veblen (1899) wrote so critically over a century ago seems to have given way to rich people who work 80–90-hour weeks today. Indeed, working long hours has become something of a status symbol in its own right, and Hochschild (1997) has documented how certain workers treat work as a consumption activity.

4.4 Ecology

Surprisingly little difference in free time can be found by region, and in presumably less hectic rural areas; nor are notable differences found in different seasons of the year.

5. Subjective Aspects of Free Time

Since leisure has been argued to be a fundamentally subjective state, it should require more subjective measures to reflect it. Four types of subjective measures that have been proposed as reflective of greater leisure include are discussed next.

5.1 Greater Enjoyment

When asked to rate the enjoyment levels of different activities in their time diaries, people also rate free-time activities higher than work, but the differences are not great; moreover, the lowest-rated daily activities usually involve housework or medical treatment (not work), and the personal care activities of eating and sleeping are rated higher than most free-time activities. Indeed, when asked to rate them side-by-side, most workers rate their enjoyment of work and free-time activities equally. Saturday and Sunday activities, when free time is 50 percent higher per day than during the week, are rated as no more enjoyable than weekday activities, further supporting the indistinguishability of work and free time.

5.2 Less Time Pressure

Despite the increased free time in society, more people now describe their lives as 'always rushed' than they did 35 years ago, with less discretionary 'time on their hands.' About half of Americans describe their lives as at least moderately stressful, and continue to report that they would give up a day's pay to get a day off from work. At the same time, more Americans say they would prefer to work longer hours in general—presumably to earn extra money.

5.3 Less Fatigue

Fewer than 25 percent of workers say they are 'very tired' at the end of their work day—much the same as found in 1975. More educated workers are less likely to feel tired, as are male workers in general.

5.4 Appreciation of Quality

The arts surveys *do* find increasing proportions of Americans saying that they enjoy more 'sophisticated' forms of music like classical music or jazz. There is evidence as well of consumption of more 'gourmet' foods and beverages. Instructive data may come from patterns of beer consumption, in which American microbreweries have taken the lead in developing classic and innovative new styles, but these have yet to capture more than 3 percent of the market; the mass-produced counterparts still claim over 90 percent of the market and there is evidence that the mass-produced product is becoming less complex over time.

Further clues to how Americans feel about their time and leisure emerge from comparing their estimated activity times with their time-diary activity times. As noted above, work activities are overestimated (by 10–15 percent) but not as much as housework and other family care activities (40–50 percent) or volunteering (200–500 percent). Sleep is underestimated by an hour a day, while free time is underestimated by 50 percent or more (18 hours estimated vs. close to 40 diary hours). (TV time, surprisingly, is accurately estimated.)

The lives that Americans think they are leading, in other words, seem to match Weber's 'Protestant ethic' more than the behavior respondents report in their time diaries.

6. International Comparisons

The conclusions drawn above refer mainly to studies conducted in the USA. Many of them, however, have been replicated in other Western societies, particularly studies of time use. Using data from the 20-country archive of time-diary studies at the University of Essex in England, for example, Bittman (1998) found average cross-countries gains in free time in the period from the mid-1960s to the mid-1990s. These gains largely mirrored those reported by Robinson and Godbey (1999) for the USA. Bittman found most weekly free time reported in diaries dating from about 1978 from the Netherlands (43 hours) and Denmark (47 hours) and least in France (31 hours) and Hungary (25 hours), with the USA (34 hours) about midway between these extremes.

Based on the Essex archive database, however, Gershuny and Fisher (2000) found that British respondents in 1996 did not report more free time than they did in the 1970s. He also found an international trend toward more work hours for upper middle-class respondents across time, as work hours for the working class declined. Again, the extent that such workers experienced more leisure or pleasure from that work suggests the need for more qualitative studies. In examining specific countries in more detail, Robinson and Godbey (1999) found both objective and subjective measures of time pressure to be rather similar in the USA and in Canada. In Japan, free time had increased from 1975 to 1991, much as in the USA over the same period, with surprisingly similar overall amounts of free time in the two countries.

However, on various measures of time pressure, Japanese respondents reported lower levels of stress and subjective pressure than US respondents. In Russia, free time also increased between 1965 and the 1990s, but was still well below US levels. Reports of time pressure in Russia, in contrast, were higher than in the USA.

In all these countries, the correlations of free time and time pressure with demographic factors were rather similar to those in the USA. Women, the more highly educated, and those in their 30s reported most time problems.

7. *Summary*

The American way of life, which is increasingly emulated in other countries, has created more free time and thus far more opportunity for leisure. However, people describe their lives as increasingly hectic and remain committed to working longer hours than necessary, presumably to keep up with the culture of consumerism. Work seems to provide more enjoyment for people than is commonly believed, even if it may be far from the ideals of leisure identified by philosophers and leisure scholars.

What is needed to advance our understanding and levels of argument is more qualitative study of the meaning of various activities in people's lives. There are several excellent individual studies of this type (e.g., Viditch and Bensman 1959), but they, too, rarely connect with one another, address issues raised by quantitative research, or are conducted with representative samples. The meaning of free time and leisure could be the ideal focus for studies using the 'representative ethnography' approach described in Robinson and Meadow (1982).

What is it, then, that would represent uses of free time to satisfy criteria for leisure, or the improved quality of life implied by the term 'leisure'? Various philosophers and social critics offer alternative criteria and rare unanimity, but one notes some of the following features of experiences or activities that involve the individual developing:

(a) a (non-work) skill or talent for its own sake;
(b) a more discriminating palate or set of tastes;
(c) a personal cosmology or philosophy of life;
(d) spiritual regeneration or insight;
(e) stronger ties to some larger community;
(f) greater self-actualization; and
(g) elements of play, curiosity, and wonder.

What seems to be called for at this point is the operationalization of a set of reliable and valid 'leisure indicators' based on such concepts, that could be regularly monitored to reflect whether progress is being made on the non-material, as well as the material, quality of non-work time.

Leisure, Psychology of

The boundaries between the everyday and the scientific understanding of leisure are blurred, and the ambiguity of the term's usage in everyday language is reflected in the lack of a standard definition in the

social sciences. The first and broadest definition is based on a narrow understanding of work as paid work. Here leisure is understood to mean time free from paid work, the entire nonoccupational domain of life. In the same way as paid work reflects the obligation to secure the necessities of life and is heteronomous, leisure has connotations of freedom and autonomy. The main problem with this definition is that housework and reproductive work in the family are also accomplished in 'free' time. Such activities, for which women bear greater responsibility than men, are thus not considered to be 'real' work and are devalued in relation to paid work.

This problem does not arise in the second, narrower definition. Here, not only paid work, but all other 'obligatory' activities, and phases of passivity, such as housework, periods of mobility such as travel between the home and the workplace, time spent asleep, and so forth, are subtracted from the total time. In contrast to such obligatory activities and passive periods, the implicit view of leisure is now more that of an autonomous domain at the individual's free disposal. However, this disregards the possibilities that occupational activities may involve autonomy or, conversely, that leisure may entail external control, constraints, and duties.

In the even narrower third definition, leisure is limited to the domain which individuals describe as such, the area they see as their realm of personal freedom. As autonomy is often linked to hedonism, subjective definitions of leisure tend to overlook self-imposed duties and restrictions.

1. *The Change in Meaning of Work and Leisure*

The conception of leisure as a domain of individual autonomy evident in all definitions only developed in the nineteenth century and in contrast to the meaning of work. Prior to this, work, residence, and family life all occurred in one place, in the same environment across the lifespan. In the course of industrialization an increasingly distinct segmentation of work and leisure began. The understanding of freedom and individual autonomy could no longer be reconciled with restrictive work (in the sense of industrial labor), and instead became associated with the modern concept of leisure as the 'free' time outside of contractually defined working hours. While the working week of industrial laborers was more than 80 hours in the middle of the nineteenth century, most employees at the beginning of the twenty-first century work less than half of this, and paid work is no longer characterized by restrictions alone. Nevertheless, the understanding of a segmentation of life has survived in cases where restrictive work is still strictly separated in time and space from all activities with greater scopes of action.

The modernization process of the twentieth century was characterized by both differentiation of the spectrum ranging from restrictive labor to the independent professions and differentiation of the partly autonomous, partly heteronomous areas between work and leisure. In recent decades, there has also been a general change in values, which has implied a shift—rather than a loss—in the meaning of work. Paid work is again more strongly determined by the demand for autonomy and self-realization, and leisure time is increasingly characterized by constraints and duties.

At the beginning of the twenty-first century, a complete dissolution of the work–nonwork segmentation can frequently be observed. This is the case wherever autonomy is required in the increasingly flexible regulation of the times, places, contents, and forms of work, and wherever unpaid work in leisure time is increasing. One can almost speak of an obligation to autonomy or controlled autonomy. This can also be said for leisure in the narrowest sense of the definition. Time at the individual's free disposal is increasingly seen as time for 'work' on oneself, for example, on one's body. The differentiation of each domain of life and the dissolution of the clear spatial and temporal boundaries between them mean that new, autonomous forms of coordination and integration are required: activities spread over the course of the days, weeks, and years must be cognitively related to one another, screened for interactions and priorities, planned in time and space, negotiated with partners, and so forth. Here again, the experience of freedom is linked to that of constraint.

2. *Leisure Research in Psychology and the Social Sciences*

Against this background, the research traditions can now be enumerated: first, leisure research across the disciplines is based on the narrow definitions and investigates leisure without reference to work. Second, psychological research takes theoretically based approaches with rather different themes, and studies subjectively significant, autonomous goals, thus indirectly dealing with leisure in the narrowest sense. Third, work–nonwork research with a sociological and psychological orientation is explicitly directed at the relationships between the domains of life. Here, the broad view of leisure—that is, time free from paid work—is taken, and insufficient attention is paid to the domains of housework and family life, for which women bear greater responsibility.

The first, applied field of leisure research does not take theoretically original approaches, and some of the many studies on, for example, time budgets or attitudes borrow theories from sociology (with respect to lifestyles or changes in values) or from developmental psychology (concepts of the stages of life). The studies deal with the use of various media, communication technology, cultural programs and

consumer goods, with travel aspirations, favorite hobbies, sports, and so forth. Particular areas of leisure time are brought to the fore, as are intragroup and intergroup comparisons on the basis of age, cohort, social status, gender, and so forth.

The second field comprises theoretically based psychological approaches to 'personal projects,' 'personal goals,' and 'personal strivings,' intersecting with self-concept and identity research as well as motivation and action theory (e.g., Little 1993, Beck 1996). Here, it is not directly a question of leisure, but of the subjective structuring of complex, longer term fields of action in everyday life and across the lifespan. However, it is noticeable that such projects often fall under leisure in the narrowest sense of the definition. Above all, when a number of action situations can be clustered together in a longer-term project with an overarching goal, the associated experiences of autonomy and heteronomy, and self-efficacy or control, are constitutive for self-concept and identity.

3. *Research on the Relationships between the Domains of Life*

In the third field of work–leisure research, individuals are not asked directly about the relationships between their thoughts, feelings, and actions in the two main domains of life. Instead, the features of each domain are surveyed separately and then correlated. Hence, indicators of experiences and actions at work are gathered on the one hand, and indicators of leisure behavior (e.g., time budgets for hobbies, membership of associations) and leisure satisfaction on the other. Results can be classified according to the central research hypotheses (Wilensky 1962). The 'generalization hypothesis' assumes a transfer of subjective positive or negative cognitions, emotions, and behavioral patterns from one domain to the other. Hitherto, the 'the long arm of the job' (Meissner 1971) has been emphasized, and the findings of many studies conducted in the USA have been interpreted in the sense of a rather one-sided influence of work on leisure. The 'compensation hypothesis' implies that it is possible to compensate for negatively valued experiences and behavioral patterns at work by engaging in positively valued ones in leisure time. This hypothesis is supported by weaker findings in subdomains and subpopulations. The 'neutrality hypothesis' postulates that thoughts, feelings, and actions in the two domains of life are unrelated. Weak or zero-order correlations in most of the studies conducted in the German-speaking countries seem to support this hypothesis.

Numerous objections can be raised to the majority of the studies. Cross-sectional studies do not show whether one-sided influences, such as that of leisure on work, or interactive processes are operating. Furthermore, the processes of generalization and compensation are not necessarily mutually exclusive, and positive correlations in certain subgroups can be canceled out by negative ones in others, resulting in zero-order correlations. In this context, however, it should be noted that compared with the original work–nonwork research (Staines 1980), later studies were more likely to differentiate between occupational groups (e.g., Kabanoff and O'Brien 1986) and emphasize the impact of the increase in women's employment on their work-free domain and associated life satisfaction (e.g., Tait et al. 1989).

Figure 1
Classification of subjective theories. The relationships between work (W) and leisure (L) are symbolized by connecting lines; the directions of determination are indicated by arrows; the valences of the domains of life are marked as positive (+) or negative (−)

One objection to the neutrality hypothesis opens up a new perspective: if the assumption that there is no consistency of actions between the two domains of life (or that these are determined by different personality traits) is rejected on the basis of an interactional paradigm, zero-order correlations must be interpreted differently. These may well signify a subjective conception that one's own thoughts, feelings, and actions are independent. This conception could then be interpreted as a compensatory strategy operating whenever extremely negative experiences at work threaten to overshadow leisure time.

When adults are directly asked whether they see a relationship between the two domains of life, the classification of subjective 'theories,' that is, conceptual patterns, shown in Fig. 1 is obtained (Hoff 1992). Thus, not only conceptions in which work is seen as the cause of leisure experiences and actions (forms 2–5), but ones which postulate a reversed influence of leisure on work (forms 6–9) are conceivable. It is evident that private problems can be compensated in working life (form 6), or that thoughts about favorite nonwork activities can detract from work (form 7). The final form (10) consists of a reciprocal interaction of the thoughts, feelings, and actions of occupational and private life.

This classification has proved its worth in first empirical investigations. Subjective conceptual patterns can also be formulated in a generalized form and in view of personal past and future. They develop over the course of the occupational and nonoccupational

biography in connection with real constellations of restrictions and scopes of action.

4. Final Remarks on Future Research

As mentioned above, insufficient attention has been paid to housework and family life in work–leisure research. While the significance of this field has decreased since the early 1990s, there has been an expansion in research investigating the relationships between occupation and family life. Here, equally little attention has been paid to leisure in the narrow sense. Topics of investigation include conflicts due to the discrepancy of occupational and private goals, the double burden placed on working mothers, and integration problems both in everyday life and in the planning of the life course. In the future it would be useful to relate the research traditions of work and leisure to those of career and family—this would be of interest primarily where new forms of work such as tele-homework (cf. Büssing and Aumann 1996) are concerned. Occupational and gender comparisons would then be possible, and the significance of both leisure (in relation to paid work and the family) and family life and housework (in relation to paid work and leisure) could be investigated. Further research topics could include partners and their shared organization of leisure, their shared projects, and the ways in which they manage to integrate the shared domains across the life course.

Leisure, Sociology of

Leisure studies, paradoxically, are as much about work as about leisure. Indeed, central issues in the sociology of leisure revolve around leisure activities' emergence from historical changes in the structure and organization of work, the effects of work on workers and their 'need' for leisure, and the 'consumption' of leisure made possible by employed labor in the West. There are widely differing social science views on the character and meaning of leisure in the modern day, and they reflect both disciplinary and ideological stances of the researchers. This article characterizes recent approaches to the study of leisure by sociologists. It reviews the history of leisure as a sphere of activity in the West and looks at two themes that organize much of the literature on leisure—the time and place of leisure, and leisure as a reflection of culture. Finally, the article suggests trends that will likely inspire changes in leisure patterns and, hence, sociological research.

1. Approaches to Leisure

Although leisure is an increasingly organized and economically important social activity in the developed world, sociologists have rarely made leisure a central focus of study. Rather, leisure is typically treated as ancillary to the study of work, and sometimes to the study of culture. Work, sociologists often assume, defines the character, need, type, and meaning of leisure, making leisure a consequence, or a residual category in studies of work.

Sociologists are not the only social scientists to study leisure. Neoclassical economists typically defined leisure as 'nonwork,' the time 'left over' after work, with workers' preferences determining how they allocate their time. Gary Becker (1965) revised this presumption by arguing that leisure, as well as work, is an economic activity. Leisure is the time used for consuming goods purchased through wages. Recent economic approaches follow on Becker's ideas and often concern the ways in which people make tradeoffs

in their expenditure of time working or consuming. For example, economists have examined the ways in which culture (Scitovsky [1976] 1992) and regulation affect this tradeoff (Schor 1991).

Anthropologists and some sociologists have treated leisure as a form of cultural activity that includes artistic expression, play, and community building (Fine and Holyfield 1996). Anthropologists have been concerned with the impact of the recreation activities of the affluent of the developed world on the culture of those who inhabit underdeveloped regions being transformed by tourism.

Social psychologists treat leisure as an activity that can contribute to the mental and social health of actors, a sense of 'well-being.' For example, those who work too much and leisure too little can become stressed and suffer social pathologies such as isolation. Social psychologists look at the role of leisure in the life course, trying to ascertain how organized leisure contributes to social integration and psychological well-being. This approach underlies much of the curricula of professional recreation management programs and marketing studies examining the impulse for the consumption of leisure (Zins 1998).

Sociologists have tended to view leisure from the perspectives of either social class or culture, or sometimes both (Biggart 1994). Class theorists, largely rooted in British sociology, focus on the conditions that create different life circumstances for workers and see leisure variously as an opiate for harsh work conditions or as ameliorating those conditions. Culture theorists focus on leisure as either an expression of values—including gender, class, and racial values—or as an autonomous sphere that produces cultural values.

2. *Work and Leisure in Historical Perspective*

Sociologists and social historians have conducted a long-running debate on whether leisure, as a separate sphere of activity, is a modern concept in the West (nearly all studies of leisure are concerned with leisure in Western civilization). The historical record certainly shows that people have always had leisure activities. In the Greece of Aristotle's era, leisure, not work, was considered the highest form of occupation. Sports and cultural activities were important elements in the ethic of self-cultivation held by elite Athenians who did not need to work; productive labor was largely performed by slave labor and agricultural territories under military control.

In the feudal period of European history elites continued to live lives of leisure when not conducting military activities. Chivalric games and hunting served both as recreation and practice for military endeavors. Peasants, too, had ample time off from work when compared against modern standards. The workday was dictated by the amount of daylight and the demands of agriculture, and was as long as 16 hours in the summer. Tradition, however, conferred time for three meals a day, naps, and refreshments. Historians have also noted that workers sometimes 'played' while working, for example by singing and dancing as they labored. The number of days free from work varied in different parts of Europe, but probably averaged about one-third of the year. The religious tenor of the time assured observances for holy days of various sorts including long Christmas and Easter breaks and observances for the birthdays of saints. The word 'holiday' comes from 'holy day.'

Although there was ample free time in premodern Europe, was it leisure in the modern sense of time away from work (see Marfany and Burke 1997). Clearly, both elites and the lower orders amused themselves at fairs and tournaments, and had substantial free time, but they did not 'go to work' or 'go on vacation.' Life was lived more holistically with little separation between labor, leisure, religion, and secular life.

The ascent of industrial capitalism gave rise to the idea of work as a separate sphere of life and, therefore, to leisure as an alternative set of activities. The newly affluent ownership classes emulated the traditional aristocracy in leisure activities such as travel to spas and exotic locales. Workers displaced from traditional rural roots found leisure in drinking establishments, and a new commercial leisure industry rose to provide workers with travel and space for taking holidays at newly constructed seaside resorts and sporting arenas. The owners of new transportation technologies, such as trains, promoted their use for leisure excursions.

3. *Time and Place*

Paradoxically, it was the industrialization and urbanization of work that led to leisure as it is known in the modern world, the recreation (literally 're-creation') of the worker. Removed from the land and forced to find work in urban factories, laborers were also removed from traditional land-based activities such as hunting, fishing, and outdoor games. The time devoted to work grew dramatically with industrialization, too, from less than 2,000 hours in 1600 for an English male, to more than 3,500 hours in 1840, often under brutish factory conditions (Schor 1991, p. 45).

The idea of the 'workday' as fixed time for labor started in the fourteenth century in textile mill towns (Le Goff 1980). Employers rationalized work hours and pay, and instituted 'work bells' to note the beginning and end of a standardized day of employment. Although vigorously opposed by workers, the idea of a workday and the temporal control of labor were well established by the eighteenth century. There was relatively little free time for leisure in the eighteenth century, however, in either Europe or the

USA, but the time away from work was indisputably 'owned' by the worker. The separation of private and work spheres was a firmly incorporated understanding by then.

The factory system and other technological advances greatly improved worker productivity during the nineteenth century, and labor hours gradually shortened. Workers had more time in which to leisure and by the end of the century a 'leisure ethic' developed. This ethic encouraged people to use spare time for self-cultivation and civic activities. It was an era of the development of clubs—for gardening, sports, hobbies, and all manner of scientific and literary pursuits—and physical education programs in schools and colleges. It was also the period in which governments began to develop park and recreation facilities, and to see their management as a government responsibility.

World War I and its aftermath quickly ended the leisure ethic and the movement toward a shorter workday in the USA. The industrial complex that developed during the War spewed out more goods than a peacetime economy would consume. Concerned about economic growth, retailers and manufacturers promoted consumption through advertising and credit sales. A consumption ethic—'to consume is to be modern'—was widely promoted by business.

Labor practices established in the twentieth century have greatly influenced the availability of leisure for many workers. In the early decades of the century managers began to receive paid time off as a benefit, but by 1955, 90 percent of US industrial workers enjoyed paid vacations (Editors of *Fortune* 1958). After the depression of the 1930s, welfare state policies more firmly regulated work hours and conditions in developed nations. In the USA the eight-hour day was designed in part to spread available work to more laborers. Coupled with a consumption ethic, workers had both the time and justification for consumption of leisure products and services after World War II. Leisure as cultural and social practice, and as an industry, began to take its modern form.

This brief account obscures important variations. Leisure time has varied by race, social class, gender, and other social categories. African-Americans, for example, never had the same rates of regular employment as the white majority. Social and economic exclusion historically created forced 'leisure,' with some arguing that this time gave birth to cultural creativity in music and other art forms (La Rose 1996). Time budget studies of North America and Europe show that women do more childcare and housework and have less time to leisure than men (Hochschild 1997, Pronovost 1998). Europeans leisure considerably more than North Americans. Some argue that this is because Americans value consumption of material goods more than time off, but others argue that Americans have little choice about the hours they work (see Schor 1991).

Leisure practices vary by cohort and place in the life cycle, too (Pronovost 1998). Cohorts are groups of people born at about the same time. Leisure researchers note, for example, that adults born after World War II—the 'baby boomers'—have higher rates of cultural participation (e.g., museum going, theater attendance) than cohorts born earlier. In part this is due to the 'period effect' of being born during an era of prosperity with an emphasis on education. Cohorts tend to change their leisure habits depending on where they are in the life cycle, too. For example, young people consume more mass media such as films and popular music, and are more likely to participate in physically active sports than those over the age of 40.

Older people in the developed West are expected to—and expect to—retire. Retirement, a period of leisure and consumption, is expected to follow a period of work and production. Retirement is an idea that emerged at the end of the nineteenth century (Graebner 1980) and is supported by legislation, government welfare programs, the investment industry, and social expectations. Retirees are important targets of the leisure industry as retirement has increasingly been defined as a period of activity for the consumption of travel, education, and sports such as golf and organized exercise.

4. *Culture and Leisure*

The sociology of leisure increasingly has been entwined with cultural studies. Social historians and sociologists have noted that leisure practice, indeed the idea of leisure, is always imbricated with cultural values. For citizens of Ancient Greece, leisure was highly valued as a time for discussion and contemplation because elites placed a high value on self-perfection (the original meaning of 'scholar' is *to leisure*). In religious premodern Europe, holy days taken off from work were intended in part as time for devotion. In contrast, the Puritan colonists of America frowned on leisure as time taken away from the performance of God's work; they saw leisure as performing the work of the devil and prohibited dancing and card playing. In an era of rising productivity at the end of the nineteenth century, US values shifted toward the *proper* use of leisure as good for civil society and good for the development of the self. The Young Men's Christian Association (YMCA) dates from this period. Its secularized vision promoted physical fitness as part of the development of moral character. Leisure ideologies and practices are a useful lens through which to understand the character of a society.

Recent culture studies scholars have continued the tradition of understanding social order through leisure practices. The mass production and commodification

of leisure goods and services have given people of modest means and social status access to recreation activities that once were limited to the truly affluent. Cruises, time-share condominiums in luxury resort areas, user-friendly museum exhibits, and foreign cuisine are within the means and understanding of many employed workers. Global trade in media images and cultural goods transform traditional authority relations and cultural experiences once segregated by class and ethnicity.

5. Trends

Leisure is now firmly established as an acceptable and even expected part of a good life. Social practice and government regulation to limit work hours, and rising affluence in rich countries have given firm footing to the development of the leisure industry. Indeed, the scholarly recognition of leisure as an economically significant part of the economy is overdue. Spending on travel, entertainment, and vacations in the early 1900s represented about 2–3 percent of GDP in the USA, but grew to an extraordinary 10 percent of GDP by the end of the twentieth century. The influence of international travel and leisure activities on local income is substantial for a number of tourist destination cities and regions. International travel affects the balance of payments of nations. The leisure industry is increasingly large, professionalized, and globalized, and is both cause and effect of cultural and economic shifts.

The movement of people around the world for reasons of recreation, whether through travel or vicariously through film and television, has made distant events take on an immediacy and relevancy not true for earlier generations. Politics is no longer merely local, and causes such as environmentalism and ethnic conflicts take on new meaning for well-traveled populations and consumers of media images. Adventure travel and ecotourism to Nepal and the Galapagos can become the foundation for activism at home. The political implications of contemporary leisure have barely been noted.

The unification of work and play in preindustrial society was transformed into separate geographic and temporal spheres under capitalism. There is evidence that the relationship between work and play is shifting again, at least in some industries. Information technology, especially, is making it possible to work at all times of the day and night in any location. The eight-hour day has little meaning for many knowledge workers, the vanguard laborer of the twenty-first century. Many work from their residences and the rigid boundaries between the workplace and home have little meaning. Leisure practices will remain entwined with the organization of work, but in new configurations.

Lesbians: Historical Perspectives

A discussion of lesbian history requires, first, the definition of the term 'lesbian.' Contemporary popular understandings of the concept rest in part on the sexual identities asserted explicitly by individuals, groups, and communities. Herein lies the difficulty for historians. How does one talk about sexual identity, especially cross-culturally and during periods when such identities were not necessarily linked to particular kinds of sexual behavior? How does one talk about sexual identity cross-culturally or during periods in

which the meanings of such behaviors were dramatically different than they are in the early twenty-first century? Can we use the term lesbian to describe only those women whom we can 'prove' had genital sexual contact with one another? Or should we broaden our definition to encompass multiple kinds of passions between women, including intimate friendships that might or might not have been sexual? Alternatively, should we talk only about lesbians historically when women identify themselves explicitly as 'lovers of women' or at the points when self-conscious communities formed around shared sexual identities? The answers to and debates over these questions have served as points of departure for scholars seeking to illuminate lesbian history. Such answers also require locating historical records that speak of female same-sex erotic ties—a challenge that is compounded by the fact that women generally left few sources behind. The records become even scarcer when the focus is on women from subordinate racial or ethnic groups or the lower classes.

Like the field of women's history, initial scholarly forays into lesbian history concentrated on individual women such as Anne Lister. Lister was an early nineteenth-century English 'gentlewoman' who, in coded diary entries, recorded the details of her sexual involvement with other women. Anne Lister understood herself as a woman who was attracted to and enjoyed sex with other women and she developed what one historian has characterized as an elaborate sexual 'vocabulary' to define her desire (Vicinus 1996). That she hid her records of her sexual relationships from potentially prying eyes through coded language suggests that she also understood that others might judge her sexual desires and actions as 'deviant.' With Lister we have all the needed ingredients to make a clear judgement that she was a lesbian—written discussion of genital sexual contact with other women available for scholarly perusal, a self-awareness, and an explicit statement of her desire for other women. Legal records provide similar unequivocal evidence of sexual contact between women. During the same historical period Amsterdam court records demonstrate a flurry of prosecutions of women for 'tribadism.' Defined as sexual acts between two women that approximated the sexual interaction between a man and his wife, these cases also seem to provide indisputable evidence of 'lesbianism' (Van der Meer 1991).

But what about other relations between women that were more ambiguous? One of the key paradigms for researching lesbian history has been that of 'romantic friendships.' The term was used to describe intimate relationships between women from the seventeenth through the twentieth centuries, characterized by declarations of undying love for one another expressed in poetry and passionate letters replete with references to kissing, cuddling, and sharing a bed. Some historians have defined these relationships, especially during the eighteenth and early nineteenth centuries in Western Europe and the United States, as marking almost a lesbian 'golden age.' According to this perspective, during this period women's abiding affection for other women, especially in the emerging bourgeoisie, was not perceived as threatening to either heterosexual marriage or dominant standards of sexual morality (Faderman in Smith-Rosenberg 1985). In fact, the cultural norm of intense female friendships among white women of the middling and upper classes was well established in England and the United States by the eighteenth century and rested on constructions of women from the dominant race and class as by nature virtuous and predominantly asexual. Thus, the acceptability of these relationships resided in their ostensibly nonsexual nature, women in these relationships characterized their feelings for one another as 'love,' yet did not proclaim, and often disclaimed any erotic attachment. There are numerous examples of 'romantic friendships' that conform to this platonic model, while others suggest relationships of a more explicitly sexual nature. Mary Grew and Margaret Burleigh were lifelong companions in eighteenth-century America.

In writing of their friendship, Grew characterized it as a 'closer union than that of most marriages' while also describing her love for Burleigh as 'spiritual' not 'passionate' nor 'sexual.' Almost a century later, however, two other 'romantic friends,' Molly and Helena, implicitly acknowledge the passion that was central to their relationship. In a letter just prior to Helena's marriage, Molly wrote to Helena's betrothed that she and Helena had loved each other 'almost as girls love their lovers' (Smith-Rosenberg 1985). At the same time Frances Willard, a white middle-class female activist and creator of the Women's Christian Temperance Union, agonized in her diaries about her love for Mary, her brother's fiancée. She understood this love to be 'abnormal' and reproached herself endlessly for the desires she felt toward her friend (Gifford 1995). In another example, two free African-American women, Addie Brown and Rebecca Primus, were involved for nine years in a relationship that was both 'highly visible' within their Hartford, Connecticut, community and explicitly sexual (Vicinus 1996). Moreover, even in relationships that generally were perceived as 'above reproach,' popular suspicions of sexual deviance abounded. Jane Pirie and Marianne Woods were 'romantic friends' who opened a boarding school for young girls in Edinburgh in 1809. In 1810 the grandmother of one of the girls withdrew her granddaughter from the school for 'very serious reasons'—her granddaughter, Jane Cumming, alleged a sexual relationship between the two women. Pirie and Woods sued the grandmother, Lady Cumming Gordon, for libel and eventually won their case. It remained nonetheless a pyrhhic victory as they had lost all of their material means during the course of the nine-year litigation. For Pirie and Woods, the allegation itself might not have been sufficient to stir the

countryside, but their long companionship, lack of male suitors, and commitment to reside together combined to heighten fears of sexual deviance (Moore 1992 in Vicinus 1996).

