Robert Carneiro (1970), like Sahlins a student of Leslie White, developed a theory of the evolution of the state that would become one of the most famous theories of this phenomenon. The critical factors in Carneiro's theory were population growth, warfare, and what Carneiro called environmental circumscription. Circumscribed environments are those in which areas of fertile land are surrounded by natural barriers that prevent or impede the movement of people out of the area. These barriers include such things as mountain ranges or large bodies of water. Warfare is the result of population growth and resource scarcity, and when land is plentiful people respond to war by simply moving away to new land. But in circumscribed environments this process can only be taken so far. Land is eventually filled up, and the solution to more population pressure and resource scarcity becomes political conquest, a process that eventually results in the type of political society known as the state.

About the same time Gerhard Lenski (1966), a sociologist, was using the ideas of Childe and White to develop a theory of the evolution of social stratification. For Lenski the key to the rise of stratification was technological advancement and increasing economic productivity. As societies advance technologically, their economic productivity rises to the point where they can begin to produce an economic surplus, or a quantity of economic goods above and beyond what people need to survive. When economic surpluses arise competition and conflict over their control emerge, and as these surpluses grow larger the struggles between individuals and groups intensify and stratification systems become more elaborate and polarized.

One of the most important theories of social evolution of this period was that of Marvin Harris (1977). He broke ranks with such theorists as Childe, White, Sahlins, and Lenski on a critical point. These other theorists saw social evolution as a generally adaptive and progressive process that was driven by technological change. When new technologies became available, people readily adopted them because they saw their potential for improving the quality of life. According to Harris, technological change came about for a very different reason: the tendency of societies to deplete their environments as the result of population growth. When populations grew, pressure on resources intensified and standards of living dropped. At some point people had no choice but to advance their technologies so as to make their economies more productive. Thus farming replaced hunting and gathering, and farming with the use of the plow replaced farming with the use of simple hand tools. But technological change itself leads to further population growth and greater environmental depletion, and so a new wave of technological change will soon become necessary.

For Harris, social evolution, at least in preindustrial societies, is a process in which people have been running as hard as they can just to avoid falling farther and farther behind. Sanderson (1994a, 1994b, 1995) has built on the evolutionary ideas of Harris. He has formalized, extended, and to some extent modified them by developing a comprehensive theory that he calls evolutionary materialism. He uses evolutionary materialism as a general framework within which to understand three great evolutionary transformations: the Neolithic Revolution, the rise of the state and civilization, and the emergence of the modern capi-

talist world-economy. Like Harris's, Sanderson's view of social evolution is nonprogressivist and in some respects even antiprogressivist.

About this same time a very different kind of evolutionary theory was developed by the sociologist Talcott Parsons (1966, 1971). Parsons concentrated not on the evolution of technology and other features of material life but on the evolution of ideas and social institutions. Parsons formulated the concept of the evolutionary universal, which is a new kind of social structure or process that allows a society to achieve a new stage of evolutionary adaptation and thereby improve its level of functional efficiency. An early evolutionary universal was social stratification, which allowed a more efficient form of societal leadership to emerge. Later such evolutionary universals as administrative bureaucracy and money and markets emerged. An important evolutionary universal in more recent times, Parsons claimed, was the democratic association, which gave the use of power a broad societal consensus.

3. *Typologies of Evolutionary Stages*

Most theories of social evolution have involved the delineation of evolutionary stages. This was no less true in the nineteenth century than it is today. Spencer used two different evolutionary typologies. One of these was based explicitly on Spencer's notion of evolution as increasing differentiation: simple, compound, doubly-compound, and trebly-compound societies. At one end of the scale of differentiation we have simple societies, which are politically headless or have only rudimentary forms of headship. At the other end, that of trebly-compound societies, we have civilizations such as the Egyptian empire, ancient Mexico, the Roman empire, or the contemporary United States. Spencer's other typology distinguished between what he called militant and industrial societies. Military societies are those in which individuals are subordinated to the will of society and forced to obey its dictates. They are produced by the needs associated with warfare and the preparation for it. Industrial societies, on the other hand, are characterized by an emphasis on economic activities rather than warfare, and are notable for their much greater individualism and overall freedom. Although Spencer did not work out in any precise way just how these two typologies corresponded to each other, just as he saw evolution as a process of increasing differentiation he also saw it as a generalized movement from militant to industrial societies. For Spencer the epitome of industrial societies was his own nineteenth-century Britain.

Morgan divided societies into three major stages, which he called 'ethnical periods': savagery, barbarism, and civilization. The first two of these are divided into lower, middle, and upper substages. Societies in the stage of savagery are the oldest and most primitive. They survive by hunting and gathering and use rudimentary tools, such as spears or bows and arrows. Societies have reached the stage of barbarism when they have begun to domesticate plants and animals and live by agriculture rather than by hunting and collecting. Civilization is achieved with the invention of the phonetic alphabet and writing. Tylor made use of a very similar typology, as did other nineteenth-century thinkers. However, Morgan also employed another typology, which involved the distinction between *societas* and *civitas*. Societies at the stage of *societas* were organized on the basis of kinship and had relatively egalitarian and democratic social and political arrangements. Societies having reached the stage of *civitas*, by contrast, rested on property and territory as organizational devices. Kinship declined greatly in importance and was replaced by the state as the integrator of society. Economic inequalities became prominent, and the democratic arrangements of earlier times gave way to one or another form of despotism.

Marx and Engels introduced a typology of stages that was to become one of the most famous of all time. For them a society rested upon one of four possible modes of production: primitive communism, slavery, feudalism, or capitalism. The earliest human societies were at the stage of primitive communism. Here technology was very primitive, and people subsisted by hunting and gathering, by simple forms of agriculture, or by animal herding. Private property had not yet emerged, nor had class divisions. People lived in harmony and equality. Slavery, sometimes called the ancient mode of production, was characteristic of such earlier civilizations as Egypt and Mesopotamia and ancient Greece and Rome. Technology had undergone major advances since the stage of primitive communism, but as a result private property and class divisions had emerged. A small class of slave-owning masters confronted a large class of slaves. Slavery was followed in due course by feudalism, which characterized Europe during the Middle Ages. Slavery had largely given way to serfdom, and the major class division in society was that between landlords and serfs. The transition to capitalism was associated with another major upheaval in social life. Landlords and peasants were replaced by capitalists and workers as societies industrialized and urbanized. In due time the capitalist mode of production would fill with internal contradictions and eventually burst asunder, giving way to a socialist society without class divisions.

In recent decades very useful typologies have been produced by Gerhard Lenski (1966, 1970) and Elman Service (1971). Lenski has distinguished five major stages based on the level of technological development: hunting and gathering, simple horticulture, advanced horticulture, agrarianism, and industrialism. Hunting and gathering societies are the simplest and oldest. Here people survive by living on what nature provides. Men hunt and women collect fruits, nuts, vegetables,

and other plant matter. The transition to simple horticulture was made with the Neolithic Revolution that began in some parts of the world about 10,000 years ago. Simple horticulturalists subsist by a rudimentary form of agriculture that is based on the cultivation of gardens with the use of digging sticks. They often use a form of cultivation known as 'slash-and-burn' cultivation. This involves cutting down a section of forest, burning off the accumulated debris, and then spreading the ashes over the garden area as a form of fertilization. Usually gardens can only be used for a few years because soil fertility is quickly lost, so they will be abandoned in favor of other areas, only to be returned to many years hence. Advanced horticulturalists use the same basic form of cultivation but till the land with metal hoes rather than digging sticks, which give them a technological advantage. Agrarian societies are based on the plow and the harnessing of animal energy for plowing. Fields are completely denuded of shrubs and trees and slash-and-burn is abandoned. Industrial societies began to emerge with the Industrial Revolution of the late eighteenth century. They are based on industry, the factory system, and urban life.

Service's typology is based on the form of sociopolitical organization rather than the mode of technology, and distinguishes four stages: bands, tribes, chiefdoms, and states. Bands and tribes are similar in that they lack any formal mechanisms of social control. Leaders exist, but they have no real power or authority to compel anyone to do anything. They lead by example and they advise and suggest, but their decisions have no binding force. A band is usually a residential association of nuclear families, with a population anywhere from about 25 persons to 100. A tribe may be thought of as a larger collection of bands. Often the term tribe is used to designate a population, numbering in the thousands or tens of thousands, that shares a common culture and language. This cultural and linguistic whole is composed of politically autonomous and economically self-sufficient villages, which may consist of anywhere from a hundred to several hundred persons. Chiefdoms develop when the villages of the tribe come to be subordinated to an administrative structure of the whole. This structure is hierarchical and is dominated by a chief and at least a few subchiefs, each of whom has the capacity to compel the actions of others. Chiefdoms rest on at least some degree of coercion, but by definition this coercion is not sufficient to prevail when there is a rebellion from below. When such a degree of coercion has been achieved, a state has emerged. States are thus large-scale, highly centralized political systems in which rulers have a monopoly over the use of force.

Other typologies exist, and all have their strengths and weaknesses. Morton Fried (1967) developed a typology based on the degree of social inequality: egalitarian, rank, and stratified societies. Eric Wolf (1982) formulated a Marxist typology of stages based on the mode of production: the kin-based mode, the tributary mode, and the capitalist mode. And Talcott Parsons (1966) formulated a typology based on three major stages, which he called primitive, intermediate, and modern societies. There is no one way to create a typology of evolutionary stages. What is important is that the typology describes a real directional sequence or process based upon a clearly identified mechanism of change. All of the typologies identified here do that to one extent or another.

4. *Social Evolution: Its Main Outlines*

The discussion now moves from typologies and theories of social evolution to the actual process of social evolution itself. There is considerable disagreement about what the most important dimensions and driving forces of this process are, but the following sketch probably would not produce too much controversy among social evolutionists (Sanderson 1995).

Virtually all social evolutionists would agree that the first great social transformation was the Neolithic Revolution, which introduced plant and animal domestication into the world. The most striking thing about the Neolithic from an evolutionary perspective is that it occurred in remarkably parallel form in several major regions of the world. Beginning about 10,000 years ago in southwest Asia, the transition to communities based on agriculture rather than hunting and gathering occurred at later times in other parts of the Old World—southeast Asia, China, Africa, and Europe—and three parts of the New World: Mesoamerica, South America, and North America. It is now generally understood that most if not all of these Neolithic transitions occurred independently of one another, a phenomenon that can only be explained in evolutionary terms. The effects in these various regions were much the same too. The transition to agriculture led to settled and more densely populated communities that for a while remained relatively egalitarian but eventually gave way to stratified societies organized into chiefdoms.

By around 5,000 years ago in several parts of the world societies that had evolved into chiefdoms were beginning to make the transition to a state level of political organization, or to what many scholars have called civilizations. This occurred first in Mesopotamia and Egypt, and then later in China, the Indus valley in northern India, parts of Europe, and Mesoamerica and Peru in the New World. Civilizations are societies with highly centralized political institutions involving a monopoly over the use of force, elaborate social stratification, urbanism and city life, occupational differentiation and craft specialization, trade and markets, monumental architecture, and writing and record keeping. Most civilizations have been agrarian societies, thus cultivating the land with plows and draft animals and intensively fertilizing the soil. Like

the Neolithic Revolution, the transition to civilization and the state was a process of independent parallel evolution in several parts of the world.

Social evolution occurred rapidly throughout the world between 10,000 and 5,000 years ago, but once the stage of civilization had been reached there was a considerable slowing of the evolutionary process. Social change continued in that societies became bigger and more densely populated, technology advanced, trade and markets expanded, and empires grew larger and more powerful. However, there was no qualitative leap to a new mode of social organization in the sense that there had been with the transition from hunter–gatherer to agricultural communities or to civilization and the state. Lenski (1970) has distinguished between simple and advanced agrarian societies on the basis of the possession by the latter of iron tools and weapons. He has suggested that advanced agrarian societies were in many ways so different from simple agrarian societies that it is difficult to include them in the same category. Yet both types were based on the same technological and economic foundations and the differences between them were more quantitative than qualitative. It was to take another several thousand years before there was a shift to a qualitatively new mode of social organization.

What was this shift and when did it occur? This is where sociologists enter the picture. Most sociologists have taken the view that it was the Industrial Revolution of the late eighteenth century that introduced a qualitatively new form of social life, industrial society. However, in recent years some sociologists, along with social scientists from other fields, have moved this qualitative transformation back in time to the sixteenth century (Wallerstein 1974). The qualitative shift is then considered to be the transition to a capitalist world economy. Capitalism—selling goods in a market in order to earn a profit—in some form or another had existed for thousands of years, but after the sixteenth century it began to get the upper hand and to replace earlier, precapitalist forms of social life. From this perspective, the Industrial Revolution was simply part of the logic inherent in the advance of capitalism. Most scholars have treated the rise of capitalism as a unique feature of European society and Europe's decisive contribution to the world. However, at about the same point in history a society at the other end of the world, Japan, began to undergo a capitalist transition of its own, and it is possible to identify a number of striking similarities between Europe and Japan that may have facilitated their transition to the new economic system (Sanderson 1994b).

Once the transition to capitalism had been made and the Industrial Revolution had commenced, strikingly similar changes began to occur among rapidly industrializing societies. Today's industrial capitalist societies all have very similar occupational structures, governments based on parliamentary democracy, systems of mass education that are closely linked to the work world, similar stratification systems with relatively high levels of mobility, and rationalization in the form of advanced science and technology. Some sociologists and most historians will protest that recognition of these similarities should not prevent us from seeing the many important differences among industrial capitalist societies. That is certainly true, but from the perspective of the evolutionist, it is the similarities that are more compelling.

5. *Conclusions*

It was noted above that evolutionary theories of society have ebbed and flowed in their popularity ever since they were introduced. They were extremely prominent between 1850 and 1890, fell to a low point between 1890 and 1930, and rose to prominence again around the middle of the twentieth century. But the bubble burst again, and beginning in the 1970s evolutionary theories fell from grace. They have been criticized on numerous grounds (Nisbet 1969, Sztompka 1993). Among other things, it has been charged:

(a) that they overestimate the amount of directionality in history;

(b) that they rely on teleological explanations, which are illegitimate;

(c) that they have a strong endogenous bias and ignore, or at least insufficiently attend to, the external relations among societies;

(d) that they employ a specious concept of adaptation; and

(e) that their progressivist view of history is much too optimistic.

All of these criticisms have been answered at length (Sanderson 1990, 1997). Precedent suggests that evolutionism will once again become prominent in sociology and anthropology. This type of theorizing has fared well in optimistic periods of history and poorly in more pessimistic periods. Western society and Western social science have long been in a pessimistic period, but this cannot last. With the eventual turn toward greater optimism, evolutionism will again assume its rightful place as a major perspective on social life and its historical changes.

S. K. Sanderson

Social Evolution, Sociology of

The term social evolution describes sociological theories that study the changes and development of societies as a whole, by adopting a long-term perspective. These theories have alternately emphasized: (a) the characteristics of successive social orders; (b) the mechanisms and laws that articulate this succession; (c) the *direction* of this evolution; and (d) its *progressive* character. Although explicit references to social evolution were certainly not lacking in the reflections of philosophers who dealt with the whole history of human evolution (Plato, Vico, Bossuet), actual theories on social evolution were only established in the eighteenth century (Mandeville, Hume, Ferguson, Smith, Savigny), and nineteenth century (Saint-Simon, Comte, Marx, Spencer, Menger, Durkheim, Tönnies). Even though they are radically different, these theories all identify a tendency to progress from relatively simple and uniform social organizations characterized by a small or even nonexistent division of labor, to social organizations that are marked by a growing division of labor and a considerable increase of population.

In spite of their shared minimalist presuppositions, two currents of sociological theories have been established, each interpreting social evolution in a radically different way: (a) theories that try to understand society's inevitable *laws of evolution*; and (b) theories that interpret social evolution as an unintended process generated by the spontaneous combination of individual actions.

1. *Social Evolution as an Ineluctable Development*

Many philosophers, sociologists and economists have tried to single out the laws that clearly explain the succession of different social phases. They have tried to identify *evolutionary criteria* that would allow them to look back at changes that have already taken place, and foresee future changes. According to Saint-Simon, a *law of progress* supports the *process* of evolution and this *progress* is not linear, since 'organic periods' of progress necessarily alternate with 'critical periods' of temporary and partial regression. However, the

industrial revolution and scientific progress inevitably lead to a more evolved organic period that was organized according to the principles of 'positive science' which puts power in the hands of scientists. According to Comte (Comte 1875), 'the development of civilization follows a necessary law', which individuals 'are subject to by invariable necessity': the 'law of the three phases'. This law establishes that every society goes through 'theological, metaphysical and positive phases' which follow a fixed and predetermined scheme. The positive phase characterizes the most advanced stage of social progress, dominated by a new and higher form of science, 'social physics', that permits the organization and management of society as a whole. Marx considers 'dialectic materialism' the progressive law of all society, marking the inevitable evolution from 'primitive communism' to the 'feudal' phase that leads to the 'capitalistic' phase, which in turn leads to the inevitable success of 'communism.'

These theories, based on a *holistic* view of society that considers social evolution a *teleocratic* process, have been subjected to a great deal of methodological criticisms. The impossibility of foreseeing how human knowledge will develop and the inevitable emergence of unintended consequences are sufficient criticism to the determinism of these theories. There is also a fundamental epistemological objection to the claim these theories have of giving a scientific explanation to the entire social process: in order to explain a social phenomenon scientifically, universal laws are necessary, i.e., laws that are not empirically assessed only on the phenomenon itself. Where social evolution is concerned this is not possible, because it is a historically unique process. Consequently, there are no scientific 'laws of evolution' to be discovered, but only 'tendencies' that can and must be explained by laws (Popper 1957). In a more general sense, these evolutionary theories view society as a *closed system* where it is possible to determined the evolutionary dynamics. Marx, on the basis of a situational analysis, considered social evolution an *emerging effect*, and attributed a necessary and universal quality to mere tendencies, simply because he did not allow for the fact that a social system is necessarily *opened* by, and to, new information from the outside.

2. *Social Evolution as a Spontaneous Order*

Individualistic theories on social evolution are formulated in a completely different way. They do not seek *laws of evolution*, but try to define a *principle of evolution* that is determined as the spontaneous combination of subjectively rational, individual actions. Social order and its evolution are conceived mostly as the unintended result of the interaction between individuals with limited knowledge, pursuing their private interests through an ultimately positive *exchange* with others.

B. De Mandeville and *Scottish* economists and philosophers of the eighteenth century (Hume, Ferguson, Millar, Smith) are among the first supporters of this theory. They proposed an *invisible hand explanation* for the origin and development of the most important social institutions. Even before, Smith, Mandeville explained the affirmation of the division of labor as a spontaneous result generated by the necessity of satisfying the needs of the individual in an increasingly efficient way. The division of labor, like other social institutions is therefore, according to Ferguson's famous definition, the 'result of human action but not of human planning.' Among the *Scottish* philosophers, Adam Smith particularly drew his conclusions at a more completely macro-sociological level, identifying trade as the mechanism behind social order, since it spontaneously *combines* single actions. Smith believed that in the exchange with others, individuals are driven 'by an *invisible hand* to support objectives that were not part of their original intentions. [---] By pursuing their own interests, they advance society's interests more efficiently than was deliberately intended.'

Owing to Burke's influence on the German historical school (Savigny, Neibuhr), the evolutionary approach was established in linguistics (Humboldt) and law in the early nineteenth century. It was thus adopted first of all in the human and social sciences, and only later in the natural sciences (for example, with Lyell in geology and Darwin in biology). In fact, Hayek had defined these theories of evolutionism as 'Darwinian prior to Darwin.' As the evolutionary theory was increasingly accepted in biology, theories on social evolution were given new impetus. This was also thanks to Spencer, who should be considered one of the most significant theoreticians of social evolutionism based on individualism, which was later developed by the economists of the Austrian school. Spencer considered social evolution as a process generated by a combination of individual actions, which tend to organize spontaneously, establishing rules and social organizations that are selected on the basis of their fitness to perform the basic functions of human society (survival of the species, production of riches). The 'obligatory co-operation' at the base of 'military society' and the 'spontaneous co-operation' at the base of 'industrial society' are the two most important 'types' of social orders that have selectively evolved. Spencer believed that societies where spontaneous cooperation was established had an *evolutionary advantage* because they maximised the *problem solving capacity* by safeguarding individual liberty and allowing the greatest possible safeguarding individual liberty and allowing the greatest possible number of compatible individual plans to be accomplished. For this reason, Spencer gives 'spontaneous co-operation' an ethical value because it is the best solution to reproduction of

the species and communal welfare, which he considers the two most important issues of humanity.

The Austrian Economic School is probably the strongest current of theorists of social evolution with an individualistic foundation. It spanned the nineteenth and twentieth centuries with Menger, Böhm-Bawerk, Mises and Hayek and the neo Austrian Americans (Rothbard, Kirzner, Stigler). By emphasizing the primacy of the theory in the social sciences and suggesting that they be refounded on an individualistic basis, Menger harshly criticises the 'pragmatist' theories that consider the genesis and evolution of social order as effects of intentional plans. In his opinion, 'law, language, the State, currency, trade [---], in their various expressions and incessant changes, are largely the spontaneous result of social evolution.' Mises developed a momentous theory of rationality (praxeology), providing an epistemological defence of social order as produced by market, and demonstrating the impossibility of making an 'economic calculus' in a planned economy.

But, it was above all F. A. von Hayek who suggested the strong link between methodological individualism and social evolution. Hayek harshly criticised the reification of the *Kollektivebegriffe* starting from the 'social system', and based his methodological individualism on an *ontological individualism*. He stated that there are only individuals whose intentional actions (and their unintentional consequences) tend to combine spontaneously, giving rise to a 'spontaneous order' meaning *open systems* that are self-generated and self-regulated. In Hayek's view, the great 'misunderstanding' of evolutionists is confusing the study of social evolution with the impossible search for the 'laws of evolution' on one hand, and on the other, with studying the selection process between single individuals (social Darwinism). Social evolution is actually the result of 'group selection', meaning the competition between groups organized according to different rules, that are selected on the basis of their functional adaptation. Hayek, like Spencer, demonstrates the *evolutionary superiority* of the 'spontaneous order' (*Cosmos*) by distinguishing it from 'contrived order' (*Taxis*). This superiority is generated by the fact that the spontaneous order allows each individual to use the generalized knowledge of others to reach their goals. *Competition* between different types of organizations and individual plans is therefore the means of *propagation* and *retention* of evolutionary selection results. It is the method for exploring the *unknown* and as such, is the driving force of social evolution.

These individualistic theories of social evolution are based on a fallibilistic view of knowledge, and as such they harshly criticise the rationalistic and 'constructionist' claims of scholars who try to discover the inevitable laws of social evolution and then, on the basis of this discovery, plan social order or at least a significant part of it. Social order should be seen instead as the unintended result of the spontaneous combination of rational, subjective actions that relate to situations in an *adaptive* way. This nomocratic order is an autopoietic system that incorporates the principle of its own evolution: a spontaneous cooperation between free individuals. As such, it is teleonomic, since it has a tendency to self-organization, and is not teleological, because it is not guided by any previously determined, predictable, and inevitable goal.

3. *The Evolution of Social Systems*

Several other important theories of social evolution exist beside these two currents of thought. Although they do not attempt to define the inevitable laws of development, they study the characteristics and sequential succession of cultural structures, systems and social phases, considering them separate and above the order of the single individuals of which they are composed. Durkheim and Parsons are the most significant exponents of these theories.

Even though Durkheim's works do contain interesting examples of the *invisible hand explanation* (such as the explanation of the genesis of the family in *De la division du travail social*), he also harshly criticises Smith and the 'economists' who interpreted social evolution as a result of the interaction between single individuals pursuing their private interests. Society cannot be 'deduced' from individual behavior because 'the agents in exchanges remain mutually estranged', since a subjective interest is 'the least constant thing in the world.' Durkheim considers society a '*sui generis*' reality, and therefore 'collective life is not the result of individual life; on the contrary, the latter is the result of the former.' Society exercises 'moral authority' over individuals and has a 'collective conscience.' In archaic societies, which are characterized by a 'mechanical solidarity', the collective conscience entirely replaces individual conscience. In more advanced societies characterized by an 'organic solidarity', a progressive individualization occurs that is not however sufficient to free the individual from collective *tutorship*. Evolution that leads to modern society is produced by the division of labor, which in turn, according to Durkheim (influenced by Spencer in this case), 'varies in direct proportion to the volume and density' of society. Having given up trying to define a *law of development*, Durkheim finally explained the division of labor in a way that is similar to the invisible hand explanation. He writes in fact that 'the economic services which the division of labor can provide are insignificant compared to the moral effect it produces, and its true function is to achieve solidarity between two or more individuals.'

Parsons' 'neo-evolutionism' has a *culturalistic* imprint. After the Second World War, he clearly revised the views he expressed in *The Structure of Social*

Action. Parsons defines three 'levels' of social evolution: 'primitive society' (centered on family relations), 'intermediate society' (regulated by religious institutions), and 'modern society' (established by the industrial revolution). The passage from one social stage to another can be explained by *the laws of general evolution* and the *law of cybernetic hierarchy*. The general laws of evolution (for which Parsons is much indebted to Spencer), explains how societies evolve through the 'increase of adaptive capacity' namely through their capacity to 'transform the environment in order to satisfy their needs (Parsons 1971).' Successive social phases, under the pressure of functional adaptation, are therefore characterized by a progressive 'differentiation' (of roles, functions and sub-systems) and by their 'integration.' The *law of cybernetic hierarchy* explains that the 'social system', works and evolves by the restraints placed by 'cultural structures' (i.e., systems of rules and values) on the 'social system' and on individual actions, which Parsons places on the lower levels of the cybernetic scale. Parsons describes society as a '*sui generis reality*' explicitly following Durkheim's theories. Social evolution is therefore the result of the 'evolutionary change' of cultural variables. These variables have the 'function' of 'legitimizing the rules of a society', providing a view of society in its 'totality.'

4. *Evolution and Social Progress*

A dogma of theories on social evolution in the eighteenth and nineteenth century, based on the Enlightenment and positivism, was that evolution coincided with *progress*. Saint-Simon, Comte, Marx and Condorcet before them, all believed that the *laws of evolution* coincided with the *laws of progress*, meaning that social evolution occurs in a predictable way that is equated with a necessary human progress. This attempt to make *historic development* and *human progress* coincide is invalidated by ' Hume's law', which states that it is not *logically* possible to derive *prescriptions* from *descriptions*. The idea of progress cannot therefore be *rationally founded*. This does not prevent social evolution from being defined as *positive* or *progressive*, or being either optimistic (Spencer, Hobhouse, Childe, Withe, Parsons) or pessimistic (Malthus, Speigler), for these are *evaluations* based on subjective value choices. As such, they can be debated and critically discussed, but they cannot be considered as describing a necessity.

It is possible to avoid the *naturalistic fallacy* of confusing *goodness* with *evolution* by following ′Hume's law.' In order to assess the results of evolutionary adaptation, it is necessary to move from a historical-sociological plane to an ethical one. Individualistic evolutionists, like Spencer and Hayek, separated evolution from progress and—fearing that social evolution might alter the nature of the spontaneous order—gave progress a moral value by turning it into an ideal to be defended and developed should certain value choices be accepted (individual liberty, the increase of wealth and knowledge, etc.). The purpose of evolutionary ethics is precisely to demonstrate that spontaneous cooperation based on free individual actions is the best means to achieve these values.

5. *Adaptation and Innovation*

The *variation/selection* mechanism is the *hard core* of both biological and social evolution. As neo-darwinian models were increasingly accepted in biology and theories of self-organized complex systems were increasingly accepted in physics, social sciences also began to study this evolution-generating *mechanism*. However, the dynamics of this mechanism can be interpreted in different ways that once again oppose individualism to collectivism. It is possible to have a 'structural' view of innovation, by seeing it as a deterministic product of *environmental instruction* according to Lamarck's theories. Variations would then be the manifestation of *functional needs* that arise from, and are selected by, the need to guarantee the social system's equilibrium. Social changes would therefore be essentially conceived as 'endogenous', i.e., part of the social structure and necessary to its reproduction. Individualistic evolutionists, like Weber and Schumpter proposed a completely different view of social innovation. They emphasized the individual, unpredictable and *strategic* character of innovation by focusing respectively on the innovative role of the charismatic *élites* and of entrepreneurs. Innovation does not answer a question posed by the environment, it is the result of individual strategies, and strategies between individuals, who both condition and are conditioned by the environment in which they develop. *Variations* cannot be explained by strict Lamarkian theories, because the social organism's ingrained environmental needs and tendencies do not deterministically generate them. On the other hand, they also cannot be interpreted using an orthodox darwinian model, since they are not *random* or *random-like*.

These two pure types of innovation correlate to two *pure* kinds of adaptation. Parsons reduces adaptation almost exclusively to its functional dimension, defining it as a process that allows society as a whole (as well as its subsystems) to respond to some essential, functional needs. Another view of adaptation considers it closely linked to a biological model (especially Spencer and Hayek). Adaptation is seen as an *endless order generating process* that reduces the variety of configurations produced by variations through a *rule and group selection*. This selection essentially refers to groups that spontaneously adopt different rules and organizations. Among these groups, only those which are better equipped to address the most important social needs will survive.

On another level, a similar and complimentary process of *selection through competition* takes place between individuals belonging to the same group, and this process determines the subjective actions and projects that are most adaptable to environmental circumstances and particularly to the rules of the group itself. However, the fact that emphasis is placed on *group selection* does not mean that this evolutionary prospect denies methodological individualism (as stated by D T Campbell 1995). Organized groups are the spontaneous result of the fact that individuals follow specific rules of conduct that are conveyed and spread by *learning through imitation*. Following these guidelines, one eventually considers tradition as a necessary element of evolution since it characterizes the process of retention of kinds of actions and dispositions.

6. Social Evolution and Evolutionary Epistemology

D T Campbell has used the expression 'evolutionary epistemology' to describe epistemological theories (from Poincaré and Mach to Popper) that saw the evolution of human knowledge as a process that progresses by *trial and error-elimination*, creating new hypotheses and selectively eliminating false ones. Evolutionary epistemology also helps to better understand the social evolution process, which is also a *discovery procedure* that *lato sensu* has a cognitive nature. Social innovations are nothing more than attempts to resolve problems (intentionally proposed or occurring spontaneously), that are selected on the basis of their capacity to deal with *problematic situations*. Comparing the two evolutionary processes, it can be said that: (a) *fitness* is nothing more than the elimination of errors; (b) the transmission of selected solutions (in social and cognitive contexts) means *learning by error*; and (c) the increase of complexity in social systems is simply an increase of *background knowledge*. Like the evolution of knowledge, social evolution will never reach a state of *equilibrium* because new *instructions* will result in an environmental change that will be the *background* of new variations. Finally, an important distinction should be made between social evolution and the evolution of the knowledge. Even though the former cannot be reduced to a Lamarckian model, its *environmental instruction* is more significant while the evolution of knowledge (if one excludes the collectivistic theories of some contemporary science sociologists such as Bloor, Barnes and others), is articulated by *creative inventions* that, unlike social innovation, are much less affected by *external selection*.

Social Facilitation, Psychology of

Social facilitation refers to the effect of the presence of others on the individual. This phenomenon is of psychological interest to scholars who regard the presence of others as a minimal condition for social influence.

1. History of the Term

The term *social facilitation* was coined by the American Floyd Allport in an early textbook of social psychology (Allport 1924). Allport's was a behavioral treatment of the field. As part of his *Social Psychology*, Allport maintained that a response called forth by a nonsocial stimulus could be augmented by an incidental social stimulus. He termed this contributory influence *social facilitation*. Allport reported demonstrations of the social facilitation of students' task performance from the sight and sound of other students performing the same task. Allport's research participants cancelled vowels more quickly, multiplied

numbers more quickly, and generated word associations more quickly when they were working alongside peers than when they were not.

When an individual is in the presence of others, the others will invariably assume some role. Sometimes they are watching the individual, as members of an audience. Sometimes they occupy the same role as the individual, and all are engaged in the same behavior. In this latter case, the others are said to be *co-actors*. Audience and co-action researchers seek to infer social facilitation from experimental data, by comparing individuals who are in the presence of others with individuals who are alone. However, it is difficult to collect valid evidence of social facilitation, because the monitoring that the experiments require may compromise research participants' sense of solitude. In such cases, no one is truly 'alone,' and the impact of others' presence is difficult to isolate.

Social facilitation was first reported in an 1898 journal article by Norman Triplett. Studying records of bicycle races, the sports psychologist noted a tendency for cyclists to race more quickly when riding alongside competitors than when riding alone against the clock. Triplett developed a laboratory-based analogue of this social phenomenon, when he had school children turn a fishing reel alone and in the presence of coacting classmates. The presence of these young coactors produced faster reel-turning, an effect that Triplett attributed to a 'dynamogenic' increase in motivation. Years later, Triplett's 1898 study of others' presence was dubbed the first experiment in social psychology, although its claim to this title has been disputed.

2. *Effects of the Presence of Others*

Social facilitations have been observed in a number of species. Chickens peck at food more quickly when other chickens are pecking; rats press a bar faster in the presence of other rats; cockroaches run with greater speed when running alongside other cockroaches. To the biologically oriented psychologist (e.g., Clayton 1978), these demonstrations of animal social facilitation hold profound interest.

People can be affected in many ways by the presence of others. Physiologically inclined researchers report social facilitations of human heart rate, blood pressure, and electrodermal activity. If often the presence of others increases an individual's physiological arousal, sometimes affiliation with others can reduce high levels of arousal (Mullen et al. 1997). Psychological investigators have documented social facilitations of various behaviors (Kent 1994). In the presence of others, people eat large meals, express conventional judgments, and show a tendency to smile. Gender and cultural differences in social facilitation are sometimes observed. In the presence of others, males (but not females) display a heightened tolerance for pain. In the presence of others, Japanese (but not American) students conceal facial signs of distress.

Since Triplett's pioneering investigation, psychologists have reported hundreds of experiments on the social facilitation of human task performance. The evidence that they have amassed indicates that the term social facilitation may be a misnomer. If sometimes the presence of others facilitates a person's task performance, often it has the opposite effect. In the presence of others, people have trouble unscrambling anagrams; in the presence of others, people lack motor coordination; in the presence of others, people do poorly on memory tasks.

When is a person's task performance facilitated by the presence of others, and when it is impaired? Psychologists had been pondering this question for decades before they found a convincing answer. In 1965, social psychologist Robert Zajonc published an article in the prestigious journal *Science*. There, Zajonc contended that the impact of the presence of others on task performance depends on the complexity of the performer's task. The presence of others serves to facilitate the performance of simple tasks and to impair the performance of complex tasks, Zajonc claimed. Subsequent evidence verifies that the impact of the presence of others does, indeed, depend on task complexity. At the same time, it indicates that social impairments of complex performance are stronger than social facilitations of simple performance. People perform simple tasks more *quickly* in the presence of others. However, there is little evidence that others' presence has any effect on simple performance *quality*, a quantitative review of 241 'social facilitation' studies concluded (Bond and Titus 1983).

3. *Explanations of Social Facilitation*

Psychologists have attempted to explain social effects on task performance. In his 1965 article, Robert Zajonc proposed the most influential explanation. According to Zajonc, the presence of others increases an individual's level of generalized drive. Generalized drive, learning psychologists Clark Hull and Kurt Spence hypothesized, functions to energize an individual's dominant response tendency toward any stimulus compound. Generalized drive enhances this dominant response tendency, to the exclusion of any weaker tendencies. According to Zajonc's drive theory of social facilitation, the impact of the presence of others on the performance of a task should hinge on the performer's dominant response tendency when attempting the task. On simple tasks, where the dominant tendency is toward a correct response, the presence of others should facilitate performance. On complex tasks, where the dominant tendency is to

make a mistake, the presence of others should enhance this error, thereby impairing performance.

Zajonc's theory intensified interest in the study of social facilitation. Many experiments were designed to test this drive theory of social facilitation, and the theory was often corroborated. When the presence of others caused errors in athletic performance, undermined spatial maze learning, and enhanced response tendencies that had been trained to dominance in the laboratory, researchers claimed evidence for the operation of a socially induced drive. The presence of others was shown to have different effects on task performance at different stages in the learning of the task—retarding individuals' acquisition of novel skills, then facilitating execution of those same skills once performance reached a plateau. Over training, drive theorists reason, correct response tendencies come to dominate over errors; thus dominant-response enhancements can explain these opposing effects.

Although for a time theorists agreed that the presence of others functioned as a source of generalized drive, there were debates about the origin of the drive. Zajonc attributed drive to the unpredictability of species mates, and an individual's need, in the presence of others, to be alert to the unexpected. Other social psychologists (notably Nickolas Cottrell) believed that drive reflected a learned tendency to associate the presence of others with positive and negative outcomes. Only when others were in a position to confer such outcomes would they have any effects on the individual, Cottrell implied.

Positive and negative outcomes are often associated with the presence of others, all psychologists agreed. Many wondered, however, whether the *mere* presence of others would be sufficient to influence the individual, independent of any associative processes. In search of effects of the mere presence of others, experimenters conducted some colorful studies. They fed rats in the presence of anaesthetized rats; confronted chickens with a dead companion; and had undergraduates trace spatial mazes in front of blindfolded mannequins. When results indicated that individuals can be affected by others who are merely present, many psychologists acted as though Cottrell's analysis of social facilitation could be discarded. More recently, the theoretical significance of mere presence effects has been revisited. Robert S. Baron argues that if an individual learns to associate positive and negative outcomes with the presence of others, then others who are merely present should become a conditioned stimulus for those outcomes. From Baron's perspective, mere presence effects are simply conditioned responses, and have no bearing on the origin of any socially induced drive. No doubt, there will be continuing discussion about the theoretical significance of the effects of the mere presence of others. In the meantime, it is apparent that others' mere presence can have some effects.

As drive theorists engaged in intramural disputes, alternative theories of the effects of the presence of others were being developed (Geen 1989). A self-presentational analysis attributed the social facilitation of task performance to the performer's regulation of a public image, and the social impairment of performance to embarrassment from a loss of public esteem. Theoretically, performers lose esteem when they must attempt complex tasks in public. Complex tasks, theorists note, are ones on which the individual makes many mistakes. Self-awareness theories held that the presence of others prompts individuals to compare their task performance to a performance standard. These self-evaluations may inspire performance facilitation or occasion a withdrawal from the task, depending on the outcome of the comparison. Cybernetic models of the self-comparison process were constructed. Performers must divide their attention between a task and any others who are present, an influential distraction-conflict theory emphasized. This theory made the novel prediction that social distractions would facililtate simple task performance, and inspired evidence of an audience-induced attentional overload (Baron 1986). The inability to visually monitor others' reactions arouses uncertainty, and this is the key to understanding mere presence effects, writes the Australian psychologist Bernard Guerin (1993).

4. *Related Phenomena*

Alongside social facilitation from the presence of others are broader facets of the psychology of public performance. Performances, for example, take place in front of audiences of greater or lesser size. Mathematical equations have been developed to relate the number of people in the audience to the audience's impact on the performer. Data have been fit to the proposed equations, and reveal a negatively accelerating impact, as an audience grows in size. An audience may be supportive of the performer, or it may be hostile. Traditionally it was assumed that audience support would benefit the performer, and create a home-field advantage in sports. However, audience support may intensify pressure and make the performer choke, some paradoxical data suggest. Performers may bring positive expectations or negative expectations to a task. The presence of others benefits performers who expect to succeed, and impedes performers who expect to fail, the self-efficacy theorist Lawrence Sanna writes. The presence of co-actors may obscure the individual's contributions to a group effort and provide an incentive to loaf, a related research tradition emphasizes. Psychologists continue to pursue these and other possibilities as part of their century-long study of social facilitation.

Social Geography

1. Introduction—When and What

Social geography emerged as a significant sub-discipline during the 1960s. Although earlier references to 'social geography' can be found, Johnston (1987) notes that it is barely mentioned in reviews of geography published in the 1950s. The development of the new sub-discipline was part of exciting theoretical and methodological change that geography experienced in the 1960s. In the 1970s and 1980s, vigorous theoretical debates led to a variety of conflicting approaches to research in social geography. By the early 1980s, the sub-discipline was of major importance within human geography. Indeed, a recent discussion of the area claimed that it became 'virtually synonymous with the whole field of human geography' (Johnston et al. 1994, p. 562). Nevertheless, the growing prominence of cultural geography towards the end of the 1980s and into the 1990s had a major impact on social geography. This was neatly symbolized by the decision of the 'Social Geography Study Group' of the Institute of British Geographers (which had been formed in the early 1970s) to change its title to 'The Social and Cultural Geography Study Group' in the 1990s.

What is social geography and what do social geographers do? The rapid growth of the sub-discipline and the significant theoretical debates within it have involved shifts in its definition and practice. In 1965, Pahl suggested that it was about 'the theoretical location of social groups and social characteristics, often within an urban setting' (p. 82). In 1975, Emrys Jones argued that 'social geography involves the understanding of the patterns which arise from the use social groups make of space as they see it, and of the processes involved in making and changing such patterns' (p. 7). The emphasis on social groups evident in Pahl's earlier definition remains of particular importance, in that what is held to make social geography 'social' is its concern not with individuals but with people as members of groups. However, there are some significant changes between the two definitions. First, Jones' definition introduces the idea that social processes produce spatial patterns and vice versa. This understanding of social geography remained dominant into the 1980s. Second, Jones' definition includes the phrase 'the use social groups make of space *as they see it*' (author's emphasis). This signals an increasing interest in people's subjective experiences in specific places—an interest that has become increasingly prominent in research designs.

The understanding of the scope and aims of social geography implied in Jones' definition endured until the mid-1980s when it came under increasing attack. These attacks and their implications for the development of social geography make better sense in the context of the account of the type of work that social geographers did from the 1960s to the mid 1980s, presented below.

2. Engaging with Positivism

2.1 Describing the Social Characteristics of Urban Areas

A major focus of research during the late 1950s and 1960s was the statistical description and analysis of the characteristics of the populations of urban areas. Central to this project was the identification of systematic patterns in the location of different social groups. Analysts examined which groups were likely to be segregated from other groups and whether there

was evidence for particular patterns of location for different groups within cities.

At this time, there were also important moves within human geography to apply positivist philosophy and methodology to the pursuit of geographical knowledge. These moves encouraged, on the one hand, attention to clearly specified theoretical statements and predictions and, on the other, the use of quantitative data and statistical techniques that were presented as allowing rigorous, scientific testing of hypotheses. Also associated with the growing commitment to positivism, was a desire for predictive models of the location of human activity and people's 'spatial behavior,' often drawing on neoclassical economics. For geographers interested in social groups and in cities this implied a need to develop predictive theories of the spatial form of cities, including theories of the location of social groups within urban areas.

Geographers looking for theoretical and methodological inspiration turned to the work of urban sociologists. First, they drew upon the work of the Chicago School—including Louis Wirth, Robert Park, and Ernest Burgess—who carried out extensive studies of Chicago in the first half of the twentieth century. They used maps of a wide range of statistical information in order to identify 'natural areas'—residential areas with distinctive physical and cultural characteristics—that the Chicago School sociologists argued developed from unplanned processes of competition and cooperation amongst urban residents. Burgess had developed a general model of urban residential land use as a series of concentric zones focused around the Central Business District.

Second, urban geographers were drawn to the work of Eshref Shevky and Wendell Bell who had studied characteristics of the populations of Los Angeles and San Francisco. Shevky and Bell had argued that the 'increasing scale' of society resulting from the increasing complexity of economic organization and the associated growth of urban areas could be linked to three dimensions of urban residential differentiation: 'social rank' or 'economic status'; 'urbanization' or 'family status'; and 'segregation' or 'ethnic status.' A key feature of their work was the development of 'social area analysis' using data on census tracts. They selected variables to represent the three dimensions and then used these to categorize census tracts in terms of 'high' or 'low' economic, family, or ethnic status. Although the theoretical links between increasing societal scale and the three dimensions of economic, family, and ethnic status were poorly specified and strongly criticized, geographers enthusiastically embraced the use of census data to characterize areas of the city.

During the 1960s, computers that were more powerful allowed geographers to use sophisticated statistical techniques to analyze data on census tracts. Factorial ecology was particularly popular—the use of factor analysis or principal component analysis to identify a few general constructs which underlie a large number of variables. Shevky and Bell's three status dimensions often emerged from the census data. The analyst could also classify census tracts in terms of the underlying constructs and map the results to see whether any systematic spatial patterns in characteristics of census tracts could be identified. These maps were compared with Burgess' concentric model of urban form and comparisons between factorial ecologies of different cities also made. Similar techniques were also used to look for relationships between residential differentiation, location, and patterns of crime, deviance, and mental health.

The availability of census data for many cities (mostly, in the 'developed' world) and increasing access to computers allowed social geographers to indulge in an orgy of analysis. However, there were some clear limitations to this work. First, the nature of the constructs identified was limited by the available census data: they could be as much a reflection of the data available as of the social 'reality' of urban areas. Second, because the data related to areas rather than individuals, false associations between variables may have been made (the 'ecological fallacy'). Moreover, differences in the sizes and rules for creating census tracts between countries limited the comparability of the results. Third, although the practitioners of these analyses aspired to work within a positivist framework much of the research was inductive description rather than tests of clearly specified hypotheses linked to well identified theoretical propositions. Nevertheless, this body of work provided a considerable body of descriptive information on residential differentiation that has become part of the taken for granted knowledge of geography.

2.2 *The Behavioral Challenge*

The descriptive analysis of urban residential characteristics was not the only type of work in social geography done during the 1960s and early 1970s. There were those who, despite their hopes for a positivist approach to the development of theory within geography, were dissatisfied with the approaches to studying human behavior that were used widely at that time.

In the 1960s, much research in human geography drew its inspiration from models in economic geography that posited that people possessed perfect information and were rational and optimizing in their behavior. Dissatisfaction with these assumptions prompted some researchers to turn to psychological theory concerned with cognition and decision-making in order to investigate what information people had available to use in spatial decision-making and how they used it. The principal method employed in these studies was the questionnaire survey, frequently incorporating some variety of attitudinal and personality

tests drawn from social psychology. The research carried out within this broad framework is known as 'behavioral geography.'

Work in behavioral geography was concerned with the locational decision-making of firms, individuals' decisions over where to live, people's everyday movements, and their information and ideas about space and place. Gould's work on mental maps was particularly influential (Gould and White 1974). His initial research examined American undergraduates' views of each US state as a place in which to live after graduation. The results showed that individuals had a strong preference for their home area and that this preference was superimposed upon an image of a national space with marked variations in preferences. The idea of an incomplete, biased and personal vision of the spatial world conjured up by the term 'mental map' became part of geographers' ideas about how people made decisions about both everyday movement and migration. Information about space and place was also recognized as important within studies of residential mobility and of people's everyday travel behavior. In the former, researchers were influenced by the early work of the sociologist Peter Rossi whose 1955 book *Why Families Move* was subtitled *A study in the social psychology of residential mobility*. A large number of studies of residential mobility in different cities and countries resulted. In the latter, diary data on travel behavior were used to develop inductive theories about the way people choose and order travel destinations. Travel behavior and migration research explored how people searched for information in space and developed strategies for choosing locations.

Research using the perspectives of behavioral geography—while part of social geography—remains marginal to the field because of its focus on the individual rather than on people as interacting with and partly constituted by their social milieu. However, the impossibility of such an individualist approach is evident in much of the work actually carried out. Researchers often examined contrasts between individuals drawn from different social groups (for example, different income, class, age and, occasionally, gender groups). Others examined the influence of the resources available to individuals on their spatial cognition and so ended up investigating differences between social groups. The research is also significant to social geography because criticisms of its individualistic approach were important to the development of alternatives.

3. Competing Approaches

During the early 1970s, many geographers became dissatisfied not only with the philosophical approach of positivism but also with the lack of critical political engagement that they detected in contemporary research. These concerns grew out of the radical ideas promoted in America and Europe as part of opposition to the American war in Vietnam, anti-nuclear campaigns (especially in Britain and European countries), civil rights (particularly in America), and the growing 'rediscovery' of poverty in the prosperous countries of the West. What was needed, it was felt, was research that could suggest how to change society, not merely how to understand it. Positivism was criticized for suggesting that an objective approach to social science was necessary, feasible, and desirable and that it was possible to find 'universal laws' of human society. Diverse competing 'radical' approaches were proposed; they all shared the desire to challenge the inequalities and injustices of contemporary society although some sought this through changing our valuation of human beings, some through institutional change and some through revolutionary political action. A sketch of some of the main approaches follows. Although here they are separated into demarcated 'boxes,' in reality their boundaries were fuzzy.

3.1 Humanistic Geography

The humanistic geography that emerged in the 1970s was animated by a desire to present an alternative to positivism. It shared the behavioral geographers' critique of some positivist approaches as dehumanized—insofar as they did not engage with the world as experienced by individuals—but added to this the more fundamental criticism that positivist social scientists made false claims to objectivity—by failing to recognize the subjectivity of both the observed and the observer. Here, humanistic geography made a decisive break with positivism and turned to approaches which require empathy with people's own perception of the values and meanings which inform their action (Jackson and Smith 1984). Two other important features of humanistic approaches were the insistence that people were active agents shaping their own worlds and a fascination with the links between place and social identity.

Although links have been made between the humanistic geography of the 1970s and a variety of early work in geography, the most immediate influence was the Chicago School. Humanistic geographers turned to the wealth of studies of the 'cultural life' of 'natural areas' produced by the Chicago School, as well as drawing on the 'community studies' tradition in sociology which had itself been partially inspired by the Chicago School. One of the major strands of work focused on understanding the way of life of particular social groups in particular areas of a city (although a few studies of rural areas were also carried out). It used ethnographic methods including participant observation, firsthand observation and interviews as well as

documentary information and census materials. Other researchers used ethnographic methods to explore features of crime and deviance in selected neighborhoods, often using factorial ecology to identify suitable areas for study.

Humanistic geographers also engaged with what were for 1970s geographers the new philosophical approaches of phenomenology and existentialism. There were two important consequences. First, a move towards thinking of the individual as constituted through the social interactions in which they take part. These social interactions and the everyday behaviors in which people engage create a taken-for-granted world which the social scientist can attempt to deconstruct. Second, there was an attempt to avoid prior theorization about the values and meanings of those people who are studied and to be open to understanding the world through their eyes. However, this still allows the findings of such studies to be interpreted within a theoretical or practical context and for disagreement about such interpretations to be fierce.

Another focus was on understanding the cultural meanings of, and values attached to particular landscapes and built forms. This work employed the methods of hermeneutics (for example, Meinig 1979). In the 1970s, this work was considered to be on the margins of social geography and soon became seen as part of the revival of cultural geography. As such, its investigation of the multiplicity and instability of meanings, their communication and reformulation began a tradition of work that has had important implications for contemporary social geography.

3.2 Welfare and Weber

David Smith's *Human Geography: A Welfare Approach* (1977) addressed what had begun to emerge as a new approach to human geography of particular significance to social geography. This approach focused on 'who gets what, where, and how'—that is, on issues of social justice and inequality. It therefore involved both arguments about what constitutes social (and often, territorial) justice and attempts to measure empirically various types of social inequality. An early focus was on developing social indicators to measure inequality between social groups living in different areas at a variety of scales ranging from the city to the world. This research built on the expertise developed in earlier descriptive analyses of census data on cities. It also included measurement of people's spatial access to services (for example health care or education) or proximity to negative factors such as pollution. However, although this answered questions of where inequality or deprivation might be found and who suffered such problems, it did not answer questions of how this inequality arose. Consequently, researchers developed a range of analyses of the operation of particular agencies and agents whose actions seemed significant to the distribution of resources.

A substantial body of work thus developed around state and private institutions' management of the distribution of resources, drawing on the theories of Max Weber. The concept of 'managerialism' was prominent. It was first proposed by Pahl (1975), who suggested that within both the state and private sector there were 'gatekeepers' whose decisions were crucial to access to resources and so to people's quality of life. Within social geography, the ideas of managerialism stimulated a wide range of studies of access to both public and private sector housing. These were counterposed to the earlier studies of housing search and housing choice to suggest that they had paid too little attention to the constraints on people's choices in the housing market. The theme of choice and constraint reappears within this body of work applied not only to housing but also to resources like health care, education, services for the elderly, parks, and open space and delivery services in rural areas. However, the ideas of Weber also introduced an increasing interest in conflict between and among institutions and groups. Here social geographers drew upon the ideas of the sociologist John Rex (1968) on housing classes, as well as on Weberian ideas about the operation of bureaucracies and professional groups, to explore conflicts over the distribution of resources.

A different approach to access used the ideas of time geography developed by the Swedish geographer Hagerstrand (1975). He suggested that time and space are resources which people must use to realize the 'projects' which they wish to carry out. Since traversing space requires time and many activities require the co-presence of individuals or presence at a particular location, not all projects can be realized. People's ability to carry out particular projects is limited by capacity, coupling, and authority constraints. Despite the enthusiasm of some geographers and a few empirical studies, the potential of these ideas remained regrettably underdeveloped. Most empirical use of Hagerstrand's ideas focused on the physical limits to access and did not develop the possibilities of a more fully realized social theory of human behavior in space and time.

The majority of welfare-focused research was concerned with cities in 'developed' countries; however, attention was also paid to inequalities in the rural areas of such countries and these perspectives have been used in studies of developing countries, Eastern Europe and the former USSR. There were overlaps with other radical approaches. The study of conflict and constraint often employed ethnographic methods to explore the values and patterns of behavior of gatekeepers and the social groups attempting to access resources. Attempts to answer the how element of welfare geographers' problematic often drew on research using Marxist theory which sought to situate

explanation of issues such as housing access within an analysis of the operation of capitalist society.

3.3 Marxist Approaches

The book that best illustrates the thinking that drew geographers to Marxist theory was Harvey's *Social Justice and the City* (1973). A key event also was the founding of *Antipode: a Radical Journal of Geography* in 1969 at Clark University in the USA. Harvey's book charts and explains a shift in his thinking from liberal to Marxist. At the start of the 1970s, very few geographers knew anything about Marxism, and Marxist analyses of the political economy of cities and regions were rare. By the end of the decade, there had been a major expansion in the use of Marxist approaches sufficient to create a new orthodoxy. This had implications across all geography while in social geography Marxist approaches were embraced with particular enthusiasm.

The analysis of residential differentiation and change had been a central part of social geography since its inception. The new Marxist theory offered ways of understanding these processes through ideas of class struggle and capital accumulation and large-scale patterns of investment, and disinvestment could be interpreted in terms of crises in processes of accumulation. Such analyses were applied to gentrification and suburbanization. Processes of socialization within residential areas could also be theorized as involving the reproduction of particular social subgroups (class fractions). These early formulations were challenged by an important new body of socialist-feminist work that developed in the early 1980s. While this incorporated many of the postulates of Marxism it criticized the conceptual and practical neglect of gendered power relations and the failure to identify and explore the links between gender and class relations. Critical empirical research on both gentrification and suburbanization sought to explore the ways in which gender relations were involved in the construction of the spatial structure of the city and the implications of this for women's oppression in society. In general, this socialist-feminist work was more sensitive than other Marxist approaches to the role of human agency and to humanist claims concerning the partiality of knowledge.

The approach to analyzing access to services was also strongly affected by Marxist analysis. Castells' work on collective consumption and social movements was highly influential. Castells defines collective consumption as the provision of services that are produced and managed collectively, and distributed through non-market allocation processes. He argued that these were provided through the State apparatus because they were necessary to the reproduction of labor power but would not be provided directly by the capitalist market because of a lower than average profit rate. Castells made a highly contentious definition of the city as 'a unit of collective consumption corresponding more or less to the daily organization of a section of labour power' (1976, p. 148). More importantly to research in social geography, he also spelt out how a variety of social movements might arise in response to inadequacies in the provision of collective consumption. Such social movements might fragment class solidarity and reduce the possibility of radical political change or enhance it. Castells' ideas stimulated extensive conceptual and empirical research in both urban sociology and in social geography.

3.4 Critiques and Cross-fertilization

By the early 1980s, social geographers had become better versed in social theory and more critical and sophisticated in its application. There were debate and cross-fertilization of ideas amongst researchers working in the three areas identified above and increasing awareness of their shortcomings as well as their strengths. There were strong critiques from humanists and feminists of the neglect of human agency in Marxist approaches in geography and this encouraged geographers' interest in the sociologist Anthony Giddens' 'structuration' theory (Giddens 1981). This attempted to show how human agency and structures were mutually constitutive within a time-space framework and drew on the earlier ideas of Hagerstrand. These critiques encouraged attempts to develop a more 'humanistic' Marxism sensitive to both human agency and contingency. At the same time, those concerned with issues of welfare and social justice were increasingly using some form of political economy approach deriving from Marxism to frame their research. All three approaches, as well as earlier work in social geography, were criticized by feminist geographers for their neglect of gender (Bowlby and McDowell 1987) and a major new body of research by feminist social geographers began to develop. This involved ethnographic empirical study of the everyday life of women and incorporated ideas drawn from welfare geography (in relation to issues of access and inequality), humanistic geography (in relation to women's experience of and social relations within particular places) and, as indicated above, Marxist geography. Some of this feminist work was linked to another major development within geography—the explosive growth of cultural geography during the late 1980s with its insistence that because meaning is constantly created and changed through shared but contested discourses, both individual and group self-definitions are unstable and contested.

This new cultural geography drew on earlier humanistic social geographical research as well as on feminist and postmodern critiques of modernist theory. In particular, modernist theory was criticized for assuming a white, bourgeois, and masculine subject and for its attempts to discover universal truth. The

impact of these critiques, and of the new empirical work done in the 1980s and 1990s in both cultural and economic geography, has been to call into question both earlier definitions of social geography and the coherence of the sub-discipline.

4. *What is 'the Social' in Social Geography?*

The later 1980s and the 1990s saw a progressive destruction of the main features of Emrys Jones's 1975 definition of social geography. That definition involved the separation of social process and spatial pattern and a focus on the use of space and creation of spatial patterns by social groups.

4.1 *Social Process and Spatial Pattern or 'Spatiality'?*

The 1980s saw growing dissatisfaction with the idea of social processes as distinct from spatial patterns, on the grounds that, because all social interactions necessarily take place in and through space, spatial pattern cannot be isolated from social process. These attacks derived from Marxist, humanistic, and cultural geographers' critiques of positivist analyses of abstract space as an empty container of social processes. Instead, Marxists argued that space was produced through capitalist social processes and through processes of class and other groups' opposition to capitalism. Humanistic and cultural geographers were also using phenomenological theory and empirical research to argue that our understandings of space are produced through our everyday social activities and do not draw on prior concepts of abstract space.

4.2 *The Social vs. the Economic*

In the early work, people's participation in the life of social groups made social geography social and distinguished it from approaches that focused on the individual. The existence of social groups and the salience of characteristics such as ethnicity or income were largely taken for granted. Questions about which social groups to study, and why, have had a number of implications for social geography.

First, increasing familiarity with Marxist and Weberian social theory made social geographers more aware of the need to define what were significant social groups in relation to the major constellations of power in society. Since economic relations are clearly of central importance to social power this required social geographers to consider the relations between the social and the economic. Were social relations to be seen as simply derivative of more 'fundamental' economic relations? If so, was social geography of less significance than economic geography?

Second, social geography had always concerned itself with issues of social reproduction—with housing, education, health care, and crime. However, as the new feminist work of the 1980s soon established, they had neglected some central aspects of social reproduction—notably those to do with domestic labor and the home. This feminist work also showed through analyses of the links between the gendering of the 'home' and the 'workplace' how untenable was the division between social reproduction and production. Thus, they claimed that 'production and reproduction—the conventionally accepted subjects of economic and social geography respectively—cannot analytically be separated' (Bowlby and McDowell 1987, p. 305). At the same time, researchers in economic geography were arguing for analyzing economies and economic relations as social constructs. During the 1990s, the importance of examining the social relations embedded in economic exchange was re-emphasized by a number of researchers. In particular, feminist research on labor markets showed clearly the interpenetration of the social and the economic (Hanson and Pratt 1995). Thus, the term 'social' no longer clearly delimits the subject matter for social geographers.

4.3 *Discourses and Social Groups*

Meanwhile a resurgence of cultural geography and associated growth of interest in postmodern theory has called into question social geographers' accustomed ways of thinking. On the one hand, these developments have drawn attention to the power relations inherent in the definition of social groups and to the political problems of representation this poses. They have also stressed the fluidity and contested nature of such definitions. On the other hand, postmodern approaches have questioned the validity of modernist 'grand theory' such as that of Marx and Weber that has been part of the stock in trade of social geographers from 1975 to 2000. Cultural geography has thus required social geographers to examine processes of representation and communication more closely and to question the idea that there is a single 'social reality' to be uncovered through research.

4.4 *What Future for Social Geography?*

There are significant vulnerabilities in the current situation of social geography. It now lacks a distinctive focus. In the 1990s, the definition of social geography given in the *Dictionary of Human Geography* was 'The study of social relations in space and the spatial structures that underpin those relations' (Johnson et al. 1994, p. 562). This is so broad that it is difficult to see where social geography ends and other sub-disciplines—for example, economic, political, or cultural geography—start.

It is also arguable that the term has become shorthand for research that concentrates on issues of 'social relations in space' only in Western societies. Despite the existence of much research in developing countries which, if carried out in a Western society,

would be termed 'social geography' there has been too little interaction between those researchers working on developing and developed countries. There are, however, some indications that this is changing with greater appreciation of the implications of the globalization of communication and economic relationships and the significance of diasporic cultures.

For many social geographers the growth of cultural geography presents an opportunity to combine many of the themes of the two sub-disciplines in fruitful investigation of social inequality and difference and to focus on and destabilize definitions of a wider range of 'social groups'—such as disabled people and gay and lesbian people. Social geographers' tradition of political engagement and ethnographic research can combine positively with cultural geographers' sensitivity to discourse and symbolic expression of difference. The rapprochements between social, cultural, and development geographers seem likely to produce valuable research. Nevertheless, the term 'social geography' on its own—as opposed to 'social and cultural geography' or 'social and development geography'—seems likely to revert to its earlier obscurity.

Social History

The term 'social history' refers to a subdiscipline of the historical sciences on the one hand and to a general approach to history that focuses on society at large on the other hand. In both manifestations social history developed from marginal and tentative origins at the end of the nineteenth and the beginning of the twentieth centuries and experienced a triumphant expansion from the 1950s to the 1980s. Throughout, social history can be best defined in terms of what it wants not to be or against that to which it proposes an alternative.

On one hand it distinguished itself from political history, which had been dominant during most of the nineteenth and the early twentieth centuries. Consequently, the 'social' in social history meant dealing with the structures of societies and social change, social movements, groups and classes, conditions of work and ways of life, families, households, local communities, urbanization, mobility, ethnic groups, etc. On the other hand social history challenged dominant historical narratives which were constructed around the history of politics and the state or around the history of ideas by stressing instead social change as a core dimension around which historical synthesis and diagnosis of the contemporary world should be organized. With these aims in mind, social historians (including historical sociologists and economic historians) sought to uncover the relationships between economic, demographic and social processes and structures, as well as their impact on political institutions, the distribution of resources, social movements, shared worldviews, and forms of public and

private behavior. For the comprehensive variant of 'social history,' the term 'history of society' (*Gesellschaftsgeschichte*) has gained currency. Not only in Western Europe and North America but also in other parts of the world, the establishment, expansion, and specialization of social history belong among the significant trends of interwar and particularly postwar intellectual and academic life. Nevertheless, in recent years, it shares with other fields of the humanities and social sciences a 'time of doubts' (Chartier 1993), a period of challenges from interpretative, constructivist, and discursive approaches (Palmer 1990, Bonnel and Hunt 1999).

1. *Early Institutionalization (Late Nineteenth–Early Twentieth Century)*

Like other generations of historians in the twentieth century that have at some point used the label 'new' for themselves, the claim to innovation by social historians in the 1960s and 1970s obscured the rich diversity of predecessors and competitors, which goes back to the second half of the nineteenth century (Kocka 1986). In that period, the academic professionalization and disciplinary differentiation of economics, sociology, and political science on the one hand and history on the other prevailed.

The mutual contact zones or, by contrast, the strength of boundaries were marked by significant national differences. The resulting interactions and hierarchies between these 'fields of knowledge' (Ringer 1992) differed in respect to the amount of space they provided for historical approaches. The 'Historical School' of political economy in Germany, dominant in the last third of the nineteenth century, is a case in point. It was part of economics and did not gain much recognition in the discipline of history. Some professional historians took part in a process of specialization in 'social and economic history' that kept a critical distance as much from this strand of economics as from the traditional history of great men, events, and ideas. The development of the combined field 'social and economic history' marked a double opposition, on the one hand to the history of political events and on the other hand to an increasingly ahistorical economic science.

The creation of a specialized journal in Germany allows one to give a precise date to the development of this subdiscipline of historiography. In 1893 the journal for social and economic history was founded, which was continued after ten years (and still exists today) as the *Vierteljahrschrift für Sozial- und Wirtschaftsgeschichte* (VSWG), under the direction of the Austrian socialist Ludo Moritz Hartmann and the conservative medievalist Georg von Below. That journal served as a direct reference for Lucien Febvre and Marc Bloch (see *Bloch, Mark Léopold Benjamin (1886–1944)*) when they founded the *Annales* in 1929 in Strasbourg. Not surprisingly, their journal was first called *Annales d'histoire économique et sociale* (1929–1939). The international exchanges and mutual observation between some of the protagonists of historiographic innovations in the early decades of the twentieth century were intense. Thus, only two years after the French flagship, the Polish journal *Roczniki dziejow spolecznych i gospodarczych* (Yearbooks for social and economic history) appeared. These early journals shared a further characteristic which distinguished them from the mainstream political history around them, namely a keen interest for 'universal,' non-nationalistic history.

In Germany, social and economic history remained a specialized branch without much impact on general history. In England, economic history maintained close links to social themes. After World War II, the French *Annales* historians tended to move their journal away from its earlier identification with this 'subdiscipline.' Similarly, the program represented by Ernest Labrousse for a history of class relations taking as its starting point the economic 'basis' broadened out more and more into the areas of urban history, quantitative analysis of social strata and the integral description of regional societies. Where 'social and economic history' continued to be an institutionalized specialty, it did not necessarily figure as an area of major innovations, as was later the case with the 'new' history of the 1960s and 1970s.

These early efforts to establish a specialized field and an alternative view of history with 'society' as the main object and organizing principle of analysis were paralleled by similar movements in various countries. In the USA, the *New History* of the turn of the century; in France, Henri Berr with his *Revue de Synthèse* (*Historique*) starting in 1900 and the reception of Durkheimian sociology by historians; in Germany, the development of a historical sociology by Max Weber and others; and in Great Britain in the first half of the twentieth century the impulses of George Unwin and R. H. Tawney for the development of an economic history that included social and cultural factors, were all among the most influential strands of socio-historical thinking (Iggers 1975).

Two characteristics of these debates and innovations deserve emphasis: the challenge of Marxism in a broad, nonorthodox sense provoked both emulation and animosity. Secondly, it is interesting to note in light of current discussions that especially in the German context the concept of 'culture' rather than that of 'society' was conceived as the vantage point for the synthetic organization of knowledge in the social sciences. In the 1950s the representatives of French 'new history' used the term 'history of civilization' to define the broadest possible framework of historical synthesis. Even Trevelyan's 1942 definition of social history as 'the history of a people with the politics left out' which is cited as often as it is refuted provides a surprisingly wide room for the 'social,' implicitly

including culture, mentalities, everyday life. (For a detailed treatment of the above topics see *Historiography and Historical Thought: Indigenous Cultures in the Americas*; *History and the Social Sciences*).

In recent times a further root of social history has attracted wider attention. It lies in the antimodern nationalist currents, critical of industrialization, which in particular in the 1920s and 1930s presented a special attraction for the younger social and human scientists. The interest in rural life, population, and race combined particularly in Germany with aggressive nationalism and criticism of the new political borders (Raphael 1997). This historical writing opposed conventional research subjects and forms; it turned away from the state and classical political history, looked for alternatives to the traditional focus on elites, and took as its example the methods which had already seen much progress in demography, geography, and anthropology. In the 1930s and 1940s a number of representatives of this so-called *Volksgeschichte* (history of the people) moved closer to National Socialism and became active as wartime political consultants. As some of these historians and social scientists played a significant role in the modernizing of the human sciences in the German Federal Republic, a debate arose as to the extent to which lines of continuity led from 'history of the people' to social history, and concerning the relation between its representatives' rightist views and their proposed 'structural history' of modern industrial society (Schulze and Oexle 1999, Conrad 1999).

2. *Postwar Expansion (1950s to 1970s)*

Not only in Western Europe and North America but also in other parts of the world, the establishment, expansion, and specialization of social history belong among the significant trends of interwar and particularly postwar intellectual and academic life. The spread of the 'new' histories since the 1960s occurred at a time when systems of higher education in Europe and North America were dramatically expanding. The general increase in academic jobs, student enrolments and Ph.D. candidates, as well as the massive growth in book publications and journals, allowed the various strands of social history to find ample space without replacing or pushing aside more traditional ways of writing and teaching history.

The institutional growth of social history followed different national directions. But it can generally be said that in the 1970s a high point was reached as far as the establishment within universities and among the larger public was concerned. The most impressive indicator is the founding of new journals concentrated around the year 1975: *Social Science History* (USA, 1975), *Geschichte und Gesellschaft* (West Germany, 1976), *History Workshop Journal* (UK, 1976); *Social History* (UK, 1976). Along with the *Journal of Social History* (USA) founded in 1967 they represented the new 'historical social science,' complementing the older 'school-forming' reviews such as above all *Annales ESC* (France, refounded 1946) and *Past and Present* (UK, 1952).

2.1 *National Variations and International Circulation of Ideas*

The triumph of social history in the 1960s and 1970s was a transnational phenomenon. The themes, questions, and methods were astonishingly similar in different countries; the international specialist public was interconnected through increased contacts. In many places the attractiveness and legitimacy of new approaches were aided by models coming from other countries. Particularly the French '*nouvelle histoire*,' often described by others as the *Annales* school, developed into a veritable export hit. Already at the international historians' congresses in Paris in 1950 and in Rome in 1955, its French representatives and Italian or English allies very much set the tone (Erdmann 1987). In the following decades the international circulation of concepts and approaches took on greater strength through the translation of books. A few historiographic models or theoretical influences (such as for instance the work of Fernand Braudel) became widespread in the countries of southern Europe and South America, while others won international recognition via their reception and dissemination on the North American market.

Yet for all that the national differences remained considerable, even in retrospect and after several decades of approaches and exchanges. The strengths of the French school remained—with a few exceptions—limited to the Middle Ages and the early modern period. Not the genesis of industrial society but the explanation of the revolution of 1789 was and remains the dominant theme for French historians. By contrast in Great Britain, an early market society and 'first industrial nation,' historians gave particular importance to these factors. The central approach which English social historians shared with social reformers and social scientists was however focused on the persistence and dynamism of class society.

It is by no means a coincidence that E. P. Thompson in his pioneering work *The Making of the English Working Class* (1963) made decisive strides for social history in this field. And the historical self-examination in other countries can also—though certainly not entirely—be characterized through central motives in their social development: the USA as an immigration and frontier society, in which ethnic cleavages are given more weight than class conflicts; Sweden with its experiences of mass emigration and social crises at the end of the nineteenth and beginning of the twentieth centuries; and finally Japan, which after

World War II looked to describe its latest developments in terms of Marxian-inspired modernization models (Conrad 1999). The political breaches and catastrophes of the twentieth century also formed the node of the new German social history, which was especially influenced by the political social history by the 'Bielefeld School' historians. The German *Sonderweg*, the German divergence from the West, and the social conditions for the national-socialist rule were the central preoccupations of a whole generation of historians who broke with 'historicist' (see *Historicism*) and individualizing explanatory models (Kocka 1999, Welskopp 1998).

2.2 Topics, Neighbors, Models

The place of social history in the intellectual landscape of the historical and social sciences of the post-World War II era can be understood by tracing the main trends with respect to its preferred research topics and questions, interdisciplinary alliances, methods, and explanatory models. These trends were most conspicuous in the period from the late 1950s to the 1970s, which witnessed the most pronounced change toward the 'new' social history. The reorientation effected by the spread of social history is most obvious with respect to the subjects chosen for monographs, in the programs of congresses or in the contents of major journals. The history of social classes and social stratification in general entered into the historical mainstream.

In researching social mobility and standards of life in the past, historians in Europe and North America tended to prolong the prehistory of their contemporary societies into the nineteenth century (and later even further back). Labor history (*Labor History*) left its subaltern and ideological niche and expanded its focus to the realities of work, family, and everyday life. The economic interests and social position of political actors were taken seriously and entered into the 'social interpretation' of great processes like the American and French revolutions, colonialism and imperialism, the development of political parties and social movements, or the causes of war. The fluctuation of harvests, prices and wages, the ebb and flow of population movements and land use, even microbes and the climate were considered with growing technical sophistication and by an increasing numbers of istorians.

Population history with the more micro-oriented historical demography became a leading sector of the new historiography: migration, demographic behaviour, household structure were reconstructed by large research projects. The Cambridge Group for the History of Population and Social Structure founded in 1964 by Peter Laslett, E. A. Wrigley, and Roger Schofield as well as the historical department of the French *Institut National d'Etudes Demographiques* represented the effort of making history 'scientific,' and influenced similar enterprises in Germany and Austria, the Scandinavian countries and North America among others. Similar aims were held by historically minded sociologists, political scientists, and economists who joined historians in the USA to create a discussion forum under the heading of 'Social Science History' (with conferences since the 1960s and a journal of the same name since 1975).

The flourishing subfields, each with their own journals, congresses, and experts, read like a repertoire of social history themes (Stearns 1994): labor, demographic, family, urban, rural, ethnic, women's, and gender histories emerged and became aspects of a more encompassing social history (*Social History*). Internal sequences and echoes were to be observed in the establishment of subdisciplines and the proliferation of new topics: the growing emphasis on mentality, agency, subjectivity, and experience since the late 1970s was itself a response to the establishment of abstract, often quantitative studies on standard of living, family and demography, social and geographic mobility, or political interest groups. Women's historians criticized the unspoken gender assumptions of much of historical demography and family studies, as well as of the history of labor markets and welfare states. The very meaning of the term 'social' was itself reconceived; it lost its direct association with 'socialist' movements or 'social policy' and embraced instead the whole abundance of the life-world. The enlarged thematic spectrum of the Amsterdam-based *International Review of Social History* (1956), the Parisian *Le Mouvement Social* (1960) or the German journal *Archiv fuer Sozialgeschichte* (1961), are examples of this transition which had gained considerable ground by the mid-1970s.

The shift in interdisciplinary alliances mirrored and underpinned topical interests. The nearest neighbors to history were no longer philology, philosophy, or law, but economics, political science, and sociology. For the French *Annales* School the close relationship with geography and demography was particularly important. The West German focus on a 'political social history' of the late nineteenth and early twentieth centuries led to an alliance with historical sociology and political science. Various strands of descriptive, often quantitative economics, social surveys, and sociography are found among the more practical roots of historians who embarked on studies of living standards, family formation, or business cycles. Equally it should not be forgotten that the enormous growth of sociology in the postwar era held a particular attraction for historians.

The varieties of social and cultural anthropology, or ethnology as it is called in some countries, served as models for a minority of social historians, especially those working on early modern history. The journal *Comparative Studies in Society and History* (founded in 1958) became an important forum for historically

minded anthropologists and anthropologically interested historians and social scientists. The relationship between history and anthropology—a discipline which has also changed dramatically during the last three or four decades—is a good indicator for the underlying change of emphasis from 'society' to 'culture' within social history. Natalie Z. Davis's influential collection of essays *Society and Culture in Early Modern France* (Davis 1975) or the wide impact of Clifford Geertz's writings, especially his 1973 collection *The Interpretation of Cultures*, are cases in point.

Parallel to these shifts, the protagonists and agents of the new social history reflected on the mechanisms of scientific change as such. What appeared to be happening under their own eyes and with their help in the humanities and social sciences seemed to resemble a 'paradigm shift,' as Thomas S. Kuhn had described it for physics in his influential book *The Structure of Scientific Revolutions* of 1962. Notwithstanding Kuhn's own doubts as to whether his model could be applied to the social sciences, the 'paradigm shift' became a battle cry in the nascent struggle to establish social history over and against the history of politics, great men, or ideas. The implications of Kuhn's work for the history of science were also welcomed by social historians. Indeed, the emphasis on social and external factors in the development and application of knowledge clearly corresponded to the efforts of social historians to stress context, interests, and structural constraints when dealing with ideas and ideologies (Appleby et al. 1994).

Although at the time many were fascinated by the idea of a 'paradigm shift,' in retrospect we see a more subtly differentiated, less abrupt transition. It is certainly true that in individual national academic traditions there were in part intense debates as to the 'right' sort of history. And in most cases a political dimension was also present, in which social history was defined as being more to the left, and political history more to the right. However rather than superseding an old paradigm, social historians could work on several levels (institutional, methodological, and thematic) and go about broadening and innovating their field within quite different time frames. If one sees the success story of social history as a pluralistic project fed from many different sources, it becomes easier to understand its expansion and, later, its reorientation in the direction of cultural history. In fact the many social-political and intra-academic forces which were involved in the rise of social history have continued to develop independently, and gradually cast doubt upon the plausibility of their own basic assumptions.

These definitional clarifications should not, however, obscure the impact of the new social history on the traditions of historiography. The historicist principles of the historians' craft were challenged by analytical, theory-driven approaches. The borrowing of concepts and even the adaptation of 'middle range theories' (R. K. Merton) as tools in historical research and writing has become a trademark of social historians as compared to traditional 'narrative historians' (Le Goff and Nora 1985, Fairburn 1999). The use of comparative methods gained wide currency (Tilly 1984). Theories of modernization (*Modernization, Sociological Theories of*) became more attractive, above all for historians of the nineteenth and twentieth centuries. Even if the explicit use of theories remained in general limited, process-oriented terms such as industrialization, urbanization, secularization, and professionalization became ever more widely used in historiography. And they were by no means limited to social history in the more restricted sense. Modernization, industrial society, even democratization, all were part of the meta narrative governing a good part of social history writ large—albeit with national differences and often heavy criticism from alternative political currents within social history (see for example Judt 1979). Yet despite evident tension the height of the social history wave was marked by a good deal of common ground.

The explanatory models proposed by the 'new' histories of the 1950s, 1960s, and 1970s shared the aim of explaining collective behavior and social relations by linking them to the structures of the economy and society. Although most opposed the rigidity of official Marxism-Leninism, many historians conceived of society as an architecture which resembled a vaguely materialist interaction between 'basis' and 'superstructure.' In her work on the French revolution Lynn Hunt explicitly rejected the widespread partition of monographs in three levels of economy/demography, society, and politics or mentality by simply turning it on its head (Hunt 1990, pp. 102–3). Interests, world views, political stances were largely understood as collective responses to objective social positions. Since the 1970s, social history has experienced shifts in its basic assumptions about causality that have led to a much less homogenous situation. But there seems to be a widespread refocusing first on agency and practices, secondly on meaning and identity, and thirdly on microprocesses.

2.3 *The Will to Synthesis*

The social-historical approach to history set other requirements on the writing of an overall historical account as conventional political history. The narrative structure of political events, the periodization by means of wars or revolutions, and the intentionality of a historiography oriented towards the 'big players' could not be simply transposed on to social history. In this new field syntheses therefore had to contain—whether one liked it or not—a reflection on the character of 'society.' The will to synthesis is for this reason part and parcel of social history's emphasis on a comprehensive approach to history. Here social

history sets itself off most clearly from the study of social and economic phenomena within a context which continues to be defined in political terms.

The authors of large syntheses in social history are for that reason also more or less explicitly protagonists of a 'history of society,' or of a *histoire totale* in the French tradition. Mikhail Rostovtzeff's *Social and Economic History of the Roman Empire* (1926) and Marc Bloch's *Société féodale* (1939–1940) are both early and distinguished examples. Fernand Braudel, Eric Hobsbawm, and Hans-Ulrich Wehler emphasized in their own way this requirement with monumental general histories. But they could do so only by consciously borrowing concepts and models from the neighboring social sciences, and by setting out theoretical considerations on social structure and on the motors of social change. Whether these involved models on temporal and geographic structures such as Braudel's, or a flexible use of Marxist theories such as Hobsbawm's, or an explicit use of modernization theories such as Wehler's—in each case this type of general history distinguished itself from the conventional historiography also in its explicit theoretical orientation. Yet a clear difference in the degree to which theory governs the historical narrative or the display of arguments remains between these works and those of historical sociologists such as Immanuel Wallerstein, Theda Skocpol, Charles Tilly, or Michael Mann—authors who nevertheless share common interests with the historians.

But also at a more humble geographical and temporal level social historians have continuously endeavored to reconstruct the object of their investigations, society, as a coherent if multifaceted system, sometimes even in a literary way. Above all however they continue writing within their respective national historical frameworks (Wehler 1987–1995). Often this takes the form of collections of articles in which various authors describe the individual aspects of society (a recent example is Thompson 1990). But even the short, broad-based handbook giving an overview of the state of research belongs in this category. In part this reflects the tendency to specific research on social classes and strata which leaves out further societal, cultural, and political contexts (Charle 1994). Although the emergence of the newer directions of gender, experience, and cultural history has increased the fear that social history would become even more fragmented, José Harris (1993), for example, has explicitly endeavored to integrate these very perspectives into a general historical account.

3. *The Revenge of Success*

However, social history's expansion in quantitative scale and conceptual scope was large enough to produce serious side-effects. First, specialization increased dramatically. Greater demand for technical expertise such as quantification, the creation of such subfields as historical demography, or the tendency of methodological approaches like oral history to take on a life of their own contributed to the differentiation of the field. Second, the proliferation of topics as well as of local or regional units of analysis deemed worthy of a monograph concurred to create a very colorful map of approaches and subjects. In the late 1980s and later, representatives of social history looking back on the success story of their field could made out the first signs of self-doubt already in the second half of the 1970s, at the highpoint of social history's intellectual and institutional glory (see contributions in Kocka 1989). More than any other approach to history, social history gradually came to be marked by fragmentation and dispersion. Third, social history as a general approach gained access to other historiographical periods and to other disciplines in the humanities. In literary criticism and modern languages the social history of literature became a trademark in the 1970s and early 1980s and, since then, has met with growing skepticism and disillusionment.

Certainly it must be said that these developments represent a tribute to the success of social history. In the course of differentiation and specialization, the new approaches and subfields which had established themselves under the heading of social history gradually changed their character and underlying priorities (Burke 1991). What is often described at the end of the twentieth century as a cultural 'turn' in fact emerged over the years. Indeed, disillusionment with the social history of the 1970s can best be understood not as a 'paradigm shift' but rather as an incremental, self-reinforcing, sometimes conflictual transition on different, non-unified, levels of historical work: research methods, preferred topics and sources, examples taken from other disciplines, new 'buzz words' and concepts, more hidden understandings of causality, agency, and evolution. Without question, the more recent set of shifts, from social history to the 'new cultural history,' makes us think harder about the establishment of social history and its concomitant changes of the societal and political context in earlier decades.

The recent 'cultural turn' can first of all be understood immanently, that is intra-academically. In its various manifestations, social history continued in the tradition of an oppositional approach against the historical mainstream. Small wonder that it has attracted attacks from every new wave of critical and revisionist historians as well as the revival of older (biographic, narrative) forms of historical writing. The concept of gender has in many countries been at the forefront of debates around structure and agency, macrosociological categories and deconstructivist criticism. Particularly in Germany, a fierce debate with aspects of a generation conflict divided the 'history of society' embodied in the Bielefeld school of *Gesellschaftsgeschichte* (Iggers 1975, Kocka 1986,

Wehler 1987–1995) and the 'history of everyday life' (*Alltagsgeschichte*) represented by grassroots history workshops and a number of younger academics at the margin of the profession (Ludtke 1995).

Yet one must also consider the external, extra-academic factors which in the last decades have changed the relationship of the social sciences to society. The social and political movements of the postwar years made their mark on social history. Especially in the USA the expansion of themes and problems in social history since the 1960s had been given a strong push by the corresponding conflicts in American society: the movements of Afro-Americans, of students, of women, and of gays and lesbians added to the traditional input from the workers' movement and radical intellectuals. Since the 1980s, the already proverbial trinity of race, class, and gender reflected these social forces in an academic discourse. In Europe, too, a similar, by no means linear elective affinity could be observed between social movements (the alternative left, the women's, ecological and peace movements) and fresh ideas in history (gender, everyday, and microhistory).

The 1980s and 1990s experienced a strong move toward independence and pluralization of identity politics and the associated attempts at claiming one's own history for oneself. Taken together these trends have aided the transition away from a history of anonymous social processes and structures. This reorientation became even stronger with growing critique of the ethnocentric dominance of industrial societies in social history leading up to this time. In recent years, the slow inroads which postcolonial discourses have also made into historical science have on the one hand furthered the significance of classical social history, this time in the countries of Asia, Africa, and Latin America. On the other hand the established concepts of modernization, development, progress, and culture were subject to a thoroughgoing critique and redefinition. Finally, the breakdown of actually existing socialism in 1989/1990 and the resulting political and economic transformation led to reflection on the basics of politics and the economy (Kocka 2000).

The answers to these challenges and interrogations are by no means clear. The voices which speak of a 'crisis' are not restricted to social history, but are directed at the historical sciences, if not the humanities in general. Two trends can be made out: beyond all methodological differences the self-reflection of the academic historian has moved to center stage. The idea that one can produce reliable knowledge about society—contemporary or past—was in 2000 taken far less for granted than a few decades previously (Bonnell and Hunt 1999). On the other hand the historicization of all forms of knowledge has become, as it were, a patent remedy in all debates. In opening up towards this sociocultural direction, it is true that social history may have lost in unity, perhaps in recognizability, but it has gained in intellectual dynamism.

Social Identity, Psychology of

1. Social Identity

Social identity is those aspects of the self-concept that are derived from belonging to social groups and categories. Social identity theory was developed by Henri Tajfel and colleagues at the University of Bristol in the 1970s and 1980s. Social identity is a concept that continues to be used widely in the social psychology of intergroup relations, social influence, and the self. This article describes social identity theory and associated work on intergroup relations and group processes. It points to the diverse areas of research to which the theory has contributed and concludes with issues that are currently being explored.

2. Minimal Conditions for Intergroup Bias

In the 1960s and 1970s social psychology underwent a crisis of confidence that generated a powerful critique of individualistic theorizing and research. In response, European social psychologists began to develop theories that concerned the relationship between individuals and society. Social identity connected cognitive processes of categorization with the social structure of society. Research on social identity therefore ranges from the detailed analysis of cognitive processes underlying stereotyping and prejudice to wide-ranging questions such as reactions to group disadvantage. Tajfel's early work on social categorization included development of the minimal group paradigm. In this widely used paradigm people are randomly allocated to categories that have little meaning (e.g., A group and B group, or people who prefer Klee vs. Kandinsky). Research participants are unaware of which other individuals belong to the category, or what their characteristics might be. Evidence shows that minimal group membership is a sufficient basis for people to allocate points or money preferentially to anonymous members of their own category. They also evaluate in-group members more positively, although it seems that reward allocation and evaluations are not highly correlated. If a trivial categorization is sufficient to generate in-group bias, it can be reasoned that more significant and meaningful categorizations have substantial real-word consequences. An important theoretical implication of in-group bias in the minimal group paradigm is that in-group bias does not necessarily have its roots in objective or realistic intergroup conflict or in personality differences or interpersonal dependency.

3. Social Identity Theory

Social identity theory (Tajfel and Turner 1979) offers an explanation for minimal intergroup bias, and also a broader statement of how relationships between real-world groups relate to social identity. According to social identity theory, there is a continuum on which identity and relationships can be depicted as purely personal and interpersonal at one extreme, and purely social, or intergroup at the other. Personal identity is derived from personality, idiosyncratic traits and features, and particular personal relationships with other individuals. A special emphasis of social identity theory is that an effective account of group and intergroup phenomena is not possible if the theory only considers personal identity and relationships. Social identity is the individual's knowledge that he or she belongs to certain social groups together with the emotional and value significance of the group memberships. Social identity affects and is affected by intergroup relationships. The theory aims to explain the uniformity and coherence of group and intergroup behavior as mediated by social identity (see Hogg and Abrams 1988 for a detailed account).

3.1 Categorization

Categorization leads to accentuation of differences among objects in different categories, and accentu-

ation of similarities of objects within categories. When social categorizations are salient, accentuation results in stereotypical perceptions of both categories. When people categorize one another they generally include the self in one of the categories. Attributes that are stereotypical for the in-group may then be ascribed to self, a process labeled self-stereotyping. As a result of self-stereotyping the self is 'depersonalized.' This means that the self and other in-group members are seen as interchangeable in their relationship to out-group members.

3.2 Self-categorization

Self-categorization theory (Turner et al. 1987) extends social identity theory. It proposes that the salience of self-categorization depends on a combination of the relative accessibility of the categories (i.e., the perceiver's readiness to make use of them) and the comparative and normative fit between the social stimuli (i.e., people being perceived) and the available categories. The more that the targets are classifiable by a clear criterion (such as gender) and the more that their behavior seems to fit the category normatively (e.g., being domineering vs. considerate), the more readily the categorization will be applied. The categories will be represented in terms of prototypes based on a meta-contrast ratio that minimizes the differences within categories and maximizes the differences between categories on criterial dimensions. Categorizing self and others involves perceiving them in terms of their closeness to the relevant group prototype, rather than in terms of their unique personal characteristics. According to self-categorization theory, stereotyping of in-group members, out-group members, and the self is a normal functional process that responds flexibly to the particular categories that are being compared. The theory therefore challenges traditional models of stereotyping as a form of bias, and of the self-concept as a stable psychological structure (see Abrams and Hogg 2001).

3.2.1 Social influence. Depersonalization is thought to underlie social influence within groups. When social identity is salient, in-group prototypes serve as norms or reference points. For example, attraction to group members is affected more strongly by shared social identity than by interpersonal similarities (Hogg 1992). The coordinated and consistent behavior of crowd members also seems to be more explicable in terms of a shared social identity than in terms of characteristics of the individuals, resulting from a process of referent informational influence (Turner 1991). In classic social influence paradigms such as Asch's conformity experiments, or Sherif's norm formation experiments, people are more strongly influenced when they share a category with the source of influence than when they do not. Moreover, reactions to group deviants are much more hostile if they are deviating toward an out-group norm (Marques et al. 1998).

3.3 Motivation

3.3.1 Positive distinctiveness. Social identity theory offers a motivational explanation for in-group bias. First, judgments about self as a group member are held to be associated with the outcome of social comparisons between the in-group and relevant out-groups. Second, it is assumed that people desire a satisfactory self-image, and positive self-esteem. Positive self-evaluation as a group member can be achieved by ensuring that the in-group is positively distinctive from the out-group. Usually group members will engage in social competition with out-groups to try to make the in-group positively distinctive. For example, in minimal group experiments, people show a consistent bias both towards maximizing in-group profit and toward maximizing differential profit in favor of the in-group, even when the total in-group profit suffers. The theory does not argue that material considerations are unimportant, but that the symbolic meaning of the group's position relative to other groups is a powerful motivating consideration.

3.3.2 The self-esteem hypothesis. The motivational component of the theory, sometimes described as the 'self-esteem hypothesis,' has been scrutinized in some detail (Abrams and Hogg 2001). Two corollaries of the hypothesis are that expression of in-group bias should maintain or increase self-esteem, and that lowered self-esteem should motivate the expression of in-group bias. These hypotheses only relate to the specific evaluations of self as a group member immediately before and after judgments or allocations have been made toward the in-group and the out-group. However, few empirical tests have adhered to these requirements, and the evidence supporting them is weak or mixed. Evidence does suggest that people with higher personal self-esteem are more likely to show in-group bias and favoritism. As a consequence of theoretical and practical difficulties of the self-esteem hypothesis, other motivational processes have been suggested. Brewer (1981) has proposed that people seek optimal distinctiveness, such that they have some assimilation to a group, but the group has some distinctiveness from other groups. Hogg and Abrams (1993) have suggested that people are motivated to reduce uncertainty, and that clarification of group membership, adherence to group norms, and associating positive group features with

the self are ways to achieve this. However, apart from conformity to pre-existing biased in-group norms, there seems to be no strong alternative candidate to the self-esteem hypothesis as an explanation for in-group bias.

3.4 Social Structure

A second component of social identity theory explicitly addresses the status relationships among groups. To maintain or enhance social identity, people may engage in a variety of strategies. The choice of strategy will depend on perceptions of the relationship between their own and other social groups. The boundaries between groups may be viewed as permeable or impermeable, the status differences as legitimate or illegitimate, and the nature of these differences as being stable or unstable. When status differences are seen as legitimate and stable, the differences between groups are secure. If group boundaries are permeable, the individuals may have a social mobility belief structure. In this situation they may strive to improve their identity by moving to the higher status group. For example, it is possible to go from school to university by passing the relevant entrance examinations. Social mobility belief structures are strongly endorsed by Western individualistic democracies, in which individual effort and ability are viewed as the basis for the allocation of social goods and resources. When boundaries between groups are viewed as impermeable (e.g., that between men and women, or between blacks and whites), members consider that their social identity can only be improved if the social relationship between the groups changes (a social change belief structure). When the social structure is viewed as illegitimate and/or unstable, the intergroup relationship is 'insecure,' and it becomes possible to imagine cognitive alternatives to the status quo. Members of lower status groups will engage in social competition with higher status groups to evaluate and reward their own group more positively. In the absence of cognitive alternatives, group members may still find ways of conferring positive distinctiveness on the in-group, using a social creativity strategy. Social creativity strategies include comparing the groups on new (in-group favoring) dimensions, trying to re-value the existing dimensions of comparison so recasting in-group attributes positively, and engaging in comparisons with other, lower status, out-groups. There is considerable evidence from experimental tests of the theory that these strategies are adopted (e.g., Ellemers et al. 1999).

3.5 Language

Social identity has been studied widely in natural intergroup settings. One important area of research is language use and maintenance. Language is an important marker of social identity. For example, use of the matched guise technique, in which the same speaker delivers a passage using different accents or dialects, has revealed that judgments of in-group and out-group speakers reveal clear in-group favoritism. Moreover, speakers' accents converge or diverge depending on whether they view the relationship positively. The ability of a group to sustain its language may reflect its ethnolinguistic vitality, which is a function of the perceived status, demography, and institutional support that it has (Giles and Johnson 1987). Finally, there seems to be a linguistic intergroup bias in which people describe positive in-group and out-group attributes in more abstract terms using more specific terminology (Semin and Fiedler 1991).

3.6 Collective Behavior

A second significant area of research is collective behavior and protest. Traditional theories, such as relative deprivation or frustration–aggression theory, have depicted mass protest, rioting, and revolution as products of frustration or dissatisfaction felt by individuals. However, research has shown that social protest and mobilization is predicted by the perception of deprivation of the group relative to other groups. In turn, collective action is more likely when group members feel there is no legitimate alternative, no possibility of social mobility, and when they identify strongly with their group. Some evidence suggests that collective action is usually a last resort, but other evidence suggests that participation in collective action is likely when people identify strongly with their group (Kelly and Breinlinger 1996).

3.7 Organizational Behavior

Social identity is also highly relevant to organizational behavior. Commitment to organizational goals and willingness to contribute to organizational activities, as well as lowered absenteeism and turnover intentions, have all been shown to be associated with higher identification with organizations (Ashforth and Mael 1989, Tyler and Smith 1998). Moreover, people's endorsement of leaders seems to be affected at least as much by the leader's perceived prototypicality (representativeness of the specific in-group norm) as by how effective or stereotypically leader-like the person is.

4. Critical Comments and Future Directions

The concept of social identity is widely accepted in social psychology and has contributed to a large volume of research (Robinson 1996). Current work is moving away from the idea that group members are

primarily motivated by self-enhancement, and examines the idea that people may be motivated to reduce uncertainty or find meaning from their group memberships. In addition, identification may be manifested in different ways (Deaux 1996), and there are individual differences that affect people's behavior, such as differences in how strongly they identify with particular groups, differences in their social dominance orientation, and differences in their willingness to express prejudice. It seems that the strength with which people identify with groups, and the degree of threat to social identity, can moderate the relationship between group status and intergroup bias (Ellemers et al. 1999). Current work is also examining the cognitive processes that affect the self–group relationship. For example, some researchers argue that the self is the primary psychological unit and that it simply extends to include in-groups, in contrast to the idea that the self can be redefined by salient self-categorizations. Recent research also shows evidence of a rapprochement between social cognition approaches to intergroup relations and the social identity perspective (Abrams and Hogg 1999).

Social Inequality and Schooling

Do systems of education in modern societies help to break down the inheritance of privilege from one generation to the next, thereby providing opportunities for mobility for members of less privileged groups, or do schools largely reinforce and legitimate the inequalities among individuals evident in the larger society? This article shows that social background affects educational attainment; discusses mechanisms through which family privilege is translated into advantaged educational opportunities and achievement; identifies unequal school resources and opportunities as determinants of inequality in outcomes; and shows that egalitarian-based school reforms have generally failed to reduce social inequalities in education significantly. Unequal educational outcomes derive both from inequality in educational opportunities and inequalities in family environment and resources.

1. Social Background and Educational Inequality

1.1 Basic Relationships

A relative constant about education in the modern world is that social background has a major impact on educational performance and on educational attain-

ment, even net of ability: on average, students from more advantaged class and/or status backgrounds perform better in school and go further in the educational system, thereby obtaining higher-level educational credentials (Ishida et al. 1995). The association between family background and educational outcomes is even stronger in the developing world than in advanced industrial societies and is less strong in the USA than in the many European countries in which more explicit class and gender barriers in access to schooling (e.g., in the form of fees for secondary schooling and gender-segregated schools, respectively) have existed historically (see Brint 1998). Given that educational performance and credentials are important determinants of adult success, education thereby plays an important role in the reproduction of social inequality. Some theorists propose that education is a form of 'social capital' that has replaced property as a means of intergenerational status transmission (Bourdieu 1973). Whereas elite families once ensured their children's future positions by passing on property, they now ensure their children's futures by helping them obtain the 'best' educational credentials. Nonetheless, even the strongest proponents of class reproduction theory recognize that education does not perfectly reproduce the class/status structure of modern societies. It also provides opportunities for some talented individuals from less advantaged backgrounds to succeed.

Social scientists have for decades tried to determine why class and status inequalities in educational outcomes occur. Part of the explanation, as discussed more fully below, is or has been due to unequal educational opportunities. Further, the growth of mass education throughout the world has nominally equalized educational opportunities at some levels (primary education in the developing world, secondary education in the developed world) while displacing the level of education that has real consequence for adult success to a higher level—one to which elites retain privileged access (e.g., the university level in developed countries). School expansion, therefore, has not reduced the educational advantage that elite children enjoy (Walters 2000, pp. 254–7).

But even when educational access is formally equal, inequalities in outcomes still occur. Some of this is due to class or status segregation within schools or school systems: Disadvantaged children tend to go to schools with largely disadvantaged student bodies (i.e., there is between-school segregation), or be in streams or tracks within schools that are fairly socially homogeneous (i.e., there is within-school segregation). That is, the proximate schooling experience is class- and status-segregated to a large extent in many societies, and this segregation has an adverse effect on disadvantaged children's achievement (Oakes et al. 1992).

Some of the inequality in educational outcomes is also due to the direct effects that families and family background have on learning, achievement, and educational experiences, aside from wealthy parents' ability to buy private schooling for their children or, in some developing countries at present, poor families' dependence on child labor, which interferes with schooling. Children from more advantaged families, for example, are more likely to start school with strong academic skills, be helped in their school work by their parents, have parents who actively intervene in their schooling careers, exhibit linguistic patterns preferred by teachers, have resources to buy learning materials or supplemental help, and in general live in a family environment that supports learning and academic accomplishment (Brint 1998, pp. 208–14).

In many societies, educational programs have been established to help disadvantaged children make up for their family-based learning 'deficits' (one notable example is Project Head Start in the USA). With the exception of far-going educational reforms in some socialist states, however (see Sect. 2.3), reforms have not attempted to deprive children from advantaged families of most of their sources of educational advantage.

1.2 Bases of Social Inequality

The particular social groups that are educationally 'advantaged' and 'disadvantaged' vary by places and times, depending on the stratification system in place in the larger society. Generally, those groups that are advantaged in society at large are advantaged with respect to educational opportunities and educational outcomes. In most societies in the modern world, social class position confers tremendous educational advantage or disadvantage. Children from advantaged social classes have better educational opportunities, have higher levels of 'achievement' as officially measured and recognized by the school, and receive on average 'better' educational credentials. In capitalist societies, upper-class and upper-middle-class children reap these educational class advantages. In socialist societies, children of party elites reaped educational class advantages, official policy notwithstanding (see Shavit and Blossfeld 1993). Class is arguably the most important source of educational advantage or disadvantage, and the source that has been most consistent in recent decades.

Another common social distinction that has important educational consequences is race and ethnicity. The degree of educational disadvantage associated with being a member of a disadvantaged racial or ethnic group has varied historically. The USA and South Africa, for example, historically had public educational systems that segregated blacks into separate schools and offered them far fewer educational opportunities; in both cases, changes in state policy eliminated the explicit racial barriers to school access although some forms of racial inequality in education persist. There is also significant cross-

cultural variation in the racial or ethnic groups that are educationally disadvantaged: For example, Koreans and other Asians perform better than whites in American schools but are educationally disadvantaged in Japan (Brint 1998, p. 216).

The final major basis of social inequality in education is gender. Gender inequality in education—both in terms of access and outcomes—has decreased dramatically in recent decades in most advanced industrial countries. Whereas girls were once commonly barred from certain types or levels of education, gender barriers in access are insignificant in most industrial countries at present but remain in those less developed countries in which women are still largely restricted to the private (family) sphere. Similarly, in most industrial countries schools offer similar if not identical curricular opportunities at present to boys and girls, and girls outperform boys in some important respects (e.g., in the USA girls earn better grades on average than boys and have higher rates of graduation from high school and college). The significance of gender as a basis of social inequality in education has declined significantly, then, in many parts of the world but remained high in societies in which gender remains a significant basis of differentiation in the larger society.

2. *Social Inequality in School Access and Resources*

2.1 *Translating Advantaged Family Background to Educational Advantage*

The ways in which children from advantaged families gain access to advantaged schools or schooling experiences vary from society to society. Most European societies have long been known for their class-based systems of education (which are also often ethnic-based), characterized by a clear differentiation into educational streams at relatively early ages. Children from advantaged backgrounds were more likely to enter streams leading to university-level education at the ages of 10 or 12, whereas at the same time working-class children or racial and ethnic minorities were more likely to enter streams leading to earlier school exit and vocational training. At present, some European states retain a system of early branching (e.g., Germany and Austria), albeit in modified form from prior decades. Others, however (e.g., France, England, and Sweden), have eliminated early branching, have combined vocational and academic training in the same secondary school buildings, and allow easier movement among streams at the high-school level—in part because of the explicit recognition that early and relatively permanent branching maximizes the effect of family background on schooling outcomes (see Brint 1998, pp. 29–64).

But even in the USA—a society whose educational system is regarded as more open, in which most students attend comprehensive high schools, in which most students get second, third, or more chances for access to high-level education, and in which a private school secondary education is less important for access to the top universities—inequality in access to 'good' educational opportunities is still evident. In part this is due to the ability of advantaged parents to use their personal resources to send their children to expensive private schools if they so choose. But largely it is due to wide variation in the USA among states, within states, and among school districts in the quality of public schools. This variation favors those states and localities in which advantaged families predominate, because of the historic reliance in the USA on local property taxes to fund public education. Unlike the financing basis of state-supported schooling in many other industrialized countries, this system allows wide variation in per-student school funding.

This reliance on local taxes in the USA has produced a system where the 'best' schools—the ones with the most expensive facilities, the better-trained and most highly paid teachers, the most advanced curricular opportunities that 'produce' students with the highest standardized test scores, and send the highest proportion of their graduates to college—are located in those local areas with the highest concentrations of wealth, largely very wealthy suburbs of large metropolitan areas (Kozol 1987). This system produces sharp inequalities in educational access by class and race, the latter because African-Americans are concentrated in central cities, which have crumbling and fiscally strapped public-school systems.

2.2 *The Importance of School Resources*

Starting with the publication called the Coleman Report in the United States (Coleman et al. 1966), numerous studies by social scientists have been interpreted to show that schools—or, more precisely, resources devoted to schools—do not matter. Coleman found that family socioeconomic background is a much more important determinant of educational achievement as measured by standardized test scores than spending on schools. One implication of this finding is that any observed differences in public moneys spent on schools attended by the elite versus schools attended by the disadvantaged is irrelevant with respect to class or status differences in educational outcomes. In other words, families are implicated in the creation of inequality in educational outcomes, but schools are not.

As politically popular as this argument has proven to be, at least in the USA, a number of recent meta-analyses show that the existing studies offer stronger proof of a positive effect of resources on student test scores than an absence of an effect (e.g., Hedges et al.

1994; but for a counter interpretation see Hanushek 1994). Further, an important longitudinal experimental study in Tennessee, in which students were randomly assigned to different-sized classes, demonstrated that placement in relatively small classes, an important type of school resource, had a significant effect on students' performance on standardized tests in the first and subsequent years of the study (Krueger 1999).

There are other problems with the argument that inequality in school resources is inconsequential with respect to educational outcomes. One, Coleman's (and many others') measure of educational outcome was ability, not achievement, years of schooling completed, entry to college, or the like, all of which are far more consequential for adult success than one's score on an ability test. A number of studies have found positive effects of school resources on educational attainment and on adult earnings (see review in Card and Krueger 1996). Two, aggregate school-level family social economic status and school funding co-vary, making it hard to disentangle the effects of family background and school spending. Three, what families 'know' themselves about the importance of going to a well-funded school belies the argument that school spending doesn't matter: when given the opportunity, families go to extraordinary lengths to get their own children placed in resource-rich schools.

2.3 Egalitarian School Reforms

Although it is doubtful that eliminating class, race, gender, and other bases of inequality in access to schooling or the quality of schooling would result in equality in educational outcomes (because of the strong effects family background have on school performance and persistence), it is clear that the presence of class, race, gender or other barriers to access to school or to particular levels of school promotes social inequality in education and in adult life. Thus, in the past several decades many countries have instituted school reforms intended to eliminate historic patterns of unequal access to education. In those places where racial minorities were allowed only separate—and unequal—educations, desegregation was an important step toward equalization of opportunity. In societies in which class barriers to secondary education existed in the form of school fees and the like, such as Ireland, elimination of fees was intended to equalize class access to secondary education (Raftery and Hout 1993). Some socialist societies went much further, instituting systems that gave clear preference in access to education to children from formerly disadvantaged backgrounds (see Shavit and Blossfeld 1993). Interestingly, in very few cases did these reforms, even the most far-reaching ones, succeed in eliminating former class or status disadvantages in schooling. Social differentials in educational attainments, for example, have proven remarkably resistant to egalitarian school reform (Shavit and Blossfeld 1993). One major reason for this is that increasing the access of formerly disadvantaged groups to a particular level of schooling—say secondary education—increases the proportion of advantaged children attending as well *and* generally does not significantly alter class or status effects on the likelihood of entering that level of education (Raftery and Hout 1993, p. 60). Further, once secondary education, for example, is readily available to formerly disadvantaged groups, higher education becomes the significant arena in which class and status advantages are preserved (Walters 2000). Gender is an exception: in some Western societies, women are now more likely than men to obtain baccalaureate degrees, although not Ph.Ds.

It appears that the only way to significantly reduce class or status inequalities in educational outcomes is to combine egalitarian school reform with a variety of social policies that significantly reduce inequalities in living conditions, family-based resources, and occupational opportunities. Of the 13 countries covered by Shavit and Blossfeld's (1993) important edited book, for example—including a range of countries from capitalist to state socialist—only in Sweden and the Netherlands were egalitarian school reforms coupled with social welfare policies that substantially reduced inequalities in family resources and did educational inequality significantly decline. Further, the substantial decline in gender inequality in education witnessed in some societies is due to school-based reforms *as well as* a significant decline in gender stratification in the public sphere.

The failure of sweeping school reform in a number of socialist states, including 'reverse discrimination' policies intended to favor children of working-class or peasant backgrounds, is particularly illuminating. To an important degree, new elites took the place of old elites (e.g., party elites replaced old class elites) but children of elites still enjoyed educational advantages. Further, none of these reforms closed off all possible means by which even former elites could ensure their children's educational advantage: for example, bribes, favors based on personal ties, passing on various forms of cultural capital that helped children overcome formal barriers to their access to privileged schooling, and the lingering effect of family financial capital (see summary in Walters 2000, p. 255).

3. Summary

Social inequality in education is an enduring feature of the twentieth century. There have been changes in which social groups are advantaged and disadvantaged, but groups that are disadvantaged in the larger society are generally—though not always—disadvan-

taged with respect to educational achievement and attainment, if not with respect to educational opportunities. Many societies have implemented changes that make access to education formally more open to disadvantaged groups, but these changes and reforms have not succeeded in creating equality of educational outcomes. Inequality in family-based resources and patterns of stratification and inequality in the larger society continue to be determinants of social inequality in education.

Social Inequality in History (Stratification and Classes)

As a universal fact of all human civilization, social inequality has been shaping advanced societies in a most fundamental way for many thousands of years, especially since the rise of more complex cultures and political systems in the wake of the 'Neolithic Revolution.' The concept of social inequality refers to an unequal distribution of positions in society, a distribution which is determined by structures of power (e.g., the modern state and its administrative elites), of technology and economy (e.g., industrial technology and capitalism), and of cultural expression and perception (e.g., Christian religion and its attempt to define and explain a 'holy' order of worldly society).

In modern societies, social inequality is often framed as a differentiation of society in distinct groups of similar positions conceivable as 'layers' of the social order on a vertical scale. A general term for this type of social inequality structure is 'stratification.' In the Western tradition, the concept of stratification often—in a more or less explicit way—refers to a ranking of social positions according to the distribution of economic resources; the conflicting groups resulting from this are frequently called 'classes' (in a broad sense). The notion of a society divided into classes, which through their collective action fundamentally shape the dynamic processes of society, has been most widely applied to the specific historical case of Western industrial societies with their market economy, but has also been transferred from here to the description of agrarian societies in ancient or medieval times.

Since around 1970, concepts of stratification and class have been criticized for their neglect of other dimensions of social differentiation and inequality such as gender, race, or ethnicity. Important as this recent restructuring of the debate on historical (and contemporary) modes of inequality is, stratification and class have been essential concepts for social history in the past (and appear to remain so in the future, if in a modified way). Indeed, it may be said that the development of social history as a field of historical research is hardly conceivable without the analytical concepts of stratification and class. In considering social inequality, stratification, and class in history, two perspectives may be taken. First,

stratification is an empirical problem, a problem of historical subject matter. In this regard, one can follow the development of systems of social inequality throughout history, from antiquity to the twenty-first century. Second, stratification refers to an analytical and theoretical problem in (social) history; it appears as a problem of conceptualizing historical processes and structures. In this vein, one can look at concepts, approaches, and methods in research on stratification and class, and consider their development, especially since the nineteenth century, and their usage in different historiographical traditions.

This article will concentrate on the second, the conceptual level. However, both perspectives are intimately linked, since there is no empirical description of inequality without an acute awareness of concepts and language. However, for historians (as opposed to social theorists), all methodological discussion eventually points to empirical research in order to better understand systems of social inequality in the past, and therefore, in the present.

1. *Theories of Social Stratification and Class Formation: Historical Development Through the 1960s*

Even before the rise of the modern social sciences with their more elaborate theories of social structure, the explanation (and justification) of inequality was an important part of intellectual thought in advanced, literate societies, often within a general philosophical or theological context. In ancient Athens, Aristotle regarded society as consisting of three hierarchically ordered groups, among which he favored the middle, or '*mesor*,' as being most important for the stability of the *polis*. Aristotle's scheme of 'stratification' remains influential in attempts at defining society in terms of 'upper,' 'middle,' and 'lower' classes or strata, among which the middle class is held in highest regard (e.g., in political culture and public discourse in the USA.

In feudalist Western Europe during the Middle Ages, a different kind of tripartite scheme of inequality gained prominence: the idea of a functional differentiation of society into the three orders of Christian clergymen, noblemen, and peasants. With the rise of cities and the emergence of town burghers as an influential group, the functionalist scheme was adapted to new social realities, but it remained a central concept for the interpretation of inequality.

While these theories are themselves a subject of historical inquiry because they tell a lot about the framing and self-understanding of pre-modern societies (Duby 1978), a major shift toward modern concepts of stratification and class only occurred in the late eighteenth and nineteenth centuries. In the historical and philosophical works of the Scottish enlightenment (e.g., Adam Smith, Adam Ferguson, and John Millar), principal stages of civilizational development were associated with particular systems of social inequality and stratified class structure. The language of social inequality that is still in use, with its typical metaphors of 'class' and 'strata,' is heavily indebted to scientific discourses of the eighteenth century, and especially to the enlightenment's quest for 'classification' (Karl v. Linné) and order in the realms of both nature and culture. In the following decades, with Adam Smith and David Ricardo providing important linkages, attention in the theory of stratification increasingly shifted towards a search for the origins of inequality in economic systems of production.

The most powerful, and historically most influential, theory of class as a product of basic economic forces was for a long time Karl Marx' (and Friedrich Engels') concept of Historical Materialism, a theory according to which at each stage of society, an oppressed lower class rises against the economic and political dominance of a ruling class, and eventually overturns the old system through class struggle and revolution. Whatever critical may be said of Marx' theories and its political consequences, it nevertheless became the major reference point for most theories of inequality and stratification until the middle of the twentieth century, and possibly also thereafter. For social history in particular, it provided an extremely suggestive framework for understanding historical change in terms of economic progress, class formation, and societal conflict, instead of referring to diplomacy, politics, and the 'great men' as driving forces of history, as was the case in much traditional nineteenth and early twentieth century history. After Marx, theories of inequality based on functional differentiation and the division of labor played an important role for a while (e.g., with Herbert Spencer in the UK, Gustav Schmoller in Germany, and Émile Durkheim in France), but they too were primarily grounded in the idea of economic foundations of particular class systems.

At the beginning of the twentieth century, German sociologist Max Weber in some ways moved class analysis back to Marxian scope and intentions, while on the other hand he developed, if in a fragmentary manner not easy to grasp for later scholars, a broader, historically more flexible, and less dogmatic, framework for the interpretation of social inequality and class structures. Although Weber, like most of his contemporaries, under the impression of industrial capitalism's triumphant advance, acknowledged the enormous impact of economic forces on the molding of society, he was also prepared to systematically consider other dimensions of stratification. Political power, in Weber's view, often played a crucial role in determining positions in a class system; and also inequality for him appeared as fundamentally shaped by 'culture': by general interpretations of the world and the social order as, for example, provided by religion (*Weltbilder*), as well as by the honor, prestige,

or status attributed to an individual (or to members of a larger group, such as a specific profession) within the normative setting of a society (see Weber 1978).

After a brief period of neglect, Weber's concepts of social inequality and social class exerted a strong influence on both American and European social science after 1945. In postwar American sociology and political science in particular, stratification became one of the dominant topics in the field, a topic that all major 'schools' and theoretical currents had to reckon with (see Barber et al. 1968). Despite an enormous variety of approaches and methods, some common features of stratification research in the 1950s and early 1960s stand out, making them attractive for historians. Often, they were not just present-minded, but embedded in a macro-sociological and historical framework of thought. Typically, they were interested in linkages between class and political power structures, and in the cultural dimensions of inequality as expressed in neo-Weberian concepts like 'status' or 'prestige' (Bendix and Lipset 1953, Lenski 1966).

Since the late 1950s, Weberian and functionalist research in stratification began to overlap with a renaissance of critical theories of society and inequality that were attempting to benefit from the Marxian tradition in an undogmatic manner. Authors like Ralf Dahrendorf or Anthony Giddens were widely read for their innovative intellectual combinations of Marxism and liberalism, or Marxian and Weberian traditions (see Dahrendorf 1959, Giddens 1973). In Western social science, the revival of the Marxian tradition proved short-lived and mostly faded away in the late 1970s, leaving some strands of cultural Marxism as survivors into the then emerging new age of culturalism in the social sciences. However, Weber's influence, because of the historical depth of his work and a rare combination of flexibility and analytical precision in his categories, never quite vanished, and his work continuously remained inspiring for historians doing research on stratification and class. At the same time, Weber proved remarkably resistant against changing intellectual moods since the late 1970s and 1980s, when classical concepts of stratification and class came under attack. He thus continued to be a starting-point in some of the most important recent approaches in the sociology and social history of inequality and class.

2. *Stratification and Social Classes in Historiography: Trends and Examples*

With the rise of social history to intellectual dominance in the 1960s and 1970s in most Western countries, research on the history of stratification and class, mostly in modern societies since the Industrial Revolution of the nineteenth century, became a central historiographical theme, and even a topic defining what the 'New Social History' was all about. In the general political and academic climate of the 1960s, with its social-democratic air and its resurgence of Neo-Marxian theories, interest for the less privileged groups of industrial society—and especially for the working class—spilled over into history and not only generated a host of special studies on stratification, mobility, and class formation, but also influenced synthetic approaches in social history and the general discourse of historians in that field. While this was a pervasive international tendency, it rendered different results within the national traditions of social history. Therefore, Germany and the US will be considered as two important examples.

2.1 *Germany*

With its strong methodological roots in nineteenth-century historicism and its political conservatism in the historical profession, Germany was a late-comer in the development of postwar social history, and in many respects remained dependent on the reception of theoretical innovation from other countries such as France, the UK, and the USA. However, due to its strong traditions in social theory, and the theory of class in particular (Marx, Weber), and also because of the great historical significance of class structures in late nineteenth- and early twentieth-century Germany, topics like stratification and class formation quickly took center stage in West German social history during the late 1960s and 1970s. To a larger degree than in other countries, stratification and class emerged as the paradigmatic categories of research in social history (see, e.g., Kocka 1975), a tendency that came under attack in the 1990s as competing concepts such as gender and ethnicity by many historians were regarded as at least equally important.

For the history of stratification and class in the 1970s and 1980s, two approaches deserve special mention. First, as was the case elsewhere, the history of classes in the beginning concentrated on the less privileged groups and lower strata of society. Here, a particular focus was on the formation of a modern, industrial working class in the nineteenth century, and on the problem of the homogenization of that class from the origins of a multitude of pre-industrial, agrarian, and artisanal occupations and interests. In what he termed the 'Weberian application of a Marxian model,' historian Jürgen Kocka studied the formation of a German proletariat, which he conceived as a Marxian class in its basic socio-economic determination, and at the same time as a Weberian ideal type with which reality can never fully correspond (see Kocka 1980, 1987, see also: *Labor History*; *Working Classes*, *History of*). Class formation in this approach was considered an historical process progressing through different levels. It proceeded—

ideally, though not necessarily in historical reality—from economic homogenization in the workplace towards increasing social and cultural coherence and might end with class consciousness and the political organization of the working class. Since the 1980s, class formation models have also been applied to the upper strata of German society, particularly the bourgeoisie and the professional middle classes, but it appeared that in this case, 'culture' seemed to operate as a much more influential determinant of class than a common economic position.

Second, German traditions in social theory fostered an unusually strong interest in the historical conceptualization of the overall class structure and stratification system, again with an emphasis on the period of German modernization and industrialization from the late eighteenth century onwards. In conceiving social history as the 'history of society,' and the history of society as grounded in structures and processes of social inequality, stratification, and class, German historian Hans-Ulrich Wehler in a very influential project attempted a synthesis of modern German history in terms of a history of inequality and class. His *Gesellschaftsgeschichte* in a systematic way asks for the transformation of the estate system of preindustrial society into an industrial society comprised of social classes, with the bourgeoisie and proletariat in the center, but also giving attention to the nobility and to agrarian classes such as farmers or farmworkers (Wehler 1987–95). Typical for much German social history in the 1970s and 1980s, Wehler's approach is methodologically under the heavy influence of Max Weber's categories; and it politically adheres to a vision of an increasingly equal, less classrifted (if not classless) society.

While most other German authors are not as ambitious and comprehensive as Wehler in their concern with social structures, they have, however, been more inclined to expand the explanatory framework of social inequality into the realm of culture. A new focus of research is on the complicated relationship between social structure on the one hand, and cultural perceptions and practices on the other hand.

2.2 United States

In its self-image, the US has been born as a country of equality, defined by a lack of class and stratification in the European sense, and by the predominance of a broad middle class. The fact that the US has never known an estate system of social order has indeed, in combination with the country's more pragmatist tradition in social thought, exerted a deep influence on social scientific and historical approaches toward class structure and socio-economic inequality in America. On the other hand, critical strands in social theory and historiography, which were able to identify and discuss inequality of class, appeared earlier than in Germany and remained stronger in the first half of the twentieth century—with the 'Progressive historians' such as Charles Beard being the most important example.

During the 1960s, the blossoming of the 'New Social History,' together with a more self-critical mood in American society in general, prompted a new interest in the history of social class and inequality in America, much in the same way as in other Western countries at about the same time. With regard to approach and method, historians often concentrated on less privileged groups, such as workers and immigrants, and they often did so in case studies of particular cities and through the study of social mobility among the lower strata of urban society (Thernstrom 1964; see also *Social Mobility, History of*). For some time around 1970, Neo-Marxist approaches to the study of class and 'class struggle' in American society drew some attention, but on the whole, even leftist historians of class and inequality undertook much less theoretical effort in conceptualizing their topics than in Germany.

Similar to trends in European social history, however, quantitative methods (as in the study of social mobility) since the late 1970s lost much of their earlier appeal. Instead, the problem of class was more often approached through qualitative, even hermeneutical methods, and through the lenses of class culture and class experience. Also, outside the somewhat narrowing field of working class and labor history, the study of social classes shifted its main focus from the lower classes to the middle classes and their origins in nineteenth-century social change (e.g., Blumin 1989, Zunz 1990). This shift may be understood as an attempt to deconstruct the pervasive myth of the American middle class, and at the same time to historically explain the middle class orientation of twentieth-century America.

In a broader perspective, the study of stratification and class as such after the 1970s retreated from the center of concern for social historians much more quickly, and more pervasively, than in Europe. Obviously, the most important reason for this is the existence of other, competing dimensions of inequality in American society, especially the inequality of race and ethnicity. Class formation in the US rarely occurred in ethnically homogeneous milieus, and often racial and ethnic identity turned out to be more important, and certainly of a much more durable character, than class identity and economic position.

For the same reason, synthetic efforts with generalized views on American society from the perspective of stratification and class were hardly undertaken by American historians. The one large project that probably comes closest to such a synthesis is the two-volume textbook 'Who Built America?,' collectively conceived and written by the American Social History Project under the intellectual guidance of labor historian Herbert Gutman (See, American Social History Project 1989–92). The book attempts a synthesis of

American history from colonial times to the present by centering its narrative around the development of social classes—particularly the industrial working class—and the struggle of less privileged groups for participation in the economic and political resources of 'mainstream' America. At the same time, the authors' efforts demonstrate that a narrative of American social history from the viewpoint of stratification and class alone cannot make sense; it needs to be expanded by, and connected with, additional categories of inequality such as race, ethnicity, and gender.

3. *The Challenge of Culture in the History of Stratification and Class*

The discussion of the two national examples, especially the case of the US, has already hinted at important new trends in historical research which have begun to change the field in fundamental ways since the 1980s and will probably continue to do so in the future. Although many of the recent tendencies stem from similar motives—e.g., the increasing dissatisfaction with interpretations of class based on the structures of male industrial work—and therefore often overlap in historiographical practice, it is useful to distinguish two horizons of criticism and expansion of the classical stratification and inequality paradigms. Some scholars, for different reasons, fundamentally question the relevance of concepts such as 'class' and 'stratification' and try to develop alternative concepts, or alternative theoretical and methodological viewpoints on the problem of inequality in history (see Sect. 4). Others consider 'class' and 'stratification' as still important, or even indispensable notions for social history, yet argue that they have to be redefined in order to meet the challenges of social reality and social science at the turn of the twenty-first century. This ongoing redefinition of class is in most cases centered around the idea of 'culture.' Culture, especially in the forms of 'language' and 'experience,' is now widely believed to be the prime factor in determining stratification systems and class structures. However, at a closer look, the challenge of culture differentiates into a number of theoretical and empirical approaches.