Characterizing these diverse examples as lesbian turns on the question of how we define the term. Is spiritual love between women sufficient for such a definition? Is explicitly sexual love sufficient? Must the women themselves or the culture in which they reside perceive such relationships as 'deviant' from heterosexual norms of behavior in order to speak of them as lesbian?

Romantic friendships would continue as one dominant framework for relationships between women into the twentieth century in both Western Europe and the United States. By the late nineteenth and early twentieth centuries, however, the infant 'sciences' of sexology and psychology were beginning to identify such relationships as sexually deviant. Sexologists like Magnus Hirschfeld (Germany), Richard von Kraft Ebbing (Germany), and Havelock Ellis (England) characterized same-sex relations between both men and women as 'sexual inversion.' While 'romantic friendships' generally were depicted as the 'least deviant' form of such 'inversion,' their formal inclusion in the category nonetheless resulted in heightened public scrutiny of close female 'friendships.' At a point historically when some white, middle- and upper-class women were increasingly able to survive economically outside of marriage, the classification of their intimate friendships with other women as potentially deviant was a serious blow to such involvements as well as to the emerging female public activism that these relationships engendered and maintained.

According to sexologists the 'most deviant' form of same-sex relations were those that involved a 'masculine' or 'mannish' woman and a 'feminine' female counterpart.

Scholars' attention to the 'mannish' woman and female cross-dresser has been another mode of inquiry for historians of lesbians. Cross-dressing, in the literal sense, sometimes, though not always, signified sexual desire for another woman. In the Western tradition, the cross-dresser also was symbolic of the potential female usurpation of male social, economic, and sexual power and privilege. In indigenous North American cultures prior to European colonization, in contrast, the female assumption of a male gender identity and vice-versa ritually was scripted and provided for women to engage in male work, adopt male dress, attire, and social standing and also allowed for such women to take wives. The Navajo used the term *nadle* to refer to a woman who had been transformed ritually into a man. This man was honored by the culture. In other cultures like the Lakota this change involved a woman becoming a third category or 'man/woman.' These ritual alterations institutionalized same-sex sexual relations and the Mohave had a particular word to describe the sexual relations between a transformed woman and her female sexual partner or wife (Roscoe 1988, Rupp 1999). In contrast, female cross-dressing in Western Europe and the United States was an explicit transgression of gender boundaries and from the seventeenth through the twentieth centuries carried with it the presumption of sexual deviance. That said, European and Euro-American women donned male attire for a variety of reasons, including accessing the greater economic, social, and sexual freedoms that were available to men. There were untold numbers of women who cross-dressed and served in the military as sailors and soldiers. We have the stories only of those whose identity was exposed for some reason. Once discovered cross-dressing women often faced public censure and some were tried under fraud and impersonation laws. Catherine Margaretha Linck was a cross-dressing soldier in eighteenth-century Germany. After leaving the army Linck married a woman. Her/his masquerade was discovered when his/her wife told her mother of Linck's secret, resulting in the mother bringing Linck to court for the deception (Faderman 1981, Rupp 1999).

While Linck was sentenced to death for her/his transgression, other cross-dressing soldiers who were 'discovered' faced lesser punishments for their acts and some were even lauded publicly. Deborah Samson was a cross-dressing soldier who served in the Continental Army during the American Revolution. Samson's 'exploits' were celebrated as epitomizing the patriotic fervor of the colonists in their war against England. Although Samson married a man after leaving military service, the presumption that sexual deviance would accompany her actions was made apparent by her subsequent apology for her 'masquerade,' and assurances to public audiences that she had not engaged in any sexual transgressions during her cross-dressing years (Meyer 1996, Wheelwright 1989).

Although Catherine Linck married a woman after her military service, there is no way of knowing whether she cross-dressed in order to engage in sexual relations with another woman. In contrast, during the late nineteenth and early twentieth centuries in the United States some women's cross-dressing was a means of explicitly claiming such a sexual desire. Prescriptive sexual norms of the period depicted women as sexually passionate, but mandated that passion be directed at men and contained within marriage. In such a context, some women dressed as men to make explicit their sexual desires for and relations with other women (Newton 1984). During the twentieth century, in North America and Western Europe, the cross-dresser and the mannish woman became archetypes of the sexual invert or lesbian. This connection between 'mannishness' and female sexual inversion or lesbianism was supported by sexologists' and psychologists' arguments that gender inversion,

defined by female cross-gender behavior or appearance, signaled potential sexual inversion. In 1934 the German sexologist Magnus Hirschfeld went even further when he drew a direct connection between women's desire to enter the military and their potential homosexuality.

Hirschfeld believed that female soldiers, because they engaged in the 'most extreme' cross-gender behavior, were the most 'confused' sexually (Meyer 1996, Wheelwright 1989). By the 1920s psychiatrists and psychologists would include sexual object choice in their definition of homosexuality, however, gender inversion remained a powerful cultural marker of female homosexuality in Western Europe and the United States throughout the twentieth century.

The popular conflation of mannishness and lesbianism was articulated through assumptions that masculine occupations and pursuits like military service or sport would both attract and produce female homosexuals. Women entering the military in England and the United States during World War II, for example, found that they had to engage with popular presumptions that their military service was an indicator of their potential sexual deviance. Similarly, the participation of women in sports during the twentieth century was framed by the figure of the mannish lesbian athlete. The institutional answer to such presumptions was to present both female athletes and soldiers as 'feminine' and avowedly heterosexual (Meyer 1996, Cahn 1994). While institutional responses were meant to decrease lesbian visibility, such reactions also made the association between lesbians and gender inversion more culturally salient. Therefore efforts to repress sexual deviance resulted in heightened public consciousness of particular sexual identities and the community spaces that supported them (Foucault 1990). Individual servicewomen and female athletes positioned themselves within these discussions by defining themselves or 'others' as lesbians. Thus, while many women who were heterosexual found themselves accused of sexual deviance because of military service or sports activity, others flocked to these all-female cultural spaces precisely in order to find others 'like themselves,' allowing for the common identification among lesbians.

Cross-culturally and historically many same-sex institutions provided space and cultural approbation of female enclaves in which some women could explore their sexuality. From the medieval period forward, convents and monasteries provided another same-sex environment within which women might develop intimate relationships with one another. The early seventeenth-century Italian records of an ecclesiastical investigation into the case of Benedetta Carlini, Abbess of the Convent of the Mother of God, document her sexual relationship with another sister (Brown 1982). Catholic female religious orders in Western Europe warned routinely against 'particular friendships' that might develop between members of a sisterhood. Although the sexual relations were not explicitly proscribed, the presumption remained that emotional intimacy could lead to sexual intimacy. In the early twentieth-century United States, prisons for women and girls came under heightened scrutiny because of reports that inmates engaged in sexual relationships with one another. The single-sex environment commentators saw as facilitating such behavior augmented suspicions of other such venues like female boarding schools and colleges. In both England and the United States the publicly accepted 'crushes' that schoolgirls developed for one another were increasingly viewed with alarm rather than the amused tolerance that had greeted such relations in the nineteenth century.

While female same-sex communities provided the possibility for some women to develop sexual relationships with one another, such communities were not themselves necessarily 'lesbian communities.' The investigation of communities created around shared sexual identities marks another investigative route for scholars of lesbian history. Communities of women identifying themselves by their sexual desire for other women have been documented as early as the eighteenth century in London and in such unexpected places as Salt Lake City, Utah, in the United States. In the 1920s and 1930s a group of white, middle-class women of predominantly Mormon backgrounds created a community for themselves based on their common identity as lesbians. This group included several women who were married to men, others who set up households with women, and some who were 'unattached.' The members of this community confined their social activities to their homes, downplayed sexual expression as a factor in their relationships, and tried to lead otherwise 'respectable' lives. Their lack of visibility as sexual vs. social actors and the protections offered them by their class and racial status mitigated against their encountering any hostility because of their sexual identities. In contrast, by the 1920s working-class lesbians in the United States began to develop communities that made visible a lesbian sexuality symbolized by and articulated through a 'masculine' woman and her 'feminine' partner. While butches, recognizable by their masculine attire, haircuts, and mannerisms were the targets of harassment throughout the mid-twentieth century, their *femme*-partner's attire, haircuts, and mannerisms were more conventionally feminine. These working-class, urban, lesbian communities and the butch/*femme* cultures at their centers, formed around their members, shared identities as lesbians. Most significant, individuals within these communities were understood to be and articulated themselves explicitly as sexually desiring other women. In cities like Buffalo, New York, United States, working-class lesbians carved public spaces for themselves in bars and restaurants and resisted police raids and street violence to create for themselves a community of women who engaged in sexual relations

with other women. This resistance prefigured the Gay Liberation Movement of the 1970s.

Defining communities and individuals as lesbian requires some indication of how they understood and presented themselves. Returning to the example of Anne Lister, we see a woman who described herself not only as engaging in sexual relations with other women, but as part of a community of women who desired women. Similarly, members of working-class butch/*femme* communities through the 1960s saw their sexual relationships with other women as essential to their identity as lesbians. The Salt Lake City community, in contrast, consisted of women who downplayed any sexual aspect of their identities, although they understood themselves as lesbians. Likewise, lesbian feminists in the United States and Great Britain during the 1970s and 1980s denigrated what they characterized as the 'role-playing' evident in butch/*femme* relationships and emphasized the importance of women's relationships with other women *sans* sex. Some defined lesbian as a continuum that encompassed sexual relations between women and also included nonsexual female friendships.

Scholars have been divided equally on the question of how to characterize lesbian identities historically. Some have argued against a focus on sexual activity as the defining characteristic of lesbian lives. These historians contend that focusing instead on the variety of 'passions' between women or behaviors and lives that were 'lesbian-like' will tell us more about the context within which women made sexual and social choices. Other historians have asserted that we must acknowledge the ways in which women's same-sex love has always challenged male power and 'sexual prerogatives.' As such, understanding lesbian history is essential to understanding women's history and the history of gender relations.

While there is no one answer to the queries posed at the beginning of this article, what is clear is that, in the end, sexual identity has been both self-disclosed and externally imposed or 'assumed' from various cultural markers. There are many lessons to draw from the exquisite difficulty of illuminating lesbian lives historically. Narrow the definition of lesbian too much and you risk erasing the experiences of many who loved women—draw the circle too broadly and you risk rendering any definition of lesbian that emerges from historical investigation meaningless. This tension frames 'lesbian history' and the historical search for lesbian lives including women's passionate friendships, sexual desire for other women, and the creation of communities. This tension continues as we enter the twenty-first century at a moment when lesbian and gay is being replaced by lesbian/gay/bisexual/transgender, is being replaced by 'queer.' The question remains—is this simply a move to a greater pluralism? Does it mark a sea change in contemporary understandings of sexuality? Or does it represent the erasure of the particularities of sexual identity and the material and ideological circumstances informing such particularities? The answer to these questions is the next challenge for scholars of same-sex or lesbian sexuality.

Lesbians: Social and Economic Situation

Lesbians, or women who primarily have sexual and emotional relationships with other women, face a distinctive set of social, legal, and cultural challenges and stigmas in many parts of the world that are not faced by heterosexual women. Although lesbians have proven relatively difficult to study, increasing social science attention has illuminated key features of lesbians' social and economic situation, including workplace outcomes, employment discrimination, and family formation. An overview of this body of research reveals that lesbians generally face economic and social disadvantage, both in the workplace and in organizing their family life.

1. *Legal and Normative Challenges*

In almost all countries, lesbians' economic and social conditions are determined within a social, legal, and cultural context that is at best negligent in responding to lesbians' particular needs and at worst hostile to the existence of lesbians (Rosenbloom 1996). As of this writing, lesbians are treated differently from heterosexual women in every known legal system. In many countries, same-sex sexual practices between women are punishable by prison terms (although apparently this is enforced rarely against lesbians compared with gay men). States also actively oppress lesbians through arrests and police harassment, discrimination in government employment, exclusion from military service, and censorship of lesbian voices and organizations. Political action by lesbians and gay men has resulted in some expansions of rights for lesbians in some countries, however, such as the explicit bans on sexual orientation discrimination contained in the constitutions of South Africa, Ecuador, and Fiji.

In many societies, norms about gender roles and sexuality stigmatize women who form primary and intimate relationships with other women, and lesbians are often denied the protection of law against the social, physical, and economic abuse that accompanies social stigma. Some evidence of the existence of norms against lesbianism (or homosexuality more generally) comes from public opinion surveys from Russia, Serbia, Romania, and the United States (see Rosenbloom 1996). Reports from 30 countries provide examples of physical violence against lesbians, including rape, murder, forced conversion therapies, incarceration, and suicide.

The potential economic consequences of social stigma include being cut off from family support, being denied housing or access to important public resources, and facing discrimination in employment. While human rights laws in most countries ban many forms of sex discrimination and offer recourse when discrimination occurs, human rights laws rarely protect lesbians from discrimination based on sexual orientation. Firing or refusing to hire a lesbian because of her sexual orientation is legal in most of the world.

Legal distinctions and social stigma also greatly influence lesbians' family position. No country allows two women (or two men) to marry legally. In a few countries (the Netherlands, Sweden, Norway, Denmark, Hungary, and Iceland) two women are allowed to form and register a state-recognized relationship but are excluded from some rights pertaining to marriage, such as adoption rights or the right to a state church wedding. In some other countries or parts of countries (as in certain cities in the United States), more limited recognition is accorded same-sex couples for purposes of certain social programs, inheritance rights, or employment benefit provision, for example. Discriminatory family policies also often deny lesbians access to reproductive services, child custody, parental status, and public and private resources available to married couples.

Overall, behavior motivated by antilesbian norms about sexuality and gender and the laws that permit such behavior place lesbians in an unequal position vis-à-vis heterosexual women.

2. *Methodological Issues in Studying Lesbians*

Since the 1970s, researchers have begun to study the economic and social position of lesbians. Research on lesbians must first address the tricky issue of defining 'lesbian.' A study of sexuality in the United States reveals the lack of concordance between several possible definitions (Laumann et al. 1994). Women

who are attracted sexually to other women will not necessarily act on those attractions. Women who have had sex with women may not refer to themselves as 'lesbians.' Researchers have focused generally their attention on women who have sexual relationships with other women or who identify themselves as lesbian, depending on the historical period or on the culturally appropriate and legally relevant definition (see *Sexual Orientation: Biological Influences*; *Sexual Orientation: Historical and Social Construction*).

Because lesbianism, however defined, is not a readily identifiable physical trait, and because of the social stigma attached to being a lesbian, lesbians have often kept their sexual identities and intimate lives hidden from a hostile society. This protective strategy makes research on lesbians difficult, and researchers continue to find recruitment of subjects challenging. Many researchers have addressed this situation by using 'convenience samples' drawn from bars or organizations frequented by lesbians, for instance. Others have used 'snowball sampling' methods to recruit study participants through personal networks of other lesbians. These nonprobability sampling strategies do not allow researchers to generalize a study's findings to the broader population of lesbians, unfortunately, since respondents might differ in important ways from the typical lesbian. Probability sampling allows generalizations but faces the problem of encouraging accurate responses to survey questions on sexual orientation, and only a few such (quite expensive) studies have been attempted. (For an excellent survey of these methodological issues, see Solarz 1999.)

As a result of these problems, existing research on lesbians' economic and social conditions must be interpreted carefully. Generalizations about all lesbians based on a nonrandom sample are inappropriate, and even generalizations from probability samples might be inappropriate if disclosure of sexual orientation on a survey is biased in some way. Furthermore, without a larger random sample of lesbians than has yet been constructed, attention to differences among lesbians based on race, ethnicity, class, or nationality, for instance, is impossible.

In addition to the methodological challenges, research on lesbians has been hampered by the stigma associated with such research. Some political scientists and sociologists in the United States and lesbian researchers from 14 countries, for instance, have reported difficulties in doing research on lesbian and gay-related topics, including job discrimination, professional isolation, and lack of funding (see Solarz 1999).

Despite these roadblocks, researchers have persevered, spurred on by social scientists' recognition that the study of lesbians (and gay men) can shed light on larger social and economic dynamics (e.g., Blumstein and Schwartz 1983) and by the need for knowledge created by political debates arising from an international movement for gay and lesbian rights (see *Gay/Lesbian Movements*). A growing cadre of social scientists in sociology, anthropology, psychology, economics, history, political science, and other fields has analyzed lesbians' situation with respect to employment and other economic issues and to family life.

3. *Lesbians' Position in Employment*

Social scientists, particularly economists and sociologists, have become increasingly interested in how social identities, such as race, class, and gender, influence an individual's labor market experience and economic position. Researchers have also begun to study discrimination based on sexual orientation, since lesbians are legally vulnerable to employment discrimination. Survey data is available from several countries which suggests that discrimination is not a rare occurrence, although most of these surveys are nonrandom and particular statistics cannot be generalized. (Also, in some cases, lesbians and gay men were lumped together for reporting purposes in the original studies.)

A review of surveys conducted over time in different parts of the United States found that between 11 percent and 44 percent of lesbians and gay men reported experiences of employment discrimination at some point in their lives (Badgett 1997). In 1993, 8 percent of British lesbians surveyed believed that they had been fired because of their sexual orientation, and almost half (48 percent) had been harassed at work (Rosenbloom 1996). Almost one-quarter (23 percent) of Irish lesbians and gay men surveyed had experienced discrimination in training, hiring, or promotion (GLEN and NEXUS 1996). No independent confirmation of these experiences exists, in general, but the credibility of these claims is supported by the fact that employers surveyed in some countries, such as the United States (Badgett 1997) and Zimbabwe, plainly state to researchers that they would not hire or promote lesbians (or gay men).

Not surprisingly, then, concealing sexual orientation is a dominant strategy for lesbians to avoid employment discrimination. In surveys of gay men and lesbians in the United States, anywhere from one-half to four-fifths of respondents reported hiding their sexual orientation at work. Over two-thirds (68 percent) of the British lesbians surveyed concealed their sexual orientation from some or all of their co-workers. Only 42 percent of Irish lesbians and gay men considered themselves to be completely 'out of the closet' at their workplaces. Concealment might provide some protection from direct discrimination, but that strategy also imposes costs on lesbians, who may face increased workplace stress and the sacrifice of career-enhancing social contact with co-workers.

The evidence of self-reported discrimination is obviously suggestive of a serious economic issue for

lesbians. One standard independent test for the presence of discrimination looks for lower group earnings as evidence of discrimination. Evidence from random samples of lesbians and gay men working full-time in the United States (the only country with appropriate data) show that gay men earn significantly less than heterosexual men after controlling for productive characteristics, but lesbians' and heterosexual women's earnings are basically indistinguishable (Badgett 1995, Klawitter and Flatt 1998).

While the earnings evidence appears to contradict the claims of discrimination against lesbians, they might experience discrimination without earning less than heterosexual women for several reasons. First, lesbians might be crowded into the same female-dominated, relatively low-wage occupations as heterosexual women in which wages are closer to (or equal to) the minimum wage and thus cannot be reduced much for lesbians. Second, since lesbians will not have a male partner's earnings to fall back on, lesbians might actually have more labor market experience, skills, or training. Support for this possibility comes from the fact that some studies show that lesbians have higher labor force participation rates than do heterosexual women. But if lesbians are more skilled or experienced, they ought to earn more than heterosexual women, and a finding of earnings equality is evidence of discrimination. Unfortunately, available datasets do not have explicit measures of training or of labor market experience, so researchers cannot control for any sexual orientation-related differences in these characteristics in earnings comparisons. Third, it is possible that predominantly male supervisors are more prejudiced against gay men than against lesbians. Future research will be necessary to distinguish between these possibilities.

A clearer form of discrimination that reduces lesbians' economic well being relates to the interacting effects of labor market practices and family law. In some countries, such as the United States, significant parts of employee compensation come in the form of non-wage benefits, such as pensions and health care coverage. Employers often incorporate family members in such benefits, providing healthcare coverage for employees' legal spouses and children as well as for the employee. Since lesbian workers cannot marry their same-sex partners, those partners are ineligible for spousal benefits, reducing lesbians' effective total compensation. A small but growing number of employers in the United States and Canada recognize employees' same-sex domestic partners for benefits purposes.

4. *The Position of Lesbians and Their Families*

Social scientists long have studied and theorized about families as social and economic units, and some attention has focused on lesbians and their families. Work by anthropologists and sociologists demonstrates that lesbians form relationships with other adults that would typically be recognized as kinship relationships. Lesbians often form primary relationships with one other woman, in some cases entering into state-sanctioned partnerships where those are allowed or going through religious or personal union ceremonies without state recognition (see Blumstein and Schwartz 1983 or Lewin 1998 for studies of the United States). Other kinship structures, such as the 'families we choose' described in the San Francisco Bay Area by Weston (1991), extend beyond household boundaries and include individuals tied to one another through emotional and sometimes material bonds. No statistically legitimate estimates of the proportion of lesbians forming such relationships exists in any country, unfortunately.

Many lesbian families include children. Several surveys based on probability samples of the United States suggest that 20–32 percent of lesbians have children in their households. Many of those children, if not most of them, are from past heterosexual relationships, and an unknown number are probably the result of donor insemination or adoption in the so-called 'lesbian baby boom' of the 1980s and 1990s. Research in the US and UK has found that children raised by lesbians are well cared for and have scores on standard psychological tests that indicate healthy psychological adjustment (see surveys by Patterson 1995, 1998; see also *Nontraditional Families and Child Development*).

Studies of the inner workings of lesbian families find some similarities in the types of tasks and pressures faced by those families. Lesbians in families raise children, divvy up housework, take jobs to support their families, and care for the family's adult members. As with heterosexual families, lesbians appear to arrive at family decisions through bargaining and appeals to norms, individual preferences, individual skills, and efficiency.

Although the processes within families show some similarities to heterosexual families, other contextual factors are quite different and result in marked differences. Studies of nonrandom samples of lesbian and heterosexual couples in the US and Britain show that lesbian couples have more equal distributions of housework and labor market work than do heterosexuals and that their power relations are less affected by which person has higher earnings than is true of heterosexual or gay male couples (Blumstein and Schwartz 1983, Kurdek 1995, Dunne 1997).

Social scientists have offered varying explanations for these patterns, with the hypotheses rooted in different theories about the division of family labor. Lesbians might have different and more egalitarian norms related to the contributions of partners and the economic role of women. Lesbians' expectations about likely labor market earnings for each partner might be more equal than those for married opposite-sex

couples, reducing the advantage of having one partner do all the housework and the other partner earn all the money income. Lesbians do not have access to marriage, an institution that encourages stricter specialization of household labor. Or two lesbians' bargaining power might be more equal as a result of more equal earnings potential. All of those hypotheses would explain more egalitarian divisions of labor within the household, and additional research will be necessary to identify which explanations are most appropriate.

The legal and institutional conditions within which lesbians form and organize families are also quite different from heterosexual women. As noted earlier, lesbians cannot marry their same-sex partners. And outside of the few countries giving lesbians the option of a registered partnership, lesbians are excluded from the kind of legal framework and public resources that support other families. Lesbian couples lack legal ties to each other that assign inheritance rights, allocate property after a breakup, provide access to income security programs, and make couples eligible for spousal employment benefits, for example.

In most countries lesbian mothers face the prospect of losing custody of their children to heterosexual fathers (Rosenbloom 1996). Lesbian mothers usually cannot become a legal parent of a child born to or adopted by her lesbian partner, and a nonlegal parent has no legal rights to visitation or custody of the child if the couple splits up. These legal disadvantages for lesbians and their families imply that lesbians face the same family-oriented tasks and challenges as heterosexual women and their families but do so with additional uncertainty and without legal and economic support.

5. *Future Research Directions*

As noted, many important questions about lesbians' position have provisional answers and await further research. Knowing more about lesbian's workplace conditions—including their experiences of discrimination and occupational choices, for instance—and family lives—including alternative family forms, the division of household labor, and childbearing decisions—will require the development and use of large-scale probability samples that allow generalizations. With larger samples, more attention can be paid to differences among lesbians, such as those related to race, culture, class, and nationality. In addition, more extensive use of qualitative methods will be necessary to research the often subtle processes at play in workplaces and families. Researchers in the United States and Canada and in Western Europe are already moving in these directions.

Studies of lesbians and gay men might also present 'natural experiments' for researchers interested in the impact of policy changes and in social and cultural change. As norms evolve and if collective action by lesbians and gay men results in political victories, lesbians and their families will likely respond to cultural and legal changes in ways that will help to illuminate the underlying social processes that interest social scientists.

Lesion and Behavior Approaches in Neuroscience

One of the earliest and most frequently employed experimental research methods used to investigate how the brain is involved in controlling behavior and behavioral processes involves ablation (removing) or lesion (destruction or functional disruption) of brain structures or areas. While considerable information has been obtained regarding brain-behavior relations from clinical cases where the damage is a result of either head injury, tumor, vascular problems, brain surgery, or disease (see *Cognitive Neuropsychology, Methodology of*), the nature and extent of the damaged and affected areas in humans are difficult to determine and often are not known. By employing laboratory animals and experimental lesion approaches, it is possible to obtain more precise and localized damage to the brain. Further, with the use of animal-testing techniques any changes in behavior can be carefully determined, the brains can then be obtained for detailed histological analysis, and the actual damage to the brain can be subsequently correlated with changes in behavior. Thus, by using the lesion approach together with experimental animals to study brain function, meaningful conclusions can be drawn regarding the relationship that exists between specific areas of the brain and how they are involved in behavior (e.g., localization of function).

1. *Localization of Function*

Issues surrounding the extent to which control of various behaviors is localized in specific brain areas have been around for many centuries (see Corse 1991). It was the work of Franz Josef Gall (1758–1828) and Johann Casper Spurzheim (1776–1832) that established the theory of phrenology, i.e., the theory that particular parts of the brain controlled separate mental faculties. Specifically, these early investigators proposed that personality types are related to bumps located in specific places on the skull. Phrenological theory was spelled out in sufficient detail that some components of the theory could be tested experimentally, and not many years passed before Pierre Flourens (1794–1867) developed the technique of damaging the brains of animals to study the changes produced in their behavior. The result was not only the refutation of phrenology, but justification for the use of the experimental lesion method in studying and attempting to understand brain function. Localization of function continued to receive considerable attention during the nineteenth century with the discovery by Paul Broca (1824–1880) that a discrete area of damaged cortex interfered with speech, and the demonstration by Gustav Theodor Fritsch (1838–1929) and Eduard Hitzig (1838–1907) that movements of particular parts of the body could be elicited by applying electrical stimulation to specific regions of the animal and human brain.

One of the most systematic early attempts to use a lesion approach to determine where in the brain a complex behavioral process is controlled can be found in the research of Karl Lashley (1890–1958). Lashley devoted a lifetime of research to what he described as 'the search for the engram,' that is, the physical representation of learning or the site in the brain where the trace of the memory of a learned thing is stored. The approach he used involved the training and testing of rats to perform tasks of various levels of difficulty, and ablating or using knife cuts to various parts of the cortex either before or after learning. Rather than finding that memory for learned tasks is localized in specific areas, Lashley found that the amount of damage to the cortex was more important than which part was removed (Lashley 1950).

2. *Lesion Techniques and Procedures*

A variety of techniques and procedures have been used to produce selective damage to the brain. In studying the functions of the cortex, early researchers removed large areas on the external surface of the brain by first removing a flap of skull, directly exposing the brain, and then excising brain tissue with a knife or with vacuum suction. A similar technique is often used in current research, especially research involving nonhuman primates. While this approach is feasible for the cortex, damaging structures and/or areas that are deep within the brain creates special problems. Systematic exploration of subcortical areas had to wait until 1908, when Sir Victor Horsley and Robert H. Clarke developed the stereotaxic instrument, a device that permits the precise positioning of electrodes deep within the brain. Thus, by carefully implanting electrodes in known locations, investigators could for the first time damage, stimulate, or record from areas below the external surface of the brain. One lesion technique that is still used in research involves passing direct current through an electrode that is insulated except at the tip, thus creating a localized area of

damaged tissue. A similar technique involves electrocauterization using high frequency current (e.g., radiofrequency).

A major problem associated with the use of conventional lesions (aspiration, electrolytic, radiofrequency) is that the resulting damage is nonspecific. Thus, there is frequently loss of cells in adjacent areas, axons that pass through the area of the lesion are interrupted, and the vasculature can be compromised. For this reason, there has been an increase in recent years in the use of intracerebral injections of neurotoxins. By employing stereotaxically placed focal injections, and procedures that minimize the spread of the toxin to adjacent areas, one can limit the damage to the intended structure. Further, most neurotoxins do not damage fibers of passage, afferents that terminate in the area are minimally affected, and the vasculature is spared. Since the resulting damage is specific, the investigator is in a better position to attribute changes in behavior to damage to a specific structure.

It is especially helpful that some chemicals are selectively toxic to specific kinds of neurons. For example, 6-hydroxydopamine is a chemical that resembles the catecholamine neurotransmitters dopamine and norepinephrine. Because of this resemblance, when the toxin is injected into an area it is selectively taken up by the axons and the result is death of the cell. Investigators have used this approach to produce an animal model of Parkinson's disease.

It was discovered in 1971 by Olney and his colleagues that glutamate, a putative excitatory neurotransmitter, had an excitatory effect on neurons and that high concentrations caused cell death. Several analogues of glutamate have been found that are especially toxic to specific types of cells. For example, when kainic acid is injected peripherally, the result is behavioral convulsions accompanied by the loss of specific cell populations within the brain. Focal injections of kainic acid directly into some brain structures also result in a loss of cells, not only of neurons at the site of injection, but distant damage that is thought to be mediated by seizure activity. Because one population of cells that is especially sensitive to kainate damage is found in the hippocampus (see *Hippocampus and Related Structures*), the toxin has been used in a number of behavioral experiments concerned with learning and memory.

A number of other glutamate analogues have been found that produce restricted damage when injected directly into brain structures. Foremost among these is ibotenic acid, a toxin extracted from the mushroom *Amanita muscara*. This toxin not only produces discrete and circumscribed lesions at the site of injection, but it does this in most structures without causing seizures and without damaging either axons of passage or afferents that terminate in the area (Jarrard 1991). Because of the axon-sparing properties, both ibotenic acid, and a similar analogue n-methyl-d-aspartate, have been used to produce restricted damage in a number of experiments involving both rodents and monkeys.

A recent approach used to produce brain lesions with greater selectivity involves suicide transport and immunolesioning techniques (Wiley 1992). In both of these techniques cytotoxins are targeted to restricted groups of neurons. Suicide transport involves the axonal retrograde transport of toxic lectins from the site of injection back to the cell body with the resulting destruction of the neuron. Monoclonal antineuronal antibodies are used in immunolesioning techniques to deliver cytotoxins selectively to only those neurons that have surface characteristics recognized by the antibodies. An advantage of immunolesioning is that the toxins not only destroy a specific type of neuron at the site of injection but the toxin is transported in a retrograde direction back to the cell body from the injection site. While these newer approaches offer considerable promise, there are a number of potential problems associated with using these extremely toxic chemicals in the laboratory.

Still another lesion approach that has been developed only recently involves the gene-knockout approach. By using biochemical methods to direct a mutation at a particular gene, one can destroy or alter widespread systems of cells or subsystems within cells.