3.1 *Class as Social Action, Experience, and Culture*

In 1963, the English Marxist historian E. P. Thompson published his two-volume 'Making of the English Working Class,' which is arguably among the dozen most influential works in twentieth-century social history (Thompson 1963). At that time, classical approaches to class formation grounded in systematic sociology or political science were still widely in use, and in some countries just beginning to influence the expanding field of social history. Thompson's massive study was rather conventional in the sense of its practical empiricism and its Marxian notion of a working-class winning identity and togetherness in the struggle against its bourgeois class enemy. What was new, however, was Thompson's insistence that 'class' was not a quasi-objective structure determined by certain economic forces, but a very fluid result of practical action and social experience on the part of the lower classes in the decades around 1800. As Thompson largely focused on pre-industrial work and living experience, he discovered the roots of class in traditions and re-inventions of popular culture. In many respects, Thompson's book was ahead of his time. Reception and debate in Germany, for example, only took off in the 1980s and turned his pioneering work into a major stimulant for the then emerging culturalist turn in social history (see *Cultural History*).

3.2 *Class Experience: From Production to Consumption*

Classical approaches to the history of stratification, from the enlightenment theories of a division of labor to Marx and beyond, have based their identification of certain classes, and their description of the overall inequality structure of society, on the sphere of production, and on the relative position an individual (mostly seen as a male adult and family head) acquired in that society's system of work and employment. As the nineteenth-century fascination with factory work and industrial production faded and the twentieth century increasingly developed the self-image of a consumer economy and society, it seemed appropriate to search for social spheres of class formation outside the workplace experience: at home, in leisure activities, and especially in consumption. In American and in British historiography in particular, the history of consumption has been one of the most significant discoveries for the field of social and cultural history in the 1990s (see *Consumption, History of*), and several attempts have been made to conceptually link consumption and class, some of which build on much earlier efforts such as Thorstein Veblen's 'Theory of the Leisure Class' with its ideas about the role of 'conspicuous consumption' for the life of the upper classes.

The notion of consumption can play a key role because of its ability to connect the perspective of economy—the appropriation of goods by groups with different economic resources—with the perspective of culture—insofar goods serve as symbols and as expressions of (individual or collective) identity and lifestyle. It also allows for a more adequate consideration of female and private-life contributions to the formation of social inequality and class. In an important empirical study on Chicago in the 1920s and 1930s,

historian Lizabeth Cohen investigated the formation of class identity among ethnic workers and their families through their shared experience of consumption and modern mass culture institutions like radio (Cohen 1990). As the history of consumption still flourishes at the turn of the twenty-first century, it is likely that its impact on the history of inequality and class will grow even larger in the near future.

3.3 Pierre Bourdieu: Class and Cultural Distinction

The first two examples for the cultural expansion of the history of class represent developments within the historical profession, yet trends and new concepts in other social scientific disciplines have also had their impact on the topic. While national traditions of thought remain influential—with Max Weber, for example, still being of prime importance in Germany, and anthropologist Clifford Geertz stimulating American debates—in international perspective one scholar's work in particular has received near unanimous attention and acclaim by social historians during the 1980s and 1990s, namely French sociologist Pierre Bourdieu's theory of class and cultural distinction as developed in his major work *La distinction* (Bourdieu 1979).

Arguing from his research on contemporary French society, Bourdieu secures a central place in social research for the problem of inequality and even sticks to the concept of class. Yet in a brilliant way he enlarges that concept by understanding class as the result of a complex ensemble of not just economic, but also social and cultural resources or types of 'capital.' Similar to the category of 'prestige' in 1950s American sociology, Bourdieu defines an individual's position in society in terms of his or her 'distinction' and 'habitus,' a concept referring to socio-cultural outlook and self-stylization. Though obviously fitting the self-oriented consumer and leisure society of the later twentieth century especially well, the appeal of Bourdieu's approach also extends to the analysis of more traditional societies in the early modern era, and even to non-Western societies, not least because of Bourdieu's own intellectual origins as a social anthropologist. As Bourdieu at the same time draws on 'classical' authors of stratification research such as Weber and Marx, his work is extremely important in providing a bridge between the classical theoretical tradition and the more recent approaches that center around language, experience, culture, and consumption.

4. Beyond Class, Beyond Stratification?

While the 'culturalist turn' in the humanities has substantially expanded and reframed perspectives on stratification and class in history since around 1980 other scholars have gone a step further in arguing that the conceptual framework of stratification and class might better be abandoned altogether and replaced by alternative concepts of social order. However, that does not mean that they would deny the existence, and empirical relevance, of stratification systems and class formation under certain historical circumstances. Rather, the argument is that the category of class itself is a historical product of the nineteenth century, and that therefore the continuing conceptual primacy of class endangers the ability of scholars to recognize different lines of social division and inequality.

4.1 Gender, Race, and Ethnicity

This point has been most persuasively made by feminist social scientists and historians who have argued that the predominance of class in social history has in fact only been able to describe the male half of the social world—and even that in an inadequate manner, because class formation among male individuals (or, household heads) cannot be conceived of independent from the family and gender systems out of which the sphere of production and patriarchy grows (see Canning 1992). In a similar way, historians of race and ethnicity have maintained that the stratification of a society in terms of individuals' economic positions never functions as an independent variable in multiracial societies such as the US, Brazil, or South Africa—nor even in European societies which are increasingly being shaped by their immigrant populations. It has hence become almost a standard method in American, and now also in British social history, to frame the problem of social inequality in the trias of 'race, class, and gender.' In the view of many feminist historians, however, this solution is a dissatisfactory compromise, because it implicitly affirms a conceptual primacy of class by molding the two other concepts after the example of class, or as mere expansions of it (see Scott 1986).

Therefore, the history of gender is in need of developing specific theoretical foundations out of twentieth-century social theory in order to establish itself as an independent approach in social studies, and not just a part of the 'litany of class, race, and gender' (Scott 1986, p. 1055). In the near future, we will perhaps see more theoretical efforts, and empirical historical studies, going in that direction, not just in gender history, but also in the history of ethnicity.

4.2 From Classes to Life-Styles, 'Milieus,' and Radical Individualism

A completely different line of thought, which also calls traditional concepts of stratification and class into question, has emerged in recent sociological work on contemporary western societies in their 'postindustrial' stage. As industrial work, and the labor and class relations so intimately connected with it, loses its central status for the definition of modern societies,

these societies may no longer be adequately described as stratified class societies. The large, socially coherent and even politically self-conscious groups such as the 'working-class' are considered to be rapidly dissolving, without new, equally coherent group structures building up. Instead, social relations in modern society may be described as based on radical individualization, and a similarity of social status at best finds expression in rather diffuse social 'milieus' (see Beck 1986, Hradil 1987). Western societies, in this perspective, are not becoming completely leveled societies with citizens of equal material resources, but the absence of material wants, and a re-definition of the value system towards post-material orientations, dramatically diminish the relevance of occupational situation, income, and even class-specific consumption patterns.

As 'social inequality' (in the form of social strata and classes) was the defining element of nineteenth and early twentieth century societies, these authors hold, categories like 'risk' or 'information' are defining societies on the verge of the twenty-first century. Although not yet widely received in social history, these new developments in theoretical and empirical sociology will probably have a considerable impact on historical views on inequality and social structure in the future. They offer important insights into the now rapidly expanding field of twentieth century social history, but it may also be asked whether societies before the industrial age can be interpreted beyond the classical thought system of social estate, class, and stratification.

4.3 Constructing Class, Constructing Inequality: From Economic Realism to Cultural Relativism

With the class structure of industrial societies appearing more as an historical exception rather than historical normalcy, and with the interest in the socio-economic foundations of inequality and class diminishing, historians have become more sensitive to the relativist or constructivist character of social structure in general and of 'class' in particular. Especially in British social history, questions have been asked about the 'language of class,' that is, about the use of concepts such as class by the historical actors themselves, who were trying to express collective self-identities by communicating new notions of social bonding. With regard to the working classes, the main thrust of this research was on political organization and political action (e.g., in English Chartism), and the objective nature of class was hardly fundamentally doubted (see Stedman Jones 1983).

Especially in the 1990s, however, and with empirical interest somewhat shifting to the middle classes, the language approach was radicalized under the double influence of cultural and linguistic theory on the one hand, and of 'radical constructivism' in epistemology and the sociology of knowledge on the other hand. Stratification and class were now analysed as 'imaginary' realms of communication and culture; they figured as notions that expressed 'visions' of the social order as perceived by the contemporaries, rather than realities of economic and power structure as described by social scientists and historians (see Corfield 1991, Joyce 1991, Nolte 2000, Wahrman 1995). Some of these approaches fundamentally undermine any 'realistic' concept of social inequality and class, and therefore sound like a triumphant signal for the final abandonment of any social scientific or historical study in stratification and class structures. Yet at the same time it can be argued that the language-oriented and constructivist approaches have introduced important expansions to the more traditional methods of social history. They have provided bridges between social and intellectual history and have induced historians to a more careful usage of language and concepts. Also, ironically, in devoting so much energy to the problem of class in historical language and self-consciousness, this work has also underscored the importance of inequality and class in past societies.

5. Conclusion

After a long period of undisputed reign as a kind of master concept in the study of present and past social structures, theories of stratification and class are now undergoing a period of substantial challenge and criticism, redefinition, and even rejection. The question may thus arise whether theoretical and empirical interest in social inequality will persist in the future, especially in the discipline of history, which is now characterized by a very pronounced shift away from problems of socio-economic structure in favor of a history of culture, symbolism, and subjectivity.

It is almost certain that inequality, stratification, and class, will lose (and already have lost) some of their original relevance as defining ground for social history as such, when compared with the 1950s to 1970s boom of those topics in the social sciences. In addition, the emerging intercultural debates on the history of non-Western societies may prove that concepts such as 'class' and 'social strata,' which are obviously deeply rooted in the Western tradition of thought and culture since classical antiquity, are not suitable instruments for analyzing Indian, or Central African, societies, be it past or present. As 'post-colonial theories' in the social and cultural sciences describe the 'hybrid' character of such societies, the hybridity of class and competing principles of social relations may also be a distinctive mark of their inequality structures.

On the other hand, three points may be made which serve as a reminder for the continuing importance, not only of the general notion of social inequality, but also of more specific concepts like stratification and class. First, social inequality—whatever it is grounded on, and in whatever way it is communicated—is an anthropological feature of all human civilization, not

only in the West. Second, inequality has often taken the form of a hierarchical order, or 'stratification,' of distinct groups according to their access to power, their rights, and material well-being. Moreover, the hierarchical mode of social differentiation is a widespread mark of the less advanced, less technologically and culturally complex societies in which historians are often especially interested. Third, it is hard not to acknowledge the success, and the astonishing flexibility, of the concept of 'class' for describing systems of inequality. As new and intellectually promising approaches have been developed since around 1980 that link 'culture' with 'class,' and as these approaches are now applied in empirical research, there can be little doubt about the fact that the history of inequality, stratification, and class will retain a prominent place in the field of social and cultural history.

Social Influence, Psychology of

Social influence refers to the ways people alter the attitudes or behavior of others. Typically social influence results from a specific action, command, or request, but people also alter their attitudes and behaviors in response to what they perceive others might do or think. Social psychologists often divide social influence phenomena into three categories—conformity, compliance, and obedience—although the distinction between the categories is often difficult to discern. *Conformity* generally refers to changes in opinion or behavior to match the perceived group norm. These changes are voluntary, although the individual may not always be aware that he or she is conforming. *Compliance* refers to changes in behavior that are elicited by a direct request. These requests

usually call upon the individual to buy a product, do a favor, or donate money or services. *Obedience* refers to responses to direct commands or demands from an authority figure. Although individuals are not physically coerced into these responses, they often feel as if they have little choice but to obey the command.

1. *Conformity*

People exhibit conformity when they change their attitudes or behavior to resemble what they believe most people like them would think or do. Everyday examples of conformity include selecting clothes to match what other people are wearing and recycling newspapers because it appears that most people support recycling. Psychologists have identified two primary motives to explain conformity behavior—*informational influence* and *normative influence* (Deutsch and Gerard 1955). When informational influence is operating, individuals conform because they want to be accurate. People agree with the perceived norm because they lack confidence in their own judgment and assume that the typical judgment is correct. When conformity reflects normative influence, the individual's primary concern is to gain social approval and to avoid the consequences of appearing deviant. People go along with the perceived norm because they hope their conformity will lead to acceptance from the group or because they hope to avoid the criticism, ridicule, and possible rejection that may follow a failure to conform. In practice, informational influence and normative influence often operate hand in hand. For example, a conforming individual may hope to gain acceptance from a group and may also believe that the majority of group members are correct in their judgment.

The first demonstration of information influence in a conformity study was reported by Muzafir Sherif (1936). This classic investigation placed male participants in a totally darkened room. Periodically a small dot of light appeared on a wall approximately 15 feet away, and the participants' task was to report how much, if any, they saw the light move. In fact, the light did not move. Sherif took advantage of a perceptual illusion known as the *autokinetic effect*—the tendency to see a stationary point of light move in a dark environment. When three participants sat together and reported their perceived movement aloud, Sherif found that over time the estimates each participant gave tended to resemble those of the others in the room. In other words, each group established its own norm for the amount of movement they perceived, and the group members tended to see an amount of movement close to that norm. These participants typically were unaware that they had been influenced by the group, and later investigations found participants continued to rely on the group norm even after the other individuals were no longer in the room.

A second set of early conformity studies demonstrated the power of normative influence. Solomon Asch (1951) asked participants to engage in a simple line judgment task. In the standard procedure, several individuals at a time were presented with a picture of a 'standard' line accompanied by three comparison lines. The task was to identify which of the comparison lines was the same length as the standard line. The individuals gave their responses aloud for the experimenter to record. Because the length of the lines differed by noticeable amounts, the task was an easy one. However, only one of the individuals in the study was a real participant. The others were confederates who, beginning with the third line judgment task, began to give wrong answers (before the real participant's turn to respond). On 12 of the remaining 16 trails, the real participant heard each of the others select a comparison line that clearly was incorrect. The question was whether the participants would give what they knew to be the correct answer, or if they would go along with the response given by the group.Typically, participants went along with what their senses told them. However, on 37 percent of the trials the participants conformed to the norm and gave the same response as the rest of the group. Moreover, approximately three-quarters of the participants went along with the majority at least once.

Most of the conforming participants in Asch's studies were motivated by normative influence. That is, these individuals were concerned about how they would look in the eyes of the other participants if they were to express their true judgments. When participants in one study were allowed to give their responses in private, the rate of conformity dropped dramatically (Asch 1956). However, at least some informational influence also appeared to be operating in the Asch studies. That is, some people came to believe that the shared perception of the group must be more accurate than their own visual perception.

1.1 *Variables Affecting Conformity*

Although numerous replications of Asch's findings provide persuasive evidence for the power of conformity, not all people conform to the same degree in the same situation. For example, cultural variables have been found to play a role in the conformity process. Bond and Smith (1996) reviewed 133 studies using the Asch procedure conducted in 17 countries. They found participants from collectivist cultures (see *Cultural Psychology*) were more likely to conform to the group norm than people from individualistic cultures. These investigators also found a trend toward less conformity since the 1950s in studies with US participants. Thus, changes in societal standards, such as the value placed on independence and autonomy, may affect the extent to which members of a given culture conform. Age also appears to play a role in this

process. Consistent with conventional wisdom, researchers find that young adolescents are particularly prone to conforming with the behavior of peers. Finally, several investigations find that personality plays a role in conformity. People who have a high need to feel in control are less likely to conform, whereas those who are highly concerned with the impression they make on others are more likely to go along with the perceived norm.

Psychologists have not always agreed on the extent to which gender influences conformity behavior (Cooper 1979, Eagly and Chravala 1986). Although some disagreement remains about the size of the effect, it does appear that women are more likely to conform than men. Moreover, this tendency to conform seems to be especially likely in face-to-face situations like the Asch procedure. Explanations for this difference include men's need to appear independent and women's tendency to promote smooth social interactions.

Finally, the number of other people in the situation affects conformity behavior. Asch (1956) varied the number of confederates in his procedure, creating conditions with one to fifteen confederates. He found that conformity increased noticeably as the number of confederates grew, but that this effect leveled off after three or four. In other words, five or fifteen confederates giving an incorrect response to the line judgment task generated no more tendency to conform to the norm than four confederates. Other researchers have developed elaborate models to account for the effects of crowd size on conformity (Latane 1981, Tanford and Penrod 1984). These models consider such variables as characteristics of the individuals in the group and physical proximity of the group members.

1.2 Perceived Norms

The impact of norms is not limited to situations like the Asch paradigm, in which people observe the behavior of others and face immediate social consequences. Rather, many daily decisions are influenced by what individuals believe to be the normative behavior for a given situation. Whether people give money to a charitable cause, yield the right of way to pedestrians, or take an extra copy of the paper from a newspaper box depends to some degree on what they perceive to be the normative behavior in that situation.

Researchers have identified two kinds of perceived norms (Cialdini et al. 1991). *Injunctive norms* refer to correct behavior, that is, what society says one should do in the situation. Injunctive norms tell people they should give to charitable causes and that they should not take a newspaper they have not paid for. *Descriptive norms* refer to what most people actually would do in the situation. Although people typically do not have adequate data to make an accurate assessment of what most people would do, they commonly rely on whatever information they have to estimate the descriptive norm, however incorrect they may be.

Injunctive and descriptive norms often are very similar and lead us to the same decision about our behavior. However, psychologists also point to some notable exceptions. For example, a widely accepted injunctive norm states that people should not litter in public settings. But a parking garage filled with bits of litter suggests to passersby that the descriptive norm—what people actually do—is quite different. Whether people respond to the injunctive or descriptive norm in this situation may depend on which of these two is brought to their awareness. Researchers in one set of studies placed useless flyers on windshields in a parking garage (Reno et al. 1993). When the drivers' attention was drawn to the litter that others had apparently tossed to the ground (descriptive norm), they tended to also drop the flyer on the ground. When these drivers were made aware of the injunctive norm, such as when they saw another person pick up a piece of litter to keep the environment clean, most decided against littering.

2. Compliance

People demonstrate compliance when they agree to an explicit request, such as a request to buy a product or to volunteer their time. Much of the research on compliance has examined the effectiveness of sequential-request procedures. By presenting participants with certain kinds of request in specific sequences, investigators have identified many of the psychological processes that lead people to accept or refuse a request. Four of these procedures are described here.

The most widely researched of the sequential-requests procedures is the *foot-in-the-door* technique (Freedman and Fraser 1966). The procedure begins with a small request that virtually everyone agrees to. At some later point, the same requester or a different individual returns and presents a larger request. This second request is known as the target request, because getting participants to agree with the larger request is the real purpose of the procedure. If the foot-in-the-door manipulation is successful, participants will comply with the target request at a higher rate than if they had been presented only with the target request.

Numerous investigations demonstrate that the foot-in-the-door procedure can increase compliance to the request. However, reviews of this literature find that many studies fail to produce the effect and that the overall size of the effect is not large (Burger 1999). Part of the problem with this research is that investigators have used a variety of procedures to create a foot-in-

the-door manipulation, some of which are not effective. For example, the foot-in-the-door procedure is more likely to increase compliance when participants are allowed to perform the initial request, when the initial request requires more than a minimal amount of effort, and when the second request appears to be a continuation of the initial request (Burger 1999).

Researchers disagree on the psychological processes underlying the foot-in-the-door phenomenon. The most widely cited interpretation for the effect is the self-perception explanation. According to this account, agreeing with the initial request causes people to alter the way they think about themselves. When later presented with the target request, these individuals are said to use their compliance to the small request as an indicator of their attitude toward such causes or toward participating in these kinds of activities. Because they agreed to the small request, they are more likely than control participants to agree to the target request.

Another common sequential-request procedure begins with an initial request so large that most people refuse. These individuals then are presented immediately with a smaller (target) request. If this *door-in-the-face* technique is successful, participants will agree to the target request more often than if they had not first rejected the large request (Cialdini et al. 1975). For example, participants in one study were asked to volunteer for a two-year placement working as a youth counselor. After they refused, experimenters asked participants if they would chaperone some children on a two-hour trip to the zoo. These participants agreed at a higher rate than those asked only the target request (Cialdini et al. 1975).

The door-in-the-face procedure is said to be effective because the requester takes advantage of a widely practiced social rule called the *reciprocity norm*. The reciprocity norm governs many social exchanges and requires that people return favors and acts of kindness (Gouldner 1960). Most people feel a strong sense of obligation to someone who has done them a favor, even when that favor was not requested. Moreover, studies find that people often give back more than they received in order to relieve themselves of their obligation. When applied to the door-in-the-face situation, the requester 'gives' the individual what appears to be a concession. That is, the requester seems to give up something he or she wants, and the individual reciprocates by giving something to the requester, i.e., the target request.

Another sequential-request procedure begins when the participant agrees to a request at a given price. Requesters using the *low-ball* procedure then raise the cost of the request slightly. The procedure leads to more compliance at the higher price than when the price is presented at the outset (Cialdini et al. 1978). For example, undergraduates in one study agreed to participate in a psychology experiment. The students then were informed that the experiment was to be held at 7.00 a.m., thus making participation more costly than they probably had imagined. Nonetheless, these students showed up for the early morning experiment more often than those told about the time of the experiment at the beginning (Cialdini et al. 1978). The effectiveness of the low-ball procedure is said to result from a sense of commitment that develops when the individual agrees to the initial request. The individuals feel committed to perform the agreed-upon behavior, or at least to do something for the requester (Burger and Petty 1981). This sense of commitment causes people to continue to agree to the request even at the higher price.

In contrast to the small-to-large price progression used in the low-ball technique, the *that's-not-all* procedure uses a large-to-small price progression. Requesters using this procedure present the request at a given price, then improve the deal before the individual can respond (Burger 1986). For example, participants in one study were told the price of a cupcake was one dollar. Before participants could respond, the salesperson said the price really was 75 cents. The participants in this condition were more likely to buy the cupcake than those told at the outset that the price was 75 cents (Burger 1986). The that's-not-all procedure is said to work in part because, as in the door-in-the-face procedure, the requester appears to be making a concession. The procedure also is effective because it appears to alter the 'anchor point' the individual uses to decide if the final price is a good or fair one. That is, participants are said to use the initial price as a reference point when deciding whether to agree with the final price. Because the final price is lower, participants are more likely to see it as reasonable than when they are presented only with the lower price.

3. *Obedience*

Obedience refers to an individual's response to a command from an authority figure. Implicit in this description is the notion that the recipient of the command is reluctant to engage in the behavior and probably would not unless give direct orders to do so. Consequently, psychologists' ability to conduct controlled laboratory studies of obedience has been limited by concerns for the welfare of participants who are torn between obeying commands and following their conscience. As a result of heightened concerns for the ethical treatment of human participants in recent years, most of the insights psychologist have about the obedience process come from a series of demonstrations conducted in the 1960s by Stanley Milgram (1974).

The basic procedure in Milgram's studies used one real participant, one confederate posing as a participant, and an experimenter. The study was described to participants as a learning experiment designed to

test the effects of punishment. The participant's task was to teach a list of word associations to the confederate by punishing the confederate for incorrect answers. The method of punishment was electric shock, with the participant instructed to give increasingly severe shocks to the confederate for each wrong answer. The participant's dilemma occurred when the confederate complained about the shocks and demanded to be released from the shock apparatus. In most versions of the procedure the participant could hear the confederate screaming in pain through the wall that separated them. Although it was apparent that the confederate was suffering and was probably receiving dangerous levels of electric shock, the experimenter commanded the participant to continue giving shocks. The procedure continued until the participant refused to go on, or until the participant pressed the highest button on the apparatus (labeled 450 volt) three times, for a total of 33 shocks.

The results of the study were unexpected. Prior to conducting the investigation, Milgram asked students, middle-class adults, and psychiatrists to predict the results. Everyone agreed that the typical participant would stop very early in the shock sequence and that virtually no one would continue to the 450 volt level. However, in the basic procedure Milgram found that 65 percent of the participants continued to follow the experimenter's commands all the way to the end.

Milgram (1974) conducted a series of variations on the basic procedure in an effort to explain the participants' high level of obedience. He found that proximity of the participant and confederate appeared to play a role. Obedience dropped to 40 percent when the participant was in the same room as the confederate, and dropped to 30 percent when the participant was required to touch the confederate to administer the shock. Although the original studies were conducted with male participants, a similar pattern was found when Milgram used women as participants. The level of obedience did not diminish when the experimenter gave his commands in a meek manner, but dropped to 20 percent when the commands were given by another confederate posing as a participant. Milgram concluded from this last finding that obedience does not depend on the authority figure's personality or charismatic style, but rather that obedience requires only that the individual be recognized as a legitimate authority.

Most social psychologists point to Milgram's research as an example of the often-unrecognized power of the situation to influence behavior. Although personality characteristics of the participants can affect whether they obey or refuse the command (Blass 1991), the discrepancy between people's predictions and the actual outcome of the Milgram studies suggests that the situation had a greater influence than most people recognize. Other psychologists point out that Milgram's procedure also took advantage of conformity and compliance processes. For example, by moving from small to progressively larger shocks, Milgram placed participants in a situation similar to that used in foot-in-the-door demonstrations. Milgram also found a drop in obedience when participants had information about descriptive norms. When participants saw two other participants (actually confederates) refuse the command, only 10 percent obeyed the experimenter's commands to the end.

4. Future Directions

Although researchers have identified many social influence phenomena, questions remain about the psychological processes underlying some of these behaviors. Future research is likely to examine these processes, with particular attention to the way multiple processes combine to produce conformity and compliance. Investigators also may focus on variables affecting social influence. In particular, cultural differences in conformity and compliance behavior are likely to be explored. However, future research on obedience probably will be limited by concerns for the ethical treatment of human participants. For many years now, these concerns have prevented researchers from replicating the procedures used by Milgram in his obedience studies. The challenge for investigators is to develop procedures that create a realistic obedience situation without exposing participants to excessive emotional stress.

Social Insurance: Legal Aspects

1. Social Insurance and Private Insurance

The notion of insurance is widespread and clear: insurance is a way of providing for the consequences of negative future events (risks or contingencies) in a collective manner with a special technique of financing. The distinction between private and social insurance is less clear: social insurance is organized by public authorities through legislation, and is usually compulsory, while private insurance is usually voluntary. Social insurance seeks to provide coverage against the consequences of risks like sickness, industrial accident, invalidity, old age, and unemployment for a large part of the population of a nation. To attain these goals, a compulsory form of insurance is considered a necessity. Bismarck's social insurance in Germany is in some ways the prototype of social insurance. However, his social insurance covered only workers rather than the general population (Koehler and Zacher 1982).

The difference between social and private insurance can be found in the goals, the techniques of protection, the legal form of the insurance bodies as private or public organizations, and the way of financing the benefits. But there is no clear distinction between them. Sometimes, the goals of social insurance are attained by compulsory private insurance and, in some countries, the bodies responsible for social insurance are private bodies.

One of the main distinctions between social and private insurance concerns the ways in which risk is calculated and financed. In the field of private insurance, the basis of calculation of the premiums is the risk. In the field of social insurance, the risk is less important, and social aims (such as health and welfare) prevail against the economic criterions.

Private insurance, moreover, distributes the burden of an individual risk across a group. Social insurance has the same effects, but it also effects income redistribution between those who are healthy and sick, richer and poorer, younger and older people, or households without and with family members.

2. Two Characteristic Items of Social Insurance: Financing and Organization

Thus, two characteristic items of social insurance remain, which allow us to distinguish between social insurance and other techniques of social protection. Those interlinked items are the ways of financing social insurance and the organization of social insurance.

2.1 Financing

Social insurance benefits were originally financed by contributions levied on earnings and divided between employee and employer, thus expressing the shared responsibility between employer and employee with regard to work-related social risks. State subsidies completed the financing. However, this scheme changed over time. Some countries introduced increasing state subsidies, while others changed the proportion of the contributions burden payable by employer and employee. In Germany, for example, the employees had to relinquish a public holiday to compensate employers for the new financial burden created by the introduction of long-term care insurance. Currently, there are ongoing discussions about changing the financial basis from the earnings of employees to the surplus value of enterprises.

2.2 Organization

Originally, social insurance bodies were special bodies that were not directly integrated in the administrative organization of a state. Sometimes, they are co-

administered by representatives of employers and employees. This kind of self-government is more prevalent in countries where social insurance bodies are private organizations. In countries with special public authorities for social insurance, but without self-governing or autonomous elements of administration, the ideal image of social insurance is left behind.

3. Social Insurance and Social Security

The concept of social insurance should not be confused with the concept of social security (cf. UN Declaration of Human Rights, art. 22), which is an international goal of social policy. Social insurance is considered a special, nevertheless widespread technique of social protection. It combines the scope and character of a compulsory insurance on the one hand, and the financing of the benefits by obligatory contributions on the other.

From the perspective of international law, social insurance does not entail special legal problems. Nevertheless, international law scholars have taken a special interest in social insurance as a mechanism of social protection. Thus, many international treaties and other international or regional instruments, especially involving Europe, address social insurance.

In the field of social security, international law has two main dimensions: (1) coordinating different national social security schemes to guarantee freedom of movement, and (2) defining social standards and aims (e.g., minimum standards, standards to attain, principles).

The coordination task was originally primarily due to the migration of workers, while the standard defining task began with the treaty of Versailles, which can be considered the basis of the development of an international social policy (Zacher 1976).

4. Fulfillment of International Requirements (International Standards of Social Insurance)

Two kinds of requirements prevail internationally: attainment of minimum standards and achievement of higher levels than a given minimum.

4.1 Minimum Standards

The best known and most basic international instrument to set minimum standards of social security is Convention 102 of the International Labor Organization (ILO) (1952). This convention, ratified by 40 states, contains minimum standards regarding medical care and benefits in the case of sickness, unemployment, old age, employment injury, maternity, invalidity, and for survivors. This convention applies to insurance schemes as well as other schemes of protection.

4.2 Higher Levels of Social Standards

The European Social Charter (1961) of the Council of Europe, a regional instrument for the European countries, serves as a social standard instrument for the European Union nations. It is now ratified by 24 states. In the frame of the Council of Europe, other social security conventions (e.g., Code of Social Security) also aim at higher social standards.

5. Social Insurance Benefits

5.1 Range of Benefits

The range of risks covered by social insurance schemes, labeled as 'traditional' social risks or contingencies, is described in ILO Convention 102 on minimal standards of social security (see Sect. 4.1) (von Maydell and Hohnerlein 1994). As new social risks develop, it is not clear whether protection will be provided by social insurance schemes or by other means (van Langendonck 1997, Pieters 1998).

Social insurance bodies do not provide benefits unique to social insurance. Other bodies of social protection and even private insurance bodies provide comparable or identical benefits. However, there are typical links between social insurance and the benefit provided, especially for those cash benefits designed to replace former earnings, e.g., sickness benefits or old-age pensions. As the insured person pays contributions based on his/her earnings (usually a certain percentage of the income), the benefit replacing the earnings is calculated as a function of the former earnings and is not provided as a flat-rate sum.

Whereas private insurance is almost always paid in cash, social insurance benefits can be either benefits in kind or in cash.

5.2 Guarantee of Benefits

In some countries, entitlement and even qualifying periods for social insurance entitlement are protected by the constitution. In the German constitutional doctrine, contributions to the old-age pension scheme are protected by the constitution as property. The new Ukrainian Constitution gives another kind of guarantee which may apply to social insurance benefits: it requires that the content and scope of existing rights and freedoms shall not be diminished in the adoption of new laws or in the amendment of laws that are in force.

5.3 Public/Private Mix of Benefits

Initially, social insurance benefits were the only way of providing a subsistence base in the case of risk occurrence. Nowadays, social insurance benefits are increasingly complemented by other means of protection. Mainly in the field of old-age pensions, the interplay of public, occupational, and private protection increasingly serves as a current mode of protection (International Bank for Reconstruction and Development 1994).

6. Future Developments in the Field of Social Insurance

To reach the goals of social security the technique of social insurance was one of the most important tools in the evolution of the welfare states. Social insurance, in the sense of Bismarck's social insurance, has undergone major changes. The initial role of social insurance, the social protection of workers, has lost its importance as the personal scope of social insurance has widened. Other forms of social protection, especially state-financed social programs for families, unemployed people, or for persons in need are increasingly prevalent.

Today, there is no unique mode of using social insurance to address social problems. Social insurance schemes rely mainly on financing by contributions and are thus, as regards their financing basis, dependent on the evolution of earnings. This reliance is considered a critical factor in the future financial stability of social insurance schemes and is broadly under discussion (Pieters 1999b).

Social Integration, Social Networks, and Health

Since the mid-1970s there have been dozens of articles, and now books, on issues related to social networks and social support. It is now recognized widely that social relationships and affiliation have powerful effects on physical and mental health for a number of reasons (House et al. 1988, Berkman and Glass 2000, Cohen et al. 2000).

When investigators write about the impact of social relationships on health, many terms are used loosely and interchangeably, including social networks, social support, social ties, and social integration. The aim of this article is to discuss: (a) theoretical orientations from diverse disciplines which are fundamental to advancing research in this area; (b) findings related to mortality; (c) a set of definitions of networks and aspects of networks and support; and (d) an overarching model which integrates multilevel phenomena.

1. Theoretical Orientations

There are several sets of theories that form the bedrock for the empirical investigation of social relationships and their influence on health. The earliest theories

came from sociologists such as Emile Durkheim, as well as from psychoanalysts such as John Bowlby, who first formulated attachment theory. A major wave of conceptual development also came from anthropologists including Bott and Mitchell, as well as quantitative sociologists such as Burt, Laumann, and Wellman who, along with others, have developed social network analysis. This eclectic mix of theoretical approaches coupled with the contributions of epidemiologists form the foundation of research on social ties and health.

Durkheim's contribution to the study of the relationship between society and health is immeasurable. Perhaps most important is the contribution he has made to the understanding of how social integration and cohesion influence suicide (Durkheim 1897). Durkheim's primary aim was to explain how individual pathology was a function of social dynamics. In light of recent attention to 'upstream' determinants of health, Durkheim's work re-emerges with great relevance today.

Bowlby (1969), one of the most important psychiatrists of the twentieth century, proposed theories suggesting that the environment, especially in early childhood, played a critical role in the genesis of neurosis. Bowlby proposed that there is a universal human need to form close affectional bonds. Attachment theory, proposed by Bowlby, contends that the attached figure creates a secure base from which an infant or toddler can explore and venture forth. The strength of Bowlby's theory lies in its articulation of an individual's need for secure attachment for its own sake, for the love and reliability it provides, and for its own 'safe haven.' Primary attachment promotes a sense of security and self-esteem that ultimately provides the basis on which the individual will form lasting, secure and loving relationships in adult life.

1.1 Social Network Theory: A New Way of Looking at Social Structure and Community

During the mid-1950s, a number of British anthropologists found it increasingly difficult to understand the behavior of either individuals or groups on the basis of traditional categories such as kin groups, tribes, or villages. Bott (1957) and Mitchell (1969) developed the concept of 'social networks' to analyze ties that cut across traditional kinship, residential, and class groups to explain behaviors they observed such as access to jobs, political activity, or marital roles. The development of social network models provided a way to view the structural properties of relationships among people.

Network analysis 'focuses on the characteristic patterns of ties between actors in a social system rather than on characteristics of the individual actors themselves and use these descriptions to study how these social structures constrain network members' behavior' (Hall and Wellman 1985, p. 26). Network analysis focuses on the structure and composition of the network, and the contents or specific resources that flow through those networks. The strength of social network theory rests on the testable assumption that the social structure of the network itself is largely responsible for determining individual behavior and attitudes, by shaping the flow of resources which determine access to opportunities and constraints on behavior.

2. Health, Social Networks, and Integration

From the mid-1970s through the present, there has been a series of studies showing consistently that the lack of social ties or social networks predicted mortality from almost every cause of death. These studies have been done in the USA, Europe, and Asia and most often captured numbers of close friends and relatives, marital status, and affiliation or membership in religious and voluntary associations. These measures were conceptualized in any number of ways as assessments of social networks or ties, social connectedness, integration, activity, or embeddedness. Whatever they were named, they defined embeddedness or integration uniformly as involvement with ties spanning the range from intimate to extended.

In the first of these studies, from Alameda County (Berkman and Syme 1979), men and women who lacked ties to others (in this case, based on an index assessing contacts with friends and relatives, marital status, and church and group membership) were 1.9 to 3.1 times more likely to die in a 9-year follow-up period than those who had many more contacts.

Another study in Tecumseh, Michigan (House et al. 1982) shows a similar strength of positive association for men, but not for women, between social connectedness/social participation and mortality risk over a 10–12 year period. An additional strength of this study was the ability to control for some biomedical predictors assessed from physical examination (e.g., cholesterol, blood pressure, and respiratory function).

Similar results from several more studies have been reported, one from a study in the United States and three from Scandinavia. Using data from Evans County, Georgia, Schoenbach et al. (1986) found risks to be significant in older white men and women even when controlling for biomedical and sociodemographic risk factors, although some racial and gender differences were observed. In Sweden, two studies (Welin et al. 1985, Orth-Gomer and Johnson 1987) report significantly increased risks among socially isolated adults. Finally, in a study of 13,301 men and women in Eastern Finland, Kaplan et al. (1988) have shown that an index of social connections predicts

mortality risk for men but not for women, independent of standard cardiovascular risk factors.

Studies of older men and women confirm the continued importance of these relationships into late life (Seeman et al. 1993a). Furthermore, two studies of large cohorts of men and women in a large Health Maintenance Organization (HMO) (Vogt et al. 1992), and 32,000 male health professionals (Kawachi et al. 1996) suggest that social networks are, in general, more strongly related to mortality than to the incidence or onset of disease.

Two studies, in Danish men (Pennix et al. 1997), and Japanese men and women (Sugiswa et al. 1994), further indicate that aspects of social isolation or social support are related to mortality. Virtually all of these studies find that people who are socially isolated or disconnected from others have between two and five times the risk of dying from all causes compared to those who maintain strong ties to friends, family, and community.

Social networks and support have been found to predict a very broad array of other health outcomes from survival post-myocardial infarction to disease progression, functioning and the onset and course of infectious diseases. The reader is referred to several lengthy reviews mentioned earlier for additional information.

3. *A Conceptual Model Linking Social Networks to Health*

Although the power of measures of networks or social integration to predict health outcomes is indisputable, the interpretation of what the measures actually assess has been open to much debate. Hall and Wellman (1985) have commented appropriately that much of the work in social epidemiology has used the term social networks metaphorically, since rarely have investigators conformed to more standard assessments used in network analysis, according to calls to develop a second generation of network measures (Berkman 1986, House et al. 1988).

A second wave of research developed in reaction to this early work, and as an outgrowth of work in health psychology, that turned the orientation of the field in several ways (House and Kahn 1985, Sarason et al. 1990). These social scientists focused on the qualitative aspects of social relations (i.e., their provision of social support or, conversely, detrimental aspects of relationships) rather than on the elaboration of the structural aspects of social networks.

Most of these investigators follow an assumption that what is most important about networks is the support function they provide. While social support is among the primary pathways by which social networks may influence physical and mental health status, it is not the only critical pathway (Berkman and Glass 2000). Moreover, the exclusive study of more proximal pathways detracts from the need to focus on the social context and structural underpinnings that may have an important influence on the types and extent of social support provided.

In order to have a comprehensive framework in which to explain these phenomena, it is helpful to move 'upstream' and return to a more Durkheimian orientation to network structure and social context. It is critical to maintain a view of social networks as lodged within those larger social and cultural contexts which shape the structure of networks. In fact, some of the most interesting recent work in the field relates social affiliation to social status, and social and economic inequality (Kawachi et al. 1997).

Conceptually, social networks are embedded in a macrosocial environment in which large-scale social forces may influence network structure, which in turn influences a cascading causal process beginning with the macrosocial to psychobiological processes to impact health. Serious consideration of the larger macrosocial context in which networks form and are sustained has been lacking in all but a small number of studies, and is almost completely absent in studies of social network influences on health.

Networks may operate at the behavioral level through at least four primary pathways: (a) provision of social support, (b) social influence, (c) social engagement and attachment, and (d) access to resources and material goods. These psychosocial and behavioral processes may influence even more proximate pathways to health status, including: (a) direct physiological responses, (b) psychological states including self-esteem, self-efficacy, depression, (c) health-damaging behaviors such as tobacco consumption or high-risk sexual activity, and health promoting behavior such as appropriate health service utilization or exercise, and (d) exposure to infectious disease agents such as HIV, other sexually transmitted diseases (STDs), or tuberculosis. The four primary psychosocial or behavioral pathways by which networks may influence health will be reviewed briefly. The reader is referred to Berkman and Glass (2000) for a lengthier review.

3.1 *The Assessment of Social Networks*

Social networks might be defined as the web of social relationships that surround an individual and the characteristics of those ties. Burt (1982) has defined network models as describing 'the structure of one or more networks of relations within a system of actors.' Network characteristics cover:

(a) *range* or *size* (number of network members),

(b) *density* (the extent to which the members are connected to each other),

(c) *boundedness* (the degree to which they are defined on the basis of traditional structures such as kin, work, neighborhood), and

(d) *homogeneity* (the extent to which individuals are similar to each other in a network).

Related to network structure, characteristics of individual ties include:

(a) *frequency of contact*,

(b) *multiplexity* (the number of types of transactions or support flowing through ties),

(c) *duration* (the length of time an individual knows another), and

(d) *reciprocity* (the extent to which exchanges are reciprocal).

3.2 Downstream Social and Behavioral Pathways

3.2.1 Social Support. Moving downstream, discussion follows of the mediating pathways by which networks might influence health status. Most obviously the structure of network ties influences health via the provision of many kinds of support. This framework acknowledges immediately that not all ties are supportive, and that there is variation in the type, frequency, intensity, and extent of support provided. For example, some ties provide several types of support while other ties are specialized and provide only one type. Social support typically is divided into subtypes which include emotional, instrumental, appraisal, and informational support (House 1981). Emotional support is related to the amount of 'love and caring, sympathy and understanding and/or esteem or value available from others.' Emotional support is most often provided by a confidant or intimate other, although less intimate ties can provide such support under circumscribed conditions.

Instrumental support refers to help, aid, or assistance with tangible needs such as getting groceries, getting to appointments, phoning, cooking, cleaning, or paying bills. House identifies instrumental support as aid in kind, money, or labor. Appraisal support often defined as the third type of support, relates to help in decision-making, giving appropriate feedback, or help deciding which course of action to take. Informational support is related to the provision of advice or information in the service of particular needs. Emotional, appraisal, and informational support are often difficult to disaggregate and have various other definitions (e.g., self-esteem support).

Perhaps even deeper than support are the ways in which social relationships provide a basis for intimacy and attachment. Intimacy and attachment have meaning not only for relationships that we think of traditionally as intimate (e.g., between partners, parents, and children) but for more extended ties. For instance, when relationships are solid at a community level, individuals feel strong bonds and attachment to places (e.g., neighborhood) and organizations (e.g., voluntary and religious).

3.2.2 Social influence. Networks may influence health via several other pathways. One pathway that is often ignored is based on social influence. Shared norms around health behaviors (e.g., alcohol and cigarette consumption, healthcare utilization) might be powerful sources of social influence with direct consequences for the behaviors of network members, quite apart from the provision of social support taking place within the network concurrently. For instance, cigarette smoking by peers is among the best predictors of smoking for adolescents (Landrine et al. 1994). The social influence which extends from the network's values and norms constitutes an important and under-appreciated pathway through which networks impact health.

3.2.3 Social engagement. A third and more difficult to define pathway by which networks may influence health status is by promoting social participation and social engagement. Participation and engagement result from the enactment of potential ties in real life activity. Getting together with friends, attending social functions, participating in occupational or social roles, group recreation, and church attendance are all instances of social engagement. Thus, through opportunities for engagement, social networks define and reinforce meaningful social roles including parental, familial, occupational, and community roles, which in turn provide a sense of value, belonging, and attachment. Several recent studies suggest that social engagement is critical in maintaining cognitive ability (Bassuk et al. 1999) and reducing mortality (Glass et al. 1999).

In addition, network participation provides opportunities for companionship and sociability. Rook (1990) argues that these behaviors and attitudes are not the result of the provision of support *per se*, but are the consequence of participation in a meaningful social context in and of itself. One reason measures of social integration or 'connectedness' may be such powerful predictors of mortality over long periods of follow-up is that these ties give meaning to individuals' lives by virtue of enabling them to participate in it fully, to be obligated (in fact, often to be providers of support), and to feel attached to their community.

3.2.4 Person-to-person contact. Another behavioral pathway by which networks influence disease is by restricting or promoting exposure to infectious disease agents. In this regard, the methodological links between epidemiology and networks are striking. What is perhaps most remarkable is that the same network characteristics that can be health-promoting can at the same time be health-damaging if they serve as vectors for the spread of infectious disease.

The contribution of social network analysis to the modeling of disease transmission is the understanding that in many, if not most, cases, disease transmission is not spread randomly throughout a population. Social network analysis is well suited to the development of models in which exposure between individuals is not random but rather is based on geographic location, sociodemographic characteristics (age, race, gender), or other important characteristics of the individual such as socioeconomic position, occupation, or sexual orientation (Laumann et al. 1989). Furthermore, because social network analysis focuses on characteristics of the network rather than on characteristics of the individual, it is suited ideally to the study of diffusion of transmissible diseases through populations via bridging ties between networks, or uncovering characteristics of ego-centered networks that promote the spread of disease.

3.2.5 Access to material resources. Surprisingly little research has sought to examine differential access to material goods, resources, and services as a mechanism through which social networks might operate. This is unfortunate given the work of sociologists showing that social networks operate by regulating an individual's access to life-opportunities by virtue of the extent to which networks overlap each other. In this way networks operate to provide access or to restrict opportunities in much the same way that social status works. Perhaps the most important among the studies exploring this tie is Granovetter's classic study of the power of 'weak ties' that, on the one hand lack intimacy, but on the other facilitate the diffusion of influence and information, and provide opportunities for mobility (Granovetter 1973).

There are five mechanisms by which the structure of social networks might influence disease patterns. While social support is the mechanism most commonly invoked, social networks also influence health through additional behavioral mechanisms including (a) forces of social influence, (b) levels of social engagement and participation, (c) the regulation of contact with infectious disease, and (d) access to material goods and resources. To date, the evidence linking aspects of social relationships to health outcomes is strongest for general measures of social integration, social support, and social engagement. However, it should be noted that these mechanisms are not mutually exclusive. In fact, it is most likely that in many cases they operate simultaneously.

4. Conclusion

The aim in this review was to integrate some classical theoretical work in sociology, anthropology, and psychiatry with the current empirical research underway on social networks, social integration, and social support. Rather than review the vast amount of work on health outcomes which is the subject of several excellent recent papers, a conceptual framework that guides work in the future has been developed.

With the development of this framework, two issues of profound importance stand out. The first is the 'upstream' question of identifying those conditions that influence the development and structure of social networks. Such questions have been the substantive focus of much of social network research, especially in relationship to urbanization, social stratification, and culture change. Yet little of this work becomes integrated with health issues in a way that might guide us in the development of policies or intervention to improve the health of the public. Of particular interest would be more cross-cultural work comparing countries with different values regarding social relationships, community, or sense of obligation. The same might be true to specific areas within countries, or specific cultural or ethnic groups with clearly defined values.

The second major issue relates to the 'downstream' question. Many investigators have assumed that networks influence health via social support functions. The framework in this article makes clear that this is but one pathway linking networks to health outcomes. Furthermore, the work on conflicts and stress points out that not only are not all relationships positive in valence, but that some of the most powerful impacts on health that social relationships may have are through acts of abuse, violence, and trauma (Rook 1992). Fully elucidating these downstream experiences, and how they are linked to health via which biological mechanisms, remains a major challenge in the field.

L. F. Berkman

Social Intervention in Psychiatric Disorders

As early as the nineteenth century psychiatrists already suspected that harmful influences from the social environment might promote the appearance of mental illnesses or have a deleterious effect on their course. In that era, the isolation of the mentally ill in the 'healthful' milieu of institutions far removed from their original living environment was thought to be an appropriate means of shielding the patients from the disease-producing influences of their surroundings. The objective of psychiatric reforms since the mid to late 1950s was to resettle chronically mentally ill persons from large custodial institutions to community settings. The idea behind this was to (re-)integrate patients in their normal living environment as rapidly as possible, because it was thought that their natural social network would make a major supporting contribution to the healing process (Rössler 2001).

This reform has changed the perception of mental illness. Enabling disabled persons to live a normal life in the community caused a shift away from a focus on an illness model toward a model of functional disability (Grove 1994). As such, other outcome measures aside from clinical conditions became relevant. Since then social role functioning including social relationships, work, and leisure, as well as quality of life and the family burden, became of major interest for affected individuals living in the community as well as for the health professionals involved in treatment and care of those persons. Most of the social intervention

strategies as applied by health professionals in the community can be integrated within the concept of psychiatric rehabilitation (Rössler 2000).

In current scientific discourse, environmental and psychosocial factors are often relegated to the status of a single variable of merely peripheral interest, without further specification. Biological science has indeed made enormous progress toward an understanding of mental disorders, but it should not be forgotten that research in social sciences also yielded a considerable body of knowledge with respect to the psychosocial and environmental factors that influence it (Rössler 2001).

The relevance of psychosocial and environmental problems is also reflected in the DSM IV and ICD-10. Axis 4 of the DSM (American Psychiatric Association 1994) and codes Z 55–Z 65 and Z 73 of the ICD-10 (WHO 1993) are assigned for reporting psychosocial and environmental problems that may affect the diagnosis, treatment, and prognosis of mental disorders.

1. *Target Population of Social Interventions*

Although the majority of the chronically mentally ill have the diagnosis of schizophrenic disorders, other patient groups with psychotic and nonpsychotic disorders are targeted by social interventions. All patients suffering from severe mental illness (SMI) now require social interventions. The core group is drawn from patients with:

- persistent psychopathology,
- marked instability characterized by frequent relapses, and
- social maladaptation (Royal College of Psychiatrists 1996).

There are other definitions currently used to characterize the chronically mentally ill, but they all share some common elements, i.e. a diagnosis of mental illness, prolonged duration, and role incapacity.

Furthermore, up to 50 percent of persons with SMI carry dual diagnoses, especially in combination with substance abuse (Cuffel 1996). Young adult chronic patients constitute an additional category that is diagnostically more complicated (Schwartz et al. 1983). These patients present complex pictures of symptomatology difficult to categorize within our diagnostic and classification systems. Many of them also have a history of suicide attempts. All in all, they represent a patient population that is mostly difficult to treat.

2. *Models of Vulnerability*

There are several vulnerability–stress models forming the theoretical basis into which biological and social intervention approaches of psychiatric treatment, rehabilitation, and care can be integrated. These models were developed mainly for persons with schizophrenic disorders, but they apply essentially to all individuals with SMI.

In the *vulnerability–stress* model it is presumed that socioenvironmental stressors superimposed on an underlying and enduring biological vulnerability lead to abnormalities in central nervous system functioning (Zubin and Spring 1977). In the *vulnerability–stress–competence* model (Nuechterlein and Dawson 1984), individuals, families, and natural support systems can cope with stressors and have the competence to create a higher threshold for symptomatic illness. In an *interactive–developmental* model (Strauss et al. 1981), the persons affected do not remain in a passive role but actively interact with their environment. They modulate and select the kind of help they get from other people, they choose to comply with the treatment, and they seek or avoid social support and stressful situations.

The interactive–developmental model is the basis for the consumer movement in mental health care. People with mental disorders and their caregivers prefer to see themselves as consumers of mental health services with an active interest in learning about psychiatric disorders and in selecting the respective treatment approaches. Consumerism makes it possible to take up the affected person's perspective and to consider seriously courses of action relevant to them (Kopelowicz and Liberman 1995).

3. *Conceptual Framework of Social Interventions*

The overall philosophy of social interventions in psychiatric disorders comprises two intervention strategies: the first strategy is individual-centered and aims at developing the patient's skill in interacting with a stressful environment. There is no consensus among researchers as to what this individual-centered approach actually does accomplish. Some understand developing patient's skill as an approach to help disabled persons to compensate for impairments and to function optimally with the deficiencies they have. Others assume that different forms of individual-centered interventions help with recovery from the disorder itself, while the contributing factors to the healing process are not clear (Strauss 1986).

The second strategy is an ecological approach directed toward developing environmental resources to reduce potential stressors. This approach includes social interventions concerning housing and occupation as well as measures to build natural networks, as many chronically mentally ill and disabled persons lose close and stable relationships in the course of the disease. Most disabled persons need a combination of both approaches.

In contrast to acute treatment there are mostly no legal powers to enforce social interventions in long-term care. Thus, the sufferer's autonomy concerning treatment decisions should be respected. Within this

frame, therapeutic alliance plays a crucially important role in engaging the affected persons in their own care planning. As such, the therapist should acknowledge that disagreement about the illness between patient and therapist is not always the result of the illness process (Eichenberger and Rössler 2000).

4. *The International Classification of Impairments, Disabilities, and Handicaps*

The long-term consequences of major mental disorders targeted by social interventions might be described on different levels. A useful framework is provided by the international classification of impairment, disability, and handicaps (WHO 1980). In addition to acute symptoms, chronically mentally ill patients, in particular individuals with schizophrenia, have impairments in the most basic cognitive processes concerning information input, memory, and abstraction. These cognitive impairments are present even when all symptoms have subsided, and they seem to be enduring markers of a vulnerability to the illness. Persistent and severe impairments lead to disability, i.e., affected persons will be limited in performing certain roles in their social and occupational environment. Finally, handicaps occur when disabilities place the individual at a disadvantage relative to others in society.

On more specified levels concerning impairments, medication and cognitive training are provided. Effective pharmacotherapy and cognitive training stabilize affected persons so that they are more responsive to learning from their environment. Interventions concerning disability encompass mainly social skills training and family intervention. Furthermore, social interventions emphasize vocational training suitable to the extent of the handicap.

4.1 *Reduction of Impairments*

4.1.1 Medication. Even when taken regularly, medication is only able to reduce rather than abolish symptoms, and delay rather than prevent relapse. In addition to that, many of the traditional drugs have adverse effects and can weaken patients' ability to perform their social roles or can impair their social and vocational functioning. As such, it is not surprising that noncompliance with medication is one of the most serious problems in the long-term care of persons with SMI.

Several treatment strategies have been developed for improving compliance with medication. For patients with cognitive deficits, the complexity of the medication regimen should be reduced (Gaebel 1997). Some patients need to be given the medication by a professional service on a regular basis. Depot medication (i.e., intramuscular injections that release the medication slowly into the bloodstream) might be especially useful for patients with fluctuating motivation or insight. It is also useful to involve families and caregivers in increasing compliance with medication.

Yet, many patients living in the community have to take responsibility for their medication themselves. Training in self-management of medication (Eckman et al. 1990) emphasizes the patient's autonomy and increases acceptance of and responsibility for treatment. This also includes variation of medication without consultation within certain limits.

4.1.2 Cognitive training. With respect to cognitive deficits, consistent results emerged from most studies in so far as remediation of specific deficits through repeated practice or related techniques is successful. But it is not clear if and how recovered cognitive deficits should facilitate the remediation of functional outcome and community functioning. Addressing these limitations, Brenner et al. (1992) developed a comprehensive cognitive training program which they called 'integrated psychological therapy' (IPT). IPT comprises five stages: cognitive differentiation, social perception, communication skills, interpersonal problem solving, and social skills training. It is presented to groups of five to seven patients for 30 to 60 minutes two or three times a week. The hierarchically arranged program is aimed at facilitating acquisition and maintenance of more complex skills by remediating cognitive deficits. Findings indicate that IPT reduces psychotic disorganization and improves social, cognitive, and problem-solving skills (Penn and Mueser 1996).

4.2 *Remediation of Disabilities*

4.2.1 Skills training. In recent years, social skills training in psychiatric rehabilitation has become very popular and has been disseminated widely. The most prominent proponent of skills training is Robert Liberman, who has designed systematic and structured skills training since the mid-1970s. Liberman and his colleagues packaged the training in the form of modules which focus on different topics such as medication management, symptom management, substance abuse management, basic conversational skills, interpersonal problem solving, friendship and intimacy, recreation and leisure, workplace fundamentals, community (re-)entry, and family involvement. Each module is composed of skill areas. The symptom management module, for example, encompasses skills areas such as identifying warning signs of relapse, developing a relapse prevention plan, coping with persistent symptoms, and avoiding alcohol and drugs. The skills areas are taught in exercises with demonstration videos, role play and problem-solving exercises, and *in vivo* and homework assignments (Liberman 1988).

The results of several controlled studies suggest that disabled individuals can be taught a wide range of social skills. Social and community functioning improve when the trained skills are relevant for the affected person's daily life, and the environment perceives and reinforces the changed behavior. Unlike medication effects, benefits from skills training occur more slowly. Furthermore, long-term training has to be provided for positive effects (Penn and Mueser 1996).

4.2.2 Family intervention. As a consequence of deinstitutionalization, the burden of care has fallen increasingly on the relatives of the mentally ill. It is estimated that up to 65 percent of mentally disabled individuals live with their families (Goldmann et al. 1981). This is a task many families do not choose voluntarily. Additionally, not all families are equally capable of giving full support to their disabled member, and may not be willing to replace an insufficient health care system (Johnson 1990). But families also represent support systems which provide natural settings for context-dependent learning important for recovery of functioning (Schooler 1995). As such there has been a growing interest in helping families since the beginnings of care reforms (Strachan 1986).

One area of interest dealt with the expectations of relatives concerning the provision of care. Relatives quite often feel ignored, not taken seriously, and insufficiently informed by health professionals. They also may feel that their contribution to care is not appreciated, or that they will be blamed for the patient's problems. It is certainly not surprising that there is a lot of frustration and resentment among relatives related to the extent of the physical, financial, and emotional family burden. As important research has demonstrated a relationship between a negative affective family atmosphere and an unfavorable course of a mental disorder, the need for helping families and patients with family intervention programs became clear.

All family intervention programs include an educational aspect covering basic information on the etiology, treatment, and prognosis of schizophrenia. Although family interventions differ in the treatment focus, all family interventions are organized around the principal goal of providing family members with more information about the disorder and strategies for managing common problems. There are more common features: family interventions are concrete, practical, and focus on everyday coping.

Family intervention programs have produced the most promising results. Family intervention is effective for lowering relapse rate and improving outcome (e.g., social functioning). Possibly, family intervention can reduce family burden. Furthermore, the treatment gains are fairly stable.

However, it is not clear what the effective components of the different models are. Additionally, family interventions differ in frequency and length of treatment. There are also no criteria for the minimum amount of treatment necessary.

Finally, it should be noted that most of the familiy interventions were developed in the context of Western societies during deinstitutionalization. Family caregiving might be quite different in a different cultural context. This refers to other cultures in total as well as to minority groups in Western societies (Guarnaccia 1998).

4.2.3 Reduction of handicaps by vocational rehabilitation. The beneficial effects of work for mental health have been known for centuries (Harding et al. 1987). Vocational rehabilitation therefore has been a core element of psychiatric reforms since its beginnings.

Vocational rehabilitation is based on the assumption that work not only improves activity, social contacts, etc., but may also promote gains in related areas such as self-esteem and quality of life, as work and employment are a step away from dependency toward integration into society. Enhanced self-esteem in turn improves adherence to long-term care of individuals with impaired insight (McElroy 1987).

Vocational rehabilitation originated in psychiatric institutions, where the lack of activity and stimulation led to apathy and withdrawal among their inpatients. Long before the introduction of medication, occupational and work therapy contributed to sustainable improvements in long-stay inpatients. Today occupational and work therapy are no longer hospital-based, but represent the starting point for a wide variety of rehabilitative techniques teaching vocational skills (Royal College of Psychiatrists/College of Occupational Therapists 1992).

Vocational rehabilitation programs in the community provide a series of graded steps to promote job (re-)entry. For less disabled persons, brief and focused techniques are used to teach them how to find a job, fill out applications, and conduct employment interviews (Jacobs et al. 1988). In transitional employment a temporary work environment is provided to teach vocational skills that should enable the affected person to move on to competitive employment. But too often the gap between transitional and competitive employment is so large that the mentally disabled individuals remain in a temporary work environment. Sheltered workshops providing prevocational training also quite often prove to be a dead end for disabled persons.

Today, the most promising vocational rehabilitation model is supported employment. In this model, disabled persons are placed in competitive employment as soon as possible and receive all the support needed to maintain their position. Skills are taught in

the actual environment, tailored to the job and the individual. If necessary, additional advice is given to the employer. As the course of SMI is unpredictable and job requirements often change, the support provided is neither time-limited nor delivered on a fixed schedule (Wallace 1998). Participation in supported employment programs is followed by an increase in the ability to find and keep employment (Baronet and Gerber 1998). But most of the research does not allow evaluation of the impact of vocational rehabilitation programs on nonvocational domains.

Although findings regarding supported employment are encouraging, many critical issues remain unanswered. Most individuals in supported employment obtain unskilled part-time jobs. Therefore, the high drop-out rate (up to 40%) is not surprising. Since most studies only evaluated short (12–18 months) follow-up periods, the long-term impact remains unclear. At the time of writing, it is not known which individuals benefit from supported employment and which do not (Mueser et al. 1998).

It must be acknowledged that the integration into the labor market by no means depends only on the ability of the persons affected to fulfil a work role and on the provision of sophisticated vocational training and support techniques, but also on the willingness of society to integrate its most disabled members.

One result of the difficulties of integrating mentally disabled individuals into the common labor market has been the steady growth of cooperatives which operate commercially with disabled and nondisabled staff working together on equal terms and sharing in management. The mental health professionals work in the background providing support and expertise (Grove 1994). Cooperatives serve as a bridge between sheltered workshops and competitive jobs on the common labor market.

4.2.4 Developing environmental resources. Effective community psychiatry requires individualized and specialized treatment which has to be embedded in a comprehensive and coordinated system of community services. But even when a variety of services is available, they are poorly linked in many cases, and costly duplication may occur.

While developing community support systems it became obvious that there was a need to coordinate and integrate the services provided as each professional involved concentrates on different aspects of the same patient. Therefore, as a key coordinating and integrating mechanism, the concept of case management (CM) originated. CM focuses on all aspects of the physical and social environment. The core elements of CM are the assessment of patient needs, the development of comprehensive service plans for the patients, and arrangement of service delivery (Rössler et al. 1992).

Since the 1980s, a range of different models of CM have been developed which exceed the original idea that CM intends mainly to link the patient to needed services, and to coordinate those services. Today most clinical case managers also provide direct services in the patient's natural environment. This model is called intensive case management (ICM). ICM is difficult to distinguish from assertive community treatment (ACT).

The basic compounds of ACT were developed by Stein and Test in the 1970s (Stein and Test 1980). The original program was designed as a community-based alternative to hospital treatment for persons with severe mental illnesses. A comprehensive range of treatment, rehabilitation, and support services in the community is provided through a multidisciplinary team. ACT is characterized by an assertive outreach approach, i.e., interventions are provided mainly in the natural environment of the disabled individuals (Scott and Dixon 1995). Research on CM and ACT indicates that these models can reduce time in hospital, but have only small or moderate effects on improving symptomatology and social functioning (Mueser et al. 1998).

5. *Conclusions*

The goal of social intervention embedded in the broader concept of psychiatric rehabilitation is to help disabled individuals to establish the emotional, social, and intellectual skills needed to live, learn, and work in the community with the least amount of professional support (Anthony 1979). The refinement of all these approaches as described has achieved a level where they should be made readily available for every person with SMI.

But we have to be aware that it is a long way to translate research into practice. In 1992, the National Institute of Mental Health, for example, funded the 'schizophrenia patient outcome research team' (PORT) to develop and disseminate recommendations for the treatment of schizophrenia based on existing scientific evidence. The recommendations address in essence all interventions as presented above (Lehman and Steinwachs 1998). Lehman and colleagues assessed the patterns of usual care for schizophrenic patients and examined the conformance rate with the PORT treatment recommendations. The conformance rate was modest, generally below 50 percent. As such, it is obvious that current care practice has to be improved substantially in the light of the outcome research available (Lehman et al. 1995).

Serious mental illness can devastate the lives of people who suffer from it. These persons have a right to be treated according to current knowledge. But mental illnesses are associated with a significant amount of stigma, resulting in social isolation and discrimination in housing, education, and employ-

ment opportunities. Mentally ill people are even disadvantaged in receiving appropriate treatment and care, so stigma and discrimination further increase the burden on affected persons and their relatives. Yet, social interventions aim at reintegrating the mentally ill into the community and improving their quality of life. For these reasons a responsive and open-minded environment is indispensable. Therefore, translating research into practice always encompasses combating stigma and discrimination of mental illnesses as well (World Psychiatric Association 1999).

Social Justice

Social justice is a subcategory of the wider term justice and concerns justice as it refers to the distribution of valued goods and necessary burdens. Such distributions can take place at all levels of societal aggregation: at the micro level of face-to-face interaction, at the meso level of intermediate institutions and organizations, and at the macro level of a society's basic structure. The ways in which these various levels provide (or deny) access to social positions, in which they regulate the allocation of rights and duties as well as of scarce goods and necessary burdens, and in which they interact through an encompassing framework of institutionalized rules and procedures, form the subject of social justice.

1. *The Levels of Social Justice*

1.1 *The Macro Level*

The macro level is itself subdivided into several layers. The highest layer is that of the constitutional order of a society: its polity determining the (permitted) forms of government and the ground rules, as well as scope, of 'normal' politics; its economic regime, its social and legal systems, and the integration of its major institutions into one large scheme. The next lower layer is that of concrete politics. Here, different social groups compete for influence in the designation of particular policies concerning all aspects of social life which can become a matter of political and legal regulation under the chosen constitutional frame. And finally, there are the policies themselves, e.g., particular fiscal, economic, educational, welfare, etc. policies. The initial design of such policies can have far-reaching implications for future policies because once a particular policy structure or pattern is established in a given field, it tends to shape the public's expectations towards it and to lead to a certain degree of inertia, making radical changes difficult and limiting the options available to future policy makers. In many ways, these policies also affect what happens at the meso level.

1.2 *The Meso Level*

This is the level of organizations. When considering organizations from the point of view of social justice, it is useful to distinguish between types of organizations according to the societal sector or social subsystem into which they fall, e.g., business organizations belonging to the economic system, political parties belonging to the political system, hospitals belonging to the health system, schools belonging to the educational system, etc., because the various subsystems follow different logics of operation, subjecting their organizations to separate 'local' rationalities which in turn affect the ways in which these organizations (and their representatives) conceive of and deal with 'local' justice problems. Local justice problems concern the allocation of various in-kind (and mostly non- or not fully marketable) goods such as university places, jobs, public housing, and scarce medical resources; in short, the rules for inclusion into or exclusion from organizations and for the distribution of some of their main 'products' and services. The problems are typically dealt with and resolved by the respective organizations themselves. However, both the degree of local autonomy and of local scarcity are subject to the influence of macro level decisions. Thus, the state can mandate particular principles that must be observed in their handling (e.g., anti-discrimination laws) or it can refrain from doing so; it can issue rules for some such problems but not for all of them, and these rules can be more or less determinate. As for the degree of scarcity, on the other hand, the state's influence is particularly evident in the health sphere. The lower the budget assigned to healthcare as a whole (macro allocation level), the greater the need for rationing in the various branches of the health system (micro allocation level).

1.3 *The Micro Level*

This level is not to be confused with the above micro allocation level referring to problems arising within organizations. Instead it concerns a separate societal

level, namely that of interactions between individuals in relatively unorganized social contexts. An example are families and the ways in which they allocate the burdens facing them in their everyday life. It is obvious that at least theoretically this level of decision making leaves the widest scope for individual choice. However, in reality this scope is multiply constrained by cultural traditions framing the perception of appropriate choices, even though the traditions themselves may undergo constant changes. Moreover, higher-level decisions can have a significant impact on this micro level as well. Thus, if a welfare state exists which provides generous old age pensions, then this will obviously relieve the youngers' (immediate) duties against their parents. Likewise, if such a welfare state implicitly favors a pattern of lifelong, uninterrupted full-time employment, then, given a cultural background in which it is 'normal' for women to bear the bulk of child-rearing duties coupled with a tendency for work organizations to allocate better paid jobs to men, this will weaken women's bargaining position in the negotiation of the distribution of household chores.

2. *Theories of Social Justice*

Most theories of social justice focus on the macro level. Some, like the famous Theory of Justice by John Rawls (1971), view this level, or more precisely, its highest layer, as the primary, if not only subject of a theory of social justice (see also Barry 1995). Other conceptions, such as Michael Walzer's (1983), include a much wider range of issues.

Many theories of the first type deliberately restrict themselves to the formulation of principles for a society's basic structure. Once these principles are met, they are willing to leave the 'rest' to the political process. If the rules by which political decisions are made are fair, then, according to these theories, the outcomes must be accepted as legitimate by everyone because they have been brought about in a manner against which no one can reasonably object. Hence, the obligation to comply with policies and norms even if one objects to their content. The nature of these theories is thus predominantly procedural (e.g., Habermas 1983, Röhl and Machura 1997), although some, like the Rawlsian theory, also formulate one or more substantive principles. There are also macro level theories which go beyond the basic structure and address issues of normal politics as well, e.g., welfare policies relating to public education, medical care, or unemployment benefits, as in the case of David Miller (1976).

The second group of theories is much broader in scope, covering the whole range from micro to macro issues. More recently, there has been a development towards more specialization on particular types of justice problems arising within single subsystems of society. An example of this is the proliferating work in the so-called applied ethics, especially in the fields of medical and bioethics. Some of these theories also cover issues of distributive justice, with special attention devoted to problems of medical triage. Another recent development is the aim to cut across the various social subsystems and to cover, in a systematic way, the whole range of micro allocation problems facing intermediate institutions and organizations. This is the local justice approach developed by Jon Elster (1992). And finally, there is a growing body of feminist literature (e.g., Okin 1989). Much of this work starts from relative disadvantages that women encounter at the micro and meso levels and looks at the ways in which macro level institutions or policies account for them.

One pervasive problem in the theoretical literature on social justice is a widespread lack of awareness of differences in the subject matters of the available conceptions. The result is that the participants in the pertinent debates often talk past each other. They will, for instance, argue, that a principle suggested by a particular theory is unsuitable for a particular problem, but ignore that the principle was never meant to regulate problems of that sort because its suggested scope is much more limited than the critics impute. Or they will argue that a theory fails to give due weight to a particular principle, but fail to realize that the principle in question may be appropriate for some situations, but not necessarily for the ones forming the subject of the criticized theory. A favorite target of this sort of criticism is John Rawls' theory.

A second problem is that much of the theorizing in the philosophical literature lacks a proper understanding of the structure and functioning conditions of modern society. But political theories (as they often conceive themselves) that do not 'know' the society whose operations they seek to guide (see Luhmann 1980 for this criticism) are unlikely to be politically very instructive. The social theory underlying most normative theories of social justice is often rather simplistic, variously modeled after the Greek polis, a medieval village community, the market place or a handful of stranded islanders having to regulate their common affairs. The complexity of modern society is mostly ignored by this kind of theorizing—although its principles are proposed for the operations of real societies, not fictitious ones.

A third problem is that the available theories of justice are anything but clear about the meaning of social justice. Some associate it with a particular understanding of equality, others equate it with some notion of fairness, and still others use the term in still another way. There is a plethora of theories promoting different principles of justice, some favoring desert (or equity) as the first principle, others rights, and still others needs, but even those choosing the same principle may interpret it very differently. For example, how is one to determine, measure and

remunerate a person's deserts (and in which contexts are they relevant)? No consensus exists on any of these questions in the pertinent literature. Moreover, there are not only various single-principle conceptions, but also proposals for pluralist theories, some covering all three of the above principles, others allowing for as many principles as there are 'spheres' of justice. In the latter case, the meaning ascribed to social justice becomes largely a function of the problem at hand. Taken together, these (and further) difficulties leave the impression of a great deal of messiness and ambiguity in the (mostly normative) theorizing of social justice.

3. *Empirical Work on Social Justice*

Not much different is the situation in the social science literature on social justice. Here, the starting point is often some ideal of equality drawn from the enlightenment tradition and forming a standard against which the performance of a society's institutions is judged (e.g., Kluegel and Smith 1986). The ideal is rarely openly expressed or explicitly defended, but nevertheless drives ongoing attempts at laying bare inequalities in all areas of life and the social mechanisms underlying and reproducing them, with the implicit message being that the contradiction between ideal and reality calls for social reform. One problem with this literature is its hidden normativity, its unquestioned support for a certain notion of equality whose rightness is presumed (and presupposed) rather than argued for. Another problem is that it possesses no measure for admissible degrees of inequality or for prescribed degrees of equality. This problem is discussed with great vigor and sophistication in philosophy (see, e.g., Dworkin 1981a, 1981b) and (welfare) economics (e.g., Sen 1992). The advances made in this literature, however, have so far remained both unattended and unmatched in the social scientific work on inequality.

In a related way, this problem also comes up in a second body of social science literature on social justice, that on judgments of justice. Its primary subject is that of income (in)justice and (in)equality (see, e.g., Alves and Rossi 1978, Kluegel et al. 1995). To simplify somewhat, a recurrent finding across societies and social categories is that most people tend to favor some degree of inequality over absolute equality (although they disagree about the proper extent and about the fields in which inequalities may prevail or should exist). They also tend to underrate the factually existing income (and hence, wealth) differences. Still, they would mostly prefer a narrowing of the differences that they believe to exist, even though most people are roughly satisfied with their own earnings. Furthermore, there is a widespread belief that people's earnings roughly reflect their economic desert and that this is also what they should reflect. At the same time, market economies are generally preferred over planned economies, and their outcomes are largely taken to be desert-based. However, market allocations are anything but that; they are, as has been noted repeatedly, in principle unprincipled (Hirsch 1977). And this is by no means the only inconsistency; the one impression that inevitably emerges from the literature on people's judgments is that these judgments are multiply confused. So what is one to make of them?

A third type of empirical work on social justice is Elster's local justice approach. This work is concerned less with judgments of justice than with the ways in which justice problems arising in organizations are actually resolved and with the weight that justice considerations are accorded in such situations (see Elster 1995, Schmidt and Hartmann 1997). The aim is to supplement the normative literature with factual knowledge about the fields into which it seeks to intervene, the underlying premise being that normative theories need empirical foundations in order to render them applicable to a social reality which is much more complex than philosophical theories usually allow for.

Finally, in a series of articles Raymond Boudon (1997, 1999; see also Boudon and Betton 1999) has suggested a rationalist and cognitivist conception of justice and morality more generally, according to which there are objective normative truths just as there are objective scientific truths, the basis for accepting them being in both cases their grounding in strong reasons. This conception, which is directed primarily against relativistic and culturalistic positions, seems very promising but also raises a number of methodological questions: how are we to determine, by sociological means, what these truths are, how can we 'find' and accurately identify them, and what are the techniques needed to separate them from those normative statements and proposals which only claim to be true? Given the novelty and as yet mainly programmatic nature of Boudon's approach, it seems too early for a final assessment of its merits.

4. *Desiderata*

The concept of social justice is used very differently in the available literature, so if one is not already committed to a particular definition, it is hard to distil a common core out of its many usages. To some extent this has to do with the term's indiscriminate application to almost any kind of distribution problem without consideration of the different quality of problems arising at different levels and in different subsystems of society. A first desideratum is therefore that these differences be adequately acknowledged in attempts at theorizing about the concept: social justice in the design of a society's basic structure may not mean the same as social justice in the determination of wage levels by firms or in the distribution of household

duties. To the extent that there are overlaps between the term's meaning and links between single justice problems and/or levels of societal aggregation, they must be carefully examined and extracted. But if the term social is to have any serious meaning at all, then it is also important to develop a clear sense of the types of problems it is to be applied to, of their differences, their relative interdependence and independence. Or, to put it differently, what is needed is greater clarity about the locus of regulation of different categories of problems. Some such problems need to be regulated at the macro level, others are better left to lower-level instances. And it is quite likely that even a well-ordered basic structure will leave many problems of social justice unresolved and hence cannot prevent all injustices in the spheres for which it provides no determinate answers. If this is the case, then it is all the more important that the theoretical discussion be more focused and less diffuse.

Second, there is a need for more cross-disciplinary exchange, allowing the empirical and normative approaches to enrich each other reciprocally (see Miller 1999, Schmidt 1994, 1999). The philosophical literature needs an improved understanding of the real world because elegance is no guarantee for relevance; in fact, it frequently is an impediment because simplification can easily result in simplistic ideas about real world problems and their suitable regulation. The social science literature, on the other hand, needs more terminological, methodological and conceptual sophistication, and a better understanding of the categorical and epistemological differences between 'is' and 'ought' questions, in order to find its proper place in the analysis of normativity. A familiarization with the pertinent philosophical literature can be of great benefit in this regard.

Social Learning, Cognition, and Personality Development

Social learning theory views the course of human development on the basis of children's socialization experiences and acquisition of self-regulation. Children's development of personality characteristics, such as dependency and aggression, as well as their skill in academics, sports, arts, or professions, are assumed to emerge from learning experiences embedded within the social milieu of their family, peers, gender, and culture. This article describes a social learning perspective and describes the intellectual context from which it emerged, changes in researchers' emphasis over time, and current emphases, methodological issues related to the construct, and directions for future research.

1. Defining a Social Learning Perspective

Social learning theory defines children's socialization in terms of specific social learning experiences, such as modeling, tuition, and reinforcement, and the cognitions, emotions, and behavior that emerge from these formative experiences. Children's personal reactions were explained historically using personality constructs, such as identification, conditioning, or drive reduction, but are explained contemporaneously in cognitive terms, such as personal agency beliefs and self-regulatory processes. Social learning experiences are responsible for children's development of self-regulatory competence to adapt to changing settings, including those associated with their age or level of physical development. Self-regulation is essential to children's development because socialization involves giving up immediately pleasurable activities or familiar methods of coping to achieve delayed benefits.

2. Intellectual Context for Social Learning Research

Social learning research grew initially out of a seminar offered at Yale University during the late 1930s by Clark Hull. Among the members of that historic class of students were John Dollard, Neal Miller, Robert Sears, and John Whiting. The goal of the seminar was to provide learning explanations for key aspects of children's personality development that had been discussed by Freud, such as dependency, aggression, identification, conscience formation, and defense mechanisms. Of particular interest to class members was the psychoanalytic notion of children's identification with powerful models, such as parents or other adults, which Freud used to explain a wide range of personality characteristics, such as, dependency, aggression, and even psychosexual development. Identification was singled out by Miller and Dollard (1941) in a series of experimental studies of imitative learning. They found that a general tendency to imitate could be learned through reinforcement and that rewards could be structured to teach counter-imitation (i.e., the opposite choice of a model) as well as imitation. They concluded that imitation was a learned class of instrumental behavior but was not a learning process in its own right. Sears studied the impact of parents and their relationship with their children on the youngsters' personality development, especially socialization processes that could explain how children internalize the values, attitudes, and behavior of the culture in which they were raised. According to Sears' identification theory, social learning experiences lead to the internalization of self-sustaining drives to emulate their parents and other adult figures. Sears was particularly interested in children's development of self-control over aggressive behavior. Whiting conducted cross-cultural studies of differences in children's socialization to determine whether the severity of these experiences could lead to cultural differences in anxiety, guilt, and the formation of conscience.

3. Changes in Emphasis Over Time

Albert Bandura's first book with Richard Walters on adolescent aggression tested Sears' identification theory as a basis for internalization of controls over children's aggressive behavior. This research ultimately led these researchers to reject the psychoanalytic theoretical basis for social learning in a second book (Bandura and Walters 1963). They disproved the Freudian hypothesis that modeled violence would reduce observers' aggressive drives through identification and catharsis by demonstrating that such modeling actually taught or facilitated aggression, especially when modeling was accompanied by vicarious rewards. In other research, Bandura and his colleagues showed that through modeling and vicarious reward experiences children could learn new responses without actually performing them or receiving rewards. This disproved earlier instrumental conditioning accounts of modeling and imitation, and led Bandura to distinguish the cognitive effects of learning due to modeling from the motivational effects of rewards on imitative performance. To explain these two aspects of imitative learning, Bandura distinguished four subprocesses: two that affect vicarious learning—attention and retention—and two that affect imitative performance—production and motivation. To learn a new skill socially, a learner must attend to and encode a model's actions, and to perform a skill imitatively, a learner must be motivated and motorically able to produce the response. Bandura used the label *observational learning* to describe these distinctive influences of modeling without reference to Freudian identification, Hullian acquired drives, or instrumental conditioning.

During the late 1960s and early 1970s, social learning researchers began to study vicarious learning of abstract properties of a model's performance, such as grammar or conceptual classes underlying spoken language. They discovered that children could acquire a variety of abstract rules with minimal mimicry of a model's specific behaviors, such as imitating a model's style of questioning but not the model's exact words (Rosenthal et al. 1970). These demonstrations of abstract modeling on children's concepts, rules, and reasoning attracted adherents looking for alternatives to stage views of children's development. Many learning researchers, including those interested in social learning processes, questioned the validity of claims of an invariant sequence of qualitative stages that are resistant to direct training and are transituational in their impact. Instead they sought to demonstrate that children could be taught advanced

Figure 1
Reciprocal causation among triadic classes of social learning determinants

stage Piagetian concepts, Chomskian grammatical rules, and Kohlbergian or Piagetian moral judgments and that task and situational variations could cause cross-stage variations in these measures. Mary Harris, Robert Liebert, Ted Rosenthal, James Sherman, Grover Whitehurst, and Barry Zimmerman, among many others, used abstract modeling techniques to teach advanced stage functioning among children of a variety of ages, and the results were chronicled in the book on social learning and cognition (Rosenthal and Zimmerman 1978). Although age-related shifts in children's functioning were of interest to social learning researchers, they sought to explain these outcomes more on the basis of changes in social learning experience, hierarchies of goals and knowledge, and level of motoric competence rather than simply cognitive growth and development. From a social learning perspective, shifts in children's personal functioning at the approximate ages of 2, 7, and 12 years by numerous stage theories are better predicted by social learning experiences and accomplishments, such as the acquisition of speech and mobility, entrance into school, and the onset of puberty. When considering later lifespan developmental issues, social learning researchers have focused on adult life-path experiences associated with employment, marriage, child rearing, and physical declines in functioning rather than cognitive stage indices.

During the late 1970s, social learning researchers began to shift their interest from children's initial acquisition of important personal skills via modeling to the other end of the developmental spectrum—the point at which they can regulate these skills on their own. To explain children's development and use of self-regulation, Bandura (1977) depicted social learning experiences in triadic terms involving reciprocal causal relations between personal (cognitive-affective), behavioral, and environmental sources of influence (see Fig. 1). Each of the three components of his theory influences the other components bidirectionally. Cognitive events, although central to learning and performance, were constrained by specific features of social environmental contexts and by specific performance outcomes. The close bidirectional linkage of cognitive-affective processes to performance outcomes and situational contexts enabled Bandura's triadic model to explain dynamic features of children's development, such as variations in children's aggression across settings, as well as enduring individual differences. Walter Mischel also used a triadic social learning formulation to explain children's development of self-regulatory capability to delay gratification. He found that both modeling experiences and cognitive encoding enhanced children's willingness to defer a small reward for a later larger one. Michael Mahoney and Carl Thoresen studied adults' self-control of a range of clinical problems triadically in terms of covert personal forms of self-control as well as environmental and behavior forms. Bandura (1977) undertook a series of clinical training studies using highly effective (or mastery) models to improve the self-control of patients plagued with disabling fears, such as snake and dog phobias. These modeling studies were designed to enable patients' to overcome their phobia by showing the effectiveness of specific handling techniques with the feared animal. Bandura discovered that although these patients were confident about the effectiveness of a model's techniques to handle the feared animal, they were not confident about their own ability to learn and use those techniques, and this cognitive and affective deficit greatly affected their willingness to change. Bandura defined these personal perceptions of capability to learn or perform as self-efficacy beliefs.

4. *Emphases in Current Theory and Research*

Increasing evidence of the importance of cognitive aspects of self-regulation, especially self-efficacy beliefs, led Bandura to rename his approach as social cognitive theory (Bandura 1986). His book inspired numerous researchers, such as Gail Hackett, Robert Lent, Alan Marlatt, Ann O'Leary, Frank Pajares, Dale Schunk, Ralf Swartzer, Anita Woolfolk Hoy, Robert Wood, and Barry Zimmerman, among others, to begin studying the role of self-efficacy and self-regulatory processes in a wide variety of areas, such as academic functioning, physical health and medicine, sports, business and management, mental health, and the arts. A social cognitive model was used very extensively to explain how students acquire the sense of self-efficacy and the self-regulatory skill to assume responsibility for their academic learning (Schunk and Zimmerman 1994). Much of this research focused on how modeling experiences could lead school-aged children to acquire self-regulatory control of their academic performance and pursue desired careers.

During the 1990s, Bandura undertook a series of studies of the psychosocial influences of families, peers,

and schools on children's development of self-efficacy to self-regulate their academic and social attainments. In research with Claudio Barbarelli, Gian Vittorio Caprara, Manuel Martinez-Pons, Concetta Pastorelli, and Barry Zimmerman, Bandura found that self-efficacy beliefs and goals of parents for their children significantly affected the youngster's self-efficacy beliefs, aspirations, level of depression, and adherence to moral codes of conduct. Children's self-efficacy was assessed in a variety of areas of functioning, such as perceived social efficacy and efficacy to manage peer pressure for detrimental conduct, both of which were found to contribute to the youngsters' academic attainments. In 1997, Bandura published a 20-year review of research on self-efficacy involving hundreds of studies that spanned such tasks as mental and physical health, sport, academics, and business and management (Bandura 1997). Self-efficacy proved to be highly predictive of such motivational measures as free choice, persistence, and effort, of measures of self-regulation, and of social and academic learning outcomes.

5. *Methodological Issues*

In order to capture the triadic interdependence of person-related processes, such as children's self-efficacy beliefs, with their behavior and environmental setting, Bandura has advocated situationally specific forms of assessment and microanalyses of cognitive and behavioral functioning. By assessing children's, peers,' and adults' functioning in this specific manner before, during, and after efforts to perform behaviorally, researchers can test causal relations among social and self-regulatory processes. There is a body of evidence indicating that task-specific measures, such as self-efficacy judgments, are more predictive of actual performance efforts and outcomes than global trait measures of self-belief (Bandura 1997). The greater predictive power of task-specific measures was also reported by Mischel (1968) when he reviewed the literature on a wide range of personality traits, such as friendliness or conscientiousness. He found higher correlations when situationally specific measures than when trait measures of personal processes were employed, and he concluded that context-free measures of personal belief or competence were unable to explain variations in behavioral functioning across contexts.

6. *Future Directions for Research and Theory*

To explain better the sequential cognitive and behavioral aspects of self-regulation, Zimmerman (1998) developed a three-phase, cyclical self-regulation model. Forethought phase processes anticipate efforts to learn and include self-motivational beliefs such as self-efficacy. Performance phase processes seek to optimize learning efforts and include the use of imagery, self-verbalization, and self-observation. Self-reflection processes follow efforts to learn and provide understanding of the personal implications of outcomes. They include self-judgment processes such as attributions and self-reaction processes such as self-satisfaction, defensiveness, or adaptation. These self-reactions are hypothesized to influence forethought processes cyclically regarding future efforts to perform. It is also expected that as children develop skill in an area of functioning, they will show stronger cyclical links among these self-regulatory processes.

Schunk and Zimmerman (1997) identified four successive social learning levels associated with children's development of a particular skill, such as writing or golf. A first level, observational learning, occurs when a learner induces the major features of skill or strategy (for complex skills) from watching a model learn or perform, whereas a second level, emulative learning, is attained when a learner's motoric performance approximates the general strategic form of a model's. Emulative accuracy can be improved further when a model assumes a teaching role and provides guidance, feedback, and social reinforcement during performance efforts. A third level, self-controlled learning, is attained when a learner masters the use of a skill or strategy in a structured setting outside the presence of a model by relying on a previously abstracted standard from a model's performance. A fourth level, self-regulated learning, is attained when learners can systematically adapt their performance to changing personal and contextual conditions without reference to a model. It is not assumed that this is a stage model; thus, learners do not have to advance through the four levels in sequence or that the highest level of self-regulation will be used continuously without regard to motivation or context. Rather, it is hypothesized that students who master skills or subskills (in the case of complex tasks) according to this social learning sequence will display greater motivation and achievement than students using self-discovery methods. This multilevel formulation integrates the findings of modeling research with those of self-regulation research within a sequential model of children's socialization.

Social Mobility, History of

1. General Questions

Social mobility was one of the important themes of social history during its beginnings in the 1960s and the 1970s. Historians explore social mobility for two reasons. First, they want to study the general question of the history of equality of social opportunities. The question whether modern societies enlarged or reduced chances of social ascent for men as well as for women was attractive for historians. The rising openness or reinforced exclusiveness of modern elites, the rising or declining opportunities of upward social mobility for men and women from the lower classes, immigrants, poor families, and ethnic groups, the broadening or reduced access to channels of social ascent such as education, careers in business or public bureaucracies, and politics, and the role of family networks were central topics. Second, historians discuss the history of social mobility in a comparative view. European and American historians explore the myth of the opportunities for social ascent in America, which were unique compared to Europe. Historians also investigated the myth of unblocked social mobility in communist countries before 1989/91 compared to Western Europe. Social mobility was a historical theme to which major contributions did not only come from historians, but also from sociologists and political scientists.

2. Definitions and Sources

Studying the history of social mobility, historians usually investigate only the social mobility of individuals. They usually do not explore under the heading of social mobility the grading up or grading down of entire social groups or entire social classes. Moreover, the study of social mobility primarily focuses upon mobility in social structures and hierarchies rather than upon the geographical mobility of individuals as the term might suggest. It also mostly concentrates upon occupational mobility. If investigating career mobility (or intra-generational mobility), historians trace the mobility of individuals between different occupational positions or their persistence in the same occupation throughout the life. If they investigate mobility between generations (or intergenerational mobility), they compare the occupation of the father, the mother or the ancestors at specific points of their life with the occupations of a historical individual. Occupation is usually seen as the crucial indicator of the situation of an individual in a historical society. To be sure, historians are fully aware of the fact that the activity of an individual in history, more often than today, might comprise a variety of occupations at the same point of time or might include professions that still are in the making. Historians of social mobility work to link various historical sources and to trace individual persons through marriage license files, census materials, tax files, last wills, records of churches and public administrations, and autobiographical sources. The competence of historians in linking various sources has grown distinctly.

During recent years, the study of social mobility has become highly sophisticated. Individual careers are more frequently explored in micro studies of as many details as possible. These studies investigate a few richly documented individual cases rather than all members of a local society. They often use autobiographical materials difficult to analyze quantitatively. This type of micro study rarely concentrates only on social mobility, but covers a large variety of aspects. At the same time, the international and interregional comparative study of the history of social mobility has become somewhat more frequent, using the rich results of about 30 years of historical research in this field.

3. Three Main Debates

A first debate on social mobility by historians covers the increase of social mobility from 1800–2000. In this debate the rise of social mobility has various meanings. It sometimes means a more meritocratic recruitment, especially for the few most prestigious, most powerful, and best paid positions. It sometimes means more

mobility between occupations, upward mobility as well as downward mobility, and job mobility in the same occupation as well as mobility between occupations in the same social class. Sometimes, the increase of social mobility includes the chances of both genders and of minorities. Sometimes it means a clear increase of the opportunities of the lower classes compared to the opportunities of the upper and middle classes and not just more social mobility for everybody. One has to make sure what meaning is used by individual authors.

The advocates of the rise of social mobility usually think of a general increase of mobile people, but often also of a rising number of upwardly mobile persons since industrialization. They argue that various major social changes should have led to more social mobility and to more social ascent: the general decline of the fertility rate during the late nineteenth and early twentieth centuries made it possible for parents not only to invest more in individual help and education of their children, but also to promote their own professional careers. The rapid expansion of secondary and higher education especially since the end of the nineteenth century enlarged the chances for better training enormously. The rapid increase of geographical mobility since the second half of the nineteenth century led to a widening of the labor market and to a greater variety of new chances. The fundamental changes of the active population from the predominance of agrarian work up to the nineteenth and early twentieth centuries to the predominance of service work especially since the 1970s generated substantial social mobility between occupations. The distinct increase of the sheer number of occupations in all modern societies since the Industrial Revolution also must have led to more social mobility. The general change of mentalities, the weakening of the emotional identification with specific professions, social milieus, and specific local milieus, and the rising readiness for job mobility and for lifelong training further enlarged the number of socially mobile persons. The rise of the welfare state, the mitigation of individual life crisis, and the guarantee of individual social security clearly improved the chances for further training and for the purposeful use of occupational chances. Deliberate government policies of enhancing educational and occupational opportunities for the lower classes, for women, ethnic and religious minorities, and immigrants should also have had an impact on social mobility. In sum, a substantial list of factors in favor of an increase of social mobility from 1800–2000 can be put forward from this side of the debate.

The advocates of stability or even the decline in social mobility are a heterogeneous group. Arguments stem from very different ideas of social developments. It is sometimes argued that nineteenth and early twentieth century industrialization not only led to a rising number and a fundamental change of occupations, but also to a class society in which the major social classes, the middle class, the lower middle class, the working class, the peasants, and in some societies also the aristocracy tended to reinforce the demarcation lines to other social classes and, hence, to reduce rather than to enlarge the number of mobile persons. Other advocates of the skeptical view argue that the fundamental upheaval of modern societies during industrialization led to a unique rise of social mobility, of upward as well as downward mobility, and that modern societies thereafter became more closed since the generation of pioneers in business ended, as most occupational careers became more formalized and more dependent on formal education, as modern bureaucracies emerged and as mentalities adapted to the modern, highly regulated job markets. Other advocates argue for the stability of social mobility rates in a different and much more narrow sense. They argue that the long-term change of social mobility from the Industrial Revolution until the present was mostly structural, that is, it depended almost exclusively upon the redefinition of the active population rather than on the reduction of social, cultural, and political barriers. In this view social mobility remained stable if one abstracts from the changes simply induced by alternations in occupational structure (as peasants, for example, became workers, a real change, but not necessarily a case of upward mobility). Still other advocates of the long-term stability of social mobility posit a stable inequality of educational and occupational chances of lower classes, women, and minorities in comparison with the educational and occupational chances of the middle and upper class, the male population, or the ethnic majority, respectively.

This long debate has led since the beginning of quantitative studies of social mobility after World War II to a large number of historical studies of social mobility and to a wide range of results. To sum up briefly, three main results ought to be mentioned. First, only in very rare cases could a clear decline of social mobility rates to be found. Most studies show either stable or increasing rates of social mobility, depending upon the type of community and country and the generation and the period under investigation. There is no overwhelming overall evidence, either for the stability or for an increase, of social mobility rates. Second, changes of overall social mobility rates do in fact depend to a large degree on changes in occupational and educational structure. So one can say that modern societies became more mobile to a large degree because education expanded so much and because occupational change became so frequent and normal. Finally, there is much evidence that the educational and social mobility of the lower classes and women did not increase to the detriment of the educational and occupational chances of the middle and upper classes and men. Except for the Eastern European countries in some specific periods, social mobility was usually not a zero numbers game.

A second debate covers the more advanced social mobility in the United States. This old debate dates at least from the early nineteenth century, when the French social scientist Alexis de Tocqueville argued that American society offered more opportunities of social ascent than did European.

Various pieces of evidence was presented in favor of the American lead. Some empirical studies by sociologists demonstrated that in some crucial aspects a clear American lead could be shown. This was especially true for mobility into the professions. Higher education was more extensive and offered more chances than in Europe. Hence, the social ascent from the lower classes into the professions that are based on higher education was clearly more frequent than in Europe. In addition, comparative historical studies on the late nineteenth and early twentieth century American and European cities showed that in a special sense a modest American lead existed during that period: unskilled workers in fact moved up into white-collar positions in American cities somewhat more frequently than in European cities. Finally, historians demonstrated that the important difference between American and European societies could be found in the American creed in more opportunities in America than in closed European societies.

Other recent comparative studies tend to argue that a general lead of the American society no longer exists in comparison with Europe. According to this view industrialization and modernization led to about the same opportunities everywhere. Various international comparisons of social mobility rates support this view and demonstrate that the overall rates were not distinctly higher in the US than in old societies such as Western Europe or Japan. As these comparisons almost exclusively deal with the second half of the twentieth century, the results might be due to the fundamental social changes in Europe and Japan since World War II.

The lead of communist countries in social opportunities especially in the USSR during the 1920s and 1930s and in the Eastern European communist countries in the late 1940s and 1950s is the topic of a less intensive, but important debate. Some historical studies of social mobility demonstrate that during these periods rates of upward social mobility into the higher ranks of the social hierarchy were substantial compared to Western European societies. This was true partly because of the rapid expansion of higher education, the communist abolition of the middle class, and the rapid change of the employment structure due to rapid industrialization. However, the rise of social opportunities in communist countries, if it rose at all, was largely limited to the period of the system upheaval. Most comparative studies of the 1970s and 1980s show that rates of social mobility were not distinctly higher in Eastern Europe compared to Western Europe. This was partly because the communist political and administrative elite became exclusive and gentrified, because social change slowed down, and because the expansion of higher education was reduced in several communist countries.

Gender contrasts in social mobility were explored only by a small number of studies by historians. A debate among historians has not yet started. But gender contrasts undoubtedly will add new important aspects to the general debate about long-term trends in social mobility. Four conclusions can be expected from the few studies. First, in a more radical sense than in the study of male mobility, female mobility raises the question whether social mobility should in fact be centered around occupational mobility or other factors such as marriage and unpaid or partially paid work in emerging professions are to be taken in account much more than so far. Second, the question of a rise of downward mobility during the transition to modern society, i.e., during the rise of female activity outside the family sphere, is to be explored. A study of female social mobility in twentieth century Berlin demonstrates a high rate of intergenerational declassement of active women during the early parts of the twentieth century. Third, the study of the social mobility of women demonstrates much more clearly than that of males the effects of economic crises and fundamental transitions on social mobility. Opportunities for women seem to have depended strongly on economic prosperity, on long-term social stability. In periods of economic crisis and rapid transitions such as the upheaval of 1989/91 women more than men belonged to the losers. Here again the study of female mobility might draw the attention of the historians to a more general aspect of mobility that was not investigated enough. Finally, the social mobility of women also demonstrates that definite changes of social opportunities can only be reached in a long-term perspective. It was shown that even when important channels of upward social mobility such as education offered equal chances to women, they did not lead to a parallel improvement of occupational chances for women. Besides the study of institutions and policies, the historical study of the experience of social mobility and the perception of social mobility will become crucial.

4. *The Future Historical Research on Social Mobility*

During 1980–2000 social mobility was much less frequently investigated by historians. The declining interest in social mobility has partly to do with the rising research standards that are more and more difficult to match by projects limited in time and financial resources. Moreover, the initial questions asked in this field lost the former attraction because it became widely accepted that social mobility rates were about the same in most societies and did not rise distinctly during in the nineteenth and twentieth

industrialization and modernization centuries. Finally, the general thematic trends in historical research made social mobility look unlike a modern theme.

The future of the study of social mobility is that of a normal theme among many others in history rather than a top theme in an expanding branch of history as in the 1960s and 1970s. One can hope for four sorts of studies of neglected aspects of social mobility. A first future aspect is the historical study of social mobility in Eastern Europe, but also outside Europe, and thereafter the international comparisons reaching beyond Western Europe and the US. The question of the particularities of social mobility in Europe might then be answered differently. A second future aspect of social mobility is gender contrasts of social mobility. We need a well-reflected number of case studies of contrasting countries, different female activities, contrasting general conditions such as prosperity and economic depression, peace and war periods, stability and transitions. A third future theme is specific factors of social mobility such as religion, types of family, immigration, unemployment, and poverty and more generally the impact of background social milieu. It seems that historians will explore these contexts of social mobility often in looking at a limited number of individuals and that they will include also the subjective experience of social mobility. The fourth future topic is to be the history of the debate on social mobility, as an aspect of the history of identities, e.g., the European or American identity. The debate among historians was inspired by this debate and this topic will help us to understand better why historians became interested in this theme in the 1960s.

Social Movements and Gender

Social movements can be defined as collectivities acting outside institutionalized channels to promote or resist change in an institution, society, or the world order. Although there are a diversity of theoretical approaches to the study of social movements, until recently mainstream theory and research in the fields of social movements and political sociology have ignored the influence of gender on social protest. Beginning in the 1990s, scholars trained in the gender tradition that flourished in the social sciences during the 1980s turned their attention to questions pertaining to the gender dynamics of a variety of historical and contemporary movements. As a result, a thriving body of research demonstrates that gender hierarchy is so persistent that, even in movements that do not evoke the language of gender conflict or explicitly embrace gender change, the mobilization, leadership patterns, strategies, ideologies, and outcomes of social movements are influenced by gender and gender differences. This article delineates the way gender relations and hierarchy influence various social movements, including feminist, antifeminist, men's, labor, civil rights,

gay and lesbian, nationalist, rightwing, and fascist movements. It ends by discussing the broader implications of integrating gender to mainstream theories of social movements.

1. Linking Gender and Social Movement Theories

Notions of femininity and masculinity, the gender division of labor in private and public spheres, and the numerous institutions, practices, and structures that reinforce male dominance are not expressions of natural differences between women and men. Rather, the gender order is constructed socially and gender is a pervasive feature of social life. Although gender scholars fairly universally adopt social constructionist perspectives to understand gender relations, there is considerable variation in the epistemologies, contexts, and levels of analyses of the various theories that have developed to explain gender hierarchy. The most sophisticated conceptualizations treat gender as an element of social relationships that, like race and class, operates at multiple levels. Gender categorizes and distinguishes the sexes and ranks men above women of the same race and class (Lorber 1994). Multilevel frameworks seek to avoid universal generalizations that are impervious to the historicity and contextualized nature of perceived differences between the sexes by conceptualizing gender as operating at three levels. Multilevel approaches, first, view gender as organizing social life at the interactional level through the processes of socialization and sex categorization that encourage gender-appropriate identities and behavior in everyday interactions. Second, multilevel theories emphasize the complex ways gender operates at the structural level, so that gender distinctions and hierarchy serve as a basis for socioeconomic arrangements, the division of labor in families, the organization of sexual expression and emotions, work and organizational hierarchies, and state policies. Finally, multilevel theories attend to the cultural level, specifically to the way gender distinctions and hierarchy are expressed in ideology and cultural practices, such as sexuality and language, as well as in the symbolic codes and practices of institutions such as art, religion, medicine, law, and the mass media.

Recent writings on social movements treat the social construction of gender as taking place at these three respective levels. The significance of gender is more apparent for some movements than for others. Its relevance is obvious in the case of women's movements targeting discriminatory policies and practices pertaining to employment, family, reproduction, and sexuality. Nevertheless, gender is also constructed in movements that do not explicitly evoke the language of gender conflict. One example is McAdam's (1992) landmark study of the US 1964 Freedom Summer campaign, when white college students spent the summer in the South participating in the US civil rights movement. The traditional sexual double standard meant that women were less likely to be recruited to the Mississippi project than men because of the taboos associated with interracial sexual relationships, especially those between Black men and white women. Those women who managed to make it to Mississippi were more likely to be slotted into traditional female roles—specifically, clerical work and teaching rather than canvassing and voter registration. Furthermore, the biographical consequences of participation differed for men and women. Men were more likely to remain activists over the course of their lives than women, and women who participated in Freedom Summer were less likely to marry than men. To provide another example, masculinity is integral to nationalist politics in the contemporary world (Nagel 1998). Gender hierarchy is expressed in forms such as the construction of patriotic manhood and exalted motherhood as icons of nationalist ideology. The relevance of gender can also be seen in the domination of masculine interests in the ideology of nationalist movements and sexualized militarism that simultaneously constructs the male enemy as over-sexed and under-sexed (as rapists and wimps) and the female enemy as promiscuous (sluts and whores).

A systematic incorporation of gender into an understanding of social movements requires that we examine the way gender processes are embedded in the factors that trigger and sustain social movements. The most influential theoretical perspectives on social movements combine the insights of classical collective behavior theory, resource mobilization theory, and new social movements theory (McAdam et al. 1996). They emphasize three factors that explain the emergence and development of any movement: shifting political and social opportunities and constraints; the forms of organization used by groups seeking to mobilize; and variations in the ways challenging groups frame and interpret their grievances and identities. Let us examine the way gender comes into play in each of these three broad sets of conditions that are relevant to the emergence and operation of social movements.

1.1 Political and Cultural Opportunities and the Gender Regime of Institutions

One of the major premises of social movement theory is that changes in the larger political and cultural context can stimulate or discourage people from participating in collective action. Shifts in gender differentiation and gender stratification in the particular sociohistorical context have been important facilitating conditions for the emergence and operation of feminist movements. In modern welfare states, public policy with respect to pregnancy and mother-

hood historically has been formulated either by treating women and men the same with gender-neutral policies or by recognizing women's special needs as child bearers and mothers and providing female-specific benefits. In the US, during the early twentieth century, government support of maternity often took the form of 'protective legislation' that regulated women's hours, working conditions, and prohibited women from working in occupations thought to be dangerous. While nineteenth century feminists, by and large, supported special female legislation and other policies consistent with women's primary identity as mothers, by the late 1960s the feminist campaign to formulate public policy switched to the sameness side of the sameness/difference divide, reflected in campaigns for policies such as the Equal Rights Amendment and the Family and Medical Leave Act.

Feminist movements in the US historically have targeted gender inequality in a wide range of institutions, including medicine, religion, education, politics and the law, the military, and the media. For instance, feminists criticized the medical system's bias against women in medical research, the labeling and classification of medical conditions, and doctor/patient relationships. The entry of larger numbers of women into the medical field beginning in the 1970s and 1980s facilitated the growth and expansion of feminist women's health centers and women's self-help movements focused on conditions unique to women, such as rape, battering, breast cancer, childbirth and pregnancy, and postpartum illness.

1.2 Gendered Mobilizing Structures

Expanding political and cultural opportunities create possibilities for collective action, but the emergence of a movement depends upon whether aggrieved groups are able to develop the organization and solidarity necessary to get a challenge underway. Gender differences and relations figure heavily into the pre-existing mobilizing structures or nonmovement ties that exist among individuals prior to mobilization and the organizational form a movement takes once it is underway. Gender, racial, class, ethnic, and other inequalities are often embedded in the informal networks, clubs, and formal organizations that provide the incentives for people to take the risks associated with participating in protest groups. In her study of African American women's participation in the US civil rights movement, Robnett (1996) identifies a distinct form of grassroots behind-the-scenes leadership carried out by women who were prevented from occupying formal leadership positions by the exclusionary practices of the Black church. Gender divisions can also facilitate mobilization. For example, sex-segregated women's colleges, clubs, associations, and informal networks historically have been fertile grounds for the growth of feminism. Blee's (1991) research on women in the 1920s Ku Klux Klan provides further evidence of the importance of sex-segregated networks. She reveals how women drew upon family ties and traditions of church suppers and family reunions to mobilize. She describes the way Klan women deployed women's gossip in the form of 'poison squads' to spread a message of racial and religious hatred.

The connective structures that link leaders and followers and different parts of a movement, allowing them to persist, can also be gendered. Some scholars have argued that there is no particular structure essential to a feminist organization. Others, however, find that some feminists' beliefs in fundamental differences between female and male values have led to feminist organizations with distinctive emotion cultures that dictate open displays of emotion, empathy, and attention to participants' biographies. By contrast, the large-scale all-male meetings of the Promise Keepers, a mostly white, middle-class, and heterosexual men's rights movement that arose in the late 1990s to reassert essentialist views of women's and men's roles in the family, were steeped in an aura of powerful masculinity, holding meetings in stadiums associated with organized sports events (Messner 1997). Gender can also be a subtext in the organizational logic, beliefs, and practices of movements that do not make explicit gender claims. Einwohner (1999) found that prevailing ideas about gender and gender differences are a driving force behind the largely female composition, emotion-laden strategies, and negative reactions of the public to the contemporary animal rights movement. The well known decentralized grassroots Alinsky model that influenced early social welfare activism since the early 1970s, according to Stall and Stoecker (1998), is organized along an essentially masculine logic that views community organizing as a means to power, in contrast with 'the women-centered model,' which treats community building as a goal of organizing. Brown (1992) implicates gendered organization in the decline of the Black Panther Party. She recounts the way the male power rituals of the Party—specifically its military structure, use of violence and aggression, and promotion of sexual rivalries—not only excluded women from the Black power struggle but planted the seeds of its destruction.

As this last example illustrates, gender inequality often persists within social movement organizations as Fonow (1998) reports in her research on women's participation in the 1985 Wheeling–Pittsburgh steel strike. In this case, major strike activities—picket duty and meal preparation—reflected a gender division of labor. While working kitchen duty helped mobilize the support of the larger community by bringing together the wives and families of workers and nonworkers, the exclusion of women steelworkers from the picket lines—seen as an expression of 'virile unionism'—

undermined solidarity between men and women steelworkers.

1.3 Gender and Framing Processes

Social movements often appropriate gender ideology to legitimate and inspire collective action and to identify a challenging group's commonalities. Contemporary scholars of social movements rely upon two concepts for analyzing the unique frames of understanding that people use to define their shared grievances: collective action frames and collective identities. To the extent that gender operates as a constitutive element of social interaction and relationships, it is not surprising that images of masculinity and femininity appear in the language and ideas social movement activists use to frame movement demands and injustices. Gender dualism, for example, was woven tightly into German National Socialism. Not only was masculinity glorified and male bonding considered the foundation of the Nazi state, but gender-linked oppositions served as the metaphor for the polarization of Jews as weak and emotional and Aryans as strong and rational. The language of gender difference and power is pervasive in contemporary women's self-help movements and serves as a major framework for understanding the problems that trouble women. In the postpartum self-help movement, gender plays a pivotal role in mobilizing participants. Activists linked postpartum illness to women's responsibilities for parenting, to ideas that mothers (not fathers) have to be self-sacrificing, and to the gender bias of the largely male medical establishment (Taylor 1999). Social movement scholars use the concept of collective identity to research the question of how challenging groups define and make sense of the question 'who we are' and the complex and changing process collective actors use to draw the circles that separate 'us from them.' Gender difference in virtually every culture is key to the way actors identify themselves as persons, organize social relations, and symbolize meaningful social events and processes. That means that the identities that social movements of all kinds create and recreate are bound to be molded, at least in part, by gender meanings and practices. For example, Taylor and Whittier (1992) argue that in the lesbian feminist movement of the 1970s and 1980s, the drawing of boundaries between male and female promoted the kind of oppositional consciousness necessary for organizing one's life around feminism. Similarly, some branches of the contemporary breast cancer movement frame women's commonalities in gender terms by connecting the experiences of breast cancer survivors to the societal emphasis on women's breasts as crucial to women's attractiveness to men. At the same time, such activists point out, the medical establishment has provided less funding and attention to breast cancer than to diseases that affect men more than women (Klawiter 1999). If gender symbolism plays an important role in the socially constructed solidarities that mobilize collective action, the development of gender solidarity is never automatic, even in women's movements. Analyzing African American women's autobiographies written before 1970, Brush (1999) shows that the messages that came from the civil rights movement encouraged them to interpret their grievances in terms of race rather than gender, while the women's movement made gender seem irrelevant to Black women's experiences. The tendency to see the generic 'Black' as male and the generic 'woman' as white shows that using gendered meanings to construct a group's commonalities can exclude some people, since deciding who 'we' are also entails deciding who 'we' are not (Collins 1990).

Gender as a set of cultural beliefs and practices figures heavily into many of the identity movements that have swept the political landscape in recent years. In attempting to privilege white racial identity, the contemporary white supremacist movement not only presents a range of racial enemies but deploys gender metaphors—e.g., treating the Black male body as dangerous and animal-like and the white female body as always at risk and in need of protection—to appeal to the growing number of disillusioned white males who feel threatened by what they perceive to be the successes of social movements for gender and racial equality (Ferber 1998). Finally, gender symbolism and ideas about masculinity and femininity figure heavily in the modern gay and lesbian movement, which challenges the notion that women are feminine and men masculine and, further, that erotic attraction must be between two people of different sexes and genders (Gamson 1997).

2. The Significance of Integrating the Study of Social Movements and Gender

Feminist scholars interested in the study of social movements recently have called attention to the gendering of social movement processes and social movement theory. The role of gender in the emergence and dynamics of social movements, even those seemingly not about gender, has been obscured through the gender-neutral discourse that characterizes prevailing theories of social movements. Treating gender as an analytic category illuminates a range of new questions pertaining to the political opportunities, mobilizing structures, and framing processes of movements. A synthesis of the theoretical literatures on gender and social movements also has the potential to advance the field of gender. Theories of gender emphasize the maintenance and reproduction of gender inequality and neglect countervailing processes of resistance, challenge, conflict, and change. The literature on social movements spotlights the role of human agency in the

making and remaking of femininity, masculinity, and the existing gender system.

Social Movements: Environmental Movements

Since World War II environmental issues have increasingly entered Western political discourses. From the 1992 UN-conference in Rio de Janeiro onwards, environmental issues appeared on the government agendas of the South and of reforming countries and were promoted by international programs under the label of sustainable development. This contribution examines the ways in which environmental issues were taken up by non-formal collective political action—often referred to as the 'New Social Movements.' It looks at the informal actors participating in the movements and how they organize themselves and identify with their demands. Furthermore, it focuses on their strategies for engaging with power, which have redrawn the lines of what is regarded as 'political' and 'politics.'

1. Social Movements and New Social Movements: Theoretical Perspectives

Research on social movements—as the term is understood today—dates back to the 1930s when US sociologists, who were confronted with the turmoil of the emergence of fascism and communism in Europe, concentrated on ideological aspects of collective behavior, and perceived collective political action as a threat to the established order (Eyerman and Jamison 1991, p. 10). Herbert Blumer from the Chicago School was the first to outline the positive potential of the new forms of social interaction. In contrast to this social-psychological focus emphasizing the individual, Talcott Parsons took a structuralist-functionalist approach drawing on the classic work of Max Weber and Emile Durkheim. The combination of the two views resulted in a framework which has come to be known as the collective behavior approach, balancing the micro-oriented approach with the macro-oriented.

This perspective dominated research on social movements until the 1960s (Eyerman and Jamison 1991, p. 11f.). However, the civil rights movements and the students' demonstrations of the late 1960s led American sociologists to criticize the functionalist logic of the collective behavior theory, which devalued action as reactive behavior without strategic capability. US sociologists directed their attention instead toward the costs and benefits of taking part in social movements, grounding their concepts in actors as 'movement "entrepreneurs"' who make rational choices, using the material and symbolic resources available. Critics have pointed out that this emphasis on resources normally held by influential social groups leads to the destruction of the resistance due to marginalized actors. Moreover the exclusive focus on

rational choices does not take adequate account of emotions (Della Porta and Diani 1999, pp. 7–9).

As a response to this criticism the field of political research has directed its attention toward interactions between political establishment insiders and outsiders, and toward the outsiders' less conventional forms of action. This framework allowed social movements to be viewed as part of political debates and dialogs rather than as excluded from the political system. Despite their insights, however, analysts of political processes have failed to generate an explanation for the innovative nature of social movements and the new spaces created and occupied by contemporary movements of youth groups, of women, and of homosexual or minority ethnic groups (Della Porta and Diani 1999, p. 10). Della Porta and Diani draw upon concepts developed by European scholars, whose criticism of the deterministic Marxist models shed new light on the 'New Social Movements' in Europe. In particular, Alain Touraine's so-called post-industrial approach has become influential. It posits that the ruling and popular classes remain major antagonists and forces of social change. The New Social Movements are characterized by their decentralized and participatory organizational structures as well as their critical attitudes towards ideology and solidarity structures. As Alberto Melucci states, material claims are—in contrast to the workers' movement—no longer central to the Movements' agenda. Guaranties of security and state welfare are no longer demanded. Instead, the intrusion of the political-administrative system into daily life is something to be resisted (Della Porta and Diani 1999, p. 12f.).

Although the exchange between European and American scholars has intensified and research on social movements taken up by a variety of disciplines, Calderon criticizes the still predominant structuralist research paradigm, arguing that a structuralist view cannot provide sufficient insight into the social expression brought about by the movements (Calderon 1992, p. 23). Referring to Melucci, David Slater (1997, p. 259) uses the metaphor of the 'nomads of the present' for the post 1989 movements, capturing the fluidity and territorial flexibility of today's mobilization. Intensified cooperation between the disciplines and the theoretical schools has led to regarding manifestations of resistance and opposition as something increasingly independent from universalist discourses. Connected in terms of space, these new mobilizations stick together as 'archipelagos of resistance' characterized both by their global reach and their local embedding and specificities (Slater 1997, p. 259). This framework seems particularly helpful for understanding the emergence of social movements with an environmental focus. Before turning to environmental issues, however, it is necessary to consider the state's changing role in confronting collective political action.

Thirty years ago collective action was strongly oriented toward the state and state politics. Today, collective practices create their own cultural identities and specific spaces for social expression, taking advantage of and contributing to the severe crisis faced by nation states worldwide (Calderón et al. 1992, p. 23). Globalization processes are undermining what used to be the territorial state's significant spaces of action. Furthermore, the state is faced with the fragmentation of civil society: segments of society create their own spaces, often with a self-determined distance from the state which—in its modernist conception—has traditionally furthered integration by excluding certain social categories (Calderón et al. 1992, p. 25). Thus the state has lost its central role as the focus of attention for social movements, i.e., for collective action concerning ethnic or ecological questions. In general, both emerging forms of social and political participation as well as highly influential economic players are challenging the legitimacy of the state and its political representatives on environmental issues.

Taking his analysis of resistance even further, Steven Pile (1997, p. 3) criticizes social movements research that operates exclusively with the dual model of 'authority' on the one hand and 'resistance' on the other. He perceives resistant political subjects as also influenced by driving forces '…such as desire and anger, capacity and ability, happiness and fear, dreaming and forgetting,' which mobilize forces not simply based on the antagonism of established power and opposition. This analytical frame seems useful for understanding social movements organized around issues of identity and natural resources.

2. *Characteristics of Social Movements with an Environmental Focus*

The first of the New Social Movements started in 1968 with the student revolts in Western Europe. Independent of established political institutions, these new forms of social and political participation contrasted sharply with the traditional workers' movements. Starting out as student riots supported by feminist activists and intellectuals, this movement soon grew, also becoming more critical of transformations occurring in industrial society. The New Social Movements questioned modernism and economic progress, focusing on the costs of social transformation. In the 1970s these issues were extended to environmental conflicts in Western Europe. Protest groups not only questioned the values of industrial society and the price of such things as economic progress, security, and sustainability, but also the political process, its parties, and politicians. Touraine identified such central conflicts in post-industrial society as the struggle for the control of symbolic production.

In addition the organizational structures developed by the New Social Movements are different from those

of traditional political parties: they are more decentralized and follow participatory organizational principles. They usually involve people who have not been interested in traditional politics or who have not been integrated into traditional political parties before. In general these movements want to experience new forms of democracy and focus on environmental and non-profit issues.

Another characteristic feature of the New Social Movements—especially of those concerned with environmental issues—is the high involvement of women, minorities, young people, and people from the South. Seager (1996, p. 271) in her writing on 'hysterical housewives' points to the high percentage of women participating in environmentalist and conservationist organizations. Women around the world would, according to Seager, support more restrictive environmental laws and spend more money on ecological projects. However, they often face inflexible bureaucracies which adhere to fixed beliefs about economic growth and success. The potential of the politics of resistance lies in the interstices of self-determination, interpersonal and international solidarity as well as solidarity with future generations and the environment.

According to Della Porta and Diani (1999, p. 14f), the New Social Movements evince at least four characteristic features:

(a) Informal interaction networks. The movements can be regarded as informal interaction networks between a plurality of individuals, groups and/or organizations with loose and dispersed links. Such networks promote the circulation of essential resources for action (such as information or material resources), creating and preserving a system of meaning through adequate organizational resources. In many cases the networks intend to create a new model of democracy based on greater participation and decentralization than in traditional democracies.

(b) Shared beliefs and solidarity. Another characteristic feature of the New Social Movements is the set of beliefs and the sense of belonging they share. Social movements help to find new approaches to existing environmental conflicts, to raise new public issues and to create visions. By contributing to a symbolic redefinition of reality and possible future perspectives they construct new collective identities and value systems. In many cases it is up to the leaders of movements to create appropriate ideological representations.

(c) Collective action focusing on conflicts. The actors of social and environmental movements are usually engaged in political and cultural conflict. Very often they set their value system against that of a powerful establishment. The actors involved in the movements share common interests, values, collective experiences, and a feeling of belonging to certain places and environments.

(d) Use of protest. The movements make use of unusual patterns and deviating forms of political behavior and public protest, e.g., civil disobedience, collective action, and the mobilization of public opinion by spectacular activities (Della Porta and Diani 1999, p. 14f).

3. *New Actors and Alliances in the Political Struggle on Environmental Issues*

According to Calderón et al. (1992, p. 24) the reason for the emergence of social movements lies in the tension between social demands and the inability of the existing political institutions to hear these demands, not to mention give in to them. The protagonists of traditional social movements were rather large social entities easily identified by one common social denominator, e.g., their identity as workers or peasants. Unlike the protagonists of earlier social movements today's activists are not held together by a political force, i.e., by an aggregation of interests and actions. Although the New Social Movements are led by seemingly unimportant social actors, i.e., people in the lower ranks of the social hierarchy, such as black people, mothers, indigenous or disabled people, they leave a considerable mark on public platforms (Calderón et al. 1992, p. 26). Their highly specific interests and demands enable them to challenge the established structures more effectively. As Steven Pile (1997, p. 1) describes it, they perform 'acts of resistance [that] take place (…) in the spaces under the noses of the oppressor … .' This framework requires a more complex understanding of power and how it is distributed. The simple model of authority in the upper rank and its victims among the lower ranks has to be dropped.

In many of the New Social Movements feminist and ecological activists have joined together for collective action. There are several reasons for this (Rocheleau et al. 1996, p. 15ff): declining ecological and economic conditions which activate women because they threaten the survival of families; the impact of structural adjustment policies and the 'retreat of the state' from support of public services, social welfare, and environmental regulations; consciousness raising and political awareness; the political marginality of most women; the expansion of the women's movement to address converging issues of gender, race, class and culture. They focus on policy and environmental management issues, access to and distribution of resources under conditions of environmental decline, resource scarcity and political change, and environmental sustainability.

The unequal 'Geometries of Power' (Massey 1993) are responsible for generating social movements with an environmental focus and have led to a shift in scale between locally anchored movements and international organisations with global impact. In many

cases small indigenous groups succeeded by involving Non Governmental Organisations (NGOs) from Western countries in their struggles and were able to achieve their goals by globalizing the conflict. Some small and spontaneous local movements have expanded to become influential global players in environmental and human rights arenas. Several international NGOs, e.g., Friends of the Earth International, the WWF, Greenpeace, Global 2000, Peace Brigades International, have become global social movements with highly sophisticated organizational structures and professional fund raising.

In some cases local social movements with a specific environmental focus obtained wider social support and political influence, and were finally transformed into political parties (see below). Several Green Parties in Europe have developed along this line (Wastl-Walter 1996).

4. *Issues*

4.1 *Preservation of Natural Diversity*

Of the world's biodiversity, 98 percent exists on lands controlled by indigenous peoples. The land uses that sustain this diversity are intimately tied to the survival of the people in question, who often struggle to preserve their 'space' and lifeways against exogenous forces (Della Porta and Diani 1999, p. 12). Power relations are usually tilted against indigenous peoples, who have little political and social capital. These relations are further blurred by values that differ from those of the West. For some indigenous peoples, land is not only life, it is sacred. Hence many conflicts are also cultural in nature, and can only be won if indigenous groups obtain the support of Western social movements, which can contribute their strategies and resources for successful confrontation with global economic powers. A well known example is the conflict of interest dating from 1988 concerning the construction of the world's biggest dam on land belonging to the Kayapo Indians on the Rio Xingœ in Brazil. If the project were realised, 7.6 million ha would be flooded and 11 indigenous peoples would be forced to leave their land. Furthermore a unique ecosystem would be destroyed. The actors involved are the Government of Brazil, the World Bank, the Kayapo leaders and people, the OAB (Ordem de Abogados do Brasil), the NWF (National Wildlife Federation), the EDF (Environmental Defense Fund), Amnesty International, Survival International, Cultural Survival, and the International Society of Ethnobiology. The example shows that the actors involved range from local groups to groups with an international dimension. The groups differ vastly in terms of interests. Since various peoples would lose their home and hence their existence, human rights issues—and therefore the possibility of new alliances—should be considered as well.

4.2 *Preservation of Resources and the Right of Access to Environmental Resources*

A central aim of social movements with an environmental focus is the preservation of and right of access to environmental resources. Natural resources are endangered by the rich world's resource-intensive, wasteful, and polluting habits of production and consumption as well as by the environmentally destructive practices of the poor, who are forced to intensify their production under inappropriate conditions leading, for example, to depletion and degradation of large areas. Similar conflicts could be mentioned: in terms of land use, this means food crops vs. cash crops or sustainable farming vs. industrialization. One of the first famous examples of conflicts of this kind was the Kalinga women's struggle against the Chico Dam project (Philippines) from 1967 until 1987. The women linked the sociopolitical issue of emancipation with their ecological interests, questioning the right of access to environmental resources as such. The dam project, which was financed by the IWF/World bank, was their first that had to be cancelled due to the opposition of the indigenous population.

In Europe the first conflicts where social movements were concerned with environmental issues were the anti-nuclear power movements of the seventies. Again the main actors in terms of protest and the key speakers were women and mothers (*Mütter gegen Wackersdorf* in Germany). They were worried about the preservation of a healthy environment for their children and spoke against further economic and technological development at any price. They also questioned the legitimacy of technical experts.

5. *Methods and Strategies of the New Social and Environmental Movements*

These examples illustrate how the New Social Movements are forced to apply differing strategies and methods to succeed against the political establishment and the economic powers that be. Steven Pile draws our attention to the specific geographies around which acts of resistance unfold: 'on the streets, outside military bases, and so on, or, further, around specific geographical entities such as the nation, or 'our land,' or world peace, or the rainforests; or, over other kinds of geographies, such as riots in urban places or revolts by peasants in the countryside or jamming government web sites in cyberspace' (Pile 1997, p. 1).

The groups involved are often poorly resourced and act on a local level. In order to succeed they go public thus extending their reach, i.e., allying themselves in 'Joint Ventures' with global-players such as NGOs. For that reason, as Jayanta Bandyopadhyay states, social movements with an environmental focus cannot only develop fighting strategies; they also have to invest in public relations in order to become a trend-setting movement (Bandyopadhyay 1999, p. 880).

The movements are forced to use reassessed indigenous knowledge to overcome the arguments of modern scientific knowledge systems. And these alternative sources of knowledge need to be fed into channels of modern communication technology in order to reach a broad audience.

Local movements brought about by so called 'disposable people' (Ekins 1993) need to create a myth about themselves which triggers activists and solidarity movements among the more privileged. In many cases these groups have charismatic leaders or 'movement poets' (as they are called in the Chipko movement in India), who by personalizing the conflicts manage to obtain access to the mass media. Several such people have gained an international reputation in the course of their commitment, e.g., Medha Patkar, the leader of the movement against the Sardar Sarovar Dam in India, who was awarded the alternative Nobel prize.

The history of the Green party in Germany reveals a different developmental pattern: the party come to represent the 'Eco-Establishment' (Seager 1993, p. 170). A social movement has become an official public agent. The debate between 'fundamentalists' and 'realists' was about whether to promote social change from within the system (realists) or from the outside (fundamentalist). Spontaneous demonstrations relying on a very affective approach have yielded to pragmatic and committed politics using the official channels of public life. Professional respectability has replaced passionate involvement. A change in essence and style towards the perspectives of the establishment can be noted, with an acceptance of free market economy criteria, an emphasis on practicability, efficiency, and scientific arguments (Seager 1993, p. 201).

6. *Social and Political Relevance of Environmental Movements*

Environmental problems are caused by conflicting interests regarding natural resources and the preservation of the environment. Apart from those problems social movements also view environmental conflicts as a crisis of democracy and participation and as a cultural and ethical crisis because of the uneven power relations and conflicting systems of values and norms involved. With new actors entering the political field, traditional national politics and even states themselves are called into question by environmental movements. Traditional political parties lose members and voters while green parties or more spontaneous political groups gain influence.

In most cases it is impossible to solve the conflicts at either the local, regional, or national level. The issues at stake are manifold, each interest group portraying its own perspective. It is the interstices between self-determination and solidarity with human and non-human agents which are likely to create a substantial mobilizing potential. Hence new networks, operating at an international level and able to consider the differing interests and to mediate the uneven power relations, have to be built up in order for social movements with little formal political power to be heard.

D. Wastl-Walter

Social Movements, Geography of

Social movements, like all social relations, are geographically constituted. What one means by 'social movements,' however, is open to a wide range of interpretations. Here, social movements are defined broadly as collective mobilizations of people seeking social or political change.

While social movements necessarily take place somewhere, their geography involves considerably more than an inventory of their locations. Geography is not a background onto which aspatial social processes are mapped. Rather, it is a fundamental aspect of the constitution of all social processes, affecting their evolution and outcome directly. It is part of the explanation of social processes, as well as an outcome (Massey and Allen 1984).

While a variety of geographic concepts can be employed in the analysis of social movements, three core geographic concepts are particularly important: space, place, and scale. Each of these concepts has its own evolution, which can be seen in the ways in which analyses of the geography of social movements have changed over time.

1. *Evolving Geographic Concepts and the Analysis of Social Movements*

1.1 *Spatial-analytic Analysis of Social Movements*

The spatial-analytic paradigm that dominated geographical analysis in the 1960s and 1970s worked from a conception of space that was based, by and large, on measures of distance. In this paradigm, social phenomena are described and explained in terms of absolute (e.g., with reference to a fixed grid such as latitude and longitude) or relative (e.g., transportation costs or travel time) location. Virtually all social phenomena have been shown to possess a 'distance decay' function as interaction costs increase with distance from the activity center. The spatial diffusion of information, as well as barriers to such diffusion, became a common theme in much spatial-analytic research, including that addressing social movements (see *Diffusion: Geographical Aspects*). The growth and mobilization of social movements is clearly dependent upon flows of information, as demonstrated by Sharp's (1973) analysis of the spatial diffusion of US postal strikes, and Hedstrom's (1994) work on the spatial diffusion of Swedish trade unions. Most spatial-analytic work on social movements, however, examines the co-presence of specific social conditions within clearly delimited places. Adams (1973), for instance, examines the co-location of factors promoting urban protests, while Cutter et al. (1986) consider how characteristics measured at the state level are associated with support for nuclear weapons freeze referenda (see *Peace Movements, History of*). In the 1970s, attempts to explain the occurrence of social phenomena in terms of distance or co-location came under heavy criticism for ignoring power relations, and in particular, the relation between 'the social' and 'the spatial.'

1.2 *Contemporary Conceptions of Space and the Analysis of Social Movements*

Influenced by the work of Henri Lefebvre and others, contemporary conceptions of space emphasize the mutual constitution of 'the social' and 'the spatial.' Space is seen increasingly as a necessary component of the constitution of power relations. Equally significant, space is no longer conceptualized primarily in terms of the physical location of material objects. Instead, both material spatial practices, as well as symbolic or representational spaces, are examined.

As political economy approaches swept through the social sciences in the 1970s and 1980s, the spatial constitution of material interests was linked explicitly to the geography of social movements. The relationship between the geography of political and economic conditions, and the incidence of protest is demonstrated in detail in Charlesworth's (1983) atlas of rural protest in the UK. Bennett and Earle (1983) show that the failure of socialism in the USA can be linked directly to geographic patterns of wage and skill differentiation; where differentiation was substantial, working class solidarity was undermined (see *Labor Movements, History of*). Similarly, Massey (1984) argues that the spatial division of labor affects directly the material interests that underlie political movements. Markusen (1989) makes a somewhat different point: a region's stage in the profit cycle shapes the types of movements that are likely to emerge in it. Environmental movements are more likely to emerge

in economically booming regions where rapid growth places stress on the environment, while pro-growth politics are common in regions of decline (see *Social Movements: Environmental Movements*).

Geographically differentiated state systems also shape the geography of social movements. Kitschelt's (1986) comparison of the political structures of France, Sweden, West Germany, and the USA shows that differences in central state structures are related to national-level variations in anti-nuclear mobilization. Other studies link local-level variation in social movement mobilization and success to differences in political opportunity structures among local states (Duncan et al. 1988, McAdam 1996, Tarrow 1996). In the USA many social movements began as highly localized movements in politically opportune places, then spread nationally (see *Citizen Participation*).

Symbolic or representational spaces affect the geography of social movements as well. The symbolic codings of spaces, i.e., the often subtle and unacknowledged signs that shape people's reactions to spaces, may indicate belonging for some groups and exclusion for others, empowerment for some groups and repression for others, safety for some groups and danger for others. Such codings can foster or hinder social movement mobilization. The creation of symbolic space is intertwined with the process of collective identity formation, as Marston (1988) shows for ethnic identity, Rose (1993) demonstrates for gendered identity, and Ruddick (1996) illustrates for interlocking 'race,' class, and gender identities (see *Social Movements and Gender*). Such identities are crucial to the formation of solidarity necessary for movement mobilization (see *Social Movements, History of: General*). The dominant symbolic codings of space are open to contestation, and counter-representations are often constructed by insurgent groups. Representational spaces, and their internalization, relate directly to the ways in which social movement messages resonate in some places, and not in others.

1.3 Place and the Analysis of Social Movements

Many geographic analyses emphasize the place-based constitution of social processes. Place is best understood as a multidimensional concept entailing 'locale,' i.e., the geographical setting of everyday social relations, 'location,' i.e., geographical position vis-a-vis wider scale interactions; and 'sense of place,' i.e., the esthetic and emotional bonds to locale (Agnew 1987). The concept of place stresses the unique ways in which social processes may interact in specific milieus, calling our attention to the 'situatedness' of all human action and institutions. At the same time, place is not to be equated with 'the local.' Place implies the articulation of localized processes, with other processes operating at broader scales.

Much of the geographical literature on social movements stresses the ways in which identities and allegiances are shaped in place. Thrift and Williams (1987) analyze the ways in which consciousness and identity are produced through place-specific social practices and the time–space paths of individuals' everyday lives. Katznelson's (1981) work can be interpreted as a place-sensitive analysis of US workplace and community politics, stressing how distinct places shape identity in distinct ways. Savage's (1987) analysis of British working-class politics demonstrates how the interactions of workplace and lifeworld spaces have effects on identity that vary from place to place. Recent work on identity construction stresses the place-specific interplay of spaces of production, reproduction, and the state that produce multiple, fragmented, and sometimes contradictory identities, all with direct implications for social movement mobilization (Ruddick 1996, Cope 1996, Brown 1997). Place itself can be a primary basis for collective identity construction. The defense of places associated with specific collective identities is a common theme of many new social movements (Melucci 1994). Increasingly, cities find themselves in competition with each other for capital investment; in response, place-based identification and coalition building has often taken precedence over class and other axes of social identity (Hudson and Sadler 1986, Swyndegouw 1989).

Identity is not all that is shaped in place. Agnew (1987, p. 59) observes that 'different places produce different degrees and orientations of organizational capacity.' Routledge (1993), for example, shows that social and environmental movements in India faced opportunities for, and constraints to, mobilization that relate to place-specific social networks, systems of meaning, and patterns of political repression. Miller (2000) shows how a variety of place-specific characteristics, including political opportunity structures, available resources, material interests, and attachments to place, shaped the strategies and effectiveness of peace-organizing differentially in several Boston area municipalities.

1.4 Scale and the Analysis of Social Movements

The concept of place clearly carries within it issues of geographic scale. Geographic scale has commonly been thought of as a fairly straightforward technical issue relating to the telescoping frame of geographic analysis (from local to global), but such a notion of scale as pre-given or unproblematic is increasingly challenged.

Most analyses of social movements assume that the appropriate scale of analysis is that of the nation state, but such an assumption overlooks the often critical subnational, as well as international, constitution of

social movement processes. Moreover, rather than being seen as an 'external fact awaiting discovery,' scale should be viewed as a 'way of framing conceptions of reality' (Delaney and Leitner 1997, pp. 94–5) that is employed by social movement organizations and their opponents as a way of gaining political advantage. As Smith (1993, p. 90) explains:

> The construction of scale is not simply a spatial solidification of contested social forces and processes; the corollary also holds. Scale is an active progenitor of specific social processes. In a literal as much as metaphorical way, scale both contains social activity and at the same time provides an already partitioned geography within which social activity takes place. Scale demarcates the sites of social contest, the object as well as the resolution of contest.

2. *Geographic Tactics and Strategies of Social Movements*

Given that all social movements are geographically constituted, all social movement organizations must make decisions regarding the geographic tactics and strategies they employ. Sometimes these decisions are explicitly considered, often they are not.

Social movements frame their messages in particular ways that they hope will resonate with particular groups. Given a highly differentiated geography of culture, symbolization, and interests, the resonance of any given frame will depend in substantial measure on the geographic targeting of the message. Similarly, the recruitment of social movement members is intertwined inextricably intertwined with the geography of mobilization activities (Harvey 1985, Miller 2000).

While identities constructed in place and place-based identities frequently are central to social movement solidarity, the absence of such bases of solidarity can be rectified through efforts to construct new places of group interaction and identity. Castells (1983), for example, details how the growth of gay bars, businesses, and gathering places was crucial to the construction of shared identity in the San Francisco gay community. Castells also shows how, in the case of the Madrid citizens' movement, the construction of a community center in the Orcasitas shantytown was essential to breaking down social walls and building broad, place-based bonds around which the movement organized.

The tactics and strategies that social movements employ to challenge the existing social order are rooted in an often-unexamined normative geography. Cresswell (1996) makes a compelling case that spatial structures and systems of places provide ideologically-loaded schemes of perception. Dominant conceptions of what is 'normal' and 'appropriate' is defined 'to a significant degree, geographically, and deviance from this normality is also shot through with geographical assumptions concerning what and who belong where' (p. 27). He illustrates his argument with several examples, including that of the Greenham Common women's peace camp that challenged British participation in the nuclear arms race through 'out of place' behavior that 'denaturalized the dominant order [and] showed people that what seemed natural, could, in fact, be otherwise' (p. 125).

Indeed, social movements can be mobilized and social conditions can be changed through a re-symbolization of existing spaces or through a re-territorialization of existing symbolization (Pile and Keith 1997). Harvey (1989, p. 233) makes a case for the re-symbolization of space when he argues:

> If workers can be persuaded … that space is an open field of play for capital but a closed terrain for themselves, then a crucial advantage accrues to the capitalists … power in the realms of representation may end up being as important as power over the materiality of spatial organization itself.

An example of the re-territorialization of existing symbolization can be found in the recent work that has been done in several US metropolitan areas to recast the ongoing political battles between central cities and suburbs. In several metropolitan areas this common conception of territorial interests is being replaced with one that aligns the central cities with the inner ring suburbs, creating a far more powerful territorial alliance behind the movement for a more equitable metropolitan distribution of affordable housing, school funding, and tax revenue (Orfield 1997).

Many of the efforts of social movements to redefine the spaces of struggle involve attempts to 'jump' to a more favorable geographic scale (Smith 1993). In addition to changing symbolic geography, altering the scale of material processes can be central to social movement strategy. Examples include shifting from regional to national-scale labor bargaining (Herod 1998), and seeking out more favorable political opportunity structures at a different level of the state, e.g., local rather than central (Miller 2000).

The geographic tactics and strategies adopted by social movements and their opponents play a powerful role in the nature of social movement mobilization and the degree of success or failure social movements achieve.

Social Movements, History of: General

Social movements, according to sociologist Sidney Tarrow's definition, are 'collective challenges, based on common purposes and social solidarities in sustained interaction with elites, opponents and authorities' (Tarrow 1998, p. 4). This definition, derived from studies of both historical and contemporary social movements, locates the earliest movements in the late eighteenth and early nineteenth centuries. The emergence of social movements was contemporaneous with: (a) the increased centralization of national states that accompanied war and revolution in western Europe and North America; (b) the rise of the popular press and the circulation of notions of natural rights and liberty put forward by Enlightenment and revolutionary thinkers; and (c) particularly in England and the English-speaking colonies of North America, the rise of evangelical and nonconforming religions in which literacy and reading were cultivated and principles of human rights formulated. From that period and place, social movements have proliferated to the world.

The chief focus of this article is the history of social movements in the West that have attracted most scholarly attention; it draws particularly on studies done in the years 1975–2000—a period in which the concept of social movement has been redefined and developed—for its theoretical framework and empirical base. The British movement for the abolition of slavery—an emblematic, and by some criteria the first social movement—serves as a concrete example of an early crusade that embodied many of the central features of the phenomenon.

1. The Abolition of Slavery in Great Britain

The eighteenth and nineteenth century British abolitionist movement was distinctive in that it was aimed at an institution which had only a minor presence in Great Britain, whereas most social movements have been concerned with issues close to hand. Slavery nevertheless involved many Britons: British ships sailing from Liverpool were active in the slave trade carrying slavers to Africa and slaves to the Americas, and the 'peculiar institution' was common in Britain's North American and universal in its Caribbean colonies. The question of the legality of slavery in Britain was raised as early as the 1720s, but it was not until 1772 that Lord Chief Justice Mansfield ruled that slavery was illegal under English law. English members of the Society of Friends had developed the earliest critique of slavery as contrary to Christian teaching, and local Quaker meetings first excluded slave traders in 1761 and later slave owners from membership.

Quakers then turned to political action to end British involvement in the slave trade, establishing in 1787 the Society for the Abolition of the Slave Trade, commonly known as the London Committee. This organization welcomed non-Friends as members, and recruited both middle and working-class adherents. The political technique utilized by the Committee in this and later campaigns was mass petitions to Parliament. Thomas Clarkson, a gifted organizer, and other activists worked outward from London and local Friends meetings to form regional organizations, recruit members, distribute leaflets, and collect signatures on petitions to Parliament calling for the end of the slave trade. (Clarkson and his associates began their crusade with an exclusive focus on the slave trade, as less contentious than abolition.) Visual images portraying the horrors of the slave trade such as a print of the cross section of a slave ship with its tightly packed human cargo and Josiah Wedgwood's medallion of a kneeling chained slave, inscribed with the motto 'Am I not a Man and Brother?' were highly effective in attracting supporters.

There was an outpouring of support, with about 60,000 male signers on the first petitions, including 11,000 men from Manchester, the center of the burgeoning cotton spinning industry. Parliamentary sympathy for the cause seemed strong up to 1792, when 519 petitions with up to 400,000 signers were collected. However, legislative support dropped with the slave revolt in Haiti, the contemporaneous radicalization of the French Revolution, and the outbreak of war against France. In 1794, the House of Lords decisively rejected the abolitionist resolutions presented to it.

Political opportunities for action on abolition reappeared in 1804, after Britain's victories in the Napoleonic Wars and its seizure of the French Caribbean colonies. Clarkson and other organizers again canvassed the country seeking signatures; he also sought support from members of Parliament, in particular William Wilberforce, an Evangelical MP from Yorkshire who spoke eloquently about the evils of the trade and Samuel Whitbread, a nonconformist Protestant already known as a social reformer. Clarkson's powers of persuasion and his Parliamentary allies combined to produce in 1807 a majority vote in Parliament to forbid British ships' participation in the slave trade to both British possessions and foreign slave-holding colonies. The African Institution, founded in the same year, took as its task ascertaining the effectiveness of the British legislation.

Although British diplomats signed agreements eschewing the slave trade with other European powers, and indeed paid compensation when they did, the results were uneven. British activists resolved to continue their efforts, founding the Society for the Amelioration and Gradual Abolition of Slavery (known familiarly as the Anti-Slavery Society) in 1823 and the Agency Committee (1831), which demanded immediate and unconditional slave emancipation. The Agency's professional organizers traveled around England, promoting local petition drives and pressure on candidates in the Parliamentary elections to declare their support of full abolition. Members of the House of Commons elected under the 1832 Reform Act were ready to vote for the abolition of slavery in British possessions, but the House of Lords was not. The outcome was a compromise Emancipation Act of 1833 that set August 1, 1834 as the date on which slavery would end, but stipulated a complex gradual process to complete freedom.

The former slaves would become 'apprentices,' working for pay three-quarters of their time for their ex-masters; one-quarter of the ex-slaves' time was to be reserved for them to cultivate their newly-granted plots. Slave owners would be compensated by the state for the loss of their 'property.' The story did not end there, however. Disagreements about strategy between the Anti-Slavery Society (which had accepted the compromise Emancipation Act) and the Agency (which had not) continued, and the latter established yet another organization (the Central Negro Emancipation Committee) and sought to persuade Parliament that oppressive conditions still prevailed. In

the end, the complex system based on the 1833 Act proved difficult to manage, and the planters themselves ended apprenticeship in 1838.

The international abolition movement matured in the 1830s, and began to hold annual congresses (which some American abolitionists attended) in 1840. The United States Civil War (1861–5) was the outcome of a series of legal and political disputes about slavery and state's rights. In 1863 President Abraham Lincoln's Emancipation Proclamation ended slavery in the Confederacy, and during the postwar Reconstruction the Thirteenth, Fourteenth, and Fifteenth Constitutional amendments (which completed abolition, made the ex-slaves citizens, and guaranteed their right to vote) were ratified. The abolition of slavery in Cuba (1886) and Brazil (1888) ended legal slavery in the West.

2. *The Social Character of Movements*

Over the period 1975–2000, sociologists have begun to define 'contentious politics'—confrontations of ordinary people with authorities and/or elites—as the building blocks of social movements. Sidney Tarrow defines the conditions under which contentious politics is triggered:

> When changing political opportunities and constraints create incentives for social actors who lack resources on their own, they contend through known repertoires of contention and expand them by creating innovations at their margins. When backed by dense social networks and galvanized by culturally resonant, action-oriented symbols, contentious politics leads to sustained interaction with opponents. The result is the social movement (Tarrow 1998, p. 2).

The case of the British movement for the abolition of the slave trade and slavery illustrates this definition:

(a) the movement was collective and interactive, between authorities and the populace; it was conducted early on through organizations established for the purpose and spread by movement professionals;

(b) it was aimed at political authorities (in this case Parliament) which could take action to achieve the movement's goal;

(c) each phase of activism on abolition began with an opening of political opportunity and ended when new political constraints closed off forward movement;

(d) the network of Quaker meetings was the first activated in the cause, but other church groups and local branches of the anti-slavery societies joined the abolitionist network over the period;

(e) interaction was contentious and drew on symbols that helped promote action;

(f) and participation in the movement came to be perceived by activists as constitutive of their identities.

3. *Woman's Suffrage in the United States*

The formation of the United States woman's suffrage movement was closely connected to the social groups and organizations that promoted the abolition of slavery there. For example, American woman's suffrage activists Lucretia Mott and Elizabeth Cady Stanton first met each other at the London World Anti-Slavery Convention of 1840, where they discussed the possibility of organizing an organization to promote women's rights. Mott, a New Englander then living in Philadelphia and the senior of the two had founded the first Female Anti-Slavery Society in the United States; her home was a stop on the 'underground railroad' through which slaves escaped to Canada and freedom. The well-educated daughter of a judge, Stanton was born in western New York State, married an abolitionist leader, and eventually settled with her family in Seneca Falls, NY. Stanton and Mott renewed their acquaintance in 1848, when they and three like-minded women issued a call to a women's rights conference in the summer. To their surprise, some 300 women and men came, applauded Stanton's speech echoing the Declaration of Independence and passed a resolution on women's suffrage: 'Resolved, that it is the duty of the women of this country to secure to themselves their sacred right to the elective franchise.'

The movement developed slowly through annual conferences, spreading primarily to the Middle West and East coast. In 1851, Stanton met Susan B. Anthony, then a paid organizer in the temperance movement. Anthony brought her organizational skills to women's rights, beginning a drive in 1854 based on organizers in each county of the state of New York who recruited local women. These in turn collected signatures for a petition calling for women's control of their own earnings, mothers' guardianship of children in divorce, and women's suffrage. The first concrete accomplishment—a New York state law granting women property rights—was passed in 1860.

With the outbreak of the Civil War in April 1861, organizing efforts were temporarily suspended. Not for long, however, as Anthony and Stanton reactivated their abolitionist and women's rights networks in 1863, issuing a call to a mobilization meeting in New York. The outcome was the National Women's Loyal League that set to work gathering close to 400,000 signatures on a petition for the Thirteenth constitutional amendment that would free the slaves. Women also served on the Civil War Sanitary Commission, which raised funds and organized and administered nursing and support services for the military hospitals and convalescent centers.

The campaign for ratification of the Fourteenth and Fifteenth amendments (the first made male ex-slaves citizens and the second granted them the vote) split the former abolitionist movement colleagues between those who supported rights for the ex-slaves as a first

priority, and those who supported universal suffrage. In 1869, two new organizations dedicated to women's suffrage emerged from the split: the National Woman Suffrage Association founded by Anthony and Stanton which objected to the Fourteenth and Fifteenth Amendments because they specified male ex-slaves; and the American Woman Suffrage Association, founded by Lucy Stone, her husband Henry B. Blackwell, and Mary Livermore. These associations pursued the cause by different methods and separately for 20 years during which the westward movement was completed, the country industrialized, and new women's associations such as the Women's Christian Temperance Union (1874) and the National Association of Colored Women (1895) were founded. In 1890, the National and the American Associations merged to form the National American Woman Suffrage Association, with Elizabeth Cady Stanton as its first president; she was succeeded two years later by Susan B. Anthony who served to 1900.

Led after 1900 by Carrie Chapman Catt, a gifted organizer the National American Association continued its strategy: seeking constitutional change state by state. Catt resigned in 1904 to play an active role in founding the International Woman Suffrage Alliance launched that year. There was little activity around the woman suffrage ('Susan B. Anthony') amendment to the United States Constitution for over 10 years. New tactics appeared in 1913, devised by the more militant new movement recruits Alice Paul and Lucy Burns who were appointed to the National American Suffrage Association's Congressional Committee. They promptly organized a demonstration of some 5,000 women who marched in Washington in support of a constitutional amendment the day before Woodrow Wilson's inauguration for a second term. Despite the organization's permit for the parade, the police were unprepared for the crowd reaction and the women were mobbed and jeered. Later that year Paul and Burns established the Congressional Union, and their organization eventually became independent of the National American, which continued to pursue its state-by-state strategy, with only slow progress.

In 1915, Carrie Chapman Catt agreed to lead the campaign for women's suffrage in New York State, and once again became president of the National American Suffrage Association with a newly energetic board committed to her plan for a renewed campaign for a national constitutional amendment. (The Congressional Union and its successor the Woman's Party did not join the effort. The Woman's Party nevertheless contributed to the process by courting arrest through disruptive and provocative action, which made the National American's actions look reasonable.) At its convention in late 1917 the latter warned that if Congress did not approve the suffrage amendment before the next election, it would adopt the British suffragette method: opposing the election of Congressional candidates who opposed the federal amendment, no matter what their party. The amendment passed in the House of Representatives by the required two-thirds majority in January 1918, the Senate in 1919, and ratification by the requisite proportion of states was completed in 1920.

4. *Twentieth Century Social Movements: Italian Fascism*

In the early twentieth century, several movements demonstrated unequivocally the adaptability of the social movement to regressive ends. The Italian Fascist movement serves as an example.

After the end of World War One late in 1918, Italy was swept by waves of contentious politics: demobilized troops demanded jobs; peasants and agricultural laborers agitated for land; consumers called for price controls; and workers struck for higher wages. Among the groups engaging in collective action were the *fasci di combattimento* founded by Benito Mussolini (formerly a revolutionary socialist) who convened the first *fascio* in Milan on March 21, 1919. At a public rally two days later the national program was only vaguely described (it was not fully formulated and publicized until months later). The program called for integration of all Italian 'national' territory into the nation, and pledged to oppose all neutralist politics no matter the party involved; other radical social and political demands included universal (male) suffrage, a constituent assembly, a republic with local autonomy, the eight-hour day, worker participation in factory management, land to the peasants, elimination of the Senate and all noble titles, and an end to conscription, expropriative taxes, speculation, and monopoly.

The Fascists' first public action (April 15, 1919) was a counter-demonstration together with students, World War veterans, and revolutionary syndicalists which attacked an anarchist/socialist march protesting repression in Milan. It ended with the sacking and burning of the headquarters of the socialist newspaper *Avanti*! In the next two years most Italian popular contention was dominated by socialists and organized social Catholics (represented by the newly-founded Popular Party) who both sought to control and lead the strikes in northern industries and large-scale agriculture in the Po Valley, the land occupations, and eventually in fall, 1920, the factory occupations. These struggles all occurred in northern Italy, where socialist and Popolari strength was concentrated. The Fascist counterattack from its urban bases (again in the north) began in the same period: physically assaulting unionized farm workers on strike, the headquarters of peasant leagues, cooperatives, and unions, burning left wing newspapers' offices and printing plants, and breaking up meetings of the socialist communal councils as well.

Socialist and Popular Party organizations crumbled as Fascist membership and attacks both increased.

The Fascists had become a political force to be reckoned with and their success went hand in hand with the demobilization of the left. In August 1921, Mussolini signed the so-called Pacification Pact with the socialists and Popolari, promising to eschew violence, but his followers forced him to back away from the agreement and he publicly renounced it later in the year. He also announced the formation of a political party, which he described as a rival to the state, outside traditional politics. Violent clashes between socialists and Fascists continued into 1922, when the Fascist threat to seize the state forced the cancellation of a general strike planned by an ad hoc group of unions; by then the entire Po Valley, and much of North and Central Italy was in Fascist hands.

As the constitutional parties called for a new government, Mussolini threatened to march on Rome to seize power. The march never happened; instead, Fascist Black Shirts occupied provincial government and party headquarters, post offices, and police stations (again in the north, where socialist power had been concentrated) sometimes without resistance. Fascist threats and his own concerns led the king to refuse to sign the declaration of martial law which the prime minister had drawn up, and Mussolini's first government (based on a coalition of center and right parties) was formally constituted on October 31, 1922. Mussolini used nationalism wreathed in patriotism as a weapon against the left, and he continued to be a master of language and image once in power.

Although there had been social movements in the European colonies (and in China, as well) before the outbreak of World War I in 1914, there were many more non-Western movements in the twentieth century; they ranged in principal concerns from nationalism to widow burning and female circumcision (in India and Kenya respectively). Nationalists sometimes rejected Western notions of modernity and connected customs that seemed unacceptable to Westerners to colonial cultural authenticity. Two examples are Mahatma Gandhi in his representation of himself with a spinning wheel and in his advocacy of *khadi* (handspun and woven cotton cloth which he himself wore in his later years), and Kenyan nationalist Jomo Kenyatta who defended female circumcision on behalf of the Kikuyu Central Association, a pre-independence nationalist organization. More recently, televised news reports and rapid communication by telephone, fax, and e-mail have made possible the almost instantaneous transmission of news not only in print, but of visual images as well. To what extent can we speak of transnational social movements?

5. *Transnational Social Movements*

The above discussion of anti-slavery and women's rights as social movements notes the international dimensions that were integral to social movements even in the late eighteenth century; similarities and connections of social movements across borders are not new. Sidney Tarrow offers a more restrictive definition of a transnational social movement:

> sustained contentious interactions with opponents—national or nonnational—by connected networks of challengers organized across national boundaries … What is important … is that the challengers themselves be both rooted in domestic social networks and connected to one another more than episodically through common ways of seeing the world, or through informal or organizational ties, and that their challenges be contentious in deed as well as in word (1998, p. 184).

Tarrow discusses three movements that fit his definition: the contemporary ecological and environmental movement, the European and American peace movement of the 1980s, and Islamic fundamentalism.

The ecological/environmental movement, which mounted coordinated worldwide Earth Day demonstrations in the late 1970s and early 1980s, provides the example discussed here. Some of its social movement organizations and their coordinated activities across borders do qualify as transnational organizations, as Tarrow demonstrates. Greenpeace, for example, has been a genuinely transnational social movement organization, with professional organizers and offices in many countries, and supporters who share a common world view and are willing to support its advocacy. Founded in Vancouver, Canada, according to its 1992–3 report it had over five million supporters (contributors), 43 offices, and over a thousand paid employees. It developed out of domestic movements that had similar goals, organized advocacy networks, and conducted contentious politics that cross national boundaries. Its members and sympathizers demonstrated against French nuclear testing in the Pacific and against abusive fishing for whales by Japanese and Soviet whalers.

Nevertheless, most international connections are less sustained and less professionalized than Greenpeace. Not all issues can attract support across the varied conditions of world polities, and most political, social, and economic international movements continue to work within states and national-level private institutions like large business organizations or labor unions rather than through transnational voluntary associations which represent individuals' world views directly.

6. *Overview: Social Movements from the Eighteenth to the Twentieth Century*

Sidney Tarrow's definition of the social movement (quoted in the opening sentence of this article) posits its applicability to the entire period since the first appearance of social movements in the late eighteenth century up to the present. His definition is based on the premise that although the issues and tactics of social

movements have changed over the two centuries in which they have proliferated the defining form of social movements—their collective nature, common purposes, and shared base in social solidarities with roots in the social structure in which they occur—have remained relatively unchanged. Not all social movement scholars agree with this premise; among European sociologists and political scientists in particular the concept of 'new social movements' has been developed since 1985.

Kriesi et al. (1995) argue that a new type of social movements which address similar issues yet vary significantly in form according to the national political context has emerged in Western Europe since 1968. Kriesi and his colleagues emphasize contemporary cross-national variation in domestic politics and corresponding differences in the timing and other characteristics of social movements. The examples that they discuss under the rubric of new social movements include 'the ecology movement (with its antinuclear energy branch), the solidarity movement (with the Third World), the contemporary women's movement, the squatters' movement, as well as various other movements mobilizing for the rights of discriminated-against minorities' such as gays (1995, p. xii). The new type of social movements discussed by Kriesi et al. (1995) is classified according to the chief constituencies of the movements and the connections among them. Tarrow's definition of social movements leaves open the characteristics of their members and their goals and stresses the movements' longstanding form. Two alternatives present themselves: in terms of their political concerns and context then, recent social movements may herald changes in some aspects of movement politics and require redefinition of the concept. Alternatively, the broad definition with which this article begins argues for stability in the form of social movements even as the issues that bring them into the public arena change. Whether either one of these alternatives will contribute to understand contemporary and future social movements better is an empirical question that can only be determined with a longer span of observations.

Social Movements: Psychological Perspectives

Social movements are sustained actions undertaken by organized groups of people seeking social or political change. The groups involved in social movements are structured, have goals and ideologies, and pursue their goals over time. The psychology of social movements focuses on the motives that lead people to join, work on behalf of, and stay within social movements.

One reason for people to join social movements is because of the desire to adopt a favorable identity and/or engage in positive actions. Social identity theory notes that people use groups to define themselves, so joining a group is one way to create a favorable identity (Tajfel 1982, see *Social Identity, Psychology of*). When people identify with a group, they take on the values and lifestyle of that group, seeing themselves as defined through the attributes that define the group. People joining a sports team, for example, will come to think about themselves in terms of their athletic ability—a prototypical attribute of the group.

In addition to giving people values or attributes to define themselves, identifying with groups provides people with information about their self-worth. Since people value positive self-worth, they are more likely to identify with and join a group when the group they join has a favorable reputation. Of course, people can also work collectively to better the reputation of their group, as in the gay rights movement, the civil rights movement, or other social movements motivated by the desire to enhance the stature of low status groups (Kelly and Kelly 1994, Simon et al. 1998). Social identity theory suggests one motivation for joining social movements—to create a favorable identity and to work on behalf of the values and lifestyle that identity represents. Although this is an important motivation for social movements, this positive motivation has not been the focus of most of the

psychological research on social movement participation. Instead, the focus has been on protest movements, which people join in response to perceived injustice. That motivation is explored in several theories, the earliest being the theory of relative deprivation.

1. Relative Deprivation

The factors that shape the generation of the grievances that lead to social movements are first addressed by the psychological literature on relative deprivation. This literature argues that people's feelings about their social conditions are only loosely connected to their objective situations. Instead of developing directly from people's objective circumstances, subjective feelings of satisfaction and dissatisfaction are linked to the comparisons that people make of their own outcomes to other outcomes. This work makes the important point that it is the interpretation of grievances that is key to their role in shaping social movements (see Klandermans 1989).

One type of comparison involves temporal comparisons of one's current outcomes to one's outcomes at some other point in time. Temporal comparisons are the basis for several of the best known models of the psychology underlying the development of social movements (Davies 1962, Gurr 1970). Gurr (1970) distinguishes among several different patterns of relative deprivation, each of which can create the necessary conditions for social movements. The best known pattern is progressive deprivation, which describes a situation in which both prospects and expectations are rising, but expectations are rising higher (Davies's 'j-curve'). In this case, the discrepancy between expectations and prospects increases, leading to dissatisfaction and support for social movements.

A second type of comparison involves social comparison to the outcomes of others. Again the key point is that people's satisfaction is not directly linked to the objective quality of their outcomes. Instead, it is comparative. The main question is how people decide to whom to compare the outcomes they receive (Suls and Wills 1991).

Studies suggest that when people are comparing their outcomes to standards, they apply principles of entitlement or deservingness (see *Justice: Social Psychological Perspectives*). Use of these justice-based principles shows that people's feelings about outcomes are linked to their assessments of their fairness. The importance of evaluations of outcome fairness ('distributive justice') has been compellingly demonstrated in the literature on the distribution of rewards in work settings, where equity is a central principle of justice. This literature shows that people are most satisfied when they receive equitable outcomes (Walster et al. 1978).

Justice theories also suggest that people react to the way that outcomes are distributed, that is, to the process of decision making, and to their treatment during that process ('procedural justice,' Thibaut and Walker 1975). Studies demonstrate that people's assessments of the fairness of procedures shape their satisfaction with their outcomes and with authorities and institutions (Tyler et al. 1997, Tyler and Smith 1997).

These findings link people's motivation to join social movements to their views about the fairness of social outcomes and procedures. In particular, they suggest that people react negatively to experiencing unfair procedures. However, the experience of injustice can potentially lead to either individual or collective actions: people can respond to perceived injustice by acting as an individual, or they can join a group. Only those actions that involve a collective response to injustice are relevant to the issue of social movements.

2. When do People Act Collectively?

Early research on both distributive and procedural justice focused primarily upon the feelings of the individuals who experienced justice or injustice. On this level, there was widespread evidence that justice played a central role in shaping people's feelings and behaviors. Further, people both reacted to their own experiences of justice or injustice and acted to provide justice to other people when they observed injustice. However, most of this research did not acknowledge that justice can also be conceptualized and responded to on the level of groups, not individuals. People can think about injustice in terms of unfairness to groups and they can respond to injustice on a group level. The perception of group level injustice is the key to the development of social movements.

The first crucial insight is that people can think about injustice in terms of unfairness to groups. This insight is contained in the early distinction between egoistical and fraternal deprivation (Runciman 1966). Instead of being concerned with personally receiving fairness, people can judge the fairness received by groups. Psychologists have increasingly recognized that group memberships are an important element in people's self-definitions (Hogg and Abrams 1988) and this has heightened attention to people's reactions to the experiences of the groups to which they belong, as well as to their own personal experiences.

The key issue is how people interpret experiences, that is, their view about the reason for the injustices they experience or observe. If people feel that the injustice is occurring to someone as an individual person, either themselves or someone else, and is due to their personal actions, they will respond personally. If they feel that the injustice is occurring to someone due to their membership in particular groups, or to all the people who share a common group membership, they will respond collectively.

Social identity theory argues that the way people interpret their experience is determined by how they

think about people. In particular, people are influenced by the degree to which they construct their sense of self in terms of the groups to which they belong (Hogg and Abrams 1988). To the degree that people think of themselves or others in personal terms, they interpret experiences as reflecting unique personal characteristics and behaviors, and they think about fairness in personal terms. To the degree that they think of people in terms of the group(s) to which they belong (their 'social' self), they interpret experiences as reflecting treatment as a member of groups and think about justice in group terms.

Studies confirm that those with strong social-selves are more likely to interpret experiences as being shaped by others attitudes toward the groups to which they and others belong, and to respond to injustice by engaging in collective behavior (Grant and Brown 1995, Kelly and Kelly 1994). So, thinking about injustice in collective terms leads to acting collectively in response to injustice, for example, by joining social movements.

Decisions about whether to respond to injustice individually or collectively are not only shaped by judgments about why injustice is occurring. Choices among possible behavioral responses are also influenced by people's judgments about the intergroup situation (Ellemers 1993). For example, people are influenced by their assessments of the permeability of group boundaries. If people believe that it is possible for individuals to move from low status groups to higher status groups, they are more likely to act as individuals. If people believe that the group's boundaries are not permeable, they are more likely to act collectively to raise the status of their group. Interestingly, studies suggest that very few low status group members need to be successful for people to view the group's boundaries as sufficiently permeable to justify individual, as opposed to collective, action (Wright et al. 1990).

People are also influenced by the perceived stability of group status. When they believe that group status can change, people are more likely to act collectively on behalf of the group. People are similarly affected by their views about the legitimacy of the status of existing groups. If people view current social arrangements as illegitimate, they are more likely to engage in collective action to change them (Major 1994).

Finally, people are influenced by pragmatic concerns. They respond to their sense of the probable gains and losses associated with various types of actions (Klandermans and Oegema 1987). When people decide that injustice has occurred, their general behavioral reaction is to do nothing. This inaction reflects the real risks associated with confronting powerful others, and an objective recognition of the low likelihood of success. On the other hand, risk is not enough of an explanation for people's behavior. For example, although the willingness to engage in collective action is influenced by the likelihood of success (Klandermans 1997), studies of collective action suggest that people often engage in collective actions against injustice even when the likelihood of success is small.

Similar factors shape people's motivation to engage in groups for positive, identity based, reasons. If people feel that their identity is firmly rooted in their group membership (stability), they will act to try to build the stature of their group through collective action. An example is ethnicity, which is often linked to physical appearance. If people feel that their status is not changeable, they are more likely to identify with that group, and to work to improve its status. Of course, such identification can also be strong when physical appearance is not involved. For example, many people identify strongly with being gay, even though they could 'pass for straight.' However, when people are members of a low status group they are more strongly tempted to leave the group as an individual and join a higher status group, instead of defining themselves in terms of group membership.

3. *Types of Collective Responses to Injustice*

Two dimensions distinguish among collective responses to injustice. One dimension is sustained vs. temporary action. The other dimension is normative vs. nonnormative.

Many of the most dramatic and widely seen collective responses to injustice are temporary events. Riots have this quality. They erupt quickly in response to some instance of injustice that reflects underlying issues of injustice. Riots typically spread rapidly and widely, and end quickly. They are not sustained and have little formal structure, or even a clear agenda beyond responding to an injustice. In contrast, social movements have leadership structures, political agendas, and long-term plans. Such movements may engage in actions such as violent protests, but these actions are typically planned and in the service of long-term goals.

The second dimension of collective movements distinguishes normative vs. non-normative responses to injustice. People can work for groups within the context of social norms in the political process to get their candidate elected. They can also step outside of social norms to engage in illegal and even violent social protests.

4. *Summary*

The psychological perspective on social movements examines the factors that encourage people to join and participate in social movements. Studies suggest that the experience of injustice is key to the development of a personal sense of grievance. When injustice is viewed as being linked to group membership, it is likely to

lead to participation in collective actions, such as social movements.

Social Movements: Resource Mobilization Theory

Resource mobilization theory (RMT) is premised on the idea that the central factor shaping the rise, development, and outcome of social movements is resources. 'Resource' here is taken broadly to mean any social, political, or economic asset or capacity that can contribute to collective action. Thus, solidarities and cultural outlooks of groups that enable them to act collectively as well as individual resources, such as communication skills, discretionary time-schedules, and independence from negative constraints, as well as organizational resources (e.g., leadership, meeting and communication facilities, and an *esprit de corps*) are relevant. Drawing on a rational choice approach to collective action, RMT views social movements as collective attempts to bring about change in social institutions and the distribution of socially valued goods. Typically hailed as the dominant paradigm in contemporary social movement research, some have contended that it is opposed by a rival 'new social movement' approach (Dalton and Kuechler 1990) but recent developments (discussed below) have shown that most arguments about the formation of collective identities and the role of values and social networks in collective action can be integrated into RMT. Research informed by RMT has focused on three major issues: (a) the microprocesses giving rise to individual participation; (b) organizational processes shaping mobilization; and (c) the political opportunities that guide social movement development and outcomes.

1. Collective Goods and Individual Participation

Early RMT argued that grievances stemming from structural strains and relative deprivation are secondary or possibly irrelevant to movement partici-

pation and that what changes, giving rise to social movements, is the availability of resources (McCarthy and Zald 1987, Jenkins and Perrow 1977). This assumption, however, has been questioned as researchers have shown that grievances in the sense of articulated collective claims about social injustice, including suddenly imposed grievances (Walsh and Warland 1983), are critical to individual participation. Drawing on rational choice assumptions, some point to the utility calculations of participants, arguing that they respond to perceived costs and benefits (Opp 1989), including the incentives of solidarity and self-esteem flowing from acting on principle. A major focus of debate has been Olson's (1971) theory of collective action according to which selective incentives (i.e. individual benefits) are critical to participation while collective goods *per se* create free riding. Arguing against this selective incentive thesis, Klandermans (1995) shows that most free riding is due to ignorance, high perceived costs in terms of work and family obligations, weak integration into interpersonal networks which provide both information and solidary incentives, and the perceived irrelevance of participation. Marwell and Oliver (1993) argue that free riding is an option only when individuals perceive that their contributions to the collective good follows a decelerating production function (i.e., each contribution makes others' subsequent contributions less worthwhile). Mass mobilization follows an accelerating production function (i.e., each contribution makes the next one more worthwhile). Hence, there may be large start-up costs to collective action but there is no point of diminishing returns. Thus, the key questions are expectations about the number of likely participants and the likelihood that the goal will be achieved.

RMT argues that collective identity and solidarity stemming from interpersonal networks provide for participation. Marwell and Oliver (1993) contend that organizers (or movement entrepreneurs) pay much of the start-up costs by building solidary networks, developing injustice frames (Snow et al. 1986), and creating collective perceptions of an accelerating production function. Klandermans (1997) shows that both selective and collective incentives matter with some movements depending more on selective incentives and others on collective commitments to movement goals. Thus, the women's movement and unions rely more on selective incentives while purposive commitments are paramount to the peace movement.

2. *Organizational Processes*

Zald and McCarthy (1987) argue that contemporary movements are professionalized, led and maintained by paid full-time staff with minimal 'grassroots' support. 'Conscience constituents' in the sense of sympathetic bystanders, wealthy patrons, and institutional sponsors are the major contributors to these movements. 'Speaking for' rather than mobilizing the aggrieved, grassroots grievances are seen as secondary if not irrelevant to these movements. Mass media (including direct mail solicitation and the Internet) has lowered organizing costs and the development of professional advocacy careers and training schools provide a ready supply of movement entrepreneurs. Thus, there has been a proliferation of professional movements, as in the environmental movement, sections of the women's movement, the peace and human rights campaigns, and other 'public interest' causes (Berry 1997). Drawing on organizational ecology theory, the increased density of social movement organizations (or SMOs) creates organizational survival problems with increased SMO mortality (Minkoff 1995). Similarly, issue attention cycles limit the ability of professional movement entrepreneurs to mobilize external support, forcing them to migrate among causes as public attention.

This argument, however, has been criticized for overstating the importance of professionalization and misdiagnosing its origins. Many contemporary movements are based indigenously on the voluntary labor of direct beneficiaries who are integrated by loosely structured networks, strong collective identities, and volunteer organizers. Morris (1984) shows that the Southern civil rights movement was centered organizationally in African–American churches and organized by a loosely knit coalition of ministers and college students. While external institutional resources may be central to the professionalization of movements, these contributions are often spurred by indigenous protests. Thus, the civil rights protests mobilized by the more militant groups spurred foundations and government officials to donate to the more moderate SMOs, creating a 'radical flank' effect (Haines 1986). Professionalization did not, however, demobilize these movements but rather channeled them into more moderate institutional activities, including the implementation of public policy gains (Jenkins and Eckert 1986). Thus, the professional model is most relevant for post-movement SMOs that have become institutionalized interest associations and 'public interest' movements that lack cohesive constituencies, such as the environmental, consumer, and general human rights movements.

3. *Political Opportunities*

A core rational choice idea is that participants respond to perceived costs and the likelihood of success. Thus, movement development should be shaped by political opportunities. Drawing on Piven and Cloward's (1977) thesis that elite divisions legitimize movement demands and thus facilitate protest and Tilly's (1978)

arguments about elite-challenger coalitions that lead to revolutionary situations, McAdam (1982) showed that competition between Democratic and Republican Presidential candidates for the African–American vote facilitated the rise of the civil rights movement. Jenkins (1985) showed that a dominant left-center governing coalition removed political obstacles to farm worker unionization and strengthened the institutional sponsors of the United Farm Worker Union, thus giving it more organizing space. Kriesi et al. (1995) show in a comparison of Western Europe that decentralized federal states, left-center governments, and strong alliances with unions facilitate the rise of the environmental and women's movements but opportunities mattered little for the more culturally-oriented homosexual and counter-cultural movements. Distinguishing between 'early riser' and 'late riser' movements that develop within a general protest cycle, Tarrow (1998) argues that 'late risers' are more successful because they can benefit by the policy precedents and resources created by 'early riser' challenges.

In a widely cited analysis, Gamson (1975/1990) argues that opportunities along with strategies are central to movement outcomes. Movements that 'think small' in terms of narrow incremental gains, use formal organization and thus avoid schisms, have allies, use unruly and violent tactics, and organize during political crisis periods are more likely to secure political acceptance and tangible benefits. By contrast, movements that attempt to overthrow their targets, rely on decentralized informal organization, lack political allies, use conventional tactics, and organize during periods of stability are less successful.

Subsequent research has focused largely on small-scale policy changes, such as the passage of favorable legislation and public expenditure showing that the resources under movement control (especially disruptive protest) combined with political opportunities are central to bringing about favorable policy outcomes (Jenkins 1985, Amenta 1998). Cress and Snow (2000) show that combinations of favorable strategies and opportunities are critical to the policy victories of homeless movements in US cities. Burstein (1985) argues that favorable public opinion is the key factor in equal employment legislation with nonviolent protest serving merely as a catalyst for greater public support. However, violent and highly disruptive protest often creates public opinion backlashes, making it more difficult for movements to gain favorable policies and raising the possibility of political repression.

It is also important to examine the broader impact of movements on culture and social institutions. Thus, expanding on Gamson's (1975/1990) typology of movement 'acceptance' and 'tangible gains,' movements also create new cultural codes and collective identities, such as in the women's and counter-cultural youth movements. The women's movement made it more legitimate for women to pursue full-time careers, to treat motherhood as optional, and promoted changes in social institutions from schools to collegiate sports and family practices that insured broader social inclusiveness. Movement participation also has profound biographical consequences, creating 'bridge-burning' experiences that channel activists into specific adult careers and transform their personal lives. Thus, McAdam (1988) shows that the adult lives of the white 'summer of 1964' student activists who went South to aid the civil rights movement were changed dramatically, leading most to embark on careers in the law, academe, and social work that allowed them to act on their political activist beliefs and leading to life course experiences, such as lower marital stability, geographic mobility, and lower income.

A major problem in inferring the effects of social movements is distinguishing between authentic movement impacts vs. ongoing social changes that are contributing simultaneously to both movement mobilization and changes reflecting the proclaimed goals of the movement. Most research is 'movement-centered' in that it takes the activities of the movement as central and focuses on the ostensive impact (e.g., public policy changes) of movement activity. It thus neglects the broader context in which movements emerge. Some contend, however, that these changes would have occurred without the movement or that, by working through movement activity, these deeper social changes are more important. Thus, for example, the changes in work and family typically attributed to the women's movement are also rooted in deeper cultural changes emphasizing individual autonomy and in the structural growth of service sector employment where most women have found work. Thus, while the women's movement may be central in these changes, evaluating how important it is relative to broader social changes that have also facilitated the women's movement is complex and difficult. Another complexity is that movement impact is often indirect and unintended. Thus, the women's movement encouraged more women to go into professional careers, which reinforced the number of feminist activists and legislators, which in turn strengthened pressures for feminist legislation, and so on. Similarly, social revolutions rarely have the outcomes intended by revolutionary leaders but, nonetheless, may have major unintended impacts on people's lives and the societies in which they live. Thus, RMT currently is being expanded by research on movement impact as well as by efforts to assess the social and cultural processes involved in mobilization.

Social Movements, Sociology of

For the whole set of actions and events subsumed under the heading of social movements, the problem of boundary demarcation is not to be taken lightly. Social movements unquestionably are, as Hanspeter Kriesi (1988, p. 350) puts it, 'elusive phenomena with unclear boundaries in time and space.' Furthermore, the question is not a mere empirical one to be solved, in each case, by deciding when a social movement begins and when it ends, or by circumscribing the social field in which it takes place and evolves. Social movements are also hard to grasp conceptually. First of all, even if a social movement as such cannot be equated with an organized group (or several ones), it has distinctively collective features: in this respect, Heberle (1951) had grounds for defining it 'as a kind of social collective.' Second, the scholar must be aware of two pitfalls: on the one hand, it is mistaken to consider a social movement to be a self-perpetuating crowd, for a crowd totally lacks mechanisms for sustaining association between people; on the other hand, it is an unduly narrow view of social movements to conceive them as necessarily linked to class-based actions, although the history of the concept can, as we will see, account for this usage. Finally, drawing the line between social movements and other close phenomena is, as a general rule, difficult, and that is why Turner and Killian ([1957] 1987) characterized these phenomena as 'quasi movements.' A classical instance of these borderline cases is to be found in some religious movements, such as messianic and millenarian sects: at the beginning of the twenty-first century, it is generally agreed upon that they both fall within the ambit of social movements when they set up meetings for voicing protest and aim at establishing a new type of social order.

What emerges from this view is perhaps the main criterion for defining a social movement, that is, its critical relation to social change. Herbert Blumer (1946, p. 199) aptly dwelt on this point when he suggested that social movements should be viewed 'as collective enterprises to establish a new order of life,' and his concise wording may still be used as a starting-point. But social movements may differ both in the direction and the nature of the change aimed at: some act 'to promote a change,' some others 'to resist' it, in the words of Turner and Killian ([1957] 1987); and the change claimed sometimes is a partial one, and sometimes implies a transformation of the whole social order.

A second distinctive feature of social movements is the use of uninstitutionalized means by participants, at least in some occasions and situations. A third one is also worth noting: the actions of a social movement are protest-oriented and even contest-oriented; therefore they have political relevance. We are now in a position to state an elementary, although tentative, definition of a social movement: it is 'a collective enterprise of protest and contention which aims at bringing about changes of varying importance in the social and/or political structure by the frequent but not necessarily exclusive use of uninstitutionalized means' (Chazel 1992, p. 270).

1. From the Formulation of the Idea to the Development of a Self-contained Field

The term *soziale Bewegung* was first used and coined by the German scholar, Lorenz von Stein ([1850] 1964) in his pioneer study, first published in German as *Geschichte der sozialen Bewegung in Frankreich von 1789 bis* auf *unsere Tage*. Rejecting Hegel's idealism, he did not study socialism and communism as forms of social thought, but regarded them as expressing the strivings of the industrial proletariat toward economic and political power; in his view, they were an essential development of the period and it is why, for him, the social movement meant the efforts of the rising industrial working class at organizing and sustaining mass action. Although Marx and Engels shared many interests with Stein, they did not themselves use the term. But Stein's conception remained influential until the beginning of the twentieth century. In Werner Sombart's ([1896] 1909, p. 2) wording, the social movement is still defined as 'the conception of all the attempts at emancipation on the part of the proletariat.'

Rudolf Heberle is to be credited with the discarding of this exclusive identification of the notion with proletarian movements in industrial society: the definition must be enlarged to take account of such important phenomena as peasant movements, Fascism, and National Socialism, or independence uprisings against colonial powers. It is to be noted that Heberle is still under the restraining influence of the traditional conception, when he states that 'the main criterion of a social movement is [to] aim [at] bring[ing] about fundamental changes in the social order, especially in the basic institutions of property and labor relationships' (1951, p. 6) or when he draws a somewhat arbitrary distinction between 'genuine social movements' and more or less short-lived 'protest movements.' Yet Heberle's work must be acknowledged as a landmark in the field, paving the way for the systematic study of social movements: he also points out their political implications and relevance, and therefore subtitles his book, *Social Movements*, as *An Introduction to Political Sociology*.

However original his work was, Heberle, belonging to a generation of political exiles, was the heir to European social theory, and research in social movements mostly developed along other lines in the USA. Social movements were to be conceived as one major form of collective behavior which Robert Park, who coined the term, defined as 'the behavior of individuals under the influence of an impulse that is common and collective, an impulse, in other words, that is the result of social interaction' ([1921] 1969). This notion has broad applicability and, while rather denoting for Park an approach to social phenomena, it quickly became a label for a distinctive field of investigation.

Some valuable studies and surveys of social movements, such as those, already mentioned, of Blumer, Turner, and Killian, have been worked out within this framework. But Neil Smelser's (1962) *Theory of Collective Behavior*, which is the most ambitious attempt at building up an elaborate theory, cannot be categorized in such a straightforward way, because he approaches the empirical phenomena subsumed under the field of collective behavior from a quite different theoretical perspective, the Parsonian hierarchy of 'components of social action.' By using criteria derived from this conceptual frame of reference, Smelser draws a demarcation line between 'panics,' 'crazes,' and 'hostile outbursts' on the one hand and social movements on the other, while making a further distinction between 'norm-oriented movements' and 'value-oriented movements.' This latter distinction, because it proceeds from an analytical basis, is more significant than purely descriptive ones, and it may be quite appropriate for differentiating, within a large movement, between a reform-oriented trend and a more radical one. Yet participants to social movements often account for their normative commitments by referring to widespread values. Discriminated as they are by their relation to a distinctive component of social action, these different kinds of collective behavior share common attributes, as Smelser makes clear in his formal characterization. All episodes of collective behavior imply 'an uninstitutionalized mobilization for action in order to modify one or more kinds of strain on the basis of a generalized [belief]' (Smelser 1962, p. 71).

Two major features of this conception are to be pointed out: the sharp contrast between the uninstitutionalized character of collective behavior and established behavior and Smelser's emphasis on beliefs of a very peculiar type, because they entail a 'process of short-circuiting,' that is, 'the jump from extremely high levels of generality to specific, concrete situations,' (p. 82) and these are the very points which will later on give rise to much controversy.

The irony of an unexpected outcome also is worth noticing: students of collective behavior were so keen on bringing out the salient characteristics of social movements that this topic gradually became a teaching and research area in itself. A quite significant instance of this development can be found in Robert Faris's *Handbook of Modern Sociology* (1964), in which the chapter on 'Social Movements,' written by Lewis Killian, is next to the one on 'Collective Behavior' by Ralph Turner.

2. New Emphases in Theory and Research

The turbulent 1960s aroused much interest in social movements, and many scholars did not agree with Smelser's statement that social movements are, as any other kind of collective behavior, 'the action of the

impatient.' During this period important developments internal to the social sciences were also under way, with systematic attempts at tackling sociological problems in terms of the economic paradigm. Facing troubled times that they had not predicted, as often happens, and grappling with theoretical puzzles of a new kind, sociologists and political scientists were thus induced to take a fresh and finally inventive approach to social movements.

In this process, Mancur Olson's *The Logic of Collective Action* (1965) was a seminal step. Olson drew attention to a vexing paradox, unnoticed in traditional theory: 'it does *not* follow, because all of the individuals in a group would gain if they achieved their group objective, that they would act to achieve that objective, even if they were all rational and self-interested' (p. 2); indeed, in very large groups individuals will not as a rule act to obtain a collective good. In Olson's view, there is only one way of preventing rational actors in such 'latent' groups from not mobilizing to provide a collective good: it consists of an incentive which discriminately operates upon some individuals in the group and which, by offering positive inducements to them or by coercing them, leads these individuals to act in the common interest. Actually, Olson's theoretical importance lies less in 'selective incentives,' which have been appraised by several scholars as a quite limited remedy, than in his skill in throwing light on the social dilemma of movement participation itself: mobilization never is to be taken for granted.

Thus the true significance of Olson's book rested in its setting a theoretical puzzle to a new generation of scholars: how and when are social actors able to overcome the dilemma of movement participation? These attempts at solving the dilemma resulted in what is now known as 'resource mobilization' theory. Yet, because there are different emphases within this theoretical approach, we can differentiate three distinctive ways of overcoming the dilemma, all of which ascribe weight to organization. The first one, which may be regarded as classic, has been elaborated by Anthony Oberschall in his book *Social Conflict and Social Movements* (1973). As Oberschall stresses in his 'sociological theory of mobilization,' collective protest is more likely to be present in a collectivity which has a strong organizational base, whether it is of a communal or of an associational kind, and which also is cut off from the rest of society, that is, is 'segmented.' A second way of getting over the dilemma was put forward by John McCarthy and Mayer Zald, who coined the convenient label, 'resource mobilization': they assert that particular attention must be paid to outside support, funding, and leadership; consequently, they dwell on the prominent part of 'conscience constituents' and 'adherents' on the one hand, of political entrepreneurs on the other, arguing that they 'turn Olson on his head' (1977). It is a theoretical point worth noticing, although it may be observed that Zald and McCarthy overrate the aggregate import of 'professional social movements' during the 1960s.

The third way of solving the dilemma perhaps is not so closely connected with resource mobilization theory; but the major questions at issue are the same. Charles Tilly (1978) puts as much emphasis as Oberschall or Zald and McCarthy on organization and interests, yet he stresses the political context in which mobilizations take place. Therefore he calls attention to emerging coalitions, of which a quite significant kind brings together 'members' of the 'polity' and 'challengers' aiming at entering it; and he takes account of the role of the government in this process, which can facilitate as well as repress an emergent mobilization.

Taken as a whole, this stream of thinking is to be considered 'revisionist,' as William Gamson aptly called it in his 'Introduction' to the collected essays by Zald and McCarthy (1987), and it is so, on two basic points. First, the advocates of the new approach assume that participation in social movements is to be explained in terms of rationality, as opposed to the prevailing view, which was exemplified by Smelser's emphasis on 'generalized beliefs.' Second, they are anxious to downgrade the psychosocial approach to social movements, as it was used and developed by collective behavior theorists. When at a later date Doug McAdam (1982) boldly asserts that social movements must be regarded as political phenomena, no more as psychosocial ones, he is in full agreement with this line of thought.

The theoretical import of McAdam's (1982) book has to be pointed out. In many respects he brings resource mobilization theory to completion, by joining the strand derived from Oberschall (although the relative weight of 'indigenous organizational strength' vs. outside support in the civil rights movement is a bone of contention between them), and the one derived from Tilly whose term, 'political process,' he took up. But on an important point, which resource mobilization theorists did not tackle, he makes a significant advance by drawing attention to potential participants' cognitive activity. Thus McAdam paves the way for attempts at multidimensional synthesis, in which, somewhat ironically, the psychosocial viewpoint will be awarded due consideration. For both of these achievements, his book can be regarded as a landmark.

3. *Contemporary Advances and Issues*

Any comment on the latest trends is open to question and correction but it is worth trying to outline the main line of development and, as already mentioned, the keynote of the times seems to lie in attempts at multidimensional synthesis.

Yet the path has gradually to be mapped out, and there are heuristic blind alleys, which are often linked

with some overemphasis on one analytical dimension or empirical type of social movements. Truly, social movements are in many respects significant political phenomena and, as mentioned, Tilly and McAdam opened up new vistas. But it does not follow that the whole approach must center in the concept of 'political opportunity structure,' which then is unduly stretched. As William Gamson and David Meyer aptly put it:

> the concept of political opportunity structure is ... in danger of becoming a sponge that soaks up virtually every aspect of the social movement environment ... Used to explain so much, it may ultimately explain nothing at all (1996, p. 275).

It is well known that with new waves of contention different problems are to be put on the research agenda. Thus the 'new social movement' school was quite justified in investigating the distinctive features of this type of movement. But the wrong inference that these movements were unparalleled was not always resisted: 'new social movements' perhaps are not so new as they appeared to be. Nevertheless this approach, by stressing the search for a collective identity, revives interest in the cultural dimension of social movements, as opposed to the resource mobilization stream of thinking, which had little regard for it; therefore the reconciliation of these quite divergent viewpoints is urgently needed.

The abundance of books on social movements during the 1990s, such as those edited by Aldon Morris and Carol Mueller (1992), Hank Johnston and Bert Kandermans (1995), McAdam et al. (1996), or the individual works by Sidney Tarrow (1994) and Klandermans (1997), along with the publishing of a specialized journal, *Mobilization*, first testifies to the institutionalization of an academic field. But their theoretical significance lies mainly in systematic attempts at integrating mobilizing structures and organizations, political opportunities, and 'framing' processes. A true synthesis seems to be under way, although it is not an easy job to articulate distinctive dimensions with one another.

A last point is worth noting: the clarifying of cognitive and discursive processes, whether in terms of causal attribution, as by Myra Ferree and Frederick Miller (1985), or in terms of 'frame alignment' and 'frame resonance,' as by David Snow and his associates (1986, 1988), is part and parcel of this development. This new interest in collective beliefs can be construed as Smelser's revenge, but it is an ambiguous one: as opposed to 'generalized beliefs,' the beliefs which are now to be investigated are reasonable ones and can be interpreted in terms of a rational, though not simply rationalistic, model.

Social Network Models: Statistical

Late twentieth-century developments in statistical models for social networks reflect an increasing theoretical focus in the social and behavioral sciences on the interdependence of social actors in dynamic, network-based social settings. As a result, a growing importance has been accorded the problem of modeling the dynamic and complex interdependencies among network ties and the actions of the individuals whom they link. The early focus of statistical network modeling on the mathematical and statistical properties of Bernoulli and dyad-independent random graph distributions has been replaced by efforts to construct theoretically and empirically plausible parametric models for structural network phenomena and their changes over time. These models in this article are based on graphs where the nodes are individual actors, which are 'linked' by lines representing relational ties (see *Graphical Models: Overview*).

1. Statistical Models for Social Networks

1.1 Notation

In most of the literature on statistical models for networks, the set $N = \{1, 2,\ldots, n\}$ of network nodes is regarded as fixed and the edges, or ties, between nodes are assumed to be random. The tie linking node i to node j $(i, j \in N)$ may be denoted by the random variable X_{ij}. In the simplest case of binary-valued random variables, X_{ij} takes the value 1 if the tie is present and 0 otherwise. Other cases of interest include:

(a) valued networks where X_{ij} is assumed to take values in the set $\{0, 1,\ldots, C-1\}$;

(b) multiple relational or multivariate networks, where the variable X_{ijk} represents the possible tie of type k from node i to node j (with $k \in R = \{1, 2,\ldots, r\}$, a fixed set of types of tie); and

(c) time-dependent networks, where X_{ijt} represents the tie from node i to node j at time t.

In each case, network ties may be *directed* (e.g., X_{ij} and X_{ji} are distinct random variables) or *nondirected* (e.g., X_{ij} and X_{ji} are not distinguished). The $n \times n$ array $\boldsymbol{X} = [X_{ij}]$ of random variables can be regarded as the adjacency matrix of a random (directed) graph on N; the state space of all possible realizations of these arrays may be denoted by Ω_n. The array $\boldsymbol{x} = [x_{ij}]$ denotes a realization of $\boldsymbol{X}$, with $x_{ij} = 1$ if there is an observed tie from node i to node j, and $x_{ij} = 0$ otherwise. In some cases, models may also refer to variables measured on actor attributes: for instance, the mth attribute $Z_i^{[m]}$ of actor i gives rise to a random vector $\boldsymbol{Z}^{[m]}$ with realization $\boldsymbol{z}^{[m]}$.

The adjacency matrix of an illustrative nondirected binary network is shown in Table 1. The data are from a study of interorganizational networks amongst mental health agencies conducted by Morrisey et al. (1994). The nodes of the network are 37 mental health agencies in one of the US cities in the Morrissey study; an edge links two agencies if they engage in regular and mutual exchange of information. The graphical representation of these data is shown in Fig. 1. We use this network to illustrate several of the distributions and models described below.

1.2 Bernoulli Graphs

A simple statistical model for a (directed) graph assumes a Bernoulli distribution, in which each edge,

or tie, is statistically independent of all others and governed by a theoretical probability P_{ij}. In addition to edge independence, simplified versions also assume equal probabilities across ties; other versions allow the probabilities to depend on structural parameters (Frank and Nowicki 1993). These distributions have often been used as models (Bollobas 1985), but are of questionable utility due to the independence assumption. Bernoulli graph distributions are described at length by Erdos and Renyi (1960) and Frank (1981).

1.3 Dyadic Structure in Networks

Statistical models for social network phenomena have been developed from their edge-independent beginnings in a number of major ways. In one important series of developments, the p_1 model introduced by Holland and Leinhardt (1981), and developed by Fienberg and Wasserman (1981), recognized the theoretical and empirical importance of dyadic structure in social networks, that is, of the interdependence of the variables X_{ij} and X_{ji}. This class of Bernoulli dyad distributions and their generalization to valued, multivariate, and time-dependent forms, gave parametric expression to ideas of reciprocity and exchange in dyads and their development over time. The model assumes that each dyad (X_{ij}, X_{ji}) is independent of every other and, in a commonly constrained form, specifies:

$$P(\boldsymbol{X} = \boldsymbol{x}) = \prod_{i<j} \exp\left\{\lambda_{ij} + \theta\left(\sum_{i \neq j} x_{ij}\right) + \rho\left(\sum_{i<j} x_{ij}x_{ji}\right) + \alpha_i\left(\sum_j x_{ij}\right) + \beta_j\left(\sum_i x_{ij}\right)\right\} \quad (1)$$

where θ is a density parameter; ρ is a reciprocity parameter; the parameters α_i and β reflect individual differences in expansiveness and popularity; and λ_{ij} ensures that probabilities for each dyad sum to 1. This model is log-linear (see *Multivariate Analysis: Discrete Variables (Loglinear Models)*).

An important elaboration of the p_1 model permits the dependence of density, popularity and expansiveness parameters on a partition of the nodes into subsets that can either be specified *a priori* (e.g., from hypotheses about social position) or can be identified *a posteriori* from observed patterns of node interrelationships (e.g., Wasserman and Faust 1994). The resulting stochastic blockmodels represent hypotheses about the interdependence of social positions and the patterning of network ties (as originally elaborated in the notion of blockmodel by White et al. 1976). A potentially valuable variant of these models regards the allocation of nodes to blocks as a latent classification; Snijders and Nowicki (1997) have provided Bayesian estimation methods for the case of two latent classes. Another valuable extension of the p_1 model is the so-called p_2 model (Lazega and van Duijn 1997). Like the p_1 model, the p_2 model assumes dyad independence, but it adds the possibility of arbitrary node and dyad covariates for the parameters of the p_1 model, and models the unexplained parts of the popularity and expansiveness parameters as random rather than fixed effects.

1.4 Null Models for Networks

Despite the useful parameterization of dyadic effects associated with the p_1 model and its generalizations, the assumption of dyadic independence has attracted

Figure 1
Graphical representation of interorganizational networks amongst mental health agencies in one US city (data from Morrissey et al. (1994)).

sustained criticism. Thus, another series of developments has been motivated by the problem of assessing the degree and nature of departures from simple structural assumptions like dyadic independence. Following a general approach exemplified by early work of Rapoport (e.g., Rapoport 1949), a number of conditional uniform random graph distributions were introduced as null models for exploring the structural features of social networks (see Wasserman and Faust 1994 for a historical account). These distributions, denoted by $U \mid Q$, are defined over subsets Q of the state space Ω_n of directed graphs, and assign equal probability to each member of Q. The subset Q is usually chosen to have some specified set of properties (e.g., a fixed number of mutual, asymmetric, and null dyads, as in the $U \mid MAN$ distribution of Holland and Leinhardt 1975). When Q is equal to Ω_n the distribution is referred to as the uniform (di)graph distribution, and is equivalent to a Bernoulli distribution with homogeneous tie probabilities. Enumeration of the members of Q and simulation of $U \mid Q$ is often straightforward (e.g., see Wasserman and Pattison, in press), although certain cases, such as the distribution that is conditional on the indegree $\left(\sum_j x_{ji}\right)$ and outdegreee $\left(\sum_j x_{ij},\right)$ of each node i in the network, require more complicated approaches (Snijders 1991, Wasserman 1977).

A typical application of these distributions is to assess whether the occurrence of certain higher-order (e.g., triadic) features in an observed network is unusual, given the assumption that the data arose from a uniform distribution that is conditional on plausible lower-order (e.g., dyadic) features (e.g., Holland and Leinhardt 1975). For example, the network displayed in Table 1 has 84 edges, and 333 and 69 triads with exactly 2 and 3 edges, respectively. If Q denotes the subset of complete Ω_{37}, with 84 edges, the expected number of triads of each kind is 250.1 and 50.8, and the observed values lie at the 0.003 and 0.005 percentiles of the $u \mid x_{++} = 84$ distribution, respectively. This general approach has also been developed for the analysis of multivariate social networks. The best-known example of this approach is probably the

quadratic assignment procedure or model (*QAP*) for networks (Hubert and Baker 1978). In this case, the association between two graphs defined on the same set of nodes is assessed using a uniform multivariate graph distribution that is conditional on the unlabelled graph structure of each univariate graph. In a more general framework for the evaluation of structural properties in multivariate graphs, Pattison et al. (in press) also introduced various multigraph distributions associated with stochastic blockmodel hypotheses.

1.5 Extra-dyadic Local Structure in Networks

A significant step in the development of parametric statistical models for social networks was taken by Frank and Strauss (1986) with the introduction of the class of Markov random graphs. This class of models permitted the parameterization of extra-dyadic local structural forms and so allowed a more explicit link between some important network conceptualizations and statistical network models. Frank and Strauss (1986) adapted research originally developed for modeling spatial dependencies (see *Spatial Statistical Methods*) among observations to graphs. They observed that the Hammersley-Clifford theorem provides a general probability distribution for $\boldsymbol{X}$ from a specification of which pairs (X_{ij}, X_{kl}) of edge random variables are conditionally dependent, given the values of all other random variables (see *Graphical Models: Overview*).

Define a dependence graph $\mathbf{D}$ with node set $N(\mathbf{D}) = \{(X_{ij}: i, j \in N, i \neq j\}$ and edge set $E(\mathbf{D}) = \{(X_{ij}, X_{kl}): X_{ij}$ and X_{kl} are assumed to be conditionally dependent, given the rest of $\boldsymbol{X}\}$. Frank and Strauss used $\mathbf{D}$ to obtain a model for $\Pr(\boldsymbol{X} = \boldsymbol{x})$, denoted p^* by Wasserman and Pattison (1996), in terms of parameters and substructures corresponding to cliques of $\mathbf{D}$. The model has the form

$$\Pr(\boldsymbol{X} = \boldsymbol{x}) = p^*(\boldsymbol{x}) = (1/c)\exp\left\{\sum_{\mathbf{P} \subset \mathbf{N(D)}} \alpha_{\mathrm{P}} z_{\mathrm{P}}(\boldsymbol{x}\}\right\} \qquad (2)$$

where:

(a) the summation is over all cliques P of $\mathbf{D}$ (with a clique of $\mathbf{D}$ defined as a nonempty subset P of $N(\mathbf{D})$ such that $|P| = 1$ or $(X_{ij}, X_{kl}) \in E(\mathbf{D})$ for all $X_{ij}, X_{kl} \in P$);

(b) $z_{\mathrm{p}}(\boldsymbol{x}) = \prod_{\mathrm{x}ij \in \rho}^{\mathrm{x}_{ij}} x_{ij}$ is the (observed) network statistic corresponding to the clique ρ of $\mathbf{D}$; and

(c) $c = \Sigma_{\mathrm{x}} \exp\{\Sigma_{\mathrm{p}} \alpha_{\mathrm{p}} z_{\mathrm{p}}(\boldsymbol{x})$ is a normalizing quantity.

specification of a dependence graph raises a deep theoretical issue for network analysis: what constitutes an appropriate set of dependence assumptions? Frank and Strauss (1986) proposed a Markov assumption, in which $(X_{ij}, X_{kl}) \in E(\mathbf{D})$ whenever $\{i, j\} \cap \{k, l\} \neq \phi$. This assumption implies that the occurrence of a network tie from one node to another is conditionally dependent on the presence or absence of other ties in a local neighborhood of the tie. A Markovian local neighborhood for X_{ij} comprises all possible ties involving i and/or j. Any network tie is seen both as dependent on its neighboring ties and as participating in the neighborhood of other ties, so the resulting model embodies the assumption that social networks have a local self-organizing quality. In the case of Markovian neighborhoods, cliques in the dependence graph correspond to triadic and star-like network configurations. A homogeneity assumption, that model parameters do not depend on the specific identities of nodes but only on the network configurations to which they correspond, yields a model that expresses the probability of the network in terms of propensities for subgraphs of triadic and star-like structures to occur.

For example, a homogeneous Markov model for the network of Table 1 with parameters corresponding to edges, 2-stars, and triangles appears to be a substantial improvement in fit over a Bernoulli model with just an edge parameter, since the mean absolute residual for fitted edge probabilities drops from .220 to .175. Pseudolikelihood estimates for model parameters (Wasserman and Pattison 1996) are –3.31, 0.056, and 0.616 for edges, 2-stars, and triangles, respectively, suggesting that graphs with a large number of triangles are relatively more likely in the assumed homogeneous Markov p^* distribution than those with few.

p^* random graph models permit the parameterization of many important ideas about local structure in univariate social networks, including transitivity, local clustering, degree variability, and centralization. Valued (Robins et al. 1999) and multivariate (Pattison and Wasserman 1999) generalizations also lead to parameterizations of substantively interesting multirelational concepts, such as those associated with balance and clusterability, generalized transitivity and exchange, and the strength of weak ties.

1.6 Prospects for Structural Models

The p^* family of random graph models poses many interesting questions, both substantive and statistical. A major empirical question is the sufficiency of these local structural descriptions: do they suffice, or do they need to accommodate other characterizations of local dependence, more global considerations, other types of constraints (e.g., temporal and spatial), or variability in local structural dependencies? On the statistical side, major questions are raised by the complexity and rich parameterization of models that are deemed to be theoretically plausible. For instance, does a Markov chain Monte Carlo (see *Markov Chain Monte Carlo Methods*) maximum likelihood approach to parameter estimation offer a viable alternative to approximate methods such as pseudolikelihood esti-

mation (Strauss and Ikeda 1990)? How can these distributions best be simulated, and what are the convergence properties of various approaches, such as the Metropolis-Hastings algorithm?

2. Dynamic Models

Empirically and theoretically defensible parametric models for networks constitute one challenge for statistical modeling, but an arguably more significant challenge is to develop models for the emergence of network phenomena, including the evolution of networks and the unfolding of individual actions (e.g., voting, attitude change, decision-making) and interpersonal transactions (e.g., patterns of communication or interpersonal exchange) in the context of longer-standing relational ties. Early attempts to model the evolution of networks in either discrete or continuous time assumed dyad independence and Markov processes in time.

A step towards continuous time Markov chain models for network evolution that relaxes the assumption of dyad independence has been taken by Snijders (1996). These models incorporate both random change and change arising from individuals' attempts to optimize features of their local network environment (such as the extent to which reciprocity and balance prevail) and use the computer package *SIENA* for fitting. A tension function is proposed to represent the function that actors wish to minimize and Robbins-Munro procedures are used to estimate free parameters. The approach illustrates the potentially valuable role of simulation techniques for models that make empirically plausible assumptions; clearly, such methods provide a promising focus for future development.

The value of simulation has also been demonstrated by Watts and Strogatz (1998) and Watts (1999) in their analysis of the so-called small-world phenomenon (the tendency for individuals to be linked by short acquaintanceship network paths). They considered a probabilistic model for network change in which the probability of a new tie was determined, in part, by existing patterns of neighboring ties (a clustering component) and, in part, by a small random component. They used simulations to establish that only a small random component was needed for the simulated network to be likely to possess the small-world property.

3. Models Bridging Analytic Levels

A recurring theme among social theorists is the need for models that integrate the dynamic, interdependent, interpersonal, and cultural contexts in which social action occurs. The network modeling challenge posed by such framing of the nature of social processes is the development of models that represent interdependencies across several analytic categories (e.g., individuals, relational ties, settings, groups).

Snijder's (1996) model for network change represents one step in this direction; the class of social influence models represents another (Friedkin 1998). These models are exemplified by the network effect model for the mth attribute variable:

$$\mathbf{z}^{[m]} = \alpha \boldsymbol{x}\boldsymbol{z}^{[m]} + \boldsymbol{y}\boldsymbol{\beta} + \boldsymbol{\varepsilon} \tag{3}$$

where α is a network effects parameter, $\boldsymbol{y}$ is a matrix of exogenous attribute variables with corresponding parameter vector $\boldsymbol{\beta}$, and $\boldsymbol{\varepsilon}$ is a vector of residuals.

A further step in the direction of modeling interdependent node attributes and network ties has been to generalize the dependence graph approach to p^* network models (Sect. 1.5) so as to include both node attribute variables ($\boldsymbol{Z}^{[m]}$) and relational variables ($\boldsymbol{X}$). This step is facilitated if directed dependencies are permitted in the dependence graph (i.e., dependencies in which one random variable is assumed to be conditionally dependent on a second, but the second not on the first). Robins et al. (in press) drew on graphical modeling techniques to construct models with directed dependencies among network ties and individual attributes. If the dependencies are directed from network ties to node attributes, models for social influence are obtained; with dependencies oriented from node attributes to network ties, social selection models result. Indeed, this generalization introduces substantial flexibility in model construction, with potential applications to joint influence and selection models, discrete time models for network change, network path models, and group-level attribute models.

The dependence approach of Sect. 1.5 has also been used to construct principled models for more general multiway relational data structures representing interdependent analytic categories. Examples to date have included bipartite (Faust and Skvoretz 1999) and k-partite (Pattison et al. 1998) graphs and illustrate how this general distribution has the capacity for a systematic and coherent approach to a variety of major network modeling challenges.

4. Conclusion

In addition to some of the specific future prospects already noted, a more general expectation is that the current classes of models are likely to be the foundation of substantial empirical and model-building activity in the early twenty-first century. From their early beginnings, statistical approaches to network modeling have

now reached a point where sustained interaction is likely to be empirical research that allows the development of greatly improved models for processes occurring on networks, with important applications in many fields of social and behavioral science, including epidemiology, organizational studies, social psychology, and politics.

For more information on these approaches to social networks analysis, please see Wasserman and Faust (1994) and Wasserman and Pattison (1996, in press).

Social Networks and Fertility

Explanations offered for fertility decline in both developed and developing countries underwent fundamental changes in the last decades of the twentieth century. In addition to more refined economic reasoning and the introduction of cultural aspects, theories of the fertility transition now routinely reserve a place for diffusion effects. Such effects arise because individuals are themselves members of larger groups. The information that is known to group members, the choices they make, and the norms and values they adhere to, can all exert a powerful influence on

individual incentives to innovate. In settings in which fertility has been high, for example, innovation might take the form of adopting modern contraception and fertility limitation. Social interaction with group members represents one important avenue along which such innovative demographic behavior can diffuse: peers, community members or relatives may provide relevant information to potential adopters of family planning, and they also represent the institutional and social structures that may facilitate or constrain individual fertility or family planning decisions.

Theories of diffusion usually encompass two central elements. First, they emphasize a particular set of social interactions that are associated with the adoption of innovations, such as social networks, opinion leaders, public media, etc. Second, diffusion models have an explicit dynamic dimension in which the adoption of an innovation is often associated with 'contagion' or 'tipping point' phenomena, which can accelerate social change. Because fertility transitions are often rapid, irreversible, and only weakly associated with the specific socioeconomic conditions in a population, such diffusionist explanations have appealed to demographers ever since the European Fertility Project was carried out (Coale and Watkins 1986)

At the same time, diffusionist approaches have been criticized for several key reasons, such as the unclear definition of what diffuses, the unclear connection with economic models of behavior, the mostly indirect empirical evidence, and the insufficient knowledge about the preconditions for the onset of the diffusion process. Several of these potential problems can be overcome by investigating the diffusion process with the tools of social network analysis.

1. Why Social Networks Matter for Understanding Fertility

The theoretical perspective of social networks rests on one central insight: human action is not carried out by individuals who make their decisions in isolation and independence, but by socialized actors who are deeply rooted in their social environments. These environments consist of other individuals with whom a focal actor stays in various relationships such as kinship, love, friendship, competition, or business transactions. Within these relationships, norms are negotiated and enforced, and information and goods are exchanged (Mitchell 1973). On the one hand this implies that a network member has access to resources owned by other network partners. In addition, a network enables its members to use the resources of community members to whom they are tied only indirectly. Social networks therefore constitute a pool of resources which form opportunity structures for action (Lin 1999). The kind and quality of these resources are decisive for the goals that are attainable for the network members. On the other hand, social relationships create, maintain, and modify attitudes (Erickson 1988). People feel uncomfortable if the attitudes of their network partners are too different from their own. Social networks therefore bring the attitudes of their members in accordance with each other. Alternatively, if the network fails to bring attitudes into conformity, the relationships become less intensive or are abandoned.

The resources that are available in a network, and the tendencies towards similar attitudes, depend on the characteristics of individuals' direct relationships with one another as well as on the structure of the entire network. One basic characteristic of network relations is their strength (Granovetter 1973). Strong relationships, i.e., relationships that are characterized by a high frequency of contact or by a high level of emotional intensity, can be influential because they tend to transfer more valuable goods, more binding norms and more trustworthy—but also more redundant—information. On the other hand, a fundamental dimension of the network structure is its density. A dense network, i.e., a network in which a high proportion of the individuals are in direct contact with one another, can lead to a high degree of normative pressure on its members and it can provide intensive support for members in situations when help is needed. Less dense networks are characterized by a greater degree of heterogeneity. Such networks provide more opportunities for individual development, and they are the source of more diverse and heterogeneous information.

The mechanisms by which social networks affect the diffusion process can be summarized under the headings 'social learning,' 'joint evaluation,' and 'social influence' (Bongaarts and Watkins 1996, Montgomery and Casterline 1996). At early stages, potential adopters need to be informed about the existence of new methods of fertility control, their availability, costs and benefits, and possible side effects. 'Social learning' is defined as the process by which individuals (a) learn about the existence and technical details of new contraceptive techniques, and (b) reduce the uncertainties associated with the adoption of these methods by drawing on the experience of network partners.

The spread of information about modern contraceptives is always accompanied by the spread of new ideas about the social role of women, the status of the family, and the desired number of children. 'Joint evaluation' refers to the fact that social networks (a) facilitate the transformation of these new ideas into terms that are meaningful in the local context, and (b) assist in the evaluation of the respective social changes. A woman's decision to adopt a modern form of contraception, however, rests not only on information, conviction, and discursive evaluation, but also on the normative pressures of dominant groups or actors. 'Social influence' describes the process by

which an individual's preferences and attitudes are influenced by the prevailing norms and values of the social environment. The direction of this social influence can differ in different stages of fertility decline. In the early stages, social influence may constrain the adoption of contraception, which demographers may interpret as being in a woman's best interest, because deliberate control of fertility is still considered deviant. Once a noticeable fertility decline has set in, however, the direction of social influence can shift. As low fertility becomes commonplace, the interaction among women or couples is likely to encourage a decline in the demand for children and behaviors that lead to a limiting of fertility.

2. *Empirical Evidence*

The earliest systematic evidence for the influence of diffusion processes and social networks on fertility decisions is found in two seminal analyses of demographic change. First, the European Fertility Project (Coale and Watkins 1986) showed that areas which are culturally similar, in language or ethnicity for example, often exhibit similar fertility patterns despite substantially different socioeconomic conditions and development levels. Thus, new ideas about fertility as well as new contraceptive methods seem to have diffused within cultural and linguistic boundaries. More sophisticated approaches employing similar methodological ideas have used the correlation pattern in pooled time series to show support for the role of social interactions in the adoption of family planning over time (Montgomery and Casterline 1993). Second, the Taichung family planning experiment in Taiwan (Freedman and Takeshita 1969) used a randomized experiment and longitudinal follow-up to show how direct interventions of a family planning program targeted to some individuals spread to others who were not directly contacted by the program. The study thus suggests that family planning interventions extend beyond the direct effect on the contacted individuals and that interaction in social networks constitutes an important aspect in the diffusion of new contraceptive methods and ideas.

The above evidence, although intriguing, is far from conclusive. In all of these data, the evidence is indirect and based on correlated fertility developments in geographically and/or culturally close populations. Support for the relevance of social networks in fertility transitions requires more individual-level data, gathered either in structured surveys or ethnographic studies. The work of Watkins and collaborators in South Nyanza, Kenya, for example, represents an important step in this direction. Qualitative group interviews show that casual conversations about family planning occur frequently as women go about their daily activities. The network partners in these conversations are usually geographically and socially close to one another and are of a similar age or education. Frequently they also know each other and share multiple relations, e.g., stemming from money lending, help in the household, or family ties.

These qualitative impressions are further supported by survey data that include individuals and their social networks. Until recently, only one effort had been made to assemble such data, and this was by E. Rogers and colleagues in their pioneering work in rural Korea (Rogers and Kincaid 1981). Currently there are several related research projects being conducted in Kenya and Malawi (Watkins and colleagues), Thailand (Entwisle and colleagues), and Ghana (Casterline and colleagues). In all of these projects socioeconomic panel information on women and couples is being collected along with data on social networks that may have influenced contraceptive decisions. Research using these data has consistently shown that the prevalence of contraceptive use in social networks is positively associated with the probability of women using family planning, and that the use of family planning by network partners tends to increase both the knowledge about modern methods and the willingness to use them (Entwisle and Godley 1998, Kohler et al. 2001, Montgomery and Chung 1998). Although this association is robust across different socioeconomic settings and studies, a causal interpretation is not necessarily warranted. In particular, it has been challenging for researchers to distinguish between true network effects on fertility decisions on one side, and other unobserved factors which render the behavior of network members similar on the other. Nevertheless, additional work that fully exploits the panel nature of the above studies and improves the temporal measures of interactions and the adoption of family planning has the potential to overcome this limitation.

A further criticism of existing empirical work is that the link between the theoretical arguments of why social interaction matters and the respective empirical implementation is weak in many analyses. One possible way to overcome this limitation is to use additional information about the structure of the social network, e.g., the density. Dense networks impose more behavioral constraints on the adoption or nonadoption of family planning than do sparse networks, which are more open to innovative information and behavior. Thus, density can be used as an indicator for the mechanisms of 'social influence' and 'social learning.' If the prevalence of contraceptive use in dense networks is more relevant for the decision to adopt contraception than it is in sparse networks, then social influence is the most relevant aspect of social networks.

If it is the other way around, however, then it is social learning that is the dominant component. In the South Nyanza district of Kenya, for instance, evidence for both pathways of influence can be found. Moreover, the relative importance of these two mechanisms depends on the socioeconomic context of the regions.

Social learning seems to be relatively more important in areas with higher levels of market activity (Kohler et al. 2001).

Although the empirical evidence supporting the argument that social networks play an important role in fertility decisions is accumulating from various sources, it remains inconclusive in important aspects, e.g., as regards the empirical identification of causal network effects. Nevertheless, the extensive efforts currently in progress to collect data, combined with both an improved theoretical understanding of social interaction and a more sophisticated empirical methodology, are likely to reveal further insights.

3. *Implications of Social Networks For Fertility Change*

Current research on social networks and fertility is in part stimulated by the fact that the dynamic implications of fertility models that include social interactions seem to be more consistent with the empirical evidence on fertility transitions than individualistic models. However, specific theoretical analyses of social interactions and fertility decisions are required as further support for this conclusion. Early formal models treat the diffusion of low fertility in a similar manner to the way the spread of contagious diseases is treated in epidemiological models (Rosero-Bixby and Casterline 1993). More recent developments have used stochastic processes or simulation, and they explicitly consider the interplay between social networks, women's fertility decisions, and economic incentives on a microeconomic level (Kohler 2000a, 2000b).

The main consequence of interactions in social networks is that fertility decisions of women or couples in a population become interdependent and exert mutual influences on each other. The implications of this interdependence can be illustrated in a simple nonlinear model of social interaction. In particular, assume that the probability that a woman ever adopts modern contraception is given by

$$\mathrm{P}\,(\textit{woman adopts modern contraception}\,|\,x,\bar{y}) = F(\alpha(\bar{y}-0.5)+\beta x+\gamma) \qquad (1)$$

where α and β are positive parameters, γ represents individual characteristics, x is the level of family planning effort, F is the cumulative logistic function, and $\bar{y}$ is the proportion of women in the population who use modern contraception in the reference period. Hence, the social utility term $\alpha(\bar{y}-0.5)$ captures the dependence of a woman's contraceptive choice on the fertility behavior in her network, where we assume for the sake of simplicity that this network includes all members of the population. The model implies that social effects are absent in a population in which half of the members use modern contraception and the other half do not. If the proportion of contraceptive users exceeds (is below) 0.5, then the social network increases (decreases) the probability of using contraception. This simple model already reveals that the aggregate properties of fertility dynamics in the presence of social interaction are distinct from the fertility dynamics in a purely individualistic model. In particular, the relevance of social interaction arises from three factors: social multiplier effects, multiple equilibria, and dense vs. sparse networks.

Figure 1
Implications of social networks for population dynamics. In the left-hand panel, social networks exert a relatively weak influence on individual contraceptive decisions ($\alpha = 3$), while in the right-hand panel the social network effect is relatively strong ($\alpha = 6$)

3.1 Social Multiplier Effects

Social interaction implies the presence of multiplier effects which change how the fertility level adjusts to changes in family planning programs. An increase in family planning effort x, for instance, increases the probability of choosing modern contraception in two distinct ways. The direct effect reflects the increase in the propensity to choose modern contraception while holding the population prevalence $\bar{y}$ constant. However, because the increased level of x affects all community members, the prevalence of modern contraception in the population tends to increase as well. This change in the community has a feedback or social multiplier effect on individual behavior in future periods via the social utility term in Eqn. (1). This means that the total change in the prevalence of family planning exceeds the direct effect. The left-hand panel of Fig. 1 shows how this total effect is composed of a direct effect and an indirect effect through social interaction. The interaction in social networks thus enhances the changes in contraceptive behavior that follow changes in family planning efforts or other socioeconomic changes.

3.2 Multiple Equilibria

Many formal fertility models assume that there is only one aggregate fertility level, denoted as 'equilibrium,' associated with any given level of socioeconomic conditions. When the interdependence of fertility decisions in social networks is sufficiently strong, however, multiple equilibria can emerge (right-hand panel of Fig. 1). This possibility of there being multiple equilibria is relevant because in this case a population can be 'stuck' at a low level of contraceptive use, even though a second equilibrium exists with a higher level of contraceptive use and higher individual utility levels. In this case, increases in the policy level x (or other socioeconomic changes) can induce a transition from the low contraceptive use to the high contraceptive use equilibrium. These transitions between equilibria are often thought to occur at a rapid pace, resulting in significant changes in fertility behavior within a relatively short space of time. Moreover, both the high and low contraceptive use equilibria are stable, so that a transitory increase in the family planning effort can yield sustainable long-term changes in fertility levels.

3.3 Populations With Dense Versus Sparse Networks

An important question in diffusion models is whether 'more' interaction in networks always leads to larger multiplier effects and more rapid diffusion. It can be shown that already in simple models such as Eqn. (1) social networks can be status-quo enforcing: the long-term effect associated with changes in the program effort can decrease with an increase in parameter α, which reflects the importance of the network influences in individual fertility decisions. The changes in contraceptive use resulting from changes in the program effort can therefore be smaller for very densely knit societies than for more sparse societies.

Social Networks and Gender

One of the most frequently cited causes for inequalities in the distribution of income, power, and status to men and women in the workplace is gender differences in

social networks (Baron and Pfeffer 1994). The term network refers to the set of relationships defined by an individual and his or her direct contacts with others (see Ibarra 1993 for various definitions). Networks shape careers by awarding access to jobs, providing mentoring and sponsorship, channeling the flow of information and referrals, augmenting power and reputations, and increasing the likelihood and speed of promotion (e.g., Brass 1985, Burt 1992, Ibarra 1995, Kanter 1977). This article reviews the last two decades of research on men's and women's work networks and proposes a social structural perspective that can integrate findings about gender differences in network characteristics and their consequences. A social structural view underscores the embeddedness of social relationships within structural contexts that constrain the availability and ease of developing various kinds of social contacts. But such a perspective also gives prominence to the interaction patterns that intervene between causal processes at the macrostructural level of socioeconomic organizations and those operating at the individual level.

Three broad sets of factors moderate the relationship between gender and work-related networks: sex stratification, interaction dynamics, and gender beliefs and identities. Women are under-represented in executive positions and men and women are segregated into different jobs, occupations, firms, and industries such that women are over-represented in lower paying jobs (Baron and Pfeffer 1994, Reskin 1993). Men and women interact on a daily basis in social life, but the structure of gender roles outside the workplace is such that they engage in different activities and form part of different social circles outside of work (Ross 1987). Voluntary group activities, for example, mirror and reinforce the gender segregation found in the workplace (McPherson and Smith Lovin 1986). Furthermore, as in the workplace, women's social roles tend to be lower in status and prestige than men's; as a result, although men and women interact frequently, only a minority of these cross-gender interactions occur between people of roughly equivalent power and status (Ridgeway and Smith-Lovin 1999).

Kanter (1977) established the effects of differences in power, opportunity, and numbers on interaction dynamics and individual attitudes. Interaction dynamics, which are both cause and consequence of stratification inside and outside the workplace, further reinforce differences in networks via several mechanisms. Well-documented preferences for homophily, i.e., same-gender interaction, lead men and women to organize discretionary interaction within different social circles (Smith-Lovin and McPherson 1993). Preferences for interaction with high status individuals—those who are powerful and upwardly mobile—influence the dynamics of interpersonal attraction and network formation (Ibarra 1992). But, 'female' is a lower ascribed status than 'male' (Ridgeway 1991). Thus, for women, preferences for homophily and preferences for status conflict, while these preferences are congruent for men. This serves to further segregate networks and aids in the perpetuation of stereotypic beliefs about gender and work competency (Ridgeway and Smith-Lovin 1999). Gender beliefs and identities, which are themselves a product of interaction patterns, affect how people interact with the constraints of their structural contexts, shaping what contacts men and women seek and how they negotiate their interactions (Ridgeway and Smith-Lovin 1999).

In sum, the literature on work networks suggests that social structures, social interaction, and social identities intertwine to differentiate women's and men's networks. Macrostructural demographic and job stratification patterns interact with the microdynamics of interpersonal exchange and identity construction to reinforce gender differences in networks as well as in the types of networks that each need in order to further their attainment. Below is reviewed the research evidence in each of these areas.

1. *Differences in Networks*

Structuralists have typically studied how men and women enter the occupational world with different human capital and how they are distributed in different jobs, hierarchical levels, firms, and even industries. These structural factors account for most of the differences observed in men and women's networks and related mobility outcomes. When men and women hold similar jobs, occupations, and hierarchical levels, they have similar networks and attain equally central informal positions (Brass 1985, Ibarra 1992, Miller 1986, Burt 1992, Aldrich et al. 1989, Moore 1990).

Regardless of position, however, organizational demography affects networks by regulating the availability of same-gender contacts that are also influential (Ibarra 1992). Compared to men, therefore, women typically have fewer, high-status, same-gender contacts available to them for work-related interaction (Ibarra 1992). As a result, women working in male-dominated industries, firms, or jobs tend to develop 'functionally segregated' networks with personal and professional contacts relegated to different, rarely overlapping networks. This differs from the networks of their male counterparts, who tend to develop more 'multiplex' network relationships, i.e., relationships that have both a personal and professional dimension, rather than just one. The trust and loyalty associated with coaching and advocacy for promotion is more likely to develop in relationships defined by multiple dimensions (Kanter 1977).

Outside the workplace, family and life-course factors also produce similar structural effects. Kinship ties tend to account for a greater proportion of women's ties and this effect is heightened with child rearing when the effects of occupation are held

constant (Campbell 1988, Fischer and Oliker 1983, Moore 1990). Sex segregation of activities inside and outside the workplace, therefore, limits the status of contacts and multiplexity of women's work relationships and thus the career instrumentality of their network.

2. *Differences in the Relationship Between Networks and Professional Outcomes*

More recent research suggests that, due to the structural factors outlined above, women must use different network means to achieve the same career goals as men. Many studies, reviewed in more detail below, find that an interaction between gender and human capital or structural position—rather than main effects for either—explains network characteristics.

Men appear to be better able than women to convert positional and human capital resources such as hierarchical rank, educational attainment, and external professional contacts into access to central network positions (Ibarra 1992, Miller 1986, Miller et al. 1981). Burt (1992) found that men furthered their career mobility by creating networks rich in 'bridging ties' to people who were not directly connected to one another. Women, by contrast, required strong ties to strategic partners to signal their legitimacy and thus contribute to their advancement. He argues that networks dominated by strong ties, i.e., relationships high in emotional intensity, intimacy, or frequency of interaction (Granovetter 1982), while detrimental for men are beneficial for women by serving to compensate for their lower status and legitimacy in the managerial world. In a study of Fortune 500 middle managers, Ibarra (1997) found that fast-track men reported networks much like those of Burt's highly mobile managers, while the fast-track women built networks that were higher in both the tie strength and range of contacts. These findings are consistent with Granovetter's (1982) argument that weak ties are less advantageous for people in socially or economically insecure positions.

Women may also develop different network routes in order to compensate for the few women available to them in the workplace. Men's workplace ties are primarily with men, regardless of the type of relationship involved; for women, by contrast, contacts with men provide certain types of instrumental access, while relationships with a mix of men and women serve as sources of social support and friendship (Ibarra 1992, Lincoln and Miller 1979). Brass (1985) found that homophilous workplace networks were more detrimental for women than for men because those who control the promotion process tend to be male. Ibarra (1997), by contrast, found that same-gender ties help managerial women advance. When women are under-represented in managerial and professional ranks, homophilous ties play a critical role in helping those in the minority gain advice from others who have had similar experiences. A beneficial side effect is that reaching out to other women typically requires women to extend their network links beyond the immediate workgroups or functional areas, adding breadth and range to their networks.

3. *Effects of Identity on Networks*

Network behavior is not only driven by instrumental motives such as career advancement. People initiate and maintain relationships as expressions of valued social identities, and participate in activities and institutions that are congruent with those identities (Stryker and Serpe 1982). Gender identity, therefore, may affect a person's choice of social contexts (within which different types of potential network contacts are more or less available) as well as the discretionary contacts that are developed within those contexts. But, the simple existence of homophily on some trait is not sufficient motive for tie formation (Ibarra 1997).

Women vary in the strength of their identification with their multiple identities, and this fact may explain large within-gender group differences in network homophily. Chatman and Brown (1996) found that social identity mediates the effects of demographic similarity at the dyadic level on friendship formation in business school student networks. Thus, identification with one's gender group explains variance in the formation and nature of network ties over and above that explained by demography. Demography, however, is still expected to play an important role because ascribed categories such as gender acquire their meaning in the context of social interaction (Wharton 1992). In work environments in which the distribution of power and status favors men numerically, the extent to which gender is a salient identity will affect women's interaction choices. Ely (1994), for example, found a correlation between the organizational demography of law firms and the quality of peer and hierarchical relationships among women in those firms. She argued that this correlation was mediated by the extent to which the women in those firms identified with each other on the basis of gender.

People have multiple identities (e.g., consultant, wife, mother, tennis player, Protestant) that vary in their importance to the individual and in the degree to which they are reinforced or embedded in one's network (Stryker and Serpe 1982). Stryker and Serpe argue that a person's 'commitment' to any given identity is a function of the number, affective importance, and multiplexity of network ties that are formed by the person when enacting the identity. As discussed above, the demographics of the workplace and social groups outside work make it easier for men's personal and professional contacts to work

synergistically; women's are more likely to be uniplex, or valuable on a single dimension.

This pattern is exacerbated by life course and family factors because gender interacts statistically with major family transitions to change network patterns (Elder and O'Rand 1995). Munch et al. (1997) found that childbirth leads women to drop their job and career-related ties in order to limit the overall size of their networks, while men substitute family ties for male social friends, but without losing job contacts. Changes in family status, therefore, are associated with changes in patterns of social relations, which shape and give meaning to women's and men's experiences, both in their families and jobs. The network configurations created by major family transitions, in turn, will shape the hierarchical ordering of social identities and the cultural assumptions that women and men make about the appropriate balance of job- and family-related work. Changes in network characteristics associated with family transitions may explain cohort and individual differences in women's responses to job–family demands.

4. Conclusion

The existing evidence suggests that different network configurations are effective in promoting the careers of men and women. In most organizations men and women differ in the jobs they hold, in their opportunity for informal interaction with high-status, same-gender others, and the expectations that govern their interactions with others. Outside the workplace, men and women are subject to different role demands. They come to develop different types of networks because they are, in fact, operating in different social contexts that require different network configurations to accomplish similar objectives. These findings raise critical questions for future research on the interaction between gender and networks as it affects the demographics of the workplace and course of careers. They suggest that future research should shift focus from comparing men's and women's networks towards exploring why different networks work for women and men, and what factors affect the formation of networks with such characteristics.

Social Neuroscience

Social neuroscience refers to the study of the relationship between neural and social processes. A fundamental assumption in the science of psychology is that neurophysiological processes underlie social and psychological phenomena. The early American psychologist William James (1890/1950) was among the first to articulate this assumption; to recognize that developmental, environmental, and sociocultural factors influence the neurophysiological processes underlying psychological and social phenomena; and to acknowledge that these influences could be studied as neurophysiological transactions. James also asserted that unnecessary diseconomies and conundrums would result if neurophysiological events were the exclusive focus of psychological investigations.

Despite this early recognition that molecular processes and mechanisms bear on molar social psychological processes and vice versa, the early identification of biology with innate mechanisms and the identification of social psychology with self-report data contributed to an antipathy that endured long after each field became more sophisticated. Accordingly, neuroscientific analyses tended to be limited to behavioral phenomena occurring within an organism (e.g., attention, learning, memory), whereas social psychological analyses traditionally eschewed biological data in favor of self-report and behavioral data.

As neuroscientific approaches were applied to the study of diseases and to elementary cognitive and behavioral processes, subtler medical and behavioral phenomena succumbed to neuroscientific inquiry. The 1990s were declared by the US Congress to be the 'decade of the brain,' reflecting the interest in and importance of the neurosciences in theory of and research on cognition, emotion, behavior, and health.

1. *Doctrine of Multilevel Analyses*

The decade of the brain has led to a realization that a comprehensive understanding of the brain cannot be achieved by a focus on neural mechanisms alone. The brain, the organ of the mind, is a fundamental but interacting component of a developing, aging individual who is a mere actor in the larger theater of life. This theater is undeniably social, beginning with prenatal care, caregiver–infant attachment, and early childhood experiences and ending with feelings of loneliness or embeddedness and with familial or societal decisions about care for the elderly. Mental disorders such as depression, anxiety, schizophrenia, and phobia are both determined by and are determinants of social processes; and disorders such as substance abuse, prejudice and stigmatization, family discord, worker dissatisfaction and productivity, and the spread of acquired immunodeficiency syndrome are quintessentially social as well as neurophysiological processes.

Indeed, humans are such social animals that a basic 'need to belong' has been posited (Baumeister and Leary 1995, Gardner et al. in press). People form associations and connections with others from the moment they are born. The very survival of newborns depends on their attachment to and nurturance by others over an extended period of time. Accordingly, evolution has sculpted the human genome to be sensitive to and succoring of contact and relationships with others. For instance, caregiving and attachment have hormonal (Uvnas-Mosberg 1997) and neurophysiological substrates (Carter et al. 1997). Communication, the bedrock of complex social interaction, is universal and ubiquitous in humans. In the rare instances in which human language is not modeled or taught, language develops nevertheless (Goldin-Meadow and Mylander 1983, 1984).

The reciprocal influences between social and biological levels of organization do not stop at infancy. Affiliation and nurturant social relationships, for instance, are essential for physical and psychological well-being across the lifespan. Disruptions of social connections, whether through ridicule, separation, divorce, or bereavement, are among the most stressful events people must endure (Gardner et al., 2000). Berkman and Syme (1979) operationalized social connections as marriage, contacts with friends and extended family members, church membership, and other group affiliations. They found that adults with fewer social connections suffered higher rates of mortality over the succeeding nine years even after accounting for self-reports of physical health, socioeconomic status, smoking, alcohol consumption, obesity, race, life satisfaction, physical activity, and preventive health service usage. House et al. (1982) replicated these findings using physical examinations to assess health status. In their review of five prospective studies, House et al. (1988) concluded that social isolation was a major risk factor for morbidity and mortality from widely varying causes. This relationship was evident even after statistically controlling for known biological risk factors, social status, and baseline measures of health. The negative health consequences of social isolation were particularly strong among some of the fastest growing segments of

the population: the elderly, the poor, and minorities such as African Americans. Astonishingly, the strength of social isolation as a risk factor was found to be comparable to high blood pressure, obesity, and sedentary lifestyles.

Social isolation and loneliness are associated with poorer mental as well as physical well-being (e.g., Ernst and Cacioppo 1999, Gupta and Korte 1994, Perkins 1991). People who report having contact with five or more intimate friends in the prior six months are 60 percent more likely to report that their lives are 'very happy,' as compared to those who do not report such contact (Burt 1986). People appear to be cognizant of the importance of social relationships. When asked 'what is necessary for happiness?' most rated relationships with friends and family as being the most important factor (Berscheid 1985).

Initially, studies of the neural structures and processes associated with psychological and social events were limited to animal models, post-mortem examinations, multiple determined peripheral assessments, and observations of the occasional unfortunate individual who suffered trauma to or disorders of localized areas of the brain. Developments in electrophysiological recording, functional brain imaging, neurochemical techniques, neuroimmunologic measures, and ambulatory recording procedures have increasingly made it possible to investigate the role of neural systems and processes in intact humans. These developments fostered multilevel integrative analyses of the relationship between neural and social processes. Cacioppo and Berntson (1992) coined the term social neuroscience and outlined several principles for spanning molar and molecular levels of organization.

1.1 The Principle of Multiple Determinism

The principle of multiple determinism specifies that a target event at one level of organization, but particularly at molar (e.g., social) levels of organization, may have multiple antecedents within or across levels of organization. For example, consider the multiple factors that contribute to drug abuse. On the biological level, researchers identified the contribution of individual differences in the susceptibility of the endogenous opiod receptor system while on the social level investigators have noted the important role of social context. Both operate, and our understanding of drug abuse is incomplete if either perspective is excluded. A corollary to this principle is that the mapping between elements across levels of organization becomes more complex (e.g., many-to-many) as the number of intervening levels of organization increases. One implication is that the likelihood of complex and potentially obscure mappings increases as one skips levels of organizations.

1.2 The Principle of Nonadditive Determinism

The principle of nonadditive determinism specifies that properties of the whole are not always readily predictable from the properties of the parts. Consider an illustrative study by Haber and Barchas (1983), who investigated the effects of amphetamine on primate behavior. The behavior of nonhuman primates was examined following the administration of amphetamine or placebo. No clear pattern emerged between the drug and placebo conditions until each primate's position in the social hierarchy was considered. When this social factor was taken into account, amphetamines were found to increase dominant behavior in primates high in the social hierarchy and to increase submissive behavior in primates low in the social hierarchy. The importance of this study derives from its demonstration of how the effects of physiological changes on social behavior can appear unreliable until the analysis is extended across levels of organization. A strictly physiological (or social) analysis, regardless of the sophistication of the measurement technology, may not have unraveled the orderly relationship that existed.

1.3 The Principle of Reciprocal Determinism

The principle of reciprocal determinism specifies that there can be mutual influences between microscopic (e.g., biological) and macroscopic (e.g., social) factors in determining behavior. For example, not only has the level of testosterone in nonhuman male primates been shown to promote sexual behavior, but the availability of receptive females influences the level of testosterone in nonhuman primates (Bernstein et al. 1983, Rose et al. 1972). Within social psychology, Zillmann (1994) has demonstrated that exposure to violent and erotic materials influences the level of physiological arousal in males, and that the level of physiological arousal has a reciprocal influence on the perceptions of and tendencies toward sex and aggression. Accordingly, comprehensive accounts of these behaviors cannot be achieved if either biological or social levels of organization are considered unnecessary or irrelevant.

2. Insights Fostered by Multilevel Analyses

Recent research has provided growing evidence that multilevel analyses spanning neural and social perspectives can foster more comprehensive accounts of cognition, emotion, behavior, and health (e.g., Anderson 1998).

First, important inroads to the logic of social processes have emerged from theory and research in

the neurosciences (e.g., brain organization and localization of function, genetic determinants of behavior). Research in the neurosciences, for instance, has revealed that early ideas about memory, in which knowledge and skills were thought to be served by the same underlying mechanism, are incorrect. Instead, separable neural systems underlie the memory of people, episodes and ideas (declarative, episodic memory), and the memory of procedures, interactions, or skills (procedural, implicit memory).

Similarly, research in the neurosciences has influenced what are thought to be the processes underlying social attitudes and decisions. Mechanisms for differentiating hostile from hospitable environmental stimuli are imperative for the survival of species and for the formation and maintenance of social units. The human brain and body therefore can be conceptualized as being shaped by natural selection to calculate utility and to respond accordingly. Evaluative decisions and responses are so critical that organisms have rudimentary reflexes for categorizing and approaching or withdrawing from certain classes of stimuli, and for providing metabolic support for these actions (Lang et al. 1990). A remarkable feature of humans is the extent to which the evaluation of utility is shaped by learning and cognition.

The processes subserving the evaluation of hostile and hospitable events are also physiological processes and cannot be understood fully without considering the structural and functional aspects of the physical substrates. Noninvasive investigations of the physiological operations associated with evaluative processes provide an important window through which to view these processes without perturbing them. For instance, the neural circuitry involved in computing the utility of a stimulus (i.e., evaluative processing) diverges from the circuitry involved in identification and discrimination (i.e., nonevaluative processing). Furthermore, evaluative discriminations by humans (e.g., attitudes) have traditionally been conceptualized as being bipolar (hostile–hospitable) and have been measured using bipolar scales to gauge the net affective predisposition toward a stimulus. Such an approach treats positive and negative evaluative processes (and the resulting affective states and judgments of utility) as equivalent directions on a single scale, reciprocally activated, and interchangeable in the sense that increasing one is equivalent to decreasing the other. Physical constraints may restrict behavioral manifestations of utility calculations to bivalent actions (approach–withdrawal), but research in the behavioral and social neurosciences now suggests that approach and withdrawal are behavioral manifestations that come from distinguishable motivational substrates. This work has led to evolutionary models of affect and emotion in which a stimulus may vary in terms of the strength of positive evaluative activation (i.e., positivity) and the strength of negative evaluative activation (i.e., negativity) it evokes. Furthermore, the underlying positive and negative evaluative processes are distinguishable, are characterized by distinct activation functions, and have distinguishable antecedents (Cacioppo and Berntson 1994).

Second, the study of social processes has challenged existing theories in the neurosciences, resulting in refinements, extensions, or complete revolutions in neuroscientific theory and research. Classically, immune functions were considered to reflect specific and nonspecific physiological responses to pathogens or tissue damage. It is now clear that immune responses are heavily influenced by central nervous processes that are affected by social interactions and processes. For instance, the effects of social context now appear to be among the most powerful determinants of the expression of immune reactions (Glaser and Kiecolt-Glaser 1994). It is clear that an understanding of immunocompetence will be inadequate in the absence of considerations of psychosocial factors. Research on these interactions was activated by investigations demonstrating the direct and moderating effects of psychosocial factors (e.g., conditioned stimuli, bereavement, social support, major life events) on immune competence (Kiecolt-Glaser et al. 1984). Thus, major advances in the neurosciences can derive from increasing the scope of the analysis to include the contributions of social factors and processes.

Third, the social environment shapes neural structures and processes and vice versa. Meaney and colleagues (Liu et al. 1997, Meaney et al. 1993), for instance, have found that experimental manipulations of maternal care influence the development of individual differences in neuroendocrine responses to stress in rats. As adults, the offspring of mothers that exhibited more licking and grooming of pups during the first ten days of life were also characterized by reduced adrenocorticotropic hormone and corticosterone responses to acute stress. As mothers, these rats also tended to lick and groom their pups.

Finally, deciphering the structure and function of the brain is fostered by sophisticated social psychological theories in which the elementary operations underlying complex social behaviors are explicated, and by experimental paradigms that allow these social psychological operations to be studied in isolation using neuroscientific methods. Brain imaging studies of the neural bases of emotion have contrasted positive and negative emotions based on the assumption that these emotions are served by the same neural structures. Research and theory in the social and behavioral sciences now suggests that the processes underlying positive and negative emotions are separable, and paradigms for eliciting positive and negative emotions have been developed. Accordingly, recent brain imaging studies in which positive and neutral emotions are contrasted, and negative and neutral emotions are contrasted, have revealed the activation of distinguishable neural structures during positive and negative emotions.

In sum, social neuroscience is an interdisciplinary field that is helping to illuminate questions ranging from the social sciences to the neurosciences by examining how organismic processes are shaped, modulated, and modified by social factors and vice versa.

Social Properties (Facts and Entities): Philosophical Aspects

One area of philosophical concern, dating from the very beginning of philosophy itself, is ontology: what is there?; or, what kinds of things are there? Many questions about existence are straightforwardly em-

pirical, and hence of no interest to the ontologist. Are there unicorns, wombats, planets circling stars other than our Sun? But other existence questions are not empirical, and these are the province of the ontologist. Are there any physical objects, ideas, forms, numbers, sets, propositions, minds, concepts, a Deity, social wholes? To answer these questions is to engage in producing a list of the metaphysical kinds of things that one believes exist.

'Existence' in what sense? Some philosophers have held that each metaphysically different kind of thing exists in its own, special sense of 'existence'; or they may distinguish between being, existence, subsistence, and so on.

A more plausible view is that 'existence' is univocal, that whatever exists exists in the same sense, and that differences in the 'mode' of existence, say, of mind and body, arise not because *existence* differs in the two cases but because of the differences between minds and bodies themselves. Bodies have a spatial 'mode' of existence, it might be thought, and minds do not, but, if so, that is because of the differences between them, not because they exist in different senses of that word. Besides, if existence had a special sense for each metaphysical kind of thing, ontology could become somewhat trivial. To the question of whether, say, propositions really exist, it would be anodyne simply to say that they do exist, but only in the special proposition-sense of existence. Or that minds exist, but only in the special mental sense of existence. Or that possibilia subsist rather than exist (since that is what possible things do) whereas actual things exist rather than subsist. Ontology would entail no honest labor, and therefore no real rewards.

1. *Ontological Commitments and How to Wriggle Out of Them*

When we speak, indeed even whenever we simply think, we typically take ourselves to be speaking or thinking about various things. It is not easy to capture this notion of aboutness, but here I rely on the readers' intuitive grasp of the idea.

I do not always think or speak about anything, whenever I speak or think: in (a) 'whoever is a bachelor is neurotic,' I am not trying to speak or think about any particular thing, or even about any set of things. In (a), I am merely linking up two properties: the property of being a bachelor and the property of being neurotic, but I am not speaking about those properties. If I want to speak about the set of bachelors and the set of neurotic persons, I could say: (b) 'The set of bachelors is a proper subset of the set of neurotic persons.' (b) is certainly not equivalent to (a), since (b) has ontological commitments of which (a) is wholly innocent.

I might be thinking or speaking about Socrates or the man I met yesterday or the tallest building in New York. Let us call whatever I think or speak about 'entities.' There are a number of ways in which things can go wrong when I speak about entities. First, I can make mistakes, e.g., when I take myself to be thinking about something that does not in fact exist: Atlantis, Vulcan, witches, or phlogiston. These are cases in which we really are *intending* to think about something, but fail. Let us call these sorts of cases, 'cases of elimination.' There simply are no such things, and if we have at first placed them on our list of what there is, on finding that they do not exist, we remove or eliminate them from the list. Some philosophers have said this about minds, or mental states. In cases of elimination, nothing can be salvaged from talk about such things as it stands. Such talk is plain false (see Lycan and Pappas 1972).

Second, there are cases which, on first appearance, seem to be ones in which I am speaking or thinking about something, but closer inspection dispels the appearance. Not all cases of apparently thinking about something turn out, on analysis, really to be such. I may not be really intending to talk about the thing in question at all. I may, for example, talk about the average family, but such talk or thought is not really about what it might seem to be about. There is no such thing as *the* average family about which I am talking.

Average-family talk or thought is merely shorthand for talking about the number of people in the country divided by the number of households (or something like this anyway). There is no such thing as the average family, nothing that should be taken ontologically seriously, beyond taking seriously households and people.

Let us call these cases, 'cases of replacement.' The original talk, r_1 ('the average family') has apparent ontological commitments of some sort. The replacing talk, r_2 ('households' and 'persons') does not have those same apparent ontological commitments (although of course it has some of its own). The burden of proof, in such cases, falls on the person wishing to show that some of the ontological commitments of the original talk are apparent but not real. He or she must indicate the replacing talk that lacks them. In these cases, our original talk gets salvaged, because it is true, if the replacing sentence without the same apparent ontological commitments is true.

What must be the case for the replacing talk, r_2, to count as an adequate replacement for the original talk, r_1? The two talks, r_1 and r_2, must convey the same information, and part of that requirement is that r_1 if and only if r_2. No two sentences can convey the same information unless they at least have the same truth values. Beyond this, matters get controversial, but the same-truth-value condition will suffice for our purposes.

It is not required that the replacement can actually be carried out in practice. Actually replacing r_1 by r_2 might be cumbersome, complicated, long-winded, or whatever. The replacement must be theoretically

possible, and the supporter of the replacement needs to show how the replacement is possible in principle, but not necessarily in practice.

Third, and closely related to the above, are cases in which our talk or thought really and not just apparently is about some entities, but they turn out *not* to be *sui generis*, since they can be reductively identified as or with another thing. These are, appropriately, cases of reductive identification.

This is the reductive identification which claims so much of philosophers' energies. There are, it may be said, physical objects, but they are really only sets of sense data; there are mental states, but they are identical with brain states; there are numbers but they are merely the same as sets of sets. Such attempts at reductive identification allow the philosophical cake to be both had and eaten. Along with common sense, it can be asserted that there are such things. But, along with some ideal of philosophical acceptability, they can be shown to be reductively identified as merely another thing after all.

Insofar as philosophical reductive identification succeeds, it allows us to shorten our ontological list, while not denying the claims of common sense. It is for this reason that the term 'reductive' is appropriate; these identifications permit a reduction in the number of basic ontological commitments. On a materialist reductive analysis, for example, there are minds, but they do not have to be taken ontologically seriously, beyond taking bodily or brain states or whatever seriously. Or, according to Berkeleyian idealism, there are tables, chairs, and so on, but they are only ideas in the mind. Once ideas in the mind are on the ontological list, adding tables and chairs would be superfluous. Tables and chairs are already on the list, if ideas in the mind are.

Again, in cases of reductive identification, our talk gets salvaged, since the original talk is true if the analysis containing the reductive identifier is (see *Reduction, Varieties of*).

2. *Entities, Properties, Facts*

Socrates or the man I met yesterday or the tallest building in New York are concrete objects. Sets and numbers and propositions, if there are such, are abstract objects, which are neither spatial nor temporal. Other things we think or speak about include spatio-temporal nonconcreta: events and actions, such as the eruption of Mount Vesuvius and the first running of a mile under 4 min; processes such as the erosion of the soil in some specific place over a specific period; and states such as the lake's remaining calm on such-and-such a night or the stillness of the air on a summer's eve or the presence of helium in a balloon.

Thinking or talking about any sort of thing is caught by reference; we refer to something, namely, to that entity our thought or language is about.This entry confines itself to discussion of facts, entities, and properties, as such referents of our thought, but no discussion of social ontology could be complete unless it brought to the fore actions, and in particular social actions (see *Joint Action* and *Action, Collective*).

Typically, when I think about something, I also ascribe some feature or characteristic to it. For example, when I say of Socrates that he is snub-nosed, or of the man I met yesterday that he is a spy, or of the erosion of the soil that it was accidental, I ascribe such a feature or characteristic. Let us call these features or characteristics 'properties.' The duality of reference and ascription is captured grammatically by the distinction between subject and predicate, and metaphysically by the distinction between entity and property. (All of this needs serious qualification, and extension to other sorts of sentences, but I forego that pleasure here.)

Are there, ontologically speaking, properties as well as entities? There are at least two ways in which to handle this question. First, there is the austere point of view that says that ascribing properties is not enough to be ontologically committed to them. There are properties, only if we *talk or think about* them, *refer to* them, and if such talk or thought cannot be eliminated or replaced by other talk or thought which makes no such ontological commitment (see Quine 1963).

There are, though, cases in which we do appear to refer to properties: (a) 'The color crimson is a shade of the color red.' It is easy to show that (b) 'The set of crimson things is a subset of the set of red things' will not do as a replacement for (a). And if no such replacement or elimination is possible, then there are properties, although they may not be *sui generis*, if any reductive identification of them is possible.