All of the lesion approaches described above produce permanent damage to the brain. A technique that offers considerable promise is the focal injection of drugs that temporarily inactivate brain cells. The most direct way to produce a temporary, reversible brain lesion is to inject a local anesthetic (such as lidocaine) into the area of interest. However, local anesthetics not only inactivate brain cells at the point of injection but they also disrupt the activity of axons passing through the area. Thus, the overall effect is similar to that found with the use of conventional lesion techniques, except that the effect with local anesthetics is reversible. It was reported recently that injection of a newly-developed glutamate receptor antagonist temporarily inactivated the cells at the point of injection without disrupting fibers of passage (Riedel et al. 1999). With the development of new drugs that have temporary effects on specific transmitter systems the use of temporary inactivation as a reversible lesion will no doubt increase.

3. *On Interpreting the Behavioral Effects of Lesions*

Correctly interpreting the effects on behavior of damage to specific brain structures requires an understanding and appreciation of a number of potential problems. Since a change in behavior following damage to the brain can be caused by unwanted effects on sensory system functioning (e.g., vision or olfaction),

the motor system, attention, motivation, etc. it is important to eliminate as many of these explanations as possible by carefully designing the experiment. Over the years, scientists have devised a number of control procedures that take into account these interpretative problems. Thus, the typical lesion experiment includes not only a group of unoperated animals to serve as controls, but also a group of animals that have sham lesions, e.g., that undergo the same surgical intervention as animals in the experimental lesion group except the structure of interest is not damaged. If it is observed in subsequent testing that the behavior of the animals with the brain lesion is different from that of the sham-operated and control animals, then one can be more confident that the structure of interest caused the observed behavioral deficit.

In order to eliminate other possible explanations for an observed behavioral change following brain damage, investigators often employ an experimental design to test for double dissociation of function. In this type of design lesion 1 impairs behavior A but not behavior B, while lesion 2 (in a different region of the brain) impairs behavior B but not behavior A. An example of a double dissociation is when lesion 1 impairs an animal in learning a spatial task (say, learning to swim to a safe platform consistently located just under the surface of the water in a circular tank) but has no effect on learning to discriminate between two visual stimuli, whereas, lesion 2 impairs discrimination learning but has no effect on learning the location of the safe platform. With this type of finding, it can be concluded that the impairment in learning the spatial task is not caused by changes in attention, visual processes, motor performance, motivation, or several other behavioral processes.

Interpretation of lesion studies is also complicated by the fact that many regions of the brain are interconnected, so that damage in one area may result in morphological, biochemical, and/or physiological changes in areas of the brain not damaged directly by the lesion. Further, following damage to the brain there is often sprouting (or new growth), sparing of function, spontaneous recovery, and indirect effects on other behaviors (see Kolb and Whishaw 1996) that can complicate any interpretation.

While there are potential problems in interpreting the results of lesion studies, there are several advantages that this approach has over other available procedures. First, by developing animal models using lesions, one can attempt to understand better the nature and extent of the brain damage found with various diseases and injury in humans. Second, the specifics of the lesion can be determined by careful histological study, thus, there is a permanent record of the actual brain damage. Third, by using different procedures to study the brain (e.g., recording, functional MRI) one can often determine that several different regions seem to be involved in a particular behavior but the question arises regarding whether the structures operate serially or whether they provide separate inputs to a common structure. In this case, lesion studies are required to determine which of these structures are actually necessary for the behavior in question.

4. *Behavioral Assay of Brain Function*

Since the brain is designed to produce and control behavior, a careful analysis of changes in behavior following brain lesions is the ultimate assay of brain function. Early investigators, using lesion techniques and behavioral testing procedures available at the time, made important discoveries regarding regions of the brain that are involved in controlling such important behaviors as emotions, motivation, and learning and memory. For example, it was discovered in 1939 that bilateral ablation of the anterior temporal lobes in monkeys led to dramatic behavioral changes where previously wild and aggressive monkeys failed to display normal fears and anxieties. It is now known that the amygdala (see *Amygdala (Amygdaloid Complex)*) plays a crucial role in such emotions, especially fear and anxiety. By using more sophisticated lesion techniques it has been possible to identify the underlying brain circuitry (see *Fear: Psychological and Neural Aspects*; *Anxiety and Fear, Neural Basis of*). In 1940 Hetherington and Ranson showed that destruction of a region of the hypothalamus (see *Hypothalamus*) using electrolytic lesions produced animals that ate voraciously until they become extremely obese. With the use of selective lesion techniques, it is now known that the hypothalamus is not as crucially involved in the control of eating as these early findings indicated (see *Hunger and Eating, Neural Basis of*; *Appetite Regulation*).

The lesion approach has been used frequently to attack the most basic and challenging problem in the neurosciences, e.g., an understanding of the neural bases of learning and memory. Since the early research of Karl Lashley and 'the search for the engram,' the development of more sophisticated lesion and behavioral testing procedures has permitted major advances in this important area of research. In a recent search for the location of the engram, Richard F. Thompson and colleagues (Thompson and Krupa 1994) used a simple behavioral task (*Eyelid Classical Conditioning*) and a combination of recording and lesion techniques (both conventional lesions and temporary inactivation). By determining which structures changed activity during learning, then selectively damaging or temporarily inactivating inputs and outputs of the suspected crucial structure, the investigators were able to show that the learning (engram) occurred in a single nucleus within the cerebellum (see *Cerebellum: Associative Learning*).

Following a report in 1957 of a case of severe anterograde amnesia (e.g., inability to new material

and events) following ablation of structures deep within the medial temporal lobes, investigators attempted to understand the neural bases by developing animal models (monkeys, rats). Using monkeys, it was found that aspiration of medial temporal structures resulted in a severe memory problem that was similar in many ways to that found in the clinical case. The structure that was suspected of being responsible for the deficit in both human and monkey was the hippocampus. Research using the rat model generally failed to provide support for a global memory problem that encompassed all types of material, especially when an axon-sparing lesion technique was employed to remove the hippocampus (Jarrard 1993). Subs-equent research with monkeys employing more selective lesions has indicated that the major impairment that was attributed to the hippocampus is, in fact, a result of damage to cortical areas that are adjacent to the hippocampus that were inadvertently damaged during surgery.

5. *Future Directions*

With the development of new procedures that permit more selective lesions limited to particular structures, types of neurons, or specific proteins, it is now possible to have a level of lesion control that has been lacking in the past. A similar increase in the level of sophistication in the analysis of behavior and understanding behavioral processes has occurred as described in other entries in this volume (see *Fear Conditioning*; *Learning by Occasion Setting*; *Blocking, Neural Basis of*; *Hippocampus and Related Structures*; *Hunger and Eating, Neural Basis of*; *Thirst and Drinking*). While a more complete understanding of brain-behavior relations will necessarily depend on a convergence of results obtained from a variety of approaches used to study the brain, the careful use and interpretation of lesion studies combined with sophisticated behavioral testing procedures will make major contributions to this understanding.

Letter and Character Recognition, Cognitive Psychology of

Letters are basic constructional units in alphabetic scripts that are used to form words; in writing these words are entities which are marked by spaces. How has letter recognition been studied? What are the main results obtained and the major models proposed? These questions are considered in the first part of this article. In contrast to those scripts constructed on an alphabetic principle where symbols (i.e., letters) are made to correspond to sounds in speech, other scripts, such as Chinese, have been developed following a logographic principle, in which symbols mainly and directly encode meaning. Characters are distinct orthographic units in Chinese. Although there are notable differences between letters and characters, they share certain crucial properties, among them that both characters and letters have names, are used to form words, and are the first things that users of the corresponding script start to learn when learning how to read and write. The second part of the article addresses how characters are processed in recognition.

1. *Letter Recognition*

Different alphabetic scripts, such as Hebrew and English, make use of different sets of letters. We shall confine the discussion here to the English letters, because a good deal of research is available on them.

1.1 How has Letter Recognition Been Studied and What are the Main Results?

Early research on letter recognition aimed at identifying a set of features used in distinguishing among letters. But what is a feature? A feature (e.g., horizontal straight, closed curve, etc.) can be considered as a

specific component which can appear in combination with other components to form different letters. One way to find a possible feature set for letters is to observe systematically and analyze patterns of responses when asking people to make matching or same–different judgments on serially or simultaneously presented letters. It is typically found that considerable confusions are made between certain pairs of letters such as N and M, M and W, E and F, P and R, and Q and O, presumably because these pairs of letters share certain features (for an example of the features of capital letters and a review of related research see, e.g., Gibson 1969).

A widely used paradigm in studying letter recognition is to ask people to identify letters that are displayed very rapidly (e.g., for 50 ms or less) on a tachistoscope (i.e., a device that allows researchers to show visual stimuli for a short, fixed amount of time). A common finding in the studies using the tachistoscopic procedure is that people are more likely to confuse letters with similar features, such as E and F, than those with distinctive features, such as E and Q (e.g., Rumelhart 1970). This result suggests that people are possibly engaged in such activities as feature detection and feature analysis in letter recognition and that these perceptual activities play an important role in recognizing a letter.

Letter recognition has also been studied by using a visual search task. In Neisser's (1963) classic research, for instance, he asked people to search an array of letters for a particular target and found that search performance for the target (e.g., Z) was slower when the array was made up of letters with features similar to the target (e.g., X and V, consisting of straight lines) than when it consisted of letters with features distinctive from the target (e.g., O and G, containing rounded features). This result confirms the idea that features are used in recognizing letters.

Apart from studying how individual letters are recognized, researchers have also investigated the way in which letters are processed in context. This topic has been investigated since Cattell's study (1886) and has attracted much research interest over several decades for at least three reasons. First, letters are more often seen in a word context than in isolation. Second, there is good evidence to show that different processes are involved in the two situations. Finally, this topic is related to significant theoretical issues, such as the nature of the processes involved in reading and the relationship between the processing of letters and words. Perhaps the most well-known work on investigating letter recognition in context is Reicher's (1969) study, in which he adopted the tachistoscopic procedure previously mentioned to show three types of stimuli: four-letter words (e.g., WORK), four-letter nonwords (OWRK), or single letters (K). Immediately following the display of a stimulus item, a forced-choice recognition test (e.g., - - - $\frac{D}{K}$ or $\frac{D}{K}$) was given to the participants to judge which one of the two alternative letters had appeared in the specified position in the original stimulus. Reicher discovered that letters were recognized better in the context of a word than in the context of a nonword letter string or in no context at all (i.e., when presented individually), indicating that (a) letter recognition can be affected by context-dependent processes, and (b) word identification may not need to be based on letter-by-letter recognition. This *word superiority effect* is well known, for it provides an important, empirical basis in the development of modern models of letter recognition, a topic which will be covered in the next section.

It is worth noting here that the contextual effects in letter perception have also been investigated by researchers using a letter detection paradigm in situations more closely resembling the conventional reading environment. Healy and Drewnowski (1983), for example, asked people to read a prose passage and to detect every instance of a target letter, such as *t* or *T*. They found that people made many more letter detection errors on words (e.g., *the*) than on misspelled, consequently meaningless words (e.g., *thd*). This *word inferiority effect* not only confirms the idea that the basic encoding units in skilled conventional reading are not likely to be individual letters, it also indicates, in conjunction with the word superiority effect previously mentioned, that the effect of familiar context on letter recognition depends on task and can either be facilitative or inhibitory.

1.2 Major Models Proposed

A classic model for letter recognition is the one proposed by Selfridge (1959), called 'pandemonium.' This model involves four levels of 'demons,' which detect and analyze the properties of a visual input. The stimulus is first scanned and encoded by image demons to produce the mental representation of the stimulus (i.e., an image). The image is then processed by feature demons, each of which searches for a specific feature. Once a feature demon finds the searched-for feature, it calls out to cognitive demons at the next level of the system. Each of these cognitive demons corresponds to one single letter in English, and it pays special attention to a particular set of feature demons. Cognitive demons call out when they hear the yelling from the corresponding features demons. Finally, a decision demon listens to the noises produced by the cognitive demons and makes the final decision regarding the identity of the stimulus based on which cognitive demon is making the loudest noise, indicating that all necessary component features of the cognitive demon have been detected.

Feature-analysis models of letter perception, such as the pandemonium model proposed by Selfridge, were popular in the early days of studying letter recognition. This type of model emphasizes the role of features in recognition but de-emphasizes the pro-

cessing roles played by certain factors, such as context, expectations, and perceptual experience. The recognition and correction of this problem has stimulated the development of contemporary models of letter recognition that incorporate both bottom-up processes, such as feature detection and analysis, and top-down processes, such as expectations and context. A well-known example of such models is the interactive activation model of McClelland and Rumelhart (1981).

The interactive activation model has the following major assumptions. First, there are processing units at three levels: feature, letter, and word. Second, recognition processing occurs simultaneously at different levels (i.e., parallel processing). Third, there can be bidirectional information processing between two neighboring levels (i.e., interactive processing). For instance, top-down influences can be passed along the word level down to the letter level. Fourth, there are both excitatory and inhibitory connections between levels, whereas only inhibitory connections exist within a level.

This type of interactive activation model can easily account for the word superiority effect previously mentioned by allowing interactive activation between levels. In other words, word units that have been activated can increase activation for their constituent letters at the letter level. Consequently, under the tachistoscopic task of Reicher (1969) where only a single letter string or a letter is shown at one time, letters embedded in words can in principle receive feedback from the activated words at the word level and have a better chance to be activated than those in nonword strings or in isolation.

The word inferiority effect aforementioned can also be understood with the multilevel, parallel processing mechanism proposed in the interactive activation model. The word inferiority effect is typically demonstrated in conventional reading situations where many words are shown at once. In order to read for comprehension, readers not only need to identify each individual word in a text, they also need to integrate the meanings of those words to form a coherent understanding. Thus, a good strategy is to start to process the next word in the text as soon as possible once a given word has been recognized even if some of its constituent letters have not been processed to the level of identification. Consequently, letter detection can be disrupted by word context in conventional reading, as demonstrated by Healy and Drewnowski (1983).

2. Character Recognition

Thus far we have examined what has been done over the past decades in understanding the processes involved in letter recognition. An interesting question one might ask at this point concerns whether (or the extent to which) we can apply what we have learned about the processing of sub-word units to other non-alphabetic scripts, such as Chinese. In this section, we will consider how distinctive orthographic units in Chinese (i.e., characters) are processed in recognition.

Figure 1
An illustration of constructional units in written Chinese

2.1 Main Properties of Chinese Characters

Each Chinese character is made up of strokes, radicals (i.e., certain combinations of strokes), simple characters (i.e., characters that cannot be further segmented into radicals), or a combination of these components in a constant, square-shaped region (see Fig. 1 for an illustration of constructional units in written Chinese). Hence, different characters can differ in number of strokes (e.g., some characters, such as 一 and 丁, have only one or two strokes, but others, such as 鬱 and 鑿, are formed by more than two dozen strokes), in number of radicals (e.g., 月, meaning *moon*, and 朋, *friend*), or in manner of construction (e.g., 柑, *tangerine*, is made up of two simple characters 木 and 甘 along a horizontal dimension, while 某, *unspecified*, is formed by the same components but in a vertical manner).

Chinese characters are typically monosyllabic. Since there are far fewer syllables (about 1,300 in Mandarin Chinese) than there are characters that are commonly used (about 5,000), the degree of homophony in the language is very high. Moreover, about 80 percent of Chinese characters consist of compound characters made up of two components, one of which (the signific) provides a categorical cue to the meaning of the character; and the other component (the phonetic) may cue in an all-or-none fashion the pronunciation of the character. However, the phonetic parts in these compound characters are themselves characters, having their own pronunciation (thus providing pho-

netic cues) and meanings (typically different from the meanings of the characters in which they are embedded). The cues they provide to pronunciation are neither constant, as some may function as the phonetic part in certain characters and the signific in others, nor reliable, in that less than 30 percent of the phonetic parts provide the correct pronunciation for commonly used characters. In other words, a notable property of the Chinese script is that is has an opaque script-speech relationship.

Furthermore, being constructed following the logographic principle, Chinese characters are basically morphemes, and more than 60 percent of Chinese words are comprised of two or more characters. Since the majority of characters can join others to form multiple-character words with drastically different meanings, the meaning of a character can be highly context-dependent (for relevant research and discussion on this issue see, e.g., Chen 1992). For example, the character 生 can be used to form such distinctive words as 衛生 (health), 花生 (peanut), 生活 (life), 生長 (to grow), 接線生 (operator), and so on. In fact, we can use about 2,500 characters to form some 16,000 different words which can account for about 99 percent of the material in a Chinese corpus of about one million words (Liu et al. 1975).

2.2 Cognitive Processing of Characters

Research on character recognition has had a relatively short history compared to the study of letter recognition. In fact, although some progress has been made over the past two decades, what we have learned about the processing of characters is still very limited in comparison with what we know about letter recognition. The research on the cognitive processing of characters has usually been conducted using methods and techniques similar to those used in English research, aiming to understand the processes underpinning character recognition and related language activities.

Since Chinese characters are constructed of strokes and radicals, an important question for character recognition in Chinese is whether these constructional units are the most crucial perceptual bases used in distinguishing among different characters. Interestingly, there is some evidence to indicate that this may not be the case. For instance, Yeh et al. (1997) asked people to sort characters into groups so that those that looked alike were together. These researchers applied multidimensional scaling to the sorting data and discovered that three configurational properties of characters (i.e., arrangement of components: vertical vs. horizontal, closeness of the configuration: open vs. close, and squarishness of the configuration: square vs. nonsquare) were the most powerful dimensions in explaining the results of sorting. Not among these were the basic patterns of strokes (e.g., horizontal, vertical, oblique, or twisty lines, dots, and so forth), Gibson's (1969) set of critical features, or radicals. In other words, the global configuration of a character seems to play a more salient role in character classification than do local properties of strokes or radicals.

It is worth noting here that although individual radicals may not provide the most effective information in character discrimination, there is evidence to show that they are processed and used in the course of recognition. Indeed, it has been shown that properties of radicals (e.g., their type frequency, their location in a character, and their lexicality—whether they themselves can be used as independent characters) can exert significant effects on performance in such tasks as recognition (deciding whether a stimulus character appeared in a previous display), character decision (deciding whether a stimulus item is indeed a character used in daily life), and naming (for relevant results and/or discussions see, e.g., Li and Chen 1997, Zhou and Marslen-Wilson 1999). Thus, it appears that radicals are segmented from the base characters and their related information is utilized within the other processes resulting in the recognition of the global characters.

Another question that one might ask regarding Chinese characters is the processing role of characters in reading Chinese. There is clear evidence to indicate that individual characters are important encoding and processing units in Chinese. For instance, using Reicher's (1969) tachistoscopic paradigm, Cheng (1981) demonstrated a character superiority effect whereby a radical component could be better detected when it was embedded in a real character than in a pseudocharacter (i.e., one that was constructed following the orthographic rules of the script) or a noncharacter (i.e., one that was formed against the orthographic rules of the script). Moreover, Chen (1984) reported a character inferiority effect in reading Chinese text using a component detection task, by which more detection errors were found when a target component was embedded in genuine characters than in pseudocharacters. These results clearly indicate that characters can be better perceived than radicals and that the fundamental unit in processing written Chinese is the character, and not the radical. This raises another interesting issue concerning the role of the character in reading. Although it is the word, rather than the morpheme, that is commonly considered to be the basic unit of language processing and used as the unit of comprehension analyses, there is evidence to indicate that the character still has a significant role to play even in the case of reading text. For example, using a character detection task, Chen (1987) found that there was a clear word superiority effect in reading Chinese text (i.e., a character was better detected when it was part of a two-character word than when it was part of a two-character nonword). If the word were the most important unit of comprehension analyses, one would expect to find a

word inferiority effect rather than a word superiority effect, because the word-level processing should enjoy a higher priority than the character-level processing, and the word context should create an effect disruptive to the character detection task. This word superiority effect in reading Chinese stands in interesting contrast to both the character inferiority effect in Chinese and the word inferiority effect in English (e.g., Healy and Drewnowski 1983) and suggests that (a) characters serve as important encoding and processing units in reading Chinese text, and (b) characters play a more salient role in reading Chinese than letters do in reading English.

Finally, because different writing systems present linguistic information in distinctive forms, whether similar or different processes are activated and used in processing lexical items in the various orthographies has attracted considerable interest over the years. For instance, it has been argued that phonology plays a crucial role in the process of identifying a visually presented lexical item (e.g., Van Orden 1987). However, most research on this topic has been done using materials in alphabetic scripts. Hence, one way to verify the universality of this phonological hypothesis is to investigate whether phonology significantly influences the recognition of logographic characters (for recent research and discussion on this issue see, e.g., Chen and Zhou 1999). It turns out that there is good evidence to indicate that orthography rather than phonology plays a more crucial role in the recognition of Chinese characters, although phonology can also be activated in the course of recognition (e.g., Shen and Forster 1999). On the other hand, orthographic processing seems to play a less important role for alphabetic materials than phonological processing (e.g., Van Orden 1987). Similar evidence has also been shown in a memory research by Chen and Juola (1982) where Chinese and English were directly compared. A therefore conceivable hypothesis is that specific properties of a given script can affect related recognition and memory processes.

2.3 Research Models Proposed

At present, models of Chinese character recognition are quite scarce. Nevertheless, there are a few such models available. The existing models typically have structures similar to those developed from English materials, but with modifications to capture the properties of the Chinese language. Thus, for instance, there is a hierarchical interactive-activation model, in which there are orthographic and phonological representations structured in levels corresponding to multi-character words, characters, radicals, and strokes (Taft et al. 1999). Similar attempts have been made using parallel-distributed processing models (e.g., Seidenberg and McClelland 1989) where orthographic, phonological, and semantic representations are connected in a triangular form and interact continuously (e.g., Zhou and Marslen-Wilson 1999). However, this type of modeling work is usually not explicit and should only be considered as preliminary for the time being, since the systematic study of Chinese character processing has only just begun.

3. Conclusions

The results obtained from the cognitive studies of character recognition complement the letter recognition studies that have probed the perceptual and cognitive mechanisms that are involved in the processing of written English. Together these studies on distinctively different scripts can provide valuable insights into the formation of a genuinely comprehensive theory of human language processing in general, and the cognitive processing of subword units in particular. Although there has been in recent years an upsurge of interest in conducting cognitive research across different scripts, much work remains to be done. Identifying universal principals and script-specific processes associated with the reading of different scripts should continue to be a challenge to researchers who are interested in the psychology of language in the new century and beyond.

Lewin, Kurt (1890–1947)

1. Biography

Kurt Lewin was born on September 9, 1890 in Mogilno, a small town in the (then Prussian) province of Posen, now Poland. He was the second of the three children of Leopold and Recha Lewin who owned a general store and a small farm. Kurt was sent to a *Gymnasium*, a secondary school, in Posen until, in 1905, the whole family moved to Berlin, as did many ascending Jewish families living in the eastern provinces of the Reich and in Eastern Europe.

In Berlin, Kurt Lewin attended the humanistic *Kaiserin-Augusta-Gymnasium*. In 1909 he took up university studies of medicine and biology in Freiburg and Munich, but in 1910 he was back in Berlin to take courses in philosophy and science. His special interest soon became philosophy of science, in which field the (neo-Kantian) philosopher Ernst Cassirer and the psychologist Carl Stumpf were most influential with regard to Lewin's intellectual development. Stumpf, the director of the Psychological Institute and the patron of what was to become the Berlin school of gestalt psychology (see *Köhler, Wolfgang (1887–1967)*), became Lewin's doctoral supervisor.

Since in 1914 Lewin volunteered for the army and soon did service on the Western Front, he was awarded his doctoral degree as a soldier in 1916. While on furlough from the front in 1917, he married Maria Landsberg, a fellow student from prewar days. The same year, 1917, was also the year of Lewin's first two publications, which, in their dissimilarity, indicate the scope of Lewin's interests: a paper on mental activities in the inhibition of processes of volition, based on his doctoral thesis, and an almost phenomenological paper on the 'war landscape,' foreshadowing Lewin's later involvement in ecological problems.

Also predictive for Lewin's further intellectual as well as social development were his extracurricular activities and associations as a student, as from early on he had engaged himself in socialist student groups which took an active interest in the social and, mainly, educational problems of workers in agriculture and industry. From this enduring interest resulted two early publications in 'applied psychology,' one on rationalization in agriculture, one on the socialization of the Taylor system. Many later publications followed as a result of his and other Jewish psychologists' forced emigration to the USA.

Before the war ended Lewin was severely wounded and hospitalized. Decorated with the Iron Cross and promoted to the rank of lieutenant, he was discharged from military service.

In the following years, Lewin, who had returned to the Psychological Institute of Berlin University, and received his *Habilitation* in 1921, became assistant in the new department for applied psychology, a position which he held until his emigration in 1933. In 1927 he was appointed *außerordentlicher Professor*—a title, not a tenured position.

Although in close spatial and intellectual proximity with Köhler's group of gestalt psychologists, Lewin, who concentrated on studies of will, affect, and action, soon gathered a group of young talented students around him, 'whose background was more often than not female, Jewish, and eastern European' (Danziger 1990, p. 173). Some of Lewin's Berlin women students gained international recognition by their association with Lewin, and some shared his later fate as refugees.

But it is fair to say that Lewin's rapidly growing scientific reputation was also due to the works of his doctoral students, which Lewin represented at conventions and in journals, preferably in his own series in the journal *Psychologische Forschung*.

An important date in Lewin's vita was 1929. In this year Lewin, who had separated and divorced from his wife Maria, remarried. His second wife, Gertrud, had been a friend of the family for several years. Professionally, 1929 was the year for which he received an invitation to attend the ninth International Congress of Psychology at Yale. This was shortly after J. F. Brown, an American who had studied with Lewin, had published a paper on 'The methods of Professor Lewin' in the 1929 *Psychological Review*, which had attracted the attention of US psychologists to the work of Lewin's Berlin group. In Yale Lewin impressed his audience with a short paper on environmental forces (read in German) and an equally short, but self-made motion picture of an eighteen-month-old girl trying to sit on a stone for the first time in her life—one of the many films that Lewin found useful for the graphic representation of the life space (see below). According to G. W. Allport, who had witnessed Lewin's performance in Yale, 'This ingenious film was decisive in forcing some American psychologists to revise their own theories of the nature of intelligent behavior and of learning' (quoted in Marrow 1969 50f.). It was his first encounter with a US audience that resulted in Lewin being invited as visiting professor by Stanford University in 1932.

It turned out that after this stay in Stanford Lewin would only briefly return to Berlin, as in January 1933 the Nazis seized power in Germany. On his return trip from California via Japan and the USSR Lewin decided that he and his family could not live in Nazi Germany. Fortunately, shortly after his return he received a cable informing him that Cornell was inviting him to join the faculty staff, which he gladly accepted—just in time.

From 1933 to 1935 Lewin then worked at the Cornell School of Home Economics. In 1935 he was offered a position at the Iowa University Child Welfare Research Station. For eight years he worked in Iowa as a professor of child psychology. It was in these years that Lewin taught excellent students who became his disciples and, later, colleagues; for example, Barker, Bavelas, Cartwright, Festinger, French, Lippitt, White, and Zander. It was also during this period that Lewin's research interests shifted toward social psychological problems. In 1937 he became one of the founders of the Society for the Psychological Study of Social Issues, whose president he became in 1941.

This social engagement reflects Lewin's increasing concern with the interaction between research and practice which led to his conception of 'action research,' and to the idea and foundation of the Research Center for Group Dynamics at MIT in 1945, whose main research task was to be 'the development of scientific methods studying and changing group life and the development of concepts and theories of Group Dynamics' (quoted in Patnoe 1988, p. 9).

This institution framed the final period of Lewin's life. In 1947, in the middle of a rather hectic spell of activity, he died of a heart attack, on February 12 in Boston, at the age of 56. In the same year the Research Center moved to the University of Michigan, Ann Arbor, where it still exists as a prominent place of social research.

2. *Research Topics and Fields*

Social interaction, mainly in small face-to-face groups, was such a driving force in Lewin's professional life that it is difficult, often impossible, to single out and identify his strictly individual contribution to what the Berlin or Cornell or Iowa or MIT group produced. Conversely, psychological knowledge today owes a great deal to names such as Barker, Cartwright, Dembo, Festinger, French, Hoppe, Karsten, Kelley, Lippitt, Ovsiankina, Pepitone, Thibaut, Zeigarnik (an alphabetical, hence arbitrary, order of students and colleagues who worked with Lewin). From their oeuvre, whether published individually or as co-authors, whether during Lewin's lifetime or thereafter, it would be difficult to do an auctorial analysis of variance. But it would be futile, too, since Lewin, at least, believed firmly in the creativity of dialogical thinking. Hence, Lewin is not only an author's name, it is also a brand name for products of the interaction between Kurt Lewin and his associates.

If one is looking for a name designating the unity of products from Lewin's groups the choice, after all, would be 'field theory,' which was also Lewin's final preference although for many years the favorite was 'topology.' It has been stated frequently but is useful to repeat that 'field theory is probably best characterized as a method: namely a method of analyzing causal relations and of building scientific constructs' (Lewin 1997).

The conceptual tools of this metatheory and methodology (rather than theory and method) are found mainly in two monographs (Lewin 1936, 1938) and two anthologies (Lewin 1997, 1999). Lewin adopted the philosophical foundation of Ernst Cassirer's (1953) distinction between 'substance' and 'function,' his theory of a historical transition from 'thing-concepts' to 'relation- (or function-) concepts' and from an abstraction- to a construction-mode of concept formation. Lewin applied this conception to psychology in his 1931 paper on the transition from an Aristotelian to a Galileian mode of thought (in Lewin 1935). For him psychology deals with relations or functions (rather than thing-like entities) which are basically dynamic i.e., forces.

In accordance with gestalt theoretical principles, every individual psychological instance (experience or

behavior) is the result of an interaction of several features of a given whole or situation; ultimately, each behavior is determined by the total situation in which it occurs. For Lewin the total situation was the 'life space' organized by interdependent forces. In other words, the life space is the 'totality of facts which determine the behavior (B) of an individual at a certain moment. The life space (L) represents the totality of possible events. The life space includes the person (P) and the environment (E). '$B = f(L) = f(P, E)$' (Lewin 1936, p. 216).

It is this formula, which binds person and environment inextricably together, which has become a kind of shorthand for field theory: It is important to note that, owing to the principle of interdependence, neither person nor environment is granted independence. The field, which is structured into regions, paths, and barriers, is basically a field of forces (tendencies to change or to resist change). Some regions are attractive to the person (they have a positive 'valence'). Others are repulsive (they have a negative 'valence'). The person is also considered to be a differentiated region with similar structural and dynamic properties.

These formal characteristics of the life space may be sufficient to explain why Lewinian psychology, whether of learning, of memory, of decision, of action, or of social interaction and relations, is intrinsically dynamic and deals with tension systems (as in anger, aggression, regression, substitution, flight into irreality, etc.), with forces affecting the level of aspiration, conflict, decisions, pressure, resistance, and with styles of leadership or the social-emotional atmosphere of small groups. It was mainly the latter type of studies, their designation (of 'authoritarian' vs. 'democratic' vs. 'laissez-faire' styles of leadership), and, last but not least, the fact that they were published in the early war years, that attracted wide and lively public interest, curiosity, and critique. From these studies, in which things 'happened' that were not designed to happen (such as 'laissez-faire' in lieu of a 'democratic' style), moving toward the use of research for policies of social change, what Lewin has called 'action research,' was but a small, though consequent and innovative step. It was final confirmation for the interdependence that Lewin had postulated between theory and practice, basic research and applied science.