Second, there is the more relaxed approach, which says that we are ontologically committed to properties if they are actually instantiated (or perhaps even if only well defined), whether or not we refer to them or talk about them. Ascription alone, without reference, may still involve us in ontological commitment. If so, 'this visual patch is red,' which ascribes the property of being red to something, but does not refer to the property, commits us to the property of being red as well as to a visual patch, since the sentence insures that redness has at least one actual instance.

Finally, and much more controversially, some philosophers have believed that our account of what there is must include not only entities and properties, but also facts, for example the fact that some entity *e* has some property *P*. Facts have been enlisted for many purposes, one such being a correspondence theory of truth, and another being causal analysis. Are sentences true when they correspond to the facts? Is it the fact that the match was struck that caused it to light? These two particular uses of facts have come in for some devastating criticism. But even so, there may well be facts, even if they are useless in theories of truth and for analyses of causality.

If it is a fact that Socrates is snub-nosed, then is not there at least that fact? At least on first appearance, it seems that there are facts. If so, there are not only Socrates and the property of being snub-nosed, but also Socrates' being snub-nosed (a state) and the fact that he is snub-nosed. If there are facts, then they count as a kind of entity, if they can be referred to and occupy subject position in sentences. 'The fact that Fiorello LaGuardia was elected disturbed many of his opponents,' was no doubt true, so we do seem to refer to facts. Without mere replacement, or elimination, or reductive identification, we have facts on our ontological list, as well as entities and properties, states, and events.

Needless to say, philosophers have disputed whether all of these 'reifications' are really required, and whether some can be understood in terms of the others. Perhaps numbers are just sets. Perhaps propositions are just sets of similar sentences. Perhaps minds are just brains. Perhaps there is the fact that Socrates is snub-nosed, or perhaps there is no such thing. And even if there is this fact, maybe it is identical with the state, Socrates' being snub-nosed. But none of that need be decided here.

3. *Some Social Ontology*

Thought and discourse about society, whether lay or by the social scientist, raises these ontological questions too. Just as I can think about Socrates or the tallest building in New York, so too I can think about France or the Icelandic working class or the commodity market or the National Football League. Our very thought about society appears to commit us to believing in nation states, governments, classes, social structures, tribes, clubs, associations, and so on, just as our thought about Socrates and the tallest building in New York appears to commit us to believing in persons and buildings. And we are really committed to these social entities, unless we can show that these turn out to be cases in which either we can, without loss, eliminate discourse about social entities entirely, or we can replace such talk with other talk that makes no similar ontological commitment, or there is some reductive identification available for the putative social entities.

What does 'social' connote? The basic application of the term relates to properties (for more about social properties, see below). What makes a property a social property? This is, I think, a difficult question. Some entity's having a property may have a social cause or social effect, without making the property itself social. For example, the soil's being eroded may be caused by inept bureaucracy, and may result in a stock market plunge, but none of that makes the property of being eroded a social property. Whether a property is social depends on something intrinsic about the property itself, and not on the causes or effects of its being instantiated.

A property is social (roughly, without some refinements unnecessary here) if and only if from the fact that it is instantiated, it follows that at least two people exist and have an interlocking system of beliefs and expectations about one another's thoughts or actions. Intuitively, I think this gets our idea of sociality about right, although one might just think that the requisite number should be greater than two. For example, the property of jointly carrying something is not social on this account, and rightly so, because two men might jointly carry something without either being aware of what the other was doing, oblivious to each other's very existence. Jointly carrying requires two people, but makes no demands on their beliefs and expectations about one another. Purchasing a stone is, on the other hand, a social property on this account, and rightly so. No two people could be engaged in such a transaction without having a whole host of beliefs and expectations about the actions of the other.

Social entities, if such there be, are entities such that they have at least one social property essentially. France, for example, is essentially a nation; the Icelandic working class is essentially a class, a working class, and Icelandic. Once the idea of a social property is to hand, we can use it to introduce the idea of sociality as applied to other ontological categories. So our idea of the social fans outwards, as it were, from our idea of a social property.

Social entities, if such there be, are never concrete, in the way in which earlier examples of entities were. Concrete entities, like Socrates and the tallest building in New York, are exclusive space occupiers, no two of which can occupy the same space at the same time.

Social entities do, in general, appear to be space occupiers; France occupies a certain region of physical space, the Icelandic working class is physically in Iceland. But social entities are not exclusive space occupiers. Suppose a diocese of the Catholic Church, call it 'Sancta Gallia,' occupies exactly the same geographical area as does France. If so, two distinct social entities, France and Sancta Gallia, occupy the same physical space at the same time.

What, then, of the three options we have available, for dealing with these apparent ontological commitments of our social discourse? Elimination of discourse about social entities would seem to involve an intellectual loss; we could not even in principle say things we would want to say without the discourse. (Imagine where we would be without sociology, anthropology, and a part of economics, for example.) The issue here is not just one of linguistic economy. It is not that we could not nearly as easily say what we want without social discourse but could only do so in an altogether more baroque fashion; rather, the claim is that we would have no way in principle of conveying what we want to say without that social discourse.

On the other hand, replacement does seem possible for some very simple examples. A case which has been mentioned in the literature is 'The Jewish race is cohesive,' which appears to commit the speaker or thinker to an entity, the Jewish race. But, it is alleged, this is replaceable by 'Jews tend to marry other Jews,' etc., and the latter makes no such ontological commitment to the existence of a race. 'The Jewish race is cohesive' behaves very much like 'The average family has 3.2 members.' (See J. W. N. Watkins, 'Ideal Types and Historical Explanation' and 'Historical Explanation in the Social Sciences,' the first of which is reprinted in Ryan (1973), and both of which are reprinted in O'Neill (1973).)

I do not wish to claim that these replacements are never available; perhaps they do work for the case just mentioned. But it seems hard to see what replacement strategy would work for many other examples. Consider 'France is a charter member of the United Nations.' What sentence or sentences could replace this, yet convey the same information, at least in the sense of having the same truth value, and yet make no ontic commitments to a nation state and a world organization? I can here only invite the reader to suggest candidates; I myself know of none. Replacement does not work as a general strategy.

However, it is one thing to admit that there are such entities as France, the United Nations, and the Icelandic working class, but quite another to insist that they cannot be reductively identified with something more respectable. Many philosophers are drawn to reductive strategies of one kind or another: there are mental states, but they are (merely) identical with brain states; there are numbers, but they are (merely) identical with sets of sets; there are physical objects, but they are (merely) identical with sets of sense data.

So too various reductive strategies suggest themselves for social entities: France is (merely) a geographical area, a set of persons, etc. No one can 'prove' that no reductive strategy could work. What must be done, I think, is to evaluate each reductive strategy that suggests itself, one-by-one.

There are some general lessons one can draw, though. The vague thought, 'Nations are identical with the people who make them up,' is ill-formed. In any reductive identification, names must flank both sides of the identity sign. So, for instance, 'France = ⋯.' Well, identical with what? Name fillers for the space on the right-hand side of the identity sign will either be extensional or nonextensional entities, in the following sense. Sets and aggregates and land masses are extensional, since, if and only if a and b are sets or aggregates or land masses, $a = b$ if and only if a and b have exactly the same members, or components, or parts.

But no extensional entity in this sense could be identical with France, for example, since their identity conditions will differ. France can remain numerically one and the same, in spite of variation in its citizenry or residents, or land occupancy. Even if one considered the set of all actual citizens of France or pieces of land that France ever occupied at any time, past, present, and future, there would be counterfactual differences.

France could have occupied a different piece of land than it did, or had different citizens or residents than it did, but this could not be true of the set or aggregate of its citizens, residents, or lands. France is nonextensional; sets, aggregates, and land masses are extensional, and no nonextensional entity could be identical with an extensional one. (In fact, this little argument which relies on counterfactual differences assumes that 'France' and 'the set of ⋯.' both rigidly designate, since the identity required is identity across all possible worlds. But I would argue that this assumption is true.)

If France is a nonextensional entity and no nonextensional entity can be identical with an extensional one, then what about some nonextensional entity for the reductive identification of France? Examples that come to mind are things like groups. Is France to be identified with the *group* of French people? The problem with this suggestion is that a group seems itself to be a social entity, and hence hardly a candidate for the reductive identification of France with a nonsocial entity. What the determined reductivist needs to find is a nonextensional entity which is also nonsocial, for the reductive identification of France, and I am aware of no such obvious candidate.

So much for social entities. What sort of properties get ascribed to things when we think or talk socially? We can think or speak of either social entities or nonsocial ones like Socrates or the tallest building in New York and, in either case, ascribe social properties to them: 'France is a charter member of the United Nations' ascribes to a pair of social entities, France and the United Nations, the relational social property of being a charter member of; 'Socrates was mayor of Athens' ascribes (falsely, as it happens) to a nonsocial entity, Socrates, the relational social property of being a mayor of.

From the fact that social properties figure in our discourse, it does not yet follow that we refer to or think about social properties. The relational social property, being the mayor of, certainly figures in 'Fiorello LaGuardia was mayor of New York,' but the sentence is not *about* that social property. It is only about Fiorello LaGuardia and New York.

On the relaxed criterion, the sentence commits us to the existence of three things: a person, a city, and the social property of being a mayor of. On the austere criterion, since the sentence is only about Fiorello LaGuardia and New York, the sentence commits us only to the existence of a person and a city, but not to the existence of a social property.

But even were we to adopt the austere view, there are a host of arguments, modeled on ones about properties generally, which do move us to talking about social properties, and so to the existence of

social properties. Here are terse statements of two such arguments: (a) If Iceland is capitalist, and if France is capitalist, then there is some property that Iceland and France share; (b) If France is a charter member of the United Nations, then it follows that France is a member of the United Nations. The inference in (b) requires taking properties ontologically seriously.The first argument parallels one by Hilary Putnam (1980) on properties generally; the second parallels one by Donald Davidson (1980) on action.

So we talk and think about social properties, and I do not see how we could simply eliminate, do without, such discourse. Nor do I know of any discourse which could replace discourse about social properties, and which both lacked the ontological commitment to social properties but allowed us to convey the same information or messages. So, on the austere view, there seem to be social properties, as well as nonsocial ones. *A fortiori*, on the relaxed view, we get properties, social and nonsocial, just insofar as we ascribe them to actually existent things, or just in case they are well defined.

Could each social property be reductively identified either with some specific nonsocial property, or with some finite Boolean construction of such? I doubt whether this could be so. Let me give an indication of why I think this. Some social properties are both nonvariable and weak, in the following senses. A social property P is nonvariable if and only if P is instantiated, then some specific set s of interlocking beliefs and expectations exists. For example, the property of participating in the custom of drinking tea at breakfast is nonvariable, since the beliefs and expectations associated with it must be the set of beliefs and expectations about drinking tea at breakfast. A social property P is weak if and only if P is instantiated, then the interlocking beliefs and expectations are about types of events which are not themselves social. The social property of participating in the custom of drinking tea at breakfast is also weak, since the beliefs and expectations associated with it concern drinking tea at breakfast, which is itself a nonsocial event or activity.

But the most characteristic sorts of social property are neither nonvariable nor weak; they are variable and strong. Consider the property of being a mayor. If that property is instantiated, it is true that some set of interlocking beliefs and expectations must exist, but there is no one particular set that must exist. There is an indefinitely wide range of things that a mayor might be expected to do in various different societies or social settings. So the property is variable, in the sense of being indefinitely variably instantiable. Moreover the property is strong, since what a mayor is expected to do involves events and activities like receiving the ceremonial key to the city, opening formal events, representing the city at certain social or political functions, and so on, and these things are themselves social events or activities.

It seems to me that these two features of typically social properties make the reductive identification of social properties with nonsocial ones exceedingly implausible. One might have thought that a social property could be reductively identified with the nested and interlocking set of beliefs and expectations with which it is associated. But since there is an indefinitely long list of such sets associated with each typically social property, and these beliefs and expectations themselves require the existence of *social* events or activities, the reductive identification appears to fail.

I do not have the space here to discuss the issue at length of whether it is necessary to admit facts to our ontology. Frequently, the case for or against reduction of social science to physical science has been put in terms of facts; supervenience claims in social science typically enlist social and nonsocial facts as the terms of the debate. (See Maurice Mandelbaum, 'Societal facts,' reprinted in Ryan (1973) and O'Neill (1973).)

But what does seem plain is that *if* there are facts, then, in the light of what we have already said above about social properties and social entities, there must be social facts. A fact would qualify as social if either it was a fact about a social entity, or it was a fact about any kind of entity, social or nonsocial, and attributed a social property to that entity. So the fact that the United Nations contributed to relief in Kosovo is a social fact, since it is about a social entity, and the fact that LaGuardia was mayor of New York is a social fact, since it attributes a social property to a nonsocial entity, namely to a person.

Often, the positions described in the relevant literature about social ontology are posed in terms of individualism and holism, sometimes with the qualifying adjective, 'methodological' added (see *Methodological Individualism: Philosophical Aspects*). Sometimes, the positions are expressed in terms of facts, and at other times, in terms of entities. Supervenience claims for the social ('the social supervenes on the nonsocial') are sometimes posed in terms of facts, at other times in terms of properties. It might be claimed that there are no irreducible social facts, or that there are no irreducible social entities or that there are no irreducible social properties. As can be seen from the discussion above, the positions are not equivalent. For example, as I have claimed, some social facts ascribe social properties to nonsocial entities.

Rarely, if at all, is the distinction drawn between the existence of entities, properties, and facts. Does individualism in the social sciences eschew social entities but admit irreducible social properties? Or should it eschew both? What should it say about facts? Might there be distinct versions of individualism, so that it comes in stronger and weaker forms?

The lesson is that these terms, 'holism' and 'individualism,' do not name unambiguous positions unless and until various distinctions are drawn, and the ontological claims of each position are clearly

specified. (See S. Lukes, 'Methodological Individualism Reconsidered,' reprinted in Ryan (1973).)

Social Protests, History of

Social protests have been integral to collective life since the first complex communities were formed. One of the oldest references to protest was found on an inscription in a tomb in Egypt's Valley of the Kings from the reign (1198–66 BC) of Rameses III in the New Kingdom translated as follows: 'Today the gang of workmen have passed by the walls of the royal tomb saying: we are hungry, eighteen days have gone by, and they sat down behind the funerary temple of Tuthmosis III … the workmen remained in the same place all day' (Romer 1982, pp. 193–5).

Social protest is defined here as contentious action undertaken collectively in response to perceived injustice or unfair action on the part of those who hold legitimate political and economic power. It seeks to achieve social (as opposed to political and economic) ends, or alternatively to restore or return to earlier ways of life. Examples of such aims are a more equitable distribution of privilege or wealth, reducing inequality among persons or groups, changing or restoring religious beliefs and/or cultural practices, and reversing cultural change. This article examines social protest in Western and non-Western societies starting in Antiquity and through the nineteenth century.

1. Protest in Imperial Rome

The authoritarian regime of Imperial Rome did not offer many opportunities for peaceful communication of ordinary people's grievances or wishes; despite the city's heavy policing, however, the large agglomerations of people in the Colosseum, Circus, and theaters offered the possibility of mass (and more or less anonymous) expressions of popular opinion. In these settings, crowds could shout demands in the Emperor's presence for the disciplining of a hated official, or object to an unpopular war. The streets too were a locus for popular protest, especially that about the shortage or high price of grain. Street disorder of this type contributed to the fall of Nero. Crowds of ordinary citizens might also call for the downfall of a usurper of the Imperial throne or express their dissatisfaction with a prefect or his policy.

The grain riot or angry complaints about the high price of bread continued to be a feature of popular protest in many parts of the world, right into the twentieth century. Most medieval and early modern European states sought to regulate the grain trade and concomitantly the price of bread at retail. These controls began to be modified and eventually removed as trade was liberalized in Western Europe, and newly formulated laissez-faire theories were put into effect in the late seventeenth century. The result was an upsurge of two types of protest: (a) crowd blockage of grain being moved on roads or waterways out of a growing region with a surplus to one with a shortage, or a city (especially an administrative city or the capital) with a stronger claim on adequate supplies; and (b) the market riot with confiscation of grain, its sale by the

crowd, and often payment (at lower than the asking price, of course) to the owner for his grain. Market riots were more likely to occur in cities or towns, sometimes along with attacks on bakers and looting of their shops.

2. Protest about Food Supply and Taxation in Old Regime France

Looking more closely at the relationship of food supply and public order in *ancien regime* France, widespread food riots beginning in the late winter or early spring (when the price of grain began to rise if the fall's crop had been small) and involving large numbers of people occurred in cycles beginning in the seventeenth century and ended only in the early 1850s. The timing of the upsurge suggests a relationship with political centralization, including policy decisions concerning economic matters and the modification of longstanding paternalist policies, especially those concerning the production and marketing of grain. Several of the modern period's great revolutions (French, 1789 and Russian, 1917) began with contention about food prices, and went on to attack—and overthrow—monarchies.

Tax revolts are another common form of protest that span the centuries of European history; the well-documented case of France is again illustrative. Increased taxation to finance the dynastic ambitions and consequent wars of the Bourbon kings made heavy demands on ordinary French men and women, to which they responded with protest. In a political system in which noble status (and ecclesiastical office) exempted the upper classes from most taxation, the fiscal burden fell disproportionately on peasants and commoners. Seventeenth century disputes over the legitimacy of new direct taxes, including attacks on collectors, were usually community affairs, but sometimes transcended single communities when the tocsin was sounded at a tax collector's first stop to arouse a whole region. New indirect taxes were farmed out to individuals (tax farmers) who had the responsibility for collecting them through private agents; both tax farmers and agents were subject to attack. Although at first, punishment was more exemplary than extensive, widespread repression became common over the seventeenth century; the label 'croquant' (a countryman armed with a stick) was first applied to peasant rebels in 1594 in southwest France, Yves Berce tells us, and continued to be used in recurrent rebellions until 1752. The titles of other seventeenth and early eighteenth-century rebellions likewise suggest the commonalty: Sabotiers (shoemakers, 1658), Bonnets Rouges (red caps, 1675), and Camisards (white shirts, intermittently from 1685 to 1710). These rebellions occurred in off-the-beaten-track areas of France that had formerly been only lightly taxed or exempt from particular taxes, so that inhabitants took extreme umbrage at the imposition of new taxes or stricter enforcement of the old.

3. Early Modern Religious Protest in Europe

The revolt of the Camisards illustrates religious protest, another type of social protest which can be found across Europe in the sixteenth to eighteenth centuries. In France, the Edict of Nantes (1598, promulgated after decades of religious wars by Henry IV) had granted freedom of conscience to Protestants all over France, permitted public worship by Protestants in designated towns, and guaranteed their civil rights; in 1685, however, Louis XIV revoked the edict, thus capping several decades of decrees limiting the effect of the policy of tolerance, and increasing the pressure on Protestants. They nevertheless continued their forbidden forms of worship (often outdoors, since they had no churches), especially in the southwest province of Languedoc; there Protestant Camisard bands conducted a guerilla war in the hills, clashing over 25 years with the forces of order. The military repression was expensive, and the rebels reduced tax revenues by attacking tax collectors and destroying property, but royal forces finally succeeded in ending Protestant protest in 1710. Over the last years of the Old Regime, a more tolerant policy emerged unevenly, alternating with periods of intensified repression.

Outside France, but in Western and Central Europe, the sixteenth century was also a period of extensive social protest connected with the Protestant Reformation. The German Peasant War has been the object of controversy since it began and Catholic authorities promptly claimed that Luther's revolt against the church had promoted peasant rebellion. Historians of the rebellion have also disagreed, with Marxists—starting with Friedrich Engels—claiming that the Peasant War was socioeconomic class warfare and non- or anti-Marxists interpreting it as a conservative movement seeking to restore Catholic principles of right and justice. More recently, Peter Blickle (1981) has again emphasized the religious underpinnings of the conflict. He argues that contrasts between urban and rural revolt are not clear cut; both urban and rural ordinary people emphasized justification through scripture. And there was only one outcome: the rising ended with the defeat of the rebels and its leaders executed.

In 1536, the Pilgrimage of Grace challenged Henry the VIII's dissolution of the monasteries in England, with a brief aftermath early in 1537. Like the revolt of the Camisards, the Pilgrimage (the term includes several more or less coordinated local risings) mixed religious issues with political and economic ones; unlike the Camisards, however, the Pilgrims were protesting Henry and his minister Thomas Cromwell's

rejection of aspects of Roman Catholic doctrine. The Pilgrims' banners portrayed the Five Wounds of Christ and they were often led by priests. Among the significant political events which preceded the revolt in 1536 were the passage of parliamentary acts which dissolved the 'lesser monasteries,' and permitted the king to name his own successor; the clergy of England then rejected the doctrine of purgatory, and accepted Henry's Ten Articles making (what seemed to some) modest changes in religious doctrine, a compromise document.

The Pilgrimage began with the rising of nine 'hosts' (popular armies, including members of the gentry, clergymen, town dwellers, and peasants) starting in Lincolnshire, followed by eight more raised in Yorkshire and elsewhere in the north. Attracting new recruits on their way to take the city of York without a battle, the rebels united around the term 'pilgrimage' to designate their undertaking to ask the king's grace in preserving 'Christ's church' and their sworn oath. Robert Aske, a member of the gentry became their spokesperson. First a truce, and then a general pardon from the king were bargained and granted (it contained promises of a parliament in York and that the abbeys which had been closed under the dissolution decree would be reopened) which led to class divisions within the hosts and in January 1537, renewed rebellion, which was put down militarily. Compared to the German Peasant War, the Pilgrims of 1536 included gentry, peasants, and townsmen, but like most early modern large-scale protests, it failed to achieve its backward-looking goals.

4. *England's Glorious Revolution and its American Colonies*

England's seventeenth century Stuart monarchs struggled with Parliament over taxation and royal prerogative, a struggle that ended in civil war when Charles I ordered the arrest of his opponents in the House of Commons. Charles I was beheaded after he was defeated in battle but refused to abandon his opposition to parliamentary claims. When the Puritan Republic ended after Oliver Cromwell's death with the restoration of the Stuarts—Charles II (1660–85) and James II (1660–88)—the struggle between kings and Parliament resumed. The struggle was finally resolved in the Glorious Revolution of 1689, when James II abdicated to be replaced by William and Mary; the outcome was a greater role in English governance for Parliament.

Wars consumed the West European mainland until the mid-eighteenth century, when monarchical governments reached a new great power balance in which Spain played only a peripheral role. France and Great Britain (following the unification under the same monarch of England and Scotland) faced each other as rivals not only in Europe but also in North America and South Asia where both had colonial interests. The following paragraphs look at social protest in other world regions, both colonized and free, starting with the British colonies in North America, continuing with two Asian examples.

During the Restoration period, the British kings sought to increase their control over their North American colonies by passing Navigation Acts, based on mercantilist economic theory which would limit colonial trade and manufacturing in order to promote English trade and manufacturing. In pursuing this goal James II replaced the proprietary governments of New Hampshire, Massachusetts, and the Carolinas with royal governors and suspended their elected assemblies. The colonists resisted these interventionist efforts and overthrew the governors of New York and Massachusetts, and replaced the proprietor of Maryland. The interests of colonial populations had diverged from those of the royal governments in England, including that of William and Mary after the Glorious Revolution (1689) in which James II was forced into exile. The 13 North American British colonies increasingly became another locus for the rivalry of France and Britain that was also being played out in Europe.

With the end in 1763 of the Seven Years War, Britain took over most of the former French colonies, while domestically, it staggered under an enormous war debt. The government searched for a solution to its liquidity crisis in the colonies, attempting to contain settlement south of Canada to the area east of the Appalachians, impose new taxes, and limit self-government in North America. These heavy-handed British policies only increased colonist dissatisfaction, and to make matters worse they were followed by new revenue generating laws: the Sugar Act (to improve enforcement of the duties on molasses), the Currency Act (which forbade the colonies from issuing paper money), and the Stamp Act (which taxed the paper used in legal documents and publications). Public protest erupted in several of the colonies, with coordinated resistance in Virginia and Massachusetts, and a meeting (the Stamp Act Congress) of delegates from nine colonies in New York in 1765 to plan further protest. Colonists boycotted imports from Britain and formed the Sons of Liberty who sponsored more public meetings; attacks on tax collectors spread. Although the Stamp Act was repealed, new taxes were passed including a duty on tea; to enforce compliance special courts were established and British troops were transferred from the frontiers to eastern cities. The dispute again escalated as colonists began new boycotts and renewed attacks on tax collectors.

The tea grievance did not disappear even though the new duties were again repealed, for Parliament granted the British East India Company a monopoly (another mercantilist policy) for the importation of tea into the colonies. This time patriots disguised as Native Americans dumped a large quantity of tea into Boston

Harbor. British authorities placed the Massachusetts colony under military rule, and open rebellion followed, starting in 1776. By 1781, the colonists had defeated Britain with the help of France and a peace treaty was signed which granted unconditional independence to the 13 colonies. Spanish America also had its colonial protest and revolutions, beginning when Spain was distracted by Napoleon's invasion in 1808 and most of its colonies in the Americas achieved independence.

5. *France and Germany before and after 1789*

Protest in continental Europe in the eighteenth century fell into the patterns described for early modern England. In France, protest about grain shortfalls or bread prices continued to dominate even as the monarchy sought to improve the circulation of grain so that regional shortages would not arouse public ire. In fact, the methods that the French state followed to reduce protest—removing market and price controls—merely agitated local populations because they could no longer count on controlled grain markets. The 'free trade' solution for France's economic problems had the effect of making matters worse from the point of view of consumers, and both Napoleon and restored monarchy after 1815 reinstated some controls in difficult times.

After the establishment of the Third Republic in 1871 both the paternalist policies and old forms of protest disappeared. Expanded political incorporation via universal male suffrage—passed early in the Revolution of 1848 but manipulated under Napoleon III to produce needed electoral majorities—was finally implemented in the 1870s. Better harvests and the more efficient transportation that the railroads provided for moving grain to regions with poor harvests helped to reduce protest as well. Worker unionization became legal in 1864 and with time, strikes became a routinized form of collective action in France as well as Britain. This does not mean that violence disappeared, for violence is an interaction between police (or the military in cases of martial law) and protesters. The point is that both more professional methods on the part of the authorities handling strikes and protest and greater formalization and nationalization of political parties and workers' organizations led to the development of routinized policies for dealing with collective protest, thus reducing its impact (Tilly 1971).

The late nineteenth and early twentieth century was a watershed in typical forms of collective protest which the German states also crossed. Reports from German states such as Saxony in 1842 detailed how rural craftsmen who were dependent on wages to buy bread had mobbed grain dealers who had bought and were moving grain out of the region to more distant urban areas (Tilly et al. 1975, p. 192). By the early twentieth century the industrialization of production, unionization of laborers, and urban populations had increased disproportionately in Prussia. (Unified Germany was a federation of formerly independent states, the most powerful being Prussia, and urban public order was the responsibility of the individual states.) In 1910 there was a massive disciplined demonstration in Berlin in which the Socialist Workers Party (SPD) leaders called for a political response: reform of the Prussian three-class electoral laws. The demonstration was then still a comparatively recently adopted form of protest through which ordinary people could bring their dissatisfaction with public policies to the attention of the government.

6. *Social Protest in Nineteenth-century Asia*

We turn now to Asia, to examine two non-European cases of nineteenth-century protest: in the Dutch East Indies and China. The Dutch East India Company (founded in 1602) had displaced the Portuguese in Southeast Asia by seizing Malacca at the southern end of the Malay Peninsula and conquering the kingdom of Acheh on Sumatra as well as the western part of Java by mid-century. The Dutch built their administrative capital, Batavia in western Java, leaving the rest of the island for some years to the Javanese kingdom of Mataram. A series of civil wars and regional revolts involving the Dutch and local princes ended in the 1750s with the division of Mataram into four new princely states, but lower level war continued. By then, Chinese immigrants controlled local and inland trade and the Dutch ran plantations and long distance trade in coffee and teak. By the late nineteenth century, Michael Adas (1979) shows, Dutch control over Javanese society had profoundly undermined the island's formerly independent economy. The Dutch system for the collection of tolls on roads and canals (using Chinese subcontractors) was similar to the seventeenth and eighteenth century French tax farming and aroused similar objections. Moreover, the Dutch could not win militarily because they lacked knowledge of Java's interior and in the end, they chose expediency and limited goals, preventing further unrest and raising new revenues to pay the costs of the war. This was done by forcing Javanese peasants to dedicate part of their time to cultivating cash crops to be sold overseas by the government. Although peace was restored, Dutch agricultural policy severely distorted Javanese social and demographic patterns, and drained its economy as Clifford Geertz (1963) demonstrates in his study of 'agricultural involution.'

China was never fully colonized, but Western intervention in its economic and political affairs beginning in the eighteenth century nevertheless had a great impact on its social and economic development. The Taiping Rebellion of the mid-1800s serves as an example here. Jesuit missionaries had been active for some time in the area around Guanzhou (Canton), as were British merchants buying tea and looking for customers to buy their products, with little success.

The immediate result was a negative trade balance for the British; to remedy this European merchants together with Chinese partners imported opium from India into China through Canton, a profitable commerce that grew rapidly in the early years of the nineteenth century. When the Qing court belatedly addressed the problem in 1839 and sought to cut off the trade altogether, the British easily established their superiority in gunboats and arms and forced the Chinese to sign a treaty that opened five ports to them with very low tariffs. Soon after, a Chinese treaty with the United States legalized the importation of opium by foreigners. Chinese resentment of both missionary efforts to convert them and Westerners' privileges increased.

The study of C. K. Yang (1975) of 'mass action incidents' (group actions involving public issues) that he links with others to constitute 'events' shows an upsurge of incidents in the years 1846 to 1875. The best known of these events is the Taiping Rebellion, which started in the poor and backward region of Guanxi, to the west of Guanzhou. Its originator and leader was a disappointed office seeker who encountered Protestant missionaries in Guangxi and—inspired by the Christianity they preached to him—developed his own messianic version of the message. Believing himself to be the brother of Jesus Christ, he would found a new Heavenly Kingdom (Taiping) that would bring peace on earth.

The Qing government sent a military force to Thistle Mountain, where Hong had settled, to arrest the Taiping leaders, but the mission failed, and the Taiping continued to preach. New converts extended the membership beyond the Taiping. Life among the Taipings was highly regimented, with sex-segregated military work teams; women were forbidden to bind their feet and were welcomed as workers and soldiers. The Qing forces of order were able to chase down the Taipings who had crossed the Yanzi River and in 1853 occupied Nanjing and held it for more than 10 years. The rebellion was only crushed after the French and British, who had invaded Beijing in 1860 to punish the Qing for not following up the treaties ending the Opium War, joined the Qing army in crushing the Taipings. Frederic Wakeman Jr. (1966) concludes that the Taiping Rebellion earned the unhappy record as the world's bloodiest civil war, in which tens of millions were killed in fighting and executions. As social protest, it combined many incidents and lasted for years, but nevertheless is considered one event because of the numerous links between the incidents.

7. *Twentieth-century Protest in the West*

The twentieth century has seen new or reinvented forms of social protest such as boycotts, sit-ins, and more formalized social movements (q.v.). Citizens of most national states have by and large received rights to participate fully in the political process, but the extent to which governments respect those rights continue to differ. Whether citizens can influence policy formally (through elections and representative government) or informally (through protest) is still disputed between citizens and states in many parts of the world. What has changed is greater consensus between protestors and authorities that has largely formalized protest and how it is expressed. Even in the West, however, social protest may become violent either through design (for example, the anarchist protest at the World Trade Organization's 1999 meetings in Seattle), or through the breakdown of policing procedures that have been developed in Europe and North America to handle such situations. The contours of social protest continue to shift in many countries, especially in those in which channels for making citizens' opinions known are very limited or non-existent and where governments seek to limit or even prevent popular participation. Social protest has not disappeared: it continues to occur in both authoritarian states and those with long-established formalization of procedures as a means for expressing dissent or the desire for change.

Social Psychology

Social psychology may be defined as the scientific study of how people perceive, influence, and relate to other people. Explicit in this definition are the field's modus operandus—empirical, data-based investigations of theories and hypotheses derived from those theories—and its goal of understanding the processes by which people think about and interact with others. Traditionally, this very broad umbrella incorporates diverse specific topics, including, but not limited to, attitudes, social cognition, decision-making, social motivation, prejudice and stereotyping, social identity, persuasion, altruism, aggression, interpersonal attraction, close relationships, conformity, group dynamics, group productivity, and conflict resolution, all of which are discussed in more detail elsewhere in this Encyclopedia.

Because social interaction is fundamental to most human behavior, it is useful to consider how the perspective of social psychology fits with that of the other behavioral and social sciences. Although in its early development social psychology was closely aligned with sociology, primarily because of the shared interest in social interaction, since the 1960s these fields have become largely independent of each other. The social psychological perspective is fundamentally psychological; it tends to focus on the thoughts, feelings, and behavior of individuals, whereas the sociological perspective is more immediately concerned with the analysis of social structure and the operation of social and societal systems. Similarly, social psychology tends toward a relatively individual-centered analysis of certain questions that other disciplines such as anthropology, economics, and political science generally address at more systemic levels of analysis (although the recent emergence in those fields of such specialties as game theory and behavioral economics suggest growing commonalities).

In contrast, social psychology's interest in situations (discussed below) and normative patterns of behavior differs from that of personality psychology (see *Personality Psychology*), which tends to be concerned with individual differences and their ramifications. Whereas personality psychologists seek to understand consistencies of a single individual's behavior across varying situations, social psychologists seek to understand consistencies across persons in their responses to particular situations. Thus, the social psychological level of analysis may be regarded as a mid-station between those theoretical systems that conceptualize behavior on the one hand in terms of the individual's unique internal properties and on the other hand in terms of the external social structure.

1. Core Principles of Social Psychology

1.1 The Situational Context of Behavior

Social psychology traditionally has emphasized the latter term in Kurt Lewin's classic dictum, $B = f(P,E)$—behavior is a function of the person and the environment—to reflect the fact that behavior varies, often profoundly so, depending on the social environment in which it occurs (see also: *Lewin, Kurt (1890–1947)*). The term social environment typically is used in a very broad manner, encompassing not only patently interpersonal examples (e.g., whether there is conflict or commonality of interest between partners, whether or not a new acquaintance is a member of one's in-group, and whether performance feedback is supportive or controlling) but also its relatively more impersonal features (e.g., whether persuasive appeals are based on style or substance, whether induced behavior is logically consistent or inconsistent with personal beliefs, and whether circumstances encourage deliberate or automatic processing of social information). Regardless of which variables are included under the heading of situational context, however, social psychology's published literature is replete with abundant evidence demonstrating that context is responsible for clear, substantial, and theoretically informative differences in behavior.

Although situationism is sometimes positioned conceptually as if it were the logical antithesis of the influence of personality, in reality nearly all contemporary social psychologists believe not only that both the situational context and individual differences matter, but that each affects the other interactively and continuously. For example, situations must be perceived and interpreted by the individual to possess relevant features in order for influence to occur; these interpretations are often shaped significantly by person factors (which are not limited to traits but may also include goals and motives). Similarly, personality traits are likely to be influential only to the extent that the situation affords relevant opportunities for their expression (e.g., social anxiety may have relatively little impact during interaction with close friends, but substantial effects with strangers). Individual differences also play an important role in determining which

situations the individual enters or avoids. Thus, it is most appropriate to view social psychology as emphasizing the complex interplay of forces within the person and in the outside situation in casting an individual's interpretation of, and response to, situational contexts.

1.2 A Process Approach is Most Informative

Phenomena may be regarded in terms of their distinctive and unique features or as the product of more general processes. Social psychologists, because they believe that certain general principles underlie many specific behaviors observed in everyday social life, typically focus their attention on these processes shared in common. For example, a social psychologist interested in prejudice likely would consider psychological mechanisms responsible for negative affect toward members of outgroups, rather than the details of prejudice toward one or another particular outgroup (except, of course, insofar as those details might be informative about the general process). Similarly, social psychologists study interaction between spouses less so to understand marriage *per se* and more so to discern how high degrees of interdependence influence social interaction. This emphasis does not imply that social psychologists are disinterested in the relevance of their research to particular instances; rather it denotes their belief that theoretical analysis grounded in broadly applicable principles is likely to be most revealing.

The field's emphasis on general processes is evident in the concerted attention routinely invested to identify causal mechanisms responsible for a given phenomenon. That is, once a phenomenon has been demonstrated, researchers almost invariably seek to explain its operation by ascertaining the relevant underlying mechanisms—in other words, to know when, why, and how something occurs. Typically such investigations address questions of moderation—establishing conditions under which a phenomenon is augmented or diminished—and of mediation—determining the specific step-by-step operations by which one variable produces changes in another variable. In recent years, the field has been particularly attentive to mediation by cognitive and affective processes, as described below. Considerable attention also is devoted toward ruling out alternative explanations; that is, toward conducting fine-grained experimental tests capable of distinguishing among alternative, often somewhat similar, explanations for a given phenomenon.

1.3 Basic Theory and its Application

Kurt Lewin's other classic dictum was that 'there is nothing so practical as a good theory.' Many social psychologists, in fact, initially were attracted to the discipline because of its potential for generating solutions to the pressing social problems of the day. Thus, the oft-cited distinction between 'basic' and 'applied' research is to many social psychologists somewhat misleading in the sense that basic research is often triggered by contemporary events and societal needs, and in turn may produce important evidence not only for better understanding these problems but also for generating interventions. The credo that sound theory and rigorous empiricism provide the firmest possible foundation for social application underlies Lewin's conviction, one that is shared by many current researchers. Effective applications require good theory, and good theories have real-world relevance.

As the social psychological literature has grown, so, too, has the dissemination of its principles and findings into the culture at large. As a result, the impact of social psychology is sometimes difficult to trace, although numerous examples are readily apparent, ranging from concrete interventions derived explicitly from experimental findings to more amorphous influences on prevailing public opinions. Documented impact of social psychological research can be found, for example, on such contemporary social issues as prejudice and intergroup relations, sex discrimination, healthcare, the operation of the legal system, and family violence.

2. A Brief History of Social Psychology

Social psychological thinking has deep roots. Rudimentary versions of contemporary theories are evident in many ancient sources, such as the Bible and the writings of Aristotle, Plato, and the other Greek philosophers. But it was not until the turn of twentieth century, with the field's first experimental studies and publication of the first textbooks explicitly bearing the name, *Social Psychology*, that the scientific study of human social interaction began to cultivate its own disciplinary identity. Although the field's development has been more or less continuous since then, two distinct and noteworthy trends mark its intellectual progression.

Much of the field's most influential early work was concerned with social influence, namely the processes by which the real or imagined presence of others affects belief and behavior. Research by Muzafer Sherif and Solomon Asch are considered landmarks, but the most durable and widespread impact came from Lewin's elegant Field Theory, which conceived of social relations in terms of interdependent force fields, such that each organism (i.e., person) acts on and responds to the other organisms in its space. As compelling as Lewin's conceptual model was his emphasis on experimentation as a formal method for evaluating theoretical propositions, an emphasis that became increasingly popular during the heady post-World War II expansion of psychological science. Field theory, especially in its application to investigating longstanding questions about group dynamics and

social influence, and its accompanying experimental method quickly became a dominant theme in the field's growth.

In the late 1950s and 1960s, social psychology's purview began to widen, such that social influences on the mental life of individuals came to occupy center-stage. Notable in this trend were studies of the impact of social feedback on self-appraisals, including Leon Festinger's theory of social comparison processes, Stanley Schachter's studies of self-attribution of emotion, and Festinger's subsequent theory of cognitive dissonance, which concerned self-perceived consistencies and inconsistencies between one's beliefs and behavior. In several respects, this movement set the stage for the so-called cognitive revolution of the 1970s and 1980s, in which principles of cognitive psychology were applied to social stimuli (i.e., other people, groups) and phenomena. Fundamental to the original conception of social cognition, as this subdiscipline came to be called, was the idea that many cognitive processes are designed to enable people to contend with the basic interpersonal tasks of everyday life. In their processing of social information, it was argued, people often function as naive scientists, seeking, within human limits, to comprehend cause-and-effect associations among the many pieces of social information encountered (see *Heuristics in Social Cognition*). The earliest emphasis in social cognition research was on understanding people's attributions of causality, led by the influential theories of E. E. Jones and Harold Kelley. Subsequent work has broadened this purview considerably.

More recent trends in social psychology balance the emphasis on cognitive processes with a functionalist perspective, or as Fiske (1992) put it, 'thinking is for doing.' For social psychology, the doing, of course, is relating to others in the social world. Social cognition is thus best considered as a mediating process between the individual's interpersonal goals and circumstances on the one hand, and his or her social behavior on the other hand. Embodying this perspective, contemporary research has increasingly emphasized affect in mediating the individual-social behavior link as well as the importance of the self and its motives. The logic of this latter work assumes that because action is functional and purposive, reactions to particular situations may help reveal the social motives operative in that context. Also, there is increasing recognition of the nature of ongoing relationships as part of the interpersonal context of behavior.

3. *Methods of Social Psychological Research*

It is no accident that social psychologists pride themselves on being rigorous, broad, and clever methodologists. The field's domain is wide—ranging from society-wide intergroup relations to intimate dyads—and its principled emphasis on identifying cognitive and affective mediators—ranging from cultural norms to idiosyncratic emotions—dictates that its research methods be flexible and diverse, yet suitable to uncovering and disentangling often subtle phenomena. One reason why social psychologists are in demand across a variety of disciplines and applied settings is their deftness in balancing the demands of experimental rigor, the necessity of adapting methods to diverse questions, and the various methodological issues inherent in studying human behavior.

Social psychology's favored method is the laboratory experiment, in which research participants are randomly assigned to one of several conditions defined by an experimenter so as to permit evaluation of a prespecified hypothesis about cause-and-effect. This emphasis follows directly from the high priority ascribed to establishing an effect's internal validity: laboratory manipulation allows experimenters to construct conditions whose carefully controlled differences explicitly contrast alternative explanations for a phenomenon while ruling out experimental artifacts. Contemporary social psychology has myriad other strategies and techniques in its toolkit, reflecting the realization that many questions are more appropriately addressed by different methods and the further realization that, because all methods are limited in one way or another, the validity of a research program ultimately depends on its methodological diversity. Other popular methods include quasi-experiments (when manipulation is not possible), surveys and questionnaires, daily event recording, behavioral observation, and meta-analysis.

Technological innovation, both from within the field and by expropriating advances in other disciplines, has facilitated researchers' ability to ask more sophisticated questions of their data, and to answer those questions with a greater degree of precision. Examples of these include computerized methods for investigating cognitive or affective mediation of basic social processes, especially when such mediation occurs outside of the individual's conscious awareness (e.g., priming and response latency methods), methods for assessing psychophysiological systems that underlie social behavior, internet-based data collection, and videotape-based protocols for fine-grained analysis of observable behavior in dyads and groups. The social psychologist's readiness to capitalize on new methodologies that provide fresh perspectives on the field's longstanding conceptual interests is further demonstrated by the eager acceptance of new statistical procedures in the literature. Recent and noteworthy examples include structural equation modelling, multilevel models, and methods for analyzing data in interdependent groups and dyads.

4. *The Future of Social Psychology*

Because an understanding of social relations is in one way or another fundamental across all of the social and behavioral sciences, social psychology is a cross-

roads discipline. Managing that position, that is, acquiring theoretical insights and new methods from neighboring disciplines while exporting its own theories, findings, and tools to those disciplines, represents an important challenge for social psychology. Several boundaries seem particularly promising at this juncture: neuroscience, with its ability to identify markers of social psychological phenomena in the brain; cognitive psychology, which enhances the field's understanding of mental representation of social entities; evolutionary psychology and behavioral genetics, with particular reference to identifying and understanding the specialized mechanisms created by evolution in making humans the most social of animals; and the study of culture, a contextual variable whose specific cognitive, affective, and interpersonal manifestations ultimately influence all social behavior.

At the same time, in its zeal to embrace related disciplines, social psychology must remain focused on its core phenomena. Despite the numerous important empirical findings and theoretical insights of the past century, many more questions remain to be asked and answered. The reasons underlying the importance of building bridges with related disciplines are one and the same as the reasons why social psychology must maintain its commitment to continued investigation of the field's core processes: that many of the most important unresolved questions about human functioning and well-being concern the processes by which people perceive, influence, and relate to other people.

Social Psychology: Research Methods

Social psychological research methods involve methods in use throughout the behavioral and social sciences. The goal of social psychology is to understand human behavior as it is affected by and affects social contexts. Accordingly, social psychologists attempt to measure and explain characteristics of individuals as social actors and characteristics of the social environments in which they act. Importantly, they also attempt to understand the interactive effects of both individual and environmental variables. Social psychological methods are fundamentally empirical methods, using observation and data to guide theoretical development. Ultimately, however, those methods are simply tools in the development of theoretical insights into the nature of human social behavior.

1. Research Validities

Methods of research in social psychology are useful only in so far as they permit one to critically evaluate and develop theoretical claims. Accordingly, a set of research validities that represent criteria by which any given piece of research, and any program of research, can be evaluated is defined. Ultimately research methods that permit the accomplishment of these

validities permit the gathering of data that will be maximally informative for theory construction. Importantly, however, as will be discussed, there are no perfect methods that simultaneously maximize all of the research validities. Ultimately, convergence on theoretical insights is only gained through the use of multiple methods of research, triangulating across individual studies and individual methods, to maximize the validity of an entire program of research (for general discussions of research validities, see Brewer 2000, Cook and Campbell 1979).

1.1 Construct Validity

Theoretical claims in social psychology typically involve statements about abstract and poorly defined constructs. So, for instance, small group research in social psychology has been interested in the role of alternative leadership styles on the successful functioning of the group. Researchers in intergroup relations have explored how levels of group cohesion affect the derogation of outgroups. Research in person perception has explored how information that is inconsistent with prior beliefs about someone is cognitively integrated into an overall impression of what that person is like. In each of these examples, the phenomena that social psychologists are interested in understanding are quite vague constructs, amenable to multiple alternative definitions.

To gather data that are informative for theory development, these constructs must be measured. The success of that measurement determines the construct validity of any piece of research. In other words, construct validity concerns the extent to which the constructs of theoretical interest have been successfully captured by the variables actually measured in research. The fundamental tenant of construct validity is that multiple operationalizations of any construct are mandatory. Any one measure is only an imperfect indicator of the construct it is supposed to measure. Confidence in measurement is produced only if multiple operationalizations tend to converge or triangulate upon the same answer.

1.2 Internal Validity

Theoretical claims in social psychology typically involve claims about the causal impact of constructs upon each other (e.g., social norms cause conformity, persuasive communications cause attitude change). Once the constructs have been operationalized, then research that is informative for theory construction and evaluation is research in which one can argue not only that one variable is associated with another, but also that one variable (the independent variable) is causally responsible for variation in another (the dependent variable). Research that is more internally valid is research where causal claims are more defensible.

Internal validity is affected by the nature of the research design that is employed. Ultimately, confidence in causal claims is only possible in the case of what are called randomized experimental designs, in which the units of observation (typically persons) have been randomly assigned to levels of the independent variable. For instance, to examine whether group sizes (the independent variable) influences the quality of a group decision (the dependent variable), people would be randomly assigned to groups of different sizes. Random assignment means that the researcher typically must control and manipulate the independent variable. Random assignment is importantly not the same thing as haphazard or uncontrolled assignment. It involves careful planning so that the probability of any unit occurring in a particular level of the independent variable is constant across all experimental units.

For many research questions in social psychology, randomized experiments are not feasible. Accordingly a variety of quasi-experimental designs can be employed. As is later described, these involve the collection of longitudinal data, without random assignment of units to levels of the independent variable. Finally, from the point of view of internal validity, cross-sectional studies (also known as correlational) studies are the least valid, although data from such studies can be quite informative for other reasons. Additionally, the absence of covariation between the independent and dependent variables in a correlational study would certainly lead one to doubt the existence of a causal relationship between the two.

1.3 External Validity

Data are always collected from specific units in specific settings. Obviously, theoretical conclusions require generalization from those units and settings to broader populations of theoretical interest. The external validity of any given piece of research indexes the extent to which this sort of generalization is feasible.

In general, generalization from specific samples to populations of interest is only possible if probability-sampling methods have been used to select the units and settings from which to collect data. Although widely used in social psychology, nonprobability-sampling methods (e.g., gathering data from participants who are given experimental credit in introductory psychology classes) pose serious threats to external validity.

1.4 Tradeoffs Among Research Validities

It is exceedingly likely that there are tradeoffs among these validities in any particular study. For instance,

to effectively manipulate an independent variable in order to maximize internal validity by the use of a randomized experimental design, the construct validity of the manipulated independent variable may be seriously compromised. Historically, much of the research reported in the leading social psychological journals has relied upon randomized experiments conducted in laboratory settings with participants recruited from introductory psychology pools. Implicitly, such research has assigned internal validity paramount importance while compromising the other two validities. Although tradeoffs among the validities may be inevitable in any particular study or data collection effort, it is important to employ a variety of different research strategies and designs across a line of research, moving from the laboratory to the field, from experimental designs to correlational ones, from manipulated independent variables to carefully measured ones. In this way, across a series of studies, it becomes possible to maximize all three sorts of research validities.

2. *Research Designs*

As just defined, randomized experimental designs, in wide use in social psychology, involve the random assignment of units to levels of the independent variables. Most frequently, multiple independent variables are included in crossed experimental designs, so that their separate, as well as interactive effects, can be assessed simultaneously. The interactive effects of multiple independent variables have been of great theoretical importance in social psychology, as they suggest, for instance that the impact of situational or environmental factors may depend on characteristics of the units being assessed (i.e., person by situation interactions).

If the effects of independent variables are considered to be short-lived, then a within-subjects research design may be employed to maximize power. In other words, each experimental unit occurs in each level of the independent variable (or variables). Random assignment in this case means that the order of the levels of the independent variables to which units are exposed is counterbalanced, with units randomly assigned to the different possible orders.

Many experimental designs in social psychology involve some mixture of between-subject and within-subject independent variables, and these are typically crossed so that their interactions can be assessed. The typical analytic approach to such data involves the use of analysis of variance.

Quasi-experimental designs involve the longitudinal assessment of units on the dependent measure(s) both before and after exposure to levels of the independent variable. The classic quasi-experimental design is the non-equivalent control group design in which units are assessed on the dependent variable twice, once as a pretest and once as a post-test. Some units are exposed to the experimental treatment and others to the control condition (i.e., the two levels of the independent variable), but the assignment process is typically an uncontrolled one in which the assignment rule, rather than being random, is unknown. Analyses typically involve the analysis of differences between conditions on the post-test, attempting to remove or adjust for any pre-existing differences on the pretest (through an analysis of covariance or some other adjustment procedure).

A more elaborate version of the nonequivalent control group design uses the same basic approach except that multiple pretests and multiple post-tests are assessed. Such designs permit greater confidence about treatment effects because differences in units in spontaneous growth can be modeled, and these differences can then be ruled out as competing explanations for any condition differences.

A particularly strong version of this quasi-experimental design would be one in which the treatment variable is turned on or off at different points along the time sequence during which the dependent variable is being assessed. There may be multiple measures of the dependent variable over time and at some time during that sequence the treatment gets turned on, but the time point at which that occurs varies between units (with some units serving as control units where the treatment never gets turned on).

The regression—discontinuity quasi-experimental design is one in which a known, rather than a random assignment rule is used to assign units to either the treatment or control conditions. Although seldom used in basic social psychology, this design has received attention in more applied research endeavors (e.g., deciding who will receive a new and scarce medical treatment based on the severity of symptoms manifested by patients).

And finally, as defined above, correlational designs involve the cross-sectional measurement of both the independent and dependent variables. (See Cook and Campbell 1979, Judd and Kenny 1981, Smith 2000, and West et al. 2000 for discussions of alternative research designs and their implications.)

3. *Measurement*

As discussed under Sect. 1.1, measured variables in social psychology are assumed to be only imperfect indicators of the constructs that are of theoretical interest. Classic measurement theory has focused on random errors of measurement, assuming that variation in measured variables derives from two sources: true score variation and random error variation. According to this classic approach, the reliability of a variable is defined as the proportion of variation in the

variable that is true score variation. A variety of procedures for assessing reliability have been developed from this classic model, the most widely used being coefficient alpha which assesses the degree to which a set of items share true score variation.

More recent approaches to measurement take a more fine-grain approach, assuming those errors of measurement can involve systematic as well as random errors of measurement. Accordingly variation in any variable can be decomposed into three sources: variation due to the construct of interest; variation due to other constructs that represent sources of systematic error; and random error variation. Convergent validity assesses the contribution of the construct of interest; discriminant validity assesses the contribution of systematic sources of error variation; and reliability assesses the contribution of random errors of measurement. Procedures for disentangling these sources of error variation have been developed by collecting data according to the multitrait-multimethod matrix, where multiple measures of multiple constructs are assessed, with various measures sharing systematic sources of error, particularly due to measurement methods (Campbell and Fiske 1959).

In addition to these approaches to measurement, based on the presumption that measurement adequacy is best assessed by patterns of covariation across multiple alternative measures, some have argued for a more axiomatic approach to measurement (Dawes and Smith 1985). This approach is based on the presumption that regularities of individual responses should follow certain axiomatic principles deduced from the constructs that are assessed (e.g., transitivity). In general, this approach has not proved fruitful for empirical work since random error in responses often prohibits strong tests of these axiomatic principles. Nevertheless, a few examples, such as Guttman and Thurstone scaling, are of historical importance in the domain of attitude measurement (see Judd and McClelland 1998 for a general treatment of measurement in social psychology).

4. *Analysis*

As discussed above, historically the dominant empirical approach in social psychology has involved the use of experimental designs, with independent variables orthogonally manipulated either within or between participants. Accordingly, the dominant analytic approach to data has been the analysis of variance. As researchers have increasingly extended their bag of research tools to include field studies and other sorts of research designs, more general approaches to data analysis, based on multiple regression and the general linear model, have become more prevalent. Increasingly, researchers are employing multiple regression as a general data analytic approach, incorporating analysis of variance through the use of contrast-coded predictors (Cohen and Cohen 1983, Judd and McClelland 1989).

Longitudinal data structures as well as more sophisticated measurement models have resulted in increasing use of latent variable structural equation modeling procedures (Bollen 1989, Kline 1998). In general these procedures allow researchers to examine and test models of data that incorporate both systematic and random measurement errors, estimating the linear relations among latent constructs that are each assessed with multiple indicators. Although sample size requirements and other restrictions have placed limits on the use of these procedures in social psychology, the general data analytic approach that they represent is particularly promising.

Data analysis strategies that allow for correlated errors of measurement are particularly promising in the subfield of social psychology devoted to the study of dyadic and small group interaction. Traditional inferential procedures normally assume that observations are independent of each other and this assumption is nearly always violated in dyadic and small group research where individual persons interact and are jointly influenced by situational factors. Accordingly, considerable work has been devoted in recent years to procedures for the analysis of dependent data structures. The most general of these approaches involve multilevel or hierarchical linear models, where individual observations are nested under factors whose levels are themselves treated as random observations. Traditional analysis of variance and regression procedures do not allow for this sort of hierarchical data structure with random factors (see Bryk and Raudenbush 1992, Kenny et al. 1998).

Beyond the domain of small group and dyadic research, these hierarchical models are also particularly useful in longitudinal data structures, where individual observations are repeatedly taken from participants over time and one is interested in modeling growth or change in response to various situational factors that also vary across time. Data from various quasi-experimental designs are particularly likely to exhibit this sort of structure.

5. *Conclusion*

Although experimental laboratory research procedures have been the dominant approach to research in social psychology, increasingly researchers are using a wide range of research designs, measurement procedures, and data analytic techniques to address the multifaceted research questions of social psychology. Certainly there will remain an important role for laboratory experimental work in social psychology. However, the wide range of methods now used throughout social psychology offers tremendous po-

tential for addressing the diversity of theoretical questions addressed by social psychology in very rich ways.

C. M. Judd

Social Psychology, Sociological

Social psychology is concerned with the interplay of society and individual. In this specification, 'society' is a gloss for all relatively stable social relationships and patterns of social interaction, and the close examination of microsociological processes is included in social psychology. The major contributors to this enterprise are psychologists and sociologists.

1. The Two Social Psychologies

In practice, there are two social psychologies. Psychological social psychology assumes that 'in the beginning there is the individual' and focuses on individuals' social cognitions. Sociological social psychology assumes that 'in the beginning there is society'; its distinguishing charge is to locate interactional processes in their social structural context. This difference leads to differences in problems studied, conceptualizations of problems, and research findings. Marcus and Zajonc (1985) observe that cognitive social psychology starts and ends with persons' cognitions; sociologists note that unless the rootedness of cognitions in social structure is recognized, more causal power than warranted is accorded cognitions. Cognitive social psychologists recognize that cognitions reflect experience, but experience does not enter theoretical formulations or research designs; for sociologists how experience is organized is central to both theory and research. The former developed largely through experimental research; the latter—more eclectic in methods and exhibiting greater willingness now than earlier to use experimental methods—has preferred studying social behavior *in situ* using observational procedures or survey and questionnaire methods locating persons in social milieus. The two social psychologies share topical interests: e.g., attitudes, self, and identity. They also differ in topics, as a glance at textbooks for each will evidence.

2. Focusing on Sociological Social Psychology (SSP)

The concern here is with social psychological work reflecting sociological interests and contributing to sociology as an intellectual enterprise. This does not imply that psychological social psychology is 'wrong' or irrelevant to SSP; sociologists can learn much from their psychological counterparts. Yet, SSP has its relatively distinct approaches, interests, and objectives.

Sociologists have offered versions of social psychology as alternatives to a sociology built on social

structural concepts; Herbert Blumer's (1969) advocacy of symbolic interactionism is an important example. Today, sociological social psychologists typically understand their work as a specialization within sociology, focusing on persons as social beings and their interaction that contributes to sociological analyses in general; this view is adopted here. Most sociologists doing social psychology share a set of core ideas, largely taken for granted. They also significantly differ in approaches taken. The variations are attended to first.

3. *Variations in Perspectives within SSP*

Three perspectives are considered—interactionist, group processes, and social structure–personality—encompassing most SSP; discussion of each is selective. These perspectives are not as independent as separate treatment suggests. Interactionists incorporate fundamentals of the social structure–personality frame by recognizing structural constraints on personal development and interaction. The social structure–personality formula recognizes the mediating role of interaction processes and microstructures. And group processes work builds upon the social definitional emphases of the interactional frame and the macrostructural contexts of small group structures and processes. Nevertheless, the classificatory scheme allows the recognition of significant variation in perspectives within SSP.

3.1 *The Interactionist Perspective*

Interactionism developed under the early influence of the Scottish moral philosophers, George Herbert Mead, Charles Horton Cooley, W. I. Thomas. More recent influences include Blumer, Everett Hughes, Erving Goffman, Anselm Strauss, and Ralph Turner. Basic principles are ideas drawing on Mead. Subjectively held meanings are central to explaining or understanding social behavior. Meanings are products of persons' communication as they seek solutions to collective problems, and humans' capacity for symbolization. Of particular importance are meanings attached to self, others with whom persons interact, and situations of interaction; these guide interaction, and are altered in interaction. Implied is that who persons interact with under what circumstances is critical to the development of, and changes in, meanings and thus to interaction processes.

The centrality of meanings underwrites a basic methodological principle of interactionism: actors' definitions must be taken into account in examining their behavior. For many, this principle leads to viewing everyday life as the preferred arena of research; use of observational methods, ethnography, case histories, or intensive interviewing as preferred means of gathering data; and qualitative methods as preferred analysis procedures. Other interactionists, accepting the methodological principle involved, find these preferences unnecessarily limiting in their implied rejection of quantitative analyses of large-scale data sets for research stemming from interactionist premises.

Given these ideas, it is unsurprising that many interactionists attend to self, its dimensions or components, variability or stability, content under varying structural conditions, authenticity, efficacy, self-change, the social construction and interactional consequences of affect, the interactional sources and social behavioral resultants of self-esteem, interactional and symbolic processes in defense of self, the relation of self to physical and mental health, labeling, stigmatization, deviance, and a host of other topics. A related focus is on socialization, for the shaping of self is key to entrance into roles, normal and deviant. Attention is paid to socialization processes within institutional settings—family, school, work, etc., as well as settings that are not fully institutionalized, like child and adolescent play, informal friendship of young and old, or developing social movements, and noninstitutional settings like homelessness.

Responding to the insight that socialization is a lifelong process, attention is accorded life-course related socialization processes. Interaction itself, of both intimates and nonintimates, is the focus of other interactionists, whose studies examine (among other topics) teasing among adolescents, language use both as and in action and interaction; variations in the implicit rules governing interaction and interaction strategies in various settings (Erving Goffman has been especially influential here and with reference to the preceding topic); role relationships within both formal and informal settings, and the impact of status and power inequalities on interaction.

Such long-standing interests of interactionists continue. A comparatively recent turn is an emphasis on emotions. Present in varying degrees in earlier interactionist social psychology, the expanded interest emphasizes emotion as basic to all interaction, expressed for example in David Heise's affect control theory; the role of affect in self-processes; the social construction and interactional consequences of emotion in general and particular emotions.

Other recent developments can only be mentioned. Contemporary sociological interest in culture is seen in work on the generation of culture through interaction. A 'new look' in social movement research makes framing processes and collective identity formation of particular consequence and has reinvigorated interactionist interests in that topic. A vision of self as comprised of multiple group or network based identities has opened up work on the consequences of consonant or conflicting identities that carries theory and analyses beyond traditional role-conflict studies.

3.2 The Group Processes Perspective

Group processes work reflects diverse substantive interests with a common focus on interaction in social groups or social networks. The interaction processes attended to include: cooperation; competition; conflict; conflict resolution; social exchange; inequality; bargaining; power, status, and influence processes; procedural and distributive justice and injustice; the resolution of social dilemmas; the emergence of social structures from interaction; and the reproduction of interaction processes by social structures deriving from them. According to Karen Cook, a social interdependence theme integrates these, as do ideas about how group processes work relate to the general sociological enterprise: group and network interaction processes provide the foundations of macrosociological theory; theories developed on interacting individuals apply to corporate or collective actors; group- and network-based interaction mediates the relation of individual to society. Also, group process students have a common lineage and hold similar beliefs about how to do research and build theory.

That lineage includes Georg Simmel on implications of social forms for interaction; George Homans' exchange theory built upon principles of economics and operant conditioning psychology; Robert F. Bale's research on groups resolving tasks; 'small groups' research; theoretical as well as experimental economics work on bargaining and reward allocation; and game-theoretic inspired research in political science and psychology. Richard Emerson is especially important to this lineage, developing a social exchange theory escaping the limitations of Homans' strict behaviorism and extending exchange theory to deal with exchange networks.

This lineage led to experimentation and mathematical modeling of interaction processes. The focus on experimentation enabled programmatic research, an ideal carried out more in practice by group process researchers than by other SSP researchers. Group process researchers have provided models of such research, building small theories to explain given facts, testing the theories experimentally, discovering flaws in the fit of theory, revising theory to accommodate new data, in an ongoing process of theory building and theory testing.

Further attention is limited to two topics, social exchange and status structures, epitomizing theoretical themes of the group processes perspective and its programmatic research emphasis. Contemporary social exchange theory starts with actors' interdependency: people need others for, and provide others with, things they value and so engage in social exchange. Exchange occurs in situations of mutual dependence; persons act to increase positively valued outcomes and decrease negatively valued outcomes, exchange relations with specific others are repeated, and satiation and marginal utility apply to valued outcomes. Exchange networks—chains of exchange relations—are basic to sociological exchange theory and SSP because they bridge to larger social structures. From here, network theory and research proliferate, extending to corporate actors, the role of power in facilitating or impeding exchanges across networks, the impact on exchanges of negative (competitive) or positive (noncompetitive) network connections, the emergence of norms in exchange networks, etc.

Current work on status structures builds on expectation states theory, developed by Joseph Berger and colleagues. This theory argues that power and prestige orderings in groups arise from members' expected contributions to problem solutions. These expectations shape group interaction confirming the expectations and stabilizing the orderings. The theory further argues that in the absence of information directly linking members' abilities to tasks at hand, group members draw inferences about those abilities from the stratification system of the larger social context, thus reproducing that system. On this foundation, work on expectation states theory has expanded, systematically refining and extending the theory and examining its implications. Of particular interest under contemporary circumstances is work showing that new information about group members' task-relevant abilities can negate the effects on group interaction of stereotypes drawn from the existing stratification order, potentially changing the stratification order of the larger social context. Also of interest is the way ideas underlying this theory parallel ideas fundamental to the interactionist perspective in SSP.

3.3 The Social Structure–Personality Perspective

Described by Melvin Kohn, a major proponent, as the quintessentially sociological approach to social psychology, the social structure–personality perspective examines the reciprocal impact of macrosociological structure and person. It traces to the classical sociological work of Emile Durkheim and others, tying features of persons to types of societies. More proximately, it emerges from cultural anthropological work seeking to understand basic personality structures of society's members through analyses of culture. Influenced by psychoanalysis, this work invoked family and kinship structures as vehicles sustaining and transmitting culture, evidencing the relevance of social structure to persons produced. Social structure replaces culture in a social structure–personality perspective, bringing to the fore the economy, stratification, and work institutions as basic to personality.

An important part of social structure–personality work has been comparative, with nation as context, examining the hypothesis that similar work structures have similar psychological effects. Inkeles and Smith (1974), in a six-nation study, proposed that an

attitudinal-behavioral syndrome, 'individual modernity,' resulted from working in organizations produced by industrialization. This work was criticized on ideological and methodological grounds, and its failure to specify the empirical linkage of structure and person and how mechanisms accounting for that linkage affected subsequent work. The evolving research program initiated by Kohn provides evidence that complex jobs allowing self-direction link societal-level class and stratification structures to intellectual flexibility and self-directedness. Longitudinal analyses suggest the linkages are reciprocal. These propositions hold in comparative contexts, and under conditions of radical social change, arguing for generality of structural effects independent of cultural variation. The operative psychological mechanism underlying these relationships is taken to be learning generalization.

The social structure–personality perspective exists in work on many topics filling the structural 'space' between nation and person, for example, status attainment and mobility processes, gender, work, the life course, and both physical and mental health. Further comment, necessarily brief, on two of these topics provides both insight into the utility of SSP for sociology and why SSP is not in itself an alternative sociology.

Painted large, life course research focuses on the interaction of biography and historical social structures over time in order to understand adult developmental processes. While the complexity of this enterprise defies easy description or summary, it involves a vision of persons living their lives in the context of a continuously changing society, experiencing important historical events at varying ages and points in their lives, and undergoing (or not undergoing) a series of important age-related transitions involving status and role changes; of people's existence within multiple institutional contexts and multiple networks of social relationships, some of which are operative over lengthy portions of their lives; of the life course as implicating multiple developmental trajectories necessitating coordination. A consequence of the contextual complexity and multistrandedness of life is what Elder and O'Rand (1995) term a loose coupling between social transitions and age-gradings. Loose coupling opens up room for choices reflecting meanings and interpretations (including reinterpretations) of events and of prior experience. Persons are selected by societal allocation processes for entry into social positions and roles but also select themselves: they choose to marry, have children, take or leave jobs, divorce, etc., and these choices are consequential. In short, persons are active agents importantly constructing their own lives.

Research from a social structure–personality perspective on status attainment processes also provides a contrary moral. That research indicates that structures of relationships and interaction built on differences in socioeconomic status, race, and gender impact people's skills, motivations, and aspirations for success in schools and work. It also shows that skills, motivations, and aspirations relate to educational and occupational success, i.e., to individual mobility. At the same time, research shows that the structure of schools, jobs, and labor markets can severely restrict the impact of personal characteristics on social mobility and that even voluminous individual mobility need not alter the overall character of a societal-level stratification system. In short, there are limits on the impact of agency on social structures.

4. *Commonalities*

Underlying most work in SSP are ideas reflecting the assumption that 'in the beginning there is society':

(a) Human experience is socially organized. Societies are not invariably coherent; they are, rather, typically complex and shifting mosaics of frequently conflicting (but sometimes not) role relationships, social networks, groups, organizations, institutions, communities, and strata, sometimes related but sometimes isolated from one another. What people experience is importantly a function of just what relationships, networks, groups, communities, and strata they enter, remain in, and leave, how they enter these social structures, and how these social structures relate to one another.

(b) The forms and content of social life are social constructions, the product of the collective activities of persons as they join one another in the course of developing solutions to problems in their daily lives. To make this claim, it is neither necessary nor in accord with accumulated evidence of SSP and sociology itself to argue that processes of social construction are ephemeral or infinitely mutable, or that they occur without constraints imposed by the natural world or prior constructions.

(c) Human beings are active agents who respond selectively to social and nonsocial environments impinging on them, who initiate transactions with, and sometimes alter, those environments. Implied by the idea of social construction, action produced at the initiative of an actor presupposes the symbolic and reflexive capacities of humans, in short, presupposes a 'self,' but does not deny the power of conditioning or of normative demands. In general, all social behavior is some blend of action and reaction.

(d) The world on which humans act and to which they react is a symbolized world specified by meanings attached to the objects comprising it.

(e) There is both constraint and choice in personal and social life. Whether one, the other, or both are operative depends on particulars of the patterns of people's relationships to others in social groups and networks, and on the patterned relationships of those groups and networks to one another.

(f) A final idea within SSP can serve as a summary of the previous five and an appropriate concluding

statement: the basic responsibility of SSP is to deal with ways in which social structures impinge on people's social behavior and the reciprocal impact of that behavior on social structures. While each of the three perspectives within SSP reviewed tends to emphasize different levels of structure—the interactionist perspective stresses proximate structures closest to interacting persons (e.g., families, friendship networks); the implicit structural contexts of interaction for the small group perspective are middle-level structures (e.g., work organizations); and the social structure–personality perspective focuses on large-scale structures (e.g., the nation, stratification systems)—an encouraging development is the increasingly common recognition that structures on all levels are important to the social behaviors studied from each perspective.

Social Psychology, Theories of

Social psychology studies how individual people's thoughts, feelings, and behavior are influenced by other people (Allport 1954). Social psychology's theories account for how, why, and when people affect other people. Social psychological theories provide networks of propositions, testable by scientific observations, to describe, explain, and predict systematic phenomena in people's reactions to others. This article addresses mid-range theories, not general systems (i.e., Lewin's entire field theory) and not single phenomena (i.e., the reliable finding that first impressions matter). Because social psychology specializes in mid-range theories, the review imposes a larger framework, providing mere pointers to the theories flagged (see the cited books reviewing theory for detail).

1. Organization of this Review

Social psychology's theories each tend to center on one of a few major types of social motivation, describing the social person as propelled by particular kinds of general needs and specific goals. Most reviews acknowledge these motivational roots by reference to broad traditions within general psychology or sociology: role theories, cognitive and gestalt theories, learning and reinforcement theories, and psychoanalytic or self-theories.

As a variant, this review takes a more integrated but compatible premise, based on people's evolution in a social niche: to survive and thrive, people need other people. Several core social motives arguably result

from this perspective. Over the twentieth century, social and personality psychologists frequently have identified the same five or so core social motives, which should enhance social survival (Stevens and Fiske 1995). *Belonging* reflects people's motive to be with other people, especially to participate in groups. *Understanding* constitutes people's motive for shared social accounts of themselves, others, and surroundings. *Controlling* describes people's motive to function effectively, with reliable contingencies between actions and outcomes. *Self-enhancing* comprises people's tendencies to affirm the self. *Trusting* concerns people's motives to see others (at least own-group others) positively. While these motives are not absolute (other reviewers would generate other taxonomies), not invariant (people can survive without them), nor distinct (they overlap), they do arguably facilitate social life, and they serve the present expository purpose. Within each core social motive, distinct levels of analysis address social psychological processes primarily within the individual, between two individuals, and within groups.

2. Theories of Belonging: Role Theories

People's core social motive to participate in group life generates theories that emphasize the place of the individual in the group. Role theories define people's behavior as a function of their *roles*, their position in social structures and the expectations attached to that position, all in the context of group *norms*, the unwritten, informal rules that govern group life.

2.1 Belonging, Within the Individual

Emphatically sociological, role theories describe the effects of group roles and norms on individual self-presentation and self-understanding. In the theater of social life, so aptly described in the *dramaturgical theory* of Goffman, self-presenting people define the scene, take on roles, and follow cultural scripts. Here, *symbolic interaction* with generalized others forms the self (Mead), or others' reflected appraisals construct the *looking glass self* (Cooley).

People's motivation to fit into groups sparks strategic *impression management* (Schlenker) and *self-presentation* (Jones). Wanting to operate successfully in groups provides goals to convey desired (but not necessarily positive) self-images that are personally beneficial and socially believable, for a given audience. For example, people may ingratiate, presenting themselves as likable; self-promote, presenting themselves as competent; or supplicate, presenting themselves as helpless. When people feel under public or private scrutiny, they become *objectively self-aware*, in Wicklund's theory; this awareness motivates matching to internalized social standards. People and situations differ in motivating people to *self-monitor*; that is, to adjust their behavior to the demands of the social group (Snyder).

Belonging motivates not only selves, but also attitudes and values. Merton's *reference group* theory explained how people derive their values from belonging to particular groups or desiring to belong to them. Through face-to-face interaction, reference groups theoretically serve a *normative function*, defining acceptable standards for group membership (Deutsch and Gerard, Kelley). Some attitudes thus serve a *social adjustive* function (Katz, Kelman, Smith, Bruner, and White); that is, attitudes and values facilitate belonging.

2.2 Belonging, Between Individuals

Motives to belong and get along with other people appear in theories describing reciprocity: expectating something in return. Cialdini's *compliance principles* include reciprocity; people help other people who help them (see Gouldner on *reciprocity norms*). *Exchange theories* (see Sect. 4.2) posit that people expect fair outcomes (outcomes proportional to inputs), but later theories proposed different norms, depending on the relationship. C*ommunal-exchange theory* (Clark and Mills) describes exchange relationships (equitable outcomes) versus communal relationships (need-based outcomes). A. Fiske's *social relations model* theorizes four relationship types and norms: equality matching, communal sharing, authority ranking, and market pricing.

People's adherence to relationships over merely self-serving outcomes appears in the *dual-concern model* (Pruitt and Carnevalle): bargaining elicits both own-concern and other-concern. People also evaluate outcomes by *procedural justice*; that is, whether the process itself was fair (Thibaut and Walker, Lind and Tyler). Institutions and authorities especially are evaluated according to procedural justice, thereby eliciting loyalty or anger.

Belonging also appears in leadership theories. Milgram's theoretical analysis of destructive *obedience to authority* includes sociocultural contexts of obedience, subtle and progressive commitment, and denial of personal responsibility—all in the service of the group. More benign forms of authority appear in the *contingency theory of leadership* (Fiedler), describing how leaders influence members most successfully through relationship-oriented, rather than merely task-oriented leadership, though other contingency models (e.g., Vroom) note that effective leadership style depends on context. *Transactional leadership* (Burns) adheres to norms of leader–member reciprocity, whereas *transformational leadership* changes the demands of the followers.

Regardless, individuals gain from belonging. *Social support theories* explain how relationships benefit

health and well-being. Main effects models (e.g., attachment, see Sect. 6) suggest a monotonic relationship between relationships and health. *Buffering theories* (Cohen, House, Sarason) posit that social support undermines the ill effects of stress, if the support fits the stressor.

2.3 Belonging, In Groups

Crowds turn into groups, in Turner's *emergent norm theory*, when people cue each other's behavior. Theoretically, extreme cases result in *deindividuation* (Diener, Zimbardo); the self lost in the group.

Less radically, people join groups because they are attracted to them, according to *group cohesion theory* (Hogg); solidarity transforms aggregates into groups (see Moreno's *sociometry*). Networks of *interaction processes* (Bales) define the group structure along task, social, and activity dimensions. Groups valuing cohesion over task effectiveness suffer Janis's *groupthink*, faulty decision-making that results from conformity pressures. French and Raven's *referent power* and Kelman's *identification* both influence through desire to belong. Group-level influence processes depend on the strength, number, and immediacy of people attempting influence (Latané's *social impact theory*; Tanford and Penrod's *social impact model*). These theories elaborate Zajonc's *social facilitation theory*, which describes the presence of others facilitating an individual's dominant response, benefiting well-practiced skills and undermining less-developed performances.

In organizations, effective performance meets reviewers' standards, maintains working relationships, and satisfies individual needs, in Hackman's *normative model of group effectiveness*. Relatedly, Steiner describes *process losses* that endanger group productivity, when coordination or motivation fails. *Social loafing* diminishes motivation in groups (Latané), but *social compensation* (Williams and Karau) can enhance motivation in groups.

The predominantly positive effects of group belonging all pertain to own group (in-group). Nevertheless, in-group favoritism (rewarding one's own), not out-group deprivation, poisons intergroup relations. Tajfel's *social identity theory* describes how in-group favoritism stems from self-esteem and categorization, the latter expanded in Turner's *self-categorization theory*. These theories hold that categorization into in-group and out-group differs from other kinds of categorization (see Sect. 3) because the perceiver belongs to one of the categories: Mere categorization into groups promotes conflict. In contrast, Sherif's *realistic group conflict theory* blames intergroup hostility on competition over scarce resources. If single in-group belonging promotes intergroup conflict, multiple belonging diminishes it, in the theory of *crossed categorization* (Dovidio and Gaertner).

3. Theories of Understanding: Gestalt and Cognitive Theories

People's core social motive to hold a coherent, socially shared understanding has inspired theories that account for various social cognitive processes. *Gestalt theories* in social psychology emphasize harmonious fit among elements that constitute a coherent whole, hence their influence on *consistency* theories of attitudes and on *schema* theories of social perception (see Sect. 3.1). Their descendants, modern social cognition theories, most often focus on dual processes, one *automatic* and based on superficial, peripheral *heuristics* or *categories*, the other *controlled* and based on systematic, central, deliberation or *individuation* (see Chaiken and Trope 1999).

3.1 Understanding, Within Individuals

Derived from gestalt psychology, three types of theory focus on processes within the social perceiver: attribution, impression formation, and consistency theories. Other attitude theories and self theories build indirectly on these origins, but still emphasize understanding as primary.

Heider's theories of social perception focused on harmonious, coherent wholes: *invariance* in perceived personality. Heider's social perceiver, portrayed as a *naive scientist*, searches for consistencies in behavior, to make coherent *dispositional attributions* (inferring stable, personal causes). Other *attribution theories* developed: Jones's *theory of correspondent inference* describes how perceivers impute dispositions that fit an actor's behavior, attributions increased by a behavior's unique ('noncommon') effects and low social desirability. Kelley's *covariation theory* likewise notes a behavior's distinct (i.e., unique) target and its degree of consensus (i.e., desirability) across actors, but adds the observation of consistency over time and circumstances. Extending fundamental theories, *stage models* (Quattrone, Gilbert, Trope) converged on automatic categorization or identification of behavior, followed by dispositional anchoring or characterization, followed by controlled situational correction or adjustment. These recent theories bring dual process perspectives to attribution theories that emphasized controlled processes.

A second line of person perception theories also originated in gestalt ideas and eventuated in dual-process models. Asch proposed a *holistic* theory of impression formation, in which the parts (most often personality traits) interact and change meaning with context. The alternative, an algebraic model that merely summed the traits' separate evaluations, matured in Anderson's later averaging model of *information integration*. Asch's most immediate heirs were modern *schema theories*, examining impression formation as a function of social categories that cue organized prior knowledge. Following Taylor and

Fiske's *cognitive miser* perspective, social perceivers were viewed as taking various mental shortcuts (below), schemas among them. Eventually, a more balanced perspective emerged, describing perceivers as *motivated tacticians*, who sometimes use shortcuts and sometimes think more carefully, depending on their goals. One such dual-process model, the *continuum model* (Fiske and Neuberg), holds that perceivers begin with automatic categories (e.g., stereotypes), but with motivated attention to additional information, perceivers may individuate instead. Brewer's *dual-process* model posits automatic identification processes and controlled categorization, individuation, and personalization.

Other mental shortcuts emphasize relatively *automatic processes*, as defined by Bargh to include being unintentional, effortless, unconscious, and unstoppable. Illustrative theories address influences by stimuli that are arbitrarily *salient* in the environment (Taylor and Fiske) or *accessible* in mind (Higgins, Bargh). In Kahneman and Tversky's *heuristics*, people estimate probabilities by irrelevant but convenient processes: ease of generating examples (*availability*), ease of generating scenarios (*simulation*), and ease of moving from an initial estimate (*anchoring and adjustment*). *Norm theory* (Kahnman and Miller) posits that people retrospectively estimate probabilities via the simulation heuristic, bringing to mind similar but *counterfactual* scenarios. Although not a theory, a catalog of *inferential errors and biases* follows from people's limited capacity (Nisbett and Ross; see Sect. 4.1).

A third line of theories follows from gestalt approaches. Heider's *balance theory* posits that perceivers prefer similarly evaluated people and things also to belong together. This emphasis fits other *consistency theories*. Most prominently, Festinger's *cognitive dissonance theory* holds that people seek consistency among the cognitions relevant to their attitudes, including their cognitions about their own behavior. Attitudes change more easily than behavior, especially behavior based on counter-attitudinal advocacy, forced compliance, free choice, unjustified effort, and insufficient justification (see updates emphasizing *self-esteem* (Aronson), accepting responsibility for an aversive event (Cooper and Fazio's *new look*), and *self-affirmation* (Steele). Other consistency theories hold that people seek harmony within and between their attitudes.

Some attitude theories focus on understanding dual processes, downplaying consistency motives. The *elaboration likelihood model* (Cacioppo and Petty) describes the object-appraisal (understanding and evaluating) function of attitudes, but depicts two modes, depending on motivation and capacity: The *peripheral mode* processes persuasive communications based on superficial, message-irrelevant cues (such as communicator, context, or format), whereas the *central mode* processes message content, generating cognitive responses pro and con, which predict persuasion. Chaiken's *heuristic–systematic model* similarly proposes a rapid, simple process that contrasts with a more deliberate, in-depth process of attitude change.

Focusing on understanding via deliberate control, far from gestalt perspectives, two *subjective expected utility models* predict attitude–behavior relations. Fishbein and Ajzen's *theory of reasoned action* posits that behavior results from intention, which in turn results from attitudes toward a behavior (evaluating the behavior's consequences, weighted by likelihood) and from subjective norms. Ajzen's updated *theory of planned behavior* adds a third component to predict intentions, namely perceived behavioral control.

Like theories of attitudes and social perception, theories of self-perception emphasize coherence. *Self-schema theory* (Markus) describes few, core dimensions for efficiently organizing self-understanding. Self-concepts may be more or less elaborate, resulting in respectively more stable and moderate or volatile and extreme self-evaluations (Linville's *complexity–extremity theory*).

People learn about themselves partly by looking at others. Festinger's *social comparison theory* describes how people strive to evaluate themselves accurately, by comparing their standing relative to similar others, on matters of ability or opinion. Schachter extended this work in exploring the *fear-affiliation* hypothesis, whereby people under threat affiliate with similar others, perhaps to gauge the appropriateness of their emotional reactions. From this came Schachter's subsequent *arousal-cognition theory* of emotion, positing that unexplained physiological arousal elicits cognitive labels from the social context. Although the outside world may anchor self-understanding, other theories describe how the self anchors understanding of the world outside, as in Sherif and Hovland's *social judgment theory*, explaining how people assimilate nearby attitudes within a latitude of acceptance and contrast far-off attitudes within a latitude of rejection.

3.2 Understanding, Between Individuals

Moving to understanding in actual interactions between people: although generally these theories do not take an explicit dual-process approach, one set of theories focuses on the role of old, familiar, prepackaged information, whereas another set focuses on the role of newly processed information.

One of the fundamental principles of attraction is familiarity. The Zajonc *mere exposure theory* describes people favoring people and objects encountered frequently. Similarly, people are attracted to people in *propinquity* (close proximity) (Festinger, Schachter, and Back), perhaps because of exposure. Although explained in non-cognitive terms, familiarity effects fit the principle of liking those who seem comfortable,

safe, and easily understood. Consistent with this view, Newcomb developed the *similarity principle* of attraction, derived from balance theory (above), to explain the clear attraction to others of shared background, attitudes, etc. Similar others also maximize social influence, in Cialdini's *compliance principles*.

Just as theories describe how familiar others are liked, perhaps because easily understood, other theories emphasize dislike of dissimilar others, as in *theories of stigma* offered separately by Goffman, Jones, and Katz. *Category-based theories* of impression formation (Sect. 3.1) describe how negative outgroup categories stimulate negative understanding. Moreover, perceivers behaviorally confirm their negative categories of out-groupers, who sometimes affirm the stereotype (see Merton's theory of *self-fulfilling prophecies*, Rosenthal's theory of nonverbally communicated *expectancies*, Snyder's theory of *behavioral confirmation*, Hilton and Darley's theory of *expectancy-confirmation processes*). Mere knowledge of the stereotypes about one's group creates *stereotype threat* (Steele), undermining the performance of distracted, frustrated, targets of stereotyping.

Although familiar information tends to reproduce itself, new information has an impact, according to many theories. In noting the *informational influence* of others, Kelley, as well as Deutsch and Gerard, noted that reference groups can serve a *informative or comparative function* defining objective accuracy from the group's perspective. In Darley and Latané's *cognitive model of helping*, people consult social cues at each step of the process of noticing, interpreting, taking responsibility, deciding, and implementing help. Weiner analyzes *attributions of responsibility* as stemming from information about degrees of control and its internal or external locus. People acquire new information through *social learning* (Sect. 4.2) that encourages them to help (Berkowitz, Rushton, Staub) or to aggress (Bandura). As people learn by doing, they are socially influenced by self-*consistency and commitment*, according to another of Cialdini's compliance principles.

3.3 Understanding, In Groups

In groups, the familiar prior knowledge about own group and other groups is captured by *social identity theory* and *self-categorization theory* (Sect. 2.3). In addition, group-level schemas and categories at the societal level take the form of Moscovici's *social representations*; shared social understandings make the unfamiliar into the familiar by reference to old socially shared concepts.

People in groups also acquire new information. Some individuals hold power by virtue of *expertise or information* (French and Raven), evoking *internalization* (privately held beliefs; Kelman) in those they influence. More generally, *persuasive arguments theory* (Burnstein) describes how groups polarize shared opinions, compared to individuals, when they receive novel supporting information. Moreover, *minority influence* (Moscovici) within groups operates partly through minorities' conviction provoking majorities to systematically process their arguments.

4. Theories of Controlling: Reinforcement Theories

The core social motive to perceive some contingency between one's actions and one's outcomes is a sense of *effectance*, White's term, or control, in other formulations, drives a set of social psychology theories concerned with people's desire to effect certain outcomes. These theories often predict people's behavior from the economics of *reinforcements* (rewards and costs). People aware of situational contingencies act to maximize or at least improve their outcomes, in this view.

4.1 Controlling, Within Individuals

Attribution theories that focused on rational understanding by the *naive scientist* (Sect. 3.1) gave way to theories and mini-theories documenting the *shortcut errors and biases* of the *cognitive miser* (Sect. 3.1). Several of these errors share a focus on belief in human agency. The *fundamental attribution error* (Ross), *correspondence bias* (Jones), and the observer part of the *actor–observer effect* (Jones and Nisbett) all suggest that people over-rely on personality or *dispositional explanations* for other people's behavior. People making attributions about another's behavior underestimate the role of social situations, a phenomenon first noted by Heider. Theoretically, people explain their own behavior situationally, the actor part of the actor–observer effect.

Nevertheless, other theories emphasize people's need to believe in their own agency. For example, Brehm's *reactance theory* describes people's resistence to limits on their behavioral freedom and attraction to threatened or constrained behavioral choices. Bandura's *social cognitive theory* and *self-efficacy motivation* emphasize individual human agency. Bem theorized that people are as balanced as outside observers; his radical behaviorist *self-perception theory* suggests that people observe the contingencies controlling their own behavior and infer their attitudes from the pattern of freely chosen behavior. Indeed, people's *intrinsic motivation* (Deci and Ryan, Lepper, Greene, and Nisbett) depends on free choice, autonomy, and interest; it declines when under extrinsic reward (*over-justification effect*); that is, excessive external control. When people lack a sense of control,

theories hold that they may exhibit *learned helplessness* (Seligman), leading to depression, and *mindlessness* (Langer), leading to unintelligent behavior, but they may also increase *control motivation* (Pittman).

4.2 Controlling, Between Individuals

Various social exchange theories concern outcome-oriented standards for enacting and judging relationships. Homans's *distributive justice* applied elementary principles of operant (Skinnerian) behaviorism to social interdependence, holding that individuals expect rewards proportionate to costs. From this came *equity theory* (Adams, Walster (later Hatfield), Walster, and Berscheid) that argued that people seek fair ratios of outcome to investment. Although couched in reward–cost terms, inequity theoretically relates to dissonance (Sect. 3.1), creating a drive to reduce it. The exchange idea in relationships developed into *interdependence theory* (Kelley and Thibaut), that posits that human interactions follow from degrees, symmetries, bases, and kinds of dependence. In Levinger's *stage theory of relationships*, people begin with a cost–benefit analysis. Whether close relationships switch (Sect. 2.2) or not (Sect. 4.2) to a nonexchange (i.e., communal) orientation, people in relationships do control their own and the other's outcomes, addressed by theories of intent attribution (Sect. 3.1), *emotion in relationships* (Berscheid), and *accommodation* to disruption (Rusbult). Even outside close relationships, outcome dependence motivates *individuation* (Fiske), undercutting stereotypes. Control over one's outcomes appears in a *cost–reward model* (Dovidio, Piliavin) of helping.

Although motives to control one's outcomes theoretically underlie most positive relationships, they theoretically also underlie aggression. Excessive control over another person, to obtain desired outcomes, motivates *instrumental aggression* (Geen), following the *frustration–aggression hypothesis* (Dollard, Miller, Doob, Mowrer, and Sears). Other formulations carry an explicitly cognitive *neoassociationist analysis* (Berkowitz) of aggressive patterns. Lack of control, brought on by *environmental stressors* (Anderson) enhances aggression, as does *social learning* (Bandura), whereby people are socialized to imitate successful aggressive acts.

Incentives motivated the earliest frameworks for *persuasive communication* (Hovland, Janis, and Kelley), as well as more recent principles of compliance involving *scarcity* (Cialdini) as a threat to control over outcomes.

4.3 Controlling, In Groups

Group members theoretically analyze costs and benefits at role transitions during *group socialization* (Moreland and Levine). *Interdependence* of outcomes defines group life (Deutsch, Kelley and Thibaut, Sherif). Some people control outcomes more than others, placing them in positions of power, defined as the capacity to influence others (French and Raven); although only some *bases of power* (reward, coercive) explicitly relate to reinforcements, even the others (Sects. 2.3 and 3.2) could be viewed as incentive-based. Pure incentive orientation, however, induces only *compliance* (public performance, not private belief) (Kelman).

Belief in the power of human agency to control outcomes underlies several theories of group-level world views. Lerner's *just world theory* posits individual differences in the belief that people and groups get what they deserve. Sidanius and Pratto's *social dominance theory* posits individual differences in the beliefs that group hierarchy is inevitable; individuals high in social dominance orientation seek hierarchy-maintaining careers and exhibit high levels of intergroup prejudice; societies high in social hierarchy exhibit highly controlling social practices, including violent oppression, toward subordinate groups. *Evolutionary social psychology*, coming out of *sociobiology* (Trivers, Wilson), holds that individuals are motivated to dominate other individuals, to enhance their own reproductive outcomes (Buss, Kenrick).

5. Enhancing Self: Psychoanalytic and Self-theories

People seem motivated to have a special affection for self, and in the West this often takes the form of self-enhancement, whereas in East Asia, it may take the form of self-improvement, but with a certain sympathy for the self's difficulties. Theories of the special role of the self, especially defense of self-esteem, influenced social psychology first through *psychoanalytic perspectives*, especially from Freud, of course, but also Erikson, Maslow, and Sullivan. Subsequently, the importance of *self-esteem* became a non-Freudian truism driving a range of theories at individual, interpersonal, and groups levels.

5.1 Self-enhancing, Within Individuals

The clearest influence of psychoanalytic theory, the *authoritarian personality theory* (Adorno, Frenkel-Brunswik, Levinson, and Sanford) proposed that rigid, punitive, status-conscious child-rearing practices reinforce unquestioning, duty-bound, hierarchical-oriented obedience. To maintain safety, the child idealizes the parents, leaving no outlet for the unacceptable primitive impulses of sex and aggression. According to the theory, these are displaced onto those of lower status, notably outgroups, leading to lifelong prejudice. Altemeyer's recent *right-wing authoritarianism* has revived interest in prejudice as a self-enhancing motivational construct, absent the Freudian backdrop.

More broadly, several Western theories pick up the theme that people think, interpret, and judge in ways that elevate the self. Taylor and Brown suggest that *positive illusions* about the self, possibly inaccurate, benefit mental and physical health. Kunda describes *motivated reasoning* that protects self-esteem. Even people with stigmas buffer self-esteem by taking advantage of *attributional ambiguity* (Crocker and Major), attributing negative outcomes to prejudice instead of personal failings.

More generally, Steele's *self-affirmation theory* posits that people need to feel worthy, so a threat to one aspect of self can be counteracted by affirming another self-aspect. *Terror management theory* (Greenberg, Pyszczynski, and Solomon) holds that people specifically feel threatened by their own mortality, so to allay their anxiety, they subscribe to meaningful world-views that allow them to feel enduring self-worth. Similarly, the *ego-defensive function* (Katz, Smith, Bruner, and White) of attitudes protects the self from threat, whereas the *value-expressive function* of attitudes (Katz) more broadly affirms the self-concept.

The *self-discrepancy theory* of Higgins argues self regulation aims to attain positive self-feelings and avoid negative self-feelings. Discrepancies between the *actual self* and the desired *ideal self* cause depression, at the lack of the positive outcome. Discrepancies between the actual self and the *ought self* cause anxiety, at the failure of not living up to standards.

5.2 Self-enhancing, Between Individuals

Various theories argue that people use relationships to enhance the self. Aron and Aron's *theory of self-in-relationship* posits that relationship and self-concept merge, presumably affecting self-esteem according to relationship quality. Not all positive features of a close other boost self-esteem. According to Tesser's *self-evaluation maintenance theory*, people feel threatened by the success of close others in areas of self-identified competence, but threat diminishes with decreased closeness or identification.

Even interpersonal altruism has been hypothesized to result from egoistic motives, such as *negative state relief* (Cialdini) that puts an end to the perceiver's own guilt or sadness at another's distress. Certainly aggression has been hypothesized to result from self-protective motives. Indeed, Baumeister argues that *inflated self-esteem* underlies much aggression and violence. More broadly, *affective aggression* (vs. instrumental aggression, Sect. 4.3) theoretically results from perceived threats to self, as in *attributions of hostile intent* (Dodge).

5.3 Self-enhancing, In Groups

According to sociometer theory (Baumeister and Leary), people base their self-esteem on their standing in the group; from a broad perspective, this fits the belonging motive (Sect. 2), but the theory also specifically addresses the process of self-enhancing in the context of a group. People's sense of positive identity theoretically results from group membership (Sect. 2.1). Nevertheless, people balance group identity and personal identity, according to Brewer's optimal distinctiveness theory, to achieve a positive view of self. To the extent that people incorporate the self-in-the-group (Smith), people will experience emotions on behalf of the group, presumably including group-based self-esteem. Traditional theories of relative deprivation (Stouffer, Runciman, Crosby) distinguish egoistic deprivation, which assumes that people base their feelings about their own esteem on their standing compared to others, versus fraternal deprivation, which provides the parallel for one's group standing compared to other groups. In each case, a form of self-esteem depends on gaps within or from a group.

The group as a basis for self-esteem theoretically differs in more *individualistic vs. collectivistic cultures* (Triandis) or more *independent or interdependent cultures* (Markus and Kitayama). In relatively individualistic, independent cultures, the self is autonomous from the group, and self-esteem is personal; most theories of self-enhancement result from this North American and European cultural perspective. The autonomous self moves in and out of many groups, with multiple group identities all affecting self-esteem. In relatively collectivistic, interdependent cultures, the self is subordinate to the group, and strives to enhance the group by improving the less important self. The interdependent self remains loyal to few primary groups, which sustain the self.

6. Trusting

Just as people have a special positive feeling for the self, they also have a positive feeling for others, at least in the in-group, all else being equal. Bowlby's *attachment theory* argues for the survival value of children having secure relationships, a principle social psychologists extend to adult relationships.

6.1 Trusting, Within Individuals

Matlin and Stang's *Pollyanna hypothesis* holds that people perceive and expect positivity across a variety of domains. People especially perceive individual people more positively than comparable groups or entities, in the *person-positivity hypothesis* (Sears). Given this positive baseline, negative information theoretically differs in *salience* (Fiske), *diagnosticity* (Skowronski and Carlston), and *motivated vigilance* (Peeters and Czapinski). People are risk-averse, according to *prospect theory* (Kahneman and Tversky). Taylor's *mobilization-minimization hypothesis* describes how people react strongly to negative events, but quickly readjust to a moderately positive baseline.

Gilbert and Wilson's *durability bias* describes people's ignorance of their own readjustment to baseline after unusually negative (or positive) events.

6.2 Trusting, Between Individuals

All relationships, but especially close ones, depend on trust, according to *appraisal process theory* (Holmes). A*ttachment theory*, as applied to close relationships (Hazan and Shaver), describes how people vary in trust for others and value for self, resulting in a typology of *relationship orientations*. Trust benefits relationship quality and longevity. Trust, in an *exchange* form (Sect. 4.2) constitutes *reciprocity* (Sect. 2.2); in a *communal* form (Sect. 2.2), trust constitutes response to another's needs. When people vicariously experience each other's emotions, a strong form of communal sharing, they are more likely to help others, in accord with the *empathy–altruism hypothesis* (Batson, Eisenberg).

In *game theory* (Luce and Raiffa), trust entails cooperative instead of competitive behavior in mixed motive games, in which outcomes conflict but need not sum to zero. Structural features determine cooperation, according to Deutsch's *theory of trust and suspicion*; when people can communicate intent, they trust more. Larger groups enable less trust, according to Yamagishi and Sato's *theory of trust*.

6.3 Trusting, In Groups

Shared goals promote trust both within and between groups, in an *interdependence theory* (Sect. 4.3) analysis. But shared goals also contribute to the *identity* of the group (Sect. 2.3). Another theoretical account is that *superordinate goals* require collaborative effort (Sherif and Sherif) that creates trust and overcomes intergroup divisions. Under optimal conditions, Allport's *contact hypothesis* specifies that equal status, cooperative, pleasant, sanctioned intergroup contact reduces prejudice and increases trust between groups. Members of distinct groups may come to view themselves as *one-group* (Gaertner and Dovidio).

7. Conclusion and Disclaimer

Theories flourish in social psychology, usually accompanied by rigorous programs of research. This review has not evaluated the empirical success of the noted theories, merely recorded some prominent ones. At this count, the 32-volume American *Advances in Experimental Social Psychology*, the 10-volume *European Review of Social Psychology*, the 4-volume *Personality and Social Psychology Review*, as well as social psychological theories appearing in *Psychological Bulletin* and *Psychological Review* (by computerized search) amount to just short of 600 separate theories, not to mention the ones appearing only in 'empirical' journals or books. The present article comprises a series of pointers to theories that reflect both past and current thinking, in a social evolutionary framework of five (plus or minus five) core social motives that facilitate social life.

Social Question: Impact on Social Thought

A modern social science not only originates within an intellectual project of widening rational knowledge, but also as a means to govern what Simmel (1908) called 'the material of social processes.' The making of what Comte (1848) described as 'the preponderance of a social point of view' implied that there were problems that no established scientific approach could successfully address. Even more, the individualistic premises of modern legal and economic sciences themselves opened new problems from the vantagepoint of social organization. If the major trend of modernity has been toward the legal emancipation of the individual and the economic emancipation of labor from the burdens of traditional society, the emergence of social thought was to make evident that this could not suffice to organize a stable modern society. There was a need for models of organization and social integration, i.e., for a 'science of social order.' For such a science, the first object of analysis has been the 'social question', that is, the mass pauperism growing alongside the rise of modern liberalism that social thought regarded as a danger for social stability. This became particularly clear in France where revolutions brought the problem of popular poverty to the forefront of the political arena.

1. *The Experience of the Revolution*

The idea that the French Revolution played an important role in the rise of sociology has been established by important sociologists such as Reinhardt Bendix and Robert Nisbet. The very term 'social science' became official during the French Revolution through authors like Condorcet (Baker 1964, McDonald 1993). Less common is acknowledging that its development was linked to the question of poverty and the new political importance it assumed. The Revolution was more than an intellectual advance in rationalism; it was a dramatic experience cutting bridges with most of what was known and abruptly revealing the depth of the social crisis. The new awareness of the crisis, more than the rationalist critique, was crucial to social thought.

Nisbet (1943), stressing the impact of the French Revolution over the making of sociological concepts, suggested that the experience of the crisis focused them on the 'social group', as their own response to eighteenth century social theory centered on the opposition between the state and the individual. Social thought developed by establishing the group as an object of science, not only with an ethical implication, but also with a primary theoretical value in the study of man.

Why the group? Because the impact of the Revolution upon traditional social groups had driven the crisis until the destruction of the whole institutional frame, eroding the very bases of social belonging. The 'rational state,' as Nisbet put it, that the eighteenth century social theory had been regarded as the solution to the crisis of traditional bonds (religion, family, guilds, and associations) and the correlation to individuals' emancipation, no longer seemed able to nourish a real sense of social belonging. The group raised a new problem that could not be faced in economic or in juridical terms: to rebuild society required new foundations for the social bond. The experience of the crisis and the condition of insecurity due to the destabilization of order opened the way to a science that would fill the task of laying down the proper conditions for a new social order.

2. *The Autonomy of 'Society'*

The 'social question' was the most dramatic evidence for both the crisis and the need for a new social order. Poverty could no longer be regarded as a mere individual condition to be dealt with by charitable support and police repression, as in the Old Regime treatment of mendicancy and vagrancy. The political emancipation gained through the Revolution, as well as the economic emancipation guaranteed by a free labor, made the increase of poverty among the urban popular masses an issue of public concern (Simmel 1908). How could the poor play a role in the new social order, be inscribed in the political arena of universal citizenship and in the liberalized market of productive labor? As Hannah Arendt (1963) stressed, the social question broke the social unanimity around the revolutionary project—and from then onwards, it has been the stumbling block of any revolution.

The modern idea of rights, making the poor just citizens the same as everyone else, and the modern economic imperative to include them into productive labor, did converge in giving a new visibility to the social question. In fact, poverty challenged both the achievement of individual autonomy as well as the generalization of free labor. It was therefore important to act against the social causes of poverty, and therefore to know them, what neither legal nor economic sciences could do. The importance of the poverty question grew together with the political awareness that a stable society demanded an end to the revolution. Both social and political problems contributed to a realization that social change could not be understood through individual actions, but rather as the result of relatively impersonal processes. Society appeared to have autonomous conditions to its own development and an autonomous ability to resist changing, both impossible to curb by law or through the market.

The social question has been the first object of application where the autonomy of social thought's premises, concepts, and methods was at stake. It was thus the arena for a gradual autonomization of social thought from economic and legal categories, founding the problem of order as specifically social (Procacci 1993). In this way, it represented a crucial step toward the construction of the very idea of society as a theoretical concept and at the same time a practical field of investigation.

3. *The Science of Social Order*

The analysis of the social question had a crucial impact over the making of positive sociology. With Saint-Simon and Comte, the search for a new social order was firmly located within antisocial effects of industrial transformation: how was it possible to organize inequality in a way that would not prevent social stability? Their foundation concepts were marked by their source in the analysis of social inequality.

First of all, they carried a vision of society as an organic entity, essentially concerned with the cohesion of all its parts—hence the importance of the metaphor of social organism. Most importantly, this located sociology on the side of the whole social body, the common interest, the collective being—apart from the opposition opened by liberalism between individual and collective points of view.

Secondly, all dangers for social order were interpreted in the perspective of social pathology, calling for some kind of therapeutics. Poverty was a pathological element within the social body—the task of social thought was to identify the means for restoring a normal society. Hence the importance of medical knowledge, with the normative character intrinsic in the idea of restoring a normal society. Methods of inquiry were also drawn out of medical practice: observation of symptoms, collection of cases, and statistical recurrences. This shaped concepts animated fundamentally by a will to reform. There was no longer a pure science; the programme of positive sociology was a science able to found the criteria for acting in order to improve human conditions on positive knowledge.

Thirdly, the foundation concepts of positive sociology inherited the moral element that had characterized the philanthropic approach to poverty. Particularly with Comte, the problem of order became a question of moral consistence of society, impossible to solve through legal or economic reforms. His main theoretical questions run about the position of bourgeoisie and the working class in the new social order (Elias 1978). For this reason, once the revolution exploded again in 1848 and the popular movement claimed political and economic reforms to solve the social question, he felt the need to engage into the public debate. His 'Positivist Society', created a few days after the February insurrection, had the explicit task to oppose the positivist view of the social question to socialists. Insufficient labor did not depend upon capitalist economy, but upon an irrational organization that scientific development would overcome. The emphasis was rather on society's moral engagement to fight against poverty, a problem more difficult to solve: it required to put 'social sentiment' in the forefront, by promoting a sociability that the Comtian concept of 'duty' was to organize as the cement for new social bonds.

4. *Democracy and Socialism*

A different perspective is the one opened by Tocqueville's analysis of democracy. Elected in 1848 to the parliament by the first universal manhood suffrage, he was directly involved in writing the new Constitution which was to put an end to the revolution. As such, he politically intervened against the reforms claimed by the popular movement. Political organization of democracy above all demanded fighting its tendency to ally with a centralized power. The social question implied such a danger, strengthening the state that was expected to solve it; therefore nothing could be granted, except an exclusively moral engagement of society to reduce poverty. Distinguishing moral duties (*la morale*) from legal rights (*le droit*) was strategic in preventing the state from becoming either an economic agent providing jobs or a regulator reviving old protectionism. A political solution could only come from organising democracy: pushing people to act on collective issues and promoting public virtue instead of private freedom, were the only means for undermining the spectre of state despotism. The perspective of self-government led to rehabilitate associations as the arena where people would exert their public responsibility and resist the state.

The 1848 revolution was a crucial moment for social thought consolidation through its analysis of the social question. The work of Lorenz von Stein (1850) provided important evidence and was a crucial source for Marx. Indeed it would be difficult not to mention the influence of social question over socialist social thought, as the revolution of 1848 exemplified. The experience of French revolutions was also central for Marx's historical concept of class, conceptualizing the fundamental inequality producing poverty in a capitalist economy. But class conflict was for Marx (Marx and Engels 1848) the key to development, and not a pathology to be cured; there could not be any other solution to it but the revolution. The strategical programme of Marxian social thought deeply differed from the one of sociology: it was not a question of reanimating society through moral duties and intermediary associations. Under this light, there is more continuity with Durkheim's theory of social solidarity.

In his study on socialism, Durkheim (1895) stressed its affinity with sociology, given the central role played by organization and a set of social rules controlling the economic sphere. Since societies autonomously tend toward solidarity, the antagonism between capital and labor was a danger, and could only result from disorganization. The social question was a problem of socialization; even unions might work as a means of social integration. The concept of organic solidarity combined the characteristics of positive sociology and the attempt to enhance democratic strategies: it provided criteria for techniques reorganizing social bonds, such as the division of labor and the resurgence of intermediary groups.

In conclusion, the analysis of poverty contributed to strengthen a critique of economic and legal individualism towards a new science of social solidarity. The impact of the social question tied the fate of social science to the development of an administrative state, and engaged it into the political arena; thus promoting the re-establishment within the social body of those groups that liberalism had strategically eliminated.

Social Relationships in Adulthood

1. Basics About Relationships

1.1 What is a Relationship?

What constitutes a relationship? The answer, many relationship researchers will say, is simple. A relationship exists between two people when each person influences the other's thoughts, feelings, and/or behavior. In other words, a relationship exists when people are at least minimally interdependent (Kelley et al. 1983). As the frequency, diversity, impact, and/or time span over which people influence one another increase, the relationship becomes increasingly interdependent or, according to Berscheid et al. (1989), closer.

1.2 Types of Relationships

Interdependence takes many forms, a fact reflected in the diversity of terms we use to refer to relationships—friends, romantic partners, sibling relationships, business partners, and physician–patient relationships. Most past, and many current, relationship researchers have chosen one of these types of relationships to describe in detail. This has resulted in separate literatures on friendships, romantic relationships, marriages, and sibling relationships, and these literatures continue to expand.

Increasingly, however, researchers are focusing upon conceptual differences between relationships.

Some have identified conceptual dimensions along which relationships vary. For instance, Wish et al. (1976) find evidence for four dimensions underlying people's ratings of relationships: cooperative/friendly versus competitive/hostile; equal versus unequal; intense versus superficial; and socioemotional/informal versus task-oriented/formal. Blumstein and Kollock (1988) suggest that relationships vary according to whether they do or do not involve kin, sexual/romantic aspects, cohabitation, differences in status, and cross-sex participants.

Still others have proposed taxonomies including sets of qualitatively distinct categories. For instance, Fiske (1992) posits that four basic rules direct individuals' relations with others in all social interactions: people may share a common identity and treat one another equally (communal sharing); people may attend to status differences and give benefits accordingly (authority ranking); people may weight the utility of their behavior in achieving desired outcomes for themselves (market pricing); and finally, people may follow a quid-pro-quo principle (equality matching). Clark and Mills (1979, 1993) distinguish between: communal relationships, wherein benefits are given, non-contingently, on the basis of the recipient's needs; exchange relationships, wherein benefits are given with the expectation of receiving comparable benefits in return; and relationships in which people are simply concerned about their own self-interest. They also emphasize a quantitative dimension relevant to communal relationships—the degree of responsibility that one person feels toward another. The stronger the communal relationship, the greater the costs (in time, effort, money, and foregone opportunities) a person will incur to respond to the other's needs. Most recently, Bugental (2000) has proposed grouping relationships within an attachment domain, a hierarchical power domain, a coalitional group domain, or a reciprocity domain. In addition to thinking more about the conceptual dimensions and qualities characterizing different relationships, many researchers now emphasize understanding the interpersonal processes that influence relationships.

1.3 On What Types of Relationships is Most Psychological Research Currently Focused?

Despite recognition that a variety of conceptually distinct relationships exist, research on processes occurring within relationships is not evenly distributed among these types. Most research has been conducted on intimate, or potentially intimate, relationships (e.g., friendships, romantic partnerships, and marriages). These relationships tend to fall in attachment or reciprocity domains (Bugental 2000). Further, people expect intimate relationships to be cooperative, friendly, equal, intense, social-emotional (Wish et al. 1976), and communal in nature (Clark and Mills 1979, 1993). Increasingly these relationships are being studied longitudinally. A much smaller corpus of research exists on interpersonal processes relevant to competitive (Wish et al. 1976), market pricing (Fiske 1992), authority ranking (Fiske 1992), or hierarchical (Bugental 2000) relationships, and little of it is longitudinal in nature. Hence, just a few comments are devoted to research on competitive and hierarchical relationships here. More extensive comments are included relevant to interpersonal processes within friendships, romantic relationships, and family relationships.

2. Research on Non-intimate Relationships

2.1 Hierarchical Relationships

Many social relationships exist in which one member has power or authority over the other, and psychologists have reported some interesting findings relevant to such relationships. Fiske (1993), for instance, found that one's position in a hierarchical relationship influences one's tendency to view one's partner in stereotypical terms. Those with less power tend to pay careful attention to information about powerful people, especially information that contradicts stereotypes of these individuals. In contrast, in thinking about their underlings, those in more powerful positions rely on stereotypes. Presumably underlings have more time to attend to details about those who have power over them and are motivated to do so by a desire to gain control over the situation. Those in power who oversee many people have less time and, given the control their power affords them, less need to attend to details regarding underlings.

Other researchers have found disturbing links between some men's ideas of power and their tendencies to view women as attractive. Bargh et al. (1995) used a questionnaire to measure males' propensity to sexual aggression. Later, these men participated in a study with a woman. Some men were primed to think about power (by sitting behind a large desk), while others were not. Among those prone to sexual aggression, being primed to think about power was associated with seeing the woman as being significantly more attractive—a link about which these men were not consciously aware.

2.2 Relationships Between Negotiators

A great deal of work exists on interpersonal processes occurring between people who must negotiate with one another to come to a solution to a problem, most often involving a division of resources. Much early work focused on how individual differences in personality and gender influence negotiating, yet it yielded little in the way of findings. Other early work on how situational factors influence negotiations was more

fruitful. For example, the presence of observers has been shown to lead negotiators to express greater advocacy for previously announced positions, whether or not the observers have a vested interest in the outcome. Later work, falling within a 'behavioral decision perspective,' has explored how negotiators deviate from rationality in their decision-making. Findings suggest that negotiators are too influenced by whether risks are framed positively or negatively, rely too heavily on the most available information, and are too confident about the likelihood of attaining outcomes that favor themselves. The nature of preexisting relationships between negotiators has also been shown to influence the process of negotiation. For instance, negotiators prefer equal payoffs when the relationship is positive or neutral. In contrast, when the relationship is negative, they prefer inequality—favoring themselves. Other findings show that when relationships are close there is more information sharing, less coercive behavior, less demanding initial offers, and quicker agreements. Surprisingly, better joint outcomes are not superior overall, however. (See Bazerman et al. 2000 for a summary of this and other work on relationships between negotiators.)

3. *Research on Intimate Relationships*

3.1 *A Very Active Area With Some Well-established Findings*

Psychological research on intimate relationships is flourishing. Twenty-five years ago, the relevant literature was small and limited almost entirely to studies of initial attraction between people. The research was primarily experimental and conducted within the confines of a laboratory. When ongoing relationships were examined, the dependent measure of interest was, most often, global satisfaction. Today the relationship literature focuses largely on naturally occurring, ongoing relationships and on specific interpersonal processes relevant to forming, building, repairing, maintaining, and (sometimes) ending relationships. Although some research remains experimental and laboratory-based, field research often involving longitudinal surveys and diary studies of ongoing relationships has taken center stage. The field has advanced sufficiently that there is clear consensus on some facts about close relationships. These topics are discussed next.

3.2 *Having Relationships is Good for You*

One fact that highlights the importance of research in this area is simply that, overall, having relationships is associated with good mental and physical health. Having friends and family members with whom one maintains regular contact, and/or a romantic relationship, is associated with greater overall reports of happiness and life satisfaction (e.g., Diener 1984, Myers 1992). Researchers using self-report measures have found that people report feeling best when they are with other people. Being socially involved (as indicated by such diverse indices as one's network size, the density of that network, simply being married or not (especially for men), and perceiving that one has social support available if needed) is linked to better physical health and a lower risk of death (e.g., Berkman and Syme 1979, Cohen 1988). Indeed, many studies have related social involvement to lower susceptibility to the common cold (Cohen et al. 1997), cancer (Glanz and Lerman 1992), and cardiovascular disease (Berkman et al. 1993).

That having social relationships is linked to better mental and physical health is clear. However, why this is so remains unclear. Personality attributes may predict both good relationships and good health. Thus, having relationships may not necessarily be causally linked to good health. However, most researchers in this area believe that it is. Perhaps our relationship partners encourage good health practices. Perhaps they help us cope with and reduce stress. Perhaps just knowing that our partners are there to support us lessens our anxiety (and its physiological concomitants). Such issues are the subject of current research.

3.3 *We Can Predict Who Forms Relationships With Whom*

People tend to form relationships with those who are physically or functionally proximal to them. However, we come into proximity with many others. With which of these people will we form relationships? One factor that influences us is what members of our already existing relationships think. We tend to form relationships with people of whom our present relationship partners approve (Parks et al. 1983). Another factor is similarity. The evidence is clear that 'birds of a feather flock together.' People form relationships with those who are similar in attitudes, age, race, and educational background. In the case of romantic relationships, we also tend to form relationships with others whose physical attractiveness matches our own. This may be because we are drawn to situations which attract similar others. Alternatively, we may actively seek out similar others. Evidence suggests we generally assume people are similar to us and that the discovery of dissimilarities may be what drives people apart (Rosenbaum 1986). With one notable exception, there is very little evidence for complementariness in attraction. Opposites do not seem to attract. Even work on

masculinity and femininity does not suggest that couples including a masculine male paired with a feminine female get along particularly well. Rather, it appears that compatibility is greater when each member of a couple possess both masculine and feminine traits (Ickes and Barnes 1978, Zammichieli et al. 1988).

Performance domains appear to be the one exception to the rule that 'birds of a feather flock together.' Specifically, there is evidence that when an area of performance is central to one's self-definition—say, being good at academic subjects—a close other's good performance in the same area can be threatening to one's self-esteem. That, in turn, can drive the relationship apart. In contrast, partners excelling in different performance domains can promote the relationship. That way each person can bask in the other's reflected glory, and neither suffers from social comparison with the other (Erber and Tesser 1994). Still another important determinant of initial attraction is whether a potential partner likes you. Backman and Secord (1959) have demonstrated this experimentally, and Kenny has demonstrated this in studies of ongoing relationships (Kenny and La Voie 1982).

Finally, we note that there is ample evidence that physical attractiveness is a powerful determinant of initial attraction (e.g., Berschied et al. 1971). Although both males and females seem to value attractiveness in a relationship partner, it seems especially important to males when judging females. Evolutionary theorists suggest that this has resulted from attractiveness being a signal of the health and presumed fertility of that potential mate (Buss 1989). Evolutionary theorists' work on mate preferences also suggests that women especially value males with good resources (presumably because they can provide for offspring). At the same time, these theorists have found evidence of women placing high value on resources in males and males placing high value on attractiveness in females, they have simultaneously found that both males and females value such attributes as kindness and honesty in one another. Indeed, most people rate these attributes as being more important than resources or attractiveness.

3.4 Responsiveness to Needs is a Process that is Important to Good Relationship Functioning

Social psychologists have made considerable strides in identifying interpersonal processes that are important to good relationship functioning once relationships have been established. Responsiveness to one another's needs is one such process. It has long been recognized, initially by reinforcement theorists, that receiving rewards from one's partner is important to relationship satisfaction (e.g., Byrne and Clore 1970). However, recent theory and empirical research has demonstrated that the manner in which people meet (or fail to meet) one another's needs is very important to a person's sense that his or her partner is truly concerned for his or her welfare. This work suggests that a person needs to receive more than benefits from another person to feel intimate with that person. The person needs to believe that the relationship partner understands, validates, and, ultimately, cares for him or her. This appears to emerge from such things as the other responding appropriately to one's statements of needs, self-disclosures, and emotional expressions by listening carefully, responding with understanding and acceptance, and, ultimately, by actually helping (Reis and Patrick 1996) (see *Love and Intimacy, Psychology of*). It seems likely that these processes, in turn, are facilitated by having a partner who is high in empathic accuracy—that is, by having a partner who accurately perceives one's thoughts and emotions (Ickes 1997).

Feeling cared for also appears to be enhanced when partners do not seem to be giving benefits to get benefits. For instance, forgoing self-interest to benefit a partner enhances trust in the partner's caring more than giving a benefit that aids both the recipient and the giver (Holmes and Rempel 1989). People led to desire a close relationship with another want that relationship to be characterized by noncontingent responsiveness to needs (Grote and Clark 1998). That is, they react more positively to benefits given without strings attached than to those given with the expectation of repayment (Clark and Mills 1979), and they do not wish to keep track of just who has contributed what to the relationship in order to allocate benefits (Clark 1984). Giving benefits with strings attached or in exchange for comparable benefits calls the fundamental caring component of relationships into question.

For relationships to be characterized by responsiveness to needs, not only is it important for each person to try to meet the other person's needs, it is also important for each person to convey their needs to their partner. This greatly facilitates the partner's ability to respond to those needs. Thus, willingness to self-disclose has been shown to promote relationships (Cohen et al. 1986). So, too, does it appear that freely expressing one's emotions—which convey needs—is good for relationships (Feeney 1995).

From a personality perspective, it is noteworthy that researchers have found that individual, chronic, 'attachment styles' are closely related to perceptions that others will meet one's needs and hence to a wide variety of behaviors relevant to meeting needs in close relationships. People with a secure attachment style (presumably resulting from having had appropriately responsive caregivers early on) are more effective support-givers and -seekers than are those with insecure attachment styles (e.g., Simpson et al. 1992). Indeed, research on attachment styles has been the fastest-growing area of relationship research over the past two decades (Cassidy and Shaver 1999) (see *Adult Psychological Development: Attachment*).

3.5 Other Processes Associated With High- vs. Low-quality Close Relationships

Responsiveness to needs is not the only interpersonal process important for maintaining high-quality intimate relationships. A number of studies suggest that viewing one's partner positively and reconstruing a partner's faults as virtues is also beneficial for relationships (Murray and Holmes 1993). (Perhaps this aids in maintaining faith that one's partner really does care about one's needs.) These same researchers have also found evidence that when people who are satisfied with their dating relationships do see faults in those relationships, the negative thoughts tend to be linked in memory to positive thoughts about their partners in what they call a 'yes but' manner. For instance, a member of such a couple might say, 'I think his laziness is actually kind of funny; it gives us a reason to laugh.' Less-satisfied couples tend to link negative thoughts about the partner with other negative thoughts about the partner and the relationship (Murray and Holmes 1999). Seeing one's partner in a more positive light than one's partner sees him- or herself also seems good for one's relationship and appears, over time, actually to result in one's partner living up to one's ideals (Murray et al. 1996).

Reflection and social comparison are two more processes that appear to influence the quality of intimate relationships. Reflection refers to feeling that a partner's performance reflects on you, either positively or negatively. Social comparison refers to the process of comparing one's own performance in a given domain with a partner's performance and discovering that one has performed better or worse than that partner. Each process can benefit or harm a relationship. When a performance domain is irrelevant to one's identity, it appears that a partner's good performance in that domain enhances one's own self-esteem (and helps the relationship), whereas a partner's poor performance decreases one's self-esteem (and harms the relationship). The closer the relationship, the greater the effects (Erber and Tesser 1994).

Still other processes that appear to influence the quality of relationships have been identified. For example, research based on Aron and Aron's self-expansion model (1996) has demonstrated that when we fall in love our conception of ourselves expands to include aspects of the other person and that doing exciting and novel activities with one another can increase the quality of a couple's relationship (see *Interpersonal Attraction, Psychology of*). To give another example of processes that appear to increase the quality of relationships, Rusbult has reported research showing that highly committed couples are especially likely to respond constructively (i.e., to accommodate) in the face of a partner's poor behavior and that such couples are also likely to engage in such relationship-protective processes as seeing attractive (and therefore threatening) alternative partners as significantly less attractive than their less committed peers do (Johnson and Rusbult 1989; Rusbult and Van Lange 1996).

Interdependence theory has been particularly useful in pinpointing factors independent of ongoing interpersonal processes occurring within the relationship that influence both satisfaction and commitment to a relationship. For instance, although interdependence theorists agree with reinforcement theorists and with those emphasizing responsiveness to needs that rewards received (and costs avoided) are important determinants of relationship satisfaction, they add the important point that the expectations people bring with them to any particular relationship will influence satisfaction. The higher a person's expectations (comparison level) are for the relationship, the tougher their standards will be and, potentially, the lower the satisfaction with any given relationship.

Interdependence theorists also emphasize that satisfaction is not the only, nor necessarily even the most important, determinant of the stability of a relationship. Instead, they have identified a separate variable—commitment to a relationship—as a stronger determinant of relationship stability. Satisfaction does contribute to higher commitment to a relationship, but there are other important determinants of commitment as well. One is 'comparison level for alternatives.' The better one's alternatives, the less committed one will be to the current relationship (independent of satisfaction). This means that one could lack commitment to a relationship which is, in and of itself, satisfying or be committed to a relationship which is, in and of itself, unsatisfying (but more satisfying than one's alternatives). Investments (anything put into the relationship that cannot be easily retrieved should one exit the relationship) also influence commitment. Having investments such as joint friends, joint memories, children, a joint house, well-established routines, and so forth all increase one's sense of having invested in a relationship and, hence, one's commitment to that relationship. Finally, outside prescriptives, either coming from oneself or one's social circle, can influence commitment which, as we have already noted, is an important predictor of relationship stability as well as of partners' willingness to accommodate one another (Rusbult and Van Lange 1996).

4. Future Directions

It is always difficult to predict the future. However, it seems likely that research on the interpersonal processes that occur in, and affect the quality of, friendships, romantic relationships, and family relationships will continue to occupy center stage for a while. We can also expect to see increasing collaboration between epidemiologists and health psychologists, who have demonstrated links between having relationships and health, and social and personality psychologists, who

have investigated interpersonal processes that contribute to high-quality intimate relationships. Many researchers currently are calling for such collaboration, in the hope that the fallout will be an understanding of how and why relationships are beneficial for mental and physical health.

Further, with the increasing emphasis on studying relationships longitudinally, it may be expected that theories and empirical work on interpersonal processes occurring in relationships over time will become more frequent. Right now, we know lots about first impressions and some about the very initial stages of relationship deepening. We also know a bit about the dissolution of relationships. However, we know little about long-term trajectories of happy and unhappy relationships. We will know much more in 10 years.

It also seems likely that relationships other than those emphasized in recent research (and hence in this entry) will become the focus of more research—relationships such as teacher–student and physician–patient relationships, relationships between co-workers, and relationships between siblings.

M. S. Clark

Social Science, the Idea of

Can human studies, e.g., sociology and psychology, be properly scientific? Since the mid-nineteenth century, philosophers and social scientists have debated this question more or less continuously. It has periodically assumed considerable urgency, indeed become a focus of attention within the disciplines, as new influences on these subjects were felt or as new models of science itself were developed. Indeed, the complexity and potential obscurity of the issue is already evident. There is an implied equation, '*human studies* are/are not *science*,' in at least two variables. There has been considerable debate, at least since the 1850s, about what kinds of role human studies might play. Likewise, what is required for a discipline to be scientific has also been a matter of continuing controversy. As Peter Manicas put it (1987, p. 168), 'neither "science" nor, *a fortiori*, the branches of the social sciences are "natural kinds".' Notice, furthermore, that the variables are not entirely independent of one another. What human studies practitioners have aspired to has itself been influenced by what they think about the desirability and the possibility of making their enterprises genuinely scientific. Similarly, though perhaps to a lesser extent, what has counted as scientific has reflected the actual practices of, *inter alia*, students of sociology and psychology. To approach this question, a suitably sophisticated taxonomy of possibilities is therefore required.

1. Some Taxonomic Distinctions and a Definition

If human studies are to count as scientific, then what it takes to make a science must first be considered.

1.1 Modality

First, *empirical* and *normative* approaches to this question need to be distinguished—roughly, 'What are the sciences like?' and 'What should the sciences be like?' Of course, these two questions cannot be treated in isolation, especially in view of the widely accepted maxim that '*Ought* implies *can*.' This maxim means, in this instance, that those subjects whose scientific status is being assessed cannot sensibly be required to attain some excellence unless, of course, *paradigms* of scientific achievement have themselves attained this excellence. With these points in mind, the question about human studies can be understood in this way: given what human studies *are* like, do they or can they conceivably measure up to whatever normative standards of excellence the best scientific disciplines *do* measure up to?

1.2 Focus

Of course, there are other issues about what it takes to make a science. The question of focus is perhaps the most important. Science and nonscience can be distinguished either in terms of their *products* or in terms of their *processes*. This fundamental distinction divides pre- and post-Kuhnian conceptions of science. Whereas *before* Thomas Kuhn's epochal work *The Structure of Scientific Revolutions* (1970), science was distinguished from nonscience by the kinds of *statements* the two discourses produced, or, more importantly, by the status of these statements relative to epistemic standards of confirmation, generality, or objectivity, *after* this work, science was increasingly distinguished from nonscience in terms of the activities of its practitioners. Obviously, it will make a difference which of these criteria is deemed more appropriate. On the product conception, it might count against the scientific pretensions of sociology and psychology, for instance, that the more robust results in these subjects lack the kind of generality that robust results typically display in paradigm, 'hard' sciences such as physics and chemistry. But perhaps this lack of generality is irrelevant if a process criterion is adopted. Perhaps sociologists and psychologists obtain their less general findings by the same technical means and methods that natural scientists use in producing more general or more stable results.

1.3 Scope

Finally, there is the issue of scope. Roughly speaking, *wide* and *narrow* understandings of the sciences can be

distinguished. On the narrow reading, it is the concrete and specific particularities of the paradigm sciences that provide criteria for judging other candidate sciences. Typically, the paradigm sciences are laboratory based, involve heavy reliance on statistical techniques of data analysis, and produce results in the form of highly confirmed differential equations relating measurable variables. On the narrow criterion, then, to count as a science, any other discipline must also exhibit these specific features. On the other hand, a wide approach to the issue requires of candidate sciences merely that they exhibit some abstract and high-level virtue which is shared by paradigm scientific achievements—that they permit the attainment of objectivity, for instance. A wide approach to the issue is probably indicated; at the concrete and specific level of technique and theory, there is enough variation *within* the paradigm sciences to rule out any narrow approach.

In considering whether human studies are scientific, an approach which is normative, process oriented, and wide in its scope should therefore be adopted. The question will be, in other words, whether it is possible that human studies be conducted in such a way that they might achieve whatever levels of objectivity in their procedures as are attainable in the paradigm sciences. (The issue is phrased in this way to permit the rather complicated judgment (likely to be favored by 'postmodernists') that human studies can achieve the same *degree* of objectivity as paradigm sciences, but that neither can achieve the *kind* of 'objectivity' that was previously thought to be characteristic of paradigm, natural sciences such as physics.)

1.4 Objectivity

To assess the scientific status of disciplines such as sociology and psychology, the objectivity of their procedures must, on this account, be assessed. But what is objectivity? Of course, there may be no more determinacy on this matter than on some others which have already been alluded to. Just as 'science' does not designate any natural kind, neither does 'objectivity'; it will be a matter of persistent debate what counts as objective. Some preliminary observations can nevertheless be offered.

First of all, transcendental and nontranscendental accounts of objectivity can be distinguished. In the transcendental account, objectivity in investigative activities has been attained when and only when all that is specific to the situation in which they are undertaken, including the personalities of the investigators, has been eliminated from them. Individuals who are otherwise dissimilar must, on this account, conduct themselves in some common way when they examine the objects of their investigations. (When scientists have managed to specify methods for the replication of results, some approximation to this ideal may have been achieved.) They know how to tell others who differ from them how to negate the effects of these differences and thus achieve the same results as they have. Objectivity, on this account, consists of transcending local circumstances by eliminating all factors which vary from one situation to another.

Of course, philosophers and others working under the rubric of 'postmodernism' have widely repudiated this ideal. True transcendence of local circumstances is not possible, it is not desirable, and, indeed, it is not even necessary for a form of objectivity (that is worthy of being pursued) to be attained. Objectivity requires not that local differences be eliminated, but, rather, that they be exploited in order to discover, where this is possible, a point of convergence of otherwise very different perspectives. According to this account, objectivity is attained when an individual is able to affirm from his or her own perspective a system of propositions that can likewise be affirmed from the otherwise different perspectives of such other individuals whose agreement matters (see Rorty 1989).

2. Why the Issue Matters

Why should it matter whether human studies are or are not scientific, especially if there is little agreement about the concepts in terms of which the issue is defined. Discussing the so-called 'interpretive turn' in human studies, Geertz (1993, p. 8) put the point this way: 'Whether this [development] is making the social sciences less scientific or humanistic study more so (or, as I believe, altering our view, never very stable anyway, of what counts as science) is not altogether clear and perhaps not altogether important.' There are, in fact, at least three reasons why it matters whether human studies are considered scientific.

2.1 Institutionally

The scient*ism* of its public culture, i.e., the privilege that is granted to scientific disciplines and their methods and results, is one prominent characteristic of modernity. Science has immense, though perhaps no longer undisputed, cognitive authority, and plays an influential role in defining as well as creating the world which human beings inhabit. If human studies succeed in gaining recognition as scientific subjects, then they too could hope to exercise this kind of authority. Foucault, typically, puts the matter the other way around (1980, p. 85): 'What types of knowledge do you want to disqualify in the very instant of your demand: "Is it a science?" Which speaking, discoursing subjects of experience and knowledge do you want to "diminish" when you say: "I who conduct this discourse am conducting a scientific discourse,

and I am a scientist?" Which theoretical-political *avant garde* do you want to enthrone in order to isolate it from all the discontinuous forms of knowledge that circulate about it?'

2.2 Heuristically

Whether sociologists and psychologists see themselves and are seen by others as scientists will, of course, influence the conduct of their enquiries and the kinds of products they aspire to deliver. As Geertz (1993, p. 8) put it, the issue is 'who borrows what from whom.' Do human studies borrow techniques of observation, experimentation, and data manipulation from 'hard' sciences such as chemistry and biology, or do they, instead, look to other disciplines for their techniques or their standards of objectivity?

Indeed, this issue is part of a long-standing debate. In the late nineteenth century, the crucial questions were about the *Geisteswissenschaften*—are they concerned with understanding or with explanation? Can they articulate general psychic and/or social laws or must they, instead, confine themselves to the accurate description and contextualization of concrete and specific incidents (Windelband's *nomothetic* vs. *idiographic* conceptions)? In the middle of the twentieth century, the key issue was the cognitive status of social scientific generalizations and, indeed, their very possibility in the face of innumerable obstacles and points of difference from paradigm 'hard' sciences. At the end of the twentieth century, the question is whether interpretation, with all its vicissitudes, constitutes a more central method for human studies than law-based explanation, and, indeed, whether interpretation itself is possible in a sufficiently 'objective' manner to permit the judgment that human studies are, perhaps in some extended sense, scientific.

2.3 Morally

How human studies are conceptualized may have profound moral significance. This point is dependent on the previous two. Suppose human studies are modeled on the 'hard' sciences and that success in doing so is conspicuous enough so that these subjects gain the kind of cognitive authority that some of their practitioners have long aspired to. In this case, ideas about the human situation that are moral and cultural foundations of our longest-standing and most deeply embedded traditions are at risk of being undermined. Putnam (1978, p. 63) put it this way: '[S]uppose our functional organization became transparent to us. Suppose we had a theory of it, and we could actually *use* this theory in a significant class of cases. What would happen to us? … Would it be possible even to think of *oneself* as a *person*? … [T]he development of *that* sort of knowledge of ourselves and each other would modify our natures in ways that we cannot predict at all. Every institution we now have: arts, politics, religion—even science—would be changed beyond all recognition.'

2.4 Some Positions

Whether human studies can be scientific is therefore too important a question simply to ignore. And, of course, it has not been ignored. Philosophers, social scientists, and others have, in fact, taken a number of positions on this question. Before proceeding with more substantive matters, a threefold primary distinction among these positions should be considered.

In the middle of the twentieth century, the most common position, though not so designated until later, was *naturalism*. According to this doctrine, there is nothing methodologically or theoretically distinctive about human studies in relation to paradigm, natural sciences. In particular, social and natural scientists legitimately share both aspirations (to discover and confirm general laws covering specific phenomena) and techniques (operationalization of variables, controlled experimentation, and statistical analysis of its results).

Both earlier and later than this period, however, a very common, perhaps even the most common position was *interpretivism*. According to this doctrine, human studies are distinguished from paradigm, 'hard' sciences both in their aspirations and in their techniques. Social scientists should not try to emulate the paradigm sciences narrowly construed (see Sect. 1.3); they should strive, instead, to interpret human social and psychic phenomena, and should employ the techniques of hermeneutics, broadly construed, to achieve this.

Finally, towards the end of the twentieth century, though also but to lesser degrees at earlier periods, 'scepticism' about the social sciences has been an increasingly influential position. On this account, laws of human being cannot be discovered, nor can properly objective interpretations of what human beings do be provided. Although the results of sociological or psychological research are often presented in the form of statements of knowledge, they are not entitled to this status, and must be understood in some other, less exhaulted way.

Sceptical positions may be either local or global. Global scepticism, often associated with the work of Jacques Derrida, repudiates all claims to determinate and methodologically adequate knowledge of human phenomena. Local scepticism adopts such a dismissive attitude only to certain claims, e.g., those which have been derived in some specific way or from some specific social position. (For instance, Marxists might be skeptical in this local sense about the claims

produced by mainstream, and hence in their view 'bourgeois' sociology or psychology. Similarly, feminists are often skeptical about the claims of mainstream and hence in their view 'patriarchal' social science.)

3. Impediments to Human Studies Being Scientific

That the legitimacy of human studies has so long been a matter of discussion is *prima facie* evidence that the investigation of human phenomena is not straightforward. What, then, are some of the reasons why it might not be possible to have a genuinely scientific approach to human social and psychic phenomena?

3.1 Preinterpretation

Theorists otherwise as diverse as Peter Winch, R. G. Collingwood, and Alfred Schütz have pointed, in distinguishing human studies from science *per se*, to the fact that students of human phenomena work, whereas paradigm scientists do not work, with materials that already have meaning and significance (see, e.g., Winch 1958, p. 87). There are strong and weak versions of this point. On the weak version, students of human phenomena must always rely, methodologically, on the objects of their research in ways in which paradigm scientists need not. Saying *what* is going on is preliminary to saying *why* it is happening, and hence to any scientific explanation. But what is going on, socially or psychically, must be understood, in Geertz's phrase, 'from the native's point of view.' How the subject understands what is going on determines the description of what is going on. On the strong version, once scientists have characterized 'the native's point of view,' they have discovered all that they need to or can know about the objects of their investigation. In either case, what paradigm scientists do and what human studies practitioners do is very different. The latter seem forced to rely on the subjective perspectives of the objects of their research.

3.2 Instability

There are three, inter-related factors which make it unlikely that sociologists and psychologists will be able to develop stable, objective accounts of the phenomena they take an interest in.

First, there is the *historicity* of both the subjects and the objects of human studies research. When Gadamer (1975, p. 204) asks 'Is not the fact that consciousness is historically conditioned inevitably an insuperable barrier to reaching perfect fulfilment in historical knowledge?' he articulates this fundamental difficulty: neither scientist nor subject 'stands still,' and hence what the one should say about the other changes as they themselves change. Paradigm, natural sciences, on the other hand, typically deal with statements of 'timeless' generality.

Second, in human studies relations of representation are subject to *reflexivity* in a way that is not common in the sciences *per se*. What practitioners say about human phenomena influences how their subjects enact or react to these phenomena, and hence often undermines the claim, necessary if objectivity is sought, that scientists have accurately *represented* the behavior of their subjects. (Practitioners have, instead, caused or persuaded subjects to act so that their behavior conforms to the practitioners' descriptions of it.) To mid-twentieth century philosophers, this possibility was best known under the heading 'reflexive predictions' (self-defeating and self-confirming 'prophecies'), but the crucial points have since been generalized extensively. Of course, as Lyotard (1984, p. 57) rightly points out, reflexivity must not be understood in too one-sided a way. It is not just that sociologists and psychologists can create the objects of their investigations; it is, as well, that these objects can, *strategically*, resist the characterizations which practitioners attempt to fit them with. This too is an impediment to the achievement of objectivity as it is usually conceived.

Finally, there is radical *indeterminacy* about the objects of investigation. This point is an ontological not an epistemological one. It is not that, in some or perhaps many cases, scientists cannot tell when they have characterized some phenomenon accurately. It is, rather, that there may be no sense, in these cases, to the very idea of accurate characterization. Typically, this means that there are, in the human domain, no fixed objects with well-defined characteristics for scientists to (try to) represent. In its more familiar forms, this point is, of course, an obvious development of Dilthey's observations about the 'hermeneutic circle.' It has been much emphasized by Derrida (1978) and others of his school. Specifically, if interpretation takes place against and in terms of a background that is not 'given' but must itself be an object of interpretation, then every interpretation has the form, not of an objective (if possibly incorrect) description, but, rather, of a (performative) proposal to see the situation in one of the many ways in which it could (as) legitimately be seen. There is on this account insufficient interpretive stability to warrant attributions of objectivity.

3.3 Complexity

The economist Hayek (1978, 26f) has long emphasized the peculiar kind of complexity which human studies

practitioners must try to deal with. Such 'organized complexity' resists reduction either to deterministic or to statistical models that might be appropriated from the 'hard' sciences. The behavior of a social aggregate often cannot, in other words, be reduced to the sum or product of the behavior of its individual parts, nor can it be adequately understood by characterizing its statistical properties (as the behavior of an aggregate of gas molecules might be understood, for instance). Notice, furthermore, that there may be moral and prudential (as well as practical) reasons for refusing to reduce this complexity in ways standard in the 'hard' sciences, i.e., by 'experimentalizing' it. So, while scientists might be able to 'standardize' individual agents in an experimental setting so that their interactions *there* can be understood deterministically or statistically, there are moral objections to exporting these conditions to *extra*-experimental settings. Indeed, there may be prudential reasons for not using these techniques of standardization in 'naturalistic' settings—as is implied, of course, by Hayek's own analysis of the market. In particular, adequate functioning of a complexly organized whole may depend precisely on its individual elements *not* being standardized. In either case, there are thus limits to the objectivity (actually the 'ecological validity') of the results that might be obtained in laboratory settings.

3.4 Interim Conclusion

All these impediments manifest themselves, of course, in a simple *fact*: there is, especially compared with paradigm 'hard' sciences, a conspicuous lack of progress in human studies. In particular, multiple and opposed paradigms persist in human studies, especially in any area of investigation which is likely to be of broadly 'political' interest and concern. As Geertz (1993, p. 4) has said, 'calls for "a general theory" of just about anything social sound increasingly hollow, and claims to have one megalomanic. Whether this is because it is too soon to hope for unified science or too late to believe in it is, I suppose, debatable. But it has never seemed further away, harder to imagine, or less certainly desirable than it does now.'

4. Alternative Conceptions of Human Studies

It may not make sense to compare sociology and psychology to the 'hard' sciences. How, then, are they to be conceptualized … and hence institutionalized? There are a number of possibilities. (Manicas's cautionary note still applies, of course; if 'science' isn't a natural kind, then no more is 'literature' or any of the other disciplines with which human studies might be compared.)

4.1 Literature

If human studies cannot properly be compared to the 'hard' sciences, perhaps a comparison with literature and other forms of potentially edifying narrative or practical discourses is more appropriate. This, certainly, is the opinion of a wide range of late-twentieth century theorists, including Geertz, Charles Taylor, Gadamer, and others. Geertz, for instance, advocates (1993, p. 6) that we 'turn from trying to explain social phenomena by weaving them into grand textures of cause and effect to trying to explain them by placing them in local frames of awareness … .' Of course, it might seem, to practitioners, that such a heuristic reorientation (see Sect. 2.2) would reduce the likelihood that human studies might have significant institutional influence (see Sect. 2.1). However, it needs to be borne in mind that the institutional influence of sociology and psychology is rather patchy (this is made clear in utilization studies), and that literature still forms the basis for highly influential mass-media representations and analyses of the human situation.

Another related possibility is this. While sociology and psychology do not or cannot provide an objective account of human phenomena, they can and do provide a variety of potentially important *perspectives* on these phenomena, and thus enable human beings to orient themselves more productively to them, especially by giving them frameworks for understanding these phenomena. In this vein, Rorty (1982, p. 247) draws a contrast between scientistic goals of prediction and control, on the one hand, and, on the other, practical goals of developing 'descriptions which help one decide what to do.' Since deciding what to do depends on values and other normative elements, and since there is widespread and apparently irreducible diversity in relation to these elements, the kind of 'practical knowledge' that nonscientistic forms of psychology and sociology might provide will not, of course, satisfy the most demanding requirements of objectivity.

4.2 Critique

There is a subtle difference, but an important one between the view that human studies offer edifying perspectives on or frameworks for the interpretation of human phenomena (see Sect. 4.1) and the view that they offer a basis for critique and the advocacy of change. In the latter half of the twentieth century, critical theorists (e.g., Habermas), genealogists (e.g., Foucault), feminists, and advocates for other marginalized groups (see Seidman 1994) proposed and in some cases made progress in achieving a 'takeover' of human studies activities and institutions. Across this spectrum techniques which have some claim to being 'antiscientific' (Foucault 1980, p. 83) are widely employed. In particular, practitioners of critique shift

the focus from showing how what is, socially, is an intelligible consequence of its causal antecedents to showing how what is, socially, represents the highly contingent realization of practices and structures to which there are clear, achievable, and desirable alternatives. As Foucault says (Rabinow 1984, p. 46): '[T]his critique will be genealogical in the sense that it will not deduce from the form of what we are, what is impossible for us to do and to know; but it will separate out, from the contingency that has made us what we are, the possibility of no longer being, doing, thinking, what we are, do, or think. It is not seeking to make possible a metaphysics that has finally become a science; it is seeking to give new impetus, as far and wide as possible, to the undefined work of freedom.' It is not, then, a matter of objective representation, but, rather, of politically effective analysis of the possibilities for change. (This is, of course, an extension of Karl Marx's 11th thesis on Feuerbach: 'Philosophers have only *interpreted* the world in various ways; the point is to *change* it.')

4.3 Disciplines or Ideologies

There are (see Sect. 3.3) moral and prudential disincentives to investigating human phenomena experimentally and, *a fortiori*, to 'exporting' into 'naturalistic' settings those conditions in which objective, reproducible experimental effects have been obtained. This has not, of course, stopped such things from happening and, indeed, it is the main conclusion of Foucault and others of his school that human studies have played a key role in this process, and, in particular, that they have contributed to the production of a 'disciplinary society' in which individuals are governed via their consent, i.e., through the ways in which they are made into 'subjects.' Although Jürgen Habermas disputed much that Foucault wrote and did, he was at one with him on this point. Habermas (1994, p. 54) says, for instance: 'It is no accident that these sciences, especially clinical psychology, but also pedagogy, sociology, political science, and cultural anthropology, can, as it were, frictionlessly intermesh in the overall technology of power that finds its architectural expression in the closed institution. They are translated into therapies and social techniques, and so form the most effective medium of the new, disciplinary violence that dominates modernity.'

That human studies are 'disciplines' is one way of capturing their importance and their negative impact on the lives of ordinary people; that they have functioned ideologically is another way of making this point. Perhaps the most important issue here is the way in which human studies have been recruited by other powerful institutions to serve the specifically political interests of those institutions while seeming to provide a nonpolitical analysis, a value-neutral account of contemporary social conditions. The idea of expertise has played an important role in this development. Insofar as social and psychic problems can be modeled on purely technical problems, solutions can be offered and consumed on a purely technical basis, and the reality of their dependence on fundamentally political matters can remain inaccessible to consciousness.

5. Conclusion

Should human studies plausibly aspire to scientific status? This remains questionable, as it has long been. Can they realistically aspire to such a status? This too is questionable. Perhaps Rorty (see Sect. 4.1) is right to suggest that human studies have aspired to too much, that their two main goals are disjoint and hence cannot both be achieved under the same methodological or institutional auspices. In this case, practitioners would perhaps be wise to disentangle their various objectives, and adjust their 'aspiration levels' (Simon 1996, p. 30) to more realistic goals. Or perhaps an even more radical adjustment of aspirations and disciplinary cultures is called for. Certainly Toulmin thinks so. Toulmin (1992, p. 193) says: 'The task is not to build new, more comprehensive systems of theory with universal and timeless relevance, but to limit the scope of even the best-framed theories, and fight the intellectual reductionism that became entrenched during the ascendancy of rationalism … [thus reinstating] respect for the pragmatic methods appropriate in dealing with concrete human problems.' On this account, human studies are to be understood more on the model of *ad hoc* tools for a variety of perhaps incommensurable human purposes, and not, as in their ascendency in the mid-twentieth century, as sciences with all the cognitive and institutional entitlements which are associated with that sometimes honorific term.

F. D'Agostino

Social Security

'Social Security' denotes both a complex of public institutions to protect individuals against common life risks and the programmatic idea that a commonwealth should provide all of its members such protection that they may feel secure within that commonwealth. This concept is broader than 'social insurance' and narrower than 'welfare state,' but relates to similar problems.

1. *The Emergence of the Concept*

'Security' (Latin *securitas*) has a long-standing tradition in the political rhetoric in Europe since the Roman Empire. In early modern times it was often used together with 'welfare' and 'felicity' in order to paraphrase the duties of the prince to care for his subjects. Thomas Hobbes made 'the safety of the people' a central task for his *Leviathan*, and this idea became seminal for modern political theory and constitutional practice. Wilhelm von Humboldt (1792) was the first to distinguish clearly between 'safety/security' and 'welfare': he restricted the task of the state to the provision of 'safety/security,' i.e. on the one hand the protection of citizens' freedom from external threats, and on the other hand the internal protection of citizens' commitments and rights via the judiciary and police. 'Welfare' by contrast was now assigned to the private realm as the individual pursuit of happiness from which the state was to abstain from interfering. In the nineteenth century the idea of public safety and security became restricted to the defense and protection of individual rights, the latter becoming differentiated between security within the public realm and the reliability of legal protection. But in the twentieth century the idea of security became paramount and was related to psychology and psychoanalysis, to the theory of cognition, to industrial and technical safety as well as to social security.

The specific context for the emergence of the term 'Social Security' was the United States and the Great Depression. In American pragmatism 'the quest for certainty' was abandoned and superseded by 'the search for security' (John Dewey). Inspired by the 'four wishes' of William I Thomas, the 'wish for security' became a basic assumption about human motives and 'insecurity' a commonplace attribute of the *Zeitgeist*.

The invention of the expression 'Social Security' is commonly attributed to Franklin Delano Roosevelt or to his entourage. Roosevelt used it first in a Message to Congress on 30 September 1934 after having created a 'Committee on Economic Security' to prepare the 'Social Security Act' on 29 June 1934. However, a voluntary association promoting 'Old Age Security' renamed itself 'American Association for Social Security' in 1933 and changed the title of its journal from *Old Age Security Herald* to *Social Security* because the program of this association had been expanded from old-age pensions to all branches of social insurance (Rubinow 1934, pp. iii, 279).

In any case the expression quickly gained steam: it coined first the US 'Social Security Act' of 1935 (SSA). It then appeared in the Atlantic Charter of 1941, became the catchword for the Declaration of Philadelphia (1944) of the International Labour Organization (ILO) and found its way in 1948 into the Universal Declaration on Human Rights of the United Nations (Art. 22). After the Second World War 'Social Security' had become a leading term internationally in the programs for the development of welfare states. Its specific meaning remained vague, however.

2. *Institutional Developments*

At the time when the SSA was drafted, a public commitment to income maintenance for people in need was by no means a new idea. At the end of the nineteenth century two models were competing in Europe: public subsidizing of mutual benefit associations (called the 'System of Gent'), and social insurance along the lines of the German ('Bismarck') Model. The British social reforms brought two new principles: payment of old-age pensions for deserving poors from the budget (1908), and flat-rate contributions and benefits in unemployment insurance (1911). In 1913 Sweden created the first universal system for securing income in old age. After the

Russian Revolution the Bolsheviks drafted a comprehensive system of social protection against all major contingencies of life, following a concept which Lenin had already propagated in 1912. Starting in France (1932), hitherto voluntary child allowances of employers were made obligatory, and this ushered in a new model of administration: calling upon private bodies for the attainment of public social policy ends. Thus social insurance for dependent workers was already competing with other models of social protection. The victory of the term 'social security' over 'social insurance' was a consequence of its vague content which allowed the inclusion of all kinds of public social protection. In 1947 the 'International Social Insurance Conference' changed its name to 'International Social Security Association' and opened membership to state-administered systems (such as those of Britain and the US) which until then had been excluded.

Thus, the *American* SSA brought a new name but hardly new ideas. It had a problem, however, that was not present in Europe, namely federalism. The Supreme Court had long held attempts by the Federal Government to introduce measures of social protection to be unconstitutional. And it was only after a positive ruling by the Supreme Court on the SSA in 1937 that federal social policies took shape, including policies to combat the risks of the death of a breadwinner and of disability. Besides a federal system of Old-Age Insurance the SSA introduced a new federal instrument into American politics: matching grants to the states in order to induce them to abolish the old forms of the poor law, to introduce or to improve a system of unemployment compensation, and to provide better care to the blind as well as to mothers and children. Thus the hitherto strictly separated domains of the federal and state government became linked for the first time. This remained a continual subject of controversy in the American polity with lasting consequences for the structure of social protection: there exists a two-tiered system consisting of 'social security' on the federal and of 'welfare' on the state level. The first program, protecting most of the employed population, is well administered, highly stable, and positively valued. The second, providing help as a last resort, has remained an ever-contested object of repeated reforms. It is unevenly administered at the local level and its recipients remain stigmatized.

That which was innovative in the concept of social security was developed first in a report to the British Government entitled 'Social Insurance and Allied Services' in 1942, by a commission chaired by William Beveridge. It is *the program of a comprehensive and unified system, covering the whole population against all basic risks of life*—an idea that Beveridge had already formulated in 1924. The Beveridge report met with unprecedented enthusiasm in the British population and became the blueprint for social legislation after the war.

The Beveridge report proved seminal also for the creation of the *French* 'Sécurité Sociale' (1946/48). But contrary to the case in the United Kingdom, the principle of administrative unification of the system met with strong resistance in France from various social groups which preferred to keep or create separate insurances meeting their specific needs and interests. In *Germany* only the term was received without changing the structure of the existing system. Moreover, a semantic distinction was made between the institutional (*Soziale Sicherung*) and the normative (*Soziale Sicherheit*) aspect of social security. In *Scandinavia* the term 'Social Security' was hardly received although the systems of social protection underwent substantial improvements.

Although many industrialized countries had developed measures of social protection against certain risks *before* World War II, their impact remained generally modest. Some groups, e.g. public servants or veterans, were privileged by public budgets, whereas industrial workers received only modest benefits out of contributions. With the exception of Scandinavia, the rural population remained mostly outside of existing systems. In most countries there existed a multitude of funds respectively designed for specific risks, groups, and localities. Repeated economic crises culminating in the Great Depression often impaired the reliability of expected benefits.

After the Second World War the new ideal of 'Social Security' was received differently in different countries. Almost everywhere coverage provided by existing institutions was extended or new institutions were created to protect all or most of the population against certain risks. Most countries assimilated the regulatory frameworks of different systems which covered the same risks, or integrated the systems. Finally, the risks covered by schemes underwent an international standardization. The Convention No. 102 of the ILO on 'Minimum Standards of Social Security' (1951) distinguishes nine forms of benefit: old-age benefits, survivor benefits, disability benefits, family allowances, unemployment benefits, sickness benefits, medical care, and maternity benefits. To be sure, most advanced industrial countries' social protection institutions do not correspond one-for-one with that list of benefits, but today they indeed do tend to cover all of these risks, albeit with varying degrees of coverage and benefits.

From a *structural perspective* the institutions of Social Security form a delimited, though not everywhere equally defined system. Issues of delimitation concern the forms of benefit (in cash or in kind), of administration (centralized or decentralized; public, parapublic, or private), and of entitlement (public provision, insurance, relief), as well as the groups included (privileged or underprivileged groups are sometimes excluded) and the risks covered (family allowances, for example, are often excluded from the concept).

3. Security and Social Security as Value-concepts

The administrative codification of Social Security as a complex of institutions which provide income replacement or benefits in kind should not obscure the fact that the success of the concept is due less to these institutions than to the value connotations of the concept. President Roosevelt evinced a keen sense of these connotations when he characterized social security as 'freedom from want' (6 January 1941), and when he described social security as a functional equivalent of earlier security deriving from 'the interdependence of members of families upon each other and of the families within a small community upon each other' (8 June 1934).

But what does security mean? And why did the concept become so prominent and pervasive in the most advanced industrial countries whose populations were more remote from serious want than any generations heretofore? Security relates to human attitudes towards the future and not the present. Insecurity does not mean an imminent danger but the possibility of future damages whose probability remains uncertain. The quest for security is a correlate to the growing complexity of society and the ensuing acceleration of social change. Thus security means not only protection, but also a subjective perception of the reliability of protection and the ensuing feeling of peace of mind. But in this psychological sense, security as self-assuredness can also mean the subjective capacity to bear the insecurity of risk. Hence on the individual level the concept of security remains highly ambivalent, and has indeed been abandoned by the discipline of psychology.

Security was also a longstanding pillar of political order which had already been incorporated into many constitutional documents and became transposed by Roosevelt into a new economic and social context. Just as government had the duty to care for external and internal security it was now to provide a framework to guarantee the means of existence for all, through full employment, social insurance, or other forms of benefits or services. 'Social Security' thus became the umbrella word for economic, social, and cultural rights as expressed in Article 22 of the United Nations Universal Declaration of Human Rights: 'Everyone as a member of society, has the right to social security and is entitled to realization through national effort and international co-operation and in accordance with the organization and resources of each state, of the economic, social and cultural rights indispensable for his dignity and the free development of his personality.' These rights are then specified as the right to work (Art. 23), the right to recreation from work (Art. 24), the right to health, well-being, and social protection, with special emphasis on mothers and children (Art. 25), the right to education (Art. 26), and the right to participation in culture, science, and the arts (Art. 27).

Thus Social Security became another name for welfare in its political-philosophical sense. It became a key term in the international evolution of the welfare state after World War II. It was adopted differently on the national level, however. In most countries the institutional aspect has long dominated. In the actual context of 'crisis' or 'reconstruction' of the welfare state 'social security' shows again its normative aspect: to what extent are politics free to dispose about political regulations which aim at stabilizing the future economic protection of the population or defined parts of it? 'Social Security' means the right of everybody who belongs to a certain commonwealth to be included into the basic provisions against destitution and want. And it suggests moreover that such provisions should take a coherent and clearly accessible form for everyone, so that people are not only legally protected but also have easy and reliable access to such protection.

4. Controversial Issues

4.1 General Problems

From the perspective of the Universal Declaration of Human Rights as well as William Beveridge or Pierre Laroque, the 'father of the French *sécurité sociale*,' Social Security was not restricted to publicly organized redistribution within populations at risk but also included policies of full employment and minimum wages. There was a clear awareness of the trade-off between full employment and the possibilities for sufficiently funding social protection. *Social security as the goal of guaranteeing to the entire population the opportunity to participate in the economic and cultural life of its society implies education and employment as primary means and compensatory social protection only as a 'second-best' solution*. The reification of 'Social Security' has obscured this original perspective and focuses public attention on processes of redistribution only. The current trend to substitute 'work for welfare' in the case of the able-bodied is quite in line with the original intention, provided that a decent minimum living standard is attainable at any rate. There is a strong divergence, however, with regard to whether the role of labor markets should be exclusive (as in the Anglo-Saxon world) or whether there should be a subsidiary public role (as in the Scandinavian and German-speaking countries) in employing the less productive parts of the active population.

From the perspective of the 'Chicago School' of economics, the existing systems of Social Security are overly costly, they disguise the relationship between an individual's contributions and benefits, and they benefit the middle classes more than those who are truly in need. A negative income tax would better serve the poor, they maintain. Such a 'rationalist' economic

perspective does not take into account the existing trust in public systems of reciprocal security in most countries. The 'deal' which pools the risks of the whole population in one scheme and thus makes basic economic security a matter of democratic politics seems to find high acceptance in most countries, although many people are aware of the likelihood of being among the net payers to the system.

Given the natural inequality of abilities and the social inequalites resulting from birth, education, labor markets, and competition in general, all political endeavors to foster social security—be it in the wider or in the narrower sense—face the problem of *distributive effects*. These relate not only to the amount of individual benefit and the forms of public financing but to the institutional arrangements as well. Strong political conflicts emerged in many countries around the issue of creating a single comprehensive system for certain provisions or for maintaining a fragmented system differentiating among classes of populations at risk. A somewhat related problem concerns the issue of securing only minimal standards or advanced standards of benefits through public provision. Finally, there is an obvious political struggle in all countries concerning the level of redistribution and who should bear the costs of social protection.

Comparative research has focused mainly on the explanation of national differences in institutional design and distributive effects. Path dependency upon early national approaches seems to be an important explanatory factor for these variations, beside political power relations and cultural orientations. An interesting finding is that systems which provide high levels of protection tend to protect minimal standards better as well.

4.2 Sectoral Aspects

Most political controversies do not arise with regard to the system of Social Security as a whole but concerning particular issues. As the functional organization of social protection is different from country to country, it remains difficult to generalize about this. One may identify some broad issues, however.

The paramount problem in the contemporary debate—particularly as a consequence of demographic aging—is *the security of income in old age*. A three-tiered system consisting of universal and state-administered protection of basic standards (first tier), employment-related (and often private) protection of advanced standards (second tier), and complementary forms of personal provision (third tier) seems to be a promising model to resist the demographic and economic challenges of the decades to come. In order to ensure income security in old age for all, some public regulation and supervision of the second and third tiers remains important, however.

The second complex of risks is related to *illness, industrial diseases, and long-term disability*. Here, benefits in cash and in kind are necessary, and coverage for these risks is organized quite differently in different countries. Essentially, there are two different institutional models: the National Health Service and protection through social insurance. Both systems face the problem of containing the explosion of costs which has resulted from the compounding of a wide range of medical, technological, demographic, and economic factors.

The third complex of Social Security is related to the *protection of the family*. Since child labor has been forbidden and education made compulsory, children are no longer an economic asset for their parents, but rather a strong source of social inequality. It is still contested to what extent parents and especially mothers should be supported by public means, beyond the generally accepted subsidy in cases of manifest poverty. The low birth rate in most European populations now gives more political weight to demands to improve the living conditions and social protection of persons who are raising children or nursing their permanently incapacitated parents.

The most contested part of Social Security is *public provision for the unemployed*. Here, the trade-offs with labor-market policies and full employment are obvious, and convictions vary about how to deal with this problem.

The issue of poverty cuts across such functional distinctions. The extent to which it emerges as a separate problem which must be addressed by specific measures depends to a large extent on the institutional approaches which a country has adopted in the above-mentioned realms of social security.

The issues discussed here are those generally attributed to the concept of social security. The concept of the welfare state covers additional services such as housing, education, and personal services.

Social Simulation: Computational Approaches

Computational social simulation involves the use of computer algorithms to model social processes. These algorithms require greater precision and logical rigor than natural language yet lack the generality of closed-form mathematical equations. The use of computer simulation by social scientists has increased in recent years, due to growing interest in modeling nonlinear dynamical processes using graphical interfaces that allow highly intuitive visual representations of the results. Social simulation has also undergone a qualitative change as the emphasis has shifted from prediction to exploration.

This article reviews three 'waves' of innovation: *dynamical systems, microsimulation, and adaptive agent* models (Gilbert and Troitzsch 1999). These three approaches will be summarized as follows.

(1) 1960s: Dynamical systems simulations were empirically grounded, inductive, holistic, and functionalist.

(2) 1970s: Microsimulation introduced the use of individuals as the units of analysis but retained the earlier emphasis on empirically based macro-level prediction.

(3) 1980s: Adaptive agent models revolutionized computational social science by simulating actors not factors (system attributes). These 'bottom-up' models explored interactions among purposive decision-makers.

Although these three 'waves' overlap (e.g., economists continue to use holistic simulation of productive factors, microsimulation was invented in 1957, and nascent agent-based models appeared in the late 1960s), most of the recent excitement in computational modeling in the social and behavioral sciences has centered on agent-based simulation. So too has much of the controversy.

1. Dynamical Systems

The first wave of computer simulations in social science occurred in the 1960s (see, for example, Cyert and March 1963). These studies used computers to simulate dynamical systems, such as control and feedback processes in organizations, industries, cities, and even global populations. The models typically consist of sets of differential equations that describe changes in system attributes as a function of other systemic changes. Applications included the flow of raw materials in a factory, inventory control in a warehouse, urban traffic, military supply lines, demographic changes in a world system, and ecological limits to growth (Forrester 1971; Meadows et al. 1974).

Models of dynamical systems are functional and holistic (Gilbert and Troitzsch 1999). *Functional* means that theoretical interest centers on system *equilibrium* or balance among interdependent input–output units. *Wholistic* means that the system is modeled as an irreducible and indivisible entity. Although these models allow nested organizational levels, at any given level, they assume that sets of related attributes (such as economic growth, suburban migration, and traffic congestion) are causally linked at the aggregate level.

2. Microsimulation

The second wave of computational modeling in the social sciences developed in the late 1970s. Known as microsimulation, it represents the first step in the progression from factors to actors. In striking contrast to the earlier wholistic approach,

> microsimulation is a 'bottom-up' strategy for modeling the interacting behavior of decision-makers (such as individuals, families, and firms) within a larger system. This modeling strategy utilizes data on representative samples of decision-

> makers, along with equations and algorithms representing behavioral processes, to simulate the evolution through time of each decision-maker, and hence of the entire population of decision-makers. (Caldwell 1997)

For example, Caldwell and Keister use CORSIM, a large-scale dynamic microsimulation model of the US population of individuals and families, to integrate individual and family-level wealth behavior with aggregate-level stratification outcomes. This microanalytic approach allows researchers to avoid a serious limitation in the earlier generation of simulations: population homogeneity. For example, the relationship between wealth and age may not be uniform across ethnic or religious subcultures, geographic regions, or birth cohorts. Complex interactions across subpopulations are lost when the focus is on the correlation among aggregate factors. This precludes the ability to predict the effects of policy changes that impact only certain groups.

Microsimulation solves this problem by making individuals, not populations, the unit of analysis. The database structure consists of individual records for a representative sample of a population, with a set of attributes measured at multiple points in time. These individuals are then 'aged' by updating their attributes, based on a set of empirically derived state-transition probabilities (e.g., an individual's move from work to retirement at age 65). These probabilities are then used to predict new states of each individual, and these are then aggregated to make population projections.

3. *Agent-based Models and Complex Adaptive Systems*

The third wave, agent-based models, attracted widespread interest beginning in the 1980s. These models extend the microanalytical approach by deriving global states from individual *behaviors*, not individual attributes. In microsimulation models, individuals are inert in two ways: (a) the state of an individual is a numerical function of other traits, and (b) individuals do not interact (Gilbert and Troitzsch 1999, p. 8). Agent-based models assume an individual has intentions or goals and makes choices that affect other agents whose choices in turn affect that individual. These models impose three key assumptions.

(a) Agents interact with little or no central authority or direction. Global patterns emerge from the bottom up, determined not by a centralized authority but by local interactions among autonomous decision-makers.

(b) Decision-makers are adaptive rather than optimizing, with decisions based on heuristics, not on calculations of the most efficient action (Holland 1995, p. 43). These heuristics include norms, habits, protocols, rituals, conventions, customs, and routines. They evolve at two levels, the individual and the population. Individual learning alters the probability distribution of rules competing for attention, through processes like reinforcement, Bayesian updating, or the back-propagation of error in artificial neural networks. Population learning alters the frequency distribution of rules competing for reproduction through processes of selection, imitation, and social influence (Latané 1996). Genetic algorithms (Holland 1995) are widely used to model adaptation at the population level.

(c) Decision-makers are strategically interdependent. Strategic interdependence means that the consequences of each agent's decisions depend in part on the choices of others. When strategically interdependent agents are also adaptive, the focal agent's decisions influence the behavior of other agents who in turn influence the focal agent, generating a complex adaptive system (Holland 1995, p. 10).

Thomas Schelling's (1971) 'neighborhood segregation' model was one of the earliest agent-based social simulations using *cellular automata*, a method invented by Von Neumann and Ulam in the 1940s. Consider a residential area that is highly segregated, such that the number of neighbors with different cultural markers (such as ethnicity) is at a minimum. If the aggregate pattern were assumed to reflect the attitudes of the constituent individuals, one might conclude from the distribution that the population was highly parochial and intolerant of diversity. Yet Schelling's simulation shows that this need not be the case. His 'tipping' model shows that highly segregated neighborhoods can form even in a population that prefers diversity. The aggregate pattern of segregation is an emergent property that does not reflect the underlying attitudes of the constituent individuals.

Another example of emergence is provided by Latané's (1996) 'social impact model.' Like Schelling, Latané also studies a cellular world populated by agents who live on a two-dimensional lattice. However, rather than moving, these agents adapt to those around them, based on a rule to mimic one's neighbors. From a random start, a population of mimics might be expected to converge inexorably on a single profile, leading to the conclusion that cultural diversity is imposed by factors that counteract the effects of conformist tendencies. However, the surprising result was that 'the system achieved stable diversity. The minority was able to survive, contrary to the belief that social influence inexorably leads to uniformity' (Latané 1996, p. 294). Other researchers, including Axelrod (1997), Carley (1991), and Kitts et al. (1999) have used computational models that couple homophily (likes attract) and social influence. If local similarity facilitates interaction which in turn facilitates imitation, it is indeed curious that the global outcome is diversity, not uniformity. However, this outcome depends on interactions that are locally transitive, as in a spatially distributed population.

Schelling and Latané modeled agents with identical and fixed behavioral rules. Many agent-based models

assume heterogeneous populations with the ability to learn new rules. The 'genetic algorithm' invented by John Holland is a simple and elegant way to model strategies that can progressively improve performance by building on partial solutions. Each strategy consists of a string of symbols that code behavioral instructions, analogous to a chromosome containing multiple genes. The string's instructions affect the agent's reproductive fitness and hence the probability that the strategy will propagate. Propagation occurs when two or more mated strategies recombine. If different rules are each effective, but in different ways, recombination allows them to create an entirely new strategy that may integrate the best abilities of each 'parent' and thus eventually displace the parent rules in the population of strategies.

Axelrod (1997, pp. 14–29] used a genetic algorithm to study the evolution of cooperation in a 'prisoner's dilemma,' a game in which choices that are individually rational aggregate into collective outcomes that everyone would prefer to avoid. The results showed that strategies based on reciprocity (such as 'tit for tat') tend to be very successful. The secret of their success is that they perform well against copies of themselves. Axelrod's result has been challenged by Nowak and Sigmund (1993), by Binmore (1998), and by Macy (1995). Working independently, these researchers found that 'tit for tat,' a strategy that teaches its partner a lesson, can be supplanted by 'Pavlov' (aka. 'win–stay, lose–shift' and 'tat for tit'), a strategy that learns (Binmore 1998). The ability to learn appears to be at least as important for emergent social order as the ability to teach.

Learning involves adaptation at the level of the individual rather than the population. Artificial neural networks are simple self-programmable devices that model agents who learn through reinforcement. Like genetic algorithms, neural nets have a biological analog, in this case, the nerve systems of living organisms. The device consists of a web of neuron-like units (or neurodes) that fire when triggered by impulses of sufficient strength, and in turn stimulate other units when fired. The magnitude of an impulse depends on the strength of the connection (or synapses) between the two neurodes. The network learns by modifying these path coefficients in response to environmental feedback about its performance. Neural nets have been used to study the evolution of religion (Bainbridge 1995), kin altruism (Parisi et al. 1995), the emergence of status inequality (Vakas-Duong and Reilly 1995), group dynamics (Nowak and Vallacher 1997), and social deviance (Kitts et al. 1999).

4. *Criticisms of Simulation*

Agent-based simulations have been criticized as unrealistic, tautological, and unreliable.

(a) Simulations, like mathematical models, tell us about a highly stylized and abstract world, not about the world in which we live. In particular, agent-based simulations rely on highly simplified models of rule-based human behavior that neglect the complexity of human cognition.

(b) Like mathematical models, simulations cannot tell us anything that we do not already know, given the assumptions built into the model and the inability of a computer to do anything other than execute the instructions given to it by the program.

(c) Unlike mathematical models, simulations are numerical and therefore cannot establish lawful regularities or generalizations.

The defense against these criticisms centers on the principles of complexity and emergence. How can simple agent-based models explain the rich complexity of social life? In complex systems, very simple rules of interaction can produce highly complex global patterns. 'Human beings,' Simon contends (1998, p. 53), 'viewed as behaving systems, are quite simple.' We follow rules, in the form of norms, conventions, protocols, moral and social habits, and heuristics. Although the rules may be quite simple, they can produce global patterns that may not be at all obvious and are very difficult to understand. Hence, 'the apparent complexity of our behavior is largely a reflection of the complexity of the environment,' including the complexity of interactions among strategically interdependent, adaptive agents. The simulation of artificial worlds allow us to explore the complexity of the social environment by removing the cognitive complexity (and idiosyncrasy) of constituent individuals.

4.1 *The Exploration of Artificial Worlds*

If Simon, Axelrod, and the complexity theorists are right, then the artificiality of agent-based models is a virtue, not a vice. When simulation is used to make predictions or for training personnel (e.g., flight simulators), the assumptions need to be highly realistic, which usually means they will also be highly complicated (Axelrod 1997, p. 5). 'But if the goal is to deepen our understanding of some fundamental process,' Axelrod continues, 'then simplicity of the assumptions is important and realistic representation of all the details of a particular setting is not.' As such, the purpose of these models is to generate hypotheses, not to test them (Prietula et al. 1998, p. xv).

Holland (1995, p.146) offers a classic example of the problem of building theories that too closely resemble actuality: Aristotle's mistaken conclusion that all bodies come to rest, based on observation of a world that happens to be infested with friction. Had these observations been made in a frictionless world, Aristotle would have come to the same conclusion

reached by Newton and formulated as the principle that bodies in motion persist in that motion unless perturbed. Newton avoided Aristotle's error by studying what happens in an artificial world in which friction had been assumed away. Ironically, 'Aristotle's model, though closer to everyday observations, clouded studies of the natural world for almost two millennia' (Holland 1995, p. 146). More generally, it is often necessary to step back from our world in order to see it more clearly.

For example, Schelling's 'neighborhood segregation' model made no effort to imitate actuality or to resemble an observed city. Rather, the 'residents' live in a highly abstract cellular world without real streets, rivers, train tracks, zoning laws, red-lining, housing markets, etc. This artificial world shows that all neighborhoods in which residents are able to move have an underlying tendency towards segregation even when residents are moderately tolerant. This hypothesis can then be tested in observed neighborhoods, but even if observations do not confirm the predicted segregation, this does not detract from the value of the simulation in suggesting empirical conditions that were not present in the model that might account for the discrepancy with the observed outcome.

In short, agent-based models 'have a role similar to mathematical theory, shearing away detail and illuminating crucial features in a rigorous context' (Holland 1995, p. 100). Nevertheless, Holland reminds us that we must be careful. Unlike laboratory experiments, computational 'thought experiments' are not constrained by physical actuality and thus 'can be as fanciful as desired or accidentally permitted.'

4.2 *Unwrapping and Emergence*

A second criticism of agent-based modeling addresses a problem known as 'unwrapping.' Unwrapping occurs 'when the 'solution' is explicitly built into the program [such that] the simulation reveals little that is new or unexpected' (Holland 1995, p. 137). Critics charge that all computer simulations share this limitation, due to the inability of computers to act in any way other than how they were programmed to behave.

This criticism overlooks the distinction between the micro-level programming of the agents and the macro-level patterns of interaction that emerge. These patterns are 'built in' from the outset yet the exercise is valuable because the logical implications of behavioral assumptions are not always readily apparent. Indeed, a properly designed computational experiment can yield highly counter-intuitive and surprising results. This theoretical possibility is based on the principle of *emergence* in complex systems. Biological examples of emergence include life that emerges from non-living organic compounds and intelligence and consciousness that emerges from dense networks of very simple switch-like neurons. Schelling's (1971) neighborhood model provides a compelling example from social life: segregation is an emergent property of social interaction that is not reducible to individual intolerance.

4.3 *Rationality and Adaptive Behavior*

A third criticism is that simulation models, unlike mathematical models, are numerical, not deductive, and therefore cannot be used to form generalizations. Worse still, simulations of evolutionary processes can be highly sensitive to the basin of attraction in which the parameters are arbitrarily initialized (Binmore 1998). However, game-theoretic mathematical models pay a high price for the ability to generate deductive conclusions: multiple equilibria that preclude a uniquely rational solution. Equilibrium selection requires constraints on the perfect rationality of the agents. Simon appreciates the paradox: 'Game theory's most valuable contribution has been to show that *rationality* is effectively undefinable when competitive actors have unlimited computational capabilities for outguessing each other, but that problem does not arise as acutely in a world, like the real world, of *bounded rationality*.' (1998, p. 38) But bounded rationality often makes analytical solutions mathematically intractable. 'When the agents use adaptive rather than optimizing strategies, deducing the consequences is often impossible: simulation becomes necessary.' (Axelrod 1997, p. 4) In sum, simulation requires sensitivity analysis and tests of robustness, but properly implemented, it not only offers a solution to the problem of equilibrium selection but can also tell us something about how evolutionary systems move from one equilibrium to another.

5. *Conclusion*

From a narrowly positivist perspective, agent-based artificial worlds might seem unrealistic, unfalsifiable, and unreliable, especially when contrasted with earlier approaches to simulation that were data driven, predictive, and highly realistic (e.g., flight simulators). However, agent-based models may be essential for the study of open and complex adaptive systems, whether social, psychological, or biological. When used as an exploratory tool, 'bottom-up' simulation does not test theory against observation. Rather, these thought experiments suggest possible mechanisms that may generate puzzling empirical patterns.

A key theme that runs through these puzzles is that it is often very difficult to recognize the underlying causal mechanisms using conventional data-analytic methods. As Holland concludes (1995, p. 195), 'I do not think we will understand morphogenesis, or the

emergence of organizations like Adam Smith's pin factory, or the richness of interactions in a tropical forest, without the help of such models.'

Social Stratification

In all complex societies, the total stock of valued goods is distributed unequally, with the most privileged individuals and families enjoying a disproportionate share of income, power, and other valued resources. The term 'stratification system' refers to the complex of social institutions that generate observed inequalities of this sort. The key components of such systems are (a) the institutional processes that define certain types of goods as valuable and desirable; (b) the rules of allocation that distribute these goods across various positions in the division of labor (e.g., doctor, farmer, 'housewife'); and (c) the mobility mechanisms that link individuals to positions and thereby generate unequal control over valued resources. It follows that inequality is produced by two types of matching processes: The social positions in society are first matched to 'reward packages' of unequal value, and members of society are then allocated to the positions so defined and rewarded.

There are of course many types of rewards that come to be attached to social positions (see Table 1). Given this complexity, one might expect stratification scholars to adopt a multidimensional approach, with the objective being to describe and explain the full distribution of goods listed in Table 1. Although some scholars have indeed advocated an approach of this sort, most have instead opted to characterize stratification systems in terms of discrete classes or socioeconomic strata whose members are endowed with similar amounts and types of resources. The goal of stratification research has thus reduced to (a) describing the major forms of class inequality in human history, (b) specifying the structure of contemporary classes and strata, (c) modeling the processes by which individuals move between class and socioeconomic positions, and (d) examining the effects of race, ethnicity, and gender on such mobility processes.

1. Basic Concepts

The foregoing lines of inquiry cannot be adequately reviewed without first defining some of the core

Table 1
Types of assets, resources, and valued goods underlying stratification systems

Asset group	Selected examples	Relevant scholars
1. Economic	Ownership of land, farms, factories, professional practices, businesses, liquid assets, humans (i.e., slaves), labor power (e.g., serfs)	Karl Marx; Erik Wright
2. Political	Household authority (e.g., head of household); workplace authority (e.g., manager); party and societal authority (e.g., legislator); charismatic leader	Max Weber; Ralf Dahrendorf
3. Cultural	High-status consumption practices; 'good manners'; privileged life-style	Pierre Bourdieu; Paul DiMaggio
4. Social	Access to high-status social networks, social ties, associations and clubs, union memberships	W. Lloyd Warner; James Coleman
5. Honorific	Prestige; 'good reputation'; fame; deference and derogation; ethnic and religious purity	Edward Shils; Donald Treiman
6. Civil	Rights of property, contract, franchise, and membership in elective assemblies; freedom of association and speech	T. M. Marshall; Rogers Brubaker
7. Human	Skills; expertise; on-the-job training; experience; formal education; knowledge	Kaare Svalastoga; Gary Becker

concepts in the field. The following definitions are especially relevant for our purposes:

(a) The degree of *inequality* in a given reward or asset depends, of course, on its dispersion or concentration across the population. If some types of assets (e.g., civil rights) are distributed more equally than others (e.g., political power), then the level of inequality obviously cannot be adequately characterized with a single parameter.

(b) The *rigidity* of a stratification system is indexed by the continuity (over time) in the social standing of its members. The stratification system is said to be highly rigid, for example, if the current income, power, or prestige of individuals can be accurately predicted on the basis of their prior statuses or those of their parents.

(c) The stratification system rests on *ascriptive processes* to the extent that traits present at birth (e.g., sex, race, ethnicity, parental wealth) influence the subsequent social standing of individuals. In modern societies, ascription of all kinds is usually seen as undesirable or discriminatory, and much governmental policy is therefore directed toward fashioning a stratification system in which individuals acquire resources solely by virtue of their achievements.

(d) The degree of *status crystallization* is indexed by the correlations among the assets in Table 1. If these correlations are strong, then the same individuals (i.e., the 'upper class') will consistently appear at the top of all status hierarchies, while other individuals (i.e., the 'lower class') will consistently appear at the bottom of the stratification system.

These four variables can be used to characterize differences across societies in the underlying structure of stratification (see Table 2). As the following discussion shall reveal, there is much cross-societal variability not merely in the extent of inequality, but also in the underlying shape of the class structure and the processes by which classes are reproduced.

2. *Forms of Stratification*

It is useful to begin with the purely descriptive task of classifying the various types of stratification systems that have appeared in past and present societies. The first panel of Table 2 pertains to the 'primitive' tribal systems that dominated human society from the very beginning of human evolution until the Neolithic revolution of some 10,000 years ago. Although tribal societies have of course assumed various forms, the total size of the distributable surplus was in all cases quite limited; and this cap on the surplus placed corresponding limits on the overall level of economic inequality. Indeed, some observers have treated tribal societies as examples of 'primitive communism,' since the means of production (e.g., tools) were owned collectively and other types of property were typically distributed evenly among tribal members. Moreover, insofar as positions of power emerged (e.g., shamans), these were never inherited but instead were secured by demonstrating superior skills in the relevant tasks. While meritocratic criteria are often seen as prototypically modern, they were in fact present in incipient form at quite early stages of societal development, no doubt because the surplus was too small to permit the luxury of less adaptive forms of allocation.

With the emergence of agrarian forms of production, the economic surplus became large enough to support more complex and less meritocratic systems of stratification. The 'Asiatic mode,' which some commentators regard as a precursor of advanced agrarianism, is characterized by a poorly developed proprietary

Table 2
Basic parameters of stratification for eight ideal-typical systems

System center (1)	Principal assets (2)	Major strata or classes (3)	Inequality (4)	Rigidity (5)	Crystallization (6)	Justifying ideology (7)
A. Hunting and gathering society						
1. Tribalism	Human (hunting and magic skills)	Chiefs, shamans, and other tribe members	Low	Low	High	Meritocratic selection
B. Horticultural and agrarian society						
2. Asiatic mode	Political (i.e., incumbency of state office)	Office-holders and peasants	High	Medium	High	Tradition and religious doctrine
3. Feudalism	Economic (land and labor power)	Nobility, clergy, and commoners	High	Medium–high	High	Tradition and Roman Catholic doctrine
4. Slavery	Economic (human property)	Slave owners, slaves, 'free men'	High	Medium–high	High	Doctrine of natural and social inferiority (of slaves)
5. Caste society	Honorific and cultural (ethnic purity and 'pure' lifestyles)	Castes and subcastes	High	High	High	Tradition and Hindu religious doctrine
C. Industrial society						
6. Class system	Economic (means of production)	Capitalists and workers	Medium–high	Medium	High	Classical liberalism
7. State socialism	Political (party and workplace authority)	Managers and managed	Low–medium	Low–medium	High	Marxism and Leninism
8. 'Advanced' industrialism	Human (i.e., education, expertise)	Skill-based occupational groupings	Medium	Low–medium	Medium	Classical liberalism

class and a powerful state elite that extracted surplus agricultural production through rents and taxes (see line B2 in Table 2). This mode provides the conventional example of how a 'dictatorship of officialdom' can flourish in the absence of institutionalized private property. Whereas political assets were thus dominant in the Asiatic mode, the ruling class under Western feudalism was, by contrast, very much a propertied one. The distinctive feature of feudalism was that the nobility not only owned large estates or manors but also held legal title to the labor power of its serfs (see line B3). If a serf fled to the city, this was considered a form of theft: The serf was stealing that portion of his or her labor power owned by the lord. With this interpretation, the statuses of serf and slave differ only in degree, and slavery thereby constitutes a limiting case in which workers lose all control over their own labor power (see line B4; also see *Slavery as Social Institution*).

The historical record makes it clear that agrarian stratification systems were not always based on strictly hereditary forms of social closure. To be sure, the era of classical feudalism (i.e., post-twelfth century) was characterized by a rigid stratification of classes, but there was far greater permeability during the period prior to the institutionalization of the manorial system and the associated transformation of the nobility into a legal class. The most extreme example of agrarian closure can of course be found in caste societies (see line B5). The Indian caste system, for example, is based on (a) a hierarchy of status groupings (i.e., castes) that are ranked by ethnic purity, wealth, and access to goods or services; (b) a corresponding set of 'closure rules' that restrict all forms of intercaste marriage or mobility and thereby make caste membership both hereditary and permanent; (c) a high degree of physical and occupational segregation enforced by elaborate rules and rituals governing intercaste contact; and (d) a justifying ideology (i.e., Hinduism) that induces the population to regard such extreme forms of inequality as legitimate and appropriate. What makes this system so distinctive, then, is not merely its well-developed closure rules but also the fundamentally honorific (and noneconomic) character of the underlying social hierarchy.

The defining feature of the industrial era (see panel C) has been the emergence of egalitarian ideologies and the consequent 'delegitimation' of the extreme forms of stratification found in caste, feudal, and slave systems. This can be seen, for example, in the European revolutions of the eighteenth and nineteenth centuries that pitted the egalitarian ideals of the Enlightenment against the privileges of rank and the political power of the nobility. In the end, these struggles eliminated the last residue of feudal privilege, but they also made new types of inequality and stratification possible. Under the class system that ultimately emerged (see line C6), the estates of the feudal era were replaced by purely economic groups (i.e., 'classes'), and closure rules based on heredity were likewise supplanted by (formally) meritocratic processes. The resulting classes were neither legal entities nor closed status groupings, and the associated class-based inequalities could therefore be represented and justified as the natural outcome of competition among individuals with differing abilities, motivation, or moral character (i.e., 'classical liberalism'). As indicated in line C6, the class structure of early industrialism had a clear economic base, so much so that Marx ([1894] 1972) defined classes in terms of their relationship to the means of economic production. The precise contours of the industrial class structure are nonetheless a matter of continuing debate (see below); for example, a simple Marxian model focuses on the cleavage between capitalists and workers, while more elaborate Marxian and neo-Marxian models identify additional intervening or 'contradictory' classes (e.g., Wright 1997), and yet other (non-Marxian) approaches represent the class structure as a continuous gradation of income, prestige, or socioeconomic status.

Whatever the relative merits of these models might be, the ideology underlying the socialist revolutions of the nineteenth and twentieth centuries was of course explicitly Marxist (see line C7). The intellectual heritage of these revolutions and their legitimating ideologies can again be traced to the Enlightenment, but the rhetoric of equality that emerged in this period was now directed against the economic power of the capitalist class rather than the status and honorific privileges of the nobility. The evidence from Eastern Europe and elsewhere suggests that these egalitarian ideals were only partially realized. In the immediate postrevolutionary period, factories and farms were indeed collectivized or socialized, and various fiscal and economic reforms were instituted for the express purpose of reducing income inequality and wage differentials among manual and nonmanual workers. Although these egalitarian policies were subsequently weakened through the reform efforts of Stalin and others, inequality on the scale of pre-revolutionary society was never re-established among rank-and-file workers (see Lenski 2001). There nonetheless remained substantial inequalities in power and authority; most notably, the socialization of production did not have the intended effect of empowering workers, as the capitalist class was replaced by a 'new class' of party officials and managers who continued to control the means of production and to allocate the resulting social surplus. This class has been variously identified with intellectuals or intelligentsia, bureaucrats or managers, and party officials or appointees (see Gouldner 1979). Regardless of the formulation adopted, the presumption is that the working class ultimately lost out in contemporary socialist revolutions, just as it did in the so-called bourgeois revolutions of the eighteenth and nineteenth centuries (e.g., see *Postsocialist Societies*).

Whereas the means of production were socialized in the revolutions of Eastern Europe and the former USSR, the capitalist class remained intact throughout the process of industrialization in the West, even as ownership and control separated and a distinct managerial class emerged (see Dahrendorf 1959). The capitalist class may nonetheless be weakened by the structural changes of postindustrialism, with the most important of these being the rise of a service economy and the consequent emergence of technical expertise, educational degrees, and training certificates as new forms of property (see line C8). By this formulation, a dominant class of cultural elites may be emerging in the West, much as the transition to state socialism (allegedly) generated a new class of intellectuals in the East. This is not to suggest that all theorists of advanced industrialism posit a grand divide between the cultural elite and an undifferentiated working mass. In fact, some commentators (e.g., Dahrendorf 1959) have argued that skill-based cleavages are crystallizing throughout the occupational structure, with the result being a finely differentiated class system made up of discrete occupations (Grusky and Sørensen 1998) or a continuous gradation of socioeconomic status (e.g., Hauser and Warren 1997).

3. *The Structure of Contemporary Stratification*

The history of stratification theory is in large part a history of such debates about the emerging structure of contemporary inequality. Moreso than usual, political and intellectual goals are conflated in this literature and, accordingly, the relevant research is infused with much scholarly contention. These debates are complex and wide-ranging, but it will suffice to review four approaches that have proven to be especially popular.

3.1 *Reductionism*

Among contemporary interpreters of inequality, the prevailing approach has long been to claim that only one of the 'asset groups' in Table 1 is truly fundamental, whereas all others are somehow epiphenomenal. There are nearly as many claims of this sort as there are dimensions in Table 1. To be sure, Marx is most commonly criticized (with some justification) for placing 'almost exclusive emphasis on economic factors as determinants of social class' (Lipset 1968, p. 300), but in fact much of what passes for stratification theorizing amounts to reductionism of one form or another. Among non-Marxist scholars, inequalities in honor or power are frequently regarded as the most fundamental sources of class formation, while the distribution of economic assets is seen as purely secondary. For example, Dahrendorf (1959) argues that 'differential authority in associations is the ultimate 'cause' of the formation of conflict groups' (p. 172), while Shils (1968) suggests that 'without the intervention of considerations of deference position the ... inequalities in the distribution of any particular facility or reward would not be grouped into a relatively small number of vaguely bounded strata' (p. 130). These extreme forms of reductionism have been less popular of late; indeed, even neo-Marxian scholars now typically recognize several stratification dimensions, with the social classes of interest then being defined as particular combinations of scores on the selected variables (e.g., Wright 1997).

3.2 *Synthesizing Approaches*

There is an equally long tradition of research based on synthetic measures that simultaneously tap a wide range of assets and resources. As noted above, many of the rewards in Table 1 (e.g., income, honor) are principally allocated through the jobs or social roles that individuals occupy, and one can therefore measure the standing of individuals by classifying them in terms of their social positions. In this context, Parkin (1971) has referred to the occupational structure as the 'backbone of the entire reward system of modern Western society' (p. 18), while Hauser and Featherman (1977) argue that studies 'framed in terms of occupational mobility … yield information simultaneously (albeit, indirectly) on status power, economic power, and political power' (p. 4). The most recent representatives of this position, Grusky and Sørensen (1998), have argued that detailed occupations are not only the main conduits through which valued goods are disbursed but are also deeply institutionalized categories that are salient to workers, constitute meaningful social communities and reference groups, and serve as fundamental units of collective action. Although occupations continue, then, to be the preferred classificatory tool within this tradition, other scholars have pursued the same synthesizing objective by simply asking community members to locate their peers in a hierarchy of social strata (e.g., Warner et al. 1949). Under the latter approach, a synthetic classification is no longer secured by ranking and sorting occupations in terms of the bundles of rewards attached to them, but rather by passing the raw data of inequality through the fulcrum of individual judgment.

3.3 *Aggregation Exercises*

Regardless of whether a reductionist or synthesizing approach is taken, most scholars adopt the final simplifying step of defining a relatively small number of discrete classes (e.g., see *Class: Social*). For example, Parkin (1971) argues for six occupational classes with the principal 'cleavage falling between the manual and non-manual categories' (p. 25), whereas

Dahrendorf (1959) argues for a two-class solution with a 'clear line drawn between those who participate in the exercise [of authority] ... and those who are subject to the authoritative commands of others' (p. 170). While close variants of the Parkin scheme continue to be used, the emerging convention among quantitative stratification scholars is to apply either the 12-category neo-Marxian scheme fashioned by Wright (1997) or the 11-category neo-Weberian scheme devised by Erikson and Goldthorpe (1994). At the same time, new classification schemes continue to be regularly proposed, with the impetus for such efforts typically being the continuing expansion of the service sector and the associated growth of contingent work relations (e.g., Esping-Andersen 1999). The question that necessarily arises for all contemporary schemes is whether the constituent categories are purely nominal entities or are truly meaningful to the individuals involved. If the categories are intended to be meaningful, one would expect class members not only to be aware of their membership (i.e., 'class awareness') but also to identify with their class (i.e., 'class identification') and occasionally act in its behalf (i.e., 'class action').

3.4 Gradationalism

The prior approaches involve mapping individuals or families into mutually exclusive and exhaustive categories. By contrast, the implicit claim underlying gradational approaches is that such 'classes' are largely the construction of overzealous sociologists, and that the underlying structure of modern stratification can, in fact, be more closely approximated with gradational measures of income, status, or prestige. Although there is some sociological precedent for treating income as a gradational indicator of class, most sociologists opt for either prestige scales based on popular evaluations of occupational standing or socioeconomic scales constructed as weighted averages of occupational income and education. In recent years, such gradationalism has been subjected to criticism on various fronts, with the main objections being that (a) the fluidity and openness of the stratification system is overstated by conventional prestige and socioeconomic scales (Hauser and Warren 1997); (b) the desirability of jobs is best indexed by directly measuring such job-level attributes as earnings, promotion opportunities, complexity, or autonomy (Jencks et al. 1988); and (c) the convention of converting discrete occupations into scales strips away precisely those *gemeinschaftlich* features of discrete occupations that make them analytically so powerful (Grusky and Sørensen 1998). There is of course no guarantee that any of these criticisms will take hold; indeed, because socioeconomic scales have dominated sociological research since the 1960s, inertial forces are quite strong and will not be easily overcome.

4. Generating Stratification

The foregoing debates may be seen, then, as disputes over which data reduction techniques best reveal the fundamental features of the distribution of rewards. If one or more of these simplifying assumptions is applied and a mapping of inequality is thereby developed, it becomes possible to examine the flow of individuals between the various categories of this mapping. The language of stratification theory thus makes a sharp distinction between the distribution of social rewards and the distribution of opportunities for securing these rewards. The latter distribution has come to determine popular judgments about the legitimacy of stratification; that is, substantial inequalities in power, wealth, or honor are typically seen as tolerable (and even desirable) provided that the opportunities for securing these social goods are distributed equally. Whatever the wisdom of this popular logic might be, stratification researchers have long sought to explore its factual underpinnings by monitoring and describing the structure of mobility chances. The relevant literature is vast, but of course broad classes of inquiry can be distinguished, as indicated below.

4.1 Mobility Analyses

The conventional starting point for mobility scholars has been to analyze bivariate 'mobility tables' formed by cross-classifying the class origins and destinations of individuals (e.g., see *Social Mobility, History of*). The tables constructed can be used to estimate densities of inheritance, to map the social distances between classes and their constituent occupations, and to examine differences across subpopulations in the amount and patterning of fluidity and opportunity. Moreover, when comparable mobility tables are assembled from several countries, it becomes possible to address fundamental debates about the underlying contours of cross-national variation in stratification systems (e.g., Erikson and Goldthorpe 1994). This long-standing line of analysis, while still underway, has nonetheless declined of late, perhaps because past research has been so definitive as to undercut further efforts. The focus has thus shifted to studies of income mobility, with the twofold impetus for this development being (a) concerns that poverty may be increasingly difficult to escape and that a permanent underclass may be forming, and (b) the obverse hypothesis that growing income inequality may be counterbalanced by increases in the rate of mobility between income groups.

4.2 The Process of Stratification

It is by now a sociological truism that Blau and Duncan (1967) and their colleagues (e.g., Sewell et al.

1969) revolutionized the field with their formal 'path models' of stratification. These models were intended to represent, if only partially, the processes by which background advantages could be converted into socioeconomic status through the mediating variables of schooling, aspirations, and parental encouragement. Under formulations of this kind, the main sociological objective was to show that socioeconomic outcomes were structured not only by ability and family origins, but also by various intervening variables (e.g., schooling) that were themselves only partly determined by origins and other ascriptive forces. The picture of modern stratification that emerged suggested that market outcomes depend in large part on unmeasured career contingencies (i.e., 'individual luck') rather than influences of a more structural sort (Jencks et al. 1972). This line of research, which fell out of favor by the mid-1980s, has been recently reinvigorated as stratification scholars react to the controversial claim (i.e., Herrnstein and Murray 1994) that inherited intelligence is increasingly determinative of stratification outcomes (e.g., Fischer et al. 1996). In a related development, contemporary scholars have also turned their attention to the effects of family structure on attainment, given that new nontraditional family arrangements (e.g., female-headed households) may in some cases reduce the influence of biological parents and otherwise complicate the reproduction of class.

4.3 *Structural Analyses*

The preceding models are frequently criticized for failing to attend to the social structural constraints that operate on the stratification process independently of individual-level traits. The structuralist accounts that ultimately emerged from these critiques initially amounted, in most cases, to refurbished versions of dual economy and market segmentation models that were introduced and popularized many decades ago by institutional economists. When these models were redeployed by sociologists in the early 1980s, the usual objective was to demonstrate that women and minorities were disadvantaged not merely by virtue of deficient human capital investments (e.g., inadequate schooling and experience), but also by their consignment to secondary labor markets that, on average, paid out lower wages and offered fewer opportunities for promotion or advancement. At the same time, more deeply sociological forms of structuralism have also appeared, both in the form of (a) mesolevel accounts of the effects of social networks and 'social capital' on attainment, and (b) macrolevel accounts of the effects of institutional context (e.g., welfare regimes) on mobility processes and outcomes.

The history of these research traditions is arguably marked more by statistical and methodological signposts than substantive ones. Although there is, then, no grand theory that unifies seemingly disparate models, the field has long relied on middle-range theorizing addressing such issues as the forces making for discrimination, the processes through which class-based advantage is reproduced, and the effects of industrialism, capitalism, and socialism on mobility and attainment. The main contenders, at present, for a 'grand theory' of mobility are various forms of rational action analysis that allow middle-range accounts to be recast in terms of individual-level incentives and purposive behavior (e.g., see *Rational Choice Theory in Sociology*). Indeed, just as the assumption of utility maximization underlies labor economics, so too a theory of purposive behavior might ultimately organize much, albeit not all, sociological theory on social mobility and attainment.

5. *Ascriptive Solidarities*

To this point, the discussion has focused on class and socioeconomic inequalities, while considerations of race, ethnicity, and gender have been brought in only indirectly. This omission reflects, however improperly, the historical development of the field; that is, status groups were once regarded as secondary forms of affiliation, whereas class-based ties were seen as more fundamental and decisive determinants of social and political action. The first step in the intellectual breakdown of this approach was the fashioning of multidimensional models of stratification (e.g., Lipset and Bendix 1959) that moved beyond a strict class analytic emphasis on economic inequalities. The early multidimensionalists thus emphasized that social behavior could only be understood by taking into account all status group memberships and the complex ways in which these interacted with one another. There was much concern, in particular, that 'inconsistent' statuses (e.g., upper class and African American) might generate personal stress that would ultimately be resolved through extremist political action.

Although this old variant of multidimensionalism has fallen out of fashion, new variants have been pursued on two intellectual fronts, neither of which similarly emphasize the stressfulness of multiple or inconsistent statuses. In the postmodernist variant, the essentialism of conventional class analytic theorizing is again rejected forcefully, with the claim being that class affiliations are by no means fundamental and that various nonclass statuses are more salient in many situations. Under some postmodern formulations, even the categories of race, ethnicity, and gender have no privileged position, and instead the presumption is that individuals are simply a congeries of manifold, situationally invoked statuses. As the British sociologist Saunders (1989) puts it, 'On holiday in Spain we feel British, waiting for a child outside the school gates we are parents, shopping in Marks and Spencer we are consumers, and answering questions, framed

by sociologists with class on the brain, we are working class' (pp. 4–5).

This approach, which has not yet informed much empirical research, might be usefully contrasted to the 'intersectionist' accounts of Collins (1990), where the categories of race, class, and gender are seen as master statuses that form a new holy trinity of stratification analysis. The theoretical framework motivating this approach is not well-developed, but the implicit claim seems to be that the most fundamental subcultures in the modern context are defined by the *intersection* of race, class, and gender categories (e.g., black working-class women, white middle-class men). The social spaces defined by particular combinations of these statuses thus shape the experiences, lifestyles, and life chances of individuals and define the settings in which interests typically emerge. The obvious effect of this approach is to invert the traditional post-Weberian perspective on status groupings; that is, whereas orthodox multidimensionalists described the stress experienced by individuals in inconsistent statuses, these new multidimensionalists emphasize the shared interests and cultures generated within commonly encountered status sets.

Among stratification scholars, the attention paid to issues of race, ethnicity, and gender has thus burgeoned of late, and entirely new literatures within these subfields have of course emerged (e.g., see *Feminist Political Theory and Political Science*, *Ethnic Conflicts*, *Racial Relations*). In organizing these literatures, one might usefully distinguish between (a) macro-level research addressing the structure of ascriptive solidarities and their relationship to class formation, and (b) attainment research exploring the effects of race, ethnicity, and gender on individual life chances. At the macrolevel, scholars examine such issues as the social processes by which ascriptive categories (e.g., 'white,' 'black') are constructed, the sources and causes of ethnic conflict and solidarity, and the relationship between patriarchy, racism, and class-based forms of organization. The microlevel research tradition emphasizes, by contrast, such topics as the size and causes of the gender gap in income, the sources of occupational sex segregation, and the effectiveness of various social interventions (e.g., affirmative action, comparable worth initiatives) in reducing ascriptive inequalities.

6. *The Future of Stratification*

It is instructive to conclude by contrasting structural and cultural accounts of stratificatory change. Although there are many variants of structuralism, a common starting point is the claim that human and political capital are replacing economic capital as the principal stratifying forces in advanced industrial society. In the most extreme versions of this claim, the old class of moneyed capital is represented as a dying force, and a new class of intellectuals, managers, or party bureaucrats is assumed to be on the road to power (e.g., Gouldner 1979). There is of course much criticism of 'new class' interpretations of this sort. The (orthodox) Marxist stance is that 'news of the demise of the capitalist class is ... somewhat premature' (Zeitlin 1982, p. 216), whereas the contrasting position taken by Bell (1973) is that neither the old capitalist class nor the so-called new class will have unfettered power in the postindustrial future. To be sure, there is widespread agreement among postindustrial theorists that human capital is becoming a dominant form of property, yet this need not imply that 'the amorphous bloc designated as the knowledge stratum has sufficient community of interest to form a class' (Bell 1987, p. 464).

As is well-known, Bell (1973) also argues that human capital (e.g., education) will become the main determinant of life chances, if only because the expansion of the professional and technical sectors serves to upgrade job skills and thus requires a well-trained workforce. Although the returns to education are indeed increasing as predicted, the occupational structure is not upgrading quite as straightforwardly as Bell (1973) suggested; and various 'pessimistic versions' of postindustrialism have accordingly emerged. In the US variant of such pessimism, the main concern is that postindustrialism leads to a 'declining middle' and consequent polarization, as manufacturing jobs are either rendered technologically obsolete or exported to less developed countries where labor costs are lower. These losses may be compensated by the predicted growth in the service sector, yet the types of service jobs that have emerged are quite often low skill, routinized, and accordingly less desirable than Bell imagined. In Europe, the same low-skill service jobs are less commonly found, with the resulting occupational structure more closely approximating the highly professionalized world that Bell envisaged. The European pessimists are nonetheless troubled by the rise of mass unemployment and the associated emergence of 'outsider classes' that bear disproportionately the burden of unemployment. In both the European and US cases, the less-skilled classes are therefore losing out in the market, either by virtue of unemployment and exclusion (i.e., Europe) or low pay and poor prospects for advancement (i.e., the US). The new pessimists thus anticipate a 'resurgent proletarian underclass and, in its wake, a menacing set of new class correlates' (Esping-Andersen 1999, p. 95).

The driving force behind these accounts is, of course, structural change of the sort conventionally described by such terms as industrialism, post-industrialism, and post-Fordism. By contrast, cultural accounts of change tend to de-emphasize these forces or to cast them as epiphenomenal, with the focus thus shifting to the independent role of ideologies, social

movements, and cultural practices in changing stratification forms. This approach underlies, for example, all forms of postmodernism that seek to represent 'new social movements' (e.g., feminism, ethnic and peace movements, environmentalism) as the vanguard force behind future stratificatory change. As argued by Beck (1999), the labor movement can be seen as a fading enterprise rooted in the old conflicts of the workplace and industrial capitalism, whereas new social movements provide a more appealing call for collective action by virtue of their emphasis on issues of lifestyle, personal identity, and normative change. Under this formulation, the proletariat is stripped of its privileged status as a universal class, and cultural movements emerge as an alternative force 'shaping the future of modern societies' (Haferkamp and Smelser 1992, p. 17). Although no self-respecting postmodernist will offer up a fresh 'grand narrative' to replace that of discredited Marxism, new social movements are nonetheless represented within this subtradition as a potential source of change, albeit one that plays out in fundamentally unpredictable ways.

The final, and more prosaic, question that might be posed is whether changes of the preceding sort presage a general decline in the field of stratification itself. It could well be argued that Marxian and neo-Marxian models of class will decline in popularity with the rise of postmodern stratification systems and the associated uncoupling of class from lifestyles, consumption patterns, and political behavior. This line of reasoning is not without merit, but it is worth noting that (a) past predictions of this sort have generated protracted debates that, if anything, have re-energized the field; (b) the massive facts of economic, political, and honorific inequality will still be with us even if narrowly conceived models of class ultimately lose out in such debates; and (c) the continuing diffusion of egalitarian values suggests that all departures from equality, no matter how small, will be the object of considerable interest among sociologists and the lay public alike. The latter sensitivity to all things unequal bodes well for the future of the field even in the (unlikely) event of a long-term secular movement toward diminishing inequality.

Social Support and Health

The concept of social support as an important factor in health and illness is not new. 'Friendship is a basic human need along with food, shelter, and clothing. We naturally desire to love other human beings and to be loved by them. A totally loveless life—a life without friends of any sort—is a life deprived of much needed good.' These thoughts were expressed by Aristotle, 350 years BC (Alcalay 1983). During and toward the end of the Middle Ages the concept was even addressed as a possible remedy for illness. In 1599 Paracelsus, a pharmacist and natural scientist, actually prescribed 'love as the best possible cure for several diseases.' That love and affection 'influence life and death in both animals and humans' was further observed by a Russian ethologist (Kropotkin 1908).

In this article some of the empirical evidence that 'love and affection influence life and death' will be reviewed. The distinctions between social networks and social support are explained; the definition, concepts, and functions of social support are further described; and their impact on health and disease are demonstrated and discussed. With a focus on coronary heart disease (CHD), the most common cause of death among men and women in the developed world, the hazards of lack of social support are disentangled, and differences and similarities in men and women are discussed. Finally, implications for therapeutic interventions are considered.

Systematic and conclusive empirical studies of social support and health, however, did not begin until the 1970s, when this field emerged as a new area of research, making a bold link between people's social ties and social networks on the one hand and population morbidity and mortality on the other. In the pioneering work by Berkman and Syme on residents of Alameda County, California, modern epidemiological tools were applied to demonstrate what had long been sensed to be true: social ties are protective against ill health.

Soon a number of population-based studies mainly from the USA and Scandinavia confirmed the findings of Berkman and Syme. These findings were systematically interpreted and discussed by House et al. (1988) who concluded that the impact of lack of social ties was similar to that of smoking. With such emphasis and visibility of the concept, a new research field was established.

A general definition of social support was agreed upon, which was broad enough to incorporate most of the research traditions in the field: 'Social support is the resource provided by other persons. By viewing social support in terms of resources—potentially useful information or things—we allow for the possibility that support may have negative as well as positive effects on health and well-being' (Cohen and Syme 1985).

Soon, however, researchers began to ask why and how social ties might influence mortality and morbidity; in particular investigators were focusing on the function and contents of social ties and their assessment (Cohen and Syme 1985). On the one hand, large epidemiological studies of populations typically would find that mortality increased with a decreasing number and frequency of social contacts. On the other hand, the more sophisticated measures of social context, social anchorage, social environment, and social support were limited to specific indicators of disease such as blood pressure in smaller selected groups of persons or patients. Thus two types of research traditions developed within this area—social network epidemiology (see *Social Integration, Social Networks, and Health*) and social support psychology. Attempts to unite these traditions have not always been successful. Where the first type of research mostly examined all causes of mortality or general well-being as end-points, the latter has looked more closely at specific disease end-points, such as cardiovascular disease. The latter has become a model for research on social support and disease, and will be the focus here, because heart diseases are common, develop gradually, and are found in all populations.

Coronary heart disease (CHD) is the most common of cardiovascular diseases and the most common cause of death in highly developed and industrialized countries, and it is rapidly increasing in developing nations of the third world. In many countries it is also the most common cause of hospitalizations and an important factor in work absenteeism. The clinical manifestations of CHD are dependent on the extent of underlying atherosclerotic changes of the coronary arteries. With more advanced atherosclerosis, the risk of an acute myocardial infarction (AMI) or sudden cardiac death (SCD) is increased. The occurrence of both atherosclerosis and clinical manifestations of CHD increases with increasing age, in men as in women.

Below the age of 65, clinical manifestations of CHD, including myocardial infarction and sudden death are rare in women. In particular before menopause at age 50, women seem to be protected. Women are also relatively spared in the following decade, between 50

and 60 years of age. By the age of 60, sex differences are beginning to vanish. This may be one of the reasons why research on CHD has been so remarkably focused on men in their middle ages, under age 65. Most research on coronary risk factors and factors that are protective of CHD has been carried out on middle-aged men. Therefore knowledge about heart disease in women is less evidence-based than that of men. This is particularly true as concerns the psychosocial influences on heart disease and its risk factors.

1. *The Social Environment and the Heart*

Lifestyle and daily habits—the way we live in the broadest sense—strongly influence the atherosclerotic process. If we smoke, lead a sedentary life, eat too much fat and too little fiber, the risk of premature atherosclerosis and early heart disease is increased. It is also well known that many social environments may enhance or prevent the improvement of lifestyle and behavioral risk factors. Therefore, psychosocial influences, including the concepts of stress and social support should be recognized as relevant, both in cardiology and in general health care.

Support from social networks may help the individual to deal with stress in many ways. Network members may provide help to recognize and evaluate stressors in the environment, and they may also be helpful in identifying solutions to overcome the stressor (information/appraisal support). This means that they may provide tools to improve problem-oriented coping, and thereby enhance stress reduction. Network members may also provide emotional support that may counteract the individual's feeling of loneliness and hopelessness, and thus help him or her to deal more efficiently with problems. Supportive actions may also relieve stress by reducing tension and anxiety, and counteracting depressive reactions (emotional support). Furthermore, supportive actions may also be helpful as they provide practical help (tangible support). Therefore, the empirical evidence of social support effects may be found at various stages of the pathogenic processes leading to heart disease. An epidemiological as well as a behavioral and psychophysiological view of the relationship is scientifically sound (see *Social Support and Stress*).

2. *Social Support and Cardiovascular Health in Men*

Large epidemiologic studies of social support and social networks have mainly focused on mortality as an endpoint. Scarce networks and few contacts are generally found to increase mortality risk. The incidence of acute cardiac events such as myocardial infarction or sudden cardiac death, however, has rarely been investigated in relation to social support. Furthermore, the most commonly studied aspect of social support is marital status. In men, marriage or cohabiting seems to improve cardiovascular health and to decrease mortality (Case et al. 1992). In women, as we shall see below, the picture is more complex.

Several large-scale epidemiological studies have been conducted in Sweden and Scandinavia. Scandinavian countries have a relatively homogenous, easily assessed population, living under good material conditions, where poverty, in its concrete sense, is rare. This does not mean that loneliness and lack of social support are irrelevant. In contrast, where the basic physical needs are met and a decent standard of living provided by public or governmental services, social ties and relations with other people tend to become diminished. In addition, the cold and dark climate, characteristic of these countries, does not promote social interaction, but rather may prevent naturally occurring social encounters.

In one of the early population-based studies of risk factors for CHD, the study of 50-year-old men born in Gothenburg (men born in 1913, in 1923, and in 1933), the impact of poor social networks and lack of social support was first assessed. Scarce social ties and social isolation increased both total and cardiovascular mortality (Welin et al. 1985). In further studies of men born in 1914 in the city of Malmö in south Sweden this observation was confirmed. The provision of satisfactory social ties and adequate social and psychological anchorage was essential to good health and longevity in men (Hanson 1989).

In a subsequent assessment of the Gothenburg study group, a random sample of 776 men, who were found healthy on initial examination, were followed for incidence of AMI and death from CHD. Lack of social support, as measured by the Interview Schedule for Social Interaction (ISSI), an instrument which was modified for population based studies in our laboratory, was found to be an independent predictor of AMI and death from CHD, including sudden cardiac death. This instrument is also described in Rosengren et al. (1993). These effects were maintained even after controlling for the effects of standard cardiovascular risk factors (hypertension, hyperlipidemia, smoking, diabetes, lack of exercise, etc.). The effect of lack of support was comparable in magnitude to that of smoking (Rosengren et al. 1993).

All other risk factors, including elevated cholesterol, or fibrinogen levels, hypertension or obesity were less strong predictors. When smokers and non-smokers were analyzed separately, risk gradients between men with high and men with low support were similar in magnitude. Male smokers with little social support were at highest risk for CHD whereas male non-smokers with large networks and good support were at lowest risk (7.1 percent vs. 0.8 percent) (Rosengren et al. 1993). These and other studies have demonstrated that lack of social support and its various functions are

predictors of disease incidence, and exert an effect that is independent of physiological and lifestyle risk factors.

However, once signs and symptoms of chronic disease have occurred one would expect them to override the impact of 'soft' risk factors such as social support. Therefore the study of patients suffering from chronic disease, such as coronary disease, is crucial.

In an early landmark study of over two thousand male survivors of acute myocardial infarction, Ruberman et al. (1984) showed that, even in the presence of clinical coronary disease, social isolation and stress contributed significantly to the increase in mortality risk. These risk factors were more common in men with low education. This early finding of a social gradient in health and disease has subsequently been frequently discussed and confirmed in both population- and patient-based studies (Haan et al. 1987).

In general, findings in men support the notion that one way in which the health hazards of social disadvantage are expressed is through the lack of adequate social networks and support. In order to provide appraisal and tangible support in times of hardships, men with high education and high job positions usually have a vast network of friends and acquaintances from professional and other organizations or groups, which they can draw upon for help in difficult situations. In low job positions, networks are known to be smaller and less effective; also social activities and social interactions are known to be more centered on family and family members. Therefore, the specific functions of information and concrete practical help, which are unevenly distributed across social strata and found to be crucial for maintenance of good health (Hanson 1989) may explain why cardiovascular health and health in general is better in higher social classes.

3. *Social Support and Emotions*

Social supports are provided to the individual by his/her social environment in an ongoing interactive process. This interactive process depends not only on the availability of supportive structures, but also on individual personal characteristics, such as the coronary prone behavior and/or emotional reactive patterns, such as depressive and anxious feelings. Whether the individual is able to receive and to provide social supports makes a difference for health outcomes. This includes the frequently studied coronary prone and hostile behaviors, which particularly in men were predictive of new incidence of coronary attacks (Brummett et al. 1998).

If considered in the presence of supporting social structures some of these findings are intuitively easier to understand. In a Swedish study of 150 male cardiac patients who were followed for ten years, evidence of such interactive effects on disease risk was found, in addition to clinical cardiac prognostic factors. The psychosocial factors assessed in these patients included social integration and social support as well as the Type A behavior pattern, using the original Structured Interview procedure. In accordance with other studies at the time, Type A behavior was not found to worsen prognosis in cardiac patients (Ragland and Brand 1988): 24 percent of men with Type A as compared to 22 percent of men with Type B died from CHD during follow-up. In contrast, social isolation was a prominent risk factor for poor prognosis. Men who said they practically never engaged in social activities with others for leisure were defined as socially isolated. They had about three times the mortality risk of men who said they were socially active at least once a month (Orth-Gomér et al. 1988). The worst prognosis, however, was found in Type A men who were socially isolated, their ten-year mortality risk being 69 percent, whereas, in socially active men, the behavior type made no difference (21 percent in type B and 17 percent in Type A men) (Orth-Gomér et al. 1988).

These results suggest that investigating either social environmental or individual behavioral factors alone is insufficient. Instead an attempt to integrate social and physical environment with individual psychological reactions appears to be more meaningful. Such models have been successfully applied and tested. An important example is the role of depressive reactions and their relation to outcome in patients with coronary disease.

In several patient-based studies it has been have shown that depressed symptoms and feelings increase mortality risk in patients post AMI (Barefoot et al. 1996, Frasure-Smith et al. 1995). These depressive reactions are tied into a social context that is much influenced by the individual and collective capacity for coping with stressors (Holahan et al. 1995). Such coping capacity will in its turn depend on the provision of social supports. Therefore the more recent studies of psychosocial factors in women have been conceptualized taking these integrative aspects into consideration.

4. *Social Support in Relation to CHD in Women*

Women have rarely been studied in regard to psychosocial factors and CHD. This is true for both social contextual factors, such as stress and social support, and the more individually based aspects of depression, coping, mastery, etc. It is interesting to note that many studies of coronary risk profiles did include women—but usually in too small numbers to be conclusive about their risk profile or about gender differences. Nevertheless findings are often generalized to both men and women.

This was one of several reasons for initiating the Stockholm Female Coronary Risk Study (FemCor-

*Hazard ratio (95 percent CI), adjusted for age, P for trend = 0.01.

Figure 1
Percentage of women surviving free of cardiac events according to social support and depressive symptoms

Risk Study). This is a community-based case-control study, comprising 300 women below age 65, who were admitted to the coronary care units with acute coronary syndromes in greater Stockholm during a three-year period. Women with CHD were compared to a random sample of 300 age-matched women from the normal population, obtained via the official census registry of the same area. Psychosocial and biological risk factors were examined using interview, survey, psychosocial, and physical examination techniques. The core study objectives were:

(a) To examine psychosocial risk factor effects on CHD in women;

(b) To examine psychosocial determinants of lifestyle and the psychobiological mechanisms involved;

(c) To describe protective factors and mechanisms which buffer against noxious psychosocial influences. Several different strategies for analyses of the results have been applied, including case-control comparison, cross-sectional analyses among healthy women, prospective follow-up of women with cardiac disease, etc.

Lack of social support and social isolation was found to be one of the major stressors identified in this study group. As the sick role and the biological disease process itself may influence both social activities and social support in most people, we relied on follow-up rather than cross-sectional comparisons. Case-control comparisons were used to adjust for risk factors such as education, occupation, etc. Separate analyses of underlying coronary artery disease were undertaken, with patients being examined with quantitative coronary angiography (QCA).

QCA was carried out in 131 of the original 292 patients, based on available space at the angiographic laboratory. Patients who did and did not undergo angiography were compared, but differences in coronary risk factor profile were not found. Measures of severity (presence and number of stenoses greater than 50 percent) and measures of extent (number of stenoses greater than 20 percent) of coronary artery disease were evaluated.

After adjustment for age alone, lack of social support was associated with both measures. After adjustment for lifestyle and physiological risk factors, the risk ratio for stenosis greater than 50 percent in women with poor as compared to strong social support was 2.5 (Orth-Gomér et al. 1998). Women with poor social support also had a greater number of less hazardous stenoses, obstructing the coronary lumen by only 20 percent. After multivariate control for all other risk factors, however, this association was of only borderline significance. These associations were

not explained by severity of anginal symptoms, self-rated subjective health status, or other clinical indicators of poor prognosis.

Subsequently, the impact of social isolation and depressed affect was examined in a five-year follow-up of recurrent events in all women patients (Horsten et al. 2000). They were followed for a median of five years after admission for the acute coronary event. By means of the centralized healthcare system in Sweden, complete follow-up information for recurrent events (hospitalizations and deaths) was obtained (Alfredsson et al. 1997). A total of 81 patients (27 percent) either died from cardiovascular causes or had a recurrent AMI or a revascularization procedure.

Women patients, who at initial examination showed signs of depressed affect (two or more symptoms of depression as measured by a short instrument by Pearlin et al. 1981) had twice the risk of recurrent events as compared to women who were not depressed. When social isolation was added to the model a further increase in risk was noted. As shown in Fig. 1, 33 percent of those who showed both depressed affect and social isolation had new events as compared to 9 percent of those who were free from both these problems, an almost fourfold difference. Prognostic risk factors including age, menopausal status, diagnosis at index event, symptoms of heart failure, diabetes, systolic blood pressure, smoking, body mass index, exercise, total cholesterol, triglycerides, HDL, therapy of beta-blockers, or ACE-inhibitors did not explain the effects of psychosocial determinants (Horsten et al. 2000).

5. *Work Stress, Family Stress, and CHD in Women*

Psychosocial stress at work has been consistently studied and shown to increase the risk of CHD (Karasek and Theorell 1990). Using the concept of high demand and low control presented by Karasek and Theorell an increased CHD risk ratio of about two has been found in men workers. Although women have not been as extensively studied, it is suggested that they have about the same CHD incidence rates associated with work stress as men do (Schnall et al. 1994).

When analyzing the contribution of high demand and low control in the case-control comparison of the FemCorRisk Study an odds ratio of about two was found. A further—and stronger—source of stress was family problems. Based on the concept presented by Frankenhaeuser et al. (1989), exposure to both stressors at work and those that originate from outside work was analyzed in a structured interview procedure. The predictive values of the two different work stress measures were almost identical. In the case-control comparison the odds ratio for work stress was 2.3 whereas that for family stress originating from a dyadic relationship was 2.9. In addition both work stress and family stress were associated with low SES. As expected, women with unskilled jobs had lower control over their jobs, but they also had increased family stress, in particular from separations.

Furthermore the effects of these stressors on event-free survival in women with CHD were examined. The risk of a recurrent event in women patients with severe marital stress as compared to no or little stress was 2.8 after control for age, menopausal status, family history of CHD, symptoms of chest pain and heart failure, diabetes, smoking, and levels of triglycerides and HDL cholesterol. The actuarial five-year probability of being free from cardiac recurrent events in women without marital stress was 85 percent. In women with severe marital problems it was 65 percent (Orth-Gomér et al. 2000).

This effect was modified by individual capacity to cope with stressors, as assessed by a short instrument describing degree of mastery, obtained from Pearlin et al. (1981). This self-rated scale attempts to quantify the extent to which the individual perceives that he/she can deal with and master problems and stressors in everyday life.

In women patients with poor mastery the experience of severe marital stress increased the risk of recurrent events by a factor of eight. In women with good mastery there was no significant effect of marital stress on risk of recurrences. Furthermore, the ability to master or cope with problems was related to socioeconomic status (women with low SES having poorer mastery scores), depressive symptoms, and social isolation (Wamala 2001).

These findings may be summarized as follows: women patients who experienced marital stress, when assessed after an acute coronary event, had a worsened prognosis if they also had a low education or an unskilled job, if they had depressive symptoms, if they were socially isolated, and poor at mastering difficulties and problems of everyday life. Numbers in subgroups were too small to analyze risk ratios in these different categories, but it is probable that all these factors are interrelated and overlap. This knowledge can be used to implement and improve preventive measures aimed at secondary prevention in women. Such interventions are ongoing, both in the US (ENRICHD) and in Sweden (Healthier Female Hearts in Stockholm).

6. *Gender Differences in Cardiovascular Effects*

To our knowledge, the harmful effects of family stress, depressed affect, poor mastery, and social isolation have not been investigated in a similar way in men. However, in an earlier study of Swedish men with CHD, the question was asked which life domain had generated the most severe stress experiences, work,

family, education, or other. A majority of men (80 percent) ascribed their worst stress periods to the work situation, and only 10 percent to the family and spousal problems. This apparent gender difference is further supported by recent data from two large surveys of men and women of the general population in Massachusetts (Shumaker and Hill 1991).

When asked which person was the most important provider of social support, men were more than twice as likely to name their spouse, whereas women were most likely to name a friend or relative, usually female, as their primary supporter. In addition, women were more likely than men to report that they give more than they receive in dyadic relationships. In the FemCorRisk Study, 89 percent of the women said they were their spouse's closest confidants, whereas only 75 percent of women named their spouse as their closest confidant. In contrast to previous studies in men (see *Gender and Cardiovascular Health*), being married or cohabiting did not in itself provide any extra protection from cardiovascular ill health. Instead, for these women, the strain from a problematic spousal relationship significantly contributed to a poor prognosis over and above the effect of clinical cardiac predictors.

Therefore, the determinants, the protective health effects, and the mechanisms of social support may differ profoundly between men and women. Consequently they need to be separately conceptualized, examined, measured and analyzed, and implemented for use in clinical and community-based interventions and preventive efforts. In both men and women, however, the protective effects of social support and the health hazards of social isolation are strong and complex. Further research on processes and pathways as well as methods to implement this knowledge in preventive efforts is highly needed.

Social Support and Recovery from Disease and Medical Procedures

1. Social Support and Recovery from Disease

Evidence examining the effect of social support on recovery from illness comes from a variety of health areas. These include studies on infectious disease, as well as cancer, heart disease and other chronic illnesses. Under most circumstances, social support has been shown to moderate the negative effects of illness and improve recovery. The effect of social support, however, is dependent to a large degree on the characteristic of the illness and the match between the type of support offered and the needs of the patient.

A recent study looked at the susceptibility to developing the common cold in volunteer subjects given nasal drops containing one or two cold viruses (Cohen et al. 1997). The results showed that those volunteers with more diverse social networks had a fourfold lower susceptibility to developing upper respiratory illness than those with a smaller number of social ties. In this study, social contact *per se* was not as important as the diversity of the individual's social relationships. The more an individual had regular contact with a variety of social groups such as family, workmates, neighbors and other social networks, the more resistant he or she was to developing a cold. Another study examining the role of psychosocial factors on progression to AIDS, found stress and social support to be significant predictors of HIV disease advancement (Leserman et al. 1999). In a follow-up period of five-and-a-half years, those participants who were more satisfied with the level of social support offered by their friends and families at study entry were twice as likely to be free from AIDS than participants who were dissatisfied with their available level of social support.

As well as infectious diseases, social support has been shown to have a positive effect on prognosis and recovery in a range of other medical conditions and illnesses. A study of low-income pregnant women found social support was associated with fewer complications during pregnancy and a higher infant birth weight. Research has found women who receive higher quality social support prior to delivery give birth to healthier babies and experience less post-partum depression. In chronic illnesses, Penninx et al. (1998) found positive effects on depression for having a partner and having many close relationships, although the strength of the effect differed across illnesses. Other work has shown social support to be associated with lower levels of disability and depression in diabetics, and higher levels of compliance in patients on renal dialysis.

In the cardiovascular area, the effect of having a close confidant has been shown to have an important effect on future mortality (see *Coronary Heart Disease (CHD), Coping with*). Williams et al. (1992) followed 1,965 patients with coronary artery disease after angioplasty. After accounting for known medical prognostic factors such as cigarette smoking and family history of heart disease, the most important socio–economic variable in predicting time to death was the presence or absence of a spouse or confidant. This finding is consistent with other studies of heart attack patients which have found a spouse to play a protective role in outcome.

A study of elderly myocardial infarction (MI) patients found those with low levels of social support were more likely to die in hospital and within six months of their heart attack even after controlling for severity of MI and other risk factors (Berkman et al. 1992). The available evidence suggests that the positive effect of social support seems to be stronger for male than female MI patients. For example, a 10-year follow-up study of MI patients admitted to Baltimore hospitals found higher survival rates in married compared to unmarried patients. The positive effect for marriage on both in-hospital and follow-up survival was stronger for males than females (Chandra et al. 1983).

Recent data suggest the more similar the spouse and patient view the illness the greater likelihood of effective adjustment and recovery. In work with MI patients, beliefs about the cause of the heart attack

were associated with positive changes in health behavior six months following MI. The belief by patients and spouse that the MI was caused by a faulty lifestyle was significantly related to overall improvements in diet and to an increase in the frequency of strenuous exercise. Attributions about how the illness developed are very common following MI and show a high degree of agreement between patient and spouse. They provide important guideposts for patients and their spouses by directing coping towards controlling a future myocardial infarction. Patient and spousal beliefs that the MI was caused by a faulty lifestyle were precursors to making changes in the types of foods eaten at home and participation in regular exercise. However, the belief that the MI was caused by stress, which is the most common attribution made by patients, had no relationship with later lifestyle changes (Weinman et al. 2000).

A large number of studies have examined the effect of social support on adjustment to cancer but fewer have studied the effect of social support on mortality. The literature shows social support interventions to generally have a positive effect on emotional adjustment to cancer. For example, a follow-up study of 294 people with breast, lung, or colorectal cancer found emotional support reduced distress and promoted adjustment to the disease (Ell et al. 1992). This study also found some survival benefits for social support in women with localized breast cancer.

Some researchers have directly investigated the value of social support by using it in controlled trials with chronic illness populations. Two randomized trials seem to show some health benefits for social support interventions. Spiegel et al. (1989) randomized women with metastatic breast cancer to participate in a one-year support group experience or usual care. There were no differences at four or eight months, but at one year the interventions group reported greater levels of adjustment than the control group. In a 10-year follow-up, the researchers reported that the women who participated in the support group had a significantly longer survival time. In another study of patients with Stage I and II malignant melanoma, patients were randomized to an intervention group that combined informational and education support or to a control condition. At six years, the intervention group showed decreased recurrence and increased survival six years later (Fawzy et al. 1993).

While these findings are encouraging for social support having health benefits in some chronic illnesses, it is not clear from the research to date what part of the interventions are the most effective or in which way they may influence health outcomes. It is still equivocal whether social support *per se* is the active ingredient that results in the positive outcome from these trials. As well as providing emotional support, the research interventions also provided education and information. Moreover, some later studies that have included social support interventions have not found the same effect on health outcomes (e.g., Cunningham et al. 1998).

A popular and relatively recent source of social support for patients with chronic illness are informal support groups. Here, patients meet together to discuss their condition and the difficulties and successes they have experienced in coping with their illness. As well as sharing personal illness experiences, these groups offer the advantage of providing information about utilizing health services, normalizing experiences and concerns and providing emotional support to group members. An analysis of social support groups found that the experience of physical illness was the most common reason for participation in such groups (Lieberman and Snowden 1993). Even after excluding substance abuse groups, this American survey found coping with physical illness made up 42 percent of the self-help group population. This study also suggested that these groups were more effectively accessed by the middle class populations who often have good access to other support services. One limit of such social support groups is that participants have to be well enough to be physically able to attend meetings.

This pattern may be changing with the advent of the Internet. In the past five years there has been a dramatic increase in the use of the Internet in most Western households. This has been accompanied by an increasing number of discussion and support groups for chronic illness. Now without leaving home, chronic illness sufferers can read postings from other sufferers and participate in discussions about aspects of their condition. Recent research on these illness newsgroups suggests that certain diseases have a higher number of postings than others and these rates differ markedly from their level of morbidity in the community (Davidson and Pennebaker 1997). For example, patients with breast cancer and chronic fatigue syndrome have a high Internet usage, while postings from heart disease and prostate cancer patients are relatively under-represented. The value of Internet support groups for patients with chronic illness has yet to be evaluated but the use of this type of support is likely to rise markedly in the future.

2. *Social Support and Recovery from Medical Procedures*

Although not as extensively studied as recovery from illness, there is considerable evidence that social support also has a positive influence on recovery from hospitalization and medical procedures. In a large study of 40,820 patients admitted to a University Hospital in Ohio, researchers investigated the effect of marital status on patient outcome (Gordon and Rosenthal 1995). They found that unmarried patients presented to hospital later than married patients. Unmarried surgical patients also had a higher risk of

dying in hospital than married surgical patients, even after controlling for severity of illness, diagnosis and other demographic factors. Furthermore, unmarried patients tended to stay longer in hospital than married patients. The differences found in this study were greater in patients who had never married when compared with patients who were widowed, divorced, or separated. This study suggests that being unmarried and in particular, never having married, increases your risk of negative outcomes during hospitalization.

The effect of different types of social support on recovery has been examined in the context of coronary artery surgery. A study examining the effect of different types of social support on recovery following cardiac surgery found that the perceived availability of social support was related to emotional and functional outcomes up to a year following the operation. In particular, esteem support, or feedback that one is valued and respected by others, was consistently related to outcome over the follow-up period (King et al. 1993). It is not clear why esteem-related social support is associated with positive outcome, but it is likely that such support may give the individual in this situation greater resilience to setbacks and help instill more optimistic beliefs that they have the ability to recover from the surgery.

One fascinating aspect in the study of social support and recovery from medical procedures is the effect of the patient's hospital roommate on recovery. Research in this area demonstrates that whether a patient has a pre- or postoperative roommate can influence outcome. Patients about to undergo surgery who are also assigned to a preoperative roommate show greater levels of anxiety and a slower recovery than those assigned a roommate who has already been through surgery. As well as lower levels of anxiety prior to surgery, being placed with a roommate who had been through surgery resulted in getting out of bed more quickly following the operation and a faster discharge from hospital (Kulik et al. 1993).

It seems likely then that the positive benefits resulting from a postoperative roommate are partly due to the natural relief of seeing someone who has survived the same operation that the preoperative patient is about to undergo, and by normalizing the feelings and problems following the operation so these are less likely to be viewed as unusual or abnormal by the patient. Thus a roommate who has been through the operation or procedure can provide a practical role model for preparing patients for the post-operative pain, physical sensations and sequence of recovery following the operation.

Actions by others designed to aid or assist adjustment with medical problems is not always seen as helpful by the recipient. Negative reactions to intended helpful actions are actually quite common. One study of elderly chronic illness patients found half to receive support from their spouse they did not need and 28 percent reported not receiving assistance for a daily activity when needed. This mismatch between the need and provision of support has been the focus of study in the general social support area and is very relevant to the area of recovery from medical illness. Here, the evidence suggests that different types of support are differentially valued depending on the relationship the provider has with the patient.

In an important study with cancer patients, Dakof and Taylor (1990) found emotional support was most likely to be valued when it came from intimate others, whereas informational support was more valued when it came from a physician or another cancer patient. This study found when there was a mismatch, such as when a patient needed emotional support from a spouse but received advice or information, then these actions were more likely to be seen as unhelpful. Unhelpful behaviors noted by patients were minimizing the problem, forced cheerfulness, medical care delivered without any emotional support, and being told not to worry. A later study using patients with the chronic non-life-threatening illnesses of irritable bowel syndrome and chronic headache, found these patients to put greater value on tangible and practical assistance and less on emotional support than the cancer patients in Dakof and Taylor's sample (Martin et al. 1994).

These studies highlight how the characteristics of the illness may strongly influence the type of social support needed by patients. In some life-threatening conditions, where patients are frightened or daunted by the demand of treatment and prognosis, emotional needs are more prominent. In other illnesses, where the illness forms a major hurdle to be met on a more routine daily basis without the threat of disfigurement or death, then more practical issues such as assistance with childcare and transport become more valued.

A disparity in the intensity of social support can also cause difficulties for patients. Sometimes an aversion or fear of physical illness can cause family to avoid contact with the patient. While emotional support is the type of support most received by patients it is also the type of support likely to be perceived as most inadequate. However, overly intrusive offers of assistance and help can also cause a negative reaction and increased stress. These findings highlight the importance of finding a balance between the needs of the patient and the type and level of social support.

3. *Summary*

The available evidence suggests social support has a positive influence on individuals' susceptibility to infectious disease and recovery and adjustment to a variety of chronic illnesses. In the cardiac area there seem to be particularly strong benefits for having a spouse or close confidant and these effects seem to be even stronger for men. Social support as an intervention in chronic illness seems to hold considerable

promise but further trials are needed to confirm early findings and to identify the necessary components of successful intervention programmes. With the rise of the Internet, electronic social support groups are going to provide an important source of information and peer support for patients with chronic illness.

There is strong evidence that the lack of social support is a risk factor for negative outcomes following hospitalization. Patients low in social support are more likely to present with more advanced illness and to be more likely to die while in hospital. However, it should be noted that many of the studies in the area are correlational, and the mechanisms that link social support to recovery from illness are still largely unknown. Recovery from surgery is an example where action by others that conveys to patients that they are respected and valued has a positive effect on outcome. The type of roommate can also set up a more positive outcome from the operation by providing a constructive role model by minimizing catastrophizing and demonstrating effective coping strategies.

A critical factor running through social support and the recovery from illness and medical procedures is the match between the needs of the patient and the type of social support provided. Different types of illness and procedures cause differing needs in terms of whether they require more emotional or tangible support. Emotional support is valued highest when it comes from a significant other. A mismatch in the type or intensity of support can lead to difficulties and hamper overall recovery.

Social Support and Stress

Social support is a dynamic process of transactions between people whereby assistance is received, especially during periods of stressful demands. Assist-

ance may take the form of advice, material aid, help performing tasks, or emotional support. Indeed, emotional support may be the most active ingredient in the support process. People who have a history of being supported by others when they need it tend to feel a strong sense of attachment to a group that is caring or loving and to which they feel they belong. This perception of being closely attached to others who may help when needed is a major aspect of why social support may have health benefits. That is, social support consists both of actual receipt of help and the perception that help will be forthcoming if needed.

1. *History of the Study of the Beneficial Effects of Supportive Ties*

Although the concept of social support was introduced in the social sciences in the 1970s, the idea that social relations may have a health-enhancing function is long-standing. Moreover, medicine has often spoken of the curative aspects of love, friendship, and positive social attachments. The influence of positive social interactions on mental health were first introduced in psychiatry by the French physician, Pinel, in the early nineteenth century and the English and American physicians, Connoly and Rush, in the late eighteenth to mid-nineteenth centuries. Having witnessed the madhouses of the time at Bedlam and the Bictre, they found that maniacs were treated with great cruelty. They offered a radical alternative to treatment. They suggested instead, that the mentally ill be treated gently, with patience, and with the use of 'kindness' and 'community' as the active ingredients of treatment.

Sociological influences into the importance of positive social attachments can be traced to the seminal work of Durkheim (1897), who found suicide to be related to social alienation from others. Later, the Chicago School of Sociology represented by Park et al. (1926) in their classic book *The City*, proposed that health and social accomplishment vs. sickness and deviancy were consequences of the extent that social groups were integrated into and supported by the broader community. Their theory was ahead of its time, and clearly challenged the then current explanations that genetic or moral inadequacy was responsible for deviancy. Such genetic and morality explanations were the predominant psychological view of the time held by such eminent scholars as Lewis Terman of Stanford and Robert Yerkes of Harvard, who argued that Jewish and other 'brunette' immigrant groups were genetically inferior and should be prevented from immigrating (Kamin 1974). Moving to more recent empirical investigations, researchers in the 1970s examined the relationship between social attachments and wellbeing. They found an association between socioenvironmental conditions and infant mortality, tuberculosis, and mental illness. They noted that social disorganization and negative social conditions contributed to increased illness on psychological and physical levels.

In a pioneering investigation, Berkman (1977) examined the social relationships and health of a random sample of adults in Alameda County, California. Those individuals who had ongoing social relationships, such as marriage, close friendships and relatives, church membership, and informal and formal group associations, had the lowest mortality rates. She interpreted her findings to mean that social isolation and lack of social and community ties disrupted people's disease resistance and that the presence of positive social attachments, in contrast, acted as a resistance resource (see *Social Integration, Social Networks, and Health*). But how are social relationships translated into physical or emotional health? Sarason (1974) suggested that people obtained a psychological sense of community, and theorized that this sense of community contributed to people's wellbeing. The healthy community guards its residents by facilitating healthy behavior (caring), offering people a positive sense of who they are (self-esteem), provides for safety and mutual support, and opens access to resources. He defined psychological sense of community as 'the sense that one was part of a readily available, mutually supportive network of relationship upon which one could depend … (who are) part of the structure of one's everyday living … (and) available to one in a "give and get" way.' The work of Caplan (1974), a pioneering psychiatrist, was perhaps the first to identify the concept of social support and its importance in the stress process as the active ingredient that these other theorists were noting. Caplan identified the nature of the process by which social relationships provided psychological sustenance, acting 'to mobilize … psychological resources and master … emotional burdens; share tasks; and supply (needed resources)' (Caplan 1974). Caplan further emphasized that support provision supplied and activated resources, but also contributed to a positive sense of another critical stress resistance resource—sense of mastery.

2. *Social Support's Influence on Mental and Physical Health*

When people encounter stressful conditions they may benefit from the assistance of others. The people who they naturally might rely on are termed their social support network. The social support network consists of the constellation of individuals who have a relationship with one another that is characterized by helping. How strong the social support network is depends on how often social support occurs between

network members, the kinds of support that is communicated through the network, and the strength of the ties. Different kinds of social support networks also perform different function. To find a job, a large, loosely connected network may be of most assistance, even though the relationships are not close. The greater number of contacts may maximize the chance of learning about job openings and obtaining interviews. In contrast, many studies have shown that when major life stressors occur, such as death, illness, or divorce, then a small intimate network might prove most helpful. In such a close network, people are more likely to share their sorrows and receive consistent, ongoing help and emotional succor (see *Gender Role Stress and Health*). Moreover, the help received from intimate others has greater personal meaning (Sarason et al. 1986). Social support contributes both to mental and physical health. Social support is related to lower psychological distress in the form of anxiety and depression. Comprehensive reviews of the literature found that social support contributes to mental health both through the positive feelings that are engendered by having close attachments with others and because help is mobilized in times of need (Cohen and Wills 1985, Schwarzer and Leppin 1989). The attachment aspects of social support are seen as contributing to wellbeing whether or not stressful events are present. This has been called support's direct effect. In contrast, the contribution of the actual receipt of support and knowing support will be forthcoming if needed may prove most beneficial during high stress periods. In this regard, those who have access to social support do better in particular when challenged by stressful circumstances. This has been called support's stress buffering effect.

Research has also examined social support's positive impact on physical health. Comprehensive reviews of this literature found that social support contributes to better clinical health outcomes (i.e., less disease) (House et al. 1988) and more positive stress responding on a physiological level that is subclinical (Uchino et al. 1996). Social support is related to lower morbidity and mortality across a wide array of diseases including heart disease, cancer, and the common cold. Those who are ill but who obtain social support also have been found to have less severe symptoms including less pain, less physical disability, and more rapid recovery. On a physiological level that underlies health, social support is related to beneficial influences on cardiovascular, endocrine, and immune systems. Social support may, in part, help by encouraging positive health behavior but this does not seem to be the major channel through which its positive influence occurs. Rather, social support has direct benefits on lowering cardiovascular reactivity, improved immune responding, and more physiologically adaptive responding of stress-related hormones. As in the mental health studies, support from intimates seems most important for sustaining physical health.

In the excitement and groundswell of interest in social support, researchers and theorists almost entirely forgot that interpersonal relationships could also be a critical source of stress. Rook (1984) shattered this honeymoon with the social support concept by reminding the field that interpersonal conflict was also one of the main contributors to stress. Moreover, it is notable that positive and negative social interactions often emanate from the same people. Rook also showed that when positive and negative interactions cooccur, that the negative ones are more disruptive of wellbeing than the positive ones are health enhancing. In work with women during the Israel–Lebanon War, researchers further found that even positive social interactions could have a negative impact when people shared a crisis. They called this the pressure cooker effect, whereby stress contagion occurs among people who find their resources commonly drained and their problems accentuated by having to deal with the same severe problem. This finding is especially critical because many of life's problems impact families or groups of people in a shared way, such as the case when there is a death in the family or in the face of disaster.

3. *Social Support and the Exchange of Resources*

The process and value of social support is placed in broader ecological context by Hobfoll's (1998) Conservation of Resources (COR) theory. COR theory's basic tenet is that people strive to obtain, retain, protect, and foster that which they value. These things that they value are termed resources. Resources are either valued in their own right or serve as a means of obtaining valued ends. There are four basic kinds of resources: objects, conditions, personal characteristics, and energies. Object resources are physical entities that are valued such as transportation, a house, or a diamond ring. Condition resources are social circumstances that avail people to other resources, such as love, money, status, or shelter. They include such conditions as marriage, tenure, and employment. Personal characteristics include skills or personality attributes that enable an individual to better withstand stressful conditions, achieve desired goals, or obtain other resources. They include personal attributes such as sense of mastery, self-esteem, and optimism and skills such as job skills or social skills. Finally, energy resources are resources that can be used to obtain other resources, but that may become valued in and of themselves. They include money, credit, and knowledge.

COR theory proposes that stress occurs when people (a) are threatened with resource loss, (b) actually lose resources, or (c) fail to gain resources following resource investment. Further, people use resources in order to limit such losses or to gain resources. For example, people use self-esteem in order to bolster their self-confidence after doing poorly on

an examination. Similarly, people invest money to purchase insurance in order to offset potential financial loss. Because resources are often hard to obtain and maintain, resource loss according to COR theory is considered to be more salient and of greater impact than resource gain. Resource gain, in turn, becomes more important in the face of resource loss.

COR theory helps explain the importance of social support. People have limited resources and, especially when under stress, they may find their resources inadequate. Through social support people can rely on others to offer the resources they lack, bolster their flagging resources, or remove them from the stressful circumstances so that they can regain resources or the ability to use their resources. This may take the form of offering object resources, such as shelter or transportation, and energy resources, such as money or information. It may also take the form of bolstering personal resources that the stressful conditions have depleted. For example, divorce may compromise individuals' self-confidence, hope, and optimism. Emotional support can act to replenish these diminished resources by reminding individuals that they are loved, important, and likely to succeed in the future.

COR theory also explains the potential costs of social support. First, the resources offered may be of poor quality. Supportive messages may contain submessages that are actually undermining, such as when people offer support but imply that they have the upper hand. Second, using social support means incurring social obligations that may be costly in the future. This is the case because people often refrain from wanting to incur obligations, and because when they need to return the favors bestowed upon them they may have to risk valuable resources at an inopportune time. This may differ in communal vs. individualistic cultures, but even in communal cultures where the transport of support is more balanced, incurring obligations has social costs.

A third cost of obtaining social support is that other resources often have to be expended to call on and employ help. Reaching out to others requires time, a critical resources that may already be taxed during stressful conditions. Calling on help may also force people to admit to some inadequacy, which they may not wish to acknowledge. Particularly in Anglo-Saxon and Germanic cultures the concept of 'standing on one's own two feet' is a central value. This, in turn, may diminish self-esteem, self-confidence, and sense of mastery.

COR theory further emphasizes that social support is not just a matter of receiving resources from others when needed. Building a supportive social network requires extensive, long-term outlays of resources in order to build and maintain supportive ties. This means that to have support available requires a history of resource investment. In some relationships this may be one-sided, as in parent–child relations. Similarly, different relationships are characterized by varying histories of give and take. These patterns will set the stage for the commerce of social support when a crisis occurs.

4. *Fitting of Social Support to the Type of Stress*

The help offered by social support may or may not fit the demands of any given stressful situation. This relationship between the nature of the demand and the adequacy of social support in meeting those demands has been termed social support fit. Emotional support has been found to fit many kinds of demands, and is the most robust, wide-reaching kind of support. However, even emotional support may not be appropriate for a given demand. When advice is needed it is important that the right kind of advice be available. Similarly, when support is needed for tasks some kinds of help may hinder more than they help.

An important aspect of social support fit is highlighted by COR theory. Specifically, many stressful circumstances are chronic. COR theory suggests that resource reservoirs are finite and that even if initial support has excellent fit with demand, this does not mean that the right kinds of support will be available for the ongoing demands that ensue (Norris and Kaniasty 1996). People, however loving and helpful, may need to return to their own immediate family or may need to shelter their resources for the needs of other members of the family. How this is the case with money is readily understood, but love too takes time to communicate. Even a parent may have to withdraw resources from a needy child so as not to sacrifice the needs of other children at some point. Chronic stressors will deplete individuals' resource reservoirs and those of their support system (see *Stress and Coping Theories*).

5. *Future Research Directions*

Future research on social support is likely to take a number of directions. On the biological level, researchers are only beginning to uncover the relationships between social support and physiological reactivity and disease. Research will examine more specific diseases and the interaction of social support with the time element of disease. Hence, researchers will be examining social support's impact on premorbid states, disease onset, and recovery. On the physiological level, research will be looking at how social support influences physiological reactivity that precedes disease or sustains health.

On the more social psychological level, research will be investigating developmental aspects of social support in terms of how it comes about and how it is sustained. This will include evaluation of how culture

plays a role in social support interactions and the different meanings of social support in different cultures. Social support's impact will continue to be examined in every imaginable stressful circumstance, from university examinations, to the workplace, to disasters. With an aging population, how social support impacts the process of adaptation among older adults will be an expanding area of interest. It is clear that social support is multifaceted and can be looked at on multiple levels and interest in the topic is likely to not only continue but to actually increase in scope.