3. *Assessment*

A critical assessment of what in the first five decades after Lewin's death has variously been called the Lewin tradition, legacy, or heritage is difficult because this is a multidimensional and multiperspectival task.

It is multidimensional because of the many research fields in which Lewin was engaged, beginning with the general experimental psychology of learning, memory, affect, motivation, and action, through child and personality psychology, to social, mainly small-group psychology, education, and social change, as well as, from the start, metatheory and methodology. It is multiperspectival since, depending on which experts or resources are consulted at any given time, Lewin's influence on present psychology will be differently evaluated.

It may be easy to neglect the temporal or epochal factor. While, in the first two decades after his death, Lewin's or 'Lewinian' theory could rightly be named a 'contemporary systematic framework,' and 'field theory' occupied sizeable chapters in handbooks of social psychology, this situation had begun to change in the 1980s to such an extent that quite a few of the centennial retrospectives due in 1990 were celebrations with reservations (cf. Graumann 1992, Schönpflug 1992, Wheelan et al. 1990). Field theory was no longer one of the grand theories of (social) psychology (if indeed there were any great ones left). Topology and vector psychology were going out of fashion. Progress in mathematical psychology no longer included topology and hodology as Lewin (1936) had envisaged and practiced them. If Lewin identified himself and has been identified with topology and vector psychology, his significance for contemporary psychology has noticeably decreased. None of his influential disciples, who all remember Lewin drawing 'bathtubs and eggs' in class, has seriously pursued topology as a theoretical and methodological system. But, as outlined above, many of the 'psychological concepts' listed in Lewin's 'Topology' of 1936 have not only survived but become common psychological knowledge.

What is more important for Lewin's heritage and his presence in contemporary psychology is the diversity with which his *oeuvre* has been handed down by his disciples and followers. To name but two traditions which may both rightly be called Lewinian, but in fact have little in common, there is, on the one hand, the prominent group of experimental social psychologists, going back to Lewin's Iowa period (1935–44) and the beginnings of the MIT Research Center for Group Dynamics through Lewin's death in 1947. On the other hand, there is the tradition in which group dynamics and action research have been seen essentially as means of changing human relations, individuals, groups, and societies. The journal *Human Relations*, founded by Lewin in cooperation with the Tavistock Clinic in London, has become an outlet for publications on applied group dynamics from which so-called 'sensitivity training' and resulting 'encounter groups' have gained the broadest notoriety by growing into a movement (cf. Back 1973).

But even if one stays within Lewinian experimental social psychology, the variance of derivations from Lewin's original ideas is considerable. If one looks for the common element, most of Lewin's senior disciples testify that it was Lewin's 'style' and the 'atmosphere' he created around him—a thoroughly Lewinian re-

mark since 'Lewinian style included an appreciation and sensitivity to context—the interplay of person with environment' (Patnoe 1988, p. 88, cf. Graumann 1992). What Patnoe (1988, p. 15) concluded from the testimonies of Lewin's contemporaries, namely that 'Lewin created his own microculture,' has been taken by historiographers of psychology as an enduring characteristic of Lewin's research style. Mitchell Ash (1995), who as a historian of gestalt psychology (and of other émigré psychologists after 1933) is interested in the role of milieu changes, states that Lewin, who had already established 'a scientific microculture around him' in Berlin (Ash in Schönpflug 1992, p. 20), accomplished the same in Iowa. The (sometimes very intense) interpersonal interaction in Lewin's research group was not just different from the methods of the (other) gestalt theorists (Ash 1995, p. 272). For Kurt Danziger, who has specialized in the history of psychological research, Lewin developed an investigative practice that 'departed fundamentally from the natural scientific model of experimentation' (Danziger 1990, p. 175). Considering that Lewin's Berlin experiments were not in social but in personality psychology, it is a striking innovation that even here (and in principle) the 'investigative situation is recognized as intrinsically social, and in research on personality it must form part of the object of investigation' (Danziger 1990, p. 175).

In anticipation of and in accordance with Lewin's later theorizing, the experimental subject is not a decontextualized individual, but a person-in-a-situation, and an important interacting part of the situation is the person of the experimenter. It is here that the Galileian thought and postulate which gave birth to field theory have become instrumental in an innovative, psychologically autonomous research practice—a legacy of Lewin's that psychologists still have to appropriate.

Lex Mercatoria

Lex Mercatoria, often translated as law merchant, consists of rules that are private, autonomous, international, a-national, or transnational. Lex Mercatoria is not enacted by state courts or a state legislative body. Its practical impact, however, has been undisputed since ancient Roman times and is discussed now in relation to cyber law.

1. Historical Development and Current Definitions

In Roman law, Lex Mercatoria was part of *ius gentium*, that is, a kind of international law more flexible than the Roman *ius civile* (civil law). Lex Mercatoria comprised national customary law in international trade. Historically, it is the major root of the consensual contract (without special form). However, it is disputed whether Lex Mercatoria as part of *ius gentium* offers a precedent for Lex Mercatoria as a legal system apart from national legal systems (De Ly 1992).

The medieval *ius commune* had for centuries constituted a legal framework in Europe. Legal scholars cultivated a common understanding based on Justinian's *Corpus Iuris* despite the division of medieval Europe into many more distinct political entities

than today, all with their various local laws. Similarly, medieval Lex Mercatoria constituted a cosmopolitan mercantile law based upon transnational customs and deeds copied for similar transactions. Disputes were settled by market tribunals or special courts. The English *Carta Mercatoria* of 1303 provided certain foreign merchants with a fast dispute-settlement mechanism and application of the law merchant (as opposed to feudal law or city law) (De Ly 1992). The English admiralty courts relied on the best available sources, be they domestic or foreign, in elaborating a worldwide maritime law (Juenger 1995).

In the English common law tradition, common law courts in the seventeenth century started incorporating customary rules developed by traders and usually applied in arbitration or special courts. 'Law Merchant' was defined as

> a number of usages, each of which exist among merchants and persons engaged in mercantile transactions, not only in one particular country, but throughout the civilized world, and each which has acquired notoriety, not only amongst those persons, but also in the mercantile world at large, that courts of this country will take judicial notice of it (Lethulier's Case (1692) 2 Salk 443 (per *Holt, CJ*)).

This 'Law Merchant' was less rigid and formal than the common law. As the common law courts became the forum for commercial litigation, 'Law Merchant' lost its international character and became national commercial law. Later codifications of commercial law, as for instance the English Sale of Goods Act 1893 and the American Uniform Commercial Code (UCC), are to a large extent restatements of law merchant principles as represented in common law. Today, 'Law Merchant' is still used to refer to national common law relating to commercial transactions.

Modern usage understands Lex Mercatoria as systems of standardized clauses and general legal principles in international trade and commerce. In order to set it off from law merchant incorporated in national common law some authors prefer 'New' or 'Modern Lex Mercatoria' or 'New Law Merchant' and similar terminology when referring to modern (informal) codifications of transnational commercial law.

Systems of standardized clauses are developed by a number of intergovernmental and nongovernmental organizations through extensive comparative efforts. Such rules have often served as a model for national lawmaking or international conventions. An outstanding example of a formulating agency is the International Institute for the Unification of Private Law (*Institut international pour l'unification du droit privé*, UNIDROIT), set up in 1926 as an auxiliary organ of the League of Nations. UNIDROIT is now an independent intergovernmental organization with 58 member states. Its purpose is to examine ways of harmonizing the private law of states, and to prepare gradually for the adoption by states of uniform rules of private law. Many of UNIDROIT's drafts have resulted in international instruments and Conventions, like the Convention on a Uniform Law on the Formation of Contracts for the International Sale of Goods adopted at a diplomatic Conference of the member states in The Hague in 1964. The UN Commission on International Trade Law (UNCITRAL), formed by the United Nations General Assembly in 1966, has similar topics on its agenda. A well known example is the Vienna Convention on the International Sale of Goods (CISG). Another system of clauses referred to worldwide are the INCOTERMS, specific trade terms promulgated by the International Chamber of Commerce (ICC).

Lex Mercatoria also refers to unwritten or, at least, not systematically collected principles and clauses which are considered international trade law, usage or custom (Goode 1997). Such rules are invoked in arbitration and applied by arbitration tribunals, for example, the ICC. This kind of Lex Mercatoria is compiled and discussed in legal literature. UNIDROIT prepared a well researched collection of contract law used in international trade, the 'UNIDROIT Principles of International Commercial Contracts' first published in 1994. These principles are intended to enunciate rules which are common to many existing legal systems and are selected to accommodate the special requirements of international trade. The UNIDROIT principles do not claim binding force; they are not intended as uniform law or for an international convention and will be applied in practice by reason of their persuasive value only. In many other fields of law, general principles, guidelines, or best practices are set forth by professional bodies, trade associations, interest groups, legal scholars, governmental, or intergovernmental agencies. In some instances, like the UNIDROIT project, the objective is to establish an unbiased and well-balanced restatement; in other instances, a political or policing impact is intended.

2. *Main Characteristics and Practical Impact*

Based on the historic development and present day definitions, Lex Mercatoria can be characterized as transnational and a-national. In the absence of a 'world legislator,' international trade and commerce have developed very functional and sophisticated rules based on practice and persuasive value. Parties to transnational contracts tend to avoid recourse to domestic law. Relying on well established Lex Mercatoria-clauses, contracting parties have a chance to overcome language barriers and all kinds of biases. Furthermore, they can draw from the condensed experience in their special field of business. When writing a transnational contract, parties or their counsel rarely invoke Lex Mercatoria explicitly. Rather they make use of specific clauses and principles.

Therefore, Lex Mercatoria is not as well established in the terminology of international trade as in its practices.

Usually, substantive references to Lex Mercatoria occur in agreements of arbitration or other means of alternative dispute resolution that avoid state courts. Arbitration rules are often part of Lex Mercatoria, too, like UNCITRAL's, ICSID's (World Bank International Center for the Settlement of Investment Disputes), or ICC's rules on international commercial arbitration. In the case of Scherk vs. Alberto Culver Co (417 US 506), the US Supreme Court pointed out the purpose of such arbitration agreements:

> A contractual provision specifying in advance the form in which disputes shall be litigated and the law to be applied is…an almost indispensable pre-condition to achievement of the orderliness and predictability essential to any International transaction. Furthermore, such a provision obviates the danger that a dispute under the agreement might be submitted to a forum hostile to the interests of one of the parties or unfamiliar with the problem area involved.

This case from 1974 is in line with the 1958 United Nations Convention on the Recognition and Enforcement of Foreign Arbitral Awards, which has been ratified by over 50 countries.

3. *Theoretical Analysis*

In legal theory, it is disputed whether Lex Mercatoria is 'law.' As law, it would form a third category between national and international law. Proponents of the theory of Lex Mercatoria as an independent body of law (mainly French, English, Dutch, and German scholars and practitioners experienced in arbitration) argue on the basis of a functional or sociological concept of law. This view acknowledges the existence of an autonomous body of law governing international commerce without a source in state power: *Il existe un droit dont la source est ailleurs que dans l'Etat* (Kahn 1961).

On the other hand, theorists, especially legal positivists, who see all law based on the powers of the (nation) state, deny the existence of an autonomous Lex Mercatoria. They argue that the absence of jurisdiction cannot be offset by private agreement, for even contracts need national law in order to be enforceable. Constitutionalism, positivism, and the concept of the sovereign state are irreconcilable with rule making by private governance. A contract is only conceivable within a legal order; there is no '*contrat sans loi*'. Additionally, Lex Mercatoria is considered much too vague, difficult to ascertain, and incomplete to qualify as a legal system.

Practically, the dispute is of only limited impact. The theoretical question is resolved whenever model laws or other products of formulating agencies have been incorporated into national law. Then, we have state enacted law applicable in courts and suitable for choice of law clauses. In other cases, when the state is not a signatory state or the respective set of clauses is a private convention, courts can refer to Lex Mercatoria clauses only as incorporation of standard business conditions into the contract at hand and will test the validity of such clauses according to national law. A choice of law clause that calls for the application of Lex Mercatoria in general is certainly very rare. In such a case, the objection of vagueness would be well argued. However, the parties to a contract tend to be much more specific, and the research necessary to deal with a particular Lex Mercatoria clause does not seem more burdensome than the application of foreign law mandated by national conflict of law rules. As already mentioned, arbitration clauses are prevalent in international trade. An arbitration tribunal is free to apply Lex Mercatoria rules and reach its decision on the equities of the case. The validity of arbitration clauses is generally recognized by state courts, especially if the clause inserted is in accordance with the 'Rules of Conciliation and Arbitration of the International Chamber of Commerce,' the UNCITRAL rules on international commercial arbitration, or a similarly well-established procedure.

A third approach is the advancement of guidelines, recommendations, codes of conduct, best practices, etc. with the clear understanding that these instruments are not binding. Sometimes, such sets of rules are called 'soft law.' Nevertheless, the practical impact and even legal relevance of nonbinding principles can be considerable. The OECD Guidelines for Multinational Enterprises, for example, are recommendations addressed by governments to multinational enterprises; they provide voluntary principles and standards for responsible business conduct consistent with applicable laws (Horn 1980). Similarly, the OECD Principles of Corporate Governance are intended to assist member and nonmember governments in their efforts to evaluate and improve the legal, institutional, and regulatory framework for corporate governance in their countries, and to offer guidance and suggestions for stock exchanges, investors, corporations, and other parties that have a role in the process of developing good corporate governance.

Because 'soft law' is not binding, governments and international institutions discuss sensitive policy issues freely in an open manner and have fewer reservations to enter into agreements that are just recommendations (Dryden 1999). Seen from the perspective of the individual, guidelines, recommendations, and best practices leave private autonomy formally untouched. However, the deviation from widely recognized standards has an impact on the standing of the enterprise with respect to business partners or investors. The effect of accepted best practices is described as 'comply or explain.' The informal rule is honored by reasoned comment. Legally, noncompliance with informal standards does not lead to liability. However, the con-

struction of technical legal concepts as, for instance, the business judgment rule, may very well draw upon best practices.

Another important effect of private governance is control of access to certain activities and ensuing ramifications. A stock exchange, organized in a private form (corporation), may require stock corporations to establish audit committees in order to have their stock listed. Then, audit committees will be established even if state corporation law does not require committees as an organizational structure of the board of directors. Legislative activities, as pointed out above, quite often follow suit when well established formulating agencies propose a systematic set of rules.

4. Perspectives

Globalization of commerce, information, and other areas of life brings about challenges similar to those ancient Roman merchants and English tradesmen faced and met with the creation of Lex Mercatoria. In global electronic commerce, the realities of the borderless world of cyberspace runs headlong into geographically delimited national jurisdictions of sovereign states. The attainments of constitutionalism, the nation state and the rule of law are finite in a global market. Private régimes are gaining ground much in the same way Lex Mercatoria established itself as reality, be it legal, commercial or sociological. Self-regulation is found in the Internet as 'netiquette' and other attempts to create an environment of trust and stability that are propitious for e-commerce. The question of global regulation is not moot, though. Few governments would consider self-regulation to be a suitable approach for taxation of electronic business. Given the extreme difficulties of global regulation, the OECD, based on a broad consensus among the member countries, wants to facilitate the development by the private sector of effective market-driven self-regulatory mechanisms. Regulation and self-regulation is not seen as a dichotomy anymore. Rather, a complementary or integrated approach is favored and the dominating issue is the right mix (Dryden 1999).

The historical experience of Lex Mercatoria shows that transnational, nongovernmental régimes can be efficient and productive. Modern Lex Mercatoria includes harmonization of specific fields of law, setting standards by codes of conduct, and developing self-regulation in the new communication environment. The basic structure of the phenomenon that in the absence of an international legislator the interested parties resort to self-regulation, assisted by specialists and transnational associations, is found in other areas, too. In sports, we are used to regulation by transnational nongovernmental associations. World championships and similar events follow elaborate procedures on the basis of rules which are not law in a formal sense that requires a national law maker. Nevertheless, the private governance of a worldwide network of sports associations exercises undisputed jurisdiction over the rules of the various games.

Lexical Access, Cognitive Psychology of

In order to produce and understand language, whether it be spoken or written, an individual must have available some form of cognitive representation of the

words of their language. This pool of mentally stored information is called *lexical memory* or the *mental lexicon*, while *lexical access* refers to the retrieval of such information. Initial research into the mechanisms of lexical access focused primarily on visual word recognition and, indeed, the term 'lexical access' was originally coined in relation to this domain (Forster and Chambers 1973). However, in more recent years, the term has been more commonly applied to language production rather than to language recognition. The reason for this change in the pattern of its usage arises from the fact that it is not a theoretically neutral term and is no longer concordant with the currently dominant theoretical approaches to visual word recognition (see also *Word Recognition, Cognitive Psychology of*). This will be detailed below.

1. Use of the Term 'Lexical Access'

1.1 Accessing a Lexical Entry

The earliest attempts to explain how information is retrieved from lexical memory equated the stored representation with a dictionary entry. Thus, the task of word recognition was seen to involve access to a discrete *lexical entry*, either via a search procedure (e.g., Forster and Chambers 1973) or by activating it to some threshold on the basis of features extracted from the stimulus (e.g., Morton 1969). Thus, for a visually presented word, a match is made between a coded sensory representation of the stimulus and the representation of the form of the word as stored in lexical memory, that is, there is a *sensory-to-lexical* match. This is the process that has been labeled 'lexical access.' Once the match is made, the functional characteristics of the word become available (i.e., its meaning and its grammatical characteristics) because these are associated with the lexical entry, and any processing that makes use of this information is therefore said to be *postaccess* or *postlexical*.

In contrast *preaccess* or *prelexical* processes refer to any processing that takes place prior to the sensory-to-lexical match being achieved, e.g., the conversion of specific font information into some abstract letter code. The topic of prelexical processing is notably germane to the issue of *phonological recoding* (see later).

1.2 Connectionist Models of Lexical Processing

In the 1980s, the advent of connectionist modeling of word recognition processes led to a conceptualization whereby lexical information does not reside in a discretely defined entry.

In *localist* connectionist models (e.g., the Interactive-Activation account of McClelland and Rumelhart 1981), although there may be discrete units of activation that represent the words of the language, there are also units representing subword (i.e., *sublexical*) entities (e.g., letters). Sublexical activation is as integral to the recognition of the word as is lexical activation because there is an interaction between the sublexical and lexical levels in the determination of the output. In such a model, the process of matching the stimulus with a memory representation of the word involves not only the accessing of lexical information, but also sublexical information. Indeed, the whole word need not be represented at all, because its meaning could be activated solely via sublexical units (Taft 1991). So it is somewhat misleading, within this framework, to use the term 'lexical access' to refer to the actual matching process because it may not be based on lexical information, at least not exclusively. However, the term could be appropriately used to refer to the outcome of the matching process, namely the point at which information about the whole word is activated to some criterion of acceptability and is therefore 'accessed.'

In *distributed* connectionist models (e.g., the Parallel Distributed Processing model of Seidenberg and McClelland 1989), the presented word activates a set of input units that produces a pattern of activation in a set of output units (via an intermediate set of hidden units) with no explicit lexical representation (see *Cognition, Distributed*). This again obscures the idea of lexical access as a process of finding a sensory-to-lexical match. Nonetheless, at some point in processing, the system must settle on a particular output as being the most relevant to the input and, because this means that information about the word has become available for response, it could be argued that this is when 'lexical access' has occurred.

So, within connectionist accounts of word recognition, 'lexical access' refers most appropriately to the final outcome of processing rather than to the processing itself. The use of the term has therefore waned, because the central interest of cognitive investigations into word recognition is the nature of the actual processes involved in identifying a word and not the mere fact that the word is recognized. For this reason, the more general term 'lexical processing' tends to be preferred.

1.3 The Scope of the Term 'Lexical'

Even when the term 'processing' replaces the term 'access,' there still remains an issue of the scope of the term 'lexical,' which is simply the adjective for the noun 'word.' A word has a form (both phonological and orthographic), and also a function (both semantic and syntactic). Is the processing of the form of a word sufficient to say that lexical access has occurred, or is access to the meaning and syntactic class of the word required as well? This is rarely, if ever, specified in the literature. Certainly when the semantic (or syntactic)

information about a word participates in processing at the sentence level, this must be occurring 'postaccess,' but it is still debatable whether the actual extraction of this information should be also seen as a 'postaccess' process or part of lexical access itself.

1.4 Language Production

When language is generated, meaning is being translated into form. The term 'lexical access' is still frequently used in relation to language production (where most of the research focuses on speech rather than writing). The continued use of the term perhaps reflects the fact that the interface between the meaning and form of a word is largely arbitrary and, therefore, the processing of the form-level representation (called the *lexeme*) does not involve the gradual increment of activation based on sublexical information. However, theorists in speech production propose that a lexical item consists not only of the lexeme, but also of a functionally defined representation, the *lemma*, that is selected on the basis of the desired meaning (see *Speech Production, Psychology of*). The term 'lexical access' is used to refer to retrieval of the lemma as well as the lexeme, with the main theoretical issue being the relationship between the two (see, e.g., Dell and O'Seaghdha 1991, Levelt 1992).

1.5 A Lemma in Word Recognition?

If the notion of an abstract lexical unit (i.e., the lemma) mediating between meaning and form is accepted for word production (but see Caramazza 1997), then the same should hold for word comprehension. The involvement of such a unit in the word recognition system has only recently been considered (see, e.g., Baayen et al. 1997). A lemma-level would represent units that link form and function and, as such, could be considered the core lexical representations, that is, units that allow access to all the information about a word. In terms of word recognition, then, lexical access occurs when a lemma is sufficiently activated via the form-level representations that are appropriate to the incoming sensory information. Thus, as in word production, lexical processing in word comprehension (be it visual or auditory) can be defined in terms of access to two types of representation, one defined in terms of form and the other in terms of function.

2. Issues in Lexical Processing

For issues related to lexical processing in word production, see *Speech Production, Psychology of*. The following will concentrate solely on issues concerning lexical processing in word recognition. The focus will be on the processing of visually presented words, given the dominance of this domain as a research area. However, issues specific to lexical processing in speech recognition will be also be considered.

2.1 Modality of Access

When a word is visually presented, it is obviously a logical possibility that the form-based representation that is accessed is an orthographically coded one (i.e., one that is compatible with the visual characterization of the word). However, for a long time it has been suggested that when words are to be read, they are recoded in terms of their sound, that is, they are recoded phonologically (see Taft 1991, Chap. 4), even though they do not need to be overtly pronounced. After all, recognizing spoken language is an ecologically more fundamental skill than recognizing written language. The idea is that the form-based lexical match is made in the phonological modality, and this means that the visually presented item must be recoded into its sound prior to accessing any lexical information, i.e., prelexically. This is achievable via a set of rules that convert letters (i.e., graphemic information) into sounds (i.e., phonemic information).

However, there are languages, such as English, for which such *grapheme-to-phoneme conversion* (GPC) rules will not always be successful (e.g., there would be no way of knowing that the EA of GREAT and the EA of TREAT are pronounced differently). Therefore, the phonological representation of an irregular word (such as GREAT) must be generated on the basis of information about the whole word. So, there must be a means of accessing such information other than via a phonological recoding of the visual stimulus. That is, if phonological information about a word could only be accessed via GPC rules, GREAT would always be recoded into the same pronunciation as GREET and therefore confused with that word. Clearly, the form-level access of an irregular word such as GREAT must be achieved on the basis of orthographic information, and the associated phonology of the word can then be made available postlexically.

Saying this, however, assumes that 'lexical access' refers only to form-based access and not to access of meaning or of a lemma. 'Postlexical,' in this context, would not refer to processing that occurs after the meaning is accessed, that is, it is unlikely that the phonology of a visually presented word would only become available after its meaning does. Indeed, to the contrary, it has been proposed that the primary route to meaning is via the phonological representation (see Frost 1998). There is a large body of research that suggests that the pronunciation of a word is activated in the course of reading silently for meaning. However, it still remains controversial whether this entails phonological mediation between orthographic processing of the stimulus and access to its meaning (Frost 1998), or whether meaning is primarily accessed via orthographic information in silent reading and that

automatic activation of phonology occurs independently, perhaps for the purposes of holding the material in working memory (Taft and van Graan 1998).

2.2 Use of Internal Word Structure

Words are more than just a linear concatenation of letters (or phonemes). There is an internal structure whereby some letters go together more closely than others. In the word PICNICKING, for example, the *morphological* structure is PICNIC (stem) and ING (affix), while the stem itself has the *syllabic* structure PIC + NIC. In turn, each syllable has the same vowel plus consonant unit (i.e., IC), called the *rime* or *body*, with a different consonantal *onset* (P and N). There is a growing body of research that suggests that analysis of this internal structure takes place during the course of lexical processing. Studies in a wide range of languages indicate the importance of morphological analysis (see, e.g., Feldman 1995), while the existence and nature of syllabic processing seems to be determined by the characteristics of the language involved (e.g., Cutler et al. 1986). Onset/rime analysis has also been clearly demonstrated, but so far only in English (e.g., Treiman et al. 1995).

In theoretical terms, the importance of such units of analysis means either that they are explicitly represented as sublexical entities within the processing system (see, e.g., Taft 1991) or that they implicitly emerge as a reflection of the statistical characteristics of the relationship that exists between orthography, phonology, and meaning (e.g., Seidenberg and McClelland 1989).

2.3 Lexical Processing in Context

When a word is presented in isolation, the only basis for recognition is the sensory features extracted from the stimulus, i.e., *bottom-up* information. When presented in a sentence context, however, there is the additional possibility of anticipating what the word is on the basis of semantic or syntactic expectations (i.e., *top-down* information), thus reducing the importance of bottom-up processing. So, is it the case that lexical processing qualitatively changes when the word is placed within a sentence context?

Although the recognition of a word (e.g., MIRROR) might be facilitated by the presence of a highly predictive context, like SHE LOOKED AT HERSELF IN THE, research suggests that there is no advantage in having a compatible, but not so predictive, context, such as SHE LOOKED FOR A (Taft 1991, Chap. 3). The most robust effect of context actually appears to be its inhibitory impact on word recognition when the word is incompatible with the context. For example, the time taken to recognize MIRROR is delayed by the immediately prior presentation of SHE ATE THE DELICIOUS. It has therefore been concluded that context has its major influence at a postaccess stage and that its main role is to suppress inappropriately accessed candidates (e.g., Forster 1981).

If a word is being accessed in the same way whether it fits the context or not, the two meanings of an ambiguous word (e.g., PORT) should be accessed in the same way regardless of any contextual bias (e.g., AFTER DINNER HE DRANK A GLASS OF PORT versus THE SHIP CAME INTO PORT). The contextual bias should only come into play by suppressing the inappropriate meaning at a postaccess stage, rather than by preventing the inappropriate meaning being accessed at all. In fact, there have been a number of studies supporting this position, although there may be some impact of the appropriateness of the context at an early stage as well (see, e.g., Simpson 1984).

Note that an ambiguous word has a single representation at the form level, but two representations at the lemma or meaning level. Therefore, if context is said to have its selective effect postlexically rather than prelexically, then 'lexical access' must be used here to refer to the function-based level of access (because there is nothing at the form-based level to select). So, we see that there is potential for confusion in the understanding of lexical access because, in relation to the issue of phonological mediation in silent reading, the terms 'prelexical' and 'postlexical' were used to refer to form-based, rather than function-based access. When using such terminology, then, one needs to be aware of its scope of reference within the context within which it is being used.

2.4 Lexical Processing in Speech Comprehension

There are aspects of lexical processing that are specific to the recognition of spoken words as opposed to written words (see *Speech Perception*). First, while most alphabetically written scripts physically separate each word within a sentence, the speech signal does not provide any reliable indication of word boundaries. Therefore, in the recognition of spoken words there is no guarantee that the sensory information being processed corresponds to a whole word: It may even be that what one initially processes as the beginning of a word is actually the end of the previous word. Unlike in reading, though, the physical signal contains prosodic features (notably patterns of stress) and these have been shown to be important cues in determining word boundaries (e.g., Norris et al. 1995).

A second feature of the speech signal is that its presentation to the sensory system is not under the control of the recipient: the acoustic features of the speech signal are exposed to the auditory system fleetingly and in a fixed temporal order. Therefore, these features must either be processed continuously

on-line or accumulated within a memory buffer for later processing. When reading a text, on the other hand, one has the freedom to move one's eyes to wherever one chooses and it is possible to take in information from anywhere within a word. Furthermore, while processing a word in the foveal region of the eye, it is possible to begin parafoveal processing of the upcoming information, which can potentially influence subsequent foveal processing of that information (see *Eye Movements in Reading*). So, in speech comprehension, the temporal characteristics of the signal are likely to have a major impact on lexical processing and this is indeed a feature of models of spoken word recognition (see, e.g., Marslen-Wilson 1989).

3. *Measuring Lexical Processes*

Again, the primary focus here will be on visual word recognition. For experimental tasks in the areas of language production and speech recognition, see *Speech Production, Psychology of* and *Speech Perception*, respectively.

3.1 *Experimental Tasks*

In order to gauge the processes involved in accessing a word in lexical memory, a task is required that cannot be performed on the basis of prelexically derived information. One commonly used task is where the presented word must be overtly named and the latency to begin the pronunciation is measured. While this *naming task* provides a good measure of the processes involved in generating sound from print, it is not necessarily a good measure of lexical processing because it is possible at least to begin pronouncing many words on the basis of units smaller than the word (i.e., the initial letters).

The task that is the most widely used is one that makes use of the obvious fact that lexical memory only contains words that have been encountered before. The item FLINK could potentially be a word in English, but is actually a *nonword* or *pseudoword*. Unlike an unstructured letter-string such as LKNFI, the only way to know that FLINK is a nonword is to establish that it does not exist in the lexicon. Therefore, if asked to classify items as 'word' or 'nonword,' the only way to do so is to consult lexical memory. So the time taken to classify a word as a word in this *lexical decision task* is taken as a measure of the ease of lexical access. The sort of experiments that are undertaken using this task tend to compare two sets of words that differ in one characteristic while being as similar as possible in all other potentially important characteristics. If the two sets differ in their lexical decision response times, it is concluded that the manipulated characteristic plays a role in lexical processing. For example, two sets of words of the same length will produce different lexical decision times if they differ in their frequency of occurrence in the language and, therefore, any account of lexical processing must consider the role of word frequency (see Taft 1991 for other examples).

The characteristic that is manipulated need not be a feature of the word itself, but instead a feature of the presentation conditions. The most common presentation manipulation is to precede the target item with another item that is related in some way to it. This other item is called the *prime*. If the prime has an impact on responses to the target, it indicates that the characteristic on which they are related plays a role in lexical processing. For example, faster lexical decision times to DOG when preceded by CAT (compared with when preceded by CAP), suggests that lexical access involves a semantic level of analysis (see *Priming, Cognitive Psychology of*).