Social Support, Psychology of

The concept of social support has both scientific and popular appeal. The topic has received attention as the important influence of psychological and interpersonal factors on the health and well-being of individuals has increasingly been recognized.

1. History

Early research in this field was characterized by vague definitions, poor and inadequate samples, and inappropriate generalizations. Psychologists have long recognized the importance of the association between social support and health generally, and interpersonal factors and individual mental health specifically. It was only when the importance of these factors on physical health was documented that the research became of interest to a broader array of scientists, researchers, and clinicians. This turning point can perhaps be best identified with the early work of Berkman (Berkman and Syme 1979). Using the Alameda county longitudinal epidemiological data which followed a large representative sample of residents from the California county, Berkman and Syme were able to document that people reporting social ties with friends and organizations were more likely than people without such ties to be alive nine years later. Other studies essentially replicated these findings with respect to mortality in Tecumseh, Michigan (House et al. 1982) and Evans County, Georgia (Blazer 1982, see also Bowling and Grundy 1998 for a recent review). This began a series of studies documenting the association between social support and numerous aspects of physical and mental health, including depression, recovery from disease and medical procedures, cancer, heart disease, experience of pain, and adherence to a medical regimen (Antonucci 1990, Berkman 1985, Holahan et al. 1995).

2. Definitions

While the term social support was initially used as a nonspecific, generalized term, experts have now come to recognize the importance of providing more detailed definitions and, more importantly, of distinguishing between different related concepts. We

propose the generalized term social relations to describe the broad array of factors and interpersonal interactions that characterize social exchanges and social support between people. Under this rubric we find it is useful to distinguish three critical terms: social network, social support, and support satisfaction.

Social networks can best be understood as the objective characteristics that describe the people with whom an individual maintains interpersonal relations. Thus, one can describe one's social network members in terms of age, gender, role relationship, years known, residential proximity, frequency of contact, and the like. Describing a social network tells you about the people with whom an individual has relationships but not about the exchange that takes place within those social relations. To describe this aspect of social relations, the term social support is used.

Social support refers to the actual exchange of support. Social support has been described as an interpersonal transaction involving the exchange of one of three key elements: aid, affect, and affirmation (Kahn and Antonucci 1980). Aid refers to instrumental or tangible support such as lending money, helping with chores, or providing sick care. Affect refers to emotional support such as love, affection, and caring. Affirmation refers to agreement or acknowledgment of similarities or appropriateness of one's values or point of view. Other terms have also been used, e.g. informational and appraisal support.

The third term often used in this literature is evaluative support or support satisfaction. This term refers to the assessment individuals make about the support they receive. It is an evaluative reflection of a combination of both social network and social support characteristics as well as more idiosyncratic characteristics such as perceived and expected support. Since individuals are fundamentally psychological beings, every individual does not experience the objective receipt of support in the same way. Thus, a support provider might say to a support recipient 'I love you', which might be heard by one person as a pledge of lifelong romantic love and by another as a passing sign of affection—an indication of platonic, brotherly love, or even a sarcastic statement of disdain. Support satisfaction refers to how individuals evaluate or assess the support they receive. They might feel support is adequate, that it meets their needs. Some individuals will be satisfied with the support they receive, i.e. positively evaluate the support they receive, and others will not—even when an observer would report that the two individuals have received the same support.

3. *Measurement*

Recognition of these different concepts and the distinctly different definitions associated with them leads directly to the recognition of the problems associated with measuring these constructs. Measurement has evolved significantly over the last several years. Different types of measures have been used such as open-ended questions and structured interviews. Also interesting is the fact that many different methods have now been used to study social support specifically and social relations more generally. These include in-depth ethnographic studies, laboratory studies, as well as large representative, epidemiological studies. When assessing primary sources in this field it is important to be cognizant of the specific definitions and consequent measures which have been used to assess the social relations characteristics of interest since these facts fundamentally influence the kind of information obtained.

4. *Theoretical Perspectives*

Several theoretical conceptualizations relating to social support have been offered such as attachment across the lifespan, socioemotional development, family systems, and developmental aspects of friendships (see Levitt 2000 for an overview). It is now generally recognized that a lifespan perspective provides a critical underlying base upon which to study social relations. The most important exchanges of social support and social relations usually involve long-lasting, close relationships such as those between parent and child, siblings, husband and wife. Interpersonal relationships are lifespan in nature either because they have existed across the lifespan or because they are built on interpersonal relationships that have been experienced over the individual's lifetime. To understand how an individual experiences a relationship at any one point in time, it is most useful to understand the history of that specific relationship as well as other relationships in the person's life. Thus, the study of a 50-year-old woman and her 70-year-old mother is best conceptualized as a relationship that has continued from when the 50-year-old was an infant through her early childhood, adolescence, young adulthood into the current state of middle age. Similarly, her mother was at one time a young 20-year-old mother who loved and cared for her child then and throughout the next 50 years. The resultant mother–child relationship is likely to be understood very differently depending on these lifetime-accumulated experiences. One might even argue that a specific negative experience could and would be forgiven because of a lifetime of positive experiences. Or, on the contrary, a contemporary supportive interaction may be unable to make up for a lifetime of disappointment or neglect.

4.1 *Convoy Model*

The convoy model of social support is actually a model of social relations more generally (Antonucci

1990, Kahn and Antonucci 1980). It conceptualizes the longitudinal nature of these relations: the convoy is a structural concept shaped by personal (age, gender, personality) and situational (role expectations, resources, demands) factors which influence social support and support satisfaction. Changes in the convoy over time critically affect individual health and well-being.

4.2 Theoretical Work

Recent theoretical work has focused on explaining how social support positively affects the health and well-being of the individual. Antonucci and Jackson (1987) offer the support/efficacy model. This model suggests that it is not only the exchange of specific support that accomplishes these effects but the cumulative expression by one or several individuals to another that communicates to the target person that he or she is an able, worthy, capable person. Assuming that the support recipient perceives the support provided as accurate and altruistically motivated, the support recipient will come to internalize this same belief communicated by the supportive other. Thus, with multiple and repeated exchanges of this type, the supported person accumulates a belief in his or her own ability which will enable that person to face and succeed in the multiple goals and challenges of life, i.e., to cope with problems across the lifespan. Not all people receive support from those who surround them and not all support is positive (Rook 1992). Thus, some people, instead of being told that they are competent, capable, and worthy, may be led to believe that they are incompetent, incapable, and unworthy. Just as the cumulative effect of positive exchanges can have a positive affect on an individual's health and well-being, so the opposite can have a devastating and cumulative negative effect on health and well-being. Some support networks can have a negative effect by supporting or encouraging behaviors detrimental to health and well-being. Drug buddies, drinking buddies, eating buddies, and buddies who discourage exercise are all examples of people who help or 'support' behaviors that simply are not good for you.

Other theoretical perspectives have been offered. For example, some scholars (e.g., Thoits 1995, Pearlin et al. 1996) consider social support a coping mechanism. They argue that as people are confronted with stress, the receipt of social support from important close others is a critical and significant coping strategy. Sarason et al. (1990) have taken a more personality-based perspective, arguing that individuals with specific personality characteristics will seek and benefit from different types of social relations including specific types of social support exchanges. Carstensen et al. (1999) have suggested an interweaving of social relationships, emotional development, and lifespan experiences. Although not technically a theory of social support, Carstensen has offered a perspective which argues that at younger ages people are more likely to seek out and be advantaged by numerous exchanges and social contacts, whereas as they age people reduce the number of exchanges in which they engage to only those which are perceived as most close. Finally, two other perspectives on social relationships have focused on intergenerational solidarity (Bengtson et al. 1996) and adult friendships (Blieszner and Adams 1992). Bengtson has documented the unique perspective of each generation towards intergenerational support. Older people of the more senior generations are likely to report that they provide a great deal of instrumental and affective support to their younger, junior generational family members. Younger people, while often agreeing to feelings of solidarity with older generations, report fewer support exchanges than their senior generation relatives. Bengtson et al. explained this as important differences in developmental stake in family, generational, and close social relationships. Finally, Blieszner and Adams note the unique supportive nature of adult relationships, recognizing that adult friendships serve an important function because, unlike family relationships, they are nonobligatory, most often among peers, and therefore on an equal or nonhierarchical basis.

5. Support Findings

While there is still much to learn about the way in which social relations and, specifically social support, operates, there is quite a bit that is already known. There are both sociodemographic and cultural similarities and differences in social relations (Jackson and Antonucci 1992). It is known, for example, that most people report immediate family, mother, father, spouse, child, and siblings as their closest relationship (e.g., Antonucci and Akiyama 1995). It is known that people differentiate their relationships from very close to much less close. While all these relationships can be important, it is clear that the closest relationships have the biggest effects in most circumstances. However, it is worth noting that there can be special circumstances where a person generally not considered very close can have a significant effect on the individual. A supervisor not considered a friend but who goes out of his/her way to extend praise or deliver criticism is an example.

It is also known that social relations vary by age, gender, socioeconomic status (SES), race, ethnicity, culture, and other sociodemographic characteristics. The number of close social relationships and amount of emotional support is relatively stable across the lifespan until very old age (Due et al. 1999), when a significant decline occurs (Baltes and Mayer 1999). This seems true in most countries for which we

currently have data. Although men and women seem to have the same general structure to their social networks and very little difference in the size of their networks, it does seem to be the case that men have fewer close relationships than women. Men seem to maintain a significant, close, and high-quality relationship with their spouse, while women maintain this type of relationship with several people. On the other hand, men seem to be less burdened by their relationships and to feel less responsible for solving the problems of people in their networks. They also have fewer people they feel they can turn to in times of trouble and feel less comfortable seeking and obtaining support from others.

The data on SES indicates that the social networks, support exchanges, and support satisfaction of people from different SES levels vary considerably. To put it succinctly, people at lower SES levels have smaller networks which tend to be sex segregated and to consist mainly of family members. They exchange support with fewer people and are often, though not always, less satisfied with the support they receive. Race, ethnicity, and culture have been shown to affect social relationships although there appears to be some fundamental characteristics of social relationships that transcend group membership. Thus, for example, most support networks consist of family members but different groups have different customs and sometimes different characteristics, which influence support relationships. So, for example, the church is a formal group that provides significant support to most members of the African-American community. On the other hand, Hispanics place a particularly high value on family relationships which are characterized by large, densely knit support groups. In the United States, the daughter is often the most significant support provider and caregiver for older parents. However, in Japan, daughters-in-law more often provide support than daughters because the traditional living arrangements in Japan require daughters-in-law to live with her husband's parents. It is nevertheless important to remember that structure and culture do not always predict perception, expectation, and/or quality of support. A recent study (Tilburg et al. 1998) comparing older people in the Netherlands who often live alone with older people in Italy who often live with their children, found the Italians reporting less social integration and more loneliness than the Dutch. It may be that Italians expect more, perceive less, and therefore are more likely to downgrade the quality of the support they receive. These are important distinctions of which we are aware but about which we understand little. An additional perspective is offered by research now available which demonstrates, at the psychoimmunological level, that people who are lonely or have more hostile interactions with others are much more likely to become ill, develop heart disease, cope less well with stress, and take longer to recover from health problems (Uchino et al. 1996).

6. *Future Directions*

Future programs designed to improve social relations and social support need to be sensitive to individuals and yet not encourage or induce dependence (Silverstein et al. 1996). Social support can be most useful when it instills in the individual a feeling of being valued and competent, of being worthy and capable. We are just beginning to understand how this might happen. Acknowledged possibilities include the exchange of support, which involves both receiving and providing support, reciprocity in social relations, and the convergence of expectations, perceptions, and receipt of support. Simply stated, identify ways to maximize positive support and minimize negative support. The next important challenge in this area is finding ways to incorporate what we know about social support specifically and social relations more generally into prevention and intervention programs that will improve the physical and mental health of people of all ages.

Social Survey, History of

The social survey grew out of concerns about the social consequences in Western Europe and North America of rapid industrialization and urbanization, as well as from the desire to investigate society.

The origins of the investigation of the condition of the working or laboring classes in modern times may be traced to social investigations in the UK in the late eighteenth and early nineteenth century. Such social investigations were not surveys, but are part of the immediate prehistory of the social survey. The social survey as a tool of scientific inquiry is not much more than 110 years old.

1. *The Survey Defined*

Several specific characteristics distinguish the social survey from the modes of social investigation that preceded it. A social survey involved field work, the collection of data at first hand by a social investigator rather than reliance upon reports by others or on pre-existing data. Surveys attempted to achieve comprehensive rather than haphazard coverage, albeit initially within a local rather than a national area. The data in surveys related to individuals, families, and households rather than aggregates, and were analyzed accordingly. Survey research involved the attempt, however primitive, at counting and quantifying the phenomena with which it was concerned. And the social survey developed in close relationship with public policy and social reform.

Throughout the nineteenth century there were investigations into public health, housing, family life, and employment, particularly as these affected the working classes. Some, such as the studies by Frédéric Le Play of working-class family budgets, had wider scientific aspirations. The investigations were carried out by private individuals (many of them, in the later nineteenth century, women of some social position), certain professions (associated with, in particular, medicine), members of voluntary associations concerned with social welfare, a few journalists and (by the end of the century) one or two academic scholars. Although the methods of inquiry varied, there was some common ground. Indeed, for a period in the USA what became known as the Social Survey Movement flourished, engaging significant numbers of private, government, and academic researchers. These inquiries signified increasing upper-class and middle-class interest in the condition of the working classes as well as a desire to intervene—a desire both to remedy want and disease through voluntary or state action and to achieve a greater degree of social control through the use of scientific expertise.

There was thus a dual involvement of both social scientists and social reformers in the history of the social survey, and an interplay between them. It is important to stress that before 1940 the social survey was not associated particularly closely with academic social science, which was in any case itself quite small in scale. The modem scientific sample survey, established by academics such as Rensis Likert and Paul

Lazarsfeld, government statisticians such as P. C. Mahalanobis and Louis Moss, and market researchers such as Henry Durant and Mark Abrams, has developed since that time. Before World War II, a variety of individuals and groups, only a minority of them academics, contributed to the establishment of the social survey. Occasionally surveys have originated in an abstract desire for more knowledge about the structure and workings of society; more frequently, however, they have been carried out as an indispensable first step in measuring the dimensions of a social problem, ascertaining its causes, and then deciding upon remedial action.

2. *Studies of Local Social Conditions*

The history of the social survey can be conveniently schematized into two periods, the early studies of local social conditions—particularly poverty—and the post-1940 probability sample survey. The former were mainly local, the latter frequently national and more recently international in scope and design. However, both types of survey shared features in common. A fundamental change in the concepts guiding the acquisition of social knowledge accompanied the rise of the social survey. A comparison between Henry Mayhew's examination of the London poor in the middle of the nineteenth century and Charles Booth's surveys three decades later is instructive. Booth conceptualized the problem differently, conducted a larger-scale inquiry, attempted to measure the phenomena with which he was concerned, and collected data from multiple observers rather than relying upon a single observer. The emergence of the interview, however, was a gradual process.

The history of the social survey is usually dated in Britain to the 1880s when, as economic depression heightened social tensions, social and political groups that had competed in prosperity descended into conflict. One manifestation of these changing circumstances was sporadic social unrest. One particular question which exercised opinion in the middle and upper classes was the extent of poverty. In the 1880s, with more trying economic conditions, the problem of poverty became more insistent and the discrepancy between the numbers in receipt of poor relief and the proportion of the population having inadequate incomes due to underemployment, unemployment, family breakdown, ill-health, old age, and other misfortunes was more apparent. But how great was the difference and who would provide an answer to the question?

The absence of an adequate institutional base from which to undertake such inquiries was a major obstacle. This base was not provided by the political parties. Government departments did little at this period to gather information on social conditions. With the exception of one or two positions in economics, social science was not institutionalized in universities.

Existing methods of collecting social data about poverty were patchy and often lacking in reliability. Henry Mayhew's observational approach emphasized vivid insight and detailed description over extensive enumeration. Statistics compiled by central and local government, such as they were, related to administrative function and were neither designed nor collected by people with professional training. The interrogatory methods of parliamentary committee and Royal Commissions as devices for investigating problems were unlikely to lead to a satisfactory overall picture of social conditions, producing impressionistic results which varied between individuals. There was a marked lack of clarity in defining the phenomenon.

3. *Charles Booth*

The pivotal figure of Charles Booth looms large in the history of poverty surveys. Charles Booth was a wealthy Liverpool shipowner who was annoyed by the lack of a factual basis for the accounts of urban poverty of the time and lack of clarity about three questions to which he sought answers: How many were poor, why were they poor, and what should be done to alleviate poverty? Through careful empirical study Booth sought answers for the East End of London to the first two questions. *The Life and Labour of the People in London*, published in 17 volumes between 1889 and 1903, is the first great empirical study in the social survey tradition. The publication of the first volume of Booth's study of poverty in London in 1889 created a sensation.

Booth's originality lay in his methods of inquiry, not just in how he collected and analyzed his data, but in the way he conceptualized the problem of poverty. Booth attempted to introduce precision to the concept of the 'poverty line' where hitherto there had been vagueness, a characteristic which justifies including him as one of the founding fathers of social science. Booth sought to measure the numbers of the population above and below the poverty line with some precision, even though the classification categories that he used lacked adequate justification. This too differentiated his work from previous studies, and foreshadowed the later use of the social survey for estimating population values with some exactitude. Furthermore, although Booth's study, like most of the early social surveys, was a local study, its coverage was comprehensive—he aimed to gather information on as large a proportion of the population as was possible and especially on all families with children in the parts of London covered by the survey.

Booth was also unusual in using a team of investigators. First-hand data about the household circum-

stances of poor families were not collected directly by his research team but by what one of them, Beatrice Webb, called the method of the 'wholesale interview.' School board visitors, who entered the homes of children attending London schools, were interviewed by Booth to gather information about the circumstances of each family. Booth had printed data collection notebooks that categorized the information gained in interviews with the visitors. Great care was taken to achieve uniformity in the data collection between the different interviewers, and the information obtained was checked against other sources in an attempt to increase its reliability. The quantitative and qualitative data from the notebooks were analyzed by Booth and his staff. The published results were aggregations of the measurable and distillations of the unquantifiable. The findings had direct policy implications and contributed to movements toward social reform and old age pensions in particular.

Booth's research had important effects on the development of the social survey, independent of any influence his findings may have had, and popularized survey research. Several early US studies were derivative of Booth. And Booth's work served as a template for a large number of early social researchers.

4. *Seebohm Rowntree and A. L. Bowley*

The next major survey in Britain, Seebohm Rowntree's study of York, was conducted in 1899 and published in 1901. This further refined both the conceptualization and measurement of the phenomenon of poverty. Most important, perhaps, it used 'retail' rather than 'wholesale' interviewing; that is to say, people were interviewed directly in their own homes by members of the research team, not indirectly through reports by middle-class professionals with knowledge of individual families. This transition from reliance upon informants who could report on the circumstances of working-class people to reliance upon the response of the people themselves was a most important one. Rowntree also refined the conceptual understanding of poverty by introducing the concept of the 'life cycle,' and by showing how poverty varied between different phases of the life cycle. There were a considerable number of other local poverty studies in Britain prior to 1940, but the original studies by Booth and Rowntree, and restudies conducted in York by Rowntree in 1936 and 1951 were the most influential.

The first social surveyor to use sampling methods was Arthur Lyon Bowley in his studies of poverty in five towns, published as *Livelihood and Poverty* in 1915. This innovation, which was slow in being adopted, eventually undercut the local social survey, replacing it with the modem probability sample survey. The use of sampling in practice only emerged slowly and was first seriously taken up by US market researchers between the wars. It was used in social survey research for government and academic research only during and after World War II.

5. *Early Surveys in the United States*

Developments in the USA shared many features of this British experience. In both societies the social survey was shaped by the salience of voluntary effort, of liberal political traditions that restricted government initiatives, and of values promoting 'responsible individualism.' Thus we can speak of an Anglo-American tradition of social survey movements that shared many fundamental features. In both countries the settlement house movement provided a base for fostering social investigation. The influence of their ideas and the publicity they gave to the existence of social conditions created a more thoughtful climate for the reception of social surveys.

At the same time, the US context contained challenges not found in the British milieu. More isolated from political power, unable to draw on traditional criticisms of industrialization, and less likely to work closely with organized labor, reformers had to make the most of their middle-class resources. They also stood in a different relationship to emerging social science. By the end of the century, there was a different relationship between professional expertise and the developing skills of social investigation than in the UK, one which also had repercussions for conceptions of objectivity and of what constituted social science. In these circumstances, the social survey became even more important to middle-class reformers. For the objective data provided by the surveys were uniquely effective in mobilizing 'public opinion'—that amorphous combination of middle-class and working-class attitudes that activated politicians and labor leaders alike within the US political environment. Surveys could get action (especially when linked with sensationalist press reports) even when 'monster' meetings and petitions could not.

The social survey in the USA in the period between 1880 and 1940, while resembling and differing from its British counterpart, directly imitated Booth's work in certain respects. Florence Kelley's work on the Hull-House Maps and Papers was one of the earliest US surveys and very much in the Booth tradition. Other studies followed. The role of the settlement house movement in publicizing social conditions was not confined to poverty. Indeed issues such as child labor, the treatment of juveniles in the court system, sweated labor and poor housing conditions loomed as large if not larger in their concerns. At the state level some notable innovations were effected, for example, the establishment of the Illinois Juvenile Court in 1899. W. E. B. DuBois' study of *The Philadelphia Negro* (1899) by a young black sociologist was notable for its thoroughness and detachment.

6. The Social Survey Movement

The social survey movement, which was best expressed in the Pittsburgh Survey of 1906–9, was different. It emerged from the charity movement, and the belief among significant numbers of social workers that the roots of social problems were to be found in society rather than in the individual. The Pittsburgh Survey, funded by the newly created Russell Sage Foundation, was more in the nature of investigative journalism, with much less emphasis upon quantification. More emphasis was put on influencing public opinion. When published, a great effort was made to feed back the results of the research to the locality in which it had been carried out, by means of publicity and exhibits. This gave surveys of this type a completely different character, for they became exercises in community self-study more than scientific examinations of social questions. Indeed, its success was followed by the establishment of the Department of Survey and Exhibits at the Russell Sage Foundation, which between 1912 and 1931 supported a very large number of local surveys. The US social survey movement had run out of steam by 1930 and disappeared shortly thereafter. There were other developments, such as 'crime surveys' as an aid to administrative reform, and the country life movement and the church survey movement, but these were of little lasting methodological significance.

The geographically local social survey between 1880 and 1940 in the UK and the USA led to distinctive changes in social investigation. What distinguished Booth from Henry Mayhew, W. E. B.DuBois from Ray Stannard Baker, A. L. Bowley from R. H. Tawney, was the urge to present systematic and defensible numerical statements about the problem studied based on a large-scale data collection exercise derived from questioning individuals. Such an appeal to 'objectivity' and 'science' is one which became increasingly prominent as the twentieth century advanced. The local survey was closer to social reform and amelioration, to political action and to nonacademic institutions.

7. The Probability Sample Survey

After 1920, the social survey developed more rapidly and achieved more outstanding results in the USA than in the UK, and at the same time underwent a change in form. It is true that at the theoretical level, Britain maintained its preeminence for longer. The traffic to sit at the feet of statisticians Karl Pearson, R. A. Fisher, G. Udny Yule, and A. L. Bowley in the University of London continued until well into the 1930s. Leading US survey researchers such as Samuel Stouffer learned advanced inferential statistics from them and returned to apply those methods to good effect in the USA. At a practical level, however, the main implementation of probability sampling methods which came gradually to be used, giving the survey as a method very much greater power, took place in the USA. After Kiaer and Bowley's pioneering work, the application of sampling in national studies to provide a representative national picture may be traced to market research and opinion polling in the 1930s. From 1928, George Gallup had been successfully using probability sampling for marketing and political research in the USA. In 1936 Henry Durant established the British counterpart of Gallup's organization, the British Institute of Public Opinion (BIPO). Gallup's triumph over the *Literary Digest* in 1936 in correctly predicting Roosevelt's victory from a much smaller sample was a clear marker of the future potential of the method.

At the same time, efforts to improve social measurement were being made. During the 1920s, political scientists and psychologists, such as Harold Gosnell and L. L. Thurstone, made advances in the systematic measurement of voting and of social attitudes. Research units in government departments, one of them led by Rensis Likert, were established. Paul Lazarsfeld came to the USA from Austria as a Rockefeller Fellow, and remained there to commence survey research on mass media audiences in the mid-1930s. By the late 1930s, the basis for the development of the modern probability social survey was in place. With the outbreak of World War II and in particular the entry of the USA into the war in 1941, significant activity took place in government. The American Soldier study directed by Stouffer was important in its own right theoretically and methodologically, and for the stimulus it gave to postwar research at Harvard and Columbia. Likert's group in the Department of Agriculture became the nucleus of the postwar development of the Survey Research Center at the University of Michigan. Lazarsfeld independently widened his interest in the media to voting and the effects of mass communications in elections.

With the increases in federal government support for social science post-1945, survey research took off, becoming established in the academic world as well as in bureaucratic social survey organizations outside it. There was particularly strong cross-fertilization at centers at the National Opinion Research Center at the University of Chicago, the Survey Research Center at the University of Michigan and the Bureau of Applied Social Research at Columbia. In the UK, government was important, with the Government Social Survey remaining the main center for survey research. Other major survey research organizations and centers in Western Europe followed later. Since the mid-twentieth century, the intellectual leadership in modem sample survey research has lain in the USA, which has tended to remain in the forefront of intellectual fertility, analytic inventiveness, and methodological innovation.

Social Trauma

Social trauma is a new concept in the social sciences. It transfers a notion from the clinical psychology of individuals to the sociology of groups and cultural communities. On the social level it denotes a collectivity's response to an event that is considered to be an overwhelming and unexpected threat to its cultural identity and social order.

1. History of the Concept

Although the term trauma had been used in medical contexts before, its origin as a distinctly psychological concept is commonly attributed to Sigmund Freud. In their studies on hysteria Freud and Breuer characterized the memory of the psychic trauma as 'a foreign body which long after its entry must continue to be regarded as an agent that is still at work' (Freud and Breuer 1955 (1893–1895), p. 6). Very early Freud noticed the time delay and the possible disparity between the cause and the traumatic response: 'In traumatic neurosis the operative cause of the illness is not the trifling physical injury but the effect of fright' (Freud and Breuer 1955 (1893–1895), pp. 5–6). Freud did not yet conceive traumatic memory as a social or collective response. Instead, he refers to processes within the psychic system, in particular to the fundamental tension between instinctive drives and defensive controls. An overwhelming and threatening experience results in an indelible anxiety that is coped with by various defense mechanisms like denial, reversal of cause and effect, or projection of the evil to others.

Psychoanalysis prepared the ground, but the rise of the notion to its current use is due to its relation to Post-Traumatic Stress Disorders (PTSD) that were clinically studied and professionally treated after the First World War (shell shock) and, increasingly, after the Second World War (Holocaust survivors, war experiences, rape, violence). During the 50 years since the wars the range of possible traumatizing experiences as well as the symptomatology of trauma vastly expanded —turning 'trauma' into a key concept for the analysis of individual and collective phenomena that before had been studied under the conceptual labels of 'crisis,' 'neurosis,' 'anomie,' and 'disorder.'

2. Social Trauma as Collective Response to the Breakdown of Order

Genocide and the outburst of violence, military defeat and foreign occupation, sudden economic crisis and mass poverty, forced migration and expulsion from home—but also natural disaster and the spread of mortal plagues—are experienced as shocking events that not only cause great individual suffering, but may also result in the breakdown of social order, that is, in the collapse of the most basic 'taken for granted' social expectations. As these 'evil' events affect more than a few members of a social community, they cannot be considered as exceptional and individual misfortunes, but rather as events that affect the validity and stability of the social order itself. As a result, they erode basic trust in social institutions, in the solidarity that creates the boundaries of family, neighborhood, and country. The predictability of everyday life is suspended; ordinary time seems to stop (Neal 1998); and the social fabric is disrupted. Under the impact of the shocking event, feelings of hopelessness, apathy, fear, and disorientation spread in the community. Participation in general politics and public debates as well as economic investments and consumption decrease sharply, and crime rates increase. This sharp decline of trust and the rise of apathy and disorientation can be called a social trauma.

In distinction to individual trauma, the social trauma even extends to those members of the community who, as individuals, did not suffer from the traumatizing condition. Because social trust typically extends beyond immediate others, the distrust produced by collective trauma tends to be copied by other members of the community who are devoid of a strong personal experience of breakdown and crisis.

In this conception, social trauma is seen as a response to the sudden breakdown of legitimate social expectations and the rapid decay of social institutions and social structure. The trauma is seen as an 'adequate' or natural response to the collapse of social order, and this response can occur without a time delay, immediately after the experience of the traumatizing condition. Although there are mediating institutions and cultural patterns that reinforce and support the traumatic experience, this experience is

seen as caused by an external event or condition that is directly observable and objectively accessible. An event becomes a social trauma by its very catastrophic objectivity, that intrudes into ordinary life and resists any attempt to ignore it or to accommodate to it.

3. Social Trauma as a Construction of Collective Memory

An alternative theoretical paradigm defines social trauma as the sudden collapse of the culturally generated web of meaning that supports individual or collective identity. Because the event that disrupts the web of meaning threatens the identity of an individual or of a collectivity, it may often pass unnoticed when it happens: the mind—individual or collective—is unable to comprehend the moment when its own death may occur. Therefore, social traumas are rarely witnessed directly and immediately, but are crystallized and become available for experience only in the reconstruction of the past. It is the individual or collective memory that strives, voluntarily or forced by others, to remember and to cope with an intrusive event that crushed the social and cultural basis of identity.

This ruminating memory of a past that suddenly confronts a community with the abyss of incomprehensibility is called a social trauma. Because social traumas refer to incomprehensible or horrible occurrences, they are hard to put into narration or to represent by common images or patterns. As individual or collective identities do not refer to objects but to the subjectivity of agents, they can be named, but they escape general definitions and descriptions and so do the traumatic challenges and threats to these identities. In this respect the traumatic memory profoundly differs from the narrative memory that remembers past episodes of meaningful action. However, the narrative memory repeats the past event because it fits into the cultural patterns of the present; the ruminations of traumatic memory result from the very fact that it cannot be narrated and represented by the cultural forms at hand—it occupies our mind because it resists being integrated into our perspective on the world. The strong disturbance and disruption of the individual or collective consciousness produces ambivalent responses and fosters hysteria—obsessive anxiety and repression by denial, the fear of conspiracies and the feeling of guilt, the persecution of scapegoats and hostility towards the victims (Smelser 2001).

4. Individual and Collective Trauma

The culturally constructed trauma can appear on the level of the individual or on the level of the collective memory or on both. If individuals remember the same kind of personal traumatic memories they can—in principle at least—communicate their common or similar experiences and thus develop a collective traumatic memory as members of a generation, as a community of victims, etc. Thus the victims of rape and violence, of racist attacks or forced migration can develop a distinctive collective identity based on common traumatic experiences. But not all personal traumatic memories can be translated into the collective memory of a community. Some remain enclosed in the individual mind and body—because the individual is unable to talk about it, because no other person is expected to understand it, or because the individual trauma is framed by a collective triumph, like the victory of the nation that tends to forget the personal trauma of its soldiers. In contrast to these private and individual traumas, there are social traumas that are largely disconnected from individual experience and memory, but exist, after some time at least, only on the level of collective communication and public culture. Thus the traumatic origins of a nation, a religious community, a generation or an ethnic group can be remembered by public rituals, memorial days, and official monuments, although there may be no surviving witnesses who could claim a personal memory of the traumatizing event. Here, the continuation and reproduction of the trauma is shifted entirely from personal memory to the collective memory of a community, its social institutions, and cultural traditions. Sometimes the collective remembering of the trauma is even impeded by haunting personal memories that cannot be spoken of. After the social trauma is decoupled from personal memories, and transferred to social carriers devoid of these personal memories it can be remembered by public rituals and literature, and it has to be remembered in this way if it is not to be passed into oblivion.

Although there is hardly a traumatic memory that cannot refer to any individual suffering, the cultural construction of a traumatic past does not directly correspond to the amount of individual suffering and the actual number of victims. A victorious war may not be remembered as a trauma, although the number of casualties may exceed those produced by a war that resulted in a military defeat and that, therefore, is remembered as a social trauma. Viewed from a culturalist perspective, the social trauma is not the plain and natural result of individual suffering but its reconstruction in collective consciousness. Whoever partakes in the communicative reconstruction of the trauma can regard him- or herself to be a member of the traumatized community, regardless of whether he or she can claim personal experience of the traumatizing event.

5. Modes of Coping with the Trauma

Most analysts of social trauma agree that there are different modes of coping with traumatic memory, but not all consent to the idea that the traumatized

community has to go through a fixed sequential order in coping with the memory. Following Freud we can distinguish between the period of latency and the period of speaking out and working through, or between different responses like denial and uncoupling, reversal, and projection. In the period of latency the community is unable to speak publicly about the trauma because the personal memories are still too vivid to be soothed by public rituals. The trauma is denied or silenced in public discourse or official social representations. If the issue cannot be avoided in communication, it is decoupled from the traumatized community: the time and circumstances of victimization are regarded as being radically different from today's situation; the victims are even seen as partly responsible for their fate (reversal); the evil is projected on scapegoats or on a few unquestionably responsible individuals.

Only when some time has passed, when a new generation has entered the stage, when a large and influential group of impartial but interested observers takes part in the public debates, can the trauma be publicly addressed by political representatives and even be ritually remembered by memorial days, monuments, and museums. Collective traumas like the Irish famine or the Holocaust of the European Jews, the slavery of African Americans, or the American civil war usually take more than the timespan of a generation to be publicly remembered and recognized. Even if the social trauma can be spoken of and is publicly recognized, its representation remains mostly an issue of contestation and conflict between different generations, political camps, religious or ethnic groups. Questions as to who is to blame for the trauma and who was the most important victim imply, even for succeeding generations, closeness or distance to the symbolic center of the community and are therefore a matter of identity and interest for collective actors within this community. In parallel with these public debates and conflicts, the trauma can be transferred to specialized institutional arenas like historical research and museums, literature, or movies, where it is worked through according to the special logic of the respective institution. Finally, the trauma may be accepted by a majority of a community and become an integral part of its construction of collective identity and history. Not all communities remembering a social trauma will pass through all stages of the sequence and, frequently, different modes of coping coexist and are carried by different social groups and institutional arenas.

6. *Victims, Perpetrators and the Public Audience*

In its common usage, the concept of social trauma refers to a community of victims. The trauma of the victims resulted from a profound and unexpected denial of their claims on dignity and autonomy as subjects and cohumans. Instead, they have been treated as objects that could be traded, used, deported, oppressed, and killed. Like objects, they were considered as cases of a category deprived of a name, a face, and a place in the community. Slavery and genocide, displacement, and mass violence are the paradigm cases of this dehumanizing treatment of victims. Immediately after the traumatizing event the surviving victims, because of shame and shock, can hardly report on their suffering—they are muted and sometimes they are even isolated from the regular members of their community in special camps or asylums. It is only from a temporal or social distance that the suffering of victims is remembered, that they are recognized as subjects and symbolically reintegrated into the community. This recognition, remembering, and reintegration cannot be achieved by the descendants of the victims alone. Instead, it requires the participation of an impartial public or of a noninvolved third party who consents to this process and agrees with the cultural self-definition of victims. If a nation or an ethnic group claims the identity of traumatized victim, it remains a contingent question as to whether other nations or groups recognize this claim in a public debate.

In contrast to a vast range of research on the trauma of victims, relatively few studies center upon the trauma of perpetrators. The trauma of perpetrators results from the fact that they violated fundamental moral principles, ensuring not only the victims' status as subjects, but also their own status. Because of their shame and their ignorance, perpetrators tend to be silent and to deny the moral crisis that they have caused. In this case, even more than in the case of victims, a strong third party is required to publicly debate the victimization and insist on stigmatizing the perpetrators. Particular institutions like courts of justice, or professional experts like medical doctors, can also take this position of a noninvolved third party. Only in exceptional cases, however, is the trauma of perpetrators accepted by those who were directly and actively involved in creating the traumatizing event. Instead, it is mainly the succeeding generation and other noninvolved members of the community who can speak of the collective trauma and admit publicly to the collective guilt. Like the social trauma of victims, the trauma of perpetrators also leads to public contestations and conflicts about the question of how the boundaries of the traumatized community of victims or of perpetrators will be demarcated. It also determines who has to be included, even if he or she was not directly concerned as an individual person. In the course of this debate the social trauma of victims and perpetrators is turned into the core of a public discourse about the collective identity of the nation or of the other communities involved. As such, it tends to replace the traditional public representation of national identity that showed the nation as a triumphant or tragic hero resisting its

adversaries. This demise of heroism and the rise of social trauma as the core reference for national identity is reflected in public monuments, museums, and movies, but also by the rhetoric and the rituals of political representatives who remember the victims of the past in public.

Social Welfare Policies and Gender

In conceptualizing and defining social welfare policies, much discussion has revolved around the residual/institutional or the marginal/comprehensive distinction. This distinction is important in determining what policies are included in the term social welfare policies. Narrow definitions frequently confine social welfare policies to income maintenance programs—assistance and social insurance, and sometimes tax benefits. Broad definitions expand the policies to encompass provision of housing, healthcare, education, and an array of other social services.

The rise of the women's movement in the late 1960s and the development of women's studies prompted a re-examination of social welfare policies that focused on gender. In bringing gender into the analysis of social welfare policies, two strategies were pursued. First, the dearth of information about the impact of policies on women and differing outcomes for women and men led to an approach that primarily centered on women. A byproduct of this approach has been to make women visible in the analysis. The second strategy has stressed gender as a relational category where the inquiry explicitly deals with both women and men. Instead of making women visible, this strategy has shown how gender is involved in policies where it had previously been thought to be completely irrelevant.

A number of trends in research on gender and social welfare policies are discernible during the 1980s and 1990s. The initial emphasis on studying the impact of social welfare policies on women has been supplanted by a concern with how gender structures policies and how policies affect gender relations (O'Connor 1996). Generalizations based on the policies of a single country have given way to theory building grounded in comparative analyses (Lewis 1992; Orloff 1993; Sainsbury 1996; O'Connor et al. 1999). The first wave of theorizing was informed largely by the social welfare policies of the English-speaking countries (e.g., Wilson 1977), while a second wave reflected the experiences of the Scandinavian countries (e.g., Hernes 1987), and in the 1990s the range of countries has further expanded (e.g., Sainsbury 1999).

Comparative research has charted and attempted to explain major variations in policies across nations. The variations revealed by this research have challenged earlier generalizations derived from the experi-

ences of one nation, especially those that held specific features and outcomes were intrinsic to social welfare policies. Views on the nature of welfare policies have also shifted. In the 1970s a widespread view was that welfare policies were mainly instruments of patriarchal oppression; eventually more consideration has been devoted to the emancipatory potential of policies. This reconsideration has focused on both the unintentional consequences of policies that have benefited women or have undermined traditional gender relations (Pateman 1988) and the implications of different policy constructions (Sainsbury 1996). A parallel shift has occurred in theorizing about women's relationships to welfare policies. Previously women were regarded as the objects of policy, while in the 1990s research explored women's agency in shaping welfare policies (Skocpol 1992; O'Connor et al. 1999; Sainsbury 1999). Finally, a weakness of many earlier studies was their exclusive preoccupation with gender. Gradually, however, more attention has been paid to how gender intersects with race, ethnicity, and class in determining social entitlements (e.g., Williams 1989; Quadagno 1994).

Employing the lens of gender, scholars have called in question the definition of social welfare policies. They have been critical of narrow definitions of social welfare policies that focus solely on income maintenance programs. Feminist researchers have objected to the pivotal position of paid work in the analysis of social welfare policies. The emphasis on paid work takes men as the norm, and it obscures the importance of unpaid labor. This focus has also downplayed services and care. The incorporation of gender into the analysis has also substantially altered the research agenda on social welfare policies. Priority has been assigned to four areas of investigation: (a) the gender division of welfare, (b) the gendered construction of welfare policies, (c) welfare policies as an ordering force in gender relations, and (d) gender and explanations of welfare policies.

1. *The Gender Division of Welfare*

Social welfare policies—especially assistance and social insurance benefits—traditionally have been conceived as instruments of social protection and redistribution. At a minimum, social welfare policies should protect individuals from poverty and relative deprivation. More ambitiously, the policies aim to promote the general welfare and well being of the population. Mainstream studies evaluating the redistributive effects of social welfare policies largely have been gender blind. The units of analysis have been social class or occupational groups, households, generations, regions within a country, or nations. By contrast, feminist research has focused on the gender division of welfare and how the construction of policies has produced differences in the benefits received by women and men. The differences concern both access to benefits and benefit levels.

With this focus, studies have mapped out the gender composition of beneficiaries of social welfare policies. Early research found that a disproportionate number of women were beneficiaries, but these studies examined the English-speaking countries. When other countries were included in the examination, a different pattern emerged: men predominated as beneficiaries. In these countries social insurance schemes whose eligibility was based on labor market participation were central to social provision; men also collected family allowances as part of these schemes. Even when the allowance has been paid to the married mother, eligibility has been determined by the father's rights as an insured employee. Although men predominate as beneficiaries in some countries, households headed by women are more reliant on social welfare benefits than male headed households because men command a larger share of earnings. In many cases, especially when benefits are earnings related, the benefit levels of men are higher than those of women.

Studies have also documented disparities in the poverty rates of women and men. An initial finding was the feminization of poverty in the US in the mid-1970s. Although the poverty rates of women and men in the US had dropped substantially since the 1950s, the composition of the poor had changed dramatically so that women were overwhelmingly in the majority. In many countries the poverty rates of women are higher than those of men. However, among the industrialized countries, the poverty rate of women in the US ranks as highest, and the gender poverty gap is also the largest (Casper et al. 1994) (see *Poverty and Gender in Affluent Nations*). Nonetheless, there are countries—such as Italy, The Netherlands, and the Scandinavian countries (Sainsbury 1999)—where differences in the gender poverty gap are small or women have lower poverty rates than men. In summary, empirical research on the gender composition of beneficiaries of income maintenance programs in the US revealed an anomaly: women outnumber men as beneficiaries but their poverty rates were much higher than men's. This anomaly, together with cross-national variations, spurred theorizing about the sources of gender inequalities in benefits and the gendered construction of social welfare policies.

2. *The Gendered Construction of Social Welfare Policies*

Much analysis has concentrated on how gender norms and meanings are encoded in social welfare policies. One line of theorizing emphasizes that the gendered construction of social welfare policies results in dual welfare. This involves a two tiered system of social benefits, consisting of a 'masculine' set of programs geared to individuals who make claims as earned

rights based on labor market participation and a 'feminine' set of programs oriented to households that claim benefits to compensate for family failures. Underlying the two-tier benefit system are gender norms that define the home as a female sphere and outside work is a male sphere. Women thus claim benefits on the basis of tasks in the home and their benefits are familialized, while men's claims are primarily labor market related and individualized (Fraser 1989). Another variant of the thesis puts more weight on the dual labor market as the source of dual welfare (Nelson 1984). In any event, according to the dual welfare thesis, women and men are segregated into different types of social welfare programs: women rely more heavily on means-tested or income-tested benefits, and men on social insurance schemes. Assistance programs and social insurance are further differentiated in terms of benefit levels, political legitimacy and administrative intervention in private lives so that the quality of women's and men's social rights diverge greatly.

The importance of the dual welfare thesis is that it calls attention to the gender differentiation of social provision and specifies the differing implications for women and men. However, the thesis has been criticized on several grounds. The thesis is a generalization based primarily on social welfare policies in the US, but gender differentiation in entitlements varies in different ways across countries. Even with regard to the social welfare policies of the US the dual welfare thesis is misleading in one significant respect. The emphasis on predominance of women claiming means-tested benefits overlooks that many more women receive social insurance benefits on the basis of their husband's entitlements in the US (Orloff 1993; O'Connor 1996).

In studying the gendered construction of income maintenance policies, Orloff (1993) and O'Connor et al. (1999) distinguishes between gender differentiation and gender inequality. Gender differentiation is related to separate programs for labor market and family needs, shaping claims to benefits: women claim benefits as wives and caregivers, while men make their claims as family providers and earners. Gender inequality pertains to the differences in the benefit levels of women and men. The legislation of most countries ascribes less value to wifely and motherly labor than to paid work, resulting in gender inequalities in benefit levels. Spouse benefits and additional allowances for dependents have generally been a percentage—often around half—of the regular benefits received by men. Furthermore, the traditional division of labor between the sexes assigns domestic work and care to women, which has limited their ability to qualify for more lucrative benefits as earners.

Another important starting point has been an examination of the inscription of male breadwinner family model in social security legislation, taxation, and employment policies. As distinct from the discussions on dual welfare and gender differentiation, which look at income maintenance schemes, the male breadwinner model has been applied to a wider range of policies. Lewis and Ostner (1991) argue that this model has been built into social provision in varying degrees, and they classify countries as strong, moderate, and weak male breadwinner states. Subsequently, the weak male breadwinner category has more appropriately been termed the dual breadwinner model (Lewis 1992) or the dual earner model. A major contribution of this typology was to emphasize that the strength of the male breadwinner model as reflected in social welfare policies varied across countries. Nonetheless, the typology does assume a single basic underlying dimension, and that social welfare policies are informed by the male breadwinner model. A major criticism of this analytic construct is that it is based on two principles of entitlement: (a) as breadwinner or earner and (b) as the dependent of the breadwinner. Thus, it overlooks other bases of entitlement and it conflates women's entitlements as wives and mothers (Sainsbury 1996). The problematic nature of the typology is also revealed by its inadequacy in analyzing the entitlements of single mothers. Hobson (1994) has documented substantial variation across strong breadwinner states—such as The Netherlands, Germany, and Britain—in terms of social welfare policies providing mother only families with an acceptable standard of living.

Jenson (1997) has criticized Lewis's emphasis on the nexus between paid work, unpaid labor, and welfare, stressing that unpaid work is not a synonym for care. Jenson calls for making care central in theorizing about the gendered construction of welfare policies. More specifically, this would involve an analysis of 'the gender division of labor among caregivers, gender differences in the capacity or need to pay, and the gender consequences of different institutional arrangements for provision' (1997, p. 187).

Sainsbury (1996) has developed a framework based on two ideal types: the male breadwinner model and the individual model. This framework formalizes and expands the dimensions of variation implicit in Lewis's typology. The dimensions are: the nature of the familial ideology, the basis and unit of entitlement, the taxation system, employment and wage policies, and the organization of care work. It also clarifies an alternative policy model to the male breadwinner model. A major drawback of this analytic scheme is that it limits the models to two contrasting ideal types, but its dimensions of variation have proved to be a useful point of departure for empirical analysis and theory building.

A final development has been to theorize the gendered construction of social welfare policies in terms of gender regimes or gender policy regimes. More precisely, a regime consists of values, norms and rules, thus providing a normative or regulatory framework that influences behavior. A policy regime re-

directs the analysis from behavior to policies. Analogous to the notion of a social policy regime that emphasizes that a given state–economy organization provides a logic of it own, a gender policy regime is a given organization of gender relations associated with a specific policy logic. The organization of gender relations is determined by principles and norms (gender ideologies and practices) that specify the tasks, obligations, and rights to the two sexes (e.g., Sainsbury 1999).

All of these frameworks have furnished insights into the gendered construction of social welfare policies. Studies employing the frameworks have often challenged earlier classifications of countries' policies that neglected gender, leading to revisions and new understandings. Analyzing Britain, The Netherlands, Sweden, and the US, Sainsbury (1996) found strong divergences in the policy patterns of the four countries, and that the clustering of countries was quite different from how countries are bracketed together in analyses using mainstream typologies. In several mainstream studies Sweden and The Netherlands have been grouped together as countries with generous social welfare policies, but the gendered construction of Dutch and Swedish policies represented opposite poles, especially prior to the mid-1980s. Similarly, a study comparing the inscription of gender in the social welfare policies of Denmark, Finland, Norway, and Sweden revealed sharp differences between Norway and Sweden—the two countries that most closely approximate the social democratic welfare regime in mainstream literature (Sainsbury 1999). Orloff's examination of income maintenance policies in Australia, Britain, Canada, and the US led her to conclude that the way gender norms are encoded in these programs undermines the coherence of the liberal welfare regime (O'Connor et al. 1999).

3. *The Impact of Social Welfare Policies on Gender Relations*

Conceiving of social welfare policies as an ordering force in gender relations rivets attention on the implications of policies for reinforcing or undermining the traditional division of labor among women and men in the family and society. Theorizing on how traditional gender relations have been inscribed in policy frameworks has underlined that policies and benefit structures perpetuate existing relations and the subordination of the female sex.

Whether policies actually have these effects, however, is a matter for empirical research. In other words, it is necessary to distinguish between the gendered framework of policies and policy outcomes. Several discussions have conflated policy models and behavior. Women's labor market participation rates have been taken as evidence of a particular policy model but without examining whether policies are in place to enable or limit women's employment. For example, married women in the US have entered the labor force in massive numbers, despite income tax policy and social security measures that are biased heavily in favor of the traditional family with a single earner.

Both the principles underlying entitlement and the redistributive effects of policies have major implications for gender relations. The basis of entitlement is a crucial aspect in determining the impact of welfare policies on gender relations and whether policies buttress women's dependency on men or enhance their autonomy (Sainsbury 1996). At one extreme, women's entitlements as wives and means-tested benefits reinforce married women's dependency. If women are entitled to benefits and services as wives, i.e., their entitlement derives from their husband's rights, their dependency within the family is exacerbated. In this situation a woman's rights are jeopardized by divorce or may be contingent upon a marriage test—a specified number of years of marriage that guarantees entitlement. In means tested programs, the family is usually the unit of benefit; and need is established on the basis of family income. In these instances, benefits are familialized. Benefits based on the principle of care occupy a middle position. Although these benefits may buttress traditional gender relations, they recognize the importance of care and thus alter notions of deservingness. The principle of care also erodes the importance of marriage. Compared to entitlements as wives, benefits based on the principle of care enhance autonomy. Benefits whose eligibility is based on labor market participation or citizenship/residence have greater potential to increase personal autonomy. Even if women workers are likely to receive lower benefits compared to men workers, benefits based on labor market participation are an independent source of income and they can lessen married women's dependency on benefits based on their husband's rights. Finally, benefits based on citizenship or residence accord equal social rights to women and men. This basis of entitlement neutralizes marital status as a criterion of eligibility. It not only equalizes benefits between women and men but also between unmarried and married persons—and husband and wife. Likewise, citizenship/residence as a basis of entitlement makes no distinction between paid and unpaid work, which enhances the social rights of persons with weak attachments to the labor market.

Regardless of the basis of entitlement, welfare policies have redistributive effects that can alter the resources of women vis-à-vis men. In turn, changing resources between the sexes can affect gender relations. In countries where married women receive their own retirement pension, even though entitlement was based on their husband's rights, wives' contribution to family earnings has on average been higher compared to other couples. An even more striking example is that income maintenance programs, public provision of

affordable child care services, and/or tax benefits enable women to leave an unhappy relationship or marriage and strike out on their own. In most industrialized countries lone parent families are increasing, and social welfare policies help to make this family form a viable option (see *Lone Mothers in Affluent Nations*).

Policies that promote women's access to paid work are also vital to changing gender relations (Orloff 1993; O'Connor et al. 1999; Sainsbury 1999). Policy measures enabling employment provide both earnings and individualized social benefits, weakening or eliminating dependence on the male family provider. Women with high earnings have substantial bargaining power within the family, and this leverage can alter how partners divide unpaid domestic work among themselves.

While most analysts have empirically investigated the outcomes of policies on gender relations, Fraser (1994) adopts a normative stance and asks how can social welfare policies promote gender equity. She presents three policy models and evaluates the strengths and weaknesses of each model in terms of achieving gender equity. The first is the universal breadwinner model where policies promote women's employment so that the breadwinner role becomes universal—and is no longer reserved for men. In the caregiver parity model, public policies support informal care so that the role of caregiver is on a par with the role of breadwinner. The policies of the earner–carer model support both roles but simultaneously aim at eliminating gender differentiation. This involves policies that aid women in becoming earners and men in becoming carers (cf. Sainsbury 1996, 1999).

4. Gender and Explanations of Social Welfare Policies

In studies emphasizing the gendered construction of policies, gender relations themselves or the prevailing gender ideology are often a primary explanation of the particular form that social welfare policies take. Kessler-Harris (2000), e.g., conceives of gender as a historical agent, as an ideational force that configures and sustains systems of cultural representation. She has examined how gender mediates policy discussions between interest groups in providing or denying legitimacy to their proposals in the areas of social insurance, taxation and labor legislation.

Other studies have emphasized the role of women's political mobilization and the institutional setting in shaping social welfare policies. In attempting to explain the late introduction of social insurance schemes and the early adoption of maternal welfare measures in the US, Skocpol (1992) underlines the importance of the state in politicizing gender identities that lead groups to mobilize, the correspondence between the form of political organizing and the structure of the state that allows or thwarts a group's influence on policies, and policy legacies.

Along similar lines, O'Connor et al. (1999) suggest an explanatory framework made up of the following elements: social movement mobilization and orientation, political party configuration, the political opportunity structure, and the institutional context and legacy. The movement's orientation involves its political strategy to achieve gender equality, specifically the movement's attitude toward the state and its gender ideology, whether emphasis is on sameness or differences between the sexes. Political party configuration refers to the strength of left, center and right parties. The political opportunity structure is defined as access to the state institutions, the stability or fluidity of political alignments and relationships to allies and support groups. The institutional context and legacies encompasses the structure of the state, bureaucratic capacity, and the industrial relations framework (see also Sainsbury 1999). In short, many scholars have abandoned the view that women are simply the objects of policy, or 'policy takers' (Hernes 1987, p. 35). Instead research has focused on, first, women's power resources—organizational forms, discourses and strategies—in a variety of national and historical contexts and, second, how these contexts limit or promote women's capacities to influence social welfare policies.

D. Sainsbury

Social Welfare Policy: Comparisons

Welfare policy comparisons have been a prominent feature of macro-level social science research since the 1970s. Dominated by political scientists and sociologists, most studies focus on the advanced industrial democracies. The literature is guided by two overarching questions: One, how do we explain the rise of welfare states and their diversity? Two, how do variations in policy design affect welfare distributions? The overview that follows will treat the two questions separately.

It has been difficult to arrive at clear-cut answers to either question because of statistical overdetermination: the number of rival explanations often exceeds the number of cases that can be studied (see also *Quantitative Cross-national Research Methods*). There are, moreover, conceptual difficulties because scholars do not always compare and explain the same phenomenon. Some compare social policies (say pensions), others welfare states, and still others welfare regimes, and the difference is rarely made clear. The presence of a set of social policies does not automatically imply a welfare state which, following Marshall (1950) implies social entitlements as a matter of citizenship, comprehensive risk coverage, commitments to full employment, and active reduction of inequalities. The welfare state is also an ideological construct, a means to inculcate broad solidarities and national integration (Briggs 1961, Flora 1986). Rather than speaking of more-or-less welfare statism, the literature has moved towards typologies of kinds of welfare states. Many scholars use the concept of welfare regimes to denote the broader complex, or mix, of social welfare provision between state, market, and families (for a discussion, see Esping-Andersen 1999).

1. Conceptualizing Welfare Policy Models

Early quantitative comparisons, such as Cutright (1965) and Wilensky (1975), compared welfare policy differences through national social spending levels. This was challenged on validity grounds (spending may not reflect welfare effort, and it tells us little about what kind of welfare is being produced and for whom). As a result, research in the 1980s and 1990s has been greatly concerned with the precise meaning and content of social policies and the welfare state. Most conceptualizations begin with Marshall's (1950) emphasis on the rights of social citizenship, and programs are then compared in terms of how strong are rights, to what extent do they lessen market dependency ('decommodification'), and to what degree do they segment or unify citizens (Flora and Alber 1981, Korpi 1983, Baldwin 1990, Esping-Andersen 1990). More recently, reflecting the rise of feminist scholarship, new dimensions, such as the inherent gender bias, or the degree of women 'friendliness,' have been added (Hernes 1987, Sainsbury 1996, Orloff 1993, O'Connor et al. 1999).

The greater conceptual attention to policy content and objectives has led to a keener appreciation of the qualitative differences between national welfare systems. Drawing upon Titmuss (1958, 1974), there emerged a voluminous literature on welfare state typologies, initially focused on welfare *state* models, such as in Furniss and Tilton (1979). As research expanded to the interplay between state, market, and family welfare provision, emerged classifications of welfare *regimes*, such as the liberal, conservative, and social democratic trichotomy in Esping-Andersen (1990) and further refinements, such as Castles' (1993) notion of a unique Antipodean 'wage earners' model,' the identification of a specific, unusually familialistic and patronage-based Mediterranean model (Castles 1995, 1998, Esping-Andersen 1999). Some feminist writings have proposed typologies based on the strength of the conventional male breadwinner assumption (Lewis 1993). With the exception of the latter, most typologies classify nations rather similarly: a Nordic group, distinguished by its universalism, comprehensive coverage, generosity, and a strong pro-women bias; an Anglo-Saxon group, characteristic for

its residual public provision, its targeting of benefits, and its encouragement of private welfare; a Continental European group, which stands out for its corporativistic status-segmented social insurance; and, more controversially, a Mediterranean (and, possibly, East Asian) group primarily distinguished by its strong accent on familial welfare provision. As Castles' (1993) points out, these typologies resemble 'families of nations,' nation-clusters with a deep common historical tradition.

2. Explaining Policy Divergence

The great vitality of comparative welfare state research comes from its address to central theoretical issues in the social sciences. Existing reviews of the literature usually distinguish two broad explanatory thrusts: the convergence thesis that derives from theories of industrialism and modernization, and the 'politics matter' thesis that derives from theories of conflict and power mobilization (Shalev 1983, Esping-Andersen and van Kersbergen 1992, O'Connor and Olsen 1998). In addition, some theorists emphasize the process of nation building and democratization (Flora 1986, Flora and Alber 1981), nations' position in, and response to, the world economy (Cameron 1978, Katzenstein 1985), and also the policy-making role that state bureaucracies exert (Skocpol and Amenta 1986).

2.1 The Modernization Thesis

The earliest systematic welfare state comparisons were chiefly inspired by the theory that industrialization (accompanied by urbanization, the rise of efficient bureaucracy, and by demographic aging) erodes traditional social protection mechanisms, such as the family, and makes necessary public responsibilities. As nations industrialize, they will also converge because social risks become more similar, and because the functional necessity of public social security becomes pressing. Main exponents of this thesis include Rimlinger's (1971) as yet unrivaled historiography of the roots of welfare policy in Europe, America, and Russia, and Wilensky's (1975) quantitative demonstration that rich countries gradually converge in terms of the share of gross domestic product (GDP) spent on welfare. Wilensky provided no direct measure of political variables, and his conclusions were therefore challenged by adherents of the 'politics matter' position.

2.2 The 'Politics Matter' Thesis

The resurgence of conflict theory in the 1970s provoked two antitheses to the modernization paradigm. One was Marxian and quite functionalist, arguing that the modern welfare state was not an egalitarian response to new needs, but rather a mechanism, however contradictory, of sustaining the legitimacy of capitalist economies (Gough 1979, Offe 1972, O'Connor 1973). This perspective has produced little systematic empirical comparison.

The second antithesis argues explicitly that 'politics *does* matter' in the sense that the nature, scope, and objectives of a welfare state depend primarily on the balance of political power between 'left' and 'right.' Since it is well established that the roots of welfare policy are generally conservative, as in the case of Bismarck, this position is mainly concerned with welfare state variations in mature industrial democracies. The premise is that the collective resources of wage earners can, through parliamentary democratic means, be mobilized so as to establish a kind of welfare state that effectively circumscribes the distributional logic of markets and the decisional power of capital (Korpi 1983, Stephens 1979, Castles 1982, Hicks 2000; for an overview, see O'Connor and Olsen 1998). This thesis lies close to classical social democratic theory and its postulate that a parliamentarian transition from capitalism to democratic socialism is possible (Stephens 1979, Esping-Andersen 1990). For this reason, it is often labeled the 'social democratic' model of the welfare state. Since Sweden is the epitome of social democratic power and achievement, the thesis has been criticized for its inherent 'Swedo-centrism' (Shalev 1983).

The power mobilization hypothesis has given rise to a very large but also conceptually and methodologically heterogenous literature which, cumulatively, makes a strong case in favor of the underlying thesis (the implications of methodological design are examined in Janoski and Hicks 1994). Whether studying individual social programs, such as pensions, sickness benefits, or labor market policies (Myles 1984, Palme 1990, Korpi 1989, 1991, Kangas 1991), or more broadly 'welfare states' (Stephens 1979, Korpi 1983, Esping-Andersen 1990, Huber et al. 1993, Hicks 2000), the impact of the political strength of the left is quite robust.

Still, the 'left power' explanation is questioned by several authors working within the 'politics matter' tradition. Some argue against a simple, linear left-power effect, arguing that real politics are premised on enduring party coalitions. Postwar Christian Democracy, for example, has been seen as a functional equivalent to labor movements, producing similarly generous welfare states (Wilensky 1981). Esping-Andersen (1990, 1999), Huber et al. (1993), Castles (1994) and, especially, van Kersbergen (1995) demonstrate, however, that Christian Democracy produces welfare states that may be generous, but which are also strongly corporativistic in design, very 'familialistic,' and transfer-biased. Also Baldwin (1990) questions the simple left-power thesis because what

are usually imputed to be social democratic achievements (such as universalism) arose from entirely different political quarters (agrarians in particular). In a unique synthesis of the modernization and politics-matter theses, Pampel and Williamson (1989) suggest that all governments, left or right, will favor welfare expansion because of population and, thus, median-voter aging.

2.3 The Impact of Globalization

Since there is a strong coincidence between a country's size, its degree of economic openness, and the scope of its welfare state, the correlation between left power and welfare statism may be causally spurious (Cameron 1978, 1984, Katzenstein 1985). The point is that small, export dependent economies are prone to international shocks and need to be adaptive. This favors the emergence of centralized, consensual social pacts between the social partners, but also strong social guarantees to workers in order to assure their compliance.

Put in this way, the causal link between power and welfare state outcomes becomes ambiguous. It may be that powerful labor movements *and* generous welfare states both derive from global economic pressures. It is difficult to sort the real causal order because the number of countries we can compare is so few.

2.4 Nation-building and Democratization

The puzzle that any 'politics-matter' explanation faces is that the first social reformist steps were usually taken by conservative, sometimes anti-democratic forces, often with the explicit intent of containing working class mobilization (Rimlinger 1971, Flora and Alber 1981). Social policy *per se* cannot therefore be a robust indicator of left-political achievements. The issue is really one of historical sequence. Most would agree that the historical roots of social policy are closely connected to late nineteenth-century nation building, a means to sustain the established order in the face of emerging social, linguistic, ethnic, or religious cleavages. The 'politics-matter' paradigm, in contrast, is concerned with the epoch of actual welfare state construction in the postwar era of full democracy.

2.5 The State-centered Thesis

Modernization theory stresses the functional necessity of efficient bureaucracy for welfare state development because, without it, effective taxation and administration of complex distributional programs is simply impossible. Bureaucracy, once erected, may also come to play an active role in decision-making and thus determine policy evolution. Heclo (1974) maintained that Swedish and British welfare policy, although originally rather similar, eventually parted ways because of inherently different bureaucratic policy-making styles and traditions. The independent powers of public officials in framing key decisions have also been emphasized especially by Skocpol (1992). This, so-called state-centered thesis has proven difficult to test empirically against rival arguments. As a result, empirical applications are limited to select case studies (such as Skocpol 1992) that are difficult to generalize, and a handful more systematic, quantitative studies (Korpi 1989).

3. The Consequences of Welfare States

The literature on the consequences of welfare state differences is, possibly, as huge as the former but the protagonists tend to be different. For one, there is a longstanding tradition in economics to study the micro-economic effects of social policies on work incentives as well as its macro-economic effects on inflation, savings, unemployment, or economic growth. This literature, which, in any case, is rarely comparative, will not be reviewed here (for an overview, see Danziger et al. 1981, Atkinson and Mogensen 1993, and Barr 1993).

Closer to our concerns are studies that examine the impact of welfare state design on distributional outcomes. Most scholars agree that the focus should be on life chance dynamics, but this has been thwarted by data scarcity. The literature has therefore concentrated on cross-sectional analyses of income inequalities, poverty and, in recent years, also on gender equality.

3.1 Poverty and Income Distribution

The conventional assumption has been that equality is positively and linearly related to welfare state generosity. This was implicit in Wilensky (1975), and some early attempts at empirical verification produced positive and significant correlations (Hewitt 1977). Until the mid-1980s, however, robust comparisons were hampered by severe problems of cross-national data comparability. Only with the advent of the Luxembourg Income Study (LIS) and, later, European Union data collection, did genuinely comparable income data become available.

Most studies of the redistributive effects of welfare states (or single social programs) are based on a comparison of pre- and post-transfer/tax distributions (a representative example is Smeeding et al. 1990; an extensive review of the literature is provided by Gottschalk and Smeeding 1997). A few studies attempt to study more explicitly the impact of *types* of welfare states or social policies on distributional outcomes (Ringen 1987, McFate et al. 1995).

Quantitative comparisons come to a surprisingly consensual view: the larger the welfare state, the greater the degree of equality in net disposable income,

and the lower the rates of poverty. A less obvious finding is that welfare states targeted to the truly needy do not result in more poverty reduction than does the universalistic approach to social protection (for a review, see Gottschalk and Smeeding 1997). Reflecting the paucity of comparable panel data, studies on poverty and inequality *dynamics* are, so far, few. Preliminary evidence does, however, suggest that comprehensive, generous welfare states are substantially more able to guarantee against long-term entrapment in poverty or welfare dependency (Burkhauser and Poupore 1993, Duncan et al. 1993). Most studies conclude that targeted, means-tested policies create strong poverty traps.

The finding that comprehensive, universalistic welfare states are more redistributive than those favoring heavy targeting has provoked debate about the precise mechanisms involved. Some argue that income tests create stigma and lower the take-up rate. With their notion of the 'paradox of redistribution,' Korpi and Palme (1998) argue that the basic reason lies in crowding out of private welfare that ensues from comprehensive, universalistic policy: limited welfare states nurture private welfare plans which are extremely inequality producing.

3.2 Gender Inequality

The study of welfare policies and gender inequalities is primarily focused on family-related social policies, such as caring services and leave schemes; what Bradshaw et al. (1993) call the family benefit package. Specific policy variations are linked to either welfare state typologies (as in the case of Gornick et al. 1997, Gustafsson 1994), or to male-breadwinner typologies (Lewis 1993, Mclanahan et al. 1995, Sainsbury 1996), and welfare systems are often ranked in terms of their degree of 'women friendliness' (for an overview, see O'Connor 1996). A number of rather clear-cut empirical conclusions have emerged. One, day care provision is a powerful precondition for women's economic independence, for their capacity to harmonize careers and family, and also for safeguarding against poverty in single parent families (Gornick et al. 1997, Gustafsson 1994). A second finding is that welfare systems that grant women independent entitlements both lessen dependency and augment gender equality (Mclanahan et al. 1995, Sainsbury 1996; O'Connor et al. 1999).

G. Esping-Andersen

Socialism

A workable definition of Socialism, subject to the qualifications offered below, would be this: 'Socialism is an economic organization of society in which the material means of production are owned by the whole community and operated by organizations that are representative of, and responsible to, the community according to a general economic plan, all members of the community being entitled to benefit from the results of such socialized planned production on the basis of equal rights' (Lichtheim 1971, p. 113).

Leszek Kolakowski's survey (1978) calls attention to 'the surprising diversity of views expressed by Marxists in regard to Marx's so-called historical determinism.' However, what is 'surprising,' is not this diversity—which becomes much wider if we examine not Marxism in particular, but socialism in general. The surprising thing is Kolakowski's pontifical belief that faced with it he could 'schematize with precision the trends of twentieth century Marxism' (1978, Vol. I, pp. 6–7). His failure to attain such precision serves as a salutary warning to anyone attempting to characterize the broader and much more 'diverse' terrain of socialism, of which Marxism—nineteenth and twentieth century Marxism—is itself but a 'main current.' In what follows, which will (in Wittgenstein's words) 'strive *not* after exactness, but after a synoptic view,' attention will be paid to Cole's admonition: that 'the most that can be attempted is the discovery of some

central core of meaning, present with varying additions in all or most of the manifold uses of the word (socialism)' (Cole 1967, Vol. I, p. 1). This entails sensitivity to the shifts in meaning socialism has undergone since its inception; only beneath these shifts can a substratum of meaning emerge.

1. Capitalism, Socialism and Democracy

The word 'socialism' first appeared in Robert Owen's *Co-operative Magazine* in 1827, '*le socialisme*' in the Saint-Simonian journal *Le Globe* in 1832. It meant a projected alternative sociopolitical system—this was still offered as a definition of 'socialism' in the 1933 OED—not a political movement or demand. Early socialist doctrine contained little about the proletariat, the class system, labor, or revolution. While John Stuart Mill's *Principles of Political Economy* accordingly distinguished socialism and communism as theories, not political movements, Marx and Engels's *Manifesto of the Communist Party* of the same year (1848) identified communism as a movement that would render socialism, so defined, beside the point because it was merely a theory—utopian, that is because it was impracticable. It was communism, not socialism, that carried with it the idea of revolutionary struggle and human agency; a new and better society could not be wished or legislated into existence by benevolent doctrinaires, but had to await the advent of a politically conscious, class-based labor movement. This was a key shift in the coordinates, not just of communism, but of socialism. It too had now to be, not just thinkable, but feasible. After the failure of the 1848 revolutions, communism ceased for many years to be practical politics, yet some time was to pass before Marx and Engels consented to having their cause described as 'socialist' (Lichtheim 1969, p. 209). They did so because socialism had become not just a doctrine but a movement. Thereafter, 'Marxism created that distinctively German socialism which was soon to assume an ideological dominance over most of the continent, driving the older forms of socialism before it as chaff before the wind' (Cole 1967, Vol. I, p. 222).

The second key shift in the coordinates of European socialism occurred in 1917, when, against all the odds, communism in its Leninist form arose as a clear alternative to democratic socialism—the same democratic socialism that had itself, against all previous odds, survived World War One. Both authoritarian communism and democratic socialism laid claim to a lineage deriving from Marx; but they had little else in common. Twentieth-century communists showed no reluctance to clothe their particular doctrines in the broader mantle of socialism. The locutions, 'Union of Soviet Socialist Republics,' 'socialism in one country,' 'socialist realism,' 'socialist internationalism' (in its twentieth-century Soviet version, which meant subservience to the foreign policy of the USSR), the fact that after World War Two the East German Communist Party was officially called the 'Socialist Unity Party'—all these are instances of synecdoche, if not the sheerest verbal trickery. We should not allow them to addle us into thinking, languidly, that all twentieth-century communists were socialists, whereas not all socialists were communists. There were in the twentieth century not just non- but also anti-communist socialists aplenty, socialists actively and vociferously opposed to communism, from the very moment when such opposition first became possible, at the Berne International in February 1919, when adherence to democracy was reasserted as a prerequisite for socialism (Cole 1967, vol. IV, pp. 292–9). The socialism that survived World War One to become part of the European political landscape had had as its prerequisite not democracy but capitalism. Socialists had long been in the forefront of the struggle for democracy. (Indeed, socialism was weakest in those countries, the US and the UK, where it was a less powerful force in the struggle for democracy than it was on the European continent.) In Cole's words, Liebknecht, Bebel, and Kautsky in Germany, Guesde in France, indeed, most socialist stalwarts in Europe before World War One 'felt that they had no *right* to make the revolution without the backing, or at least the assent, of the people. They thought of the proletariat as being, or as in the process of becoming, the majority of the people; and they envisaged the mass conversion of the proletariat to the socialist cause as a necessary preliminary to the revolution' (Cole 1967, Vol. III, pp. 946–7). This democratic perspective was not necessarily reformist or purely parliamentary; democratization was also meant to encompass work relations and trade union structures, and could scarcely have avoided doing so. What the Second International socialists rightly feared was war; the solitary success of Russian Bolshevism in 1917 was as little expected or forseen as its eventual collapse was to be in 1989.

2. Marx, Marxism and Socialism

Marx casts a longer shadow over the history of socialism than anyone else—not because every socialist agreed (or was even very familiar) with what he said, but because, all the same, his presence proved impossible to ignore. It is in this sense that Marxism can be called the *lingua franca* of socialism (Cole 1967, vol. I, p. 379). Without Marx, we would still have had revolution as a word and as a concept, as the French and the Americans had put revolutionary change on the political agenda during the eighteenth century, and we would have had capitalism, socialism, communism, and (thanks to Babeuf) the proletariat too. The

celebrated opening line of the *Manifesto of the Communist Party* was designed to call the reader's attention to 'the specter haunting Europe,' to invoke, not invent, communism. It is no doubt easier to imagine a world without Marx than a world without revolution, capitalism, communism, and socialism. But in the world we actually inhabit, all these still have to be seen through Marx. He may not have coined these terms, but he decisively set his seal on them. They still cannot properly be discussed without bringing him in. Marx contributed enormously to the vocabulary of socialism (class, class struggle, class war, class consciousness, ideology, alienation, the commodity, forces, relations, and modes of production, exploitation, contradiction, and crisis). Even though 'socialist and communist movements (took) up some aspects of Marx's theory and discarded others, even this selectivity (was) carried out in Marx's name' (Gilbert 1981, p. 270).

Yet much that was carried out 'in Marx's name' was attained without much knowledge of what he had written. The revisionism debate (at the turn of the twentieth century) that almost tore apart German Social Democracy and the Second International, was about Marxist 'orthodoxy,' but was conducted in an astounding ignorance of Marx's writings. While practicing politicians commonly regard themselves as having more immediately pressing concerns than questions of textual fidelity, these same questions were never ignored among Marxists—although the theoretical corpus to which socialist stalwarts appealed was not necessarily made up of Marx's writings. The problem was not that a canon of basic texts failed to emerge. (To the contrary, textual fidelity was adhered to tirelessly—and, at times, tiresomely.) It was that the canon as it developed was not so much derived from what Marx had written as it was constructed around what little of Marx was available in published form. Historical materialism—it still amazes people when they learn that this term was not Marx's own—had its basic texts long before the first appearance in any language (during the 1930s) of so basic a text as Marx and Engels's *The German Ideology*. These texts included Franz Mehring's *On Historical Materialism* (1893), G. V. Plekhanov's *The Development of the Monist View of History* (1895), Antonio Labriola's *Essays on the Materialist Interpretation of History* (1896) and Karl Kautsky's *The Materialist Interpretation of History* (1927). Even though Marx in some sense inspired these books and others like them, what he had to say eventually needed to be disentangled from their arguments. It could in no way be directly encountered through them or explained by them (Thomas 1991, pp. 32–3).

3. *The Varieties of Socialist Experience*

Even if Marx was more known about than known, the fact remains that by the end of the nineteenth century a politically-oriented, class-conscious European socialist movement had emerged in his name; and by this time the word socialist meant what it still means today, a social and political doctrine and a political movement or system. In view of this latitude of meaning it is scarcely surprising that 'socialism' has come down to us in social science literature as a noun qualified by an adjective—as in 'utopian socialism,' 'scientific socialism,' 'state socialism,' 'revolutionary socialism,' 'evolutionary socialism,' or (until recently) as 'actually existing socialism,' or again (today) as 'market socialism.' Similarly, the adjective 'socialist' can be employed as a pendant qualifying or characterizing an abstract noun, as in 'socialist internationalism,' 'socialist economics,' 'socialist realism,' or 'socialist feminism.'

The above-listed collocations—the inventory is illustrative, not exhaustive—are not just convenient subdivisions, but serial attempts at spot-welding that can readily be arrayed in historical sequence. 'Utopian socialism,' as we have seen, dates from the 1830s and 1840s, 'Fabian' or 'evolutionary socialism' dates from the late nineteenth and early twentieth centuries, 'Guild socialism' dates from the period between the two World Wars, and 'actually existing socialism' dates from the latter days of Soviet communism. 'Socialist internationalism' peaked, then bottomed out dramatically, in the period before 1914; 'socialist realism' (like 'socialism in one country') belongs to the Stalinist period in the Soviet Union; 'socialist feminism' to Western scholarship of a later date. To array these composite terms historically in order to arrive at the meaning of their least common denominator, socialism, is not to pigeonhole them arbitrarily, nor yet to proceed reductively, if it is borne in mind throughout that each instance of spot-welding affected the coordinates of its successors.

More specifically, anarchism, syndicalism and their offshoots (whether revolutionary or not) are kinds of socialism that were defined and elaborated against state socialism (Thomas 1980); Engels in 1875 contrasted scientific with utopian socialism (even if the latter was largely a spent force, the former was to enjoy some shelf-life well into the twentieth century); Lenin defined Bolshevism, then communism as he understood the term, against the parliamentary, reformist socialism of the pre-1914 German SPD (and by extension the Second International); this reformist socialism had itself been elaborated in contradistinction to the revolutionary socialism that appeared to have had its come-uppance at the time of the Paris Commune (1871). Lenin's successors proceeded to counterpose socialism in one country against the socialist internationalism the First and Second Internationals had espoused. Overall, these developments do not add up to a tidy, formulaic picture. Yet there is a subtle patterning in the carpet. Positions and tendencies throughout the history of socialism were debated, articulated and defined in relation to other, pre-existing socialist positions and tendencies.

Socialism: Historical Aspects

1. The Meaning of a Group of Ideas

The term socialism designates a set of doctrines which originated in the nineteenth century and intended to criticize the actual social organization and values (capitalism, bourgeois society, individualism) in terms of equality. Socialist ideologies contributed to the formation of a cultural world, linked mainly with the lower classes, composed of political parties and other associations which had as their goals projects of future societies and programs calling for collective action. In fact, the term socialism must comprehend a certain number of doctrines, political opinions, ideological vocations, and feelings of rebellion and emancipation. Today, the way of considering this problem is far from the acceptance of a hierarchy and of a teleological vision, which was established essentially by the Marxist tradition and defined the history of socialism as a successive progression from 'precursors' and 'utopians' to a more and more 'mature' conception of socialism.

Socialism, in its origins, both from a linguistic and conceptual point of view, was part of that rich patrimony of ideas which originated with the French revolution and at the same time was linked to the social experiences evolving from the industrial revolution. During the nineteenth century, in continental Europe, the term was also used to define social and economic doctrines advocating an intervention of the State in the economy and/or a change in the regime of property from the individual to the collective property of the means of production. In the twentieth century, the socialist movement was widely permeated by political conflicts on how to achieve a socialist society (reforms or revolution) and also regarding what kind of model such a society should be based on. Marxism was the most influential doctrine in the constellation of socialism, both for the role it played in the history of socialist culture and in the contribution it gave to the creation of socialist political movements. The Russian revolution claimed to have created 'socialism,' and in spite of the criticism regarding the lack of democracy in this realized socialism, the idea continued to spread from Europe to other continents. Between 1917 and 1989, the term was also used to designate an actual social and economic system. According to the American Marxist Paul M. Sweezy (1949), 'the term "socialism" means a social system which is differentiated from other social systems by the character of its property relations. Thus socialism properly belongs to the same species as capitalism and feudalism.'

There is a general agreement regarding the difficulty of defining and the complexity of the term socialism. This depends on the fact that the word has always designated an overall group of very complex ideas, that these ideas have been subjected to changes in time and space, and that by placing the history of the word in a crossroads of intense ideological polemics it has often changed its meaning. From the word used by Pierre Leroux in France during the 1830s to define an anti-individualistic political and social doctrine close to saintsimonism, up until the socialist ideology of the New Left in the 1970s, the road this term and concept have followed has been long and tortuous.

2. The Origins of Socialism

When, between 1847 and 1848, Marx and Engels wrote the Communist Manifesto, the majority of their contemporaries would not have been able to precisely define the difference between socialism, communism and democracy. Even though it was the democracy which smelled 'of blood and barricades' (Rosenberg 1962), the upper classes perceived the different socialist

'schools' as a threat to property and order. These 'schools' had a common root in the political thought and in the social experience derived from the French and the industrial revolutions. At the same time, however, they were their most severe critic. In France and England, the term socialism was used for the first time in the 1820s and the 1830s essentially to designate economic orientations contrary to individualism. In the period preceding 1848 various political and cultural centers appeared which could be traced to similar trends of thought.

In France, the first equalitarian ideas after the Revolution came from the Jacobin left and are those of F. N. Babeuf, which are known to us above all through the literary works of F. Buonarroti. Babeuf tried to achieve his ideals (elimination of private property and the establishment of a society based on community property) by means of an attempted insurrection which failed. Later on, in the midst of political reflections after the French revolution and the experiences of the Napoleonic era, C. H. de Saint-Simon imagined a future society based on science and work. His ideals influenced utopian French socialism affirming an optimistic confidence in technical and scientific progress. Fourier, who was also a critic of contemporary society, proposed the construction of a harmonious society organized around the Phalanstères which were kinds of self-supporting communities promoted by free and happy men, who were able to achieve equality between the sexes and to satisfy any material necessity.

In England, differently from in France, the new doctrines were diffused in a framework of relative legitimacy. Robert Owen, who was at the same time a utopian socialist and a social reformer, tried to build communities based on the collective property of the means of production and on noncompetitive social relationships. He also succeeded in creating workers' organizations based on the same ideals, which contributed to the formation of cooperatives and unions. It was the first time—and this experience will eventually have consequences in the Chartist movement—that socialist ideas became integrated with real workers.

Both in France and in England, the 1830s marked a change in the political climate and in the panorama of social conflicts. The artisans, impoverished by the processes of industrialization, and the alienated wage workers living on the borderline of a survival level were sensitive to the ideas of socialism which had circulated before the revolutions of 1848. It was a type of socialism containing strong elements of solidarity, cooperation, emancipation, and social justice. The experiences of the previous years, thanks to the influence of these first groups of organized workers, were able to put together a first set of common ideas: unjust profit, equal salary, the presence of two worlds in opposition or—as Fourier said—of an 'upside-down world' in which a small number of privileged people were opposed to a multitude of those condemned to unrewarding work.

The spontaneous struggles of the workers, which in France both preceded and followed the July Monarchy, led to a politicization which exploited the socialist theories. Auguste Blanqui was a central figure in this context. Influenced by the theories of Saint-Simon, Fourier, and Babeuf, Blanqui was above all a conspirator: he not only created several secret societies of republican-socialist inspiration, but he was also a tireless revolutionary activist. From certain points of view, Blanqui embodies the prototype of the 'professional revolutionary' who believed that the victory of the proletariat could be reached by a determined minority ready to conquer the power and use dictatorial methods. At the same time Proudhon was one of the first to underline the libertarian aspects in the criticism of capitalism, and in his essay *What is Property* (1840), he condemned in particular the oppressive function of the state and private property. In England, between 1837 and 1848, the Chartist movement developed as a reaction to the electoral reform of 1832 and the enforcement of the Poor Law which had further worsened the living standards of the working classes. The People's Charter, which constituted the basic document of Chartism, claimed the right to universal male suffrage and considered a just electoral reform as the principal instrument for the achievement of social reforms in favor of the workers. Though Chartism was harshly repressed and completely disappeared after 1848, it constituted an important experience because of the connection which was established between social struggles and politics in that decade.

This connection had its most profound roots in the changes which took place in the lives of the lower classes between the end of the eighteenth and the beginning of the nineteenth century. In France during the Revolution the *sansculottes* were mostly concerned with the problems of subsistence, instead now there was a different attention mainly focused on the social dimensions of work, wages, and on the opposition between the bourgeoisie and the proletariat. At the same time in England the social changes brought about by the industrial revolution stimulated a connection with the radical traditions of the past in the new social reformers. In both cases ideas of emancipation, equalitarianism, and restoration of a usurped legality were diffused among the lower classes; these popular ideas coexisted and at times integrated extremely well with the works of intellectuals and political leaders. However, socialism in its entire existence was not able to offer a unanimous solution to the problem regarding the ways through which a more just society could be achieved. In fact, socialists in the period preceding 1848 were often romantic and bizarre figures (Hobsbawm) who relied more on the intrinsic rationality of their ideas rather than on a collective action to bring about the realization of their projects.

3. Marx and Engels

The revolutions of 1848 constituted a very important chronological fracture in the history of socialism. In the first place because the so called 'social question' was brought to the attention of the public due to the intense participation of socialist workers and artisans in the social struggles in the spring of that year, and particularly in the 'June Days' in France. This situation contributed to transforming the social question into a political one and it began a process in which socialists and communists became more and more different from democrats and republicans. In the second place, a shift began which later would be called a swing of the center of gravity in the development of socialism from England and France towards Germany. In preceding years the German culture had not been completely absent from the discussions regarding socialism; however, differently from other countries, intellectual reflections were isolated from the experiences of the working class.

Now, between 1847 and 1848, along a tortuous road which brought them from the study of German classical philosophy to the Bund der Kommunisten, Marx and Engels published a brief pamphlet which would come to represent a milestone in the history of socialism, the *Communist Manifesto*. In this pamphlet, political activism was combined with an analysis of the social relationships created by the development of capitalism. The *Manifesto* defined the ways through which the bourgeoisie and proletariat became social classes irremediably opposed not only on the basis of moral choices, but above all on the basis of economic and social laws which dominated the history and the existence of mankind. Communists were gifted with the scientific awareness of the development of human society and were able to guide the proletarians in acquiring their class consciousness and in achieving a classless society in which the exploitation of men against men would be eliminated. Marx and Engels not only affirmed a 'scientific' conception of socialism, they also intended to close the doors on that world of socialist ideas which had preceded them. In the third part of the *Manifesto*, they made a distinction between reactionary socialism, conservative or bourgeois socialism, and critical-utopian socialism and communism. What Marx and Engels accomplished was the creation of an arrangement of other nuclei of the socialist culture in a historical perspective in which their 'scientific' doctrine overcame the preceding socialist traditions and ended up by expressing a negative criticism on half a century of socialist culture. Instead, the importance of the old socialism actually consisted in its capacity to exploit other cultural and political trends circulating among the lower classes: anticonformism, dissent, radical jacobinism, and democracy. Without this cultural atmosphere, Marx and Engels probably wouldn't have had such a large public following. If it's true, according to an intuition of Durkheim, that socialism was not only a 'miniature sociology' but also a 'cry of pain,' it's just as true that its roots should be sought for not only in the traditions of 'scientific socialism' but also in the culture—e.g. in the beliefs, in the feelings, in the religion—of the lower classes and of the rank and file militants.

In the 20 or 30 years following 1848, the doctrine of Marx and Engels became 'marxism.' Marx published the first book of the '*Capital*' in 1867, and both Engels and he were engaged in an intense journalistic activity which accompanied the development of a first international nucleus of an organized workers movement. It's the so-called First International, inside of or next to which, new groups and doctrines came about in conflict with those of Marx and Engels. One of these groups were the anarchists, followers of Bakunin in the rural areas of Latin and Slavic Europe; others were the Russian populists, and both showed the extent of the influence exerted by the International Association of Workers; and their activism also showed the richness and complexity of socialism. In March 1871, groups of internationalists with different political origins gave birth to the Paris Commune, which Marx and Engels considered a first experience of the proletarian dictatorship. Around that date, even though a bloody repression concluded the experience of the Paris Commune, nuclei of political subjects were formed in all of Europe and through a complicated game of conflicts and unification would eventually give origin to the different socialist parties. Principally in France and Germany the working class movements will become efficient bearers of the socialist culture and will stimulate emulation in groups and organizations in other countries.

4. The Diffusion of Socialism

Beginning in 1889, the process of the formation and expansion of socialist parties as well as an incredibly varied body of organizations, associations, unions, and cooperatives which accompany them assumed a rapid and intense rhythm. A type of socialism developed in which Marxism consolidated its central role. However, it was a type of Marxism remote from the cold reasoning of Marx and Engels. Though Karl Kautsky, principal exponent in this phase of the expansion of Marxism contributed in defining it as 'scientific socialism,' it was an ideology not far from the mechanistic features of positivistic common sense. The idea of 'natural necessity' (*Naturnotwendigkeit*) so widely present in the Marxist texts and documents which exalted the automatism in the transformation of the means of production, influenced the mentality of rank and file giving them the certainty of the breakdown of the capitalistic system and the birth of socialism. The 'scientific' aspect of this conception of the past, present, and future of the society ended up by creating a certain 'rationality of history.' Thanks to

this faith in the future, the rank and file—according to Gramsci—think that they are only 'momentarily defeated,' but that 'the force of things will work for them in the long run.' Socialism became the ideology of the socialist parties and the mixture of its components became even more enriched. According to H.-J. Steinberg, along with Marxism other components must be considered as a part of the socialist ideology of the German Social Democracy: these were, pragmatism, anti-intellectualism, social Darwinism, the idea of the predictability of the final victory, and other ideas which could be found on uncertain grounds between the common sense of the lower classes and the vulgarization of Marxism.

Socialism ended up by assuming a worldwide dimension. The Socialist International (which Lenin later called the *Second* International, when he was creating the *Third*) was not only the association where general political questions were discussed or agreed upon (participation or non participation in left wing bourgeois government coalitions, to call or not to call for a general strike, etc.), but it was also the place where other aspects of the socialist mentality and culture such as internationalism, pacifism, and solidarity were expressed. It is difficult to distinguish between the diffusion of socialist ideas and the force of attraction exerted by the major socialist parties. Certainly the socialist or social democratic parties were the most efficient means for the circulation of socialist ideas in the period of the Second international. But also the ways political cultures and ideologies reacted against socialism might have played a role in the process of the diffusion of socialism and Marxism. It was in this period that the integration of socialist parties in the European political systems took place and at the same time a complex cultural effort aimed at legitimizing the socialist presence developed. Precisely because the historical dimension of the socialist culture was an integral part of its way of confronting the present, it produced a noteworthy effort directed towards the ennoblement of its past in some traditions of the European culture (from Plato to Campanella, from Thomas More to Thomas Müntzer). More in general, the study of the past of the working class movement and socialism was inextricably connected with the political passion in the works of Jaurès and Mehring, of Compère-Morel and Grünberg. Socialism influenced the historical culture also in the academic field and at the end of the nineteenth century there were many interpretations regarding the end of slavery in the Ancient world or the class struggles in medieval towns which echoed Marxist canons. The legitimation of the socialist parties provoked tensions and oppositions. However, in general at the beginning of the twentieth century it became an accomplished fact.

In reality, besides the brilliant electoral successes which consolidated the idea that the final victory was guaranteed by a slow and continuous increase of votes, socialism had at the same time stimulated and won over the intellectuals. From the American populist writers at the beginning of the century (the so called muckrakers) such as Jack London or Upton Sinclair to those writers such as the Russian Maksim Gorki, there are many artists who look towards socialism with sympathy: the old Emile Zola or the young Italian painter Carlo Carrà whose first work in 1901 was a portrait of Engels. But above all, socialism involved intellectuals and scholars in the field of the social sciences. They were challenged to interpret this key aspect in the life of contemporary societies and sometimes looked at it with sympathy. From Vilfredo Pareto to Benedetto Croce, from Werner Sombart to Emile Durkheim, each had to take a stand regarding socialism, and this meant that in a period of increasing alphabetization, newspapers, and public opinion attributed remarkable importance to this problem.

It is at this time that the political and cultural panorama of socialism became more complicated. The more socialist parties became actors in the political systems, the more intense the discussion within the party regarding the use of parliament, the role of social reform, the ways of passage toward a socialist society became. In general, during the period of the Second international, socialist thought tried to define the principal problems of the contemporary society. It radically criticized liberalism, unwillingly supported parliamentary democracy, tried to interpret imperialism, organized and coordinated the social protest, and created or unified complex labor organizations. The socialist world, however, was only partially accepted as a legitimate subject in the society: it had developed an attitude of 'negative integration,' and produced a 'subculture' closed within itself (Roth 1963). At the beginning of the century, the nonsocialist public opinion let out a sigh of relief upon seeing the relative availability of moderate socialists to enter and take part in coalition governments oriented toward social reform. However, even the most hopeful among them couldn't have predicted that in August 1914 internationalism, one of the milestones of the socialist culture, would have found itself in the midst of a crisis because of the outbreak of the war and that this crisis would have created a new irremediable rift opposing socialists against socialists.

5. *Socialisms in the Twentieth Century*

During the war, the conferences of Zimmerwald and Kienthal sanctioned the formation of socialist groups which criticized the failure of internationalism. Among them, the Bolsheviks played a particularly active role. After the outbreak of the October revolution the Bolsheviks promoted the formation of a new international organization which they called the Communist International. From that time on, the relationship between socialists and communists be-

came in certain extreme situations one of violent confrontation. Paradoxically right when the Bolsheviks were building 'socialism,' they identified 'socialists' as their principal adversaries. The development of 'socialism in one country' accompanied a progressive erosion of the democracy in Russia and caused social conflicts which were resolved only with the use of repression. In the period of the '*entre deux guerres*' socialists and social democrats (the two names coexist, the first in Latin Europe, the second in Germany and Scandinavia) strongly criticized communism, affirming the refusal of violence and exploiting the role of democratic institutions. After the experience of fighting together against fascism, socialists and communists split again during the cold war when the formation of 'socialist' or 'popular' democracies accompanied once again the implementation of repressive policies in Eastern Europe. In the East and West two opposing socialist worlds were formed: in the West, the German social democracy modified its identity by eliminating Marxism from its own political culture; in the East, Marxism was subjected to further dogmatic changes and was definitely transformed into Marxism–Leninism. After the Second World War the geography of socialism underwent a complex transformation. The crisis of colonialism and the anticolonialist tradition of the socialist movement influenced the formation of currents of socialist thought in several non-European countries. The Communist international had already exerted a worldwide influence outside the European boundaries, from Mexico to China, from Peru to Bengal but it was a simple center–periphery relationship. Starting with the beginning of the 1950s, autonomous socialist nuclei appeared especially in the Near East and in some colonies of sub-Saharan Africa. One of the examples was the so called 'African socialism' which had as its essential component the idea of a noncompetitive and nonindividualistic development with the objective of integrating religious, ethnic, and racial differences. In the 1960s and 1970s, the two different models of socialism continued to clash; on the one hand, democratic socialism, represented by political parties and experiences in coalition governments in Western Europe, on the other hand, the Soviet model. At the end of the 1980s, following an internal economic, political, and social crisis of enormous proportions, 'realized socialism' in the countries of eastern Europe ceased to exist, and with it the whole idea of socialism in the rest of the world underwent a crisis.

In the same way that it was so difficult at the beginning of the nineteenth century, it is just as difficult to offer a satisfying definition of socialism two centuries later. Anti-authoritarian opinions, nonindustrialist conceptions of nature, the desire to defend great humanitarian causes and civil rights have come back from a remote past to be seen again in the foreground, while the passion for equalitarianism and social justice shows continuity with the socialist traditions. The perspective from which these traditions were looked at has long been fairly ambiguous: often, in fact, the historians of socialism were also militant socialists, and political options have influenced the reconstruction of the past. The integration of the history of socialism in the academic environment has allowed scholars to look back at this subject with a certain detachment and has directed a special interest towards the place which socialist ideas have had in the culture of the lower classes and towards the role socialist doctrines and movements have played in the formation of contemporary political systems. Today an international socialist organization exists, socialist parties exist, and policies considered socialist exist. Their identity, however, no longer consists of a general conception of the world and of history, nor in allegiances or beliefs. Instead it consists of general cultural orientations aimed to control public expenditures in complex societies, directing resources towards citizens with lower income; in other words to extend the welfare state. Pragmatic options have substituted secular religions.

Socialist Law

Socialist law, as an actual legal order, was a major legal family whose members possessed similar characteristics. The common features of the legal systems of the Soviet Union and communist East-Central Europe resulted from the use of socialist law in maintaining communist-party dominance over state and society. Yet the law in the various socialist states differed, too, not only because of modifications in the forms of domination but also because Soviet legal solutions were imposed on diverse cultures and societies.

The ideological legacy of Marxism–Leninism is expressed in the concept of socialist law. According to Marx, law was the will of the ruling class provided with statutory validity. Certain socialist (socialistic) theories of law have emphasized the importance of law in class domination. These theories served to legitimate communist rule. Other socialist (mostly Western) theories envisioned a normative system that reflected social equality and solidarity, that is, a theory of law based on social justice.

Socialist law as the positive legal system in communist countries was understood by its proponents as the expression of the will of the working class (or, when class struggle was less emphasized, of the 'toilers'), and it was an instrument of class struggle as well as a tool for building communist society. In the early years of the Bolshevik Revolution, workers' revolutionary legal consciousness was deemed the source of applicable law. Given the totalitarian roots of the legal system, to what extent the norms of the communist state fit into any concept of law remains a fundamental problem. If law is a social phenomenon or institution that differs from its environment, is socialist law to any extent autonomous? And, is it law at all?

1. *Stages in the Development of Socialist Law*

Socialist law changed over time. It served totalitarian regimes whose efforts were not always successful. State socialism was totalitarian in the sense that it attempted to construct all-embracing state control over every sphere of social life in the service of a single goal. In the early years of the socialist revolution and during certain periods of Stalin's rule, physical control and repression through brute force played the crucial role in this attempt to achieve total social control. It followed that law as a tool of social management or one that limits government action in accordance with its own specific logic could not exist. Law was not a serious consideration for the revolutionary mindset. This disregard was facilitated by Marx's belief that there was no place for state and law in the classless society. But Marx also believed that the transition leading to the classless society would be long; and he expected that law, in socialism, would contribute to the extension of equality under the law. Lenin argued for a dictatorship of the proletariat 'based directly upon force and unrestricted by any laws.' In the postrevolutionary period, the communist-party position was uncertain regarding the future of law. Yevgeny Pashukanis, the leading authority on communist legal theory, wrote in 1928 that law was a temporary system dictated by commodity relations. Once socialism had eradicated commodity relations, legal forms would also disappear.

In the 1930s, law (not only criminal law) was structured as an unrestrained authorization, and even a command, to intervene in anything and everything. Such calls to uncircumscribed, coercive intervention transgressed the limits of legal forms. The 1930 joint decree of the Central Executive Committee and the Council of People's Commissars of the USSR, which empowered local authorities to 'take all necessary measures … to fight kulaks,' would hardly satisfy any definition of law. But legal forms continued to exist even after the planned economy was fully developed. And even during the oppressive Stalinist regime, legal forms were employed at least for show-trial and propaganda purposes. Law remained an important internal and external tool of legitimation as exemplified in the Soviet Constitution of 1936 (known as the Stalin Constitution). Law served total repression, in the 1930s, in the sense that it reminded people that they could be brutally handled for no apparent reason and without any protection from other state institutions.

As communist-party oppression neared anarchy, unlimited power turned against the elite and their supporters. Totalitarian disregard for the specific needs of the economy and other areas of social activities drifted into dysfunction. Stalin himself 'brought law back in.' But the promised legal stability had 'nothing to do with the legal restraint on power, and it coincided with the period of greatest repression.' The system moved 'from lawless repression to repressive law' (Krygier 1994). Officially socialist law was proclaimed the most developed form of law in history as it served the most developed social formation (communism). It provided socialist legality, a qualitatively superior alternative to bourgeois rule of law. In reality it often served show-trial and other propaganda purposes only, as exemplified by the Stalin Constitution.

Laws enabled the direct repression of Stalin's Great Terror, although the mass-scale extermination (the purges, the gulag, etc.) was based on action that presupposed a disregard of promulgated legal norms (trial-procedure rules, evidence). This is not to claim that the 'disregard' was not officially sanctioned and ordered: disregard of the then-existing official law was a systemic component of the totalitarian use of power. The resulting destruction of social and individual resistance to communist authority, the irrevocable stamp of fear in almost every citizen, served in the

remaining half of the twentieth century as the foundation of the repressive order, which would afford to make use of less coercive laws.

After Stalin's death, in 1953, the communist elite reverted to a certain level of legal formalism, by and large for their own protection. This was achieved by a duplication, of sorts, of the normative system. The legal authorities had strictly observed secret rules regarding actions affecting members of the communist *nomenklatura*: to proceed against one of its members required authorization from the proper body within the *nomenklatura*. The *nomenklatura* followed its own 'rule of law', which did not include the right to a hearing of the concerned. The legalistic turn had a certain spillover effect on the rest of the population. Increasingly, law became less directly coercive and punitive and, at least in some of the satellite states, in matters of secondary importance it no longer depended fully on politics. On the other hand, law was recognized as a system that provided structure to a bureaucratic state capable of economic centralization. The copying of Soviet solutions resulted in less damage to legal forms in the East-Central European states than in the Soviet Union because the use of brute, Stalinist force lasted for shorter periods in these states and because Western legal traditions existed in some of them.

The relative autonomy of law was officially recognized, beginning in the 1970s. For reasons of regime legitimation it was overemphasized to disguise a poorer reality of limited autonomy. Nevertheless, the formal characteristics of modern law (abstractness, general nature of commands, etc.) survived, although in simplified and distorted forms. The instrumental use of law served a bureaucratically ossified institutional politics. The official doctrine emphasized that the autonomy of law could be relative only vis-à-vis the economy, which determined all forms of social life. 'Legislation, whether political or civil, never does more than proclaim, express in words, the will of economic relations' (Marx 1976). In reality neither the economy nor other social relations were respected, and only specific concerns of power and domination mattered, as understood by the communist leadership. Law remained a tool of the planned economy, and it served the deliberate changes of the planning system.

Law was declared the engineering device that helped organize people in their building of communism. Revolutionary law, though an instrument of class struggle, had an element of internal legitimacy as it served social (class) justice (through murderous revenge, expropriation, and redistribution). In the instrumental understanding of socialist law moral considerations became irrelevant. Instrumentalism was also distorted, however, as 'relative autonomy' allowed only very limited respect for the characteristics of the tool. Legal dogmatics or consistency requirements were easily skirted. Yet there were actual elements of independence in law simply because the political system could not generate a unified will. There was competition within the communist political elite, which contributed to at least superficial respect for legal forms. Moreover, law-enforcement organizations had a vested interest in legalism, and to the limited extent that they played a role in party politics, law became a point of consideration. To the extent that the communists needed efficient state machinery they needed law as an instrument of control over the state bureaucracy (see Sect. 4). Law was important insofar as centralization required uniformity and unity of action.

2. *The Structure of Socialist Law*

Socialist law was understood as an ideological superstructure, and its provision were subject to ideological scrutiny. Law (its provisions and understanding) had to be politically correct as understood by whatever ideological line the communist party touted. The ideological roots and functions of socialist law led many commentators to the conclusion that it was a mutation of natural law. It was argued that it originated in a set of doctrines or expectations that were above the law. Even the vulgar Marxist claims that law as superstructure reflects economic realities might have been interpreted as being in the natural-law tradition: it was the mystical economy with its 'objective law' that determined law. Socialistic traditions of social justice also show structural elements of natural law. Max Weber criticized these socialistic tendencies to material justice as detrimental to the formal, rational qualities of law.

Socialist legal systems, as they existed in state-socialist regimes, were positivistic and functioned as positive legal orders. The prevailing definition of law (legal system) was that it was the hierarchically structured sum total of state-made norms. The profound departure from promulgated norms and principles occurred not because of the observance of some kind of higher law. On the contrary, the departure was the result of changing secret orders, commands, and expectations emanating from the communist-party leadership and secret services. Of course, once the external political intervention becomes routine or even institutionalized, one can argue that there is no more law in the sense of normative, predictable expectations; hence socialist law (at its worst) does not fit into any notion of law.

Socialist legal systems, in principle, were strictly hierarchic. Statutes (parliamentary enactments) were of absolute supremacy, while constitutions offered only guiding perspective and basic rules of state organization. Law had to originate from the people's representatives; therefore, judicial lawmaking was ruled out as ideologically unacceptable, after the early revolutionary period. Statutes were supreme because they were enacted by parliament, which was held to be

the supreme state body. The rigid position on legal origins reflected the dominant nineteenth century German and French views and a simplification of Rousseau. Each socialist regime institutionalized some kind of small and reliable body within parliament (often called a presidium). The presidium had full power to act on behalf of parliament, which convened infrequently. The presidium had the power to amend existing laws. Decrees were subordinated to statutes. In theory, decrees were to serve exclusively for the execution of statutes. But in reality, substantive issues were often determined at the level of executive decrees. Officially courts were restricted to pure application of the law. However, a number of practical issues were determined by guiding principles of supreme courts. *Stare decisis* was unknown in this system; lower courts were bound to follow interpretations of higher courts. This was imperative given the informal control over the judiciary (see Sect. 4).

3. *Substantive and Procedural Institutions*

The centralized socialist management of the economy and social life was suspicious of any expression of autonomy. The priority of 'social interests' (or 'society's interests') defined the legal system. No autonomy (in the sense of self-determination) was permitted, and legal structures enabling or protecting autonomy were pruned even from private law. The traditional continental divide between public and private law was refuted as bourgeois legality. As Lenin stressed: 'We acknowledge nothing as "private." For us *everything* in the province of economics is in the domain of *public law* and not of private law … . Hence our task is … to broaden the right of the state to abrogate "private" contracts.' In practical terms this meant not only the denial of privacy and sanctity of contract but also the primacy and special protection of state property. Depending on the period, private property and private initiative were either prosecuted, prohibited, or greatly restricted, at best. Property consisting of the 'means of production' was restricted even where it was permitted (as in the German Democratic Republic (GDR), or, as far as land was concerned, in Poland). 'Social interests,' determined by the state, were favored above all other claims. Restrictions on personal freedom went beyond etatist concerns. Freedom of movement and residence was limited, and, at least in the Soviet Union, where the czarist tradition survived, freedom of internal movement was subject to administrative approval.

Speech and press freedoms were permitted only in the interest of workers, which resulted in institutionalized or informal but total censorship. Personal choices and alternatives were limited or prohibited (including, in education, health, profession, sexual identity, and the like). State control over the individual was extended to the intimate, private sphere. Decisions regarding family relations were subject to intervention by the *Prokuratura* (State Attorney's Office). Abortion was not an issue of self-determination but a matter of demographic or workforce politics, although certain social compromises were observed in this context. In Hungary, the nearly unlimited access to state-funded abortion was the result of an official repudiation of coerced demographic policies. In other countries, like Russia, abortion as the primary form of family planning derived from a total disregard for human dignity.

The legal restrictions imposed on the general population went hand in hand with the award of privileges for supporters of the regime, although only certain privileges were codified (e.g., access to higher education to family members of committed regime supporters). Privileges were not absolute. They were the reward for loyalty to the system. But the ordinary, loyal citizen (contrary to the privileges of the *nomenklatura*) had no title or claim to privileges, which, when bestowed, were an act of grace and goodwill. The discretionary distributive powers of the public administration were used to favor the politically loyal (or, at least, to punish the suspect). This was the case, for instance, in the assignment of public housing. During the less-dictatorial periods of state socialism, these discretionary methods of allocating goods and services were the primary tools of social control. Social control through the discretionary application of law put society in a condition of permanent dependence.

4. *Administration of Justice*

The contribution of the administration of justice to the restriction of liberty varied historically. During the Stalinist terror, courts served as theaters of repression and injustice. In less dramatic times, the administration of justice promoted etatism and protected the interests of the communist party. Most administrative decisions could not be appealed in court, although in Hungary and Poland, as a rule, there was the possibility of appeal against administrative decisions, except those involving the more sensitive issues of military and police administration.

As to judges, in the formative revolutionary years of socialist power, the legally trained personnel of the previous regime were replaced with incompetent but politically trustworthy laymen. The basis of revolutionary justice was the revolutionary consciousness of worker-judges. After World War II, in the Soviet-dominated satellite states the 'democratic attitude' of lay assessors played a role in politically charged procedures. In more settled times, judges received formal legal training but worked in personal and organizational dependence on court presidents. Courts were technically under the control of the

minister of justice. These courts were not structured to be independent, and the existing political control further increased the likelihood of 'telephone justice'.

Socialist legal theory emphasized the key role of the *Prokuratura* in the administration of justice. The organizational design of the Soviet *Prokuratura* was inherited from the czarist administration. It was a select, centralized body; procurators served in total subordination to their superiors, in what was a quasimilitary organization. They were much better paid than judges. The *Prokuratura* was in charge of criminal prosecution, representing the state in court, but it also routinely supervised the activities of the state administration. Lenin considered the *Prokuratura* the bulwark of socialist legality. He knew that a centralized state power could not afford any particularism, and all local, particular normative systems represented serious deviance. Normative particularism was especially dangerous if it originated in state bodies. As Lenin wrote to Stalin 'legality cannot be legality of Kaluga or the legality of Kazan but must be one single all-Russian legality.' Thus the task of the *Prokuratura* was to 'see to the establishment of a truly uniform understanding of legality.' The supervisory powers of the *Prokuratura* included the authority to ask for ordinary and extraordinary review of court decisions, even when it was not a party in the case it sought to review. Ironically, the fear of localism resulted in minimal protection for the population: the central bodies had an interest in mobilizing local populations against local authorities, and they encouraged denunciation of local (nonpolitical) abuses to the extent that they deviated from centrally authorized injustice. The dependence of citizens on local services was attenuated in the name of central law. Rules of procedure aimed to protect the material and political interests of the state, and allowed for paternalistic intervention in private litigation. The procedures followed simplified continental models that had traditionally existed in the given country. The inquisitorial nature of the traditional continental criminal procedure was further aggravated by Soviet solutions regarding the admissibility of police-gathered evidence.

In civil matters judges were required to establish 'objective justice' and were not bound by parties' motions. The paternalistic nature of continental civil procedure dramatically increased, resulting in further dependence, as far as the parties were concerned. On the other hand, the simplifications and limited access to court yielded cheap and relatively swift administration of justice (where courts were available at all). Civil litigation rates were stable, and the most common type of litigation was divorce related. Criminal litigation (except when criminal justice was used as a tool of class struggle, in the 1930s and 1950s, stabilized at low level. Criminality was limited because of the efficient social control exercised by the oppressive state mechanism.

Socialist Societies: Anthropological Aspects

Socialist (also known as communist) societies constitute a class of twentieth-century societies sharing two distinctive features: the political dominance of a revolutionary—usually a Communist—Party, and widespread nationalization of means of production, with consequent preponderance of state and collective property. This definition excludes societies governed by socialist or social-democratic parties in multiparty systems, such as the Scandinavian welfare states. It includes the Soviet Union, the People's Republic of China, and (for some part of their histories) the East European countries, Mongolia, North Korea, Vietnam, South Yemen, Cuba, Nicaragua, Ethiopia, and Mozambique.

Socialist societies came into being with the 1917 Bolshevik Revolution and the establishment of the Soviet Union. Others founded later by various means (revolution, conquest, or annexation) all reflected the

influence—both negative and positive—of the Soviet model created under Lenin and Stalin. All employed extensive coercion and central control, yet they increased living standards, access to housing, employment, education, and medical care. Although they instituted new hierarchies, they also promoted gender equality and improved life-chances for many disadvantaged people.

1. Research on Socialist Societies

For much of the twentieth century, social science understanding of these societies was politically circumscribed. Their own scholars were under strict Party control; nonetheless, invaluable knowledge came from dissidents (e.g., Bahro 1978, Casals 1980) and from scholars in countries with strong reform movements (e.g., Kornai 1980, Wesolowski 1966). In Western Europe and the US, political and economic hostility to communist principles distorted thinking about socialist societies as epitomized in the concept of totalitarianism, which overstressed the importance of terror and top-down control. In all Western social science disciplines, impediments to on-site fieldwork hindered understanding. This situation improved in the late 1960s, for Eastern Europe, and the 1980s, for the Soviet Union and China, as *détente* and the impetus for technology transfer produced an infrastructure for intellectual exchange. The result was analyses that displaced totalitarian models to explore the societies' inner workings, with greater attention to phenomena such as kinship, ritual, the mobilization of labor, and the exchange of gifts and favors, as well as more subtle treatments of political economy (e.g., Humphrey 1983).

2. Political Economy and Social Organization

Although they varied widely in economic development (from industrialized Czechoslovakia, to agricultural China and Cuba, to pastoral Mongolia), most societies that became socialist lagged behind the advanced industrial countries economically; all embarked on programs of state-led development through central planning. The following description of their political economies emphasizes 'classic' socialism prior to the reforms introduced at various times, and draws on research in both agricultural and industrial settings in China, the Soviet Union, and Eastern Europe.

2.1 Redistributive Bureaucracies and Reciprocal Exchanges

Owing to the role of exchange in legitimizing socialism, it is appropriate to begin with Karl Polanyi's three basic modes of exchange: reciprocity, redistribution, and markets. Socialist systems suppressed the market principle, instituting redistribution as the chief exchange modality and the system's *raison d'être*: everyone would have the right to work, and the wealth they produced would be redistributed as welfare for all. Centralized redistribution required social ownership and control of productive resources, together with centralized appropriation of the product for reallocation along lines set by the Party. The instrument Party leaders developed to orchestrate production and distribution was the plan. Fulfilling it, however, depended on relations of reciprocity, both clientelistic and egalitarian.

Although these were highly bureaucratized societies, they were not Max Weber's impersonal modern bureaucracies dedicated to procedural rationality. Dense social networks sustained reciprocal exchanges that, far from constituting resistance to bureaucratic control, were intrinsic to its functioning: horizontal exchanges enabled socialist managers to do their jobs, and clientelism facilitated controlling both labor and Party cadres in seemingly noncoercive ways. Personalistic ties extended far beyond the bureaucracy as well, linking ordinary citizens with one another and with bureaucrats. The warp and woof of socialist societies, then, consisted of vertical and horizontal relations of patronage, loyalty, and exchanges of goods, favors, and gifts. Although the forms of these relations differed according to the various societies' prerevolutionary histories and cultures, (e.g., gift relations in China, *compadrazgo* in Cuba or Nicaragua, or specific kinship structures of Soviet minorities), they were widely prevalent in all. In each socialist society words indicating 'connections' (Russian *blat*, Chinese *guanxi*, Romanian *pile*, Hungarian *protekció*, Cuban *compañerismo*, Polish *dojscie*) appeared often in daily speech.

2.2 Organized Shortage

Personal relations were integral to socialism in part because of certain pervasive features of planned economies: tension between Party planners and firm managers, bargaining and soft budget constraints, and barter amid shortage. Socialist property could be productive only if the center's ownership/control rights were disaggregated and devolved on to lower-level managers charged with realizing production. Because planning could never foresee all contingencies, these managers had considerable discretionary power. Expected to achieve Party directives with inadequate wage funds and to exceed their plan targets with inadequate raw materials, they bore responsibility far greater than the means allotted them for fulfilling it. Therefore, they strove constantly to expand their local power base and their effective capacities. In doing so, they posed a threat to their superiors, who thus were motivated to encourage subordinates' loyalty with favors and patronage.

In redistributive systems governed not by demand for products but by the Party's planned allocation, materials for production could not simply be bought on a market; their availability depended on the supplies budgeted in plans and on often-inefficient central distribution. Managers, therefore, requested more supplies than they needed, hoping to obtain enough materials to fulfill and exceed their targets. Because the planning mechanism required firms to produce regardless of profitability—they operated under soft budget constraints and were rescued rather than bankrupted if they lost money—local managers could with impunity overstate their needs for materials and investments and then hoard any excess. They also strove to bargain their plan targets downward, making it easier to fill these and have goods left over. Comparable processes occurred in both industry and agriculture, as cadres everywhere manipulated information, under-reported production, and engaged in illicit trade to benefit their firm or locale.

The result of bargaining and hoarding was endemic scarcity of the materials necessary for production; thus, classic socialist societies were economies of shortage (Kornai 1980). Shortage caused competition among firms but also widespread exchanges, managers supplying from their hoard today the materials needed by others who would return the favor tomorrow. Thus, firms hoarded materials not only to cover emergencies in their own production but to backstop the supplies needed by others in their network. Shortage affected materials for production and also consumption goods, generating the queues characteristic of many socialist societies. It also affected two other crucial resources: information and labor.

Party planners could implement top-down planning only if they had detailed and accurate information. This happened rarely, for lower-level cadres had many incentives to falsify information so as to build careers by appearing successful, evade responsibility for disasters, inflate their materials requests, provide cushions against production shortfalls, overfulfill their targets to receive bonuses, etc. From these discrepant needs came a perpetual struggle over information. Higher authorities hoarded information as a source of power and engaged in continual information gathering at all levels of society (Horváth and Szakolczai 1992). Censorship and careful management of information at the top provoked information hunger below, generating a culture of rumor, gossip, selective secrecy, and conspiratorial explanations of events, as well as producing a citizenry skilled at reading between the lines. Classic socialist societies were thus a special kind of information society.

2.3 Labor Shortage and Rights in People

An additional resource subject to shortage was labor. Relatively underdeveloped socialist economies had initial problems mobilizing skilled workers where there was effectively no 'working class,' and they lacked the resources for either paying labor well or substituting capital-intensive methods. Moreover, the shortage economy encouraged firms to employ excess workers so they could complete monthly plans once sufficient materials were on hand (in a frenzied effort known as 'storming'); managers, therefore, padded their workforce, exacerbating shortage. Labor shortage, thus, had both macro and micro dimensions. Means for stabilizing the labor supply included making workplaces the locus of benefits such as daycare, housing, vacation permits, pensions, medical care, etc. Certain cities were closed to immigration and construction of urban infrastructures was limited (Szelényi 1983), thus compelling millions to become village-based 'peasant-workers.'

Within each industrial and agricultural workplace, managers had to ensure a labor supply adequate to both normal production and periods of 'storming.' Workers, for their part, might bargain for better conditions by withholding labor, through intentional slowdowns or time off for household tasks and moonlighting—that is, labor shortage gave workers structural leverage. Conflicting demands for labor put a premium on ways of accumulating rights in people. For managers, these included extending patronage and favors (e.g., access to schooling, houses, or building sites), overlooking petty illegalities, and securing loose plans that enabled them to produce a surplus they might use to create labor-securing debt and exchange relations (cf. Humphrey 1983). Both managers and others needing labor might appeal to kinship idioms, emphasize ethnic identities, participate in special rituals, and expand networks of reciprocity through gift-giving. Thus, the quest for labor further encouraged personal ties and reinforced particularistic identities.

2.4 Second Economies and Socialist Reform

Believing they alone could best determine how social wealth should be redistributed, Party leaders initially opposed economic activity not encompassed within plans. The inability of planning to cover social needs at the given level of technological endowment, however, compelled officials to permit and even legalize some small-scale private effort, known as the 'second' (or informal, unofficial, or shadow) economy. Among its forms were food production on small plots, after-hours repair work or construction, typing, tutoring, unofficial taxi services, etc. Because these activities overlapped with semilegal and illegal ones, their situation was everywhere precarious, with authorities persecuting them more in some times and places than in others. The second economy was largest in Hungary after 1968, for example, small in Cuba until Castro's 'Rectification' of 1986, harassed in Romania throughout the 1980s; it burgeoned in post-1978 China; extreme forms are reported for the Soviet Union,

where entire factories ran illegal production after hours. Crucial to understanding the second economy is that it nearly always utilized materials from the first (or formal, official) economy; its much-noted high rates of productivity were subsidized, then, by state firms. The prevalence of second-economic activity both indicated popular resistance to the Party's definition of needs and helped to fill those needs by voluntarily lengthening the working day.

Pressure from the second economy was but one of many signs of difficulty in socialist planning that led to repeated efforts at reform, initiated from both within and outside the Party. Beginning with Lenin's New Economic Policy, every socialist society experienced cycles of reform and retrenchment, devolution and recentralization (cf. Skinner and Winckler 1969, Nee and Stark 1989). Most exhibited a trend toward less stringent planning and the introduction of market mechanisms, heightened material incentives, and mixed property forms. System-wide experimentation began with Khrushchev's 1956 'Secret Speech' criticizing Stalin and increased as each society moved from 'extensive' development (mobilizing resources) to the 'intensive' phase (attention to productivity). Hungary and Yugoslavia introduced the most durable early reforms; those in the Soviet Union ended in the collapse of the Soviet bloc, while comparable reforms continued in China, North Vietnam, and Cuba. As they reformed, socialist societies increasingly diverged not only from the Stalinist model but from one another, introducing path-dependent differences that became ever more marked.

Despite these differences, the reforms everywhere redefined basic units of activity (e.g., revitalizing villages or households at the expense of collective farms, teams, or brigades); altered gender relations (usually in favor of men and patriarchal authority) and increased other inequalities; affected networks of reciprocity (expanding horizontal over vertical connections); dismantled at least some socialist property (as with China's decollectivization, begun in 1978); shifted the locus of authority (usually downward, provoking reactions from higher-level bureaucrats); and entailed new, more intimate forms of state penetration (implied, e.g., in Chinese rituals that no longer imagined gods or ancestors as inhabiting a nether world but found them immediately present).

3. *Social Engineering and Resistant Personhood*

All Communist Parties promoted massive projects of social engineering. They accorded knowledge and expertise a privileged place, under Party monopoly. Convinced of the creative power of language, Party leaders both used and modified language in commanding ways. They spoke of things that had yet to be created—the working class, the proletarian dictatorship, the new socialist man—as if those things already existed, and they developed hieratic speech with reduced vocabularies, clusters of noun phrases, and few (often passive) verbs, creating a limited, static verbal world. Party cadres intervened exhaustively in all facets of life, aspiring to create new moralities and to control populations in myriad ways. They attacked religion as superstition, instituted new socialist rituals, and expanded educational access to create enlightened citizens indifferent to religious belief. They filled the air with moral exhortations aimed at instilling a new, puritan, socialist ethic. Toward better management of resources, they introduced massive population programs, from Romania's enforced pronatalism to China's stringent birth control, insinuating themselves into people's most intimate lives, often to devastating effect (e.g., Kligman 1998).

Dedicated to building an alternative to the world of bourgeois capitalism, communist leaders announced an assault on all forms of inequality, including those based in kinship status, gender, class, and ethnonational difference. Society would be homogenized, lineage-based kinship structures broken up, gender differences minimized and authority relations in families altered, classes and private property abolished, national minorities given equal chances. New social entities emerged—state and collective farms, teams, and brigades, for instance, to take the place of kin-groups and village structures. When pre-existing social relations proved difficult to abolish, they would be co-opted and turned to the Party's purposes. From all these efforts would result the 'new socialist man,' a new kind of person, and the 'people-as-One,' a new kind of human community, bearing an exalted socialist consciousness.

The results of these interventions were decidedly mixed. To begin with, the Party failed to speak with one voice, as ministries vied for resources rather than cooperating to remold society, and as cadres built their careers by under- or over-executing central directives and engaging in rampant corruption. In addition, the annexation of pre-existing forms inevitably modified the purposes they were intended to serve. Exhibiting greater capacity to formulate goals than to implement them, socialist governments were plagued continually by the unforeseen consequences of their policies. To solve conflicts among nationalities they institutionalized ethnonational difference in ways that strengthened it; they embraced nationalist idioms that then overtook socialist ones (Verdery 1991, 1996). Parties created working classes only to find themselves opposed by their creation, as with the Polish authorities and Solidarity.

Beyond this, resistance to social engineering proliferated even as people adopted the new forms. Constant surveillance politicized behavior: small acts of joke telling became willful anarchy in the eyes of both authorities and joke tellers. Dissidents sought support internally and abroad for their critiques of the system, launching projects to build 'civil society' against the state. Less visibly, peasant refusal to accept starvation

from China's Great Leap Forward or Eastern Europe's delivery quotas ultimately forced the authorities to renounce these policies (Yang 1996, Rév 1987), while popular insistence on adequate living standards pressed the parties toward reform.

Highly complex political effects centered on the making of persons and political subjects. Redistribution and socialist paternalism tended to create subjects disposed to dependency and passive expectation; early campaigns taught the poor to see themselves as victims of oppression (rather than simply of fate) and offered them the Party's instrument of vengeance, in the form of denunciations. Thus arousing people's complicity, the Party also instilled self-denigration. At the same time, however, many adopted dissimulation as a mode of being: apparent compliance covered inner resistance. The resultant 'social schizophrenia,' 'doubling,' duplicity, or split self is described for every socialist society. It accompanied a pervasive dichotomization of the world into 'Us' (the people) and 'Them' (the authorities). More significantly, it encouraged subtle forms of self-making in people's own terms: defiantly they consumed forbidden Western goods, created self-respect through diligent second-economy work while loafing on their formal jobs, participated in ethnic- or kin-based identities and rituals constitutive of self, and gave gifts not just to secure advantage but to confirm their sociality as persons and human beings.

The collapse of the Soviet bloc hinders a balanced assessment of socialism, which once represented great hope for countless people. Undeniably, socialist societies diminished certain forms of oppression, yet they created others. In many of these societies, an early élan for the expressed goals gave way to cynicism and a feeling of betrayal, as the means used to achieve them sabotaged their fulfillment. Admirable gains in education, medical care, and social well-being counted for less against the devastating purges, labor camps, Party-induced famines, environmental degradation, and abuses of human rights. Top-down engineering foundered as socialism's leaders resisted their citizens' efforts to educate them about social relationships, self and human feeling, the value of ritual practices, and the limits to imposed change. The lessons of these citizens' refusals, their silent revolutions from below, should guide future attempts to create alternatives to the world of global capitalism.

Sociality: Anthropological Aspects

1. The Problem of Culture

Sociality is the capacity for social behavior, a capacity particularly marked among human beings, as evidenced by the intensity, complexity, and endless variety of human social life. This definition echoes the earlier use of sociality in philosophy and psychology, where it is used to denote the fact of human social interdependence and to correct a tendency in those disciplines to explain human behavior in individualistic terms alone. Sociality is used differently among evolutionary biologists, where it denotes the actually observed social behavior of a species, such as its mating system or dominance hierarchy; sociality so described is then subjected to an explanation from

natural selection (Wilson 1975). But human social behavior is so varied and so open-ended that no such simple description or explanation can be given. We must, therefore, describe human sociality as a potential, one which results in many different social systems.

To understand human sociality we need to turn first to the concept of culture. For it is culture which has borne most of the weight of anthropological efforts to think about human nature in general and about human potential, and indeed one could regard ideas about culture as anthropology's *first approximation* to a picture of human nature. This was sketched in by theorists and fieldworkers before World War II and confirmed in the great expansion of fieldwork and theory after that war.

In this first approximation, human beings are dependent upon the possession of some particular culture, both for their survival and for their recognizably human character. For culture comprises everything that we might consider knowledge, from knowledge of language and other practical techniques, through knowledge about the immediate natural world and the larger cosmos, to knowledge of social customs and social relations. Geertz captured the encompassing import of culture when he remarked that 'man's nervous system does not merely enable him to acquire culture, it positively demands that he do so if it is going to function at all' (Geertz 1973, p. 73). On this view, human beings have evolved to have culture, and each individual human being begins as a more or less blank slate upon which the knowledge of culture can be written, or as a new computer into which a program must be loaded. Moreover, the saliency of culture, as opposed to raw genetic inheritance, in human nature is certified by the tremendous variety in ways of life across the world. Humanity presents a patchwork of sharply discrete societies, each with its own social organization, its own language, and its own view of the world. It is the nature of these cultures, according to the first approximation, to be deeply traditional and resistant both to change and to mutual understanding.

Yet anthropologists' confidence in this first approximation has given way since the 1980s to sharp doubts. For such a conception of human nature is still, for all its ambition and universal scope, a narrow and partial one. It misses out the change, incompleteness, ambiguity and potential—that is the historicity—that are so prominent in human society and experience (Peel 1987, Fox 1985). Wolf (1982) showed that there have existed no peoples beyond the reach of historicity, change, and interchange between peoples, no primary and untouched cultures. Human beings do create new roles and new institutions and ways of doing things—such as the joint stock company, which has played such a great part in world history in recent centuries. And human beings do, as a matter of course, make effective contact and create enduring social relationships beyond the apparent limitations of our natal culture, as evidenced in networks of trade, in long-distance marriage networks (such as those of India), in the practice of ethnographic fieldwork, and in all the other occasions, such as migration for work, for safety, and even for conquest, that create a continual sifting and reblending of people and cultures across the globe. (For a sense of relatedness beyond ostensible boundaries, see Hannerz 1996.) Anthropologists have begun to look to human sociality to fashion a second approximation of human nature that will allow for such flexibility (see Ingold 1986, Carrithers 1992).

2. *Sociality as Intersubjectivity and Social Intelligence*

It is perhaps easiest to capture sociality to work in infancy, when the infant has not yet acquired the tools of a particular culture. Human infants already show a responsiveness to others which goes well beyond that found among any other species, including the great apes. Even a newborn can imitate facial expressions and respond to the emotions of others. This is primary intersubjectivity, in which the baby already has a dual 'self + other' orientation (Trevarthen and Logotheti 1989). By the age of one year, infants have developed the ability to share purposes and intentions with others, even if they cannot yet formulate these clearly in speech.

So the infant possesses an innate and growing social intelligence that operates with the feelings and doings of others. Upon the basis of primary intersubjectivity, for example, the infant will be able to go on in the first two years of life to achieve joint attention with others, following a carer's gaze or gesture to an object, and will learn to draw a carer's attention to an object. The intellectual achievements of intersubjectivity and joint attention form what Bruner (1983) has called the Language Acquisition Support System, the scaffolding of abilities upon which the joint capacity of speech, as well as the other achievements of culture, will be constructed. Later, at the age of three years or so, the child will begin to differentiate what they know and feel from what others around know and feel; they will then begin to simulate the knowledge and feelings of others, and on that basis will be able to experiment with a growing variety of social relationships, both in play and in earnest. Already at this age, that is, the child has begun to 'take the role of the other,' in George Herbert Mead's famous phrase, the facility upon which all distinctively human socializing is built.

It is useful to think of sociality as social intelligence, and indeed it seems quite likely that our technical and symbolic intelligence is an evolutionary by-product of the formidable abilities developed in social interaction. But there is one implication of the term 'intelligence' that must be stripped away, and that is the assumption that sociality is a strictly individual capacity. On the

contrary, it comprises an intellectual, cognitive, and emotional openness to others which runs throughout human experience, in childhood or adulthood. The child matures, but into a matured form of intersubjectivity, of self + other orientation, not into sealed isolation. This means, for example, that most human abilities and knowledge are *distributed*, a term drawn from computing to indicate the distribution of a computing problem across more than one computer (or central processing unit). One sees this on a smaller scale in the coordination of persons and sharing of information in subsistence activities among hunter–gatherers, or on a larger scale in the division of labor that brings this encyclopedia to the reader: at no point need, or can, all the necessary skills and information reside in one individual, but must be distributed across all participants. The knowledge and skills exist only with the scaffolding of persons-in-relationship who exercise the knowledge. To return to Geertz's dictum: it is not that the individual nervous system acquires culture, but that the socially intelligent nervous system completes itself with others to acquire culture jointly with them. It is a good deal more difficult for researchers to keep this more complex, more nuanced image in mind, but it is far more faithful to the character of human life.

2.1 Sociality as Mind-reading in Talk

So one achievement of sociality is to make human knowledge and skills much more than the sum of individuals, and to that extent, more powerful. But there is a cost as well, for the continual self + other orientation of people requires constant attention and a great deal of energy. We are socially calculating beings. We must be able to decide not only what to do, but to calculate the consequences of our actions on others, their probable reaction to those consequences, and the significance of those reactions for ourselves.

The calculating ability thus required can be called *higher-order intentionality*, the ability to think complexly about one's own and others' states of mind and reactions. To put this abstractly: one represents to oneself others' states of mind (first-order intentionality), or one represents to oneself others' representations of one's own state of mind (second-order intentionality), or one even represents to oneself others' representations of one's own representations of their state of mind (third-order intentionality). Here is an example of third-order intentionality: I *believe* that Amy *recognizes* that I *accept* what she is saying. One can go further: I *believe* that you *recognize* that I *think* you *understand* the general idea of higher-order intentionality. In thus, spelling out the idea of higher-order intentionality, we can see how complicated it is, and therefore how much intelligence it requires. Yet these are also the everyday, unremarked, and swiftly-deployed abilities that a mature human being needs to conduct even the most workaday talk. Whiten (1991) has called this ability 'mind-reading,' but of course it is not mind-reading as some mystical skill of seeing directly into the little grey cells, but is rather based on interpretation of the clues of glance, tone, timing, and nuance that people emanate continually in their interactions.

To weigh the significance of these central abilities in human sociality, we need first to note the cumulative effect of people's ability to conduct such everyday talk. For through such talk, we are able to create and sustain complex skeins of joint action, including the joint action of provisioning and sustaining ourselves. As Maurice Godelier remarked, 'human beings … do not just live in society, they produce society in order to live' (Godelier 1986, p. 1). On that account, sociality is a resounding practical success, opening creatively onto many forms of joint social action.

But such practical success, leading to some reliability and permanence in social relations, is only partial. For, as one can already see from the nature of mind-reading, the imputation of beliefs and attitudes to others can hardly be infallible. Slips are frequent, misunderstandings are sometimes repaired and sometimes not, and the interpretation of what one says can never fully be determined by the words themselves, as discourse and conversation analysts have so meticulously documented (see e.g., Moerman 1988). The cumulative direction of conversation cannot be controlled fully by any single participant, and all participants' interpretations and interests contribute to the process through implicit or explicit negotiation (Heritage 1984). So the seeming sureness of everyday talk is actually a laborious and uncertain business, a matter of minute-by-minute, indeed second-by-second, interpretation, with all the fallibility, but also creativity, inherent in the idea of interpretation. Max Weber's famous phrase, 'unintended consequences,' is usually used of large social phenomena, but unintended consequences begin in the fine grain of everyday life.

2.2 Sociality in Narrative Thought

So human sociality involves a noisy eventfulness that resembles that of other primate groups, but which also has notably human features. We often do things, not only because of what others do, but also because of what they might think or feel: I may *apologise* because she was *angry*, I *explain* myself because someone might *think* I am inconsiderate. So an action can be not only practical, but also have an interactive meaning with social effect: I built that fence to keep out stray cattle, but also to spite my neighbor. Moreover people can, and do, weave such actions and reactions together over a long series, linking cause and effect, action and reaction. This may be called a plot line or narrative, and indeed this larger scale mutual awareness may be called narrative thought (Bruner

1986, Carrithers 1992). Narrative thought is richly evidenced in gossip, story, history, and myth, that is, in all the ways in which people are able to represent complex skeins of action to one another. To understand the story of Oedipus, for example, the audience must be able to bear in mind the relationships between Jocasta, Tiresias, and Oedipus as they develop through a complex play of events and changes in the characters' states of mind. Moreover people are able, through narrative thought, to come to understand the underlying propensities, attitudes, beliefs—in a word, the character—of those involved in the skein of action. But narrative thought is much more than a passive competence, because it is only through understanding one's place in the various skeins of action and characters that comprise one's own life that one is able to act sensibly and appropriately to others. Societies vary greatly in their descriptions of characters and their notions of plots, but the basic theme of narrative thought, that of placing oneself with others in mutual awareness of larger time frame and a larger society, going beyond immediate events and those immediately present, is characteristic of all human life.

Moreover, this larger view over events concerns not only the past, but the future as well. Goody (1995) has written of 'anticipatory interactive planning' as a characteristic of human sociality, and Cole (1996) has shown how people use their narrative understanding of the past to project the future. He calls this *prolepsis*, 'looking ahead.' He uses the example (drawn from the observations of an (obstetrician) of a mother who said, as she held her newborn daughter in the hospital for the first time, 'I shall be worried to death when she's 18.' The remark is a sort of miniature of the complexities of human sociality. It shows the engagement of the mother with the daughter, and looks forward to a projected, predicted life cycle for the daughter. And of course the remark looks back as well, to the experience of the mother and her peers and forebears: the mother is (re)collecting her own and others' past to predict her daughter's future.

3. Sociality and Culture

In regarding human nature from the point of view of sociality, we bring human agency, human intersubjectivity, and historicity to the fore, linking human interaction and human creativity. What then of culture? It is difficult to see how culture-as-a-computer-program could fit here, but there is a fruitful alternative, namely to regard culture as a collection of artifacts. Through such artefacts human beings mediate interactions between each other, and between themselves and the natural world (Cole 1996). Actual tools are of course included, and we can see a good deal of how they mediate between people when we think of writing, books, telephones, or computers. But language itself, with all its panoply of different tools, is also a collection of artefacts for mediating between people. Thus, for example, South Asian languages tend to possess an extensive set of second person pronouns, each denoting a degree of rank difference between the speaker and the interlocutor. Such tools allow people to set a relationship … or to dispute it, by choosing a pronoun different from the one the interlocutor may wish to hear. Kinship systems are another set of such tools. There are also corporeal artefacts, such as the gesture of obeisance in South Asia known as offering *puja* or worship, which establishes a relationship of great respect to some real or spiritual other. Other artefacts include what have been called 'scripts,' the little slices of action through which people accomplish routine tasks. There are scripts, for example, for greeting people politely throughout the world, politeness being a marked feature of human sociality (Brown and Levinson 1987, Strecker 1988). These scripts may be played practically, to get the work of setting a relationship or conversation going, but also strategically, to attain some end of the speaker or interlocutor. And there are also stories, or story templates, that guide people over longer stretches of action. Many have noted, for example, how the story of the good stranger arriving in town to deal with evil-doers has often influenced American foreign policy.

It is characteristic of human ingenuity that these artefacts may not only be used strategically, but changed to achieve new ends or to meet new circumstances. Perhaps the most spectacular examples of this are the creation of writing from speech, and later books from writing, thus creating new, mediated, forms of interaction, 'exploded interactions' (Carrithers 1992), between people separated in time and space.

On the first approximation of human nature, it was difficult to see how cultures could change, or indeed how the great variety of cultures had come into being. But by regarding culture as a collection of artefacts and humans as possessing sociality beyond any prescriptions of culture, we can begin to see that any culture itself has a history, and that no one culture circumscribes finally the potential of those who use it. In this second approximation of human nature, both historicity and the creation of new cultural forms are already woven into the human fabric.

Sociality, Evolution of

Sociality involves multiple individuals of the same species engaging in a common task. Such tasks may involve any sort of behavior, but most research on the evolution of sociality has focused on the evolution of social cooperation in the production and rearing of offspring. The main goal of this research program is to explain and predict the occurrence of different social systems of multiple individuals engaged in reproduction, from aspects of the genetic, phenotypic, and ecological traits present in different species or populations. Pursuing this goal requires definition and classification of social systems.

1. *Defining Social Systems*

The purpose of defining social systems is twofold: clear communication between researchers, and classificatory structure for comparative evolutionary analysis of the causes of social evolution. To the extent that social system classifications are not based solely on phylogenetic relationships of species, they are, however, artificial constructs of humans. As such, they are more or less useful in answering specific questions, rather than more or less true and realistic.

1.1 *Social System Classification*

Reproductive social systems can be classified into three categories, based on (1) the presence and absence of behaviorally distinct sets of individuals within a social group, one of which specializes in reproduction and one of which specializes in helping the more-reproductive individuals, and (2) permanence of these behaviorally distinct sets, such that in societies with permanently distinct groups (called 'castes') some individuals become irreversibly phenotypically distinct prior to adulthood (Choe and Crespi 1997). 'Communal' societies exhibit cooperation in reproduction, but they lack behavioral specialization into 'reproductives' and 'helpers'. 'Cooperatively breeding' societies show such behavioral specialization, but it is not irreversible: some individuals can and do switch between the reproductive and helper roles as adults. 'Eusocial' ('truly social') societies exhibit castes. These three categories refer to societies rather than to species, because some species exhibit social variability across geographic regions or across the life cycle.

1.2 *Social Taxa*

Taxa exhibiting communal social systems include some bees, beetles, mites, spiders, birds, rodents, and primates. By contrast, cooperative breeding has been described in many birds, some bees and wasps, and various mammals (especially carnivores, viverrids, and rodents).

Taxa exhibiting eusociality include many Hymenoptera (ants, bees and wasps), some gall-inducing aphids and thrips, sponge-dwelling, shrimp, termites, encyrtid wasps, one species of bark beetle, naked mole rats, and damaraland mole rats (Choe and Crespi 1997). The challenge for students of social evolution is to make sense of the sporadic and idiosyncratic taxonomic distributions of these social systems and to find the commonalities and differences between groups that are responsible for their convergent and divergent social systems. The main determinants of social system evolution include genetic relatedness and aspects of ecology.

2. *Genetic Relatedness and Altruism*

Much cooperation is mutualistic in that all of the interacting individuals gain from the behavior. However, many forms of cooperation involve altruistic behavior, whereby one individual provides benefits to another at a cost to itself. The presence of such behavior appears paradoxical to evolutionary theory

Table 1
The three mechanisms leading to social cooperation

1. Benefits gained by cooperators
   a. mutualism or altruism – all benefit equally from cooperation, no incentive to cheat (i.e., exploit resources created by cooperators)
   b. mutualism or altruism – unequal benefits from cooperation, incentive to cheat, success of cheaters limited in some way (e.g., is frequency-dependent)
2. Costs imposed on non-cooperators
   a. manipulation – dominant reduces independent breeding prospects of subordinate(s), favoring helping
   b. punishment – dominant individual reduces fitness of non-cooperators
   c. policing – less-reproductive individuals prevent one another from engaging in reproductive cheating
3. Forced cooperation: dominant individual takes control of behavior away, such that subordinate individual must cooperate

because reduced fitness cannot evolve. Hamilton (1964) proposed a resolution to this paradox: that genes for altruism can increase in frequency and be maintained because they may also be present in the recipient of the benefits. Thus, by helping genetic relatives, an individual can maximize its 'inclusive fitness,' the sum of its own reproduction (descendant kin), plus its reproduction via its positive effects on collateral kin devalued by its genetic relatedness to them. Altruistic behavior can be selected for under such 'kin selection' if $rb-c>0$, where r is the relatedness of actor to recipient (the probability that a focal gene in the actor is present in the recipient), b is benefit to the recipient, and c is cost to the actor. Inclusive fitness theory predicts that genetic relatedness should be high among individuals in social systems with altruism. In accordance with this prediction, substantial levels of genetic relatednesses have been found between interacting individuals in the overwhelming majority of cooperatively-breeding and eusocial species thus far studied (Choe and Crespi 1997). By contrast, the few communal species for which such data are available exhibit colonies comprised of non-relatives or distantly-related individuals. All told, inclusive fitness theory has gained tremendous empirical support and is one of the cornerstones of social evolution theory.

Altruism can also evolve if it is reciprocal, such that the altruistic act of one individual to another is later reciprocated (Trivers 1971) (Table 1). By this mechanism, individuals need not be relatives, but there must be some means whereby cheating is thwarted lest the system break down. Such means may include recognition of individuals or the building of 'reputations' and as such reciprocal altruism may be limited to species with highly-developed cognitive abilities, such as primates.

3. *Ecology*

The ecology of a species comprises its habitat, food sources, demography, competitors, predators, parasites, and mutualists. The ecological niche of a species, and the nature of its interspecific and intraspecific interactions, form the selective context and selective agents for the evolution of social behavior (Evans 1977, Strassmann and Queller 1989).

3.1 *Habitat*

Cooperation in reproduction is concentrated in habitats that select for juveniles to stay at home after reaching adulthood, because of benefits to philopatry and costs to dispersal and independent reproduction. Among social vertebrates, the preponderance of social species are territorial and live in environments where independent breeding opportunities appear more limited than in related non-social taxa (Brown 1974, Emlen 1982). Indeed, many studies have shown a positive association between the degree of 'ecological constraint' on independent reproduction (measured in terms of some aspect of habitat availability) and the extent to which the offspring of a set of parents stay at home to serve as 'helpers,' forming a cooperative-breeding social system. By staying at home, such offspring may be able to increase their inclusive fitness via altruism towards relatives, they may eventually inherit the territory, or they may simply gain a favorable environment in which to wait for a breeding opportunity to arise elsewhere.

Among social invertebrates, sociality is more or less restricted to species that live in improvable, expansible, or defensible microhabitats that serve either as nurseries or as combined nurseries and food-rich sites (Alexander et al. 1991). For example, social aphids and thrips live in galls (hollow modified leaves or stems), social encyrtid wasps live in the body cavities of their hosts, social bark beetles live in the heartwood of trees, social snapping shrimp live in sponges, and most social Hymenoptera live in nests in the ground, in stems, or in wood (Choe and Crespi 1997). These habitats are especially valuable and tend to select for offspring philopatry and helping behavior, in the same way as do the territories of social vertebrates (Strassmann and Queller 1989). The two species of social mole rat provide a striking link between the invertebrates and vertebrates: both live in colonies underground in expansible burrows like bees, ants, or

termites, and, like social thrips, aphids, shrimp, and some termites, their food is available at the nest site.

Although cooperation is clearly associated with particular sorts of habitat in both vertebrates and invertebrates, few studies have yet to compare social taxa to closely-related non-social taxa, with regard to the specific characteristics of habitats believed to be important. Moreover, researchers are only beginning to link differences in habitat characteristics to differences in social system, to discern what aspects of habitat tend to select for communal, cooperative breeding, or eusocial behavior. The most obvious pattern to date is that virtually all species living in habitats that combine food and shelter, such that the colony members need not leave their domicile during the period of rearing offspring, exhibit eusociality, if they also have predators and the ability to defend against them (Crespi 1994).

3.2 Natural Enemies

Because the habitats of social animals are so rich in resources such as food, helpless juveniles, and shelter, they are prime targets for attack by a multitude of natural enemies, including predators, competitors and parasites (Evans 1977, Strassmann and Queller 1989). These enemies represent strong selective forces for cooperation because they can decimate entire social groups of invertebrates and because defense against them often involves the evolution of behavioral and morphological specializations that trade off with reproduction. Almost all social species have some means of defense, such as the stings of Hymenoptera, the mouth parts or modified forelegs of soldier aphids, the armed forelegs of soldier thrips, the incisive teeth of mole rats, the claws of shrimp, or the diversity of chemical and physical defenses of soldier termites (Choe and Crespi 1997). Some of these defensive traits apparently served as pre-adaptations for the origin of sociality (e.g., stings, which evolved in a non-social context and may have facilitated the origin of sociality), whereas other traits, such as those exhibited by the soldiers of termites, clearly evolved in the context of social defense.

In contrast to invertebrates, vertebrates have few of the types of natural enemies that select for sociality, except in some taxa (e.g., mongooses) that are highly vulnerable to attack by other vertebrates (Alexander et al. 1991). For most vertebrates, intraspecific competition for resources, both between and within social groups, appears to be a more important selective force for cooperation.

3.3 Demography

Social behavior evolves within the context of life history and aspects of demography, such as birth and death schedules and lifespans, have come under increasing scrutiny as factors that may influence social systems and be influenced by them. One demographic benefit of sociality is that an individual may help to rear dependent relatives when it is young, before it would normally reproduce on its own. If mortality rates of adults are sufficiently high, relative to the duration of offspring dependence, then such inclusive fitness 'head starts' may greatly increase the benefits of helping (Queller 1989). Moreover, extrinsic mortality rates of helpers are expected to be higher than those of reproductives, which results in faster senescence of helpers, extended lifespans of the reproductives, and an accelerated divergence of castes in behavior and morphology (Alexander et al. 1991). Indeed, in many Hymenoptera species, reproductives can live for many years, while helpers only survive for a few weeks or months.

In some invertebrates (i.e., gall thrips and gall aphids), sociality appears to be associated with a longer duration of the habitat (the gall) than in closely-related non-social forms (Choe and Crespi 1997). Moreover, cooperatively-breeding bird species appear to be longer lived than their non-social relatives (Arnold and Owens 1998). In both cases, the direction of casuation is unclear. In birds, cooperation may be favored by longer lifespans leading to stronger ecological constraints, or longer lifespans may result from delayed breeding. Similarly, longer-lived galls may be more vulnerable to attack, leading to the evolution of soldier castes, or having soldiers may allow for an extended gall duration. Because demography is so closely tied to fitness, assessment of its role in social evolution is one of the main imperatives of current research.

4. Mechanisms of Cooperation

Social behavior can arise not only via benefits gained by cooperators, through mutualism, altruism, or reciprocity, but also via costs imposed on non-cooperators, through manipulation, punishment, or policing, or via dominant individuals forcing others to cooperate (Table 1). Determining under what ecological and genetic-relatedness circumstances these different mechanisms evolve is critical to further progress in the study of social evolution.

5. Synthesis of Relatedness, Ecology and Mechanism

Explaining and predicting the evolution of social systems requires the development of models that combine relatedness, ecology, and mechanism into a common framework. Models of 'reproductive skew' (i.e., variation in reproductive success) parameterize aspects of ecology into two components: (1) the degree of ecological constraint on independent reproduction, and (2) the productivity benefits of cooperation (i.e.,

the benefits of cooperation and division of labor in terms of offspring production) (Vehrencamp 1983, Johnstone 2000). These two variables, plus genetic relatednesses, enter into models that seek to predict under what genetic-relatedness and ecological conditions a pair of individuals will form a stable cooperative group and to what degree reproduction in the group is skewed in favor of the dominant. A critical assumption of most skew models is the mechanism of reproductive control: the dominant individual controls the extent of reproduction of the subordinate and can thus concede reproduction to the subordinate to motivate it to stay and help, rather than leave and attempt independent reproduction. The degree to which the assumption of dominant control over reproduction is satisfied in nature is currently a matter of considerable dispute (Johnstone 2000).

Skew models have predicted a number of observed broad-scale patterns, such as low relatedness and low ecological constraint in communal social systems versus high relatedness and constraint under cooperative breeding. However, their usefulness is still limited, because analysis of their assumptions, the ecological and genetic variables involved, and their predictions is empirically so challenging. Future development of skew models requires (1) expansion of their domain of applicability to include both intersexual and intrasexual interactions, (2) enlarging their range of assumptions regarding control of reproduction, (3) consideration of additional mechanisms of cooperation, such as manipulation (Alexander 1974), policing, eviction, and punishment (Table 1), (4) incorporation of demography and an explicit element of time into the models, and (5) feedback between the findings of empirical studies and the assumptions of the models. Cooperation can arise in a wide variety of ways and a hierarchical set of skew models, encompassing this diversity of mechanisms, will spur further progress in understanding how sociality evolves.

Socialization and Education: Theoretical Perspectives

Socialization refers to all processes by which an individual learns the ways, ideas, beliefs, values, and norms of his particular culture and adapts them as part of his own personality in order to function in his given culture. Education, on the other hand, deals explicitly with intentional attempts at influencing an individual's development course. In the following, some core anthropological assumptions guiding the thinking and theorizing about socialization and education will be described. Second, major units of analysis, in particular phases of individual development, topics of socialization, socializing institutions and cultural variations will be briefly addressed. Third, an overview of three groups of theoretical approaches to socialization and educational processes, i.e., biological, psychological and sociological theories, will be presented. Finally, some elements of an integrative theoretical framework for studying socialization and educational processes will be outlined.

1. Core Anthropological Assumptions

At the heart of all theorizing about socialization and education are central prototheoretical beliefs concerning the nature and development of human beings. In fact, as Montada (1998) has pointed out, there are at least four distinguishable models of individual development depending on whether the individual and/or his environment are conceived of playing an active or passive part. Besides endogenistic, exogenistic, and self-creation theories exists a fourth group of theories which views both person and environment as active agents.

The latter group of theories rests on the common assumption that individual development is a dynamic interactional process which evolves in a sequence of reciprocally patterned person–environment transactions. Besides this basic assumption, there are at least six additional aspects that are central to a transactionals conceptualization of human development, i.e., (a) learning capacity, (b) social dependence, (c) experience formation, (d) internal representations of experiences, (e) action competence, and (f) freedom of choice. Action competence and freedom of choice, in particular, are indispensable prerequisites for innovation and change concerning individual and sociocultural conditions of life.

2. Perspectives in Studying Socialization and Education

When looking at socialization and educational processes from an empirical point of view there are at least four different, albeit interrelated, approaches that can be distinguished, i.e., a chronological, topical, institutional, and cultural approach.

In a *chronological perspective*, the course of individual development can be divided in different age-graded phases such as infancy, childhood, adolescence, and early, middle, and late adulthood. The sequence of phases and corresponding transitions is structured by individual developmental tasks (Havighurst 1953) which, on one hand, are based on physical and social cognitive maturation and, on the other, on normative expectations prevalent in a given society.

From a *topical perspective*, socialization processes have a strong impact on certain life domains such as (a) physical growth and health, (b) cognitive, social, moral, and spiritual development, (c) sex and gender differences, and (d) self and personality development.

From the vantage point of *institutions*, socialization takes place in different settings which, in some instances, are especially designed to advance the development of a broad spectrum of individual dispositions and competencies, either by formal or informal learning processes, i.e., families, schools, peer-groups, work settings, and so on.

Finally, from a *cultural* point of view, an individual's development depends a great deal on the values and beliefs that are typical of the culture to which he or she belongs. It has been shown, for example, that the prevalence of an independent-autonomous conception of the self within individualistic cultures vs. an interdependent–relational self within collectivistic cultures is closely related to distinct socialization goals and practices stressing either autonomy or relatedness (Triandis 1995).

3. Major Theoretical Approaches to Socialization and Education

Although in the present context it is not possible to give a full account of the vast array of theories dealing with the structural and dynamic aspects of socialization and education, three major classes of theories, i.e., biological, psychological, and sociological, will be briefly reviewed.

3.1 Biological Theories

3.1.1 Sociobiology and evolutionary psychology. Based on Darwin's groundbreaking ideas concerning the phylogenetic evolution of the species, sociobiology and, somewhat later, evolutionary psychology, contended that ultimate explanations of human behavior must take into account the superior goals of securing and expanding the successful reproduction of the human species. Especially mate selection and parental investment have been associated with universally evolved psychological mechanisms that are rooted in the human genotype as a consequence of phylogenetic adaptation. For example, Belsky et al. (1991) have proposed and also presented some research evidence for an evolutionary theory of socialization relating different kinds of reproductive strategies to specific childhood experiences, which in turn entail specific outcomes of an individual's psychological and somatic development. More specifically, these authors argue for two distinct developmental pathways of reproductive strategy. One is characterized by stressful contextual and rearing environments, insecure attachments, early pubertal development and onset of sexual activity within the context of short-term, unstable pair bonds, which in turn predispose to higher fertility rates and limited parental investment. In contrast, the other developmental trajectory shows the opposite pattern of rearing conditions and interpersonal relationships.

3.1.2 Behavior genetics. While evolutionary theories focus on universal adaptive strategies, behavior genetic theories concentrate on explaining the variability of individual differences that can be accounted for by genetic and/or environmental influences

(Plomin 1994). Behavior geneticists, in particular, have shown that individual differences in cognitive and socio-emotional dispositions are not only substantially influenced by the individuals' genotype but also by genetic components of the environment (e.g., via the parents' genotype impacting on their children's environment). Moreover, besides the conceptually and empirically useful distinction between shared and non-shared environments, various kinds of genotype-environment covariation and interaction have been distinguished to account for genetically informed processes of individual development. In this vein, empirical analyses of cross-sectional and longitudinal data have led some authors to challenge the environmentalist position according to which, for example, familial influences such as parenting style or family climate have a strong impact on the development of individual differences in the filial generation.

3.2 Psychological Theories

There is a wide range of psychological theories that have been applied to describing, explaining, and controlling socialization and educational processes. In fact, all theories dealing with personality and social development have much to contribute to this goal. In the following, four theoretical approaches will be briefly described with a special emphasis on the processes of socialization and education (Schneewind and Pekrun 1994).

3.2.1 Psychoanalytical theories. In classical Freudian psychoanalytical theory the operation of defense mechanisms such as identification or sublimation plays a central role in socializing the growing individual's initially untamed libidinal and aggressive drives. Especially, coping with the oedipal situation via identification with the aggressor is supposed to be a developmental milestone, because it allows the young boy or girl to enormously expand his or her learning experiences, thus leading to a gradually more realistic and differentiated satisfaction of formerly more primitive expressions of his or her drive impulses. Later on, sublimination is the most elaborate and mature defense mechanism, which provides the individual with new ways in his private or professional life to follow through with his otherwise unsatisfied libidinal and aggressive needs at a socially acceptable level.

Fixation is another important psychoanalytical concept that has been invoked to explain character formation at different stages of an individual's psychosexual development, depending on either a lack, inconsistency, or abundance of gratifications at a particular developmental stage. Thus, distinct patterns of socialization practices at different psychosexual stages have been related to particular outcomes of children's personality development. Cultural anthropologists, in particular, have followed this line of reasoning in contrasting more lenient vs. strict socialization practices in various cultures to demonstrate, albeit with only partial success, their impact on character formation (e.g., Whiting and Child 1953).

While the classical Freudian psychoanalytical model is based on the transformation of primitive into more differentiated ways of need satisfaction, neoanalytic theories, especially object relations theories, approach the issue of socialization and personality development quite differently. In object relations theories the central dynamic principle is a person's need for interpersonal relatedness (Greenberg and Mitchell 1983). In a developmental perspective, the individual acquires internal representations of the self, the other, and the relationship between self and other, which tend to become more and more differentiated. Thus, the quality of relationships that an individual is engaged in appears to be vitally important with respect to his internal representations of self and other. Empirical studies, however, are scarce and have mostly been limited to the pathology of object relations

3.2.2 Attachment theory. Although object relations theories bear some resemblance to attachment theory, the empirical status of the latter is much more elaborated. Attachment theory which combines concepts drawn from ethology, psychoanalysis, cognitive psychology, and systems theory has sparked off a multitude of theoretical, methodological, and empirical refinements (Cassidy and Shaver 1999). Of particular importance is the discovery of various attachment types (i.e., secure, resistant, avoidant and disorganized/disoriented attachment in infancy; secure, preoccupied, anxious, and dismissing attachment in adulthood) and corresponding internal working models. Moreover, it has been shown that specific aspects of socialization are related to different attachment types in theoretically meaningful ways. For example, several aspects of caregiving that promote secure mother–infant attachments have been found. These include characteristics such as sensitivity, positive attitude, synchrony, mutuality, support and stimulation. Similarly, a number of distinct interpersonal behaviors such as mutual need for intimacy, exchange of positive affect, and constructive conflict resolution have been observed in adult relationships belonging to the secure type.

3.2.3 Epigenetic theories. The common feature of epigenetic theories is that individual development is conceived as a sequence of qualitatively distinct phases concerning the structure of experience and behavior. A prominent example is Piaget's (1954) theory of cognitive development, comprising four

major periods from the sensorimotor period to that of formal operations. These are associated with specific cognitive schemes that are built on the interplay of assimilation and accommodation processes. The epigenetic principle has influenced a series of theoretical conceptualizations concerning other developmental domains including moral reasoning, distributive justice, social perspective taking, or ego development. While Piaget emphasized the epigenetic sequence of development as an inherent process of self-creation, Vygotsky (1978) put a stronger emphasis on the cultural influences on development. In particular, his concept of the zone of proximal development clearly stresses the importance of socialization and education in the progression of epigentically patterned levels of development.

3.2.4 Learning theories. This class of theories covers a wide range of theoretical approaches spanning from orthodox behaviorism characteristic of Watson and Skinner to social–cognitive and action–theoretic conceptualizations of learning. Although the principles of classical and operant conditioning are by no means outdated, the so-called cognitive revolution in psychology led to a paradigmatic shift in learning theories. One of the earliest contributions to this new type of theories was Rotter's (1972) social learning theory of personality which combines basic principles of learning within an expectancy–value framework. In particular, Rotter's concept of generalized expectancies for internal vs. external control of reinforcement and the social conditions shaping these expectancies, especially within the family and in the school, stimulated a tremendous amount of research, presumably because of the affinity of this construct to other socially relevant concepts such as autonomy, personal control, helplessness, or alienation stemming from quite different theoretical positions.

More recently, and in a similar vein, Bandura's (1999) social cognitive learning theory of personality has contributed much to the analysis and theory-guided application of specific procedures fostering the development of the self system by socialization and self-directed action. Besides his influential theorizing and research on the processes of observational learning and modeling Bandura has focused on the construct of self-efficacy, i.e., an individual's belief that he or she possesses the necessary competencies to attain specific goals. In addition, Bandura has shown that the concept of self-efficacy can also be extended to collective efficacy beliefs of groups or even societies.

3.3 Sociological Theories

Not unlike psychological theories there exist quite a few theoretical approaches that have been created within sociology to account for the processes of socialization and education. In the following, three will be briefly described because of their historical and contemporary importance.

3.3.1 Structural functionalism. The theory of structural functionalism is closely associated with the work of Parsons who has written more than 150 articles and books on this topic. The main question that Parsons addresses in his theory refers to processes of how individuals become members of a given society in order to guarantee the survival and maintenance of the social system (see Parsons and Bales 1955). According to Parsons, society is a global social system which is based on an integrated value system. The individual person participates in the social system by interacting with others in accordance with the various roles and positions he or she holds in that system. The global social system itself consists of hierarchically ordered subsystems which are characterized by corresponding institutionalized norms. On the one hand, these norms are supposed to be congruent with society's integrated value system and, on the other hand, they determine the expectations and rules attached to specific positions and roles. These are further specified with respect to a set of pattern variables comprising, for example, particularistic vs. universalistic values. In this respect, the family plays a particularly salient role (Parsons and Bales 1955). Drawing heavily on Freudian psychoanalytic theory Parsons contends that via identification with their same-sex parents boys and girls become socialized into specific male and female role patterns. More precisely, gender-related role specialization is characterized by instrumental or task-oriented roles for males and expressive or person-oriented roles for females. Again, these gender-specific complementary roles are supposed to maintain the equilibrium of the family system as well as the social system as a whole.

3.3.2 Symbolic interactionism. While Parsons' theory of structural functionalism focused on the conditions ensuring the conservation and stability of the social system, symbolic interactionism called into question whether the expectations and behaviors associated with the enactment of roles can be determined as precisely as Parsons suggested. Instead, Mead (1934), who is credited as the originator of the symbolic interaction framework, maintained that social roles are acquired by imparting and sharing the meaning of symbol systems, particularly that provided by language, in order to ensure an appropriate coordination of the actions of two or more interacting persons. The central vehicle by which this can be achieved is the process of communication which makes role-taking a necessary prerequisite. In essence, the shared meaning of symbols is a co-constructive process which is an outgrowth of interpersonal communication. Therefore, the notion of

socialization is crucial in symbolic interactionism although Mead himself never used this term. Instead he talked about the 'importation' of social symbols into a person's mind. For the developing child the process of importation is marked by two stages, i.e., a play and a game stage. In the play stage, the child is an actor with his own needs and interpretation of the situation (which in Mead's terms represents the self as subject or 'I') while in the game stage the child is an actor who is confronted with the needs and social expectations of other actors (which refers to Mead's self as object or 'Me'). In certain times and situations, however, balancing the I and Me aspects of the self may become quite conflictual, thus calling for appropriate means of intra-and interpersonal conflict resolution.

3.3.3 Conflict theories. Generally speaking, conflict within and between social groups is inevitable because the needs and interests of individuals and in-groups are more or less incompatible with the needs and interests of other individuals or groups. At the core of conflict theories is the phenomenon of power, or more precisely the imbalance of power, in particular when the powerful determine the lives and resources of the underprivileged, and at the same time ignore to a great extent their needs and interests. Conflict theories as, for example, Marx' and Engels' dialectical theory of history, try to understand the conditions leading to social inequality and injustice. However, Marxism not only provides an explanatory framework for the understanding of social inequality and conflict; it also has an emancipatory element inasmuch as it urges political action to dissolve inequality by endowing the underprivileged with more power and control to allow for a more self-determined conduct of life. Marx and Engels used their theory to explain the differences and conflict between social classes. In principle, however, Marxist theorizing can be applied to all social constellations where inequality and lack of justice cause conflict as, for instance, in feminist theories that deal with social gender inequalities.

Unresolved conflict and the plea for emancipation call for appropriate means of conflict resolution which cover a wide range from physical aggression to negotiation between conflict parties. In order to ensure that basic human rights are not violated, socialization for negotiation and constructive conflict resolution is a vital prerequisite. At a philosophical level, Habermas (1981), a prominent contemporary proponent of critical theory, has suggested to develop the art of 'communicative competence' to handle conflicts in a so-called 'ideal discourse situation.' This means that all participants in discourse are granted equal opportunity to express their own point of view and to comment critically on the contributions of their fellow participants, keeping in mind that the ultimate goal is to find a solution that all participants can live with. At a more practical level, specific procedures have been worked out to enhance constructive communication and conflict resolution skills, particularly for the family, school, and work context.

4. *Elements of an Integrative Framework for Studying Socialization and Education*

Based on the core anthropological assumptions and theoretical approaches described in the preceding sections, an integrative framework for the study of socialization and educational processes must at least cover the following five aspects.

4.1 *Units of Environmental Influence*

Since the developing person is a part of different and progressively expanding environments, the units of analysis should comprise all settings that may exert direct or indirect influences on the individual. Bronfenbrenner's (1979) ecological systems approach to human development provides an excellent framework for this purpose. By distinguishing between four systemically interrelated levels of developmental con-t-exts, i.e., the micro-, meso-, exo-, and macrosystem, the scope of the framework is sufficiently broad to encompass all possible socializing influences that an individual might have to deal with. More specifically, Super and Harkness (1994) have introduced the concept of 'developmental niche' to describe the conditions that constitute the developmental context of a particular person, especially a particular child. According to these authors, there are three major components of the developmental niche, i.e. (a) the physical and social contexts of everyday life, (b) culturally regulated customs of child care and child rearing, and (c) particular psychological characteristics of a child's parents. Together these three components constitute the proximal context which determines the child's experiential field. On the whole, broader ecological systems as well as more specific aspects of the developmental niche form the opportunity structures of the developing person.

4.2 *Characteristics of the Individuals to be Socialized*

Within systems of interacting persons the characteristics of the individuals to be socialized play an important role in shaping the processes and outcome of socialization. Particularly salient individual characteristics that moderate and mediate socializing influences are (a) basic personal characteristics (e.g., genotype, health, and maturational status of cognitive, motivational, and temperamental dispositions), (b)

characteristic adaptational strategies (e.g., information processing, coping and defense mechanisms, and volitional and emotion regulation processes), and (c) typical forms of experiencing the self and the world (e.g., self-concepts, experience of personal identity and coherence, and internal representations of relationships, situations, and environments).

4.3 Proximal Processes

To combine the characteristics of a person and his or her environment in a meaningful way, proximal processes, i.e., reciprocal interactions between the human organism and the persons, objects, and symbols in its environment (Bronfenbrenner 1995), are presumed to produce specific socialization outcomes. More specifically, Caspi (1997) has called attention to three kinds of person–environment transactions explaining developmental diversity and continuity. They are (a) reactive person–environment transactions which occur when different individuals express different forms of experience and behavior when exposed to the same situation; (b) evocative person–environment transactions, i.e., when an individual's specific personality characteristics elicit particular responses from other persons; and (c) proactive person–environment transactions which refer to the selection and creation of environments by the individuals themselves.

4.4 Goals and Values

In the behavioral and social sciences there is disagreement as to whether or not goals and values governing socialization and education should be incorporated as normative statements in corresponding theories, as is clearly the case in conflict theories of socialization. Although goals and values are undoubtedly objects of socialization theories and research, this controversy remains unresolved. However, even if the originators of socialization theories deliberately restrict themselves to descriptive and explanatory statements, such theories can nevertheless contribute to a great extent to the clarification of socialization goals, and to a better understanding of their antecedents and consequences. Thus, theories of socialization, and, particularly, corresponding research findings, provide valuable information which can be used to make informed choices with respect to one's own beliefs.

4.5 Self-socialization

Based on the anthropological assumptions presented above, socialization consists not only, as Mead (1934) contended, of the 'importation' of social symbols into an individual's mind, but deals also with the capacity to select and create personally and socially meaningful goals, due to the individual's progressively increasing action competence and freedom of choice. The latter process refers to the principle of self-socialization within the limits of personal and socio-cultural opportunity structures. In this context, human beings are creating themselves and the culture in which they live. Moreover, self-socialization enables them to work on the life-long project of designing their lives in a personally and communally rewarding way. Thus, theories of socialization and education are not only an outgrowth of humans' cultural activity but serve also as a critical guide for making well-informed choices to optimize the process of self-socialization.

Socialization in Adolescence

Socialization is the process through which individuals' behavior, attitudes, and values are shaped by the individuals and social institutions to which they are exposed. Because adolescence is a transitional time during which individuals are prepared for the roles they will occupy as adults, this period of development has received a great deal of attention from researchers interested in socialization. Among the issues most often researched are influences on academic achievement, problem behavior, and social competence.

Although we often think of the family as the main agent of socialization in children's development, young people are influenced by forces outside the family as well, including peers, schools, and broader cultural institutions, such as the mass media. The influence of nonfamilial agents of socialization is especially important in adolescence, as individuals begin to spend increasingly more time away from their parents and exposed to the potential influence of other socialization agents. Not surprisingly, much attention has been devoted in the study of socialization in adolescence to questions concerning the ability of parents to influence their children in the face of these other forces.

Research on socialization in adolescence has focused mainly on three broad questions. First, to what extent are adolescents influenced by different agents of socialization such as the family or peer group? Second, which aspects of adolescent development (e.g., school performance, drug use, prosocial behavior) are most influenced by these various socialization agents? Finally, what characteristics of individuals (e.g., age, gender, upbringing) make them more or less susceptible to different sources of influence?

1. *A Brief History of Research on Adolescent Socialization*

Early studies of socialization in adolescence concentrated on the influence of parents. Building on the prior work of scholars who had studied socialization during early and middle childhood, students of adolescent socialization examined different forms of parental discipline and their impact on the adolescent's character development. The dramatic increase in the relative size of the adolescent population during the 1960s, however, as well as growing concerns about the segregation of adolescents from adults created by the growth of secondary and postsecondary education, fueled scholarly interest in the study of adolescent peer groups and the potential influence of adolescents on each other. The publication of James Coleman's book, *The Adolescent Society* (1961) popularized the notion that young people were growing up in a separate world in which they were exposed to attitudes and values not shared by adults. Warnings about the development of a 'counterculture' provided the impetus for much of the socialization research conducted during the 1960s and 1970s, on such topics as peer pressure and the generation gap.

The spread of popular culture during the latter part of the twentieth century broadened the study of adolescent socialization further, as society began to question the impact of such forces as television, popular music, and film. The mass media were seen as responsible for a variety of social ills afflicting adolescents, such as sexual promiscuity, drug use, and violence. As was the case in earlier studies of the peer group, the mass media were cast as evil influences on adolescent behavior, attitudes, and values, and parents were portrayed as struggling to overcome this insidious force.

2. *General Challenges in Socialization Research*

Although the goal of understanding how adolescents are influenced by the individuals and institutions to which they are exposed is straightforward, answering questions about the strength of different socialization agents has proven very difficult, for a number of reasons. One substantial challenge, particularly in the study of socialization in the family, involves separating genetic from environmental influences on the adolescent. Adolescents may behave in ways that reflect their parents' interests and values, but similarity between children and their parents can be due both to

the influence of parents on children as well as to the fact that parents and children share certain genes in common. Toward the end of the twentieth century, advances in the study of behavioral genetics challenged socialization researchers to demonstrate that what they had described as parental influence was actually an effect of socialization, and not merely a reflection of shared genetic background (Plomin 1990). Although today this issue remains far from resolved, it is clear that genetic factors play a far more important role in adolescent personality and social development than had been recognized, and that much of what had been viewed as parental influence is attributable to heredity rather than socialization (Reiss et al. 2000).

A different but no less formidable challenge faces researchers interested in the influence of peers, mass media, and other nonfamilial socialization agents (Harris 1995). Because adolescents choose their friends and select the media they are exposed to, it is difficult to know whether the apparent impact of these agents on adolescent development is actually due to their influence, rather than merely indicative of the choices that adolescents make about how they spend their time. Thus, for example, similarity between adolescents and their friends could be due to the impact that friends have on each other, but it may also be due to the fact that adolescents choose as their friends individuals who share their interests. Separating out selection from socialization can only be accomplished through experimental research or longitudinal studies that track individuals over time.

3. *Adolescent Socialization in the Family*

More is known about adolescent socialization in the family than about socialization in other contexts, although far more is known about the influence of parents than about other family members, such as siblings. Research on parental socialization has traditionally examined the links between variations in adolescent functioning and variations in parenting practices (the specific things that parents do to influence their child in one way or another, such as close monitoring of the child's whereabouts) or parenting styles (the general affective climate of the parent–child relationship). Over the past 25 years, several broad conclusions about socialization in the family context have emerged (Steinberg 1990).

First, most research indicates that adolescents fare better developmentally when their parents combine firm and consistent discipline with affection and involvement in the adolescent's life. This combination of 'demandingness' and 'responsiveness' is referred to as *authoritative parenting*. In many studies, adolescents raised by authoritative parents have been compared with their peers who come from homes that are *authoritarian* (demanding but relatively less responsive), *indulgent* (responsive but relatively less demanding), or *neglectful* (neither demanding nor responsive). Generally speaking, adolescents raised in authoritative homes score higher on measures of psychological adjustment and academic achievement and lower on measures of psychological and behavior problems than adolescents from other households. Adolescents from neglectful homes, in contrast, score lowest on measures of adjustment and highest on measures of maladjustment. Adolescents from authoritarian or indulgent homes generally score somewhere between the two extremes.

Second, research indicates that adolescent development is more closely linked to the nature of their family relationships than to the composition of their household. Studies of adolescents from single-parent homes or stepfamilies, for example, find only small differences between adolescents from these sorts of families and those who live with their two biological parents. Similarly small differences emerge in studies that compare adolescents whose mother works outside the home with those whose mother do not. For the most part, the benefits of authoritative parenting transcend variations in household composition. Most, but not all, research indicates that the benefits of authoritative parenting also cut across ethnic and socioeconomic groups.

Finally, research on socialization in the family indicates that the broader context within which the family lives affects the ways in which parents behave and, as a consequence, the impact that parents have on their adolescent's development. Authoritative parenting is more likely to occur in families with greater financial and social resources, and who live in neighborhoods populated with other well-functioning families. In contrast, studies of families living under stressful conditions, such as poverty, neighborhood deterioration, or high rates of crime, indicate that such conditions tend to foster parenting that is hostile, inconsistent, or uninvolved. As a result of these variations in the broader context of socialization, adolescents growing up under different circumstances often exhibit different levels of psychological adjustment.

A different line of research has examined changes in family relationships over the course of adolescence. This work has pointed to the importance of puberty as a period of significant transformation in family dynamics, although it is not clear whether these changes in relationships are triggered by the physical or hormonal changes of puberty *per se* or by other, co-occurring events (e.g., the transition out of elementary school, the development of abstract thinking). Whatever the causes, during puberty, adolescents often become more assertive toward their parents, and parent–child conflict, especially over issues concerning the adolescent's independence, tends to increase. Most families report that this phase is temporary, however, with relationships becoming closer and less conflicted toward the middle adolescent years (Steinberg 1990).

4. Adolescent Socialization in the Peer Group

Researchers have studied the socialization influence of peers at multiple levels of analysis, including close friends and their impact on one another, cliques and social networks, and crowds, the large amorphous groups that define the social terrain of most high schools. Scholars of adolescent peer relations maintain that it is important to distinguish among friends, cliques, and crowds, because these different levels of peer influence operate in different ways (Brown 1990). It is also important to distinguish among different arenas of socialization; peers are more influential over day-to-day activities than over enduring values, for example.

As a general rule, adolescents tend to be similar to the peers with whom they affiliate, a phenomenon known as 'homophily.' Although much of this similarity is due merely to the tendency for like-minded individuals to select each other as friends, there have been several longitudinal studies that indicate that friends do in fact socialize each other. The most widely documented effects have been in the areas of drug and alcohol use, delinquency, and academic achievement.

Less is known about the influence of *cliques* (groups of between six and 10 close friends) on adolescent development, but a number of studies have examined changes in individuals' susceptibility to peer pressure over the course of adolescence. This research shows that children's susceptibility to peer influence increases steadily between the ages of 9 and 14, then gradually declines as adolescents move into the later years of high school. Boys, on average, are more susceptible to peer pressure than girls, especially when the pressure is to engage in antisocial behavior. It is important to keep in mind, however, that most peer pressure is not antisocial, and that adolescents' cliques often pressure their members to avoid drugs and alcohol and perform well in school.

Studies of adolescents in Western industrialized cultures have also examined the role of *crowds* in adolescent socialization. Crowds are large, reputation-based groups that are used to locate adolescents within the school's social world; most schools have been found to have different crowds defined by athletics, academic commitment, antisocial activities, or social adeptness. By setting norms and establishing standards for such things as attire, tastes in popular culture, and leisure pursuits, crowds socialize their members to adopt some behaviors and attitudes and to eschew others.

Contemporary studies of socialization in the peer group have, like studies of the family, adopted a more ecological perspective on adolescent development. Instead of asking whether adolescents are more influenced by peers than by parents, for example, recent research has examined how parental and peer influence interact. Although there are exceptions to the rule, most studies in this vein indicate that parental and peer influence are synergistic, not antagonistic. More often than not, adolescents select friends whose values and attitudes reinforce, rather than undermine, the values and attitudes of the family. In addition, parents may influence the process of peer socialization by directing their children toward some peer groups and away from others.

5. Adolescent Socialization and Other Institutions

Although most work on adolescent socialization has focused on the family and the peer group, some research has examined the influence of social institutions, such as school, the workplace, the neighborhood, and the mass media. One problem in drawing conclusions from this body of work is that there is considerable variability among schools, work settings, neighborhoods, and the media to which adolescents are exposed. Thus, it is difficult to draw conclusions about the impact of these institutions on adolescent socialization without examining the specific features of the institution to which an individual adolescent is exposed. Unfortunately, research on adolescent socialization in these contexts has lagged behind that on the family and peer group in both quantity and sophistication.

The study of schools mainly has focused, as one would expect, on characteristics of schools or teachers that foster classroom engagement, achievement motivation, and scholastic success, and special attention has been paid to the need to make schools more sensitive and responsive to the particular psychological needs of adolescents. Much of this research indicates that effective schools and teachers share much in common with effective parents. Specifically, students are more strongly oriented to school and interested in achievement when they attend schools that are orderly and consistent in their goals, and staffed by teachers and administrators who are firm but supportive. These characteristics are reminiscent of the attributes associated with authoritative parenting described earlier (Entwisle 1990).

Research on school programs designed to socialize certain attitudes or behaviors among adolescents (e.g., programs designed to prevent drug use, aggression, or unsafe sexual activity) has not been especially encouraging, however. Most evaluations of such deliberate educational efforts indicate that they are modestly successful in transmitting information but largely unsuccessful in changing students' behavior. Most experts agree that school-based efforts of this sort need to be accompanied by programs aimed at parents, peers, and other community institutions, and that classroom programs in isolation from other sorts of interventions have little lasting influence over adolescents' socialization.

Several investigators have examined the role of the workplace in the socialization of adolescents, especial-

ly among adolescents who hold part-time jobs during the school year (Steinberg and Cauffman 1995). Because rates of student employment are so much higher in the United States than in other countries, almost all of this research has involved American samples. We do not know if these findings are generalizable to adolescents in other countries, because the nature of work and its relation to schooling varies considerably from country to country.

The results of research on student employment in the United States have indicated that the impact of work on adolescent socialization is to a great extent dependent on the amount of time adolescents spend on the job. In moderate amounts—10 or fewer hours per week—a part-time job can be a useful means of exposing adolescents to the world of work and helping them learn to manage their time more responsibly. When adolescents work longer hours, however, the costs of employment may overshadow the benefits. More specifically, studies indicate that employment during the school year in excess of 20 hours per week is associated with diminished performance in and commitment to school, and increased drug and alcohol use, and some research links long work hours to increased delinquency. These negative correlates of working are thought to accrue because long work hours interfere with school and diminish parents' ability to monitor their teenagers, both of which have been shown to be associated with poor school performance and increased problem behavior. In addition, adolescents who work long hours have large amounts of discretionary income, which may pull them away from school and toward more recreational pursuits.

Research on the impact of neighborhoods on adolescent socialization is relatively new. This work has examined how adolescents attitudes and behavior are shaped by variations in the communities in which they live along such dimensions as the neighborhood's income, employment rate, crime, and demography (Brooks-Gunn et al. 1997). Most research to date has found relatively few direct effects of neighborhood conditions on adolescent socialization, however. Rather, studies suggest that variations in neighborhoods affect adolescent development primarily through their impact on the family and peer group. For example, adolescents living in disorganized neighborhoods are themselves more likely to be involved in antisocial activity because neighborhood disorganization is associated with ineffective parenting and with insufficient monitoring of peer group activities. This sort of finding is consistent with the general view that socialization is mediated primarily through interactions with significant others.

Despite widespread popular belief in the deleterious effects of sex and violence in the mass media on the socialization of adolescents, scientific evidence on the impact of exposure to violent or sexual imagery—in television, film, music, or computer games—is sparse and inconsistent. There is some research indicating that exposure to televised violence may increase aggression among younger children, but this issue has not been adequately studied among adolescents. The study of the influence of other media (e.g., computer games, music) or of other types of media content (e.g., sexual imagery) on adolescent socialization is virtually nonexistent.

Socialization in Infancy and Childhood

Socialization is the process whereby an individual's standards, skills, motives, attitudes, and behaviors change to conform to those regarded as desirable and appropriate for his or her present and future role in any particular society. Many agents play a role in the

socialization process including family, peers, schools, and the media. It is assumed that these various agents function together rather than independently. Families have been recognized as an early pervasive and highly influential context for socialization. Children are dependent on families for nurturance and support from an early age, which accounts, in part, for their prominence as a socialization agent.

1. Contemporary Perspectives on Family Socialization Theory

Several themes are evident in current theoretical approaches to socialization. First, the rise of systems theory (Sameroff 1994) has transformed the study of socialization from a parent–child focus to an emphasis on the family as a social system. To understand fully the nature of family relationships, it is necessary to recognize the interdependence among the roles and functions of all family members. It is being increasingly recognized that families are best viewed as social systems. Consequently, to understand the behavior of one member of a family, the complementary behaviors of other members also need to be recognized and assessed. For example, as men's roles in families shift, changes in women's roles in families must also be monitored.

A closely related theme involves the recognition of the importance of the historical time period in which the family interaction is taking place (Elder 1998). Historical time periods provide the social conditions for individual and family transitions: examples include the 1930s (the Great Depression) or the 1980s (Farm Belt Depression). Across these historical time periods, family interaction may, in fact, be quite different due to the unique conditions of the particular era. In order to understand the nature of parent–child relationships within families, a multilevel and dynamic approach is required. Multiple levels of analysis are necessary in order to capture the individual, dyadic, and family unit aspects of operation within the family itself as well as to reflect the embeddedness of families within a variety of extrafamilial social systems. The dynamic quality reflects the multiple developmental trajectories that warrant consideration in understanding the nature of families in infancy. Distinctions among different developmental trajectories, as well as social change and historical period effects, are important because these different forms of change do not always harmonize. For example, a family event such as the birth of a child may have more effects on a man who has just begun a career than on one who has advanced to a stable occupational position. Moreover, individual and family developmental trajectories are embedded within both the social conditions and the values of the historical time in which they exist. The role of parents as socialization agents is responsive to such fluctuations.

Consistent with a family systems viewpoint, recent research has focused on a variety of subsystems, including parent–child, marital, and sib–sib systems. We employ a tripartite model to understand the parent–child subsystem and the relation between this parent–child subsystem and children's social adaptation. The most common pathway is the parent–child relationship. Parents may influence their children through a second pathway namely in their role as direct instructor, educator, or consultant. In this role parents may explicitly set out to educate their children concerning appropriate norms, rules, and mores of the culture. In a third role, parents function as managers of their children's social lives and serve as regulators of opportunities for social contacts and cognitive experiences (Parke et al. 1994). In this article, we will focus on each of these pathways, as well as marital and sibling subsystems as contexts for socialization. Finally, we will examine the determinants of parental socialization strategies.

2. Quantitative and Qualitative Assessments of Mother and Father Involvement in Intact Families

In spite of current shifts in cultural attitudes concerning the appropriateness and desirability of shared roles and equal levels of participation in routine caregiving and interaction for mothers and fathers, the shifts are more apparent than real in the majority of intact families. Fathers spend less time with their infants, children, and adolescents than mothers not only in the USA but in other countries such as Great Britain, Australia, France, and Belgium (see Lamb 1987).

Fathers participate less than mothers in caregiving but spend a greater percentage of the time available for interaction in play activities than mothers do. The quality of play across mothers and fathers differs too. With infants and toddlers, fathers play more physically arousing games than mothers. In contrast, mothers play more conventional motor games or toy-mediated activities, and are more verbal and didactic (Parke 1996), although fathers in several other cultures, such as Sweden, India, and Central Africa, do not show this physical play style. As children develop, fathers become more involved in physical/outdoor play interactions and fixing things around the house and garden, where mothers are more actively involved in caregiving and household tasks, in school work, reading, playing with toys, and helping with arts and crafts. In adolescence, the quality of maternal and paternal involvement continues to differ. Just as in earlier developmental periods mothers and fathers may complement each other and provide models that reflect the tasks of adolescence—connectedness and separateness. Recent evidence suggests that fathers may help adolescents develop their own sense of identity and autonomy by being more 'peer-like' and more playful

(joking and teasing) which is likely to promote more equal and egalitarian exchanges (Larson and Richards 1994).

Why do mothers and fathers play differently? Both biological and environment factors probably play a role. Experience with infants, the amount of time spent with infants, the usual kinds of responsibilities that a parent assumes—all of these factors influence the parents' style of play. The fact that fathers spend less time with infants and children than mothers may contribute as well. Fathers may use their distinctive arousing style as a way to increase their salience in spite of more limited time. Biological factors cannot be ignored in light of the fact that male monkeys show the same rough and tumble physical style of play as American human fathers. Perhaps predisposing biological differences between males and females may play a role in the play patterns of mothers and fathers. At the same time, the cross-cultural data underscore the ways in which cultural and environmental contexts shape play patterns of mothers and fathers and remind us of the high degree of plasticity of human social behaviors.

3. *Assessing Parent–Child Interaction: Two Approaches*

Two approaches to this issue of the impact of parent–child interaction on children's socialization outcomes have been utilized: (a) a typological approach which focused on styles of child-rearing practices and (b) a social interaction approach which focused on the nature of the interchanges between parent and child.

3.1 *The Typological Approach*

The most influential typology has been offered by Baumrind (1973) who distinguished between three types of parental child-rearing typologies: authoritative, authoritarian, and permissive. Authoritative parents were not intrusive and did permit their children considerable freedom within reasonable limits, but were firm and willing to impose restrictions in areas in which they had greater knowledge or insight. In general, high warmth and moderate restrictiveness are associated with the development of self-esteem, adaptability, and social competence. In contrast, the authoritarian parents were rigid, power-assertive, harsh, and unresponsive to the children's needs. This results in the unhappy, conflicted, neurotic behavior often found in these children. Finally, in spite of the permissive parents' reasonably affectionate relationship with their children, their excessively lax and inconsistent discipline and encouragement of the free expression of their children's impulses were associated with the development of uncontrolled, impulsive behavior in their children.

Baumrind has followed these types of parents and their children from the preschool period through adolescence (Baumrind 1991). She found that authoritative parenting continued to be associated with positive outcomes for adolescents as with younger children and that responsive, firm parent–child relationships were especially important in the development of competence in sons. Moreover, authoritarian childrearing had more negative long-term outcomes for boys than for girls.

Maccoby and Martin (1983) extended the Baumrind typology and included a fourth type of parenting style which is characterized by neglect and lack of involvement. These are disengaged parents who are 'motivated to do whatever is necessary to minimize the costs in time and effort of interaction with the child' (Maccoby and Martin 1983). In infants such a lack of parental involvement is associated with disruptions in attachment; in older children it is associated with impulsivity, aggression, noncompliance, and low self-esteem.

The approach has been challenged on several fronts. First, questions remain concerning the processes that contribute to the relative effectiveness of these different styles. Second, it is unclear whether parenting styles are, in part, in response to the child's behavior. Placing the typology work in a transactional framework would argue that children with certain temperaments and/or behavioral characteristics would determine the nature of the parental style. A third concern is the universality of the typological scheme. Recent studies have raised serious questions about the generalizability of these styles across either socioeconomic status (SES) or ethnic/cultural groups. In lower SES families, parents are more likely to use an authoritarian as opposed to an authoritative style but this style is often an adaptation to the ecological conditions such as increased danger and threat that may characterize the lives of poor families (Furstenberg 1993). A second challenge to the presumed universal advantage of authoritative child-rearing styles comes from cross-ethnic studies. In Chinese families, authoritarian styles of child-rearing are more common and some (Chao 1994) have argued that the application of these stylistic categories to Chinese parents may be 'ethnocentric and misleading' (Chao 1994, p. 1111) since these child-rearing types represent an American perspective which emphasizes an individualistic view of childhood socialization and development. Contextual and cultural considerations need to be given more attention in typological approaches to child-rearing.

3.2 *The Parent–Child Interactional Approach to Socialization*

Research in this tradition is based on the assumption that face-to-face interaction with parents may provide the opportunity to learn, rehearse, and refine social skills that are common to successful social interaction

with other social partners. The style of the interaction between parent and child is linked to a variety of social outcomes including aggression, achievement, and moral development. Parents who are responsive, warm, and engaging are more likely to have children who are more socially competent. In contrast, parents who are hostile and controlling have children who experience more difficulty with age-mates. Moreover, these findings are evident in the preschool period, middle childhood, and adolescence (Parke and Buriel 1998). Although there is an overlap between mothers and fathers, fathers make a unique and independent contribution to their children's social development. Although father involvement is quantitatively less than mother involvement, fathers have an important impact on their offspring's development. Quality rather than quantity of parent–child interaction is the important predictor of cognitive and social development.

4. *Parental Instruction, Advice Giving, and Consultation*

Learning about relationships through interaction with parents can be viewed as an indirect pathway since the goal is often not explicitly to influence children's social relationships with extrafamilial partners such as peers. In contrast, parents may influence children's relationships directly in their role as a direct instructor, educator, or advisor. In this role, parents may explicitly set out to educate their children concerning appropriate ways of initiating and maintaining social relationships and learning social and moral rules.

The quality of advice that mothers provided their children prior to entry into an ongoing play dyad varied as a function of children's sociometric status (Russell and Finnie 1990). Mothers of well-accepted children were more specific and helpful in the quality of advice that they provided. In contrast, mothers of poorly accepted children provided relatively ineffective kinds of verbal guidance, such as 'have fun' or 'stay out of trouble.' The advice was too general to be of value to the children in their subsequent interactions.

As children develop, the forms of management shift from direct involvement or supervision of the ongoing activities of children and their peers to a less public form of management, involving advice or consultation concerning appropriate ways of handling social problems.

5. *Parents as Managers of Children's Opportunities*

Parents influence their children's social relationships not only through their direct interactions with their children, but also function as managers of their children's social lives and serve as regulators of opportunities for social contact with extrafamilial social partners. This parental role is of theoretical importance in light of the recent claims that parents' impact on children's development is limited and peer group level processes account for major socialization outcomes. In contrast to this view, we conceptualize the parental management of access to peers as a further pathway through which parents influence their children's development (Parke et al. 1994). From infancy through middle childhood, mothers are more likely to assume the managerial role than fathers. In infancy, this means setting boundaries for play, taking the child to the doctor, or arranging daycare. In middle childhood, it was found that mothers continue to assume more managerial responsibility (e.g., directing the child to have a bath, to eat a meal, or to put away toys).

6. *Beyond the Parent–Child Dyad: The Marital Subsystem as a Contributor to Children's Socialization*

Children's experiences in families extend beyond their interactions with parents. Evidence suggests that children's understanding of relationships is also shaped through their active participation in other family subsystems (e.g., child–sibling) as well as through exposure to the interactions of other dyadic subsystems (e.g., parent–parent).

6.1 *Influence of Marital Discord on Child Outcomes*

Considerable evidence indicates that marital functioning is related to children's short-term coping and long-term adjustment. Children exposed to marital discord are likely to have poorer quality of interpersonal relationships, including internalizing and externalizing behavior problems, and changes in cognitions, emotions, and physiology (see Fincham 1998). Two alternatives, but not mutually exclusive models, have been proposed to account for the impact of marital relations on children's developmental outcomes. One theoretical framework conceptualized marital discord as an indirect influence on children's adjustment that operated through its effect on family functioning and the quality of parenting. A second model focuses on the direct effects of witnessed marital conflict on children's outcomes rather than on the indirect effects. Both of these models have received empirical support (see *Marital Interaction: Effects on Child Development*).

7. *The Sibling System as a Contributor to Children's Socialization*

Siblings play a critical role in the socialization of children. Most children are likely to spend more time in direct interaction with siblings than parents and this

array of interactions between siblings have been found to be typified by greater emotional intensity than the behavioral exchanges that characterize other relationships. Sibling relationships contribute to children's socialization in a number of significant ways. Through their interactions with siblings, children develop specific interaction patterns and social understanding skills that generalize to relationships with other children. Relationships with siblings may also provide a context in which children can practice the skills and interaction styles that have been learned from parents or others. Older siblings function as tutors, managers, or supervisors for their younger siblings. Also paralleling the indirect influence that the observation of parent–parent interaction has on children, a second avenue of influence on children's development is their observation of parents interacting with siblings. These interactions may serve as an important context in which children deal with issues of differential treatment and learn about complex social emotions such as rivalry and jealousy (Dunn 1993).

8. *Determinants of Family Socialization Strategies*

One of the major advances in the field has been recognition of the importance of understanding the determinants of parenting behavior. Belsky (1984) proposed a three-domain model of the determinants of parenting, which included personal resources of the parents, characteristics of the child, and contextual sources of stress and support.

8.1 *Child Characteristics*

Child characteristics take two forms: universal predispositions that are shared by all children and individual differences in particular characteristics. Infants are biologically prepared for social, cognitive, and perceptual challenges and these prepared responses play a significant role in facilitating children's adaptation to their environment. Under the influence of recent advances in behavior genetics, there is increasing recognition of the role of individual differences in temperament on parenting behavior (Rothbart and Bates 1998). Although debates about the relative contributions of genetic and experiential factors to the emergence of individual differences in temperament continue, temperament clearly is a determinant of parental socialization tactics. For example, infants with difficult temperaments elicit more arousal and distress from caregivers than less difficult infants. The impact of these individual differences on parental socialization behavior are not independent of environmental conditions. Crockenberg (1981) showed that the impact of a difficult infant temperament on the parent–infant attachment relationship varied as function of the degree of social support available to the mother, which underscores the potential modifiability of temperament-based influences.

8.2 *Personal Resources*

A variety of studies support the prediction that personal resources—conceptualized as knowledge, ability, and motivation to be a responsible caregiver—alter parenting behaviors (Belsky 1984). Particularly striking are recent studies of how parental psychopathology such as depression will alter parenting behavior. When interacting with their infants, depressed mothers show flat affect and provide less contingent stimulation than nondepressed mothers; in turn, their infants showed less attentiveness, more fussiness, and lower activity levels. Differences are particularly evident when depression is protracted and not merely transient (Campbell et al. 1995).

8.3 *Social Support and Family Socialization Strategies*

Recognition of the role of the community and community agents as modifiers of family interaction is necessary for an adequate theory of socialization. Recognition of the embeddedness of families in a set of broader social systems such as community and culture is only a first step. The next task is to articulate the ways in which these other levels of social organization affect family functioning and explore the ways in which these influence processes take place. Community influence can be either positive or negative, since a high degree of connectedness with community resources is not necessarily positive. In addition, the relationship between communities and families is bidirectional and varies across development. Moreover, the influence of support systems on families may either be direct or indirect in its effects. Finally, both availability and utilization need to be separately considered. Families may have friends, relatives, and neighbors available, but fail to utilize these members of their informal social network in times of stress or crises or on a day-to-day basis.

8.4 *Socioeconomic Status as a Determinant of Family Socialization Strategies*

There is a long history of research concerning the links between socioeconomic status and/or social class and parenting beliefs and practices, in contrast to traditional assumptions that SES is a static state, SES is

a dynamic concept. Over the course of childhood and adolescence, families change social class and change is greatest in the youngest ages. Over 50 percent of American children change social class prior to entering school. In spite of the controversies surrounding this variable, there are SES differences in parental socialization practices and beliefs. Lower SES parents are more authoritarian and more punitive and controlling than higher SES families. Second, there are more SES differences on language measures than on nonverbal measure with higher SES mothers being more verbal than low SES mothers. Some SES differences are independent of race and poverty. In China, where there are relatively small differences in income across groups who vary in terms of education, less educated parents used more imperatives with their toddlers than better educated mothers (Tardif 1993). Similarly, studies of cognitive socialization found clear SES differences in African-American lower class and middle class families (Parke and Buriel 1998).

8.5 Ethnicity as a Determinant of Family Socialization Strategies

Recent cross-cultural and intracultural theories have emphasized the importance of socialization goals, values, and beliefs as organizing principles for understanding cultural variations (Harkness and Super 1995). In contrast to the older cultural deficit models of socialization, the more recent models emphasize how ecological demands shape values and goals. In the past, cultural deficit models were popular explanations for the socialization and child outcome differences observed between ethnic minorities and Euro-Americans. The focus on ethnic minority families has shifted away from majority–minority differences in developmental outcomes and more toward an understanding of the adaptive strategies ethnic minorities develop in response to both majority and minority cultural influences on their development. The parents' individual history of interaction with the larger sociocultural context, including their awareness of their ethnic group's history within the larger society, affect the manner in which they socialize their children. An important dimension of socialization in ethnic minority families is teaching children how to interact effectively in dual cultural contexts; the context of their ethnic group and the context of the larger Euro-American society. Harrison et al. (1990) have adopted an ecological orientation to explain the diverse environmental influences that contribute to the socialization of ethnic minority children. They conceptualize the socialization of ethnic minority children in terms of the interconnectedness between the status of ethnic minority families, adaptive strategies, socialization goals, and child outcomes. Emerging out of the adaptive strategies of adults are the socialization goals that they endeavor to inculcate in children to help them meet the ecological challenges they will face as ethnic minorities in a class- and race-conscious society. Ethnic pride and interdependence are two important socialization goals that enable ethnic minority children to function competently as members of both their minority culture and the larger society (see Parke and Buriel 1998).

Research needs to take into account the acculturation level of parents and children in recent immigrant families and the effects it has on family processes and child outcomes. Intergenerational differences in acculturation can create role strains between parents and children that have implications for childrearing styles, disciplinary practices, and overall parent–child relations. Together with acculturation, recognition of biculturalism as both an adaptation strategy and socialization goal is important. The effects of prejudice and discrimination on ethnic minorities, in such areas as social and emotional development, ethnic identity, and achievement motivation, deserve more attention. Language development research should also give greater attention to second language acquisition (usually English) and bilingualism and its relation to cognitive development and school achievement. More attention must also be given to the role of ethnic minority fathers, grandparents, and extended family members in the socialization of children (see also *Parenting in Ethnic Minority Families: United States*).

9. The Impact of Social Change on Family Socialization

Families are not static but dynamic and are continuously confronted by challenges, changes, and opportunities. A number of society-wide changes have produced a variety of shifts in the nature of family relationships. Fertility rates and family size have decreased, the percentage of women in the workforce has increased, the timing of onset of parenthood has shifted, divorce rates have risen, and the number of single parent families have increased (Hernandez 1993). These social trends provide an opportunity to explore how families adapt and change in response to these shifting circumstances and represent 'natural experiments' in family coping and adaptation. Moreover, they challenge our traditional assumptions that families can be studied at a single point in historical time since the historical contexts are constantly shifting. Our task is to establish how socialization processes operate similarly or differently under varying historical circumstances. In both the United States and other parts of the world a variety of changes, including the timing of parenthood, increases in women's employment, and increases in rates of divorce and remarriage, have taken place. These social changes have a major impact on children's socialization (Parke and Buriel 1998). To date, societal changes such as shifts in the timing of parenting, work participation,

or divorce have been treated relatively independently, but, in fact, these events co-occur rather than operate in any singular fashion. Multivariate designs which capture the simultaneous impact of multiple events on family socialization strategies are necessary.

10. Conclusion

Socialization is a multiply determined process; while our focus has been on families as central socialization agents, it is critical to recognize the roles of other social agents such as schools, peers, and the mass media in this process. A fuller understanding of socialization will come from more attention to the interplay among these diverse agents and how cultural and ethnic background influence socialization practices and outcomes.

Socialization: Political

In its broadest sense political socialization refers to the content, processes, and dynamics of political learning across time and space. Related, more restricted terms include civic education and citizenship training. Because of the importance commonly attached to the consequences of early socialization, scholarship in this area has focused on the pre-adult years though not to the exclusion of later periods as well. Political socialization figures heavily in discussions of political

culture, the relation of the individual to the political system, and political system stability and change. This article covers the major foci of the field, methodological approaches, and the field's evolution and development since the 1950s.

1. Major Topics and Questions

Some scholars, political scientists in particular, are concerned about the implications of political socialization for how political institutions function. Other scholars focus more on what socialization means for individuals and how they cope with their political environment.

Scholars have tended to borrow from other disciplines rather than developing original perspectives. Applications of social learning and cognitive growth theories predominate. Learning about politics occurs as a result of intentional and direct efforts as well as unintentional and indirect efforts.

The range extends from broad topics such as national identity and consensus political norms to narrower ones such as partisanship and issue preferences. The broader topics are especially important in terms of how political culture is preserved, while the narrower ones help explain individual level behavior and attitudes.

The 'agents of socialization' is one of the most explored topics, with the role of the family, schools, and political events receiving heaviest scrutiny. Complex research designs are often employed here so that the individuals being socialized can be matched up with the agents providing the socialization cues.

There are intracountry variations. Political socialization may proceed in different ways and generate different outcomes according to individual and contextual characteristics. Most attention has been paid to the role of social class, gender, race, region, religion, and birth cohort.

On the other hand cross-country variations exist. Commonalties based on individual developmental processes and differences based on institutional arrangements have been observed. Some of these conclusions are based on systematic, multicountry investigations whereas others are derived from a comparison of independent, one-country studies.

Although much emphasis has been placed on transitions from early childhood up through young adulthood, the study of political socialization increasingly is being viewed from a lifelong perspective in order to comprehend the residues of earlier socialization as well as the impact of adult life stage transitions. For many nonconsensus political beliefs and practices the formative years appear to be young adulthood, after which beliefs and practices tend to solidify. For beliefs and values of a more integral and widely shared nature, the formative years occur earlier.

Of interest to a wide range of scholars, generational and historical effects may reflect either gradual changes in the social composition of succeeding cohorts or sharper discontinuities due to secular events. Rising education levels and affluence exemplify generational effects due to social composition. Wars, depressions, revolutions, and student protest movements are examples of more abrupt, event-driven effects.

2. Methodology

The majority of the literature rests on a foundation of empirical methodology. Attention has focused more on individuals than on institutions and systems as units of analysis.

There are various modes of data gathering. Surveys of probability and nonprobability samples compose the major mode. Three variants have been used. One consists of self-administered questionnaires of elementary and secondary school students. The use of such instruments for young children has been questioned. A second variant consists of personal interviews, either face to face or by telephone. Some of these surveys employ a structured format while others are more semi-structured. Investigators using either mode typically employ statistical analysis. Other modes of data collection include intensive interviews, sometimes combined with participant observation and projective techniques, with a small number of subjects (Coles 1987). Analysis in this instance is usually qualitative in nature. Although not typically classified under the heading of political socialization, analytic biographies of political figures—employing a variety of data sources—also constitute a mode of data gathering. Studies based on experiments are relatively rare.

Most investigations are cross-sectional, that is, the subjects were studied only once. However, a few overtime studies of the same individuals exist, thereby enabling more insight into developmental patterns. Some studies stretch from pre to full adulthood and involve either special populations or more general ones. Other longitudinal projects, especially those assessing the impact of educational institutions and political events, cover a shorter period of time.

Replicated surveys of the same populations provide historical trend data. Longitudinal studies of preadult populations are now available in a number of countries via national and international archives. Similarly, replicated surveys of adult birth cohorts are widely available. These surveys facilitate analyses devoted to assessing the probable impact of preadult experiences as cohorts age.

3. Initial Development and Ascendance of the Field

The phenomenon of political socialization has a long history. The preparation of individuals for their roles in the political world is as old as political life

itself. Both political authorities and ordinary citizens have been subject to the practices and outcomes of socialization regardless of political regime type. By contrast, the systematic study of political socialization has a relatively short history. Around the turn of the twentieth century educators in the United States conducted studies of school children that included choices of exemplars, national figures most admired by the children (Greenstein 1965). These 'surveys' and occasional other investigations in a variety of settings marked the first empirical studies of what would later be called political socialization.

It was not until the post World War II era that more sustained, disciplined research emerged. The term itself surfaced in the mid-1950s. By the early 1960s the label had achieved wide academic currency among political scientists in the United States and quickly spread to other western countries. Early work in the Unites States, the initial center of the empirical investigations, focused on pre-adolescents and emphasized the positive and relatively benign processes and outcomes of political socialization. Although more realistic perceptions and understandings set in with advancing age and cognitive development, the overall effect was viewed as salutary both for the successful functioning of the political system and the citizenry (Easton and Dennis 1969).

Following in the wake of these pioneering studies came a flood of projects in the United States and elsewhere. These inquiries tended to elaborate upon, modify, and in some instances to reject the conclusions of the earlier work. Variations according to social class, race, and location were identified. Political institutions conditioned the content, processes, and outcomes in fundamental ways. Considerable attention was devoted to the agents of socialization. Although the family appeared to be the key agent, it became clear that many other forces—including individuals themselves—also contribute to the formation and maintenance of political orientations. In general the more concrete, affect-laden, and reinforced the attribute in question, the more likely it was to be reproduced in the person being socialized and to persist over time.

4. *Waning Interest*

Scholarly inquiry in this area began to decline after the mid-1970s, especially in the United States. What had been a bull market turned bearish. Two factors appeared to be at work beyond the fading effect often associated with scholarly trends. One source lay in the dwindling novelty of studying school children. Political scientists in particular were accustomed to dealing with the 'real world' of politics, one occupied and ruled by adults. A second likely source rested in the appearance of youth movements throughout much of the western world in the late 1960s and early 1970s. This development not only shifted attention away from pre-adults but also appeared to undermine the proposition that the trusting orientations observed in many of the earlier studies would persist over time. Indeed, the question of persistence posed a serious threat to the field.

Ironically, even as fresh research efforts tailed off, the concept and the term itself became embedded in any number of subfields, including public opinion, electoral behavior, the politics of race and gender, political culture, and regime stability. Political socialization came to be assumed, rather than observed. Still, research continued on in a number of countries (Percheron 1993, Ichilov 1990) and longitudinal studies began to appear (Alwin et al. 1991, Jennings and Niemi 1981).

5. *Resurgence and Future Prospects*

After a prolonged lull, scholarly inquiry began to increase in the 1990s and has continued onward. Three developments helped lead to a resurgence of interest. One development was the crumbling of the Soviet Union and the appearance of transitional regimes and new democracies around the globe. These changes generated numerous surveys of adults that emphasize generational differences and studies of how and with what effect pre-adults are being socialized under the new regimes (e.g., Flanagan and Sherrod 1998). New, large-scale immigration patterns also presented opportunities for studies of adult resocialization. Thus, dramatic events in the political world have provided a natural laboratory for examining the processes and outcomes of political socialization. A second development springs from the decline in social capital and civic virtue among upcoming cohorts said to characterize most Western countries. In an effort to understand what is happening and to propose possible solutions, a variety of institutions and scholars have turned to the question of education and training of the young. National and cross-national assessments dealing with the character and impact of curriculum and school characteristics are being employed (Smith 1999). Much of this work is being carried out under the banner of civic education inquiries (Torney-Purta et al. in press).

A third development consists of renewed interest in the question of persistence and the dynamics of learning. Results from the long-term panel studies form part of this renewal as do the shorter-term studies of children and adolescents. The accumulation of replicated surveys as represented by such projects as national election studies, the General Social Surveys, and the Eurobarometer Surveys are also relevant because they permit the tracing of birth cohorts over extended periods of time. In doing so, they enable

informed interpretations drawing upon the conditions under which pre-adult socialization occurred and how these cohorts respond to later developments. These new developments augur well for continued scholarly inquiry. At the same time, the prospects remain bleak with respect to the study of young children, a major focus of the early research efforts.

Socialization, Sociology of

Socialization generally refers to the process of social influence through which a person acquires the culture or subculture of his or her group, and in the course of acquiring these cultural elements the individual's self and personality are shaped. Socialization, therefore, addresses two important problems of social life: the problem of societal continuity and the problem of human development. Because of its broad scope and importance, socialization is claimed as a major process by most social science disciplines. Different disciplines, however, have emphasized different aspects of this process. Anthropology tends to view socialization primarily as cultural transmission from one generation to the next. Anthropological interest in socialization coincides with the emergence of the culture and personality orientation in the late 1920s and 1930s. Psychologists are more likely to emphasize various aspects of the individual's development. For developmental psychologists, socialization is largely a matter of cognitive development that typically is viewed as a combination of social influences and maturation. For behavioral psychologists, socialization is synonymous with learning patterns of behavior, primarily through environmental reinforcement or through vicarious processes such as modeling. For clinical psychologists, socialization is viewed as the establishment of personality traits, usually in the context of early childhood experiences. The subfield of child development is associated most closely with the topic of socialization within psychology, where much of the focus is on child rearing (see *Socialization in Infancy and Childhood*; *Socialization in Adolescence*; *Socialization and Education: Theoretical Perspectives*).

1. Sociological Perspectives on Socialization

Within sociology there have been two major orientations to socialization and several minor ones. One of the oldest, associated primarily with structure-functionalism, considers socialization mainly as the learning of social roles. Parsons (1955), a major architect of this theoretical perspective, maintained that individuals become integrated members of society by learning and internalizing the relevant roles and statuses of the groups to which they belong. Since roles are important elements of social and cultural systems, comprising normative and value components, socialization into roles becomes a major means of integrating individuals into social systems and, thereby, enabling the continuity of these systems. This integration is viewed as functional for individuals and for society, although Parsons's interest was more in the latter than the former. Merton (1957), another key figure in American functionalism, also viewed socialization as the learning of social roles, but conceived of the process as more problematic. His concept of 'latent function' points to the possibility of unintended and undesirable consequences of normative and institutional behavior, such as the perpetuation of social inequalities or the development of individual

dysfunction. Functionalism was the dominant theoretical perspective in sociology in the 1950s and 1960s. Its view of socialization as the learning of social roles largely characterized sociology's contribution to 'socialization' in the previous edition of *The International Encyclopedia of the Social Sciences* (Brim 1968). But it has declined since then. Role learning is still an important focus of sociological inquiry into socialization, but it is no longer the most important focus, and no longer from a primarily functionalist perspective. The other, and more prevalent, sociological orientation views socialization mainly as self-concept formation. This view of socialization is associated closely with the symbolic interactionist perspective, a pragmatically based constructivist theory of self and society that places major emphasis on the construction of meanings through symbolic (mostly linguistic) interaction. In Mead's (1934) influential writings, the self is a reflexive phenomenon (i.e., both subject and object) that emerges out of symbolic interaction. Language enables the development of role taking whereby the individual is able to view himself or herself from the perspective of another. Role taking is the means by which culture (in the form of values, role identities, norms, etc.) becomes internalized as elements of the self-concept. This internalization, in turn, reproduces society. From the interactionist perspective, both self and society depend on the same process of social interaction through which realities are created, maintained, and negotiated.

For contemporary interactionists as well, socialization is distinguished from other types of learning and other forms of social influence by its relevance for self-conceptions. As such, socialization is not merely the process of learning rules or norms or behavior patterns. It involves learning these things, to be sure, but only to the extent that they become part of the way in which we think of ourselves, because the mark of successful socialization is the transformation of social control (via agents of socialization) into self-control (in the form of conscience and other self-regulatory mechanisms). This is accomplished largely through the development of identities, the various labels and characteristics attributed to the self, and guided by various self-evaluative processes (especially self-esteem, self-efficacy, and sense of authenticity). Commitment to identities, especially those based on important roles and values, is a source of motivation for individuals to act in accordance with the behavioral expectations implied by these identities (Gecas 1986, Stryker 1980). The focus on identity also emphasizes the membership component of socialization: to be socialized is to belong to some group.

Socialization as self-concept formation occurs through various processes of learning and social influence, such as, modeling, reinforcement, role-playing, social comparisons, direct instruction, and reflected appraisals. For sociologists, the most important of these is reflected appraisals. Based on Cooley's (1902) concept of the 'looking-glass self' and Mead's (1934) ideas on role taking, reflected appraisals refers to our perceptions of how others see and evaluate us. The reflected appraisals proposition suggests that we come to see ourselves as we think others see us, especially significant others. Much of the research on the development of self-esteem, as well as programs to enhance self-esteem, is based on this idea. An important variant of this proposition is labeling theory, which was the dominant sociological theory of deviance in the 1960s and 1970s. The theory maintained that a key causal factor in the etiology of deviance is the imposition of a (usually negative or stigmatized) identity or label on a person. Individuals may come to think of themselves in terms of the imposed label, even if there was no or little initial basis for it, because of the responses of others toward them (Schur 1971). It is a form of self-fulfilling prophecy, used to explain not only the development of deviant or criminal careers but also to address classroom dynamics regarding the consequences of teachers' differential expectations of students.

Reflected appraisals, in its several forms, are an important process for self-concept formation, but it has been subject to overstatement and uncritical application. Research has found only modest support, at best, for the proposition that our self-conceptions are a function of how we think others see us (Felson 1985). Some of this is due to the effects of situational contingencies (e.g., lack of specification of the nature of the relationship between self and other, the nature of the feedback given) and methodological problems (poor measures, cross-sectional research designs). But an even more important factor, increasingly recognized as such, is the agency and influence of the self in affecting its own socialization. The self does not passively receive input from the environment. Rather, it is actively engaged 'selecting, distorting, ignoring, influencing others' (Rosenberg 1979). Even very young children try to shape and manipulate their social environments by, for example, trying to influence their parents or resisting influence attempts from their parents. An important source of the self's agency are self-motives. By virtue of having a self, an individual is motivated to evaluate it favorably (self-esteem motive), perceive it as efficacious (self-efficacy motive), and experience it as meaningful or real (authenticity motive). It is uncertain how much of the self's manipulations, distortions, and attempts to control its environment are due to these self-motives, but probably quite a bit, and more so for some people than for others. They are a source of resistance and distortion in the reflected appraisals process. But they also have broader implications for socialization. Within socialization contexts (as well as other settings), individuals will try to maximize their self-esteem, self-efficacy, and sense of authenticity. To the extent that agents of socialization can tap into one or more of these self-motives and utilize them toward socializa-

tion goals, the socialization effort will be more effective. Conversely, these same self-motives can serve as major sources of resistance to socialization pressures (Gecas 1986). In other words, the most effective socialization is self-activated, in which the individual is a willing accomplice in his or her own socialization.

The picture of socialization that emerges from the symbolic interactionist perspective is of a highly reciprocal process between agents and subjects of socialization, in which self-conceptions are affected by reflected appraisals and other forms of social influence, but that selves exert an influence in their own right on the process and its outcomes. Society and culture do provide the stage and a general script for the novice, but typically there is plenty of room for interpretation and creativity.

2. *Research on Socialization*

Much of the sociological research on socialization, past and present, is context specific, that is, it studies socialization processes within specific contexts of interaction, such as family, peers, workplace, day care, boot camp, etc. (Gecas 1981). Some of the studies guided by symbolic interaction theory use ethnographic or field methods to record in rich detail the patterns of interaction, negotiation of meanings, the normative constraints of social settings, and their socializing consequences for the participants. Becker's (1961) study of the processes by which medical students become doctors, Fine's (1987) field studies of the development of gender identities among preadolescent boys on a little league team, and Corsaro's (1997) observations on the emergence of peer group subcultures among preschoolers in day care, are excellent examples of this genre. While these studies provide rich and insightful observations of socialization processes as they occur in their natural settings, they are relatively rare because of the time and effort involved in this methodology. Most of the research on socialization, by symbolic interactionists and other sociologists, utilizes survey methods (e.g., interviews, questionnaires). This research tends to be quantitative and narrower in focus, for example, focusing on the effects of a socializing agent's behavior on some aspect of the socializee's development.

2.1 *The Family Context*

Even though socialization is not limited to experiences in childhood but occurs throughout one's life, most of the research attention has been on children (although less so in sociology than psychology). Therefore, the most important context of socialization is the family, where the initial or primary socialization of children takes place. Studies of the consequences of parent–child interaction for the development of children are numerous, particularly along the dimensions of parental support and control. Research indicates that parents are most effective as agents of socialization when they express high levels of support or nurturance combined with the use of inductive control. Under these conditions, children are most likely to identify with parents, internalize parental values and expectations, use parents as role-models, be receptive to parents' influence attempts, and develop positive self-conceptions and a strong conscience. Conversely, low parental support, combined with reliance on coercive control, is associated with unfavorable socialization outcomes (Peterson and Rollins 1987). These associations typically are due, to some extent, to reciprocal influences: not only are these child outcomes affected by these parental behaviors, but the characteristics of the child (e.g., compliance vs. rebellion, high self-esteem vs. low self-esteem) may elicit differential parental behavior. After all, children do effect parents as well as the reverse.

Besides parental support and control, there are many other important variables in the family setting affecting socialization processes and outcomes, such as political and religious values expressed by parents, performance expectations, family structure regarding number of parents and children, birth order and sibling interaction, and personality characteristics of parent and child. Sociological interest in the effects of family structure, especially single-parent vs. two-parent families, on child socialization has been increasing, as the prevalence of single-parent families continues to increase in America and other western countries. This is one of the hotly contested and political issues in the family socialization area. While the research evidence seems to suggest that child socialization in single-parent families is disadvantageous for children, compared to socialization in two-parent families (McLanahan 1999), there are numerous factors that affect this relationship (such as economic level, quality of husband–wife relationship), leaving room for ambiguity and need for further research.

2.2 *The School Context*

The school as a context of child socialization has generated almost as much public concern as has the family and almost as much research. Like the family, the school is a social institution directly involved in socializing children, although its mandate is more narrowly defined as providing formal education and developing children's knowledge and skills. In this sense, schools are less involved in primary socialization (i.e., the development of basic values, motivations, and conceptions of self) and more involved in sec ondary socialization (i.e., the development of knowledge and skills). This is not a very precise distinction, however, since a good deal of primary socialization occurs in schools as well, involving values, motivations, and self-concepts. Many school activities have

implications for the child's self-concept. One of the most important involves evaluation of the student's academic performance, and this evaluation is more public than evaluations by parents or peers. Success in academic performance is good for self-esteem and self-efficacy. But failure is not, and public failure is worse. Besides its implications for self-esteem, performance evaluations result in the categorization or labeling of students, by teachers as well as classmates, as 'smart,' 'dumb,' 'lazy,' etc. Such labels affect the way others respond to the person and, thereby, shape the person's self-concept. But students, like other socializees, are not passive recipients of the pressures they experience. Some resist negative labels, some try to change them by working harder, and some adopt failure-avoiding strategies (such as withdrawal or procrastination) which may enable maintenance of self-esteem but at the expense of academic performance (Covington and Beery 1976).

American public schools, concerned with this problem, began to develop strategies to enhance children's self-esteem. By the mid-1980s, self-esteem enhancement became part of the curriculum in many public (especially elementary) schools. Grading and public evaluations of students were discouraged, negative feedback of any kind was also discouraged, positive feedback and affirmations of self-worth were encouraged. This emphasis on self-esteem in the school curriculum had its own set of undesirable socialization consequences (Hewitt 1998) and began to decline by the 1990s.

2.3 Peer Groups

The third most important context for the socialization of children is the peer group. In terms of structure and function, the peer group is very different from family and school as a context of socialization. Peer groups are voluntary associations of status equals and are based on friendship bonds. Children's peer groups typically are segregated by sex and differ in organizational patterns: girls' peer groups tend to be closely knit and egalitarian friendships, whereas boys' peer groups tend to be loosely-knit, larger groups, with status hierarchies (Thorne 1990). An important socialization consequence of intensive association with same-sex peers and involvement in sex-typed activities is that it strongly reinforces identification and sense of belonging with members of the same sex. It also contributes to the development of stereotypical attitudes concerning members of the opposite sex. The development of gender identities and much of sexual socialization during childhood occurs in the context of peer rather than family associations.

Peer interactions have a wide range of consequences for the child's developing sense of self. In his field studies of pre-adolescent boys, Fine (1987) observed that friendships are especially appropriate for the mastering of self-presentation and impression-management skills, since inept displays usually will be ignored or corrected without severe loss of face. Friendships characterized by mutual trust and tolerance are important for exploring the boundaries of the self. A wider latitude of behavior is allowed, and even encouraged, since friends, unlike parents, are not responsible for changing or shaping the child's behavior. Mutual understanding, role taking, and empathy—important to the development of self in relation to others—develops best in the context of friendship bonds.

Peers provide an alternate reference group for children, as well as an alternate source of self-esteem and identity, and they provide a context for the exercise of independence from adult control. As such, the peer group has been described as a socialization context in which subcultures of opposition or resistance to the dominant culture develop, such as the adolescent subcultures described by Coleman (1961) and in much of the literature on juvenile delinquency. The existence of adolescent subcultures, with values, norms, and tastes distinct from and often in opposition to the mainstream culture, has tended to polarize parents and peers as agents of socialization and make them competitors for the youth's attention and loyalty (see *Youth Culture, Sociology of*).

2.4 Adult Socialization

The socialization experienced by adults generally falls into the category of secondary socialization, building on the socialization experiences of childhood. Much of this is role specific (Brim 1968), that is, learning the knowledge and skills required for the performance of specific adult roles (e.g., occupation, marriage, parenthood). As individuals become committed to the roles they play, they come to identify themselves and think of themselves in terms of these role identities (Stryker 1980).

Since work is a dominant activity and context for most men and women in modern societies, much of adult socialization involves preparation for an occupation, which usually takes place in specialized schools or training programs (e.g., medical school, college). The work setting itself can have a substantial socializing effect on workers, affecting more than just their knowledge and skills. Much of the socialization that occurs in work settings is incidental to the main activities on the job and often unintentional, involving the workers adaptations to the conditions of work. These work conditions vary considerably with regard to structural features, power relations, presence of co-workers, degree of complexity and autonomy, etc., and are consequential for many aspects of self and personality. Kohn and Schooler (1983) have found certain work conditions (e.g., complexity, autonomy, routinization) affect the development of workers' values and personality. Kanter (1977) found that the nature of work relations, especially the structure of

opportunity on the job, affects the workers' attitudes and behavior. Workers' adaptations to their work conditions do not lead necessarily to commitment to the job or self-investment in the occupational role-identity. On the contrary, a prevalent theme in the sociological literature on work, especially from a Marxist perspective, deals with the alienating consequences of work in capitalist societies (Hochschild 1983).

2.5 Resocialization Contexts

Many other contexts have socializing consequences for adults: family, church, recreation settings, and various voluntary organizations. The socialization that takes place in these contexts typically is a continuation and expansion of past socialization experiences. Resocialization, however, refers to socialization experiences constituting a more radical change in the person. Resocialization contexts (such as mental hospitals, reform schools, political indoctrination camps, religious conversion settings, some therapy groups) have as their explicit goal the transformation of the individual, because the individual is perceived by self and/or others to be fundamentally dysfunctional, misguided, sinful, or deficient. The key task in resocialization is the replacement of the person's previous set of values, beliefs, and self-conceptions with a new set based on a new ideology or worldview, that is, the 'death' of the old self and the birth of a new self. Typically, this is accomplished through intense small group interaction and pressure to change, in which the physical and symbolic environments are highly controlled by the agents of socialization. The actual techniques used to bring about change may vary considerably in resocialization contexts depending, for example, on whether the socializee is there voluntarily or not (Ofshe 1992). Resocialization contexts have received more attention from the popular press than they have from social scientists. They deserve much more research attention, since they constitute an important and more drastic type of adult socialization. Also, the prevalence of resocialization contexts in the form of religious and therapeutic groups seems to be increasing in modern societies.

3. Current Trends and Future Directions

Interest in socialization tends to increase in troubled times, when social institutions (especially family systems and public schools) are perceived as breaking down or working badly, or when the rate of social change creates stress, difficulties in self-maintenance, and anxiety about the future. These are such times in most modern societies. Consequently, current academic and public interest in socialization is high. It is also marked by controversy. Much of the controversy centers on family issues and family trends: increasing divorce rates, number of single-parent families, births to unmarried women, use of day-care centers, dual-career families, etc. It is the consequences of these trends for child socialization and wellbeing that is at issue. Current opinion (academic and public) is divided strongly on the implications of these changes for child socialization. More research is needed and will be forthcoming, since funding agencies are very interested in these issues as well.

Socialization theory and research typically lags behind societal changes and developments. It is slow in acknowledging and addressing social change. What effect will the rapidly evolving computer technology have on the socialization of children and adults? The ubiquity of computers in homes, classrooms, workplaces, and recreation centers is quite obvious in modern societies. Children are becoming involved with this technology at very early ages—even preschoolers are becoming computer-literate. Unlike television, computers are an interactive technology, more likely to engage and develop the user's cognitive and motor skills. As such, there is reason to hope that the influence of computers on children's socialization will be beneficial, as some scholars have suggested (Turkle 1995). Computers and information technologies are transforming modern societies. Surely they are also affecting processes and outcomes of socialization. But just how, when, and what these processes and outcomes might be remains to be studied.

Socialization theory in sociology has long had a primarily cognitive emphasis, especially evident in symbolic interactionism. The interactionist conception of the self as a reflexive process, that develops out of role taking (a cognitive process) and language, left little room for emotions. This started to change in the mid-1970s. Sociologists and social psychologists interested in socialization rediscovered emotions and have been trying to include them in theorizing about socialization. Special attention is given to self-relevant or reflexive emotions, such as shame and guilt, and to their importance in the development of the moral self (Shott 1979). Research on emotions has lagged far behind these theoretical developments, but is increasing and will continue to increase in the sociology of socialization.

A perennial issue regarding human development is the relative influence of biological factors vs. social factors (i.e., nature vs. nurture) in the development of mind, self, and personality. Sociology has long been squarely on the 'nurture' side of the issue, resisting any claims of biological determinism of any part of the socialization domain. There are signs that a more conciliatory stance is developing between sociology and biology. One reason is sociology's renewed interest in emotions, which increases the relevance of physiological factors. Another reason is the dramatic advances in biology (e.g., genetics, cell biology, physiology of the brain). These have potential implications

for a wide range of socialization concerns. How do biological factors interact with environmental influences to produce socialization outcomes? Research at the intersection of biology and sociology could be very important for the development of socialization theory.

Societies, Types of

While the concept of society is to be found in most sociological writings, it remains ambiguous and relatively ill-defined. Like most of the scientific concepts that are also used in common speech, that of society seems to need no introduction and to reflect reality in a rather straightforward, transparent way. Yet although it is one of the commonest, this notion is also one of the most ambiguous; the question has recently been raised whether it should not be considered obsolete or even harmful (Ingold 1990). It is not the purpose here to go that far; nevertheless, its ambiguities cannot be ignored, and it can be argued that the concept of society has probably been more a means of constructing reality than a representation of it. This is also the case with typologies that have been constructed around it, and that can be considered as useful only within quite well-defined boundaries.

1. From Society to Societies

One of the first ambiguities of the concept of society lies in the fact that it is used, with quite different meanings, in the plural as well as in the singular. In sociology, the use of the singular refers to social reality in a general way, which can be both abstract and empirical. In social anthropology, on the other hand, it is more commonly used in the plural, and it is very widely used. Like most anthropological concepts, it is

rather loosely defined, and is often presented almost as a material entity. In other words, it is used as if it were an observable fact, as if it had empirical status: a society is something that exists and can be observed; in other words, it is a clearly observable object. Consequently, social anthropologists have used the concept of society indiscriminately, and have transformed any little village into a society. The theoretical, and indeed the political, consequences of such a use are important, as shall be seen below. At this stage, it needs only to be noted that the omnipresence of the concept of society, in sociology as well as in social anthropology, does not prevent its being a rather blurred category, sometimes meaningless or at least fluid. A quick glance at different textbooks and dictionaries suffices to indicate that, although it is referred to on almost every page and seems pivotal, it does not always merit its own entry. It might, at first glance, seem useful, as there is no term more appropriate for referring to a well-knit social group differing from the more political and neighboring concepts of state, nation, or ethnic group. But this advantage soon turns out to be a handicap as one does not really know to what it precisely refers; yet it subsumes the social classes and oppositions that characterize any social reality.

It is undoubtedly legitimate, and probably inevitable, to classify social realities into types. Yet one must avoid the temptation of considering societies as well-defined objects. On the contrary, it is not the concept of society that entails comparison, but comparison that entails the concept of society; in other words, the need for typologies creates the elements to be classified (Amselle 1999, p. 21). A typology can only be provisional and of limited use. That is surely the reason why no classification can be considered as definitive. That is particularly true of the perpetually recurrent dichotomies such as those that oppose 'modern' and 'traditional' societies, which are inevitable sources of confusion. A 'type' is always the outcome of a process of classification, and can never be taken as revealing an 'essence' (Boudon 1998, p. 104).

2. *A Dichotomic Outlook*

If humans are naturally social beings, predisposed to social life, the task of sociology is to understand the mechanisms of life in society. Nevertheless, sociologists very soon stressed the limitations of a purely abstract conception of society, and attempted to distinguish between various fundamental types of society. To some extent, it could be said that the very idea of society automatically opens up into the discussion of its diversity. Furthermore, society is hardly conceivable aside of its specific instantiations. One of the most influential definitions was coined by the German sociologist Ferdinand Tönnies (1855–1936). It is interesting to point out that his definition includes a comparative perspective, since, according to him, the concept of society (*Gesellschaft*) can only be understood in reference to the concept of community (*Gemeinschaft*): community is characterized by the proximity, both affective and spatial, between individuals. Within the community, the 'we' prevails over the 'I'; the individual does not exist outside the collective. Society, on the other hand, characterizes the more modern forms of sociability and is founded on individual interests. These latter ground social relations, which are oriented toward the market and the contract. One finds traces of German Romanticism in Tönnies' conception of society, which can be considered as a theory of *Heimat*.

Tönnies' opposition between *Gesellschaft* and *Gemeinschaft* was to be taken up by Durkheim, according to whom two types of solidarities can be distinguished: mechanical solidarity and organic solidarity. The first expresses the similarity and the community of feelings that unite the members of a group. The second, on the contrary, consists of interdependence, in a division of labor, as each member contributes to the whole according to his or her capabilities. Although it has sometimes remained unnoticed, the place of the individual is central to Durkheim's conception of solidarity: according to him, the crucial element in mechanical solidarity is that individuals do not exist as such, they are completely subsumed in the collectivity (Durkheim 1978, pp. 100, 170). Organic solidarity, on the other hand, presupposes the existence of the individual; here, all individuals have a 'sphere of action' and their own personality. The individuals here are necessarily different from one another (p. 101). Durkheim also considers that mechanical solidarity is more present in 'inferior societies' and, more generally, he related the type of solidarity to the degree of division of labor: the more rudimentary the division of labor, the more mechanical the society and, in such circumstances, the individuals of a group look very much alike. Their character lacks any kind of originality; there is no psychological individuality. Conversely, among civilized people, the division of labor is at its peak, and individuals are very different from one another.

Organic solidarity replaces, little by little, mechanical solidarity, which is more present in clan-based societies, which are made up of similar entities. As society becomes more complex, solidarity becomes organic (Durkheim 1978, p. 159). Certainly, traces of mechanical solidarity remain here and there, but there is a global process of substitution of the one type for the other. In *La Division du travail social*, Durkheim seems to realize that he has validated a liberal conception of social life in modern societies, and he therefore nuances his thought by reasserting that altruism is essential to any kind of social life: in order to be able to live together, people must make mutual sacrifices (Durkheim 1978, pp. 207–9). He then suggests that mechanical solidarity never completely disap-

pears. Later on, he asks for more social justice and more equality (p. 311) and he reminds us that society cannot be conceived without some solidarity.

Durkheim did not really draw any conclusion from these last remarks that might have led him to reduce the gap between 'inferior' and 'civilized' societies. If he sees the necessity of some collective feeling in industrial societies, he admits no doubt of the idea that the individual is basically absent from mechanical solidarity. Yet one of the main difficulties of the opposition between *Gemeinschaft* and *Gesellschaft*, and indeed of other dichotomic approaches, lies in the 'annihilation' of individuals, and in the equally problematic sense of communality that is meant to be typical of preindustrial societies. Yet such a radical opposition between 'us' and 'them' is by no means limited to these classical examples. It is also to be found in more contemporary writers such as Lévi-Strauss, who opposes 'cold' and 'hot' societies on the grounds of their degree of 'historicity' (Lévi-Strauss 1973, p. 40). The French anthropologist was wise enough to recognize that such a distinction is purely theoretical and does not correspond to any concrete entity; however, one can wonder whether his warning is not purely rhetorical, as he (and others) continued to use the same kind of dichotomous categories based on the relative impact of history and change.

It is no exaggeration to say that such views have been very influential and that they have directed the way we conceptualize preindustrial societies. It is, then, important to point out that those hunting and gatherering groups that have been taken as living examples of preneolithic societies do not live in autarky, and have been in contact with more 'advanced' groups for a long time; while others in this category have in fact adopted hunting quite recently. Furthermore, as has been suggested by Lévi-Strauss himself, the passage from the type to the reality remains delicate, and it is often difficult to decide which group belongs to one or the other pole.

Those typologies often seem to derive from theoretical prejudices, such as the deeply grounded ideas either that some peoples are resistant to change or even of the absence of the individual in some groups. This latter idea was also at the basis of the opposition between holism and individualism, which, in Dumont's theory, amounts to two types of societies opposing each other. Whereas Dumont sometimes considers holism and individualism as 'ideologies,' he does not take this specification into account when he argues that they also represent two 'types of societies': 'Where the individual is the supreme value, I speak of individualism; in the opposite case, where the value lies in the society as a whole, I speak of holism' (Dumont 1983, p. 37). Elsewhere, he assimilates this dichotomy to the opposition between 'traditional' and 'modern' societies (Dumont 1966, p. 23). In his view, India then becomes the archetype of traditional societies, which might look somewhat paradoxical.

If the distinction between individualism and holism is debatable in itself, it becomes even more contestable as soon as one seeks for some empirical data to exemplify it. Indian studies, for instance, are increasingly ill at ease with the idea that the individual is absent from the Indian social system (see, e.g., Mines 1994). To consider the 'renouncer' (the ascetic) as the sole agent of social change in India (Dumont 1983) amounts to reducing India to a purely religious order in which there is no room for the military, the merchant, the king, or even the householder: in other words, a world without politics or economics.

More generally, the same criticism applies to any dichotomous representation of the world. The main *raison d'être* of typologies of this kind lies precisely in their deficiency: they soon appear as alternatives, radical and exclusive oppositions that reveal an 'essence.' They are also linked to a kind of sociological illusion that consists of dissolving individuals into a system by denying them any kind of action. They also transform the world into blocs that are said to be homogeneous (e.g., East and West, North and South). What is the relevance of this kind of dichotomy, which seems to impoverish our analyses? Recent changes in the contemporary world make this kind of view even more hazardous: globalization, migration, and the new technologies make any search for essence even more dubious. Furthermore, modern societies are far from having given up any kind of 'holism,' as is shown by some modern movements of ethnic renaissance or religious fundamentalism, or indeed in US multiculturalism, all of which promote the need for collective recognition at the expense of individual differences. Conversely, the absence of a division of labor does not entail any psychological conformity among individuals, and no structural constraint has ever succeeded in inhibiting every kind of individuality. In short, the classical distinction between 'them' and 'us' is always much less radical than is suggested by some classifications.

3. *Economic Categories*

Beyond this rather Manichean use of typologies, one can find some more elaborate attempts that base themselves on a variety of criteria in order to compare economic, kinship, or religious systems. Their main interest is allowing the possibility of comparison. However, these systems also fail to avoid the trap of reducing social realities, complex by nature, to a single criterion. One sees categories such as 'matrilineal societies' or 'polyandric societies,' which seem to imply that a specific feature can qualify a complex whole. One could argue that these classes can only be useful within very precise limits, in this case a comparison between 'marriage systems'; however, an examination of their use in practice shows that they have inevitably been used in a much broader sense, even though the

selected criterion had little relevance to the questions at issue. That is what Leach deplored : 'Comparison is a matter of butterfly collecting—of classification, of the arrangement of things according to their types and subtypes' (Leach 1968, p. 2). The comparative anthropologist, Leach complains, is a mere butterfly collector, and the types and subtypes proposed in these systems are so problematic that they lead to nothing. This is particularly the case with categories based on unilineal descent, which might be without any sociological significance: 'We must be prepared to consider the possibility that these type of categories have no sociological significance whatsoever. It may be that to create a class labelled matrilineal societies is as irrelevant for our understanding of social structure as a class of blue butterflies is irrelevant for the understanding of the anatomical structure of lepidoptera' (Leach 1968, p. 4).

The classification of societies according to economic criteria is one of the commonest forms, perhaps because it gives the impression of being based on objective elements, in a materialistic perspective that has always been influential in the social sciences. Lewis Henry Morgan was among the first to take technical inventions as the foundation for his evolutionary stages. According to him, the first two stages of humankind—savagery and barbarism—were subdivided into inferior, middle, and superior degrees, whereas the third stage—civilization—started with the invention of writing. The first degree of savagery is characterized by fruit-gathering, and the middle degree by fishing, whereas hunting only appears at the superior level. Barbarism starts with pottery, and proceeds to the domestication of animals, and ends with metallurgy. There is no need to dwell upon the deficiencies of such a model, which does not even take agriculture as constituting a significant stage. In an evolutionary perspective, comparison was above all diachronic, and aimed at stressing the sense of history. What is being compared is not 'social systems' but different stages in the development of humankind. In some ways, it is more a philosophy of history than a typology that is at stake here.

Morgan had a deep influence on Marx and Engels who also considered humankind in an evolutionary perspective: social wholes are defined from the relations of production between the various social classes, at a given level of technology. One calls a 'mode of production' a special arrangement of those elements at a specific moment of history. In a strict sense, the mode of production denotes a few specific types of relations of production. In the years 1960–70, however, the concept took on a more elaborated meaning, especially among those scholars who followed Althusser in an attempt to combine Marxism and structuralism. The mode of production was then conceived as a model or structure, that encompassed the totality of the social relations. It consisted of a special arrangement within the 'economic infrastructure' (the 'base') that determined the superstructure (politics, law, and ideology). One could say that the superstructure necessarily reflects the infrastructure; in other words, the economic base determines all social and jural relations. The mode of production became a key concept of Marxist theory, and numerous efforts were mobilized toward the delineation of the most characteristic modes of production: besides the classical Marxian major types (Asiatic, feudal, and capitalist modes of production), Marxists invented new types, such as the domestic mode of production or the lineage mode of production.

The weakening of Marxism and structuralism put an end to this line of research, which had not brought any convincing results. One of its major shortcomings was to consider social realities as systems that are closed and self-sufficient. It was quite legitimate to stress the importance of economic realities, but the overall principle of determination was somewhat simplistic, and apart from a few remarks about the 'relative autonomy' of the superstructure, it was unable to account for the influence of ideas and values in social formations. The very existence of the socialist 'democracies,' with their Orwellian omnipresence of the state, could serve to illustrate the limitations of a purely economic determinism. With the decline of Marxism in the 1980s, the mode of production became a rather obsolete concept.

Nevertheless, the type of production remained one of the major criteria used to differentiate societies. Numerous anthropological studies attempted to characterize societies on the base of hunting, pastoralism, and agriculture. Hunting societies have always been a major source of fascination among anthropologists, partly because they can be seen as survivors of the Palaeolithic era. The first anthropologists took hunting societies as living fossils surviving from prehistoric times. Such a position is hardly acceptable today since we know that most contemporary hunting societies have been in contact with more 'advanced' groups for a long time while others have only taken up to hunting quite recently. Furthermore, few peoples have lived exclusively on hunting. If the contemporary hunter can no longer be considered as typical of the first stages of humankind, hunting remains a special case of the relationship between humans and nature.

In *Femmes, greniers et capitaux*, Meillassoux (1974), a French anthropologist, showed that hunting and agriculture entailed different types of social relations. According to him, there was no rupture between production and reproduction: thus kinship relations are also determined by productive forces. One can distinguish between two economic types according to whether land is an 'object' or a 'means' of labor. Hunting groups use land as an object of labor: it is used directly, without any preliminary investment of human energy. Therefore one can speak of an economy of *ponction* (withdrawal of capital). Here, the

cycle of reproduction of the labor force (human energy) is short: there is no possible accumulation of wealth, and what is being produced must be consumed. Social relations are affected by such an organization: the producing groups are precarious, and prevent the appearance of any form of authority. The membership of a horde is constantly changing, and people move freely from one to another. This free mobility of adults between the groups is, according to Meillassoux, the main mechanism of social reproduction. According to him, the horde is not made up of kinship relations but of 'adhesion'. In other words, the social status of individuals is not fixed at birth through descent rules, but depends on the voluntary choice of the individual. These productive constraints determine a special type of social relationship.

However, it is difficult to follow Meillassoux when he argues that kinship ties are reduced to a minimum in the hunting band: we have no example to support his claim that children are easily given up at an early age, that marriages are short-lived, or even that weddings and funeral ceremonies are less elaborate than the rituals welcoming new members. The classical example of the !Kung goes against Meillassoux's assertions. His mistake was to consider that relations of adhesion necessarily contradicted kinship ties. It is now well known that the elementary family is common among most social groups, whatever their degree of complexity (see for instance Kuper 1994, p. 178). Yet, if some hunting groups have a quite elaborate social organization, the majority of them have almost no internal differentiations, except those based on age and sex. They have no state organization and have an economy that is largely based on exchange.

The concept of 'peasant society' is another interesting attempt to analyze the differences between hunters and agriculturalists. It was also a means of considering the latter in a comparative perspective. The works of Eric Wolf, Robert Redfield, or Marshall Sahlins (who spoke of a 'domestic mode of production') all tend in that direction. The problems of the 'peasant society' as a concept can be seen at first glance, since it comprehends such a vast and disparate ensemble. One could wonder what all agriculturists have in common, apart from working on the land. Yet the concept was quite fecund, and gave rise to interesting developments: Robert Redfield (1956), for instance, stressed the difference between the great and little traditions, and saw peasant communities as 'partial societies' that belong to larger entities. In France, Henri Mendras (1995) also coined a concept of peasant society based on three main features: the relative autonomy of the community, the importance of the domestic group, a relative self-sufficiency, the existence of a local collectivity, and the role of mediators between the local group and the main society.

Sociologists have always been preoccupied with the different forms of contemporary societies, and Max Weber was undoubtedly a precursor in this field. According to Weber, the rational organization of free labor is one of the main features of Western capitalism. Raymond Aron was much inspired by Weber in his definition of industrial society by five main criteria: separation between family and industry, an original type of production and division of labor, the accumulation of capital, rational economic calculation, and the concentration of the workers in the factory. Two main types of industrial societies could then be distinguished according to the role of the state in the distribution of resources and the type of property: the socialist and the capitalist society. Aron considered this distinction as typological in the sense that it had a merely instrumental nature, and therefore did not match reality. It was above all a tool. This is surely true of all typologies, which are useful inasmuch as they remain 'ideal-types,' in the Weberian sense of the term.

4. *Political Systems*

Political organization is another common means of classifying societies. Here, too, the first attempts tried to oppose 'modern' and 'traditional' societies, as the works of Rousseau or Hobbes show. In the political context, this opposition took the shape of a dichotomy between state and stateless societies. In *Primitive Society*, Robert Lowie argued that there is no radical difference between the two categories: some sort of political organization is present in any kind of group, and it is therefore possible to study its growing manifestations. However, the culturalist and relativist foundation of modern anthropology was more prone to stress the differences than the continuities, and anthropologists increasingly emphasized the gap between 'them' and 'us.' One of the most influential books in the field was undoubtedly *African Political Systems*, edited by Edward Evans-Pritchard and Meyer Fortes. Relying on their African examples, the contributors to this volume made a distinction between societies that have autonomous political institutions and those that have not. In the latter case, politics is expressed through kinship and the lineage system. The African examples were taken as having a universal value and social anthropologists saw lineages everywhere, and went as far as speaking of 'lineage societies'.

In a classical study, *The Nuer*, Evans-Pritchard (1940) asked himself how a 'society' could function in the absence of any political institutions and state organization. He discovered that while the Nuer have no state, they have a segmentary structure, in other words a division into segments of a similar nature, which merge or fight according to the circumstances. Evans-Pritchard's study became very influential, not only in social anthropology, but also in the political sciences, where *The Nuer* is considered as a case study of preindustrial society. In recent years, however,

social anthropologists became increasingly critical of the picture constructed by Evans-Pritchard. The model was undoubtedly elegant, but it contrasted with a rather chaotic reality on the ground. It also appeared that social organization was not solely characterized by the ties of kinship but that, on the contrary, the bands included many people who were not related by blood ties. In other words, the contrast between the Nuer and more advanced societies was perhaps less striking than was stated by the anthropologist. This is probably typical of the phenomenon of the insistence on the difference: in the Australian context, for instance, anthropologists have labeled as 'Kariera' and 'Aranda systems' societies that are divided into four or eight sections. Yet those very peoples also in fact live in nuclear families.

Clastres's opposition between society and the state is not very convincing either and reminds us of the dichotomies that were mentioned above. According to Clastres, primitive societies are stateless societies, and differ radically from state societies. According to him, the real revolution in history was not economic (the invention of agriculture), but political. The advent of the state, of power and domination, radically altered the mode of existence of societies and provoked a breach in human history (Clastres 1974, p. 172). The appearance of the state meant the death of 'society,' in the narrow sense of the term. Clastres was attacking Marxist economism, but he fell into a simplistic eulogy of primitivity, and amalgamated different realities under a single category.

Social anthropologists then sought to improve their typologies and spoke of bands or chiefdoms, or tribes without rulers. These categories may be useful, though only to a certain extent.

5. *From Structure to Relativism*

In sociology, the work of Talcott Parsons became one of the most interesting attempts to classify social groups according to their 'structure.' In his structuro-functionalist perspective, he identified four models of society. Radcliffe-Brown took up a similar viewpoint, and defined social anthropology as a comparative sociology, the aim of which was to compare social structures.

In social anthropology, however, his influence was undermined by a very strong reluctance to search for general laws. The studies of Ruth Benedict, for instance, put the stress on the irreducibility of every culture. By considering participant observation (or experience) as the main source of knowledge, social anthropology encouraged a kind of scepticism. Although she entitled her first book *Patterns of Culture*, Benedict spoke of the plasticity of human nature, and marveled at the infinite diversity of cultures. As for society, culture became plural. The US culturalists themselves never became hostile to comparison; but they had sown the seeds of a relativist ideology that invaded the social sciences and rejected any kind of generalization.

Relativism itself is an ideology that is historically determined. In a sense, it is true that all groups are different from one another (as indeed are all individuals), but the social sciences will have to go beyond this if they wish to prolong their existence. In that case, they will have to resume their elaboration of models and types, since classification and comparison remain elementary scientific activities. At the same time, typologies will never succeed in replacing analyses, and will always remain intellectually unsatisfactory. Moreover, when applied to societies, they also tend to reinforce the idea of homogeneous, well-defined entities, an idea that is problematic, both scientifically and politically.

Society/People: History of the Concept

'People' is a concept that has come to acquire two related, yet different meanings. On the one hand, there is the democratic, political conception of 'the people' — the people as *demos*—and on the other there is the ethnic, cultural conception of 'a people'—the people as *ethnos*. In either sense of the word, the crystallization of the modern concept of the people can be traced back to the latter part of the eighteenth century when the idea of the 'sovereignty of the people' became central to democratic political theory, and the nation-state emerged as the paradigmatic form of state institution, informed by the principle that ideally each state contained one nation/people, and that each nation/people constituted one state. In this article each meaning will be discussed, as well as their relationship to each other.

1. The 'People' and the Democratic and National Imaginaries

Prior to the eighteenth century the concept of the people was of relatively minor importance. Present from the outset were two basic meanings of the term, a general one, closely related to 'nation,' 'community,' and ' society,' and a particular one, which opposed the people to the elite. Take for example Samuel Johnson's *A Dictionary of the English Language* from 1755 which juxtaposes the following definitions: (a) 'A Nation, those who compose a community,' (b) 'The Vulgar,' and (c) 'The Commonality; not the princes or nobles.' Similarly, Abbé Fuertière's *Dictionaire universel* from 1690, list both a positive, general meaning—'the mass of persons who live in one country, who compose a nation'—and a negative one, defined 'by opposition to those who are noble, wealthy, and educated.'

During the eighteenth century the concept, which until then had carried largely negative connotations, associated with the vulgar, the lowly, and the beastly—what the Romans referred to as *plebs*—underwent a dramatic change, and 'the people' was valorized and reformulated in distinctly positive terms, as the source of both mortal virtue, political legitimacy, and cultural authenticity, a sentiment captured in the increasingly common saying, 'the voice of the people is the voice of God.' By around 1800 the 'people' was thus constituted as what Reinhart Koselleck calls a 'key-concept' (see Brunner et al. 1972–92). In dictionaries published after 1800 a veritable explosion of neologisms derived from the root-words 'people,' '*Volk*,' '*peuple*,' '*narod*,' 'folk,' and so on, can be observed, reflecting what has been called the 'discovery of the people' (Burke 1994).