3.2 *The Cognitive Neuropsychological Approach*

Conclusions have also been drawn about lexical processing by studying acquired dyslexics. These are people who were able to read normally before a trauma to the brain (e.g., through accident or stroke) resulted in a dysfunction in processing. Research into the reading behavior of such dyslexics has been influential in the development of accounts of lexical processing. If it is found that an individual has one area of functioning disrupted, but another intact, it suggests that those two aspects of processing are independent of one another. For example, some dyslexics (*surface dyslexics*) can read aloud nonwords and regular words, but not irregular words, while others (*phonological dyslexics*) only have a problem with nonwords. Such a pattern of dysfunction is taken to support the existence of two routes from print-to-sound (Coltheart et al. 1993), namely a lexical route where the phonology associated with the whole word is available (disrupted for surface dyslexics) and a rule-based GPC route (disrupted for phonological dyslexics).

3.3 *Direct Measures of Processing*

Lexical access can also be examined by looking directly at the organs involved in the process, namely the eyes and the brain. By examining eye movements, an analysis can be made of the timing and placement of fixations during the course of normal reading. Manipulations of lexical information in both the fovea and parafovea have provided a rich source of data regarding the processing of words (see *Eye Movements in Reading*).

Direct observations of the activity in the brain when words are presented (e.g., using ERP, fMRI, and PET techniques) is also beginning to provide fertile ground for an understanding of lexical processing, although

the contribution of this research is likely to be more in determining the physical locus of aspects of processing than in providing a fine-grained analysis of this processing.

Lexical Functional Grammar

1. Introduction

Lexical Functional Grammar (LFG) is a theory of language structure dealing with the syntax, morphology, and semantics of natural languages. It is different from other theories in having several parallel representations for sentences, each with its own architecture and vocabulary, subject to its own organizational constraints, and linked by principles of correspondence (mappings), not derived from one another. LFG is thus a constraint-based non-derivational unification model, unlike other generative grammar models such as Principles and Parameters or Relational Grammar. There is an extensive international community of scholars working within an LFG framework; it has been used to describe an impressive array of languages from various families and typological groups. Current research in LFG includes the role of morphology in language structure, semantic representations, and computational implementation; as well as an Optimality Theory-based model of LFG.

2. Background

From its inception in the late 1970s LFG has been concerned to be a model that is typologically grounded, computationally implementable, and consistent with psycho-linguistic understanding of language acquisition and comprehension. Bresnan (1982) sets out the original model and describes individual languages.

LFG emphasizes analysis in 'lexical' and 'functional' terms, rather than purely as phrase structure configurations (and movement of elements from one configurational position to another). Arguments in favor of separating constituency and functional representations (see Bresnan 2000, Carnie 2001, p. 339, Falk 2001) are discussed in Sects 2.1 and 2.2.

2.1 Structure–Function Mismatches

These mismatches occur where there is an imperfect correspondence between constituency and function, e.g., 'talked about' requires a Noun Phrase (NP) object and cannot have a tensed complement clause (CP) object:

(1) We talked about [$_{NP}$ the fact that he was unhappy $_{NP}$] for weeks

(2) *We talked about [$_{CP}$ that he was unhappy $_{CP}$] for weeks

However, if the CP occurs as a topic in the initial position the sentence is perfectly grammatical:

(3) [$_{CP}$ That he was unhappy $_{CP}$] we talked about for weeks

Transformational models would be required to move the CP from a post-predicate position where it cannot actually occur, while LFG is able to capture the difference in grammaticality in terms of functional differences (topic versus object—see Sect. 2.2).

2.2 *Non-configurational Languages*

In these languages word order is free and sentences have a 'flat' structure: there is no evidence for phrasal constituency asymmetries that distinguish grammatical functions. Non-configurational languages are typically 'dependent-marking' (case morphology encodes functional information), or 'head-marking' (agreement morphology distinguishes functions such as subject and object). Jiwarli (Western Australia) is a dependent-marking non-configurational language: case marking codes function; word order is free and semantically related items can appear discontinuously:

(4) *Juma-ngku* *ngatha-nha* *nhanya-nyja*
child-erg 1sg-acc see-past
ngulu *walhirrkura-lu*
that-erg naughty-erg
'That naughty child saw me'

Here the subject appears split at the beginning and end of the clause (all elements are marked for the same ergative (transitive subject) case); any other ordering or reordering of words is perfectly grammatical in Jiwarli, thus:

(5a) *Ngulu* *juma-ngku* *ngatha-nha*
nhanya-nyja *walhirrkura-lu*
(5b) *Ngatha-nha* *walhirrkura-lu* *nhanya-nyja*
ngulu *juma-ngku*
(5c) *Nhanya-nyja* *ngatha-nha* *ngulu*
juma-ngku *walhirrkura-lu*

all mean 'That naughty child saw me' (see Austin and Bresnan 1995, Austin 2001). In non-configurational languages constituency and function must be separately represented, unlike configurational languages (such as English) where the Verb Phrase constituent linking Verb and Object (but not Subject) allows function to be expressed in constituency (and word order) terms.

3. *Parallel Structures*

LFG analyses sentences in terms of (at least) four parallel structures:

- c-structures represent *constituency* facts (word order and phrasal grouping) in the form of context-free phrase structure trees of the usual X-bar theory type;
- f-structures represent *functional* information (grammatical functions such as SUBJect and OBJect, and discourse functions like TOPic) in the form of matrices of attribute-value pairs. Attributes may be morphosyntactic features like tense or number, or grammatical functions;
- a-structures represent *predicate-argument* information such as the number and type of arguments and their thematic role (such as Agent, Patient or Location), stated as arrays of predicates and argument slots;
- σ-structures represent *semantic* information through deductive assemblage of meanings based on reasoning subject to constraints; σ-structures use a linear logic building on a-structure information.

There may be other parallel structures, such as *thematic-structure* representing discourse pragmatic information, or *phonological-structure* representing sounds; they have not been elaborated in LFG work to date.

The parallel representations are linked by *correspondence principles* where information of one type can be *mapped* to other structures. Thus c-structure nodes in a configurational language map to grammatical function attributes in the corresponding f-structure (see below).

3.1 *C-structure*

Constituency information is represented as context free labeled phrase markers (trees). LFG c-structures adopt the X-bar model of head-dependent relations; 'functional' elements such as Determiners, Complementizers and Inflections are co-heads of lexical elements such as Nouns and Verbs. C-structures are subject to the *lexical integrity principle*: the minimal c-structure elements are whole words, not parts of words or empty categories. No movement of c-structure constituents (such as V to I movement) is allowed, unlike other syntactic theories. Syntax cannot see into the internal composition of words. An example of a c-structure is:

(6)

LFG uses lexical category information to deal with similarities in distribution that are captured by move-

ment in transformational models, e.g. in English auxiliaries occur in the I c-structure position, however if there is no auxiliary then the verb may appear there, as in:

(7) This child *didn't* believe that the prince has died.
(8) This child *can* believe that the prince has died.
(9) This child *believes* that the prince has died.

In Principles and Parameters the inflected verb is moved from its V position at underlying structure to I position in a later structure. In LFG the distribution is captured by classifying an inflected verb like *believes* as an I category marked for TENSE, but an untensed form like *believe* as V. A consequence is that in sentences like (9) the c-structure VP contains no head V (a principle of *economy* on c-structures says that nodes should only be expanded when necessary).

In configurational languages c-structure nodes are annotated with functional equations to pass information up from daughter to mother nodes, using ↑('information about my mother') and ↓('information about me') symbolizations. Thus, in English the DP immediate daughter of IP ('this child' in example (6)) is the subject of the sentence and annotated as ↑SUBJ = ↓. A DP immediate daughter of VP will be annotated ↑OBJ = ↓. Lexical heads like V and N simply have ↑ = ↓ annotations (i.e. they pass all their lexical information up to their mother nodes).

(10)

C-structures in configurational languages are generated by context free phrase structure rules with information-passing annotations, as in:

IP→ DP I'
↑SUBJ = ↓ ↑ = ↓

In non-configurational languages morphology plays a major role in function assignment.

3.2 A-structure

LFG includes a richly articulated lexicon expressing all morpho-syntactically relevant information for individual lexical items; for predicational elements the number and types of argument and complement slots that they subcategorize for, as in:

(11) *gives* I (↑PRED) = 'give ⟨Agent, Theme, Recipient⟩'
(↑TENSE) = present
(↑SUBJ NUMBER) = sing
(↑SUBJPERSON) = 3

A-structure and functional information (such as the Agent being the SUBJECT in simple transitive clauses) are related by lexical mapping correspondence principles (see Sect. 3.4.1).

3.3 F-structure

F-structures capture functional information and are sets of paired attributes and values in an *attribute-value matrix*. Attributes are morpho-syntactic features (derived from lexical entries) such as TENSE or NUMBER, or grammatical functions such as SUBJECT and OBJECT. LFG has a richly articulated typology of grammatical functions, including argument and complement functions subcategorized for by predicates, and adjunct functions. It also has discourse functions like TOPIC and FOCUS. In configurational languages correspondence principles map from c-structure positions to f-structure functions (see Sect. 3.4.2).

An f-structure for the sentence in (7) above would be:

(12)

SUBJ	DEF +		
	DIST proximate		
	PRED 'child'		
TENSE	past		
NEG	+		
PRED	'believe < SUBJ, COMP>'		
COMP	SUBJ	DEF +	
		PRED 'prince'	
	MOOD	perfect	
	PRED	'die <SUBJ>'	

There are three layers of f-structure: the outer f-structure (corresponding to the whole sentence) has five attribute names: SUBJ, TENSE, NEG, PRED and COMP. Three attributes are features with simple

values (PRES, +, 'believe ⟨SUBJ, COMP⟩'), while SUBJ and COMP are functions containing subordinate f-structures as values. These inner f-structures also have attributes and values – the SUBJ function of the embedded COMPlement takes a lower f-structure with grammatical features.

F-structure has an entirely different organization and vocabulary from c-structure (trees with constituents like N, DP and VP). F-structure attribute-value matrices are subject to well-formedness conditions of unification, i.e. the information within an f-structure must be:

- *unique*—attributes must have only one value
- *complete*—an f-structure must contain all the grammatical functions that a given predicate requires
- *coherent*—all the grammatical functions must be required by some predicate within the local f-structure

LFG assumes f-structures have a degree of universality: translationally equivalent sentences in different languages have identical f-structures, even if their c-structures are quite different (as they would be for English and Jiwarli, for example).

3.4 Correspondence Principles

Central to LFG are *correspondence* or *mapping principles* relating the several parallel and independent representations of sentences.

3.4.1 A-structure to f-structure mapping. Lexical mapping theory establishes correspondences between a-structure thematic roles and f-structure grammatical functions. LFG has four core grammatical functions: SUBJECT, OBJECT, OBJECT_θ (thematically restricted 'second object' in sentences like 'Bill gives John *money*') and OBLIQUE_θ (obliques with a range of thematic roles), decomposable into two features:

- $[\pm r]$ for *semantically restricted* functions; OBJECT_θ and OBLIQUE_θ will be $[+r]$
- $[\pm o]$ for *object-like* functions, OBJECT and OBJECT_θ will be $[+o]$

This gives:

$\text{SUBJ} = [-r, -o]$ $\text{OBJ} = [-r, +o]$
$\text{OBL}_\theta = [+r, -o]$ $\text{OBJ}_\theta = [+r, +o]$

Grammatical functions are hierarchically ranked from least marked to most marked:

$\text{SUBJ} > \text{OBJ}/\text{OBL}_\theta > \text{OBJ}_\theta$

Lexical mapping assumes a Universal Thematic Hierarchy (see Bresnan and Kanerva 1989) reflecting a scale of thematic prominence:

Agent > Beneficiary > Goal > Instrument > Patient/Theme > Locative

and serves to link the hierarchy of thematic roles to that of grammatical functions in a predicatable fashion (thus Agent links to SUBJ in unmarked constructions, Theme to OBJ_θ and Goal to OBJ with verbs like 'give,' etc.).

Argument mappings can be affected by *lexical rules* which change a-structures. So, *passive* is a lexical rule which removes the highest argument and makes it unavailable for mapping (hence Agent is no longer able to be SUBJECT, but Patient or Recipient can be).

3.4.2 C-structure to f-structure mapping. In configurational languages mapping from c-structure to f-structure is mediated by phrase structure annotations (see (10)) passing information from lexical items and structural positions. Information is mapped from phrase structure nodes to a *variable* (corresponding to a pair of brackets in the f-structure matrix). Variables are resolved by an *f-description*, a set of *functional equations* for all the nodes in the tree. Consider just the subject DP in (7) above with variables indicated in (13).

(13)

This gives the following functional equations:

(14) $(f_1\ \text{SUBJ}) = f_2$
$(f_2\ \text{DEF}) = f_3$
$(f_2\ \text{DIST}) = f_3$
$(f_2\ \text{PRED}) = f_4$

These are resolved as:

$$\begin{bmatrix} \text{SUBJ } f_2 f_3 f_4 & \begin{bmatrix} \text{DEF} & + \\ \text{DIST} & \text{proximate} \\ \text{PRED} & \text{'child'} \end{bmatrix} \end{bmatrix}$$

and so on for the rest of the nodes on the tree. Mapping is from c-structure configurations plus lexical information to f-structure matrices.

In non-configurational languages structural position does not define grammatical functions; this information must be derived from other sources. Nordlinger 1998 suggests that morphologically inflected forms are annotated to construct their local f-structure environment. Thus, in Jiwarli the ergative case form would construct a partial f-structure where the nominal bearing this case is SUBJECT (regardless of its c-structure position), accusative constructs an OBJECT function, etc. In head-marking languages agreement morphology is involved in resolution of functional equations to construct f-structures directly from morphological (lexical) information, without mapping from c-structure (annotated) positions.

4. *Functions in Complex Sentence Constructions—Raising and Control*

In non-finite complement clause constructions the subordinate verb may be missing a subject:

(15) Harry doesn't like to speak Sumbawan

(16) Harry doesn't seem to speak Sumbawan

The main clause subject 'Harry' is also understood as the subject of the subordinate predicate 'speak Sumbawan,' however:

- in (15) (often called a *control construction*) two thematic roles are involved: Harry bears a thematic relation to both 'like' and 'speak';
- in (16) (often called a *raising construction*) only one thematic role is involved: Harry bears a thematic relation to 'speak,' but not to 'seem.'

In transformational grammars these two constructions are analyzed as having an *empty category* (or *gap*) as the subordinate subject; for control this is PRO, which obtains its reference from the main clause subject, and for raising it is a DP trace that remains after the subordinate subject has been moved up to the main clause:

Referential control

Harry doesn't like [PRO to speak Sumbawan] (17)

Harry doesn't seem [t to speak Sumbawan]

Movement (18)

Since LFG does not permit empty categories in c-structure, the constituency of these two sentences types is identical; both have a main clause verb taking a VP' (to VP) complement with no subject DP in c-structure:

(19)

The grammatical function of VP' is XCOMP, an *open function* complement missing a subject function in c-structure. The identity of this subject function in f-structure is resolved by *functional control*. The lexical entries for *like* and *seem* are annotated to indicate that their XCOMP's SUBJect is informationally equivalent to their own SUBJect (for *like* the main clause subject is semantically selected by the verb (inside the 〈 〉 brackets in the verb's a-structure); for *seem* it is not (outside the 〈 〉 brackets):

(20) *like* V (↑ PRED) = 'like 〈 (↑ SUBJ) (↑ XCOMP) 〉'
(↑ SUBJ) = (↑ XCOMP SUBJ)

(21) *seem* V (↑ PRED) = 'seem 〈 (↑ XCOMP) 〉 (↑ SUBJ)'
(↑ SUBJ) = (↑ XCOMP SUBJ)

The functional control equation is mapped to f-structure as a link between the main subject's f-structure and the subordinate subject's f-structure (the controller *f-commands* the controllee, i.e. is part of a less embedded f-structure):

(22)

5. Long Distance Dependencies

In sentences like the following there is a dependency relationship between an element in sentence-initial position and a grammatical function later in the clause:

(23) What doesn't Harry like to speak?

(24) Which analysis does Joan seem to prefer to write about?

(25) That person, I've never seen you talk to.

The distance between initial position and the site of the grammatical function assignment is potentially unlimited; these are referred to as *long distance* or *unbounded dependencies*. Transformational analyses have movement (called wh-movement or A-bar movement) with the sentence-initial *filler* being *extracted* and leaving a *gap* (or wh-trace empty category). LFG has no movement operations; long distance dependencies must be captured in another way.

There are several accounts of long distance dependencies in the LFG literature, the most recent use *functional uncertainty* (see Kaplan and Zaenan 1989, Bresnan 2000). Essentially a functional equation identifies the initial element bearing a *discourse function* (DF) such as TOPIC or FOCUS with a *grammatical function* (GF) such as SUBJECT or OBJECT later in the sentence. The path of this identification can be indefinitely long and passes through (in English) any number of COMPlement clauses—function assignment is thus *uncertain*. There are two approaches to the functional equation: *outside-in functional uncertainty* (Kaplan and Zaenan 1989) or *inside-out functional uncertainty* (Bresnan 2000). For the former the initial topic or focus position in a language such as English has a functional equation associated with it:

(26) $(\uparrow \mathrm{DF}) = (\uparrow \mathrm{COMP}^* \ \mathrm{GF})$

This says: in f-structure identify the f-structure of an element bearing a discourse function with the f-structure of a grammatical function, passing through indefinitely many COMPlements (indicated by the Kleene star operator *). This identification is signaled by a link in f-structure, and any restrictions on the long distance dependency (so-called *island constraints*) can be stated in terms of the path from filler to gap through the f-structure. (There is also a link for raising and control structures, however this is strictly local and lexically determined.) LFG claims that c-structure information is irrelevant for long distance dependencies, contrary to transformational accounts. Evidence this is correct comes from *category mismatches* between the filler and gap (see example (3)); it is *functional* identification which is relevant.

6. Current Issues

Among areas currently of concern in LFG are:

- the role of morphology in language structure, including the contribution of morphology to functional structure independently of c-structure, the relationship between inflectional morphology and syntax (and the notions of functional category, competition and blocking), and the interface between morphology and syntax (including concepts of what it is to be a word, and how to analyze predicates that are morphologically complex, such as serial verb or main verb-classifying verb constructions);
- the nature of semantic representations and σ-structure, especially the development of a 'glue language' to relate semantics and f-structures;
- computational implementation of LFG grammar models on large data sets, computer architectures (including grammar-translation) using a data-oriented probabilistic approach to LFG-parsed corpora (called DOP-LFG)
- the relationship between Optimality Theory (OT) and LFG models, exploring how violable constraints can be added to LFG analyses to give a preference ranking between them, and how OT approaches to syntax can be informed by research on parallel constraint-based models such as LFG.

7. Conclusion

Lexical Functional Grammar is a powerful approach to linguistic analysis and theory building that has been practiced for over twenty-five years. It is characterized by parallel independent but related linguistic structures that each contribute information in their own constrained fashion. It has been applied to a wide range of languages and is being actively developed for linguistic analysis, theory construction, and computational modeling with the goal of analyzing and understanding the nature of human language.

8. Further Reading

Falk (2001) is a very readable introduction; see also Chapter 13 of Carnie (2001). Bresnan (2000) is a more advanced state-of-the-art presentation of the theory and several new ideas. Bresnan (1982) and Dalrymple et al (1995) contain classic articles that remain relevant, though now somewhat dated.

Much material is available on the internet at www-lfg.stanford.edu/lfg/ and clwww.essex.ac.uk/LFG/, and through the International Lexical Functional Grammar Association at: www-lfg.stanford.edu/lfg/ilfga/. There is also an LFG e-mail and discussion list: access is described on the web sites.

Lexical Processes (Word Knowledge): Psychological and Neural Aspects

He doth not neglect the profit of Lexicons (wherein all sayings and speeches are numbred)
E. Topsell, *The historie of foure-footed beastes*, 1607

If one looks in any psychology or psycholinguistics textbook for a definition of the mental *lexicon*, the superficial description given does not differ to one of the first uses of the word quoted above from the Oxford English Dictionary. Most modern researchers would agree that the lexicon refers to our knowledge of the words in our vocabulary. There is, however, a very broad range of opinion if one asks the next obvious questions: what is this knowledge and how is it represented in the brain?

As with many areas of higher brain function, studies of the mental lexicon generally follow one of two levels of explanation: descriptive and computational. There are currently no theories of word knowledge at the level of individual neurons. Descriptive explanations try to outline the nature of the lexicon in detail, attempting to establish both what information is represented by the lexicon and how this information is accessed. Computational explanations provide more explicit descriptions of word knowledge and lexical processes through either formal mathematical treatments or in the form of computer-based models that take a specific input and transform it to the appropriate output.

Studies on the lexicon can be grouped into four categories, each employing a number of different research methodologies:

(1) *Normal, intact subjects*: most research here relies principally on reaction time, and to a lesser extent accuracy, as the critical dependent measures. Participants are typically required to give some form of response to spoken or written words (word recognition) or to give a spoken, single name (word production). A large number of different tasks are employed in each of these modalities. These include lexical decision (deciding whether a spoken or written stimulus is a real word or not), word monitoring (listening to spoken input and indicating when a target word has been presented), picture naming, and word naming (single word reading aloud). All these techniques aim to capture variations in reaction times in terms of differences between words of different types and/or with different characteristics. Alternatively the experimenter aims to manipulate a baseline reaction time through different presentation conditions (for example, the experimenter may investigate the effect of semantic priming—presenting a target word soon after a semantically related item).

(2) *Patients with brain injury*: the critical assumption underpinning this area of research is that different aspects of language, or in this case word knowledge, are supported by different areas of the brain (concentrated almost entirely in the left, dominant hemisphere). Therefore by studying patients with damage to one of these areas, it should be possible to reveal the underlying characteristics of how the human brain supports language, including word knowledge. Unlike studies with intact, normal participants, most research in this area relies most heavily on accuracy rather than reaction times. Studies are conducted on groups of patients (comparing to normal subjects and/or different types of patient group) or individual cases. A number of recent studies have also used a technique known as case-series methodology in which patients are selected on the basis of having the same type of deficit but at different levels of severity.

(3) *Functional neuroimaging*: for those techniques that concentrate more on spatial than temporal resolution, the underlying assumption for functional neuroimaging is the same as for neuropsychological studies with aphasic patients. In this way, functional magnetic resonance imaging (fMRI) or positron emission tomography (PET) compare words that vary according to a specific characteristic either using a parametric, subtraction methodology (looking for areas of the brain that are more active for one set than another) or a correlational technique (looking for areas in the brain where changes in activation are correlated with a changing characteristic of the presented words). Other imaging techniques are able to investigate how the time-course of activation com-

pares for words of different type. Such methods include event-related potentials (ERP) and magnetoencephalography (MEG).

(4) *Computational modeling*: this is a formal technique designed to instantiate a proposed computational description of the processes that underlying a specific set of behaviors. Most computational models do this by specifying an arrangement of simple processing units (known as a *network architecture*). The architecture describes how simulated activation can potentially be passed between these units. Information is either represented in localist form (the activation of a single unit corresponds to a specific piece of information—e.g., a word) or in a distributed manner (a number of pieces of information are represented by different patterns of activation across the same set of units—therefore, the activation of a particular unit is not unique to a specific datum). These computational models also differ along another dimension. In some models, the strength of the connection between units (that governs how much activation is passed between them) is specified explicitly by the modeler. Other networks use mathematical algorithms such that the model can extract its own set of weights to performance optimally. In doing so, these latter types of network can also be used to compare patterns of development as well as mature performance between the model and human subjects. Both types of model can be used to simulate disordered behavior (e.g., through brain injury) by various means including the removal of units and/or their connections, or by adding noise to the activation of units.

These four methods have given rise to a vast literature on the nature of the lexicon and its interaction with the rest of the language system. Some of the major themes arising from this work are summarized below.

1. *The Traditional Conception of a Lexicon*

Many theories of lexical representation are not that different from Topsell's definition of 1607: the lexicon is a list of all the words in a person's vocabulary. By some form of look up, all or part (in the case of models with multiple lexicons, see below) of our knowledge about a word is retrieved. An early functional and mathematical description of this process was given by Morton with his influential logogen theory (1969), which was originally applied to explain word recognition but was extended later to address spoken and written recognition and production. The key elements to this approach are as follows. Each word is represented by a separate unit, or logogen, which gathers evidence for the presence of that word in the input (in the form of sensory input for recognition or semantic memory for production). Each logogen does this relatively independently of the others. A word is recognized or produced when there is sufficient positive evidence for that word in the nature of the input (e.g., the letters in the written input match those for the target word). At this point, the logogen makes other information about that word available—such as the word's meaning or its pronunciation. With reference to signal detection theory, Morton also included the notion of a 'threshold' which governs how much positive evidence is required before the logogen makes a response. In this way, word frequency effects in recognition and production are described in terms of different thresholds for different logogens (high frequency words have lower thresholds and thus require less positive evidence to respond).

2. *How Many Lexicons are there?*

If one considers the literate adult, the sum total of the acquired knowledge can be classified into three forms: the meaning of words; the sound of each word; and, the written form or orthography. With reference to the traditional view of the lexicon (see Sect. 1), some researchers have argued that these three forms of information are represented in separate lexicons: lexical semantics, a speech lexicon, and an orthographic lexicon. Although most models have interconnections between these different lexicons (at some level they need to combine to reflect all aspects of word knowledge), the notion is that they are discrete entities both at a functional and neural level. Functionally, each lexicon can then have its own dedicated form of representation and associated processes. At the neural level (both for neuropsychological and neuroimaging studies) this means there are distinct regions in the brain that can be damaged/activated relatively independently of each other. The cognitive neuropsychology literature, in particular, has also encouraged a further division in the mental lexicon—for input and output processes. The notion here is that there might be four separate lexicons to cover the four combinations of recognition and production for spoken and written words (for an overview, see Ellis and Young 1988). The same division is not proposed for meaning, which in a sense would be nonsensical anyway (for effective communication, the meaning driving the speaker/writer's output must be the same as that decoded by the listener/reader). The need to have separate input and output representations is still contested, however. Some neuropsychological data would seem to favor this position—for example, there are patients with word-finding difficulties (anomia) that do not have trouble understanding words (word deafness), and other patients with the opposite pattern. However, more studies are needed to rule out the possibility that the patterns reflect modality-specific nonlexical deficits or the fact that expression is always more vulnerable to impairment than receptive abilities.

Two separate strands of research have argued for another lexicon—the semantic lexicon or lemmas, that mediate between meaning and other language processes and representations (neuropsychology—e.g., Butterworth et al. 1984; speech production—e.g., Levelt 1992). In terms of neuropsychology, an impaired separate lexicon that normally acts as a gateway between meaning and language processes explains the pattern found in a number of patients who have impaired production and comprehension of speech and writing but much better understanding of nonverbal material (again, this position is contended, for a recent overview, see Lambon Ralph and Howard 2000). In speech production, Levelt (1992) has argued for a two-stage process within lexical access. First the meaning of the intended utterance is used to select a single abstract lexical form, a lemma (that also codes for syntactical markings such as gender and number), and then this in turn activates a lexemme, which makes the sound of the word available both in terms of the constituent phonemes, their arrangement and associated stress pattern. There is, however, a general concern with this direction of theorizing in that a proliferation of multiple lexicons means the potential for redundancy of representations is much higher, and tends to make the theories unfalsifiable.

3. *An Alternative Conception of the Nature of Lexical Knowledge?*

A quite different approach has been adopted by some parallel distributed processing (PDP) computational models in which there is knowledge of the words in our vocabulary but not a lexicon—at least, in the traditional sense of that word. A landmark publication in this respect was the word reading and recognition model of Seidenberg and McClelland (1989). In this framework word knowledge is represented as distributed patterns of activation across three 'primary' systems corresponding to orthography, phonology and semantic memory. Through a gradual learning process, in which the weights of the connections within and between these representational layers are adjusted, models of this type extract word 'knowledge' from the vocabulary they are trained on. Note this is quite different from the traditional metaphor of looking up an entry in dictionary or Morton's logogen theory. The Seidenberg and McClelland model does not have a list of all the known words (i.e., a lexicon) so the terms 'access' and 'retrieval' are redundant. Instead the model takes one form of input (e.g., the written word) and then computes the appropriate representation reflecting the meaning and/or the pronunciation. In this way the model can be said to have word knowledge but not a lexicon. This is further reinforced by the fact that the model processes novel words (nonwords that, by definition, cannot be in a lexicon) through the very same set of units corresponding to the written or spoken form. Another potential allure of this approach to word knowledge is that the formulation may help when future research (see Sect. 5) attempts to bridge the gap between brain and behavior. The neural basis for the primary systems of semantics, phonology, and orthography is much more obvious. It is possible, for example, that orthography reflects a stable set of representations extracted through visual perception (Behrmann et al. 1998) and semantic memory, or conceptual knowledge, reflects high-level abstraction based on all forms of verbal and nonverbal experience, perhaps supported primarily by regions within the temporal lobes (Tranel et al. 1997).

This alternative approach has also been used to address some of the data that has lead researchers, using a traditional view of the lexicon, to posit the need for multiple lexicons (see Sect. 2). For example, patients with both poor comprehension and production of words (whether spoken or written) are described from a traditional viewpoint in terms of damage to a semantic lexicon that mediates between conceptual knowledge and the language system. The same data are adequately captured by PDP computational principles in terms of the nature of the mapping between representations for words vs. pictures/objects (Lambon Ralph and Howard 2000). The fact that there is an arbitrary mapping between phonology/orthography and conceptual knowledge, unlike the mapping for pictures or objects, means that verbal comprehension and production are highly vulnerable to damage to the system that represents the meaning of both words and pictures.

4. *How Does Word Knowledge Give Rise to Specific Language Activities?*

Within the repertoire of language activities there are some that are assumed to depend directly on word knowledge or lexical information. For example, understanding words or producing words is assumed to proceed with reference to lexical information. So, as described above, within a logogen framework speech production occurs by the target meaning acting as an input to a set of logogens, which selects the correct word and then makes the spoken form available. There is also a direct use of word knowledge in PDP computational models as well—the knowledge extracted through learning the mapping between semantics and phonology is used to produce the correct spoken form in speech production. Other language activities are assumed to depend upon a combination of lexical knowledge and other nonlexical processes. So, for example, Levelt (1992) proposes that speech production is based upon a 'formulator' that specifies the syntactical frame for a sentence into which lexical representations (lemmas) and their associated knowledge are fitted. Two other well-known examples are reading aloud and the past tense transformation of

English verbs. Researchers studying the process of reading aloud have classified words into three basic types: (a) most words, known as regular or consistent words, are pronounced in line with their spellings (examples of these are YARD and MINT); (b) a smaller but still substantial number of irregular or inconsistent words deviate from the typical spelling-to-sound translations (examples of these are YACHT and PINT); and (c) we are also able to read new or novel words without extra training (e.g., EMAIL or WUG). There is a very similar classification for describing the past tense of an English verb. There are many regular verbs, all of which are turned into the past tense by the addition of -ED (e.g., *talk* → *talked* or *need* → *needed*), and a smaller number of irregular verbs which mark the past tense in another way (e.g., *speak* → *spoke* or *think* → *thought*). We are also able to produce the past tense for new or novel verbs (e.g., *email* → *emailed*, *wug* → *wugged*), again without any specific training on these novel forms. The traditional theories of verb inflection (the dual-mechanism account, Pinker 1999) and reading aloud (the dual-route theory, Coltheart et al. 1993) have both used this tripartite division of word type to argue that each language activity is underpinned by two distinctly different processes. The two theories are sufficiently similar that they can be summarized together. Irregular words/verbs (e.g., PINT → 'pint' for reading aloud and 'bring' → 'brought' for verb tense) are said to be translated by reference to a lexicon—or indeed, in the case of reading, two lexicons: one orthographic and the other phonological—that stores the whole specific word form for every irregular item in the language. The ability to read or inflect novel forms is explained in these theories by positing a task-specific, generative process encapsulated by a set of rules: three rules for the three allomorphs required for the inflection of regular verbs (/t/, /d/, /@d/) and an extensive series of rules for the translation of letters/graphemes into phonemes. Neuropsychological investigations of impairments to both reading aloud and past tense production have highlighted two contrasting patterns that have been taken to support these dual-mechanism theories (some patients have specific difficulties with irregular forms and others with novel forms: see Ullman et al. 1997 for verb morphology; an overview of acquired dyslexia can be found in Ellis and Young 1988).

Again, PDP computational models have taken a different approach (verb morphology, Joanisse and Seidenberg 1999; reading aloud, Plaut et al. 1996). In these frameworks word knowledge is not reflected in a lexicon and thus the strict division between the lexicon and the generative rules does not apply. Instead the interaction between and within the primary systems (semantics, phonology, and orthography) not only give rise to word knowledge, the models are also capable of transforming one form of representation into another (e.g., reading is orthography → phonology) for all three word types (irregular, regular, and novel). Critically, however the division of labor amongst the primary representations is not even for the different word types, and dissociations in performance can occur if one of the primary systems is damaged (for an overview of this perspective on acquired dyslexias, see Patterson and Lambon Ralph 1999).

5. *Future Directions*

Research on the psychological aspects of word knowledge will, no doubt, continue in the future. One potential area for new research must be on the neural aspects of word knowledge. There are already signs that neuropsychological and computational investigations of people with acquired language disorders (aphasia) are being used to address both psychological and more neural aspects of word knowledge (examples can be found in Ullman et al. 1997, Patterson and Lambon Ralph 1999). While there has been some use of positron emission tomography (PET) and functional magnetic resonance imagine (fMRI) to look at word knowledge (for an overview, see Price 1998), there is much more for these techniques to tell us about the neural aspects of word knowledge in the future.

Lexical Semantics

The 'core' areas of linguistics are generally agreed to be: phonology, the study of the sounds and sound systems of language; syntax, the study of grammar; and semantics, the study of linguistic meaning. Words figure in all three areas, but it is in their semantic aspect that they offer the most distinctive field of inquiry. This article presents a survey of the topics which form the principal foci of interest within the domain of lexical semantics.

1. Introduction

To the layman, words are the prime bearers of meaning in language, and formulating a message is essentially a matter of choosing the right words. This view is of course an oversimplification, and seriously understates the roles of grammar and of context, but there is more than a germ of truth in it. The branch of linguistics whose domain is the systematic study of word-meanings is lexical semantics. But before proceeding any further, it is necessary, first, to mark off an area of the slippery notion of 'meaning' which is appropriate for our purposes, and second, since other people, notably lexicographers, also concern themselves with the meanings of words, something needs to be said about what is distinctive about the activities of lexical semanticists.

If John says to Mary *Have you been to the bank and seen the manager?* and Mary replies *Yes*, there is an obvious and intuitively valid sense in which Mary's reply 'means' 'I have been to the bank and seen the manager.' Yet it is also fairly obvious that 'I have been to the bank and seen the manager' would not be a satisfactory definition of the meaning of the word *Yes*. It is therefore necessary to make a distinction between the 'inherent meaning' of a word and its 'meaning-in-context.' (The inherent meaning of *Yes* might be glossed: 'The proposition you present to me for confirmation is true.') A similar point (less dramatic) can be made about *The child ran to his mother*. Here it is clear that *the child* refers to a boy; but this, too, is meaning-in-context—the inherent meaning of *child* is something like 'immature human being.' As a first approximation, it can be said that lexical semantics focuses on inherent meanings of words: meanings-in-context are the concern of pragmaticians.

Lexicographers also are interested mainly in the inherent meanings of words. So what is the difference between a lexicographer's interest in word meaning and that of a lexical semanticist? Basically, this is a matter of theoretical vs. practical concerns, parallel in many ways to the relation between physicist and engineer, or botanist and farmer/gardener. A lexicographer aims to impart the maximum of information useful to the dictionary-user with maximum economy; a lexical semanticist wants to understand the principles underlying lexical semantic phenomena. In an ideal world there would be considerable cross-fertilization between the two fields: in reality, the cross-domain traffic has been somewhat disappointing.

2. Approaches to Word Meaning

There are numerous ways of approaching the study of word meaning, depending on certain basic assumptions one makes about it.

2.1 The Componential/Atomistic Approach

One influential approach, much criticized but constantly reborn, is to think of the meaning of a word as being a more or less complex structure, built up out of combinations of simpler, or more primitive, units of meaning, a simple example would be the analysis of *woman* as [ADULT] [HUMAN] [FEMALE]. Such 'componential' or 'atomistic' approaches come in a variety of types, depending on what is claimed regarding the nature of the analysis, the identity and nature of the units, how they are combined, and what aspects of word meaning are to be explained by them.

Some componential analyses (probably the majority) aim at a reduction in the number of combinatorial elements, that is to say, they aim to explain the large number of word meanings in terms of combinations of units drawn from a smaller set, parallel to the way that the phonological forms of all

words can be described in terms of combinations from a much smaller set of phonemes. To achieve a reduction, the basic elements must be highly reusable.

Not all analyses are reductive in this sense. One version aims only to distinguish the meaning of a word from that of all other items in the vocabulary, so each contrast potentially creates a new component. An example is the analysis of *chair* as [FURNITURE] [FOR SITTING] [FOR ONE PERSON] [WITH BACK]. This is certainly distinctive, but there is no guarantee that one will end up with fewer components than lexical items analyzed.

In the earliest versions of componential analysis, the components were the meanings of words, and the aim of the analysis was to extract a basic vocabulary, in terms of which all nonbasic meanings could be expressed. Generally speaking, the features recognized by earlier scholars had no pretensions to universality, and indeed were often avowedly language-specific. Later scholars aimed at uncovering universals of human cognition, a finite 'alphabet of thought.' Accessible introductions to componential analysis can be found in Nida (1975) and Wierzbicka (1996).

2.2 Holistic/Contextual Approaches

An atomistic approach to word meaning is predicated on the assumption that the meaning of a word can in principle be specified in isolation, without taking into account the meanings of other words in the language's vocabulary. Holistic approaches, on the other hand, maintain that words do not have meaning in isolation, but only in relation to the rest of the vocabulary.

A typical holistic approach is that of Lyons (1963, 1968, 1977), who espouses and develops the basic Saussurean notion that the 'value' of any linguistic element, whether phonological, syntactic or semantic, is essentially contrastive, that is to say, its identity is constituted by its difference from other elements with which it potentially contrasts. So, for instance, the essence of the meaning of *dog* is that it is 'not-cat,' 'not-wolf,' 'not-horse,' and so on. An important consequence of this is that it is not possible to learn the meaning of any word in isolation from other members of its contrast set; or, to put it another way, it is not enough to be able, for instance, to assign the label *dog* to any canine animal—one must also know to withhold the label from nondogs, such as foxes, wolves and so on. Lyons expounds an extended version of this, making it truly holistic, and defines the sense of a word as its position in a network of sense relations, direct or indirect, with all other items in the vocabulary. This network includes not only contrastive relations like that between *dog* and *cat*, but also relations of inclusion like that between *animal* and *dog*, and *dog* and *collie*.

2.3 Conceptual Approaches

Conceptual approaches locate meaning in the mind, rather than in language or in the extralinguistic world. Much discussion has had to do with the meanings of words in relation to conceptual categories (for general discussion, see Taylor 1989, and Ungerer and Schmid 1996).

The currently dominant view of what natural conceptual categories (concepts) are like is that they cannot in general be defined by any finite set of necessary and sufficient features, but are somewhat indeterminate in nature. One important theory, prototype theory, holds that natural categories are organized around ideal examples (prototypes), and that other items belong to the category to the extent that they resemble the prototype. There is normally no definite cut-off point dividing members from nonmembers: category boundaries are typically fuzzy, or vague.

A major difference of opinion exists over whether words map directly onto conceptual categories, or whether there is an intermediate level of semantic structure which is purely linguistic in nature. Those, like the cognitive linguistics, who argue for direct mapping, claim that there is no theoretical work for a linguistic level of semantics to do: all semantic phenomena can be given a conceptual explanation. Those who believe in an independent linguistic level of semantics argue that the fuzziness of conceptual distinctions contrasts with the sharpness of linguistic distinctions, and indicates a separate level of structure. (Think of the uncertain dividing line between 'alive' and 'dead' in 'real life' in relation to the fact that *The rabbit is dead* logically entails *The rabbit is not alive*.) They also point to cases like *book*, which (it is claimed) has a single sense (at the linguistic level), but corresponds to two different concepts, a concrete physical object (*The book fell from the shelf*) and an abstract text (*It is a very difficult book*).

A conceptual approach is not necessarily incompatible with a componential approach. Many prototype theorists characterize categories/concepts in terms of a set of prototype features, which may or may not have the status of semantic primitives. Such features are not of the necessary-and-sufficient sort, however, but have the property that the more of them something has, the better an example of the relevant category it is.

3. Core Problems of Lexical Semantics

Certain areas of investigation can be regarded as the defining core of the discipline.

3.1 Possible Words

An important question in lexical semantics is whether there are any restrictions on possible word meanings:

is there anything which can be conceived and described, but which could not constitute the meaning of a word? This is a difficult question, and there are a number of ways of approaching it.

It might be thought that there could not possibly be a verb which meant, for instance, 'to eat popcorn on a Wednesday morning while standing facing west,' or a noun denoting, collectively, a computer mouse, a used condom, and a map of the world. These are admittedly unlikely, but not logically impossible, provided they can be conceptually unified, and there is no apparent limit to what disparate events, properties, or things can be conceived as a unity in some belief system or other. (The first example above, for instance, could conceivably be part of the ritual practices of an eccentric religious cult.) Of course, prototypically, a noun denotes some spatiotemporally continuous entity, and prototypical events have a similar unity, and such tendencies are an important part of the semantic nature of words.

An apparently universal constraint on word meaning is 'structural continuity.' A simple illustration of this will have to suffice, as a precise statement of the constraint is quite complex. Take the phrase *a very old man*. A word meaning 'very old,' or 'old man,' or 'very old man' would occasion no surprise. But one meaning 'very—man,' such that any adjective applied to it would be automatically intensified (e.g., *an old very-man* = 'a very old man,' *a poor veryman* = 'a very poor man,' etc.) is inconceivable.

There are certain language-specific constraints on what can be packaged inside a single word. A famous example is the inability of, for instance, a French verb to simultaneously encode movement and manner information. In the English sentence *John ran up the stairs*, movement and manner are encoded in *ran* and direction in *up*. However, a French translation of this must package the information differently: *Jean monta l'escalier en courant*. Here, movement and direction are encoded in *monta*, and manner separately in *en courant*. The extent of such restrictions is at present insufficiently researched.

3.2 Polysemy

The meanings of words are notoriously affected by context: it is only a slight exaggeration to say that the semantic contribution a word makes is different for every distinct context in which it occurs. But the difference between two contextually-induced readings can range from relatively slight, as in *My cousin married a policeman* and *My cousin married an actress* ('male cousin' vs. 'female cousin'), to rather major, as in *elastic band* and *wind band*, with perhaps *a coat of paint* and *a coat of many colors* as intermediate examples.

A distinction can be made between cases where a word has more than one meaning and different contexts select different meanings, and cases where only one meaning is involved, which can be enriched in different ways in different contexts. The first type of case in general involves ambiguous words. These have a number of distinctive properties. Think of *bank* in *We finally reached the bank*. The two readings of *bank* are in competition, and only one can win: it is not possible to 'mean' both readings at once, except when punning. Nor is it possible to remain uncommitted with respect to the two meanings: with *cousin*, for instance, whether the cousin in question is male or female can be left open, but with *bank* one meaning or the other must be intended. In the case of *cousin* it can be said that there is a general meaning which covers both of the more specific possibilities; with *bank* there is no such 'superordinate' meaning. Contextual enrichment without polysemy may involve a type-to-subtype specification as with *cousin*, or *fly like a bird* and *sting like a bee*, where reference is to a prototypical instance of the mentioned category (i.e., not an ostrich or a drone), or it may be whole-to-part, as in *My car has a puncture*.

The distinct readings of ambiguous words may be totally unrelated, as with the two senses of *bank* and *band*: this is called *homonymy*. Lexicographers normally treat such cases as separate words that happen to have the same phonetic form. In other cases, there may be an intelligible semantic relation between the readings, in which case we speak of *polysemy*: lexicographers treat polysemy as involving a single word (with one main entry) which has two or more meanings. It is important to realize that there is no sharp dichotomy between 'related' and 'unrelated' meanings, but a continuous scale of relatedness. Some relationships are intuitively clear, such as the metaphorical relation between *branch of a tree* and *branch of a bank*, or the metonymic relation between *the old oak tree* and *It's made of solid oak*. Speakers are less sure whether they would mark *try* in *try a jacket on* and *try someone for murder* as related. Lexicographers often use common etymological origin as a criterion for polysemy, but this may run counter to current speakers' intuitions (usually more important for linguistics. Famous cases are *ear of corn* and *human ear*, which do not have a common origin, but are nonetheless felt by most people to be related, and a *glass of port* and *the ship entered port*, which have a common origin, but no relationship accessible to unaided intuition.

Some polysemic relationships are 'one-off'; others are highly recurrent, in which case the term *regular polysemy* may be used. Many metonymic relations are at least to some extent recurrent: for instance, the 'tree'/'wood' example mentioned above, or the difference between *Mary planted some roses* and *Mary picked some roses*. Metaphorical relations are typically not recurrent. For instance, both *head* and *foot* are often metaphorically extended, but the fact that one occurs is no guarantee that the other does. Hence, for instance, *foot of mountain* occurs but not *head of*

mountain, *head of school* but not *foot of school*, and so on.

Where there is a set of polysemous readings, it is often possible to identify one which is an intuitively plausible source from which the others can be derived by extension. For instance, given the three meanings of *position* in: *The house is in a wonderful position*, *John holds an important position in the company* and *What is your position on the euro*?, it is fairly clear that only the first is a plausible metaphorical source for the other two. This is commonly called the *literal* meaning. (For a general discussion of polysemy and related matters, see Cruse 2000, Chap. 6).

3.3 Specifying Word Meanings

How (or whether) one goes about the enterprise of specifying the content of a single sense depends very much on one's favored theoretical approach, and also to some extent on the purpose of the exercise. (Only a few linguistic semanticists have made anything beyond very small-scale attempts to provide full descriptions of real lexical senses.) A componentialist will seek to provide a finite set of necessary and sufficient semantic features; most meaning descriptions by cognitive linguists are also in the form of a set of features, but these are often weighted for importance, and are not necessary and sufficient. For any sort of holist, the full specification of a sense will necessarily be somewhat cumbersome. Lexicographers usually try (with varying degrees of success) to provide a watertight definition of the necessary-and-sufficient variety. This is one area where there is little in the way of consensus.

3.4 Sense Relations

The observation that the vocabularies of natural languages are at least partially structured has led to a lively interest in the underlying structuring principles—in particular, recurrent relations between meanings (usually referred to as '*sense relations*' or '*lexical relations*'). These are of two main sorts, paradigmatic and syntagmatic. It is the former that have been the most studied. (Cruse 1986 discusses sense relations in some detail.)

3.4.1 Paradigmatic relations. Paradigmatic sense relations represent sets of choices at particular points in the structure of sentences, and reflect the way a language articulates extra-linguistic reality. A limited number of sense-relations have figured prominently in discussions; they are: synonymy, hyponymy, meronymy, incompatibility, and oppositeness.

(a) *Synonymy*. Synonymy, or sameness of meaning, is not as simple as it appears. Absolute synonymy, which we can define as having the same degree of normality in all contexts, is extremely rare (if it occurs). Propositional synonyms, such as *begin* and *commence*, which have the same logical properties, are more common, but would not serve to fill a 'Dictionary of Synonyms.' Lexicographers' synonyms, such as *brave* and *heroic*, have an adequate intuitive basis, but are hard to pin down: they may be used contrastively (*He was brave, but I wouldn't say he was heroic*) but their differences must be of a minor nature.

(b) *Hyponymy*. Hyponymy is one of two important relations of inclusion. Examples are: *alligator: reptile, aunt: relative*, *truck: vehicle*. In the last pair, *truck* is the hyponym and *vehicle* the superordinate: the hyponym denotes a subclass of the class denoted by the superordinate (alternatively, the meaning of the superordinate is included in that of the hyponym). Notice that the terms *hyponym* and *superordinate* are relational, not absolute: *dog* is a hyponym of *animal* but a superordinate of *collie*.

(c) *Meronymy*. The second important inclusion relation is meronymy, the 'part–whole' relation, exemplified by *finger: hand*. (Hyponymy and meronymy must not be confused: a finger is not a type of hand, nor is a dog a part of an animal.) True parts are interestingly different from 'mere' pieces, in that they prototypically have clear boundaries, a characteristic form recognizable in other wholes of the same type, and a determinate function with respect to their wholes. (Think of the difference between the parts of a teapot—handle, spout, lid, and so on—and what typically results if a china teapot is dropped onto a hard floor.)

(d) *Incompatibility*. Incompatibility is related closely to hyponymy, being the typical relation between sister hyponyms of the same superordinate—like *dog*, *cat*, (*animal*); *apple*, *peach* (*fruit*). Incompatibility is not simply difference of meaning (sometimes termed '*heteronymy*'): incompatibles have a relation of mutual exclusion. For instance, *dog: cat* and *dog: pet* both represent 'difference of meaning.' But while it follows logically from the fact that something is a dog, that it is not a cat, hence *dog* and *cat* are incompatibles, it does not follow that it is not a pet, so *dog* and *pet* are not incompatibles. There is a parallel relationship between sister parts of a whole (co-meronymy): sister incompatibles denote classes with no members in common; co-meronyms denote sister parts that do not overlap physically (like *upper arm*, *lower arm*, and *hand*).

(e) *Opposites* (*Antonyms*). Opposites can be briefly characterized as binary incompatibles, that is, incompatibles that necessarily occur in two-member sets, several types can be recognized.

(i) Complementaries divide some domain into two, with no 'sitting on the fence.' For instance, organisms must be either *dead* or *alive*; those that are not dead are alive, and those that are not alive are dead. Other examples are *open: shut*, *true: false*, *stationary: moving*.

Figure 1
The structure of a hierarchy

Figure 2
A taxonomic lexical hierarchy (fragment)

(ii) Gradable contraries (in some systems, simply *antonyms*) differ from complementaries, first, in that they are gradable, that is, they occur normally with intensifiers such as *very*, *slightly*, *a bit*, etc., and in the comparative degree, and second, they are contraries, in that denying one term of a pair does not commit one to the other. A typical example is the pair *long*:*short*.

(iii) *Reversives* are opposites which denote counter-directional processes or actions; examples are *rise: fall*, *open: close*, *dress: undress*.

(iv) *Converses* present the same situation or event from different viewpoints: *The painting is above the photograph/The photograph is below the painting*; *John sold the car to Bill/Bill bought the car from John*.

3.4.2 Syntagmatic relations. Syntagmatic relations hold between items in the same larger unit, such as phrase, clause or sentence. They represent not choice but restrictions on choice, and control discourse cohesiveness. The effects of putting two words together in a grammatical construction can be described as 'normality' (*The cat purred*), 'clash' (*The cat barked/broke*), or 'pleonasm' (*He kicked it with his foot*). Syntagmatic relations are described usually in terms of 'selectional restrictions,' which specify the conditions for the normality of a sequence. So, for instance, for *a pregnant X* to be normal, *X* must denote a female mammal; for *Mary drank the Y* to be normal, *Y* must denote a liquid, and so on.

3.5 Lexical Structures

Sense relations form the basic structuring principles of various lexical configurational patterns in the vocabulary of a language. An important type is the lexical hierarchy, structured on the following pattern (which in principle can continue indefinitely in a downward direction, and can have indefinitely many items at each level except the first; see Fig. 1).

The two main types of lexical hierarchy are the classificatory, or taxonomic, variety, and the part–whole, or meronomic type. An important feature of a hierarchy is that, as we move down the structure, the branches proliferate, but never converge. In a taxonomic hierarchy, the successive levels represent successive subdivisions into mutually exclusive classes of items: each item is related to items higher up the hierarchy by the relation of hyponymy (as shown by the lines), and to items at the same level by incompatibility (see Fig. 2).

The structuring relations for a meronomic hierarchy are meronymy (vertical) and co-meronymy (horizontal) (see Fig. 3).

Other common lexical structures are nonbranching chains of various sorts:

Monday—Tuesday—Wednesday (etc.)
puddle—pond—lake—sea—ocean
freezing—cold—cool—lukewarm—warm—hot—scorching
millimetre—centimetre—metre—kilometre
second—minute—hour—day—week—month—year—decade—century—millennium

and 'grids' or correlated series:

sheep	mutton	mare	stallion
pig	pork	ewe	ram
cow	beef	doe	buck
deer	venison	lioness	lion

3.6 Historical Change of Meaning

Words are being used continually in ways which transform, stretch, broaden, or narrow their established senses. This flexibility is one of the strengths of language, enabling it to adapt and remain an effective tool of communication through ever changing circumstances. If a word is used repeatedly with a particular extended meaning, this may well, over time, become established, either as a new polysemous sense, or it may be incorporated as a result of a shift in the boundaries of the old sense. Many new senses can be found in the domain of personal computers: for example, *mouse*, *scroll*, *icon*, *alias*, *tool*, *save*, *back-up*. An example of changing boundaries is the incorporation of the legs of tables, chairs, etc., into the general category of LEGS, without any intuition of

Figure 3
A meronomic lexical hierarchy

figurative use. Most speakers regard the current use of *pet* in *cyberpet/electronic pet* as metaphorical extension, but in time this may well go the way of *leg*. The creation of a new polysemic sense is a sudden event (although the process of establishment is gradual). Some diachronic changes, however, are gradual. If one accepts a prototype account of meaning, then the prototype of, say, *car* has changed gradually over the last century or so, as cars themselves have changed.

4. General Questions

4.1 Dictionary vs. Encyclopedia

Many theorists (but by no means all) draw a distinction between an (ideal) dictionary of a language, and an encyclopedia. The former purports to contain information about the meaning of a word, while the latter incorporates general knowledge about the word's referents. The general assumption is that only the former is truly linguistic in nature; the latter concerns not semantics, but pragmatics. The distinction has some intuitive support: on the basis of our experience with dictionaries and encyclopedias, we have fairly clear expectations of what to find in the two types of publication. However, making the step from the likely contents of familiar publications to the contents of a 'lexical entry,' either in a theoretical model of word-semantics, or in a psychologically real 'mental lexicon,' is far from straightforward, and it has in fact proved difficult to provide a sound theoretical basis for the distinction. One proposal is that only truth-conditional features of meaning should form part of the lexical entry—that is, features which determine whether a statement containing the word in question is true or false of a particular situation.

However, this assumes that word meanings can in general be specified in terms of truth-conditional features, an assumption which is challenged by prototype theorists. Also, it is not intuitively clear why, for instance, 'can bark' should not be part of the meaning of 'dog,' even though *X is a dog* does not entail *X barks*. However, a claim that everything we know about dogs is legitimately part of the meaning of *dog* would also be intuitively suspect. One solution for a conceptualist is to say that the dictionary/lexical entry simply indicates which concept a word maps onto, but does not specify the contents of the concept.

4.2 Lexical Semantics and Syntax

An important and controversial topic is the relation between the meaning of a word and its grammatical properties. Historically, a wide spectrum of views can be noted, from proponents of the autonomy of syntax, to those who claim that all syntactic properties are semantically motivated. Probably the majority of linguists would take up some sort of intermediate position on this question: recent work by, for instance, Levin (see, e.g., Levin and Rapaport Hovav 1992), reveals a considerable amount of semantic determination of syntactic patterning; on the other hand, examples of differing syntactic behavior like the following are hard to see as semantically motivated:

I've finished the job.
I've completed the job.
I've finished.
I've completed.

A typical example of semantically motivated syntactic behavior is the following alternation:

John broke the stick.
The stick broke.

Verbs which show this behaviour must (a) denote a change of state in their transitive object/intransitive subject (*John saw the dog/* The dog saw*), and (b) must not encode any information other than the change of state, such as the nature or manner of the action performed by the causing agent (*John washed the car/* The car washed*).

5. Future Prospects

There is no doubt that considerable advances in the understanding of lexical semantics have been made in recent decades. But there remain nonetheless, areas where understanding is far from complete, and in which future progress can be anticipated. One such area is in a way the most fundamental of all, namely, what is it that distinguishes lexical semantics from phrasal or clausal semantics? An understanding of this issue might be expected to lead to a proper typology of word meanings, understood both interlingually and intralingually. This is currently in its infancy. Another vital area is that of polysemy, or more generally, variation in context. The varieties and mechanisms of contextual variation have received a great deal of attention; what is less well understood is how and why a reading crystallizes as a new, autonomous sense, with independent relational, combinatorial, and truth-conditional properties. Mention should also be made

of the eternal problem of how to specify what an individual sense of a word 'means.'

The study of lexical semantics is less 'autonomous' than that of, say, phonology, or syntax. Especially if one takes a cognitive linguistic view, there is no clear dividing line between lexical semantics and the study of conceptual categories within cognitive psychology; and advances in one field tend to have repercussions in the other. Advances in certain areas of psycholinguistics can also be expected to throw light on word meaning. For instance, there is currently a developing body of work on the time course of semantic activation. The meaning of a word is not activated all at once when a word is recognized, and the details of the activation process cannot fail to have relevance to our understanding of the internal structure of a word's meaning.

One area of practical concern, which is poised for a major take-off, but is currently held back by lexical semantic problems, is the automatic processing of natural language by computational systems. The main problems are the complexity of natural meanings and their contextual variability. The work currently being done in this area can be expected to spill over, not only into general lexicography, but also into the linguistic study of word meanings.

Lexicology and Lexicography

1. Introduction

Each language has a lexicon and a grammar, i.e., a set of elementary expressions and a set of rules according to which complex expressions are constructed from simpler ones. Some of these rules form complex words; others operate beyond the boundaries of the word, thus producing phrases and sentences. These distinctions, familiar from the days of the Greek grammarians, are not always clear cut, for at least two reasons. First, the notion of 'word' is not very well-defined (see also *Word Classes and Parts of Speech*). Second, there are complex expressions, whose meaning is more or less predictable from the meaning of its components, whereas this is not true for other complex expressions. The former are said to be 'compositional,' whereas the latter are 'lexicalized'; slightly different terms to characterize this opposition are 'productive' vs. 'idiomatic,' and 'free' vs. 'fixed'; in each case, the distinction is gradual. Lexicalization is rarely observed for inflected words (a possible exception are 'participles' such as *crooked* in *a crooked street*), but very frequent for compound words, such as *landlord* or (*to*) *withdraw*, or phrases such as *to kick the bucket*, which has a compositional as well as a lexicalized reading. Do lexicalized expressions belong to the lexicon of a language or to its grammar? There is no straightforward answer; their form is complex and rule-based, their meaning is not. Therefore, it is useful to take the term 'lexicon' in a somewhat broader sense; it contains all elementary expressions (lexicon in the narrower sense) as well as those expressions which are compound in form but not accordingly in meaning (see also *Lexicon*). The scientific investigation of the lexicon in this sense is usually called lexicology; it includes, for example, the historical development of the lexicon, its social stratification, its quantitative composition or the way in which some subfield is encoded in lexical items (e.g., 'terminology of hunting,' 'verbs of movement'). Lexicography, by contrast, deals with the compilation of dictionaries. There is considerable overlap between both disciplines, and in fact, not all authors make such a terminological distinction.

2. The Lexicon

The lexicon of a language is stored primarily in the head of its speakers, and for most of the history of mankind, it was only stored there. We do not know what form the 'mental lexicon' has (see also *Psycholinguistics*: *Overview*). There is agreement, however, that it consists of individual lexical units which are somehow interrelated to each other. There is no generally accepted term for lexical units. The familiar

term 'word' is both too broad and too narrow; one would not want to consider *goes* as a lexical unit, although it is a word, whereas expressions such as (*to*) *cut up* or *red herring* are lexical units but consist of several words. Other terms occasionally found are 'lexeme,' 'lemma,' or 'lexical entry,' but since these are also used in other ways, it is probably best to speak of lexical units.

It is important to distinguish between a lexical unit and the way in which it is named. The word *house* in a dictionary, followed by all sorts of explanations, is not the lexical unit—it is a name for such a unit. The lexical unit itself is a bundle of various types of properties. These include:

(a) phonological properties, which characterize how the lexical unit is pronounced; they include sounds, syllabic structure, lexical accent and, in some languages, lexical tone;

(b) graphematic properties, which characterize how the lexical unit is written (see also *Spelling*);

(c) morphosyntactic properties, which characterize how the unit can become part of more complex expressions; typically, they concern inflectional paradigm, word class, government relations, and others;

(d) semantic properties, which concern the 'lexical meaning' of the unit, i.e., the contribution which it makes to the meaning of the construction in which it occurs.

Some of these properties may be absent. This is most obvious for graphematic properties, since not all languages are written. There are a few lexical units without lexical meaning, such as the expletive *there* in English. Many linguists also stipulate 'zero elements,' i.e., units with morphosyntactic and semantic properties but without phonological properties (such as 'empty pronouns'); but these are normally treated in the grammar rather than in the lexicon.

Whereas these four types of properties are the defining characteristics of a lexical unit, other information may be associated with it, for example, its etymology, its frequency of usage, its semantic counterpart in other languages, or encyclopedic knowledge (thus, it is one thing to know the meaning of *bread* and a different thing to know various sorts of bread, how it is made, its price, its role in the history of mankind, etc.).

The lexical units of a lexicon are in many ways interrelated. They may share some phonological properties (for example, they may rhyme with each other), they may belong to the same inflectional paradigm, they may have the opposite meaning ('antonyms,' such as *black* and *white*), approximately the same meaning ('synonyms,' such as *to begin* and *to start*), or when complex in form they may follow the same construction pattern. Lexicological research is often oriented towards these interrelations, whereas lexicography tends to give more weight to the lexical unit in itself. In general, there is much more lexicographical than lexicological work (for a survey of the latter, see Schwarze and Wunderlich 1985); in fact, if there is any piece of linguistic description for some language, it is probably an elementary bilingual dictionary. The depth of this work varies massively not only across languages, but also with respect to the particular lexical properties. Whereas the phonological, graphematic and morphosyntactic features of the lexicon in Latin, English, French, and some dozen other languages with a comparable research tradition are fairly well described, there is no theoretically and empirically satisfactory analysis of the semantics of the lexicon for any language whatsoever. This has three interrelated reasons. First, there is no well-defined descriptive language which would allow the researcher to represent the meaning of some lexical unit, be it simple or compound; the most common practice is still to paraphrase it by an expression of the same language. Second, there is no reliable and easily applicable method of determining the lexical meaning of some unit; the most common way is to look at a number of occurrences in ongoing text and to try to understand what it means. Third, the relation between a particular form and a particular meaning is hardly ever straightforward; this is strikingly illustrated by a look at what even a medium-sized English dictionary has to say about the meaning of, for example, *on*, *sound*, *eye* or (*to*) *put up*. As a rule, there is not just one lexical meaning, but a whole array of uses which are more or less related to each other. This is not merely a practical problem for the lexicographer; it also casts some doubt on the very notion of 'lexical unit' itself (see also *Lexical Semantics*).

3. *Making Dictionaries*

Lexicographers often consider their work to be more of an art or a craft than a science (see, e.g., Landau 1984, Svensén 1993). This does not preclude a solid scientific basis, but it reflects the fact that their concrete work depends largely on practical skills such as being 'a good definer,' on one hand; and that it is to a great extent determined by practical, often commercial, concerns, on the other. Dictionaries are made for users, and they are intended to serve specific purposes. Their compilation requires a number of practical decisions.

3.1 *Which Lexical Units are Included?*

Languages are neither well-defined nor uniform entities; they change over time, and they vary with factors such as place, social class, or area talked about. A great deal of this variation is lexical. It is not possible nor would it be reasonable to cover this wealth in a single dictionary. Large dictionaries contain up to 300,000 'entries'; since idiomatic expressions are usually listed under one of their components (such as

to kick the bucket under (*to*) *kick*), they contain many more lexical units, perhaps up to 1 million. But, even so, they are by no means exhaustive. The second edition of the *Deutsches Wörterbuch* (see Sect. 5), the largest dictionary of German, covers less than 25 per cent of the lexical units found in the sources, and these sources are quite restricted themselves.

3.2 Which Lexical Properties are Described?

Just as it is impossible to include all lexical units of a language in a dictionary, it is neither possible nor desirable to aim at a full description of those which are included. Since a dictionary is normally a printed book, the graphematic properties of the unit (its 'spelling') are automatically given. Among the other defining properties, meaning is traditionally considered to be most important. Samuel Johnson's dictionary from 1755 (see Sect. 5) defines 'dictionary' as 'A book containing the words of any language in alphabetical order, with explanations of their meaning.' But Johnson also noted which syllable carries the main stress, and he gave some grammatical hints. In general, however, information on phonological properties was rare up to the end of the nineteenth century, and information on grammatical properties is usually still very restricted in nonspecialized dictionaries. But there are, of course, also dictionaries which specifically address these properties as well as some of the nondefining properties associated with a lexical entry, such as its origin (etymological dictionary) or, above all, its equivalent in other languages ('bilingual dictionary').

3.3 What is the Description Based Upon?

Usually, two types of sources are distinguished: 'primary sources' are samples of text in which the unit is used, 'secondary sources' refers to prior work of other lexicographers (and lexicologists). In fact, there is a third source, normally not mentioned in the theory of lexicography (sometimes called 'meta-lexicography'): this is the lexicographer's own knowledge of the language to be described, including his or her views on what is 'good' language. In practice, the bulk of a new dictionary is based on older dictionaries. This is always immoral and often illegal, if these are simply copied; but on the other hand, it would be stupid and arrogant to ignore the achievements of earlier lexicographers.

3.4 How is the Information Presented?

A dictionary consists of lexical entries arranged in some conventional order. Normally, an entry combines several lexical units under a single 'head word'; thus, all lexical units which include the word *put* may be listed under this head word, forming a kind of nest with an often very complex microstructure. We are used to alphabetically-ordered dictionaries; but there are other possibilities, for example, by thematic groups or by first appearance in written documents. Languages without alphabetic writing require different principles; in Chinese, for example, entries are usually arranged by subcomponents of the entire character and by the number of strokes.

These four questions can be answered in very different ways, resulting in very different types of dictionaries (see the survey in Hausmann et al. 1991, pp. 968–1573).

4. History

The first lexicographic documents are lists of Sumerian words (up to 1400) with their Akkadian equivalents, written in cuneiform script on clay tablets about 4,700 years ago. The practice compiling such word lists was continued throughout Antiquity and the Middle Ages; thus, the oldest document in German, the *Abrogans* (written around 765), is an inventory of some Latin words with explanations in German. Usually, these 'glossaries' did not aim at a full account of the lexicon; they simply brought together a number of words which, for one reason or another, were felt to be 'difficult,' and explained them either by a more familiar word in the same language or by a translation. Words were ordered alphabetically, by theme, or not at all. But there are also more systematic attempts, such as the *Catholicon*, a mixture of encyclopedia and dictionary which, compiled around 1250, was the first printed lexical work in Europe (Mainz 1460).

In the sixteenth century, two developments led to major changes. The first of these was the invention of printing by Gutenberg. By 1500, virtually all classical authors were available in print, thus offering a solid basis for systematic lexical accounts of Latin and Greek, such as Calepinus' *Dictionarium* (1502), soon to be followed by two early masterpieces: Robert Etienne's *Dictionarium seu Latinae Linguae Thesaurus* (Paris 1531) and Henri Etienne's *Thesaurus Graecae Linguae* (Paris 1572). The second major development was the slow but steady rise of national languages. Since early Italian, French, English, or German were hardly codified, a major aim of the first dictionaries in these languages was to give them clear norms. In some countries, national Academies were founded to this end. The outcome were dictionaries with a strongly normative, often puristic, stance, such as the *Vocabulario degli Academici della Crusca* (Venice 1612), the *Dictionnaire de l'Académie Française* (Paris 1694) and the *Diccionario de autoridades publicado por la Real Academia Espanola* (1726–1739).

The bulk of lexicographic work, however, was always done by enterprising publishers and engaged

individuals, such as Dr Samuel Johnson. Helped by six assistants, he produced *A Dictionary of the English Language* (London 1755), the first scholarly description of the English vocabulary, in less than eight years. It surpassed all its predecessors, including Bailey's *Dictionarium Britannicum* from 1736, which Johnson took as his point of departure, by the systematic use of quotations, taken from the best writers, and by his brilliant, sometimes somewhat extravagant, definitions (not everybody would dare to characterize patriotism as 'the last refuge of a scoundrel'). Less known, much less witty, but broader in coverage is the first comprehensive dictionary of German, Johann Christoph Adelungs *Versuch eines vollständigen grammatisch-kritischen Wörterbuchs der hochdeutschen Mundart* (Leipzig 1774–86).

The rise of historical-comparative linguistics in the early nineteenth century led to an enormous increase in grammatical and lexical knowledge. The first dictionary which tried to cover this knowledge was the *Deutsches Wörterbuch* by Jacob Grimm and (to a much lesser extent) his brother Wilhelm Grimm. Its first fascicle appeared in 1852, after about ten years of preparatory work, in which the Grimms were helped by about 100 scholars providing excerpts ('covering my desk like snowflakes,' Jacob Grimm). At that time, it was already clear that the original plan of 6–7 volumes, to be finished within 10–12 years, was unrealistic. The Grimms finished only letters A–(most of) F, and the final folio volume (of altogether 32) appeared in 1960. This long duration, as well as the varying talents and preferences of the contributors, has led to many inconsistencies; some entries got out of balance (no less than 60 pages are devoted to the single word *Geist*); still, it is an incommensurable source of lexical information.

The work of the Grimms inspired a number of similar ventures, such as Emile Littré's masterly *Dictionnaire de la langue française* (1863–1873), which is much shorter, but also much more consistent: Matthias de Vries and his numerous successors' voluminous *Woordenboek der Nederlandsche Taal* (1864–1998), and finally *A New English Dictionary on a Historical Basis* (1884–1928), generally referred to as the 'Oxford English Dictionary' (OED). It was initiated in 1857 by the philologist and churchman Richard Trench; in 1860, members of the Philological Society started to collect excerpts; in 1879, the Clarendon Press appointed James Murray as the Principal Editor. The first fascicle appeared in 1882, and the whole work was completed in 1928, 13 years after Murray's death. More than 200 scholars were involved in its production, more than 2,000 people are known to have contributed excerpts. The OED is not without flaws, even in its revised edition, which appeared in 1989 in print and in 1992 on CD-ROM; but among all attempts to describe the lexicon of a language, it comes closest to falsify what Dr Johnson stated in the preface to his own dictionary: 'Every other author may aspire to praise; the lexicographer can only hope to escape reproach.' (For a comprehensive survey of lexicographic work across languages, see Hausmann et al. 1991, pp. 1679–2710, 2949–3119).

5. *The Use of Computers*

We tend to think of dictionaries as the normal, if not the only possible way to compile and to present lexical information. But the dawn of the computer has provided us with a very different and in many ways more efficient tool. Computers can be used in at least three ways in lexicography. It is possible to transfer an existing dictionary to a computer, as has often been done over the last 20 years. Such a transfer offers several advantages: search is faster and more exhaustive; it is easier to revise and update the dictionary; and it is possible to add information not available in book format, for example, spoken sound instead of phonetic transcriptions. But essentially, the format of the printed book is maintained. Next, computers are a powerful tool in the production of a new dictionary. Rather than having a number of people read through books and newspapers and make excerpts of all occurrences which look interesting, it is now possible to compile huge text corpora that cover all varieties of a language, to scan these texts for all occurrences of words or word combinations, to sort these occurrences by various criteria, to link them to other occurrences, to add as much context as needed, etc. (see *Corpus Linguistics*).

The OED, is based on about 5 million excerpts, mostly handwritten on paper slips. A computer can easily process corpora of several hundred million words, i.e., several hundred million occurrences; new sources can rapidly be added. This allows a much broader and much more representative coverage of a lexicon than ever. But electronic corpora only provide the raw material; it still awaits lexical analysis. This analysis can be facilitated by computer tools, also; but no computer can tell us what a word means in a particular context. But even if only one minute is devoted to each occurrence in a one-hundred million corpus, it would take 10 lexicographers 100 years to go through it. This means that printed dictionaries can never reflect the wealth of information accessible in large corpora, since they presuppose that the lexicographer has finished the analysis. Therefore, the only way to make full use of large corpora is by means of lexical retrieval systems. They consist of (a) a computer-accessible and expandable corpus, (b) a set of tools, which allow, for example, not only the search for certain items but also statistical analysis or the determination of the first occurrence, and (c) a selective but steadily proceeding lexical analysis of the corpus. Thus, it is possible to add spoken forms in various dialects, information about word classes, or

the semantic analysis of some subset of lexical units, say all prepositions or all morphologically simple verbs. Similarly, translation equivalents can be added. Unlike printed dictionaries, such a lexical retrieval system will never come to an end, it is steady work-in-progress to which many can contribute and which will give us a deeper and broader understanding of the lexicon than any other method.

Lexicon

1. The Notion of Lexicon

The lexicon is standardly viewed as a listing of all the morphemes of a language, with information indicating how each morpheme behaves in the components of grammar involving phonology, syntax, and semantics. In no small part, the shape and character of grammar is determined by what the lexicon contains for these other grammatical devices. Nevertheless, both historically and conventionally, the lexicon has been seen as the passive module in the system of grammar.

More recently, the model of the lexicon has undergone significant revision and maturation. In particular, two trends have driven the architectural concerns of lexical researchers: (a) a tighter integration of compositional operations of syntax and semantics with the lexical information structures that bear them; and (b) a serious concern with how lexical types reflect the underlying ontological commitments of the grammar. In the process, the field has moved towards addressing more encompassing problems in linguistic theory, such as those below:

(a) How can we explain the polymorphic nature of language?

(b) How can we capture the creative use of words in novel contexts?

(c) How can semantic types predictably map to syntactic representations?

(d) What are the 'atoms' of lexical knowledge, if they exist at all?

In this article, we first review the conventional view of the lexicon and then contrast this with the theories of lexical information that have emerged since around 1990.

By all accounts, the conventional model of the lexicon is that of a database of words, ready to act in the service of more dynamic components of the grammar. This view has its origins squarely in the generative tradition (Chomsky 1955) and has been an increasingly integral part of the concept of the lexicon ever since. While the 'Aspects' model of selectional features restricted the relation of selection to that between lexical items, work by Jackendoff (1972) and McCawley (1968), showed that selectional restrictions must be available to computations at the level of derived semantic representation rather than at deep structure. But where did this view come from? In order to understand both the classical model of the lexicon as a database and the current models of lexically encoded grammatical information, it is necessary to appreciate the structuralist distinction between 'syntagmatic processes' and 'paradigmatic systems' in language. The lexicon has emerged as the focal point communicating between these two components, and can be seen as a hook which links the information at these two levels. One can go further still and view the elements of the lexicon as not just the building blocks for the more active components of the grammar, but also as actively engaging the building principles themselves.

While syntagmatic processes refer to the influence of horizontal elements on a word or phrase, paradigmatic systems refer to vertical substitutions in a phrasal structure. Syntagmatics evolved into the theory of abstract syntax while paradigmatics was all but abandoned in generative linguistics. In an early discussion of syntagmatic dependencies, Hjelmslev (1943) uses the term 'selection' explicitly in the modern sense and notes the importance of integrating paradigmatic systems with the syntagmatic processes they participate in. For Hjelmslev, there are two possible types of relations that can exist between elements in a syntagmatic process: 'interdependence' and 'determination', the latter of which is related to the notion of selectional restriction as developed by Chomsky (1965). As Cruse (1986) notes 'One reason that selectional restrictions were not integrated into mechanisms of grammatical selection and description in the 1970s and 1980s is that, if they are imposed correctly, the grammar is forced to model two computations:

(a) the entailment relations between selectional

restrictions as features must be modeled formally, in order to contribute to the computation of a syntactic description;

(b) the manner in which selectional features or constraints contribute to the determination of the meaning of expressions must be enriched in order to exploit these very features.'

Recently, with the convergence of several areas in linguistics (lexical semantics, computational lexicons, and type theories) several models for the determination of selection have emerged which actively integrate these central syntagmatic processes into the grammar, by making explicit reference to the paradigmatic systems which allow for grammatical constructions to be partially determined by selection. Examples of this approach are Generative Lexicon Theory (Bouillon and Busa 2001; Pustejovsky 1995), and to a certain extent, Construction Grammar (Goldberg 1995), CCG (Steedman 1997), and HPSG (Pollard and Sag 1994).

These recent theoretical developments have led to a new direction in lexical design. Rather than restricting the scope of the lexicon to that of a passive database, current frameworks have re-architected the relationship between syntactic and semantic representations and the underlying recurrence relations that generate them. These developments have helped to characterize the approaches to lexical design in terms of a hierarchy of semantic expressiveness. There are at least three such classes of lexical description, which are defined (cf. Pustejovsky 1995 for discussion):

(a) Sense Enumerative Lexicons: lexical items have a single type and meaning, and ambiguity is treated by multiple listings of words.

(b) Polymorphic Lexicons: lexical items are active objects, contributing to the determination of 'meaning in context' under well-defined constraints.

(c) Unrestricted Sense Lexicons: meanings of lexical items are determined mostly by context and conventional use. Few, if any, restrictions are imposed on how a word may refer.

Although there have been proponents for each class of lexical description defined here, the most promising direction seems to be a careful and formal elucidation of the polymorphic lexicons, and this will form the basis of our subsequent discussion of both the structure and content of lexical entries.

2. *The Structure of a Lexical Entry*

As mentioned in Sect. 1, it is generally agreed that there are three components to a lexical item: phonological, syntactic, and semantic information. In this entry, we mainly focus on the manner in which syntactic and semantic representations are encoded in the lexical entry.

There are two types of syntactic knowledge associated with a lexical item: its 'category' and its 'subcategory.' The former includes traditional classifications of both the major categories, such as noun, verb, adjective, adverb, and preposition, as well as the minor categories, such as adverbs, conjunction, quantifier elements, and determiners (see *Word Classes and Parts of Speech*).

Knowledge of the subcategory of a lexical item is typically information that differentiates categories into distinct, distributional classes. This sort of information may be usefully separated into two types, 'contextual features' and 'inherent features.' The former are features that may be defined in terms of the contexts in which a given lexical entry may occur. Subcategorization information marks the local syntactic context for a word. It is this information that ensures that the verb 'devour,' for example, is always transitive in English, requiring a direct object; the lexical entry encodes this requirement with a subcategorization feature specifying that an NP appear to its right. Another type of context encoding is collocational information, where patterns that are not fully productive in the grammar can be tagged. For example, the adjective 'heavy' as applied to 'drinker' and 'smoker' is collocational and not freely productive in the language (Mel'čuk 1988). 'Inherent features,' on the other hand, are properties of lexical entries that are not easily reduced to a contextual definition, but rather refer to the ontological typing of an entity. These include such features as count/mass (e.g., 'pebble' vs. 'water,' abstract, animate, human, physical, and so on.

Semantic information can also be separated into two categories: 'base semantic typing' and 'selectional typing.' While the former identifies the semantic class that a lexical item belongs to (such as entity, event, property), the latter class specifies the semantic features of arguments and adjuncts to the lexical item.

2.1 *Word Classes and Typing Information*

There are two major approaches to classifying lexical items by their type: syntactic and semantic. (Another influential tradition for verb classification, which we will not discuss in detail here, is a more descriptive approach to word classes, where membership is defined on the basis of grammatical behavior and verbal valency alternation, such as that elaborated on and compiled in Levin (1993)

One obvious way to organize lexical knowledge, be it syntactic or semantic, is by means of lexical inheritance mechanisms. In fact, much recent work has focused on how to provide shared data structures for syntactic and morphological knowledge (Flickinger et al., 1985). Evans and Gazdar (1990) provide a formal characterization of how to perform inferences in a language for multiple and default inheritance of linguistic knowledge. The language developed for that purpose, DATR, uses value-

Figure 1
Fragment of a type hierarchy

terminated attribute trees to encode lexical information. Briscoe et al. (1993) describe a rich system of types for allowing default mechanisms into lexical type descriptions.

Type structures can express the inheritance of syntactic features (Sanfilippo 1993) as well as the relationship between more conventional taxonomic information, such as that shown in Sect. 2.2 (cf. Copestake and Briscoe 1992, Pustejovsky 1995, Pustejovsky and Boguraev 1993) and Fig. 1.

Given a semi-lattice of types such as this, the lexical items in the language can be associated with a much richer system of differentiated semantic classes. Verbs may also be structured in hierarchical relations, as done in HPSG, LFG, and other lexical frameworks (cf. Pollard and Sag 1994, Alsina 1992, Koenig and Davis 1999).

2.2 Argument Structure

Once the base syntactic and semantic typing for a lexical item has been specified, its subcategorization and selectional information must be encoded in some form. There are two major techniques for representing this type of knowledge:

(a) associate 'named roles' with the arguments to the lexical item;

(b) associate a logical decomposition with the lexical item; meanings of arguments are determined by how the structural properties of the representation are interpreted (cf. Hale and Keyser 1993, Levin and Rappaport 1995, Pustejovsky 1995).

One influential way of encoding selectional behavior is the theory of thematic relations (cf. Gruber 1976, Jackendoff 1972). Thematic relations are typically defined as partial semantic functions of the event being denoted by the verb or noun, and behave according to a predefined calculus of roles relations (e.g., Carlson 1984, Chierchia 1989, Dowty 1989). For example, semantic roles such as agent, theme, and goal can be used to partially determine the meaning of a predicate, when they are associated with the grammatical arguments to a verb.

The theory of argument structure as developed by Williams (1981), Grimshaw (1990), and others can be seen as a move towards a more minimalist description of semantic differentiation in the verb's list of parameters. The argument structure for a word can be seen as the simplest specification of its semantics, indicating the number and type of parameters associated with the lexical item as a predicate. For example, the verb 'build' can be represented as a predicate taking two arguments, while the verb 'give' takes three arguments.

(1) (a) build (x, y)
(b) give (x, y, z)

What originally began as the simple listing of the parameters or arguments associated with a predicate has developed into a sophisticated view of the way arguments are mapped onto syntactic expressions. Williams' (1981) distinction between 'external' (the underlined arguments) and 'internal' arguments and Grimshaw's proposal for a hierarchically structured representation (cf. Grimshaw (1990) provide us with the basic syntax for one aspect of a word's meaning. Similar remarks hold for the argument list structure in HPSG (Pollard and Sag 1994) and LFG (Bresnan 1994).

The interaction of a structural argument list and a rich system of types, such as that presented, provides a mechanism for semantic selection that overcomes the difficulties mentioned in Section 2. The most direct impact of semantic type systems on syntactic subcategorization can be seen with the analysis of a simple example.

(2) (a) The man/the rock fell.
(b) The man/*the rock died.

Returning to the example in (2), consider how the selectional distinction for the feature [+/− animacy] is modeled. For the purpose of illustration, the arguments of a verb will be represented in a list structure, where each argument is identified as being typed with a specific value.

(3) (a) $\begin{bmatrix} \text{fall} \\ \text{ARGSTR} = [\text{ARG}_1 = \textbf{x:phys_obj}] \end{bmatrix}$

(b) $\begin{bmatrix} \text{die} \\ \text{ARGSTR} = [\text{ARG}_1 = \text{x:animate}] \end{bmatrix}$

In the sentences in (2), it is intuitively clear how rocks can't die and men can but it is still not obvious how this inference is computed, given what we would assume are the types associated with the nouns 'rock' and 'man' respectively. What accomplishes this computation is a rule of subtyping, Θ, that allows the type associated with the noun 'man' (i.e., human) to also be accepted as the type animate, which is what the predicate 'die' requires of its argument as stated in (3b)

(4) $\Theta\ [\textit{human} \sqsubseteq \textit{animate}]: \textit{human} \rightarrow \textit{animate}$

The rule Θ applies, since the concept human is subtyped under animate in the type hierarchy. Parallel considerations rule out the noun 'rock' as a legitimate

argument to 'die' since it is not subtyped under animate. Hence, one of the concerns given for how syntagmatic processes can systematically keep track of which 'selectional features' are entailed and which are not is partially addressed by such lattice traversal rules as the one presented here.

Selection can also be employed to solve the problem of polymorphism, where the same lexical item can appear in multiple syntactic contexts, as illustrated in (5) below.

(5) (a) Mary began to read the novel.
(b) Mary began reading the novel.
(c) Mary began the novel.

Generative Lexicon Theory handles such examples by the use of semantic selection (cf. Pustejovsky 1995) and canonical syntactic mapping rules, specifying how semantic types correspond to syntactic expressions. Here, the verb 'begin' is typed as taking an event description as its internal argument, begin (Ind, $\mathscr{E}$), which can be realized in one of the three syntactic forms shown. This illustrates how a generative system of type operations can account for polymorphic behavior of selection in the syntax.

2.3 Decomposition and Event Structure

The second major approach to the specification of lexical knowledge is that taken by decompositional theories. Most of this research has focused on the lexical specification for verbs, their arguments, and their syntactic behavior. Some recent work, however, has been done on noun semantics as well (Busa 1996). In this section, we examine the motivations for lexical decomposition in linguistic theory, and the various proposals that have emerged on how to encode lexical knowledge as structured forms. We then relate this to the manner in which verbs refer to events, since this directly impacts the nature of the lexical decomposition structure.

Since Davidson (1967), events have played an increasingly important role in the determination of verb meaning. While early researchers on decompositional models (Dowty 1979, Lakoff 1965, McCawley) made no ontological commitments to events in the semantics for verbs, a new synthesis has emerged in recent years which attempts to model verb meanings as complex predicative structures with rich event structures (cf. Hale and Keyser 1993, Parsons 1990, Pustejovsky 1991, Tenny 1994). This research has developed the idea that the meaning of a verb can be analyzed into a structured representation of the event that the verb designates, and has furthermore contributed to the realization that verbs may have complex, internal event structures. Recent work has converged on the view that complex events are structured into an inner and an outer event, where the outer event is associated with causation and agency, and the inner event is associated with telicity (completion) and change of state. Under this view, a canonical accomplishment predicate as in 'John sliced the bread,' for example, can be represented as composed of an inner and an outer event. The inner event is the telic event in which the bread undergoes a change of state, and the outer event is the event in which John acts agentively (to do whatever is involved in the act of slicing). Since the outer event causes the inner one, it is associated lexically with causation.

Although there is a long tradition of analyzing causation as a relation between two events in the philosophical (cf. Davidson 1967) and psychological literature (cf. Miller and Johnson-Laird 1976, Schank 1973) in contemporary models of natural language semantics this idea has only recently been adopted. For example, Carter (1976), one of the earlier researchers in this area, represents the meaning of the verb 'darken' as follows:

(6) x CAUSE ((y BE DARK) CHANGE))

The predicate CAUSE is represented as a relation between a causer argument x and an inner expression involving a change of state in the argument y, although there is an intuition that the cause relation involves a causer and an event. Carter does not make this commitment explicitly. Levin and Rappaport (1988) follow a similar strategy, with a CAUSE predicate relating a causer argument and an inner expression involving a change of state in the argument y. The change of state is represented with the predicate BECOME:

(7) wipe the floor clean:
x CAUSE [y BECOME (AT) z] BY [x 'wipe' y]]
x CAUSE [floor BECOME (AT) clean] BY
[x 'wipe' floor]

The work of Levin and Rappaport, building on Jackendoff's Lexical Conceptual Structures, has been influential in articulating the internal structure of verb meanings (see Levin and Rappaport 1995).

Jackendoff (1990) develops an extensive system of what he calls 'Conceptual Representations' which parallel the syntactic representations of sentences of natural language. These employ a set of canonical predicates including CAUSE, GO, TO, and ON, and canonical elements including Thing, Path, and Event. These approaches represent verb meaning by decomposing the predicate into more basic predicates. This work owes obvious debt to the innovative work within generative semantics, as illustrated by McCawley's (1968), analysis of the verb 'kill.' Recent versions of lexical representations inspired by generative semantics can be seen in the Lexical Relational Structures of Hale and Keyser 1993, where syntactic tree structures are employed to capture the same elements of causation and change of state as in the representations of Carter, Levin and Rapoport, Jackendoff, and Dowty.

Pustejovsky (1988, 1991) extends the decompositional approach presented in Dowty (1979) by explicitly reifying the events and subevents in the

predicative expressions. Unlike Dowty's treatment of lexical semantics, where the decompositional calculus builds on prepositional or predicative units (as previously discussed), a 'syntax of event structure' makes explicit reference to quantified events as part of the word meaning. Pustejovsky further introduces a tree structure to represent the temporal ordering and dominance constraints on an event and its subevents. For example, a predicate such as 'build' is associated with a complex event such as that shown in (8):

(8) $[_{\text{transition}}[e_1\text{: PROCESS}]\ [e_2\text{: STATE}]]$

The process consists of the building activity itself, while the state represents the result of there being the object built. Grimshaw (1990) adopts this theory in her work on argument structure, where complex events such as 'break' are given a similar representation. In such structures, the process consists of what x does to cause the breaking, and the state is the resultant state of the broken item. The process corresponds to the outer causing event as discussed, and the state corresponds in part to the inner change of state event. Both Pustejovsky and Grimshaw differ from the authors above in assuming a specific level of representation for event structure, distinct from the representation of other lexical properties. Furthermore, they follow Higginbotham (1985) in adopting an explicit reference to the event place in the verbal semantics.

2.4 Qualia Structure

Thus far, we have focused on the lexical information associated with verb entries. All of the major categories, however, are encoded with syntactic and semantic feature structures that determine their constructional behavior and subsequent meaning at logical form. How this is accomplished, of course, varies from theory to theory.

In Generative Lexicon Theory, it is assumed that word meaning is structured on the basis of four generative factors, or 'qualia roles,' that capture how humans understand objects and relations in the world and provide the minimal explanation for the linguistic behavior of lexical items (these are inspired in large part by Moravcsik's (1975, 1990) interpretation of Aristotelian *aitia*).

formal: the basic category that distinguishes the object within a larger domain;

constitutive: the relation between an object and its constituent parts;

telic: its purpose and function;

factors involved in the object's origin or 'coming into being.'

Qualia structure is at the core of the generative properties of the lexicon, since it provides a general strategy for creating new types. For example, consider the properties of nouns such as 'rock' and 'chair.' These nouns can be distinguished on the basis of semantic criteria which classify them in terms of general categories such as natural_kind, artifact_object. Although very useful, this is not sufficient to discriminate semantic types in a way that also accounts for their grammatical behavior. A crucial distinction between 'rock' and 'chair' concerns the properties which differentiate natural_kinds from 'artifacts': functionality plays a crucial role in the process of individuation of artifacts, but not of natural kinds. This is reflected in grammatical behavior, whereby 'a good chair,' or 'enjoy the chair' are well-formed expressions reflecting the specific purpose for which an artifact is designed, but 'good rock' or 'enjoy a rock' are semantically ill-formed since for 'rock' the functionality (i.e., TELIC) is undefined. Exceptions exist when new concepts are referred to, such as when the object is construed relative to a specific activity, such as in 'The climber enjoyed that rock'; 'rock' itself takes on a new meaning, by virtue of having telicity associated with it, and this is accomplished by integration with the semantics of the subject NP. Although 'chair' and 'rock' are both physical_object, they differ in their mode of coming into being (i.e., AGENTIVE): artifacts are man-made, 'rocks' develop in nature. Similarly, a concept such as 'food' or 'cookie' has a physical manifestation or denotation, but also a functional grounding, pertaining to the relation of 'eating.' These apparently contradictory aspects of a category are orthogonally represented by the qualia structure for that concept, which provides a coherent structuring for different dimensions of meaning.

For relations, the qualia act in a similar capacity to thematic relations, but where the individual qualia are possibly associated with entire event descriptions, and not just individuals. For discussion, see Pustejovsky (1995).

3. Consequence of Lexical Design

Considering the potential range of information that can be represented lexically results in a reconceptualization of what a lexicon is, so that the very design of the grammar is significantly impacted. Furthermore, our current understanding of psychological and computational properties of language processing suggests that the resources available for lexical storage and access are considerably higher than originally imagined by early grammatical theorists. The consequence is that, what had originally been accomplished in syntax, because of the combinatoric properties inherent in production rules, can be handled by the lexicon itself. The various approaches to lexical encoding can be analyzed in terms of two parameters.

(a) Precompiling the information into lexical items forms;

(b) Computing or generating new forms or senses during the compositional process.

Typically, idioms are presented as examples of precompiled lexical entries. But some theories have adopted this idea as fundamental for the entire

compositional operation. The best example of this is Combinatory Categorical Grammar (CCG) (Steedman 1997). CCG has recently been articulated in enough detail to handle most of the major linguistic phenomena using a library of precompiled lexical types, together with the combinatoric rules of categorical syntax. If the grammar utilizes representations with such non-local dependencies, then there must be additional mechanisms for unifying these representations; these are provided in the form of function composition rules and lexical rules (Schabes et al. 1988).

Lexical rules have been invoked in HPSG, as well, to explain the relationship between the various senses for lexical items, from grinding and packaging operations (such as that relating the animal and food senses of 'chicken' and 'lamb,' to the relation between logically polysemous items, such as 'book' information and physical object), and 'lecture' (information and event) (cf. Copestake and Briscoe 1992). In Generative Lexicon such relations are explicitly represented in context (cf. Johnston 1995). It is very likely, however, that language makes use of both types of devices, namely complex types such as dot objects, as well as the application of lexical rules. Regardless, both types of devices must be seriously constrained by the grammar in order not to overgenerate unwanted forms and interpretations.

Considered independently of the issue of precompiled vs. generated forms and senses, there is no question that the mental lexicon is large, containing arguably up to 400,000 lexical entries. This is based on fairly conservative estimates of speaker competence with active and passive vocabularies. For example, an average speaker lexicon might contain at least 5,000 distinct verbs, 30,000 distinct nominal forms, and over 5,000 adjectives. Combine this with an additional 10,000 compound forms and at least 300,000 distinct proper names. Obviously, the psychological (and hence computational) demands of these classes are quite distinct. There are two dimensions that can help us distinguish these classes: (a) the degree of combinatoric (functional) complexity of the lexical item; and (b) whether the lexical item is part of active or passive lexical knowledge. Most closed class items, for example, are functionally complex, as are many open class verbs and relational nouns. The majority of the open class items will also involve a fair amount of information regarding combinatoric possibilities. The class of names, however, is unique in that, although it is by far the largest class of lexical items, it is the least demanding in terms of computational resources.

In conclusion we see that the lexicon is neither a mere listing of morphemes in the language, nor a database of items passively waiting in the service of grammatical processes. Rather, the lexicon is a dynamic and active system of grammar, incorporating as well as dictating essential components of syntactic and semantic composition and interpretation.

J. Pustejovsky

Liability: Legal

Legal liability may be defined most generally as any legally enforceable obligation to act or refrain from acting in a particular way. Some preliminary distinctions are in order.

First, a legal liability may be potential, in the sense that a legally defined duty exists whose violation by the duty-holder would trigger liability, or it may be current, in the sense that the duty-holder has already violated it and the fact of violation either has been authoritatively determined or is not really in dispute.

Second, a legal liability may be criminal, civil, or administrative. It is criminal if violations are prosecuted by the government as an offense against the public and may subject violators to imprisonment or criminal fines under the special rules and procedures applying to criminal prosecutions, such as the 'guilt beyond a reasonable doubt' standard. It is civil if the violation is enforceable by private parties (or by the government acting in a proprietary or other analogously private capacity) seeking relief in the form of money damages, an injunction, or a declaratory judgment. It is administrative if the violation is enforceable by an administrative agency pursuant to a regulatory statute.

Third, legal liabilities may be distinguished according to the substantive law that prescribes the duty in question. This distinction is most commonly applied in connection with civil liability, where the duty may be a creature of tort law, contract law, fiduciary law, property law, inheritance law, family law, and so forth.

Fourth, the process by which liability is determined differs significantly between common law and civil law systems (Damaska 1986). This article focuses on a common law system, that of the USA, but notes several points on which the civil law systems adopt a different approach.

The discussion here is confined to general tort liability. At its most general and schematic level, the system for imposing tort liability ('tort system') consists of six elements: goals; substantive rules; procedural rules; remedies; choice of law; and institutions. A seventh element, which defines by exclusion, consists of enclaves in which tort law has been limited or eliminated (see *Torts in Law*).

1. Goals of Tort Law

Considerable controversy exists over the goals that tort law should serve and how those goals should be weighted (Calabresi 1970). According to most tort law scholars, the dominant—and for some, the only—legitimate purpose of tort law was traditionally thought to be 'corrective justice.' This is an Aristotelian notion defining justice as the restoration of the *status quo ante* by repairing wrongfully inflicted losses and annulling wrongfully obtained gains. Some scholars see corrective justice as requiring a system of tort law that enforces a direct, moral relationship between the victim and the injurer, obliging the latter to compensate the former for the injury that he or she has wrongfully inflicted. The purpose of compensation, in this view, is simply to affirm this moral

relationship and to effectuate this duty of repair, correction, and restoration (Coleman 1992).

Increasingly, however, the corrective justice conception of tort law has been augmented, and to some extent supplanted, by more functional goals. They seek to enforce not a particular moral relationship between injurer and victim for its own sake, but rather a variety of social goals to which the individual parties to the tort case are merely instrumental. The most important of these social goals are (a) the deterrence of excessive risk creation, and (b) the distribution of injury losses through the compensation of victims.

The functional rationale for compensation is that it distributes the costs of accidents more broadly; at the limit (social insurance), it spreads those costs from the individual victim to all members of society, who can better bear it. But a functionalist tort law might—depending on the dictates of benefit–cost analysis, effective deterrence, administrative efficiency, insurability, and other policy criteria—require that an entity other than the injurer (e.g., private or social insurance) compensate the victim, or might deny the victim compensation altogether. In the functional view, morality is at most a policy constraint; it is not constitutive of justice in tort law. Some scholars oppose functional justifications for tort liability because they believe that judges' use of private tort disputes to pursue broad social policy goals is institutionally illegitimate, incompetent, or both (Sugarman 1989).

2. *Substantive Rules*

Tort law prescribes a body of substantive legal doctrine (i.e., rules or principles) to govern behavior. In common law systems, these rules are derived largely by courts from general principles of justice, previously decided cases, policy considerations, and other sources, though statutes and regulations are becoming more important sources of liability rules. In civil law systems, statutes (or codes) are the principal sources, but considerable judicial interpretation, guided by general principles of justice, is often required.

Whatever their sources, these rules or principles define the legally enforceable duties that an individual (or other entity) owes to others, and the circumstances in which he or she may violate those duties (the 'standard of care'). For example, tort law prescribes the legal duties that a physician owes to his or her patient and the standard of care that he or she must satisfy in order to avoid liability for injuries to the patient caused by the physician's acts or omissions. The standard of care is usefully understood in terms of the risks of injury that the physician is permitted to create in the course of treating the patient. Ordinarily—and in the case of healthcare—tort law defines this standard of care as 'reasonable behavior or care under all of the relevant circumstances.' A failure to meet this standard of care is called 'negligence' or 'fault' (or, in the specific case of medical treatment, 'medical malpractice') (Prosser and Keeton 1984).

For certain types of activities, such as the use of explosives or the sale of defective products, the standard of care is not negligence but 'strict liability.' If an activity is subject to a strict liability standard, the actor who causes an injury to another person is liable for that injury even if he or she was exercising reasonable care (i.e., was not negligent). In common law countries such as the USA, negligence is the default standard of care and strict liability the exception. Indeed, even strict liability rules usually incorporate fault-type balancing considerations that make the liability less strict than it might appear on its face.

In addition to negligence and strict liability, there is a third liability standard: intentional infliction of harm. Although courts have defined 'intention' in a number of different ways, it is not limited to harming another with malice, ill-will, or an affirmative desire to injure, but also includes a risky action undertaken with the knowledge (or in some cases, reason to know) that it is likely to injure another. A fourth liability standard, no liability, is discussed in Sect. 7.1 under 'immunities.'

In order to establish a defendant's tort liability, the plaintiff must prove that the defendant owed him or her a legal duty of care, that the defendant breached this duty by violating the applicable legal standard (usually negligence), and that the defendant's breach of duty caused harm to the plaintiff of a kind that tort law recognizes as compensable.

Even if the plaintiff is able to establish duty, breach, causation, and damage, however, tort principles may provide the defendant with a defense. If the defendant can prove that a particular defense applies, the defense is usually a 'complete' one barring any liability. Examples include assumption of the risk (i.e., the plaintiff knowingly and voluntarily consented to the risk), statute of limitations (i.e., the plaintiff did not bring suit within the requisite period of years), and immunity (i.e., the law bars liability for certain categories of actors). The plaintiff's own negligence ('contributory negligence') traditionally was a complete defense, but this rule has been replaced by various versions of 'comparative negligence (or fault)' under which the plaintiff's negligence does not bar his or her recovery completely but instead reduces it according to the parties' relative fault (Prosser and Keeton 1984).

3. *Procedural Rules*

Procedural rules specify how claims must be presented to the court, which party bears the burden of producing evidence in the first instance, which party bears the burden of persuading the trier of fact (judge or

jury), and which standard of proof must be satisfied (usually 'a preponderance of the evidence', also described as 'more likely than not'). These rules also prescribe how jurisdiction over a party must be obtained, what kinds of notice must be provided, how discovery (i.e., disclosure of information possessed by a party or witness) is conducted, how other parties may be brought into the lawsuit, the powers that judges may lawfully exercise, how parties should conduct motion practice (i.e., the rules governing requests for judicial orders), how decisions may be appealed, and the like. Another set of quasi-procedural rules govern the admissibility of evidence, although such rules are much fewer in civil law systems where there is no need to insulate lay jurors from inadmissible evidence, thus making for much quicker and less costly and cumbersome trials (American Law Institute 2000).

4. *Remedies*

Once a defendant's tort liability is established, essentially two kinds of remedies (i.e., forms of relief) may be available (see *Remedies and Damages: Legal Aspects*). The most common remedy by far is money damages, which in turn can be subdivided into compensatory and punitive damages. Compensatory damages are designed to restore the plaintiff to the *status quo ante* insofar as money can do so. Nevertheless, under the so-called 'American rule,' each party bears its own counsel fees and costs unless a statute specifically provides for fee-shifting. The 'English rule,' which requires the losing party to defray some or all of the prevailing party's fees, is also more common in civil law countries. In those countries, however, counsel fees tend to be much lower because much of the investigatory work done by lawyers in the USA is instead done by magistrates, and also because civil law proceedings tend to be far less complex and protracted.

In the USA, compensatory damages may cover physical injuries, lost wages, medical expenses, other out-of-pocket costs, loss of profit opportunity, emotional distress, pain-and-suffering, hedonic loss, damage to intimate relationships ('consortium'), reputational loss, loss of privacy, and so forth. Punitive damages may be assessed against a defendant whose tortious conduct was particularly egregious and socially abhorrent. Tort reform statutes in many states, however, now impose a variety of limits on punitive damages (Blatt et al. 1991).

Tort law ordinarily applies to relatively sudden, unintentional, and isolated events, so the only meaningful relief is post-accident money damages. In cases where the wrongful conduct is of a continuing nature, however, injunctive relief—a judicial order requiring the defendant to act, or refrain from acting, in a particular way, on pain of being held in contempt and other sanctions—may be available. This occurs most commonly in 'nuisance' actions against polluters or others whose conduct interferes with a plaintiff's use and enjoyment of her own property (Prosser and Keeton 1984).

5. *Choice of Law*

In the USA, tort liability is largely adjudicated by state judges applying state law to disputes. State tort law mainly takes the form of common law principles, although an increasing number of statutes or regulations affect tort adjudication. Judges in the forum state (i.e., where the suit is filed) ordinarily apply the forum state's own procedural, substantive, and remedial law to the dispute. If, however, the accident and wrongful conduct occurred in another state, the judge consults the forum state's 'choice of law' rules in order to determine which state's law governs which issues in inter-state disputes of this kind. These choice of law rules may dictate that the judge apply the law of the other state (*lex delicti*) rather than the forum state's law (*lex fori*) to some or all of the issues in the case.

Many American tort cases are filed in federal rather than state court. This may be because they are 'diversity' cases (i.e., the plaintiff and defendant are from different states), which the US constitution permits federal courts to hear. Even in diversity cases, however, the federal court is required to apply the state tort and choice-of-law principles of the state in which it sits, while it must follow federal procedural rules. A plaintiff may also file tort cases in federal court if the claim arises under federal law—a federal statute, federal agency regulation, a limited body of federal common law, or (very occasionally) the US Constitution.

A number of federal statutes create 'federal causes of action' (i.e., rights to seek tort-like relief under federal law). For example, the Federal Tort Claims Act creates a federal court remedy for wrongs committed by federal officials. (Even this remedy, however, is ultimately based on state tort law; the plaintiff must show that the official's wrong would be a tort under the law of the state where the injury occurred.) A federal civil rights statute known as Section 1983 creates a remedy, in either state or federal court, for violations of federal law committed by state or local governments. The Consumer Product Safety Act creates a federal remedy for people injured by products that violate regulations issued by a federal product safety agency.

6. *Institutions*

Tort law develops and operates in a distinctive institutional context. Two of the most important of these institutions are the jury (in the USA) and insurance.

Tort litigants in the USA generally have a right to a jury trial under the federal and most state constitutions, although they may waive this right and opt for a bench trial (i.e., by the judge alone). In principle, the jury is the trier-of-fact, applying the law that the judge gives it to the factual evidence presented in the case. Because of the open-ended nature of many tort law standards (e.g., 'reasonable care'), however, jurors inevitably enjoy some leeway or discretion that enables them to introduce into jury decisions their own values and attitudes toward the parties and the law. The subjectivity and discretion of juries, together with other factors that may be closely related to the jury system (e.g., lawyers' rhetorical skills), produce greater legal uncertainty in the USA than in other countries' liability systems. Juries also increase the cost and duration of trials and often make settlements more difficult to reach (Litan 1993) (see *Juries*).

Juries usually render only a 'general' verdict (i.e., 'we find for defendant' or 'we find for plaintiff in the amount of $X'); they neither state their reasons nor make explicit findings of fact. Accordingly, their verdicts—unlike the judge's rulings on points of law—carry little or no precedential value and convey little or no information, other than the verdict itself. (In a particularly complex case, the judge may ask them to render a 'special' verdict with specific findings of fact in response to factual questions that the judge has put to them.) Juries are selected through a lawyer-orchestrated process ('voir dire') that tends as a practical matter to produce many jurors who are relatively ignorant and unsophisticated about the kinds of technical issues increasingly arising in tort cases. Much of the unwieldy and costly apparatus of the trial, including many of the rules of procedure and of evidence, are necessary only because of the risk that juries will be improperly influenced by the trial lawyers on both sides. Proceedings in Britain and in Commonwealth countries are simpler, faster, and more predictable than those in the USA because those countries have largely abolished the lay jury in civil cases (Kagan 2001) (see *Courts and Adjudication*).

Tort liability in all countries is profoundly shaped by the existence of insurance (Abraham 1995) (see *Insurance and the Law*). Many if not most of the risks of injury that tort law regulates are insurable, in the sense that third parties (i.e., insurers) would be willing to bear those risks *ex ante* in exchange for some premium. Many of these insurable risks are in fact insured, either on a first-party or third-party basis. In first-party insurance, a person who is subject to a risk of injury purchases insurance to cover some or all of that risk, as when one buys a health insurance policy. First-party coverage is usually on a no-fault basis; the insurer indemnifies the insured merely on the occurrence of the insured event, without regard to how it occurred (except in the case of the insured's misconduct). In third-party or 'liability' insurance, a person who fears that he or she may injure others purchases insurance to cover some or all of that liability risk, as when a driver buys an auto accident liability policy. Here, the insurer only pays if the insured has incurred a legal liability to compensate a third party.

The tort system, at least with respect to accidents between strangers (i.e., those who have not contracted over who will bear this risk), is in effect a system of mandatory third-party insurance. It is mandatory because even one who agrees to opt out of the tort system often cannot do so. This is especially true in the area of healthcare, where courts usually will not enforce contracts whereby a patient waives his or her right to sue the physician in tort in exchange for a lower fee or for a service that the physician would not otherwise be willing to provide. It is a third-party insurance system because the insurer is insuring a risk that its insured imposes on a third party who is a stranger to both of them. In effect, every healthcare consumer is required to purchase an insurance policy along with the physician's services. This policy gives the patient a right to seek damages in the tort system according to the principles of medical malpractice law, in the event that the physician negligently injures him or her. The cost of this policy, which is reflected in the physician's fee, is equal to the physician's potential tort liability to the patient, which in turn is equal to the premium that the physician must pay for medical malpractice insurance (or put aside for self-insurance) to cover the liability risks the physician incurs by treating the patient.

This third-party insurance feature of tort law leads to important theoretical and policy debates (Priest 1987, Croley and Hanson 1995). Third-party insurance is often criticized as being both less efficient and less equitable than first-party insurance, which permits an insured to purchase the kind and amount of coverage that he or she prefers, and permits the insurer to demand the kind and amount of information it thinks it needs in order to underwrite the particular risk at a profit. In any event, judges applying an increasingly functional tort law take insurance into account, sometimes explicitly, in framing liability rules, and they often allocate the costs of accidents to the party they think is in the best position to insure against (distribute the risk of) the particular risk that caused the plaintiff's injury (Calabresi 1970).

7. *Non-tort Enclaves*

Tort liability in the USA expanded enormously during the twentieth century, most radically and dramatically during the 1970s and 1980s, while in other countries it has been marginalized by social insurance schemes. Most American states have sought to stem this expansion by adopting so-called 'tort reform' statutes, which attempt in a variety of ways to limit the tort liabilities of healthcare providers, product manu-

facturers, governments and public officials, employers, and other categories of potential injurers. Although some legal scholars have claimed to detect some slowing, or even a reversal, of this expansion (Henderson and Eisenberg 1990), there is no question that the scope of tort liability today is still much larger than it was even as recently as the early 1960s (Schwartz 1992). This expansion is the subject of much political debate and controversy. Still, important enclaves remain in which tort principles do not apply or apply only to a limited extent. Two such enclaves are immunities and no-fault schemes.

7.1 Immunities

Traditionally, US courts declined to apply tort principles to accidents arising from certain categories of actors or relationships. Charitable institutions were generally immune from tort liability, and suits between between spouses and between parents and children were also barred. The general expansion of tort liability and the availability of liability insurance, however, have encouraged courts to narrow these particular immunities (Prosser and Keeton 1984).

Governments and their officials also traditionally enjoyed broad protection from tort liability, loosely referred to as 'sovereign immunity.' Like charitable and intrafamily immunities, courts and legislatures have narrowed the scope of sovereign immunity but it nevertheless remains quite broad. At the federal level, the Federal Tort Claims Act waives the sovereign immunity of the USA, but this waiver is subject to a number of exceptions and limitations—for discretionary decisions and many intentional torts, for example—that continue to protect the federal government from liability for many of its torts. The Eleventh Amendment to the US constitution also generally immunizes the states from being sued for money damages without their consent in federal court. Individual states are also generally immune from suits brought against them in their own courts, although all have waived this immunity to some degree. Sometimes, plaintiffs can circumvent federal or state sovereign immunity by suing individual officials rather than the government itself, but those officials are often able to claim an absolute or qualified (good-faith) immunity nonetheless, and a variety of other special rules limit suits against governments and/or their officials (Schuck 1983).

7.2 No-fault Plans

Dissatisfaction with how the tort system allocates the costs of accidents has led governments to create some schemes for compensating victims of certain kinds of accidents without requiring them to prove an injurer's wrongdoing. Workplace accidents are the most important area in which no-fault compensation has replaced the tort system, with workers compensation statutes in every state and the federal government. No-fault systems are more prominent in other developed countries, with New Zealand's accident compensation law being the most comprehensive in the world (Franklin and Rabin 2001).

Workers' compensation effects an important trade-off. Under such a scheme, an injured worker's sole remedy against his or her employer is to file a claim with the employer's workers' compensation insurance carrier, whose decision on the claim is then subject to appeal to an administrative board and ultimately to the courts. In order to receive an award, the injured worker need not prove the employer's negligence but must only show that the accident occurred in the course of his or her employment. On the other hand, the award is limited to scheduled amounts for pecuniary losses (e.g., wages, medical expenses, therapy) for a specified number of weeks; the employee is barred from recovering for the intangible losses (e.g., pain and suffering, hedonic loss, emotional distress) that he or she could have sought had she sued in tort. (The worker may still be able to bring a tort action against a non-employer such as the manufacturer of the machine that caused the injury; such third-party actions in tort are very common in certain settings, especially industrial accidents.)

Many American states have also adopted no-fault compensation systems applicable to property damage and personal injuries sustained in automobile accidents (Schwartz 2000). Almost all of these statutes, however, do not really supplant the tort system; instead, they preserve the right to sue in tort once plaintiff's losses exceed a specified threshold, which tends to be quite low. Indeed, some commentators contend that automobile no-fault schemes actually encourage tort litigation by supplying plaintiffs with some immediate no-fault payments that they can then use to finance their tort actions (Bell and O'Connell 1997). Politicians' interest in these schemes, essentially ended in the 1970s. Few, if any, states have adopted them since then, and although the US Congress has recently considered a variant of the idea, it seems unlikely to gain the necessary political support.

Some narrowly targeted no-fault laws have been adopted. Congress, for example, has enacted no-fault compensation schemes for certain vaccine-related childhood diseases, for certain swine flu-related illnesses, and for nuclear power plant accidents, and a few states have enacted schemes relating to certain perinatal malpractice claims. In each instance, however, victims may under certain circumstances reject the statutory no-fault alternative and instead proceed to sue in the tort system (Rabin 1993).

8. Conclusion

The future of tort law in various societies is difficult to predict both because each nation's legal system is

different and because the scope of tort law is linked, perhaps inversely, to that of social insurance. Although the political impulses favoring a wider distribution of risk through social insurance are always strong, new experiments with or expansions of social insurance will be impeded by global competition, the liberalization of national economies, and tax reduction pressures. The kind of individualistic, fault-based, juried adjudication that characterizes the US tort law system, however, is one that few other societies can afford or would find congenial. In the US itself, the most recent generation of tort reform statutes, which are largely designed to limit adjudication costs and liability in the interests of corporate and professional defendants (at least in the first instance), are perhaps the best evidence of what the future holds.

Liaison and Consultation Psychiatry

Consultation-liaison psychiatry delineates the work of psychiatrists with patients who are in medical treatment primarily for somatic reasons in nonpsychiatric departments of a general hospital, or in ambulatory care of a nonpsychiatric physician. More specifically, consultation psychiatry describes a practice where psychiatrists see patients treated by other nonpsychiatric physicians only when called upon to give advice about diagnostic and treatment issues to consultees, who in turn follow through on these recommendations in the treatment of patients. In liaison psychiatry, however, psychiatrists are involved more directly in the treatment of physically ill patients with psychiatric comorbidity, assuming more responsibility in joint patient care, (e.g., having the prerogative of seeing patients admitted to an internal or surgical ward without being specifically endorsed to do so in every given case) as well as starting and following through psychiatric or psychotherapeutic treatment. As in everyday clinical care, boundaries between psychiatric and liaison approaches are not clear-cut, a worldwide consensus has developed to use the phrase consultation-liaison psychiatry (or c-l psychiatry), with the notable exception of the UK, where liaison psychiatry is the only term used for both kinds of approaches.

1. Psychiatric Comorbidity in Physically Ill Patients

The need for c-l psychiatric services stems from the high comorbidity of psychiatric illnesses in patients suffering from physical diseases.

1.1 Psychiatric Comorbidity in the General Hospital

It is estimated that between 30 and 50 percent of physically ill patients in general hospitals show comorbid psychiatric disorders, especially organic psychoses (*ICD-10 F0*), psychological and behavioral disturbances due to psychotropic substances (*ICD-10 F1*), and acute stress reactions (*ICD-10 F4*), with percentages of these diagnoses ranging as high as 16 percent, 8 percent and 10 percent in medical, and 17

percent, 8 percent and 13 percent in surgical patients, respectively (Arolt 1997). Special patient populations—such as those in organ transplantation programs, intensive care units, or oncological patients—show an even higher psychiatric comorbidity. The presence of psychiatric comorbidity does not always call for psychological treatment at the same time as the underlying or concomitant physical disease is being treated by physicians or surgeons. Neverthless, conservative estimates point to a figure of some 10 percent of general hospital inpatients who should receive psychiatric care alongside somatic care.

While the evaluation of patients committed to Accident and Emergency Departments after attempting to harm themselves is an important task for psychiatrists, and will often be performed by c-l services, their care is only one part of a larger picture of care for patients suffering from medical and psychiatric comorbidity, with the latter impacting negatively on course and outcome of the former. A prerequisite for psychiatric services to achieve an impact on this group of patients is the integration of psychiatry into general hospitals. Thus, in the USA, where the foundation of psychiatric departments as integrated parts of general hospitals started as early as the 1920s, c-l psychiatry has a long tradition, whereas in the Federal Republic of Germany, for instance, where state mental hospitals have given way to general hospital psychiatric departments only since the end of the 1970s, c-l psychiatry started to gain shape only toward the end of the twentieth century. Overall, international interest in c-l psychiatry increased outside the USA during the 1980s and 1990s with special emphasis in the UK, the Netherlands, Australia and New Zealand, where c-l psychiatric sections exist within national psychiatric organizations. The history of c-l psychiatry shows that the acceptance of psychiatric care for patients with medical–psychiatric comorbidity is dependent largely on the regular availability of psychiatrists in general hospitals, which provides the opportunity to demonstrate the added value of psychiatric diagnosis and treatment to other medical disciplines in the care of comorbid patients.

1.2 Psychiatric Comorbidity in the Primary Care Sector

While c-l psychiatry developed primarily in the general hospital setting, there was growing emphasis worldwide on diagnosis and treatment of psychiatric comorbidity of patients in the primary care sector toward the end of the twentieth century. Results from the *National Institute of Mental Health Epidemiological Catchment Area Program* show that about 16 percent of the community-dwelling adult population fulfil criteria for at least one psychiatric disorder. This figure increases to at least 21–26 percent of primary care patients. Studies show that most cases of adjustment disorders and about three-quarters of depressive disorders are treated in primary care. In most cases, these patients present with physical symptoms that are not caused by physical disease (see *Somatoform Disorders*). The proportion of undetected and untreated psychiatric (co-)morbidity in this patient group is high (APM 1997).

1.3 Psychiatric Morbidity in Nursing Homes

The percentage of the population older than 65 years of age is increasing. It is estimated that 20–50 percent of these people will eventually live in nursing homes. In the USA, it is estimated that the total number of nursing home residents will exceed 4 million by the year 2040. The very high prevalence of psychiatric-related illness among those in nursing homes is documented in a number of studies, showing that up to 70 percent of nursing home residents may meet diagnostic criteria for dementia, and 90 percent may have at least one form of behavioral disturbance, such as agitation, delusions, or depression. Depression is largely undetected and undertreated in this population, despite the fact that the majority of cases treated, e.g., with antidepressants, will recover from a depressive episode. Only recently, there has been growing awareness that people with mental retardation (or learning disability) show a significantly higher percentage of psychiatric comorbidity than the average population. While attempts are made to achieve a close to normal living situation for a large part of this clientele, people with severe mental retardation—which is often complicated not only by psychiatric comorbidity but also by other physical diseases such as epilepsy—will receive adequate care only in nursing home settings (Reichman and Katz 1996).

In sum, there has been increasing awareness of hidden mental comorbidity in the general hospital, primary care and nursing home sectors, and of the need for specialist psychiatric treatment in a significant percentage of patients.

1.4 Effects of Psychiatric Comorbidity in Physically Ill Patients

Studies show a significant association between psychiatric comorbidity and more complicated illness courses, both for patients in the primary care sector, and for general hospital inpatients. Patients with somatization disorder use nine times the healthcare services of the general population, panic disorder patients have 10 times the number of visits to hospital emergency rooms than nonanxious patients, and 70 percent will see more than 10 physicians before an accurate diagnosis is made. Medically ill patients with depression have a poorer prognosis than nondepressed patients with equal somatic comorbidity. For ex-

ample, postmyocardial infarction patients with depression are at significantly greater risk of death over a period of 6 months following the infarction, and depressed stroke patients show poorer results in rehabilitation programs with more persistent disability than nondepressed stroke patients. It has been shown that a small percentage of patients are responsible for the use of a major portion of healthcare, with, for example, 10 percent of patients of a large health maintenance organization in the USA consuming approximately one-third of all primary care visits, 52 percent of all speciality visits, and 40 percent of in-hospital days. Fifty percent of those high utilizers of healthcare showed some form of psychiatric comorbidity, e.g., 20.2 percent somatization disorder, 33.6 percent generalized anxiety disorder or panic disorder, and 40 percent major depression or dysthymia (APM 1997).

In general hospital inpatients it has been shown that medically ill patients with psychiatric comorbidity show longer lengths of stay in hospitals, more frequent re-admissions, and an overall increase in costs for treatment as compared to patients without psychiatric comorbidity. Adjustment for other factors associated with longer length of stay and rehospitalizations, such as severity of underlying medical disease, did not reduce the significance of the negative impact exerted by psychiatric comorbidity (APM 1997). The elderly are exposed to special risks, with about 10 percent of elderly patients admitted to a general hospital suffering from delirium. About 30 percent of elderly medical inpatients have dementia, which makes more complex management necessary, with problems arising from, for example, diminished compliance with medication, and in following through with rehabilitation programs.

2. *The Practice of Consultation and Liaison Psychiatry*

The scope of c-l psychiatric services spans primary and hospital care settings, the care of elderly residents in nursing homes, and of clients with learning disability and accompanying psychiatric disorders.

2.1 C-l Psychiatric Services in the General Hospital

Despite the high percentage of psychiatric comorbidity in the general hospital, referrals to psychiatric c-l services amount at most to only a small number of physically ill inpatients, approaching an average number of 1 percent of general hospital inpatients worldwide. Usually, the majority of patients are referred by internal medicine departments, with a large percentage being older than 65 years of age. Despite all differences in service delivery that are due to local necessities in the provision of care for given populations, c-l psychiatrists most often diagnose delirious states and other disorders of cognition, followed by depressive syndromes and adjustment disorders, fitting well to the above mentioned prevalence figures of psychiatric comorbidity in general hospital patients. In contrast, despite their obvious frequency, patients with alcohol-use disorders are referred much less by their treating physicians. The low rate of referrals to psychiatric c-l services has led to the assumption that nonpsychiatric physicians do not recognize psychiatric disorders sufficiently, or, if they do, do not think of psychiatric interventions as being helpful to their patients. Liaison psychiatry proper takes its vantage point from this discrepancy: other than the usual psychiatric consultation with its mainly emergency psychiatric character that by default is only able to care for the tip of the iceberg of psychiatric comorbidity, i.e., patients having passed the filter of recognition of a nonpsychiatric physician. Liaison psychiatric approaches aim at the denominator (Strain 1999) of psychiatric comorbidity, triggering specialist psychiatric care, e.g., by screening patients on hospital admission, or identifying problem behavior in joint rounds with nonpsychiatric physicians, or by educating the latter in how to better identify patients that might profit from referral to specialist psychiatric care. Thus, liaison psychiatric approaches try to go well beyond the 'firefighter function' of typical psychiatric consultation, aiming at changing referral patterns of nonpsychiatric departments, e.g., enabling physicians to deal with and/or prevent the development of delirious states, or increase referral rates of depressed patients or patients with alcohol-use disorders by demonstrating the efficacy of even time-limited psychiatric interventions (Guthrie and Creed 1996).

Both in consultation, and to a somewhat lesser extent in liaison psychiatric approaches, psychiatrists have to be aware of the stages a psychiatric consultation will typically go through. In the initial phase, and due to uncertainty about how to deal with a patient the consultant's referral diagnosis might be rather imprecise. In such cases it must be the task of the c-l psychiatrist to help in working out what is in fact the problem. The ensuing intervention must then be, other than in a typical psychiatric office situation, directed not only toward the patients, but also take into consideration the whole system, including the ward doctor, nurses, and relatives. Otherwise, c-l psychiatric interventions, when performed in isolation and/or out of context, might be unsuccessful (Diefenbacher 2000).

2.2 C-l Psychiatric Services in Primary Care and in Nursing Homes

Along with the growing interest in psychiatric (co)morbidity in primary care patients and nursing home residents, international c-l psychiatry shows a remarkable shift from the general hospital setting to collaborative care practices in the primary care setting,