This production of new words had two origins. On the one hand there were the terms derived from the vocabulary of the English, French, and American revolutions, to which the principle of the 'sovereignty of the people' was the central tenet. In opposition to the Old Regime, with its feudal, hierarchical society with the sovereign king at the top of the social and legal pyramid, a new idiom was elaborated that spoke in terms of citizenship, civil liberties, and legal equality. In England the primacy of Parliament and especially the House of Commons gave expression to this new political reality, which also brought with it a new sense of common, popular English nationality. In France the Third Estate—which contained the now celebrated people—became synonymous with the nation, while the nobility was excluded from such membership, associated, as Sieyès put it, with 'incurable idleness,' 'collapse of morality,' and a variety of exclusive and insulting social and political rights, privileges, and prerogatives. And in the USA, the Declaration of Independence spoke of the rights of 'we the people' to assert its sovereignty against the tyrannical and illegitimate powers of the English king.

On the other hand, there were Romantic, ethnographic terms inspired by the German philosopher Johann Gottfried von Herder and his followers who ventured into the countryside to explore the very popular culture that hitherto had been the objects of scorn and contempt. In 1774 Herder coined the word *Volkslied*, or 'folksong,' as the title of a collection of songs he published, and a host of similar words pertaining to 'folklore' and popular culture soon became commonplace in most European languages. As in the realm of politics, 'the people' in this ethnographic sense was now to be rescued from oblivion and condescension and instead to be presented as the authentic bearer of national culture. True poetry, Herder suggested, gives expression to the 'soul of the people,' and according to Jacob Grimm such authentic, national poems 'belong to the whole people.' For Herder, the people was first and foremost a matter of history and culture, and he harbored an organic vision of the concept. Each people was thus conceived as a collective individual that possessed its own national character, its own language, its own mores, its own morality, and its own sense of self. In contrast to the political definition of the people as *demos*, Herder thus stood in the forefront on an

elaboration of the people as *ethnos*. Indeed, Herder tended to perceive the emerging modern state with a great deal of suspicion, as a 'machine,' an 'artificial form of society' that threatens the organic, authentic culture of a people.

From a wider perspective these new terms belonged to a more general phenomenon of linguistic innovation during this period. As Lynn Hunt has observed in the context of the French revolution, 'words came in torrents' as the old political, social, and economic order broke down and attempts were made to semantically capture a new one (Hunt 1984). As the rate of change accelerated, experience could no longer guide action in the present. A new interpretative language was required to make sense of the world. Thus attempts had to be made to formulate a vocabulary that no longer simply referred to what Koselleck calls 'the space of experience,' but instead reached into the future, creating a 'horizon of expectation,' terms through which prognostic political goals could be hatched (Koselleck 1985). In other words, the concept of 'the people' acquired a utopian character. As such it came to occupy a central position in the 'democratic imaginary' (Joyce 1994), as a concept that did not merely serve to describe an existing state of affairs, but also prefigured the future. By elaborating visions of popular sovereignty, a politically potent expectation was created that has come to define the context for politics ever since. Similarly, the people imagined as a form of community—the nation—was a vision that came to inform European and global politics as nationalism became a fundamental political force, erupting in the revolutions of 1848— 'the springtime of the peoples'—in the unification of Italy and Germany, in the collapse of the Hapsburg Empire after World War I in the shadow of President Wilson's ideology of the right to national self-determination, and in the politics of anticolonial national liberation movements during most of the twentieth century.

2. *Structural Relations: Who Belongs to the People?*

In structural terms the difference between these two conceptions is one of how membership in 'the people' is delimited. In the one case the inclusion/exclusion is made in inside/outside terms. Here the emphasis is on setting limits against other peoples by defining the peculiar character of one's own people and culture in relation to those of others. In its most extreme and lethal form, such as the one practiced by the National Socialists in Hitler's Germany, the people may be defined in terms of race and blood, and citizenship be determined according to the strictures of *jus sanguinis*. Alternatively, membership may be determined through participation in what Rousseau called 'civil religion,' allegiance to a national constitution and to the law, a process by which individuals become active citizens, devoted to the nation, and to the practice of civic virtue. In this context, ethnicity tends to play a less defining role, and rights to citizenship may, as in France or the USA, be conferred automatically on anyone born in the country (*jus soli*) (Brubaker 1992). However, in either case, citizenship and nationhood is by definition simultaneously a matter of inclusion and exclusion, however benign and civic the criteria for membership in the national community may be. Thus the imagined community of the people/nation is always both sovereign and limited, surrounded by and defined against other 'peoples' who likewise are bounded and sovereign within those boundaries (Anderson 1983).

This emphasis on the people as a community built on affective ties of solidarity and comradeship furthermore requires a minimum of cultural if not ethnic homogeneity, and thus nation-states have consistently engaged in efforts at 'nationalizing the masses' through public institutions such as the schools and the military, creating a nationally minded people where there previously existed diverse and culturally heterogeneous populations, divided by all manner of differences in language, custom, and law, turning 'peasants into Frenchmen,' as the historian Eugen Weber memorably put it in the case of France (Hobsbawm 1983, Mosse 1975, Weber 1976).

In the other case, associated with the democratic definition of the people, the delimitation is made along a vertical axis where 'the people' is set against segments of the population at large that are defined as not belonging to the people. This can be done by excluding groups either at the top or the bottom. So, for example, the people can be defined as the entire population except the government, or the broad segments of the population vs. the ruling elite. It has also been done by excluding groups at the bottom. Thus, to take the German case, the working class could be seen as *vaterlandslose Gesellen* whose primary identification was with the international proletariat and not with the German nation. The words *Pöbel* (from French *peuple*) and *Masse* were deployed in similar ways, to distinguish the 'real,' respectable *Volk* from the degenerate, urban underclass. Indeed, the delimitation could be made in both directions simultaneously; the Social Democrats, for example, could claim the noble title of the *Volk* defined against both the capitalist elites above and the *Lumpenproletariat* below.

In the socialist vocabulary, the concept of the people had to compete with related notions that figured prominently in the Marxist idiom, particularly 'class' and 'proletariat,' especially since it was often closely linked to the concept of the 'nation,' an idea that sat uneasily within Marxist theory. Eventually, however, 'the people' retained a largely positive status, as evidenced in the common usage of the concept of 'the people's republic' in referring to a variety of communist regimes. In the context of the liberal-democratic political system of the West, the utopian

impulse at the heart of the democratic definition of the people, one that envisions not only the sovereignty of the people but also that all individuals within a sovereign state should belong to the people/*demos*, has led, at least in theory, to an increasing democratization of society and to the abolition of traditional obstacles to citizenship on the basis of categories such as class, creed, race, or gender.

3. *National Variations: Neighboring Concepts and Political Ramifications*

While the concept of the people has played a central role throughout the Western world and beyond, the impact of this key concept has varied considerably from country to country. This is true both when it comes to the specific political impact and how the 'people' came to be understood in relation to neighboring key concepts such as state, society, community, class, proletariat, and individual rights and liberties.

In the French case the ideas of the people and the nation became strongly linked to the state and the political notion of the general will. Thus the French nineteenth century historian Jules Michelet, in his influential book *Le Peuple* (1846), focused on the role of the Revolution and democratic politics as constitutive of the people/nation, and similarly Ernest Renan, in his essay, 'What is a Nation' (1882), emphasized that the nation should not be seen as first and foremost a matter of blood, but as an expression of political will, 'a daily plebiscite.' As Renan put it, when it comes to nationality, 'the people's wish is after all the only justifiable criterion, to which we must always come back.' Here Renan was significantly arguing against fellow German historians over the status of Alsace-Lorraine, the provinces that lay in the borderland separating Germany from France, an area annexed by the Germans in the wake of the Franco-Prussian war of 1870. By contrast, the German conception of the *Volk* and the nation was, pace Herder, at heart a cultural conception that at best saw the state as a protective shell safeguarding the *Volk/Nation*, or, as in the case of Herder himself, saw the state as an artificial and even destructive form of society. At the same time, the French and the German conceptualizations of the people were similar in that they both were collectivist. *Le peuple* and *das Volk* were both formulations that suggested a collective, be it a national, ethnically/culturally defined community, or a collectivity that expressed the democratic, general will of the people.

In England the idea of the people came, as in France, to be strongly associated with political institutions and practices. However, whereas in France the idea of the people/nation tended to be associated with the collective, communal notion of the general will, which gave priority to the nation and to the social over the rights of the individual, it was in England more strongly associated with the assertion of parliamentary power, individual liberty, and the limitation of state power. Thus English national identity itself came to be linked to political as well as economic liberalism, and to a conception of the general good that took as the basic unit the freeborn individual Englishman.

These tendencies were even more fully realized in the USA, where the separation of powers and the protection of individual rights were enshrined in the constitution itself. The beginning point was the stress on the American colonists' entitlement to 'English liberties' and civil rights, rights that, it was claimed, had been trampled upon. The next step was to separate from this close association to Englishness and instead to refer, as was done in the Declaration of Independence, to the 'inalienable rights' ultimately grounded in universal Natural Law and 'the rights of man.' However, in spite of this emphasis on universality, the Constitution—and the rights and liberties it guaranteed—soon became the basis for the elaboration of an American civic nationalism, based on the idea that the American people, formed by its liberal-democratic institutions, was exceptional in its commitment to individual liberty and equality. Thus in the USA, the idea of 'We the People' as the ultimate source of legitimacy and sovereignty was informed by a pervasive individualism and an enduring suspicious of centralized government. If in the French case the primacy of the people as a unified collectivity went hand in hand with strong central government, national standards, and a distaste for local difference, it was conversely true that in the US case the primacy of the people as a collection of free individuals informed an opposite tendency.

At the same time, Herderian notions of national character also came to infuse US self-understanding of the essential character of the American people, which revolved around the idea that America as a people and a nation was more mature and evolved than other peoples by virtue of its deep-seated capacity for democratic self-government. A similar fusion of an ethnic and a civic notion of the people occurred in Sweden, where leading Social Democrats after World War I came to embrace the idea that Swedes were endowed with a peculiar propensity for democracy and freedom, amounting to what one of them referred to as having 'democracy in the blood.' Citing a long, unbroken legacy of self-government that linked modern-day Swedes to the ancient yeoman peasants, the existence of a tradition was claimed, in which 'democracy is rooted not merely in the constitution, but also in our traditions and in the disposition of the folk,' as the Swedish prime minister Per Albin Hansson put it in 1935.

On this basis, Swedish Social Democrats conjured up a vision of a *folkhem*, a people's home, which usefully can be contrasted with the contemporary German slogan, *Volksgemeinschaft*, or 'people's community,' championed by Hitler and the National

Socialists. While both concepts celebrate national community, one prefigured the Nazi racial state, while the other became the organizing slogan for the Swedish welfare state. In the Swedish case, the concept of the *folk* connoted democratic sentiment rooted in a particular, common history; in the German one, the corresponding concept of the *Volk* referred to a racial community. This is particularly clear in the adjectival forms of *folk*/*Volk*, both equally difficult to translate into English. The German word, *völkisch*, means 'national' but with a distinct emphasis on race, and specifically with an anti-Semitic thrust. The Swedish word, *folklig*, conversely, is better translated as 'popular/populist/democratic,' with an association to the democratic legitimacy of claims made by those who credibly speak in the name of 'the people,' first and foremost the nonelite, that is, workers and peasants.

Thus the precise relationship between the concept of the people and such neighboring concepts as state, society, culture, race, and the individual become absolutely central if we are to understand the political implications of the concept of the people. In one case the proximity of *Volk*/nation/culture/race/collectivism is associated with racist nationalism; in another the linkage between *peuple*/nation/state/society connotes a collectivist, if democratic, conception of popular sovereignty; in a third the association with the people/individual liberty suggests a liberal and individual rights-based political order; while in a fourth one the correlation of folk/home/solidarity/state informs the vision of a welfare state.

Sociobiology: Overview

'Sociobiology' refers to the study of social phenomena within the conceptual framework of biological science. More specifically, it usually refers to an explicitly neo-Darwinian approach that grew out of the theoretical contributions of W. D. Hamilton (1964) and G. C. Williams (1966). The hallmark of this approach is the interpretation of social behavior, and its causal mechanisms and processes, as products of the Darwinian processes of natural and sexual selection (see *Darwinism*), and hence in terms of adaptive function or 'design' (Dawkins 1986).

The term 'sociobiology' was apparently coined by J. P. Scott, a student of the genetics and development of mammalian social behavior, who began organizing paper sessions on animal behavior and sociobiology at scientific meetings around 1950. In 1956, the Ecological Society of America established a new section of animal behavior and sociobiology, the forerunner of today's Animal Behavior Society, with Scott as its chairman (Dewsbury 2000). However, the word 'sociobiology' was not widely used before 1975, when Harvard entomologist Edward O. Wilson made it the title of an ambitious volume reviewing and synthesizing information and ideas about the evolution of social behavior across the animal kingdom.

Wilson (1975, p. 4) defined sociobiology as 'the systematic study of the biological basis of all social behavior,' but although this definition is frequently quoted, it does not convey the word's meaning in actual usage. In the broadest sense, since 'biology' is 'the science of life and life processes, including the structure, functioning, growth, origin, evolution, and distribution of living organisms' (the *American Heritage Dictionary*), and since only living organisms have 'social behavior' in any interesting sense of the word 'social,' Wilson's definition could be construed as inclusive of all social science. However, 'sociobiology' is obviously not used as a synonym for 'social science' and most social scientists do not consider themselves biologists. A narrower construction of the meaning of

'biology' does not help Wilson's definition conform to usage: for most scientists, the phrase 'biological basis' connotes the genetic, endocrine, and brain mechanisms underlying social behavior, but these 'proximate causal' factors are not the primary focus of sociobiologists, and most work in these areas would not be considered sociobiological. In practice, both Wilson's tome and subsequent sociobiological work have been primarily concerned with applying theories from population biology, genetics, and ecology to the problem of explaining the evolution of social phenomena and their diversity both among and within animal species (see *Comparative Method, in Evolutionary Studies*), in much the same way as one might endeavor to understand the evolution and diversity of anatomical structures.

Like anatomists and physiologists, whose research is guided by their interpretations of the component parts and subsystems of organisms as devices 'for' digestion, respiration, vision, circulation of the blood, and so forth, sociobiologists are 'adaptationists' (see *Adaptation, Fitness, and Evolution*). That is, sociobiologists assume that social phenomena—such as mating preferences, offspring sex ratios, warning calls, systematically discriminative treatment of young by parents, situationally contingent gregariousness, seasonality of territorial defense, etc.—have a functional significance for the behaving animal that can be illuminated by appropriate hypothesis testing. Moreover, sociobiologists are 'selectionists' (see *Natural Selection*). That is, their hypotheses about the adaptive functions of social phenomena generally entail the assumption that the social attributes under consideration have been shaped by a history of Darwinian selection to be effectively fitness-promoting in ancestral environments (see *Adaptation, Fitness, and Evolution*). Indeed, effective contribution to fitness (the replicative success of the focal individual's genes relative to their alleles, and hence genetic posterity) is considered the superordinate criterion of adaptive function; more immediate aims, such as foraging efficiently, attracting mates, and protecting one's young from predators, are interpreted as having evolved as means to the end of fitness.

Sociobiological theory and research began to flourish only after the fallacy of naïve group-level adaptationism or 'greater goodism' (Cronin 1991) was dispelled. For over a hundred years, Darwin's (1859) concept of 'natural selection' was widely misunderstood, even by evolutionary biologists, who often uncritically interpreted evolved attributes as having been selected to promote 'the reproduction of the species' (see *Evolutionary Selection, Levels of: Group versus Individual*). Williams (1966) dissected and demolished this fallacy, persuading a majority of evolutionists that the capacity of Darwinian selection to create adaptive organization resides primarily in the differential reproductive success of alternative 'designs' within species, that the attributes that evolve therefore tend to be functionally organized to help individual organisms to outreproduce conspecific rivals, and that any ensuing benefits or harms to a whole population or species are incidental byproducts of organismic designs rather than what the designs are organized to achieve. This critique inspired a view of organisms as 'evolved reproductive strategists' whose attributes must be understood as tactics for effective reproductive competition against others of their own kind. (It is important to note that the 'strategy' metaphor carries no implication of foresight or intent. Indeed, the concept applies to brainless organisms as fully as to those with complex cognition. Thus, a sociobiologist might refer to a plant's 'reproductive strategy,' which is analyzed as consisting of numerous special-purpose 'tactics,' such as germinating in response to some degree of abrasion of the seed husk, flowering in response to a threshold air temperature, avoiding self-fertilization by asynchronous maturation of male and female flower parts, and so forth.)

The second main conceptual development leading to the flowering of sociobiological theory and research in the final third of the twentieth century was Hamilton's (1964) formulation of 'inclusive fitness' (or 'kin selection') theory (see *Adaptation, Fitness, and Evolution*). Classical Darwinism had construed the fitness that selection tends to maximize as personal reproductive success, but Hamilton noted that selection will favor any phenotype (see *Genotype and Phenotype*) that effectively promotes the replicative success of copies of the focal organism's genes, relative to their alleles (alternative forms of the same gene), regardless of whether those genes reside in descendants or in collateral relatives. Thus, for example, the complex brood care and colony maintenance behaviors of sterile worker ants can be favorably selected if these acts promote the reproduction of a queen who is closely related to the workers. Hamilton proposed that the quantity that selection tends to maximize is not personal reproduction (sometimes called 'direct fitness'), but the focal individual's 'inclusive fitness effect,' which is its total impact on the proliferation of its alleles via both direct fitness and any effects that the focal individual may have on the reproductive success of collateral kin ('indirect fitness'). Hamilton's analysis implied that organisms are not just evolved 'reproductive strategists,' but evolved 'nepotistic strategists' (see *Social Evolution: Overview*). In this context, 'nepotism' means directing benefits to one's genetic relatives, and the implication of Hamilton's revision of the fitness concept was, to quote Alexander (1979, p. 46), that living creatures 'should have evolved to be exceedingly effective nepotists, and we should have *evolved* to be nothing else at all.' (Note that Alexander, like most evolutionary biologists, uses the word 'nepotism' to encompass acts that promote both the direct and indirect components of fitness; confusingly, however, some authors use this term to refer only to acts that promote indirect fitness, excluding parental

care from its domain. Even more confusing is the common misuse of the term 'kin selection' as a substitute for 'nepotism,' such that an individual who is helping relatives is said to be exhibiting or engaging in kin selection. Used correctly, 'kin selection' refers to a population genetical process whose expected phenotypic consequence, on an evolutionary time scale, is nepotism, which is often but not necessarily manifested as selectivity in social response. Many sociobiologists, however, including Hamilton, have eschewed this popular phrase, both because it has so often been misused and because even its correct usage is often misinterpreted as logically parallel to, and theoretically alternative to, 'individual selection' or 'group selection'; see *Evolutionary Selection, Levels of: Group versus Individual*).

By the late 1980s, the word 'sociobiology' had begun to fall from favor. Most practitioners now refer to their field as 'behavioral ecology,' a term with slightly broader scope, in that it encompasses the adaptationist, selectionist approach not only to social phenomena but to asocial behavior as well, especially foraging. Thus, although one might suppose from its title that the journal *Behavioral Ecology and Sociobiology*, established in 1976, would cover a broader domain than that of *Behavioral Ecology*, established in 1990, the scope of the two journals is identical. Declining use of the word 'sociobiology' should not be mistaken for a decline in the paradigm's popularity. Indeed, during the 1980s, the sociobiological approach came to dominate the study of animal social behavior, as it still does (Alcock 2000).

1. *The 'Problem of Altruism'*

A central concern of sociobiological theory and research has been the 'problem of altruism': if Darwinian selection is a process that favors and refines only those attributes that contribute to their bearers' fitness relative to the fitness of conspecific rivals, then why is nature not more consistently 'red in tooth and claw'? In other words, how can such prosocial phenomena as restraint in aggressive conflict or active cooperation have evolved? In this connection, sociobiologists define 'altruism' as action whose average consequence is a reduction in the actor's direct fitness (expected reproductive success) and an increase in the direct fitness of someone else. (It should be noted that although this definition encompasses much of what might be deemed 'altruistic' in an ordinary English sense, since its essential feature is self-sacrifice that benefits others, it differs from ordinary usage in the fact that other-regarding intent is irrelevant.) At first glance, it would appear that selection must always penalize action that is altruistic in this technical sense, and yet animals often perform acts that clearly qualify, such as working to help raise others' young, or paying some energetic or predation risk cost in order to warn neighbors of danger. How these phenomena came into existence and are able to persist in a Darwinian world was a mystery before the 1960s, although the unexamined greater-goodism of many biologists kept them from recognizing that there was something in need of explanation.

Hamilton's inclusive fitness theory provided the most important answer. If the beneficiary of an altruistic act is a relative of the actor, and if that relative's gain is sufficiently large relative to the actor's sacrifice, then the net inclusive fitness effect for the actor can be positive and the altruistic tendency can increase in its relative frequency. More specifically, Hamilton theorized that the necessary condition for a heritable altruistic tendency to increase in prevalence under selection (often called 'Hamilton's rule') is $c/b < r$, where c is the cost (in units of expected direct fitness) incurred by the actor, b is the benefit (in the same currency) enjoyed by the altruistic act's beneficiary, and r is a 'coefficient of relatedness' between the actor and the beneficiary, indicative of the extent to which the two share identical genes by virtue of descent from recent common ancestors. Subsequently, more complex population genetical models confirmed the robustness and generality of Hamilton's rule, at least as a close approximation, making it a cornerstone of sociobiological theory (see, e.g., Frank 1998).

A great deal of sociobiological research has been concerned with testing whether altruistic behavior in nature can be understood as nepotism in accordance with Hamilton's rule. Supportive evidence has mostly taken the form of demonstrations that animals behave differently as a function of their relatedness to their interactants or neighbors; animals such as colonial ground squirrels and prairie dogs, for example, have been found to call out warnings of predator presence facultatively, according to the potential caller's degrees of relatedness to others in the vicinity. Progress in genetic methods of kinship assessment, especially 'DNA fingerprinting,' has fuelled an explosion of research on the ways in which social behavior in the field is affected by relatedness. There has also been considerable interest in elucidating how animals 'recognize' kin when they behave nepotistically; in some cases, they respond to cues that are under more or less direct genotypic control, such as certain odors, and in others to reliable circumstantial cues (e.g., those who share my mother's womb with me must be close kin), while in still other cases there is no evident discrimination among one's actual interactants at all but a 'rule of thumb' that does not require true recognition (e.g., behave cooperatively until I emigrate at maturity, at which time my average level of relatedness to those that I encounter will plummet).

The direct fitness costs incurred by altruists or nepotists and the fitness benefits that they bestow are usually harder to measure than relatedness, since they often depend on small changes in the risk of infrequent outcomes such as death by predation. However, one

area in which relatively precise measurement and quantitative hypothesis testing have been substantial is that of 'cooperative breeding,' where individuals other than a parent or pair of parents participate in the care and rearing of dependent young. The two taxonomic groups that have been most studied are the social insects, which manifest complex consequences of some unusual twists on genetic relatedness (Crozier and Pamilo 1996), and cooperatively breeding birds, in which helpers are usually, but not always, close kin of those they assist (Stacey and Koenig 1990). Recent theory and research on 'cooperative breeding' have focused especially on factors affecting the degree to which reproduction is monopolized or shared (e.g., Reeve 2000).

Theoretical sociobiologists have also sought nonnepotistic solutions to the problem of altruism, with particular interest in the circumstances that permit reciprocity ('you scratch my back and I'll scratch yours') to be evolutionarily stable. This issue has been addressed primarily by game theoretical models (see *Game Theory*), which have highlighted the necessity that nonreciprocators ('cheaters') be detected and denied the benefits provided to reciprocators, as well as the difficulty of establishing the requisite punishment of cheaters in multi-party games, when punishing is itself a sort of altruism (i.e., the provision of a 'public good'). Empirical investigations of nonnepotistic reciprocity in nonhuman animals have been few, however, perhaps indicating that the complex social cognition that is necessary for all but the most limited forms of reciprocation-in-kind is restricted to human beings and our near relatives.

2. *Sexual Selection and Sexual Conflict*

Another major focus of sociobiological theory and research has been sexual reproduction. Problems include when and why organisms reproduce sexually (i.e., biparentally) rather than uniparentally, and, in the event of 'dioecy' (the existence of two sexes with distinct adaptations), exactly how and why females and males differ. In 1871, Darwin supplemented his 1859 theory of evolution under the influence of 'natural selection,' by proposing a distinct evolutionary force that he called 'sexual selection' (see *Darwinism*). Whereas natural selection referred to the nonrandom differential reproduction of types as a result of differential success in coping with such exigencies as finding food, avoiding predators, and enduring climatic factors, sexual selection referred to the nonrandom differential reproduction of types as a result of differential access to mates and their reproductive labors. Darwin distinguished the two because they could sometimes act in opposition, as for example when sexual selection favors the evolution of conspicuous courtship structures, like the peacock's tail, that enhance mating success but apparently also increase mortality risk.

Sexual selection was the object of scant theoretical or empirical work for a century after Darwin proposed the concept. Williams (1966) and Trivers (1972) resurrected it as a focal topic in sociobiology, proposing that the extent to which sexual selection operates differently on females and males, and thereby induces the evolution of sex differences in anatomy, physiology, psychology, and behavior, was determined by the extent to which the reproductive efforts (especially parental care) provided by one sex constituted the principal resource limiting the fitness of the less investing sex (usually, but by no means always, males), and hence the object of competition among members of the less investing sex. More recent work has focused on the criteria and consequences of mating preferences, with particular interest in differentiating among theories that attribute the evolution of such preferences primarily: (a) to their utility for recruiting 'good genes' for one's offspring; or (b) to their utility for garnering material resources and/or minimizing such costs of mating as lost time or energy and elevated disease transmission risk; or (c) to 'sensory biases' whose primary function resides in contexts other than mate choice; or (d) to a self-reinforcing dynamic ('Fisherian runaway selection') that tends to produce display features and preferences that are arbitrary with respect to all criteria of functionality outside the mating context (see Cronin 1991, Andersson 1994).

Recent theory and research have also focused on conflicts of interest between mates (or potential mates) as well as those between same-sex rivals. Work in this area is related to problems in the evolution of communicative signals between agents whose commonality of interests is only partial (see *Game Theory*).

3. *'Selfish Genes' and Intragenomic Conflict*

An area of great contemporary interest concerns the evolutionary consequences of the fact that selection can operate differentially on different components of the genome. Because the male sex-determining Y-chromosome is transmitted only from father to son in such animals as fruit flies and human beings, for example, mutations on the Y that have the effect of biasing a progeny towards male production have been observed to increase in prevalence over generations, even when they reduce the inclusive fitness of the host individual (see *Y-chromosomes and Evolution*). Conversely, mitochondrial DNA and other cytoplasmic inheritance factors are transmitted only through daughters, and mutations in these factors that bias sex allocation towards females may similarly proliferate despite negative inclusive fitness effects (see

Mitochondria and Evolution). The consequence is 'intragenomic conflict': simultaneous selection at different genetic loci, within the same population, in favor of alleles with antagonistic phenotypic effects (Haig 1997).

The recent discovery of 'genetic imprinting,' a process whereby certain genes are differentially activated according to whether they were inherited from one's father or mother, has greatly extended the known potential for such intragenomic conflict, as for example when genes of paternal origin are selected to produce fetal and infantile phenotypes that effectively 'discount' the value of the mother's potential future offspring (who may have distinct paternity) more steeply than do genes of maternal origin, leading to the evolution of directly antagonistic phenotypic effects of maternally and paternally imprinted genes (Haig 1993). In a sense, these discoveries challenge the orthodox sociobiological view of organisms as nepotistic strategists with integrity of purpose subsidiary to the function of maximizing inclusive fitness, since selection clearly can and does favor the proliferation of genes that promote their own replication at the expense of 'their' organisms' inclusive fitness. However, the individual-level focus of sociobiological research continues to be productive (Alcock 2001), and is unlikely to be abandoned soon.

Sociobiology: Philosophical Aspects

Wilson (1975) published an overview of the evolution and adaptive significance of social behavior. It focused on the social behavior of nonhuman animals. But the final chapter applied evolutionary reasoning to human action; arguing that certain common patterns in human behavior were adaptations. That is, they exist because they conferred fitness advantages on our ancestors. Indeed, our ancestors were ancestors in part because they did, and others did not, manifest these behavioral dispositions. As a consequence, 'sociobiology' is a term often used narrowly, as a term for the evolutionary analysis of human social behavior, and that will be the focus of this article. Human sociobiology has been a very controversial enterprise (Kitcher 1985, Hull and Ruse 1998). Yet on the face of it, that is puzzling. We are evolved organisms. Human behavior has an evolutionary history; a history that must at least partially explain that behavior.

None of sociobiology's chief critics deny this basic fact. Instead, they have developed a minimization strategy, accepting the basic fact of human evolution, but arguing that human evolutionary history is largely irrelevant to an explanation of specific features of human social behavior. One idea is that human evolutionary history can explain only what is individually fixed or innate, and what is common across cultures. But the most striking features of human

experience are individual developmental plasticity and cultural variability. Thus, within the social sciences it is common to suppose that our evolved 'human nature' places only the broadest constraints on our cultural life. If humans reproduced asexually, or if human infants were independent at 18 months of age, human cultures would be very different. But human evolutionary history makes possible many human cultures and social organizations. Since every human group has a similar set of biological resources, the massive differences between groups must be explained in terms of differing cultural resources. Difference explains difference. Human evolutionary history explains how hominids developed the ability to transmit culture and the plasticity to be shaped by that culture. But that is all it explains (Lewontin et al. 1984, Levins and Lewontin 1985).

Sociobiologists resist this line of argument. In particular, Tooby and Cosmides argue that human cultural diversity and individual developmental plasticity is more bounded than the minimisation strategy suggests. And they argue that diversity itself may have an evolutionary explanation. Organisms are adapted to behave differently in different circumstances. The differences between castes of social insects are often profound. Yet these differences are different developmental expressions of a single adaptation. Equally, a single mechanism of mate choice might generate one behavior in a New York singles bar, and quite a different one in an Amish church (Tooby and Cosmides 1992). Sects. 2 and 3 outline of the development of human sociobiology since 1975. The article then concludes with three short sections introducing key conceptual and methodological issues raised by contemporary sociobiology.

1. *The Wilson Program*

Wilson and his co-workers began with the insight that behavioral differences are just as subject to selection as any other feature of an organism. Animals within a population are as apt to differ in behavior as they are in any other aspect of their phenotype. These differences make a difference to fitness. Moreover, there is good reason to expect that behavioral differences are heritable. Evolutionary histories reconstructed from behavioral traits agree well with those from morphological and genetic ones (see, e.g., Kennedy et al. 1996). So selection can work. The mound building behavior of the orange-footed scrubfowl—a bird that lays its eggs in a mound that functions as an incubator—is just as likely to be an adaptation as its large powerful feet.

Wilson simply extended this idea from animal to human behaviors. He had in mind such behaviors as incest avoidance, male sexual promiscuity and female coyness, infanticide, rape, and hostility to strangers. Just as the scrubfowl has been selected to build, guard, and monitor the temperature of its mound, perhaps humans have been selected to act with hostility towards strangers or to use infanticide to manipulate the sex ratio of their offspring (Wilson 1975, Wilson 1978).

Adaptationist analyses of behavior can seem quite plausible. Consider sex role differentiation. In some bird species, the male takes responsibility for brooding the eggs and caring for the chicks. But, in general females, and especially female mammals, have a higher initial investment than males in any reproductive act. Eggs are much larger, and hence more biologically expensive, than sperm. Second, the costs of pregnancy and postparental care are very significant. By accepting a sexual partner, a female mammal commits a serious fraction of her total life reproductive resources. That need not be true of males: they do not bear the costs of pregnancy and lactation. Sex is not without cost to males. Copulation exposes the male to predators, parasites, and pathogens. But the female also bears these costs together with those of pregnancy. So mating costs do not fall evenly on the sexes, and this suggests different optimal strategies for males and females. Males are likely to attempt to be more promiscuous; females, more coy. We might also expect some gender differentiation in caring decisions. If her young are to live, a female mammal has no choice but to engage in childcare. Not so the male, who is unconstrained by physiology. For him, all options are possible. These range from outright desertion of the pregnant female, through diversion of some of his resources to other mates and their young, to full participation in childcare.

Adaptive hypotheses of this kind about human behavior are all very controversial. This is not surprising, for they are hard to test. A standing problem for human sociobiology is to move beyond plausibility considerations to clear empirical tests, and it is not clear how that is to be done. However, the most fundamental problem with the Wilson program is its grain of analysis. Lewontin has pointed out that an adaptive explanation of a trait presupposes that the trait can, over evolutionary time, vary independently of others (Lewontin 1978). It is, thus, very unlikely that there is any selective explanation for the color vision properties of the human left eye. The color vision capacities of the left retina do not vary (heritably) independently of those of the right retina. Its receptor sensitivities are not adaptive or evolutionary atoms. Human skin color, on the other hand, almost certainly is such an atom.

Behavioral traits are sometimes atoms. The scrubfowl's mound building and mound maintaining behavior probably has evolved independently, and operates independently, of the scrubfowl's feeding, roosting, and predator avoiding activities. The human behavioral repertoire, however, is not an aggregation of independent units. The realization that human action depends on a small number of interacting psycho-

logical mechanisms propelled psychology from behaviorism to cognitivism. Our behavior is produced by mental mechanisms that play a role in many different behaviors. Some of the mental mechanisms used in hunting are also used in storytelling. Rape, xenophobia, child abuse, homosexuality, and other human behaviors very likely do not vary independently of other human actions. They could only be altered by altering the underlying mental mechanisms, and since these mechanisms are used for many different purposes, any change would have many other consequences. Particular behavior patterns are unlikely to have independent selective histories.

2. *Darwinian Psychology*

The idea that we should not be looking for adaptive hypotheses about specific behaviors has gradually become part of the accepted wisdom of human sociobiology. The psychological mechanisms that generate behavior are the proper focus of evolutionary theorizing. Sociobiologists have turned from the idea that each behavior evolved because it was selected to the idea that many different behaviors are caused by a relatively small number of cognitive mechanisms. It is these mechanisms that have evolved (Barkow et al. 1992, Plotkin 1997).

Evolutionary psychologists defend a general schema of the evolved nature of the human mind, and they have developed a discovery procedure for filling out that schema. They reject the metaphor of human psychology as a general-purpose computer programmed differently by different cultures. They replace this vision with a modular theory of mind. The mind is a cluster of evolved information-processing mechanisms. The main empirical program of evolutionary psychology is to characterize these 'Darwinian algorithms.' For example, Buss and Symons think that there are Darwinian algorithms of sexual attraction. These result in the tendency of human males to find those females attractive that bear the cultural marks of youth, and of women to find attractive those that bear the cultural marks of high status (Symons 1979, Buss 1994). Baron-Cohen and Sperber have argued that we have a specific mental mechanism, a 'mind reading' device, designed to enable us to anticipate others' behavior (Baron-Cohen 1995, Sperber 1996). Darwinian algorithms are supposed to be mental 'modules' in the sense defined by Fodor: domain-specific, mandatory, opaque, and informationally encapsulated (Fodor 1983). They are domain-specific because they deal with a specific class of situations in which the organism finds itself. The mind reader is not used to predict the outcome of physical interactions. Darwinian algorithms are mandatory. We do not choose to interpret a particular smile as false. Rather, our mechanisms of emotion recognition are engaged automatically once we recognize a particular stimulus as a face. Darwinian algorithms are opaque because their internal processes are not consciously accessible. If Cosmides and Tooby are right, we have cognitive mechanisms specifically adapted to detect cheating in social exchange (Cosmides and Tooby 1992). But we cannot tell by introspection whether we have such mechanisms or how they operate. Finally, Darwinian algorithms are informationally encapsulated because they do not make use of the information stored elsewhere in the cognitive system.

Chomsky looms large in the development of evolutionary psychology. If he is right, the differences between human languages are not profound. There are many very important features common to all human languages. The class of possible human languages is constrained quite tightly by the nature of an innate language acquisition device. Moreover, that device contains conditional elements whose different settings explain many of the differences between languages. Language thus illustrates two themes of evolutionary psychology. Diversity is less profound than it appears, and it can be explained by a single mechanism; one operating differently in different circumstances.

Evolutionary psychologists take the human mind to be a complex of modules, each adapted to solve a specific problem or cluster of problems that was central to the life of our ancestors. But how are we to identify and characterise these modules? They hope to solve this problem by the strategy of 'adaptive thinking.' Adaptive thinking infers the solution, the adaptation, from the problem, the ecological context in which the organism evolved. So the first task of the evolutionary psychologist is to identify the adaptive problems our ancestors confronted in their environments. For example, in complex and unstable social groups, our ancestors would have needed social expertise; they would have needed to be good judges of others' likely actions (Whiten and Byrne 1997). The second task is to discover the stable correlations between those aspects of the environment humans are equipped to sense, and those aspects they need to know about. We can expect natural selection to engineer into task-specific devices implicit knowledge of these correlations. So if, for example, aggressive behavior or defecting from an agreement is usually preceded by a characteristic stance or facial expression, the evolutionary psychologist would expect this to be engineered into those mechanisms specialized for managing social interaction. The third task of the evolutionary psychologist is to construct an information-processing design that could solve the adaptive problem using the available cues. The fourth and final task is to experimentally test for the existence of the hypothesized mechanisms. For many potentially useful adaptations will not actually be engineered into us.

Human sociobiology has developed from a theory of the adaptive significance of particular behavior

patterns to a theory of the architecture of the human mind, and of the adaptive significance of the components of that architecture. Much remains controversial about this program, both in its detail and its overall orientation. So this article will finish by outlining three critical issues that are still open.

3. Testing Sociobiological Hypotheses

One central problem for sociobiology is to move beyond plausibility stories to develop clear empirical tests of specific sociobiological hypotheses. It is not obvious that this problem can be solved at all. The resources of comparative biology offer one of the most powerful methods of testing adaptationist hypotheses (Harvey and Pagel 1991). For example, suppose we suspect that a certain leaf shape is an adaptation to arid conditions. If we show that within a particular tree family (e.g., the eucalypts) that there is a strong covariation between long, narrow, waxy leaves and distribution through an arid habitat, we could reasonably regard that hypothesis as well confirmed. It would be confirmed especially well if the ancestor of our (putative) arid-adapted trees did not have long and narrow leaves, for we could then rule out the hypothesis that the leaf shape was no more than an inheritance from a common ancestor. If we found the same pattern in other tree species, our confidence in our adaptive hypothesis would be stronger still. Unfortunately, we cannot apply the methods of comparative biology to test the most interesting adaptive hypotheses about human psychological mechanisms. Our closest relatives are extinct. So many of these mechanisms are found only in our own species. Even where they are shared with our closest living relatives (e.g., the facial expression of emotion) they exist in a different form. Moreover, the human lineage—and even the human and great ape lineage combined—is not bushy; the eucalypt, in contrast, boasts hundreds of species. The comparative method can tell us nothing at all about the adaptive significance of language and very little about tool making, true imitation, and many other important human cognitive adaptations.

The main alternative to comparative biology is the development of quantitative evolutionary models. If there is a good quantitative fit between model and data, we can regard the model as passing an important test (Orzack and Sober 1994, Orzack and Sober 1996). But here too the prospects are dim. First, it is often hard to actually measure the impact of behavior on human fitness. Economic resources typically are used as a measure of fitness benefits. But even in hunter–gatherer societies this is probably too crude. For fitness probably does not vary as a linear function of economic resources. Second, in developing an evolutionary model, we need to define a space of possibilities. For the adaptationist hypothesis is that the fittest behavior within that space will become established by selection in the population. Yet how do we develop a possibility space for human behavior? To recycle on example from Kitcher, what were the realistic alternatives of, say, a man in an avunculate society? Could he defect from the avunculate, directing his resources to his wife's children, rather than to his nieces and nephews (Alexander 1979, Kitcher 1985)? Finally, and most importantly, we face the problem that humans now act in a very different world from that in which human psychological mechanisms evolved. So measuring the impact of behavior on current fitness seems beside the point. Yet, of course, we have no access to the fitness consequences of behaviors in those ancestral environments.

So the problem of testing sociobiological hypotheses is very serious. The shift in theoretical interest from behavior to the mechanism that produces that behavior in one way makes the problem even more intractable. The Wilson program took the unit of adaptationist analysis to be a behavioral pattern. Such patterns are observable, though if they are patterns in sexual behavior, violence to outsiders, or infanticide, they will not be easy to observe. The program of evolutionary psychology adds to the existing methodological problems yet another: inferring cognitive mechanism from behavior. This is known to be difficult. But in one important respect, evolutionary psychology improves the prospects for testing sociobiological hypotheses. To the extent that evolutionary psychology makes specific architectural claims about human cognition, these are subject to direct empirical test. For example, Frank has argued that emotions function as commitment devices; they bind agents to future courses of action that will not then be in the agent's interest, and thus tend to maximise the agent's overall long run welfare (Frank 1988). It is a consequence of this theory both that emotions are not under central control, and that other agents are good at using emotional signals to predict future behavior in commitment situations. These consequences are directly testable by experimental psychology.

However, a positive test does not directly vindicate the adaptive hypothesis that is alleged to explain the existence of the proximate mechanism. Moreover, the relationship between adaptive function and proximate mechanism is often less direct than this example suggests. Sober and Wilson point out this in their discussion of altruism. They argue that there are good reasons to believe that humans are a group-selected species, and hence that human behavior will often be altruistic in the evolutionary sense. Its function will often be to promote the fitness of the group at some cost to the agent's fitness. But Sober and Wilson point out that while this constrains the proximate mechanism, it does not fix it. Altruistic agents might act altruistically because of irreducibly altruistic motivations, or because selection has built in internal rewards.

Altruistic behavior could be engineered either way (Sober and Wilson 1998). In short, then, despite the shift from adaptive theories of behavior to adaptive theories of psychological mechanism, the problem of the testability of sociobiology remains very serious.

4. Evolutionary Psychology and Rational Agency

Suppose the basic hypothesis of evolutionary psychology is right. Human minds are ensembles of adapted modules. What follows for folk psychology, i.e., belief/desire theories of human behavior? Many models in the social sciences depend on folk psychology, either directly or on its formalized cousin, the view that humans are rational agents that maximize their expected utility. Does evolutionary psychology drive out rational choice theory? The idea that humans are rational agents is compatible with a partially modular theory of mind, to one along the lines of Fodor's 1983 model. For he retains a central processor with the critical role of maintaining an overall model of the agent's environment, and using that model to guide rational action. A Fodorian agent could well be a rational maximizer; indeed, a rational economic maximizer. But evolutionary psychology in its standard formulation seems inconsistent with rational choice theory understood as a descriptive claim about human behavior. If there is no general-purpose device—if there is nothing like a central processor—it is hard to see how a rational actor model could accurately describe the pattern of human action. When humans respond to problems that were important in the environments in which our cognitive mechanisms evolved, and when they do so in environments relevantly like those ancestral environments, and when fitness consequences correlate well with individual welfare, then of course human behavior might maximize expected utility. But much human behavior is not directed on problems that were critical to our ancestors, and humans often act in environments very different from those in which psychologically modern humans evolved.

One defender of evolutionary psychology to confront this problem is Sperber. He defends the view that the mind is wholly an ensemble of modules. But he argues that one of these modules, the metarepresentation module, can act as a surrogate general-purpose device. The function of the metarepresentation module is to guide our behavior with respect to other humans. For we can estimate their actions best by estimating their representation of the world. Since the proper function of the metarepresentation module is to represent representations, we have a derived, second hand capacity to represent anything, or at least anything that anyone else can represent (Sperber 1996). However, this suggestion does not address the issue of integration and the effective use of information to guide behavior with respect to novel aspects of our physical environment. So it is not clear that the behavioral abilities of a Sperber agent would match those of a Fodor agent.

So we may have to choose between a wholly modular theory of the mind and rational agent psychology. Perhaps, though, evolutionary psychologists should retreat from their commitment to a wholly modular theory of mental organization. For there are good reasons for thinking that a commitment to a modular view of the mind is premature. Adaptive thinking suggests modular mechanisms have a downside: they are vulnerable to exploitation in a malign world. For if they are encapsulated, they use only a fraction of the information potentially available to an agent. Yet, if our minds are the result of an arms race, they evolved in a hostile world, not merely an indifferent one. Game theoretic models of the evolution of language have a strong cooperative element; they are close to one end of a mathematical spectrum from games of pure cooperation to games of pure conflict (Skyrms 1996). Both parties in a linguistic interaction benefit from successfully communicating their intended meaning. Even if they have further, incompatible agendas, neither will succeed unless the utterance is understood. A module for resource sharing might well be manipulated to gain a better share of resources. Similarly, if there are mate choice modules that work on inflexible, prewired cues, these two will be vulnerable to mimics.

Perceptual systems exemplify a surprising truth about human mentality. The information-processing tasks implicit in much human action are much more complex and difficult than one would intuitively expect. The outputs of the visual systems are reliable representations of what is seen, yet the signals that reach the retina are typically fragmentary and equivocal. That supports the view that those tasks could only be carried out by mental organs specifically adapted for those very tasks. This realization has generated a series of 'poverty of the stimulus' arguments in many branches of cognitive psychology. These attempt to show that human cognitive skills are too complex, and develop from too narrow an information basis, to be directed by a general learning mechanism.

However, the 'poverty of the stimulus' argument does not sustain some of the central hypotheses of evolutionary psychology. For example, Cosmides and Tooby argue that we have a module of social exchange (Cosmides 1989, Cosmides and Tooby 1989, 1992). But their reasoning is the inverse of 'poverty of the stimulus' reasoning; it depends on the fact that we usually find certain computationally trivial reasoning tasks extraordinarily difficult, but when those tasks concern social exchange we find them easier. So humans do an easy task in one domain with less difficulty than the same task in other domains. A poverty of the stimulus argument applies in the reverse situations, those where we find a computationally complex task effortless. Determining motion from

changes in apparent shape and size is computationally extraordinarily complex, yet we do it easily.

Moreover, many important problems cannot be solved by modular mechanisms. Fodor has argued convincingly that the pragmatics of language cannot be handled by a specialist device (Fodor 1983). It is one thing to know what a sentence means; it is another to know the intentions that lie behind its utterance. The latter problem is not solvable by shortcuts from a restricted database i.e., by an encapsulated device. Everything the hearer knows is potentially relevant and potentially used in decoding the speaker's intent. The same problem seems to arise for many of domains of interest to evolutionary psychology. Could an encapsulated mechanism deliver reliable judgments about the probability of a prospective partner's cheating? It is not at all obvious that there are cues that are reliable and are stable across generations. Both conditions must be met, if selection is to build a specialist mechanism to solve such problems. So the most plausible version of evolutionary psychology might be somewhat closer to Fodorian architecture; a complex of domain general and domain specific devices. If that is so, there may be ways of integrating evolutionary psychology and rational choice theory.

5. *Individual Behavior and Collective Action*

One central problem in the social sciences concerns the relationship between the explanation of individual action, and the explanation of collectives: of the nature and activity of cultures, classes, institutions, and the like. It is uncontroversial that there is a minimum constraint of the individual on the collective. Social facts supervene on individual facts, for social facts cannot change unless individual facts do, but not vice versa. A somewhat stronger claim is also relatively uncontroversial: social or collective causation requires individual microfoundations. So, for example, a theory of working-class collective action that depends on class consciousness owes us an account of the thoughts and actions of the individual agents whose pattern of individual action constitute that collective action (Elster 1989, Wright et al. 1993).

So one important issue about evolutionary psychology is concerned with the microfoundations it makes possible, and those that it rules out. Here the single most central issue concerns cooperation. Human life is pervasively cooperative, and this is a fact that is notoriously hard to explain consistently with the assumption that humans are rational economic maximizers. For the prisoner's dilemma and its relatives threaten to subvert cooperation between such agents, even though all would be better off under cooperative regimes. An array of solutions to this problem have been developed around reciprocation and iterated interaction (Axelrod 1984). These retain the assumption that individual agents act to maximize their own economic welfare, but it is far from obvious that these models are robust or realistic. For example, the famous 'tit for tat' strategy is by no means robust against error. If either player mistakes cooperation for defection, cooperation collapses (Sigmund 1993). So one important role for sociobiology might be to expand the space of microfoundational options for the social sciences. If Frank or Skyrms is right, in some circumstances evolved individual agents might reach the cooperate–cooperate option, even though agents that maximize their own expected utility would not (Frank 1988, Skyrms 1996). If Sober and Wilson are right, a proper regard for evolution does not commit us to the view that individual agents are designed to maximize their individual fitness (Sober and Wilson 1998). A theory of individual agency based on evolutionary psychology might, therefore, be significantly different from microfoundations based on an economic version of rational agency. However, the nature and importance of these differences remain to be elucidated.

K. Sterelny

Sociocybernetics

The term cybernetics derives from the Greek word for steersman. It can be translated roughly as the art of steering, and refers here to a set of related approaches, including especially general systems theory, and first- and second-order cybernetics. It can offer some interesting concepts and models to social science, and may also in that sense have a steering function.

Sociocybernetics consists of the applications of first-order and especially second-order cybernetics to the social sciences, and the further development of the latter (Buckley 1988). First-order cybernetics was developed in the 1940s, outside of the social sciences, whereas second-order cybernetics was developed to remedy the shortcomings of first-order cybernetics when applied to biology and the social sciences. For reasons of space, the essentials of first-order cybernetics and its main concepts—system boundaries; the distinction between systems, subsystems, and supra-systems; circular causality; positive and negative feedback loops; simulation—cannot be dealt with here (see Geyer and van der Zouwen 1991).

1. *Modern (Second-order) Cybernetics*

Second-order cybernetics originated in the early 1970s. The term was coined by Heinz von Foerster (1970) in 'Cybernetics of cybernetics.' He defined first-order cybernetics as the cybernetics of *observed* systems, and second-order cybernetics as the cybernetics of *observing* systems.

Indeed, second-order cybernetics explicitly includes the observer(s) in the systems to be studied. These are generally living systems, ranging from simple cells to human beings, rather than the control systems for inanimate technological devices studied by most first-order cybernetics. It could be said to have a biological approach, or at least a biological basis.

Apart from von Foerster, several other authors haven given concise definitions of the differences between first-order and second-order cybernetics: the purpose of a model vs. the purpose of the modeler (Pask), controlled systems vs. autonomous systems (Varela), the interaction among variables in a system vs. interaction between the observer and the system observed (Umpleby), and theories of social systems vs. theories of the interaction between ideas and society (Umpleby). This latter difference reflects Parsons's approach as that of a first-order systems theorist interested in system stability and system maintenance, and Luhmann's as that of a second-order cybernetician interested more in change and morphogenesis.

2. *The Usefulness of Second-order Cybernetic Concepts For Sociology*

The main concepts of second-order cybernetics—self-organization, self-reference, self-steering, autocatalysis, and autopoiesis—all start with 'self' (or 'auto'), possibly reflecting accelerating social change, whereas first-order cybernetics concepts do not point specifically to either the system or its environment.

2.1 *Self-organization*

Contemporary scientific interest in many disciplines centers on the emergent, self-organizing properties of complex aggregates, especially in biology and social science, and has stimulated second-order cybernetics. First-order cybernetics, though certainly aware of self-

organizing systems, did not pursue this line of inquiry. Ashby (1952, 1956), for example, also stressed self-organization. Recent developments in cognitive science—an interdisciplinary effort of neuroscience, artificial intelligence (AI), linguistics, philosophy, and cognitive psychology—demonstrate the importance of self-organization. Though the science only began in the 1970s, one can already distinguish two schools: cognitivism and connectionism.

Cognitivism and cognitive technology furthered the development of AI. Cognitivism conceived mental processes as manipulations according to the rules of deductive logic, as localized and serial information processing of symbols supposedly representing external reality (Varela et al. 1993, pp. 4–5). Thus, it seems to be close to first-order cybernetics. It was the mainstream paradigm in cognitive science until its drawbacks became more apparent in the 1970s.

(a) At some stage, symbolic information processing encounters the 'Von Neumann bottleneck': sequentially applied rules become problematic in case of large numbers of sequential operations, e.g., weather forecasting or image analysis.

(b) Symbolic information processing is not distributed but localized. Local malfunctioning of some symbols or rules therefore tends to result in overall malfunctioning, not having the resilience towards disturbances of distributed processing.

Connectionism, contrary to cognitivism, incorporates many second-order cybernetics views: It is explicitly bottom-up rather than top-down, eschews abstract symbolic descriptions, stresses emergence and self-organization, and assumes simple, 'stupid,' neuron-like components that develop cognitive capacities when appropriately connected. The intelligence is in the structure, in the connections made—hence connectionism—and not in the components. Hebb's 1949 rule occupies a central place. It states that learning is based on postulated changes in the brain resulting from correlated activity between neurons. If two neurons are active together, their connection is strengthened; if not, it is weakened. Thus, history—always a history of transformations—is incorporated. Simulations of a simple network of neurons according to Hebb's rule demonstrate that pattern recognition is possible, after a learning phase in which some of the connections are strengthened or weakened, provided the number of patterns presented does not exceed about 15 percent of the participating neurons.

The components of neural networks do not need an external processing unit which guides their operations. They work locally according to local rules, but global cooperation emerges when the states of all participating neurons reach a mutually satisfactory state. This passage from local rules to global coherence is the essence of self-organization—also denoted as emergent or global properties, network dynamics, nonlinear networks, complex systems, and so forth. Once one looks for it, emergence abounds. In different domains, like vortices and lasers, chemical oscillations, genetic networks, population genetics, immune networks, ecology and geophysics, self-organizing networks give rise to new properties.

The implications of these developments in cognitive science are potentially interesting for sociology, because of the possible analogies with self-organization in human societies:

(a) Autonomous systems, though computer-simulated in connectionism, give meaning to their interactions on the basis of their own history, rather than on the basis of the intentions of the programmer—or should one say a manipulating environment?

(b) Neural networks, and possibly human networks as well, produce emergent phenomena resulting from both simultaneous processes (the emergent pattern itself arises as a whole) and sequential ones (participating components have to engage in back-and-forth activity to produce the pattern).

2.2 *Self-reference*

Self-reference is typical of human beings, and possibly apes, both on the individual and the group level. It is not a concept in first-order cybernetics, which—as Norbert Wiener ([1948] 1961, 1956) stressed—concerns itself with the commonalities rather than the differences between humans, animals, and machines.

Self-reference is defined here in its second-order cybernetics meaning, where the (individual or social) system collects information about its own functioning, which in turn can influence that functioning. Minimal requirements are self-observation, self-reflection, and some degree of freedom of action. One of the main characteristics of individual and social systems is indeed their potential for self-referentiality in this sense. The self-knowledge accumulated by the system not only affects the structure and operation of that system, but also implies that (self-referential) feedback loops exist between parts of external reality and models and theories about these parts of reality.

Whenever social scientists systematically accumulate and publish new knowledge about the structure and functions of their society or subgroups within it—in principle available also for those to whom that knowledge pertains—such knowledge will often be invalidated, because the research subjects may react to this knowledge in ways that falsify the analyses or forecasts made. In this respect, social systems are different from many other systems, including most biological ones: There is a clearly two-sided relationship between the system's self-knowledge and its behavior and structure.

While biological systems also show goal-oriented behavior of actors, self-organization, self-reproduction, adaptation, and learning, only psychological and social systems arrive systematically, through experiment and reflection, at knowledge about their

own structure and operating procedures, with the obvious aim to improve these—both on the microlevel of the individual, as in psychoanalysis or other self-referential activities, and on the macrolevel of world society, as in planning international trade or optimal distribution of available resources.

The usual social science examples of self-referential behavior consist of self-fulfilling and self-defeating prophecies. Henshel (1990), for example, has studied *serial* self-fulfilling prophecies, where the accuracy of earlier predictions, themselves influenced by the self-fulfilling mechanism, impacts upon the accuracy of the subsequent predictions. However, in most empirical research, self-referential behavior does not loom large, perhaps because it is largely survey research, which offers less opportunity for self-referential behavior than depth interviews. These concentrate more on the 'why' than the 'what' of people's opinions, and thus tend to elicit self-referential remarks.

2.3 Self-steering

The futility of large-scale planning efforts has led to the realization that individuals and organizations are largely self-steering. While recognizing the usefulness of efforts to steer societies, a cost–benefit analysis of intensive large-scale steering efforts often turns out to be negative: Intensive steering implies intensive social change, i.e., a long period of increased uncertainty, with also an increased chance for changing planning preferences and for conflicts between different emerging planning paradigms during such a period.

Aulin (1982, 1988) tried to answer two basic questions in this respect.

(a) Should one opt for the 'katascopic' or the 'anascopic' view of society, for top-down planning of individual and group behavior to maximize societal survival chances, or should the insight of actors at every level, including the bottom one, be increased and therewith their competence to handle their environment more effectively and engage more successfully in goal-seeking behavior?

(b) What should be the role of science, especially the social sciences, in view of this choice: should it deliver useful knowledge for an improved centralized steering of the behavior of social systems and individuals, or should it strive to improve the competence of actors at the grass-roots level, so that these actors can steer themselves and their own environment with better results?

Aulin followed a cybernetic line of reasoning that argues for nonhierarchical forms of steering. Ashby's Law of Requisite Variety indeed implies a law of requisite hierarchy if only the survival of the system is considered, i.e. if the regulatory ability of the regulators is assumed constant. However, the need for hierarchy decreases if this regulatory ability itself improves—which is indeed the case in advanced industrial societies, with their well-developed productive forces and correspondingly advanced distribution apparatus (the market mechanism). Since human societies are not simply self-regulating systems, but self-steering systems aiming at an enlargement of their domain of self-steering, advanced industrial societies have the possibility nowadays to combine societal governability with ever less control, less centralized planning, and less concentration of power. When moving from a work-dominated society to an information-dominated one, less centralized planning is even a prerequisite. The intellectual processes dealing with information are self-steering, not only self-regulating, and cannot be externally steered by definition. Consequently, there should be no excessive top-down planning, and science should help individuals in their self-steering efforts, and certainly should not get involved in the maintenance of hierarchical power systems.

Of course, there are types of systems within a society that can indeed be planned, governed, and steered, simply because such systems have been specifically designed to exemplify the concept of the control paradigm of first-order cybernetics. However, even in first-order cybernetics control does not necessarily imply hierarchy, as even the simple case of the thermostat demonstrates. Thus, although there certainly still is a limited place for organizations that exemplify a more or less hierarchical control paradigm, modern, complex, multigroup society in its entirety, conceptualized as a matrix in which such systems grow and thrive, can never be of this type.

If one investigates a certain system with a research methodology based on the control paradigm, the results necessarily have a conservative bias. Changes of the system as such are almost prevented by definition. De Zeeuw (1988) considers a different methodological paradigm necessary if one wants to support fundamental social change and prevent 'post-solution' problems. It is based on a multiple-actor design, does not strive towards isolation of the phenomena to be studied, and likewise does not demand a separation between a value-dependent and a value-independent part of the research outcomes.

2.4 Autocatalysis and Cross-catalysis

Laszlo (1987, 1988) describes two varieties of (chemical) catalytic cycles: auto-catalytic cycles, in which the product of a reaction catalyzes its own synthesis, and cross-catalytic cycles, where two different products or groups of products catalyze each other's synthesis. An example of a model of a cross-catalytic cycle, developed by Prigogine and colleagues, is the Brusselator:

(1) $A \rightarrow X$
(2) $B + X \rightarrow Y + D$
(3) $2X + Y \rightarrow 3X$
(4) $X \rightarrow E$

With X and Y as intermediate molecules, there is an overall sequence in which A and B become D and E. Step 3 can be seen as autocatalysis, while steps 2 and 3 in combination describe cross-catalysis: X helps to produce Y, while Y helps to produce more X. Autocatalytic sets ($A \rightarrow B \rightarrow C \rightarrow \cdots \rightarrow Z \rightarrow A$) bootstrap their own evolution, provided the complexity of interactions is rich enough. The system then changes from a subcritical to a supercritical state, and autocatalysis follows. Kaufmann (1991, 1992) even uses the concept to explain the origins of life from a 'primal soup' of simple chemical elements as an inevitable production of order, rather than as a unique and extremely unlikely historical accident. Simple chemical laws coupled with the presence of a sufficient number of frequently interacting elements produce ever more complex elements. These have new characteristics, and often turn out to be part of new catalytic processes at higher levels of molecular complexity—processes which in turn boost the emergence of still higher levels of complexity. Along similar lines, Swenson (1991) likewise maintains that—in spite of the Second Law of Thermodynamics—'the world is in the order production business.'

The economist Arthur (1990), collaborating closely with Kaufmann at the Santa Fe Institute, applied the concept of autocatalytic sets to the economy—which also bootstraps its own evolution, as it grows more complex over time. Beyond a certain critical threshold, phase transitions occur. Stagnant developing countries can enter the take-off stage when their economy has diversified sufficiently; increased trade between two countries in a subcritical state can similarly produce a more complex and interwoven economy which becomes supercritical and explodes outward. Catalytic effects may also operate in 'negative' phase transitions, where critical thresholds of violence are passed as in Northern Ireland or Bosnia.

2.5 *Autopoiesis*

Autopoiesis, or 'self-production,' is a concept introduced in the 1970s by the biologists Maturana and Varela to differentiate the living from the nonliving. An autopoietic system was defined as a network of inter-related component-producing processes such that the components in interaction generate the same network that produced them. Although they considered the concept applicable only in biology, and not in the social sciences, an interesting 'theory transfer' was made by Luhmann (1988). He defended the quite novel thesis that, while social systems are self-organizing and self-reproducing systems, they do not consist of individuals—or roles or even acts, as commonly conceptualized—but exclusively of communications. When generalizing the usages of autopoiesis, developed while studying biological systems, to make it also applicable to social systems, the biology-based theory of autopoiesis should therefore be expanded into a more general theory of self-referential autopoietic systems. Social and psychic systems are based upon another type of autopoietic organization than living systems: namely on communication and consciousness, respectively, as modes of meaning-based reproduction.

While Luhmann thus views communications instead of actions as the elementary units of social systems, the concept of action admittedly remains necessary to ascribe certain communications to certain actors. Thus, the chain of communications can be viewed as a chain of actions. This enables social systems to communicate about their own communications and to choose their new communications, i.e., to be active in an autopoietic way. Such a general theory of autopoiesis has important consequences for the epistemology of the social sciences: It draws a clear distinction between autopoiesis and observation, but also acknowledges that observing systems are themselves autopoietic systems, subject to the same conditions of autopoietic self-reproduction as the systems they are studying.

The theory of autopoiesis thus belongs to the class of global theories, i.e. theories that point to a collection of objects to which they themselves belong. Classical logic cannot really deal with this problem, and it will therefore be the task of a new systems-oriented epistemology to develop and combine two fundamental distinctions: between autopoiesis and observation, and between external and internal (self-)observation. Classical epistemology searches for the conditions under which external observers arrive at the same results, and does not deal with self-observation. Consequently, societies cannot be viewed, in this autopoietic perspective, as either observing or observable. Within a society, all observations are by definition self-observations.

3. *The Science of Complexity: A Convergence of Paradigms*

Compared with simpler societies, complex modern ones are highly dynamic and interactive. Consequently, they change at accelerated rates, and are generally in a far-from-equilibrium situation. According to Prigogine and Stengers (1984) nonlinear relationships obtain in systems that are far from equilibrium, where relatively small inputs can trigger massive consequences. At such 'revolutionary moments' or bifurcation points, chance influences determinism, and the direction of change is inherently impossible to predict: a disintegration into chaos, or a 'spontaneous' leap to a higher level of order or organization—a so-called 'dissipative structure,' which requires more energy to sustain it, as compared with the simpler structure it replaces.

In stressing this possibility for self-organization, for 'order out of chaos,' Prigogine comes close to the

concept of autopoiesis. In modern societies, the mechanistic and deterministic Newtonian world view—emphasizing stability, order, uniformity, equilibrium, and linear relationships between or within closed systems—is being replaced by a new paradigm, more in line with today's accelerated social change, which stresses disorder, instability, diversity, disequilibrium, nonlinear relationships between open systems, morphogenesis, and temporality. Social scientists, often still thinking in terms of linear causality, would be well-advised to try out the explanatory powers of Prigogine's conceptual vocabulary—fluctuations, feedback amplification, dissipative structures, bifurcations, (ir)reversibility, auto-and cross-catalysis, self-organization, and so forth—on the phenomena they study, as well as the concepts and methods of second-order cybernetics in general.

It is reassuring in this novel and therefore risky field of research that there seems to be a convergence of paradigms, subsumed here under the name of second-order cybernetics. However, it might also be designated by other names like cognitive science, general systems theory, artificial intelligence, artificial life, or perhaps indeed most aptly, as Prigogine suggested, 'the emerging sciences of complexity.'

4. *Methodological Problems of Empirical Research in First- and Second-order Cybernetics: A Bridge Too Far?*

If one realizes that the social sciences mainly study self-organizing, self-referential, autopoietic systems, with their own strategies and expectations, with intertwining processes of emergence and adaptation, then one is confronted with one of the core problems of sociology, economics, and other social sciences: how to make a science out of studying of imperfectly smart agents exploring their way into an essentially infinite space of possibilities which they—let alone the social scientists researching them—are not even fully aware of.

There is indeed quite a methodological problem here. It is already very difficult to apply the principles and methods (e.g., feedbacks and nonlinearities) of first-order cybernetics to empirical social research. It is nearly impossible to incorporate a second-order cybernetics approach in one's research design. Second-order cybernetics may be a bridge too far, given the research methodology and the mathematics presently available.

Applying first-order cybernetics principles in empirical research already poses heavy demands on the data sets and the methods of analysis: Every feedback ($X_t \rightarrow Y \rightarrow X_{t+1}$), every interaction between variables [$Z \rightarrow (X \rightarrow Y)$], and every nonlinear equation ($Y = cX^2 + bX + a$), let alone nonlinear differential equation ($Y' = cY^2 + bY + a$), demands extra parameters to be estimated, and quickly exhausts the information embedded in the data set. Admitting on top of that the second-order notions that the research subjects can change by investigating them, and may even reorganize themselves on the basis of knowledge acquired by them during the research, exceeds the powers of analysis of even the most sophisticated methodologists: it equals the effort to solve an equation with at least three unknowns.

How can one obtain reliable data within such a framework, where nothing is constant and everything is on the move, let alone formulate policy-relevant decisions? How can one still forecast developments when at best retrospective analysis of how a new level of complexity has emerged seems possible? These problems are far from solved, and much work lies ahead before hypotheses derivable from second-order cybernetics will be fully testable, at least in a classical Popperian sense. However, testing hypotheses pertaining to the nonlinear dynamical regimes stressed by complexity theory and chaos studies may demand different criteria, invalidating the classical concept of a theory as a mathematical model yielding stable, consistent and complete predictions of a system's behavior. Nevertheless, the opportunities offered by the second-order cybernetic paradigm to present a truly realistic analysis of the complex adaptive behavior of interacting groups of agents seems to good to pass up. There is certainly a challenge here, for theorists and methodologists alike.

F. Geyer

Socioeconomic Status and Health

Observation of an inverse association between socioeconomic status (SES) and risk of poor health and death are not new, extending back to the twelfth century (Antonovsky 1967). In medieval Europe, Paracelsus noted unusually high rates of disease in miners. In 1790, Johan Peter Frank, one of the founders of the public health movement, wrote 'The people's misery, mother of disease.' Daniel Defoe in his *Journal of the Plague Year* echoed similar sentiments when he opined that '… the misery of that time lay upon the poor who, being infected, had neither food or physic, neither physician or apothecary to assist them, or nurse to attend.'

By the nineteenth century, systematic investigations were being conducted by Villermè into the relationship between rent levels of areas and mortality in Paris (Susser et al. 1985). In 1848, Virchow reported on the relationship between poor living conditions and typhus in Upper Silesia (Rather 1988). In England, Farr examined differences in mortality by occupation (Rosen 1993), while Engels (1848) deplored the impact of new working conditions on the health of the poor as a result of the industrial revolution in England.

Since 1850, a rich scientific literature has developed that further extends these earlier observations that link socioeconomic position with health, and in recent years there has been an exponential increase in scientific work on this topic. As a prelude to summarizing this literature, it is first necessary to briefly discuss the ways in which socioeconomic status or position has been conceptualized in this research tradition. A variety of terms have been used in the epidemiologic literature in this area, including social class, social stratification, social inequality, social status, and socioeconomic status (Krieger et al. 1997). To a large extent these terms reflect different historical, conceptual, and disciplinary roots. More extensive discussions of the details and the potential advantages and disadvantages of various approaches to measurement have been presented in reviews by various authors (cf. Krieger et al. 1997). It should be noted that in Europe, and particularly the United Kingdom, occupational measures of social class have predominated, whereas in North America there has been more focus on individual or aggregate measures of socioeconomic status derived from education, income, or occupation. In what follows, the term 'socioeconomic position' (SEP) will be used generically to refer to the various measures that have been used.

1. The Relationship Between Socioeconomic Position and Health

Figure 1 shows the association between relative risk of death and household income, after adjustment for age, sex, and household size (Wolfson et al. 1999) in a large sample of households in the United States. The figure also shows the relative distribution of levels of household income in the population. There are several important aspects of this relationship. First, risk of death, relative to mean household income, decreases monotonically with increasing income. Second, while risk of death increases monotonically with decreasing income, the greatest elevations of risk relative to mean income are found in approximately the bottom third of the household income distribution. This monotonic but nonlinear relationship between socioeconomic position and mortality risk or life expectancy has been found using many different measures of SEP and in many different countries. While a great deal of attention has been devoted to the monotonic nature of this risk relationship, much less attention has been devoted to the striking nonlinearity in this association.

Figure 1
Plot of risk relative to mean income (modified from Wolfson et al. 1999)

Figure 2
Age-adjusted death rates for selected causes for adults 25–64 years of age, by education level and sex: US 1995.
Note: Injuries include homicides, suicides, unintentional injuries and deaths resulting from adverse effects of medical procedures. Source: Pamuk et al. 1998

The association between SEP and health outcomes is not restricted to any particular age group, although some evidence suggests it is somewhat attenuated during late adolescence, early adulthood, and later old age. For example, Ericson et al. (1984) found in Sweden that lower parental SEP was associated with higher rates of perinatal mortality, prematurity, low birth weight, and being born small for gestational age; and rates of 'stunting' (below the 5th percentile in height) were elevated in children born in families living below the poverty level in the United States (USDHHS 1986). Wolfson et al. (1993), using Canadian data, showed important differences in survival after age 65 based on income levels just before retirement, and the effects of educational level on other health outcomes continue into old age (Guralnik et al. 1993).

Lower SEP is associated with increased risk for most diseases and health outcomes. Figure 2 shows the

relationship between level of education and rates of death from chronic diseases, injuries, and communicable disease for men and women in the United States (Pamuk et al. 1998). In Susser et al.'s (1985) compilation of findings from the Registrar General's Decennial Supplement for England and Wales, they noted that lower occupational class was related to higher rates of death from malignant neoplasms, endocrine, nutritional and metabolic diseases, diseases of the blood-forming organs, infective and parasitic diseases, diseases of the nervous system and sense organs, diseases of the circulatory system, diseases of the respiratory system, diseases of the digestive system, diseases of the genitourinary tract, diseases of the musculoskeletal system and connective tissue, congenital anomalies, and accidents, poisoning, and violence. For those outcomes where there is a positive relationship between SEP and disease risk, such as breast cancer, survival is generally worse for those at lower levels of SEP.

The association between SEP and health outcomes in not fixed in time, with some evidence for increasing stratification of health by SEP (Black et al. 1980, Pappas et al. 1993). For some health outcomes, there have also been changes in the direction of the association (Morgenstern 1980). These observations of changes in the magnitude and direction of the SEP–health association, as well as the substantial international variation (Kunst et al. 1998), are important because they suggest that informed interventions could possibly reduce socioeconomic inequalities in health.

2. *Explanations of Inequalities in Health*

Typical explanations for SEP-related variations in health status focus on the role of medical care, behavioral risk factors such as smoking or alcohol consumption, material standards of living, or the impact of poorer health on SEP (Black et al. 1980). While there are likely to be variations in access to and quality of medical care by SEP, with the magnitude of the difference varying widely by country, medical care is not likely to be a major cause of variations in inequality by SEP. The argument in support of this assertion is based, among other things, on observations that the introduction of widespread availability of medical care in some countries has not lowered SEP variation in health and that variations in health status by SEP are found for conditions that are not 'amenable to medical care.'

The differential distribution of high-risk behaviors among lower SEP populations also does not seem to fully explain the SEP–health association. Studies that have information on such individual-level risk factors have generally been unsuccessful in completely explaining SEP gradients in health (Marmot et al. 1978). Furthermore, even if statistical adjustment for individual higher risk behaviors did reduce or eliminate SEP-related gradients in health, SEP-related factors are likely to be antecedent, causal determinants of high-risk behavior.

Some have interpreted SEP-related gradients in health as reflecting the impact of poor health on income and wealth. In this view, the poor end up less healthy because they were, first, less wealthy. While it is undoubtedly true that chronic illness is in most contexts associated with declines in income and wealth, most researchers have concluded that these selection effects account for a relatively small amount of the association between SEP and health. For example, downward selection effects cannot easily account for the pervasive impact of level of education on health outcomes that occur long after the completion of education, nor the impact of SEP of one family member on the health of another, nor Wolfson's finding of strong variations in postretirement survival by pre-retirement income in Canadian men who had no declines in income during the years before they retired (Wolfson et al. 1993).

SEP is generally related to material standard of living, while the magnitude of the association clearly varies between countries, and over time. Nonetheless, lower SEP is generally associated with poorer housing, less nutritious diet, greater exposure to adverse environmental substances, poorer working conditions, greater exposure to crime and dangerous environments, and a wide variety of other 'material' and psychosocial factors. It seems likely that any comprehensive understanding of the relationship between lower SEP and poorer health will have to simultaneously consider a wide variety of these pathways, but the dominant analytic strategy has been to focus on the primacy of one pathway or another.

3. *Future Directions*

It is unlikely that any single set of explanations will account for the observed relationships between SEP and health across time, places, and health outcomes. Undoubtedly, any full understanding will involve many of the above pathways, and perhaps others. Current efforts are focused on a number of activities aimed at clarifying our understanding of this complex area of investigation.

3.1 *Individual vs. Area SEP*

Many studies that lack individual measures of SEP have used measures that reflect the SEP of the area in which these individuals live, e.g. median level of income, percent in poverty, or area deprivation scores. In many cases the motivation is to use these as proxy

measures of individual information. However, it is increasingly being recognized that such measures reflect properties of the social and economic environment in which people live and that these measures are not identical to individual measures of SEP. What is more, a number of studies indicate that such area measures are importantly associated with health outcomes beyond individual (Macintyre et al. 1993). Considerable work remains to clarify under what situations these area measures are related to health outcomes, their overlap with neighborhood and community phenomena, and the economic, social, and behavioral pathways that link area characteristics with health outcomes in individuals.

3.2 Inequality in Income Distribution and Health

A growing literature indicates that inequalities in income distribution are importantly related to population health outcomes beyond individual incomes (Wilkinson 1996). For example, in the United States, the share of income received by the least well-off half of the population was correlated with age-adjusted mortality rates for states and metropolitan areas, independent of measures of level of income (Kaplan et al. 1996). Greater equality in the distribution of income was associated with lower mortality rates and other health outcomes. While controversial, these findings have led to a lively debate concerning the relative role of individual income, psychosocial pathways, and material conditions in individual and population health (Lynch et al. 2000, Wilkinson 1996).

3.3 Life Course Effects

Most studies have examined SEP at only one time and few have considered either variability in SEP over the short- or long-term. However, there is considerable variation beginning in childhood, based on macroeconomic and individual pathways, on parental SEP and adult educational, occupational, or income trajectories. Some evidence suggests that income trajectories are important (Blane et al. 1996), while others suggest that adult destinations are more important (Lynch et al. 1994). A growing literature is devoted to documenting life-course effects, many of which involve variations in SEP on adult health outcomes (Kuh and Ben-Schlomo 1997).

3.4 Biological Pathways

Evidence is rapidly accumulating on the proximal biological pathways that mediate the association between SEP and health outcomes, which form much of the evidence relating to cardiovascular disease (Brunner 1997). For example, measures of SEP have been found to be associated with the prevalence and progression of subclincial atherosclerosis (Lynch et al. 1997), with levels of cholesterol and other lipids, blood pressure, and hemostatic factors (Kaplan and Keil 1993), and with the clustering of cardiovascular risk factors (Helmert et al. 1989). A growing focus is on the cumulative physiologic effects of chronic stress and adaptive efforts and their link with SEP (McEwen 1998).

4. Conclusion

The pervasive associations observed between various measures of SEP and many health outcomes, and the risk factors for these outcomes, supports the fundamental role of SEP as a determinant of health. Understanding these associations requires elucidating the variety of multilevel determinants and pathways that link SEP and individual health outcomes as well as determining the societal and individual forces that stratify these determinants and pathways along socioeconomic dimensions. An appreciation of the breadth and magnitude of the imprint of SEP on the health of individuals and populations suggests that this is a scientific area with potentially great importance for public policy.

Socioeconomic Status and Health Care

Although many factors determine the availability and use of health care, there is substantial evidence across countries in that markers of socioeconomic status (SES), including income, education, and occupational status, are significantly associated with health care utilization. This includes health insurance coverage and the use of personal health services such as visits to primary care providers and specialists, hospitalizations, dental care, vision care, mental health services, prescription-drug use, and home health care. Although there is ample evidence that people of higher socioeconomic position use more health care services and tend to receive higher-quality care, the reasons behind these disparities are not fully understood. Below, the relationship between SES and health services utilization is described, and explanations for this relationship are summarized.

1. The Relationship between SES and Health Care Utilization

Numerous studies have found a positive graded relationship between SES and most types of health-services utilization, measured by whether or not a service type was used in the past year, or as the mean number of encounters/visits for the service during a specified time period (National Center for Health Statistics 1998, Fiscella et al. 2000, Whitehead 1999). Although there are some exceptions to these general findings, the bulk of the empirical findings to date suggest that the association is positive; that is, higher SES is associated with a higher rate of health-care utilization (see Table 1 for some examples from the US). Higher SES is also associated with lower rates of untreated disease and unmet medical needs. That SES has a positive impact on health care use has been observed for both men and women, and for children and adults.

The relationship between SES and health care is especially apparent in countries without universal health insurance, where there is a strong relationship between SES and health insurance status (Bongers et al. 1997, Whitehead 1999). Those with lower levels of

Table 1
Health care utilization by poverty status for selected measures, United States 1994–1995. Data from National Center for Health Statistics (1998)

Health service	Poor	Near poor	Middle income	High income
No health insurance				
Children (< 18 years)	22.0 percent	22.8 percent	8.6 percent	4.2 percent
Adults (18–64 years)	44.1 percent	35.3 percent	13.8 percent	6.1 percent
No physician contact in the past year				
Children (< 6 years)	11.2 percent	10.1 percent	6.9 percent	4.1 percent
Adults (18–64 years)	21.2 percent	19.1 percent	14.9 percent	11.4 percent
Unmet need for health care				
Adults 18–64	32.5 percent	29.0 percent	16.0 percent	7.0 percent
Number of physician contacts in past year, age-adjusted by health status and gender	Poor	Near poor	Middle/high income	
Good to excellent health				
Males	3.9	3.8	4.6	
Females	5.4	5.0	5.8	
Fair or poor health				
Males	13.7	14.7	16.3	
Females	16.2	17.3	22.4	

income and education are more likely to be uninsured, or to have insurance coverage that only covers catastrophic health events. In turn, those who are uninsured are less likely to use health services, and to delay or forego care for serious medical symptoms (Fiscella et al. 2000, Brown et al. 1998). Importantly, SES is also related to health care use in countries with universal health insurance (Black et al. 1982; Whitehead 1999, Kephart et al. 1998). Thus, even in countries with a long history of universal coverage, SES disparities in health-care utilization are strong and apparent.

While the association between SES and health-care utilization is positive and graded in most studies, other patterns have been documented as well. An inverse association between SES and use of physician services was noted in Canada, along with the hypothesis that excess use by those of lower income and education levels is attributable to SES differences in health status (Kephart et al. 1998). In the US, those without health insurance, those living in low-income areas, and racial/ethnic minorities are significantly more likely to receive potentially-avoidable hospitalizations and medical procedures (Pappas et al. 1997, Fiscella et al. 2000).

In summary, people from lower economic and educational strata tend to have fewer physician visits for both primary and specialty care, and to use fewer mental health, dental, vision and preventive services. They also are less likely to have a usual source of care, and have significantly higher rates of unmet health needs. In some analyses, lower SES is associated with greater physician and hospital use (especially for avoidable causes of injury or illness), although it appears that these findings are primarily driven by higher rates of poor health status or medical needs in disadvantaged populations.

SES and its proxies are not the only factors related to health care use. Utilization is also patterned by gender, geography, age, culture, and other factors. While it is difficult to sort out the independent effects of SES and race/ethnicity on health care, it appears that minority status has an important independent effect. In the US, certain racial and ethnic minorities (most notably, African Americans, Native Americans and Hispanics) have been found to have lower rates of utilization in general, to receive less aggressive care for certain diseases, and to report less satisfaction with, and more experiences with discrimination regarding, health care (Fiscella et al. 2000). Even so, SES appears to be a major social predictor of health-care use. The relationship is strong across different types of health services, and is robust across a variety of study designs from a number of different countries.

2. *Explanations for the Relationship between SES and Health Care Utilization*

While the evidence for a relationship between SES and health care use is strong and compelling, there are many methodological challenges in measuring this association and its causes (Brown et al. 1998). First, the relationship is confounded by health status, which

is related to both SES and the need for services. Thus, it is important to measure health-services utilization within the context of medical need. Second, it is difficult to have all necessary variables in a single population-based dataset, including valid and reliable measures of SES, health insurance, medical need, and other confounding factors. Third, there are many different types of health services, and relationships are not uniform in magnitude or patterns across these different types. Fourth, simple measures of utilization do not provide a very deep understanding of differences that may exist in terms of the quality, content, or continuity of care.

Despite the methodological challenges for this type of research, several factors have been investigated to explain why people of lower SES generally use fewer health services than those of higher social position, and why their level of use does not appear to match their need. Dutton (1978) reported that explanations for this phenomenon generally fall into three categories: (a) explanations that focus on financial access or affordability differences (e.g., the poor use fewer services because they have fewer financial means); (b) explanations that focus on knowledge and attitudinal differences regarding care-seeking (e.g., the poor use fewer services because they value and/or understand the benefits of health care less than other people); and (c) explanations that focus on health care system factors (e.g., the poor use fewer services because of how the health care system is organized or responds to them). This set of explanations still reflects the primary reasons offered for the strong association between SES and health care utilization.

2.1 *Financial or Affordability Explanations*

Since being uninsured is strongly correlated with income and education, it is often assumed that the strong relationship between SES and health-care use operates primarily through the more proximate variable of health insurance. However, the conclusion of numerous studies is that health insurance explains only a small part of the socioeconomic differences in the use of most types of health services (Bongers et al. 1997). In addition, even among people with health insurance, lower levels of income and education are associated with lower overall health-care use (Fiscella et al. 2000).

Although access to health care is often equated with financial access, access is in fact multidimensional, and other aspects of access (such as the availability, convenience, and acceptability of providers and services) are of equal importance (Gold 1998). Also, as mentioned above, there is ample evidence from countries with universal health insurance that significant SES differences in utilization exist even within systems where there are few or no financial access barriers to services. Thus, SES differences in health care use are not fully explained by economic or financial factors.

2.2 *Knowledge, Attitudinal, and Cultural Explanations*

Another type of explanation for the lower use of health services among disadvantaged populations is that a lack of attention to health is part of a larger way of life or subculture related to poverty. Underuse of health care services is viewed as stemming in part from a lack of understanding regarding appropriate care-seeking behavior for specific symptoms or conditions. In addition, lower use of health services has been viewed as derivative of a larger set of attitudes that tend to accompany poverty and deprivation. This includes a 'crisis-oriented' approach to life, a tendency to overvalue immediate gains and rewards and discount longer-term outcomes, decreased self-reliance and self-efficacy, and increased skepticism regarding the potential benefits of medical care (Riessman 1994).

Although culture of poverty explanations for SES differences in health care use have been criticized as 'classist' and pejorative, this type of explanation continues to be used explicitly and implicitly by many researchers (Riessman 1994, Dutton 1978). Such explanations focus on social class differences in knowledge, attitudes, and psychosocial predispositions; and, as a result, programmatic and policy interventions that focus on these individual traits are not uncommon (Adler 1993, Reilly et al. 1998). While these individual characteristics have been shown to be related to health-care use, they are most often taken into account outside of the social and cultural contexts in which they were produced and the system context in which health care is provided. Thus, they provide a limited or incomplete explanation for observed SES disparities in health care use (Dutton 1978, Riessman 1994, Lantz et al. 1997).

2.3 *Health Care System Explanations*

Empirical evidence from a number of countries suggests that health care system factors, especially non-financial components of access, offer the greatest explanatory power regarding SES differences in utilization. It appears that deficits, inequities and inefficiencies in the health care system rather than patient economic or psychosocial characteristics are essential to understanding SES differences in the use of health services (Dutton 1978, Riessman 1994, Pappas et al. 1997). Research has shown that SES differences in health-care utilization are driven much more by structural elements of the health-care system than by individual factors such as health insurance or other

financial variables (Rosenbach et al. 1999). These system-level factors include cultural deterrents to care, the unwieldy nature of large medical bureaucracies, fragmentation in care, racism and other forms of provider bias, transportation barriers, and non-financial dimensions of access.

There are many ways in which the design of health-care systems leads people to feel estranged, dissatisfied, or distrustful, especially those people who are from marginalized populations because of social class, race, or ethnicity (Baker 1999). Quality of care and patient perceptions of care experiences are important in system explanations for SES disparities in health-services use. Not only is SES related to health-care utilization, it is also related to health-care quality (Fiscella et al. 2000). For example, the uninsured are more likely to receive substandard medical care and to suffer a medical injury as a result (Burstin et al. 1992).

While individual characteristics (such as financial means or attitudes regarding care) clearly play a role, it is important to view these individual characteristics within the broader context or system of how health-care services are organized, delivered, and financed. The policy implications of such findings are important; for they suggest that providing universal coverage or offering free health services to the poor is not a panacea for reducing social inequalities in health-care utilization. In the absence of significant changes in the ways in which health care is organized and delivered, improvements regarding financial access and personal beliefs will likely not do much to reduce SES disparities in health-services utilization.

3. *The Role of Health Care in Explaining SES Disparities in Health Status*

There are many explanations for the strong relationship between SES and health status, as outlined in the accompanying chapter on this topic (see *Socioeconomic Status and Health*). This includes explanations that focus on different material resources, of which health care is viewed as an important type (MacIntyre 1997). Research from a number of countries suggests that, for specific health conditions, the receipt of clinical preventive services and/or timely therapeutic care play an important role in health outcomes, and thus may account for some portion of socioeconomic disparities in health status. Therefore, it has been argued that efforts to increase the use of health services among the socioeconomically disadvantaged—primarily by reducing financial barriers to health care or health insurance—have great potential for reducing socioeconomic disparities in health status (Andrulis 1998, Fiscella et al. 2000).

Research at the end of the twentieth century, however, also suggests that the contribution of SES differences in health-care use to overall SES disparities in health status is likely to be small (Adler 1993, MacIntyre 1997). Evidence for this comes from a variety of sources, including—as described above—countries with universal health insurance. For example, the Black report demonstrated that socioeconomic inequalities in mortality in England and Wales increased rather than attenuated in the decades after the British National Health Services was established (Black et al. 1982). It has also been shown that, in developed countries, there is no relationship between health indicators (such as life expectancy) and the proportion of economic resources spent on health care (Roberts and House 2000). In addition, a cross-national study found that health-care expenditures did not explain variation in infant mortality rates above and beyond the contribution of socioeconomic resources (Kim and Moody 1992). While it is important not to overgeneralize from these ecological studies, a wide variety of research strongly suggests that differential access to and use of personal health services is but one of myriad factors contributing to social inequalities in health status (Roberts and House 2000, MacIntyre 1997).

With respect to developing countries, it is clear that economic development, growth in formal education, and public-health measures such as clean water and basic nutrition are of greater significance to population health than the delivery of health care. While the importance of personal health services (such as immunizations or oral rehydration therapy) in less-developed countries should not be underestimated, broad public health and economic development advances are believed to afford the most potential for making significant improvements in health.

This is not to suggest that health care has no impact on individual health or social disparities in health status. There are indeed some diseases and conditions for which health services can significantly reduce morbidity and mortality, and improve physical functioning and quality of life, as demonstrated in clinical trials and other types of studies (Andrulis 1998, Reilly et al. 1998, Fiscella 2000). The bulk of the knowledge generated to date, however, suggests that while reducing SES disparities in health care may help to reduce socioeconomic and racial disparities for some specific diseases or health issues, significant inequalities in health status would be likely to remain. Environmental, community, socioeconomic, and psychosocial exposures to both health risks and health-promoting resources would still exist, creating disparities in the incidence and prevalence of a number of health problems. Furthermore, many health conditions and problems are not amenable to medical interventions or to prevention practices delivered through health-care providers.

It is also important to emphasize that socioeconomic disparities in health care are not immutable (Fiscella et al. 2000). Thus, many researchers, clinicians, advocates and policymakers alike believe that efforts should continue to be made across and

within countries to reduce SES differentials in health-care access and utilization by focusing on the financial, attitudinal, and—most importantly—health system barriers that contribute to these significant disparities. The policy goal should be a health care delivery system in which all dimensions of access and the content and quality of care delivered are the same across social strata.

Sociolinguistics

Sociolinguistics is the study of the relationship between language and society. The field of sociolinguistics is arguably the best known and most firmly established of the various hyphenated varieties of linguistics (e.g., psycholinguistics, neurolinguistics, sociolinguistics) that emerged during the second half of the twentieth century. Its roots can be located in the field research of American anthropological linguists such as Dell Hymes, who noted the interesting range of ways of talking and the variety of functions of talk among native American tribes whose languages they described, and of dialectologists, such as Bill Bright, who drew attention to the social bases of much of the linguistic diversity they documented in multilingual speech communities.

Although it is a well-established field, there is still some controversy about what counts as sociolinguistics. William Labov, a pioneering and very influential American social dialectologist, has argued since the 1960s that his research constitutes core linguistics, and contributes directly to the development of linguistic theory. In the 1970s, Peter Trudgill, a leading British social dialectologist, noted a distinction between research in social dialectology, which he argued constituted the core of sociolinguistics, and research in areas such as multilingualism and language shift, which Joshua Fishman had labeled 'the sociology of language,' an area Trudgill proposed to exclude from sociolinguistics proper. While that debate has effectively been resolved—the current leading

sociolinguistics journals include research in both these areas—discussion over the precise boundaries of the term sociolinguistics continues.

This article takes an inclusive approach. The sections which follow provide a brief description of the concerns of areas which uncontroversially constitute core sociolinguistics, namely the sociology of language, and social dialectology, as well as areas which some would regard as more peripheral, such as discourse analysis (DA) and stylistics, language awareness, and applied sociolinguistics.

1. *Multilingualism; Diglossia; Bilingualism*

Sociolinguistic research in the area of multilingualism is concerned with identifying the relationship between social factors and choice of language or 'code' in specific situations. In Zaire, for example, people often use five or six languages, or more accurately 'codes' or 'varieties,' in their everyday interactions. The terms 'code' and 'variety' refer to any set of linguistic forms which are socially patterned, including different accents, different linguistic styles, different dialects, and different languages which contrast with each other for social reasons. The linguistic repertoire of a typical Zairean teenager might include three varieties of Swahili (standard Zairean, local Swahili, and Indoubil, a teenage slang variety), and two varieties of a tribal language such as Shi (a formal and a casual style). How the young person draws on and makes use of this repertoire in interaction is a matter of prime sociolinguistic interest (Goyvaerts 1988).

Sociolinguistic research aims to establish the range of social factors relevant to code choice in such multilingual contexts, and their relative weight. The use of one code rather than another in any specific situation tends to reflect such factors as the relationship between speaker and addressee(s), the formality of the context, and the function of the interaction. In Paraguay, for example, the indigenous language, Guaraní, is used in interactions with friends in the pub, while Spanish is the appropriate language to use with your doctor and the bureaucrats (Rubin 1985). Code choice may also indicate more abstract influences such as orientation to an urban rather than a rural lifestyle. More recently, researchers have begun to analyze code choice as a more dynamic activity, examining ways in which speakers change the emphasis in an interaction through linguistic initiatives, and how code choice actively contributes to the construction of particular types of interaction (see *Code Switching*: *Linguistic*).

Diglossia is a term used to describe a particular kind of societal bilingualism. In his classic article on the topic, Ferguson (1959) defined diglossia as a situation where two varieties of the same language, a H(igh) variety and a L(ow) variety, are used in a community for complementary functions, a linguistic division of labor. The H variety is restricted to formal, religious, symbolic, and literary functions. The L variety is used for everyday conversations in the home and in all informal contexts. The term proved so useful it was extended to cover a much wider variety of bilingual and multilingual situations where different languages were associated with different domains or social contexts. The term 'polyglossia' was coined to take account of communities such as Singapore with more than one H language as well as several L varieties and even some M(id) varieties falling between the H and L in terms of prestige (Platt 1977). Thus, sociolinguists have steadily modified the scope of the diglossia concept to handle more complex patterns of societal multilingualism. Moreover, further research on the four classic cases Ferguson used for exemplification (German-speaking Switzerland, Haiti, Greece, and Arabic-speaking countries) suggests that even these do not fit the original framework as neatly as was once thought.

1.1 *Code-switching*

A related area of sociolinguistic research is the study of *code-switching*. Situational code switches have been defined as responses to changes in observable features of the context, such as the participants or the setting, and they typically occur at clearly demarcated discourse boundaries. Recent research has increasingly focused on interpreting the social meaning of conversational code-switching, sometimes called code-mixing, the much less predictable rapid code-switching which typically occurs among bilinguals in informal situations (e.g., Auer 1998). The development of theoretical models that can account for the linguistic constraints on switches has been one focus of this research. Another has been the social and pragmatic meanings of switches. Analyzing code-choice in Kenya, for instance, Myers-Scotton (1997) discusses the sophisticated affective messages conveyed through complex and rapid alternations between codes, often within a very short exchange. So, for example, through subtle switching of codes, rather than any explicit refusal, a store-keeper politely rejects his sister's attempts to obtain cut-price goods from him, thus preserving their relationship. This strand of research considers how switches actively contribute to constructing a particular type of interaction, and to the dynamics of identity construction. Code-switching is one means by which bilinguals and multilinguals make creative use of their linguistic repertoires to convey social meaning.

2. *Language Maintenance and Shift; Language Endangerment/Revival*

While diglossia is defined as a society-wide phenomenon, individual bilingualism is often a transitional phase for new immigrants in a society as they shift

from the ethnic language to the dominant language of the wider society. This process of language shift is typically complete in three generations. Fishman's research dominates the area of language maintenance and shift, with studies of patterns of language use among ethnic minorities in the USA dating back to the early 1960s. A range of theoretical models has been developed to account for the relative survival rates of different ethnic languages in different countries, including measures of 'ethnolinguistic vitality' (Giles 1977), and a scale describing the steps involved in taking a language from near language death through to language revival (Fishman 2000).

A language which is spoken only in a restricted geographical area and which is under threat from a colonial or world language is typically regarded as endangered. The relative chances of survival of different *endangered languages* have been the topic of a good deal of sociolinguistic analysis. Research on the numbers of users, social contexts of use, and linguistic attitudes has been undertaken on languages as diverse as Welsh, Cree, Maori, Dyirbal, and Basque, with some disagreement between experts on the crucial conditions for preventing language death.

3. *Language Contact; Pidgins and Creoles*

While the development of bilingualism, or a shift to the majority language, are possible responses to language contact, another common development is the emergence of a pidgin language. Pidgins typically develop in situations where a *lingua franca* is needed for communication between groups who speak different languages, for example, for trade purposes, or between workers from different tribes on a crop plantation. They are structurally very simple and functionally extremely restricted. They are always ancillary languages developed for a specific and restricted purpose.

Creoles develop from pidgins when they begin to be used as first languages and therefore expand functionally and structurally into adequate means of communication for the group using them. Typically they draw on the vocabulary of the language of the culturally dominant group, while their grammar is based on local vernacular languages which contribute the substrate component. A number of official and standard languages such as Swahili, Afrikaans, and Tok Pisin had creole origins.

Current debates among creolists center mainly around the issue of the origins and development of creole languages. Do they develop according to universal linguistic principles and according to universal linguistic constraints, or are the remarkable similarities between creoles due to the fact that they share sources of input from European languages such as English and Portuguese? Another current area of interest is the decreolization process (whereby creoles gradually develop in the direction of the standard variety) which is occurring in places such as Guyana (Romaine 1994).

4. *Social Dialectology*

Social dialectologists are concerned with tracing the relationships between linguistic variation and social factors. The pioneering research of William Labov determined the direction of subsequent research in the area for several decades, both in terms of the research questions he considered worth addressing, and in relation to the innovative methodology and quantitative ('variationist') analytical techniques he developed. His influential survey of the New York East Side (Labov 1972a) demonstrated that linguistic variation was not random or 'free' as previous dialectologists had tended to assume, but rather patterned systematically according to factors such as the social class, gender, age, and ethnicity of the speakers, and the formality of the style of speech they were using (see *Language and Social Class*; *Language and Ethnicity*).

The basic patterns which Labov identified in New York were replicated in many other urban speech communities including cities in Canada, England, Australia, and New Zealand. In Europe too, variationist approaches gradually displaced those of traditional regional dialectologists, and were adopted in urban dialectology research with similar results. Researchers found, for instance, that stable variables, which typically included grammatical variables, such as multiple negation, and phonological variables, such as final *-ing* (e.g., *he don't know nothin'*) in English, tended to divide the community clearly into two major social groups. Linguistic variables involved in change, however, were typically more finely stratified with a gradient pattern reflecting a continuum from the lowest to the highest social groups. In the great majority of surveys, women lead sound change whether towards the standard or towards the vernacular variety. In New Zealand, for example, women are leading the rapid spread of the high rising terminal, as well as the merging of the vowels in words such as EAR and AIR. Recent variationist studies indicate that in specific speech communities variables such as class, ethnicity, social role, and style often interact to modify such general patterns.

Labov formalized the idea that linguistic change could be studied in progress; he analyzed 'apparent time' data demonstrating the spread of postvocalic (r) in words like *car* and *card* through different generations of the New York speech community. This approach to the study of language change has since been used by sociolinguists in speech communities worldwide.

Labov also used quantitative methods to collect people's subjective evaluations of different social accents he played to them, a method which has been

widely used since in language attitude research. He demonstrated that, despite wide variations in their linguistic production, there was a startling uniformity of evaluative norms and attitudes to language among members of the same speech community. The New York accent, for example, was universally disparaged, a pattern replicated in many other urban speech communities. On the basis of this analysis, Labov suggested that the most useful defining characteristic of a speech community was precisely such shared linguistics norms. Others have suggested shared rules of use, density of patterns of interaction, or a shared pattern of variation. More recently, some sociolinguists have begun to explore the concept of the 'community of practice' as a useful concept in sociolinguistic research which moves the focus to the ways in which communities are constructed through shared goals, activities, and verbal resources (see Holmes and Meyerhoff 1999).

Labov set the methodological standard in social dialectology, influencing all subsequent research. He used an extensive interview schedule which included word lists, reading passages, questions skilfully designed to elicit casual speech, and innovative attitude elicitation techniques. Later refinements include the use of a network approach by Lesley Milroy and James Milroy in the study of working class Belfast. Instead of using social survey results and consequently interviewing strangers, they used networking (the 'friend of a friend' approach) to contact potential contributors. They also operationalized the network concept in terms of density and multiplexity, demonstrating that those who were most closely integrated into the local community used more vernacular forms (Milroy and Margrain 1980).

Current variationist research can be found in the journal *Language Variation and Change* with material ranging from the finest vowel and consonant distinctions to the broadest features of interactional discourse. For instance, the use of quotative *be like* (as in *so she was like you aren't really going out wearing that thing and he was like why not*) provides one example of an interesting, relatively new discourse marker which is being well documented as it spreads from American English into other varieties (e.g., Tagliamonti and Hudson 1999).

5. *Social Constructionist Approaches*

Another important development over the last decade has been the influence of social constructionism on sociolinguistic research. Rather than regarding social categories, such as social class, ethnicity, and gender, as primary, with linguistic behavior reflecting membership, a social constructionist approach shifts the emphasis to language as a dynamic resource used to construct particular aspects of social identity at different points in an interaction. Social categories are not fixed but are subject to constant change; talk itself actively creates different styles and constructs different social contexts and social identities as it proceeds. So, for example, at certain times during a romantic dinner, a woman may select linguistic forms which contribute to the construction of a more 'feminine' identity, while in a Board meeting she is chairing she may linguistically construct a statusful and powerful identity. Interacting with her children or perhaps with certain subordinates, she may linguistically construct a 'maternal' identity. Even within one interaction she may use language to perform a range of social identities as she responds to the development of the discourse in context.

6. *Discourse and Style*

6.1 *Style*

The influence of social constructionism is also evident in recent research on the sociolinguistics of style. As mentioned above, Labov elicited a range of styles within the interview context by varying the interviewee's task. Subsequent research focused on the influence of the addressee (e.g., Giles and Smith 1979) and/or the 'audience' (Bell 1984). Speech Accommodation Theory, later relabeled Communication Accommodation Theory (CAT), focuses on the mutual influence of participants on a wide range of aspects of communication: so, for example, people may 'accommodate' to each other's nonverbal behavior, speech volume, rate of speaking, prosodic patterns, vowel realizations, discourse markers, and even language. Collecting social dialect data, for instance, Trudgill (1988) found he converged towards his interviewees' levels of final glottal stops for /t/ in words such as *not*. Similarly in New Zealand, convergence in levels of the use of the discourse marker *eh* are common (Meyerhoff 1994). Divergence also occurs when interlocuters wish to differentiate themselves. Giles and Smith (1979) describe, for example, a switch to Welsh as one response to outsiders' disapproval of efforts to maintain the language, and, in Australia, Eisikovits (1989) explains adolescent boys' use of vernacular forms in an interview by suggesting they are deliberately diverging from the standard speech of their middle-class female interviewer. More recently there has been some exploration of Rampton's concept of 'crossing,' where speakers apparently use out-group linguistic styles for specific stylistic effects, or code switch into varieties not generally associated with their group in order to challenge or problematize group boundaries (Rampton 1999).

Currently, then, many sociolinguists argue that style is not so much a matter of self-monitoring (as Labov suggested) or of responding to others as CAT theorists argue, but rather a matter of the way an individual chooses to present herself in everyday interaction. Style emerges from 'practice,' the individual's ongoing performance of her complex of social

identities in particular sociocultural contexts. Eckert's analysis of American adolescents' stylistic 'performance' in the school context, for instance, demonstrates that style is not just a matter of speech, but also involves 'dress, attitude and action' (2000, 211ff). Their choice of linguistic variables, however, affects every utterance. They are constantly manifesting a particular style (e.g., 'flamboyant' or conservative'), just as they are ongoingly involved in the performance of their particular social identity in the school (e.g., as 'jock' or 'burn-out').

Few would argue at the inclusion of such research within sociolinguistics. However, turning to the closely related area of pragmatics, the borderlines become much less clear.

6.2 Pragmatics

Pragmatics is concerned with the analysis of language in use. At the more linguistic end of pragmatics, researchers analyze how people disambiguate utterances such as *I watched them standing up*. Social context becomes increasingly relevant in analyzing the complex ways in which meaning is conveyed through such an apparently simple utterance as *you didn't get a paper then*? which can be interpreted as a request for information, a complaint, or even a rebuke, depending on the social relationship between participants. Similarly, *I can hear someone talking* can convey very different meanings depending on the relevant social context and participant relationships: consider, for instance, a classroom vs. police officers investigating an 'empty' house.

Closely related is sociopragmatic research on politeness, with analysis of the ways in which people express rapport and solidarity (positive politeness), as well as respect and social distance (negative politeness) (see Brown and Levinson 1987, Thomas 1995). Linguistic politeness devices include choice of pronoun (e.g., *tu/vous*, *du/Sie etc*), endearment terms (e.g., *love*, *honey*, *dear*), hedges (e.g., tag questions, epistemic modal verbs, modal particles, such as *perhaps*, *possibly*), pragmatic particles (e.g., *you know*, *of course*, *sort of*, *I mean*), and many more, some of which are very subtle.

Sociolinguists examine the patterning of such pragmatic devices in the usage of different social groups. Gender differences have been identified, for instance (e.g., Coates 1996), as well as ethnic and class differences (e.g., Goodwin 1980). More recently, researchers have examined the ways in which people draw on these devices in constructing different aspects of their social identity. Such devices are important resources in constructing ethnic identity, for example, or a 'feminine,' compliant, accommodating identity (e.g., Holmes 1997).

Sociopragmatic research has also been developed by applied sociolinguists who have examined cross-cultural differences in the way politeness is expressed, and in the realizations of such speech functions as apologies, complaints, compliments, directives, refusals, and disagreements (e.g., Gass and Neu 1996). The applied value of such work in second language teaching and learning is obvious.

6.3 Discourse Analysis

Not all sociolinguists would regard DA as appropriately included within sociolinguistics. Introductory courses and textbooks vary in whether they have sections introducing DA. Just a few approaches to DA are outlined here. In its broadest sense DA includes any analysis of spoken or written discourse. In practice, sociolinguists who adopt a DA approach to their materials generally do so in order to identify the ways in which social phenomena emerge from or are instantiated in spoken interaction. The way an oral narrative is constructed, for instance, may provide evidence of the salience for the interlocuters of a particular social or ethnic or gender identity (e.g., Labov 1972b, Cheshire 2000). Discourse markers, such as end tags (*and stuff*, *and everything*), can be used in ways which reflect or express social group membership.

Conversational analysis (CA) is one distinctive approach to the analysis of discourse based on a model of communication as jointly organized activity (Sacks 1984): like dancing, or joint musical performance, it rejects the typical linguistic model of communication as sending and receiving messages. CA is concerned with how participants work together to jointly achieve conversational closings, storytelling, disputes, medical diagnoses, the mutually dependent roles of interviewer and interviewee, and so on. CA focuses on how interaction unfolds as a sequence of actions by different participants, with the significance of an utterance or gesture highly dependent on its position in a sequence, as well as being jointly negotiated.

Others put more emphasis on the social context in which interaction takes place, and the relevant backgrounds, knowledge, and experience of the participants. This more ethnographic approach, generally identified as interactional sociolinguistics, is associated with John Gumperz and his associates. One example of recent work in this area is the exploration of workplace interactions between managers and workers, with a particular focus on areas of miscommunication and potential misunderstanding (e.g., Roberts et al. 1991).

Another approach, generally known as critical discourse analysis (CDA), has developed largely within the European tradition. CDA is distinguished by its critical focus, its broad scope, and its 'overtly political agenda' (Kress 1990, pp. 84–5). CD analysts aim to reveal connections between language, power, and ideology, and to describe the way power and dominance are produced and reproduced in the discourse structures of generally unremarkable interactions.

7. Language, Culture, and Ideology

Another important strand of sociolinguistic research which can be traced to the influence of American anthropological linguists is the quest for a solution to the conundrum of the relationship between language, culture, and thought. Edward Sapir and his pupil Benjamin Lee Whorf developed the hypothesis that language influences thought rather than the reverse. The strong form of the Sapir–Whorf hypothesis claims that people from different cultures think differently *because of* differences in their languages. So, native speakers of Hopi perceive reality differently from native speakers of English because they use different languages, Whorf claimed. Few sociolinguists would accept such a strong claim, but most accept the weaker claim of linguistic relativity, that language influences perceptions, thought, and, at least potentially, behavior.

More recently, sociolinguists such as Fairclough (1995) and applied linguists such as Pennycook (1994) have in quite different ways developed this approach. Fairclough's research uses a CDA approach to identify and expose the ways in which ideology and power are constantly instantiated and enacted in the familiar discourse of the media and of everyday interactions. Others have examined such issues as the continuing and increasingly subtle ways in which sexism, in the form of the derogation of women, or racist suppression or misrepresentation of ethnic minorities, are sustained through the ways language is used in the media or in public documents. Pennycook's controversial research also emphasizes critical awareness; he argues that the imperialist expansion of the English language has been at the cost of local languages in many countries. Not surprisingly, his views have been contested by those who regard the development of a wide variety of Englishes around the world as evidence that English no longer belongs to the English—nor even to the Americans.

8. Applied Sociolinguistics

The implications and applications of sociolinguistic research have always concerned sociolinguistic researchers. Indeed, many began their research efforts in an attempt to answer a 'real world' question such as

(a) does language play a role in accounting for differences in the educational performance of different sociocultural groups?

(b) what role can education play in the maintenance of a minority language?

(c) what is the role of the sociolinguist in the area of language policy?

(d) how can sociolinguistic information improve the workings of the legal system?

(e) what sociolinguistic competence is required by immigrants in the workplace?

As the breadth of these examples suggests, this is an extensive area of research and no more than a few illustrative examples can be provided.

Sociolinguistic research has always had important social repercussions in the area of education. The early work of the late British sociologist Basil Bernstein (1971, [1973]) was hugely influential, especially in Germany, where deficit theories of various sorts dominated some areas of sociolinguistic research for decades. Bernstein suggested that a child's social class determined their access to linguistic 'codes,' with potential cognitive consequences. His term 'restricted code' and the linguistically naive assumptions underlying some of his claims were challenged by social dialectologists, leading to the extended debates of the 'deficit–difference' controversy (e.g., Labov 1969. Its most recent manifestations range from arguments about the place of Ebonics or African American Vernacular English in the American school curriculum to debates on the linguistic rights of ethnic minorities such as Aboriginal children in Australia, British Black children in England, and the various Gastarbeiter communities in European countries.

Another area where sociolinguistic advice is often sought is in the areas of language policy and language planning. Sociolinguistic descriptions provide crucial information for planning educational policy in multilingual contexts. In Vanuatu, for example, with more than 80 vernacular languages spoken by no more than 200,000 people in total, the government's proposed policy of education in the vernacular requires extensive preparatory sociolinguistic and linguistic research (Crowley 2000). Similarly, attempts to revive a 'dying' language must start from an accurate sociolinguistic description of current numbers of users and contexts of use. Bilingual education is more likely to succeed if the sociolinguistic context in which the program is to be developed is taken into account in selecting an appropriate model. Accurate information about the way people talk can usefully counter misleading gender stereotypes which may restrict people's job opportunities. Plans for sexist language reform also benefit from accurate information about the strength of attitudes in the relevant speech community.

Forensic linguistics provides a final example where applied sociolinguistics has made a contribution. Sociolinguists have demonstrated ways in which the legal system discriminates against those who use nonstandard dialects, and those whose sociocultural rules for language use differ from those of the dominant group. In communities where Aboriginal English is used, for instance, direct questions are an inappropriate way of eliciting information (Eades 1996). Culturally conditioned responses to a lawyer's direct questions (such as silence or a formulaic *I don't remember*) may severely disadvantage Aboriginal defendants. The assumption that the norms of the Western legal system are universal regularly result in misinterpretation of the linguistic behavior of those

from different sociocultural backgrounds. Many applied socolinguists orient their research to highlighting such areas of potential injustice.

9. Conclusion

This article has necessarily been selective. The aim has been to provide a broad overview within which the range of activities of current sociolinguists can be located. Many of the topics are discussed in more detail in separate articles. Recent introductory textbooks (e.g., Romaine 1994, Wardhaugh 1998, Holmes 2001) and collections of readings in sociolinguistics (e.g., Coupland and Jaworksi 1997) provide further resources for those wishing to pursue the subject further.

How will sociolinguistics develop in the twenty-first century? The search for robust and explanatory sociolinguistic theories currently occupies many sociolinguists and seems likely to continue for some decades. The steady integration of macrosociolinguistic ('sociology of language') approaches with variationist and microsociolinguistic (interactional/DA) approaches seems a likely direction of development. Increasingly researchers using different theoretical approaches or from different disciplinary backgrounds are attempting to communicate with each other in theory development. Finally, it is safe to predict that sound descriptive sociolinguistic research will continue to provide the crucial underpinning for language policy developments in areas such as minority groups, immigration, education, and second language teaching.

Sociology, Epistemology of

The word 'epistemology' will be taken here in its etymological acceptation, which is the one kept in the Romance languages, namely as philosophy of science. Like any other special branch of the philosophy of science, the epistemology of sociology may be construed as having three main components: ontology (or metaphysics), epistemology in the narrow sense (theory of knowledge), and methodology (or normative epistemology). This order is not arbitrary, for every research strategy depends upon the type of knowledge being sought, which in turn depends on the nature of the thing studied. Thus, if the object of study is concrete, like a photon or a social group, and if what is sought is objective knowledge of it, then the scientific method will be adopted. If, by contrast, the object of knowledge is assumed to be spiritual, and if things spiritual are deemed to be beyond the reach of science, then an alternative method will be preferred—such as revelation, intuition, interpretation (Verstehen), unchecked speculation, or narrative. In this article the ontology, epistemology and methodology of sociology will be glanced at.

1. *Ontology: Nature of the Social*

1.1 *The Idealism–Materialism Dilemma*

Most sociologists adopt the vulgar view that the human being is a composite of body and mind (or spirit or soul), and do not ask how these two components are kept together. Hence they do not characterize social facts as either material or spiritual, and do not worry about the place of sociology in the system of human knowledge: they are dualists. But some sociologists do worry about these questions, and argue for or against one of two monistic worldviews: idealism or materialism. Idealism is the view that everything is either ideal or ultimately ruled by ideas, whereas materialism holds that all existents are material or concrete.

In social studies, the idealism/materialism cleavage appears notably in the place and relative weight assigned to the so-called ideal (cultural and political) superstructure vis à vis the material (biological and economic) infrastructure. This very distinction betrays a dualistic stand, even if the pre-eminence or priority of either 'structure' (system) is postulated.

Consistent idealists will assert that everything social is spiritual (or cultural), whence sociology is a *Geisteswissenschaft* (science of the spiritual). This is the view of hermeneutics, symbolic interactionism, phenomenological sociology, and ethnomethodology. By contrast, materialists assert that persons and social groups are material, though not necessarily confined to the physical or even the biological level. And, unlike idealists, they claim that all cultural and political activities are influenced or even determined by environment, reproduction, and material production. While it is undeniable that the reproductive patterns and means of subsistence condition culture and politics, it is no less true that the latter in turn help shape the former. In a systemic perspective, changes in the environment and in any of the subsystems of society (the biological, economic, political and cultural) may initiate processes altering any of the others. People may work or fight, live or die, for King and country, no less than for food and family. There is no 'last analysis.'

Marxism is the oldest, and still the most influential, of the materialist schools in social science. However, given its proposed division between the material infrastructure and the ideal superstructure, it is questionable that Marxism is consistent. Moreover, philosophical Marxism is nowadays split into a large number of different schools, neither of which is flourishing. By contrast, some of Marx's contributions to social science, particularly his emphasis on production, on the economic roots of the power elites, and on the economic causes of many an international conflict, have survived. Even some of Weber's studies are materialist, particularly those of the congruence between Hinduism and the Indian caste system, and on the causes of the decline of slavery in ancient Rome. Likewise the *Annales* historical school owes much to Marx.

Sociobiology is the newest and most popular materialist school in social studies. Sociobiologists hold that everything social is ultimately biological, for having evolved as an adaptation to the natural environment. This view overlooks all the types of self-

destructive and antisocial behavior, from suicide to military aggression to environmental degradation to gullibility and ideological zealotry. And it ignores all social inventions (like formal education) and social revolutions (like the information revolution)—hence it is basically conservative. The sociobiological speculations on the origin of mental faculties are even more far-fetched and they lack empirical support. Still, something does remain of the attempt to reduce social science to biology, namely, the reminder that sociologists cannot afford to ignore human physiology and ecology. For example, they should not ignore that malnutrition stunts development and limits productivity; that plagues, foreign invasions and wars are bound to eliminate some genes and change the immune system; and that a few more centuries of uncontrolled environmental degradation is likely to make our planet uninhabitable.

1.2 The Individualism–Holism–Systemism Trilemma

There are essentially three consistent views on social structure: that it does not exist, that it is self-existing, and that it is a property of a system composed of individuals. The first, or individualism, identifies 'society' with 'crowd.' The second view, or holism, regards society as an organism, and the individual as wholly subordinated to it. The third, or systemism, views society as a system made up of individuals linked to one another by ties of different kinds and strengths. Individualism stresses agency at the expense of structure, and tends to explain action in terms of 'rational' (self-interested) decisions. Holism emphasizes collective traits, which it claims to be unexplainable, and it explains individuals by wholes. Lastly, systemism admits the novelty of systemic properties, as well as the possibility of explaining them in terms of interactions among individuals and systems.

Individualists rightly see in individual action the root of everything social. And, even if they acknowledge the importance of the social context or situation, they resist the very idea of a social system (family, village, firm, etc.) Radical individualism cannot work in sociology if only because the idea of an individualist social science makes as much sense as the idea of a collectivist psychology. After all, sociology studies social facts and, although these result from individual actions, they have nonindividual traits. Families, businesses, schools, armies, religious congregations, and other social systems are structured groups, and a structure is a set of relations, among them the bonds holding the system together. Likewise, social processes, such as trade, governance, and war, are impersonal affairs. This is why there are no radical individualist sociologists, with the possible exception of Homans. Many who call themselves methodological individualists, from Weber and Pareto to Coleman and Boudon, admit the peculiarity of the social, and only attempt to explain it as emerging from individual actions: they behave more like systemists than like individualists.

Holists rightly emphasize the centrality of connections, but they exaggerate in claiming that social structure precedes and dominates individuals. This view is logically untenable, because there are no relations without relata. In reality there are only interrelated individuals: relations, like their relata, are only the products of abstraction. For instance, there is no such thing as 'married' in itself, any more than there are unrelated spouses. Hence relations cannot act upon individuals, but interrelated individuals can alter or even sever some relationships—though never all of them at the same time except through suicide.

Systemism, often confused with holism, is a sort of synthesis of the latter with individualism. It holds that, because individuals are inter-related, individual behavior can only be understood in terms of both intentions and social constraints and stimuli. Thus, agency and structure are mutually inseparable. And social change, though brought about by individual action, consists in structural change—that is, change in the nature and strength of the bonds that hold social systems together. A social system may be characterized by its composition, environment (natural and social), structure, and mechanism. A change in any of these features may modify the other three. However, some features may resist changes in the others. For example, social order may survive demographic turnover and environmental catastrophe. Still, all four aspects coexist and, in the long run, important changes in any are bound to alter the other three. Yet individualism ignores structure and underrates environment, whereas holism ignores composition and mechanism, and underrates the natural environment. Only systemism accounts for all four, and is thus likely to favor realistic models of social groups and effective social policies.

2. Epistemology: Knowledge of the Social

There are as many views on the nature of social studies as general views on the nature of knowledge: skepticism, apriorism, empiricism, and realism.

2.1 Skepticism

Skepticism comes in two strengths: moderate (or methodological) and radical (or systematic). The moderate skeptic doubts a thesis as long as no solid evidence for it is available. By contrast, the radical skeptic questions the very possibility of knowledge of some kind. Whereas moderate skepticism is part of the

scientific attitude, radical skepticism is destructive and even self-destructive for, if everything is doubtful, why not skepticism itself? The variety of radical skepticism most common concerning the social is cognitive relativism, or the view that social facts cannot be known objectively. This view has been falsified by the growing pile of reliable social data and approximately true sociological hypotheses. Since every research project sets out to find out the truth about something, it presupposes the ability to find it.

2.2 *Apriorism*

Apriorism is speculation without reality checks. The 'grand social theories' of old were apriorist. So are the sociobiological theories on the alleged genetic roots of all social traits, from the incest taboo to social stratification to ideals of human beauty. However, nowadays the most popular *a priori* theories in social studies are the rational choice models. All of these assume that we always act in self-interest and moreover 'rationally,' that is, striving to maximize our expected utilities. These theories are *a priori* because they are seldom if ever checked against empirical data. In particular, they postulate that agents have certain preference rankings (or utility functions), that are seldom checked. Moreover, some rational choice models are untestable. Thus, if agents behave in an obviously irrational fashion, they are said to be subjectively rational—as when they play lottery. And if people are altruistic, it will be argued that altruism is nothing but enlightened self-interest. Being impregnable to empirical data, such models are unscientific.

2.3 *Empiricism*

Empiricism is the view that only empirical data count: that they are the source, content, and final judges of ideas. Note that the emphasis is on data (reports on observable facts), not on objective facts. So much so, that the neopositivists disallow all talk of objective facts as metaphysical, in going beyond experience. However, empiricism is not limited to positivist philosophers. Behaviorism is a prime example of empiricism, since it deliberately avoids the neural springs of behavior and it eschews theorizing. Ethnomethodology, though ostensibly tributary to the anti-empiricist philosophies of Dilthey and Husserl, is another instance of empiricism, since all its practitioners do is to record overt everyday behavior.

Empiricism condemns students to the shallowness characteristic of common sense, because the most interesting facts of any kind are invisible, whence they must be guessed. For example, we can see a status indicator but not status, let alone class; and we can hear political talks, but not the interests that they manifest or disguise. Only sociological theory can suggest the search for social data that indicate social process, in particular the mechanisms behind appearances. By banning theory, or restricting it to correlating commonsense data, empiricism curtails experience. Moreover, its limitation has elicited some of the postmodern attacks upon science.

2.4 *Scientific realism*

Scientific realism, or objectivism, has two components: the ontological thesis that the world outside the knower exists on its own, and the epistemological thesis that it can be known. As applied to sociology, scientific realism is the view that social facts are just as real as physical facts, and that they can be known by blending theory with observation, measurement, and (whenever possible) experiment. Such knowledge is objective, but partial and gradual. In the case of social facts, research must include not only the facts themselves but also the way the actors perceive them—for example, the fact that people gauge social inequalities, and react to them, by reference to the adjoining social group.

Although scientific realism demands that theories be ultimately justified by data, it does not stifle the sociological imagination the way empiricism does. A realist concedes that, just as some data trigger the curiosity of the theorist, at other times untested theories motivate the search for pertinent empirical data. And, on still other occasions, advances come from the confrontation of either rival theories or mutually incompatible data. In short, according to scientific realism, theorizing and empirical research should go hand in hand, now matching, now challenging one another.

On the critical side, scientific realists will ask interpretivists and other armchair students to exhibit empirical evidence for their 'interpretations' (hypotheses). They will ask rational choice theorists to specify and justify the utility functions they impute to people. They will remind Marxists and other 'economic imperialists' that real people engage in some activities that are economically unproductive or even counterproductive, and that many a social change—such as the diffusion of the computer and the revival of religious fundamentalism—has come about with little or no class struggle.

3. *Methodology: Social Research Strategy*

Methodology is the normative or prescriptive branch of epistemology: it attempts to lay down, justify, refine, or criticize research rules and procedures. Philosophers are interested only in general or cross-disciplinary strategic principles: they leave special

techniques to specialists. Here is a tiny random sample of the class of general methodological problems: How are causation and statistical correlation related? What is a social indicator? How to infer intention from behavior? Can every social feature be quantified, or are there irreducibly qualitative properties? Is an ideographic (or particularistic) science possible? Here we shall only review three rival research strategies.

3.1 Dataism: Collect Data

In the Anglo-Saxon sociological tradition, research is equated with data hunting, gathering, and processing, whereas theory is regarded as mere data compression (as in curve fitting), or even as parasitic upon data collection. To be sure, there is no factual (or empirical) science without empirical data. But data alone a science does not make, because they are what calls for explanation. To understand a bit of the world is to explain it. And explaining involves guessing (and then checking) mechanisms—causal, random, intentional, or hybrid. Hence, theorizing is just as important as data collecting, whether in sociology or in any other factual science. Moreover, only theory, by suggesting interesting variables, can spare us the barrenness and boredom of mindless data gathering.

3.2 Interpretivism: Impute Intention

The interpretivist school holds, rightly, that we can explain an agent's behavior if we know his intentions. But it overlooks the fact that we only have direct access to behavior, not to intentions. That is, the interpretivist is faced with the inverse problem of guessing intentions from actions. (Typically, inverse problems are insoluble or have multiple solutions. Think, for example, of the problem of decomposing a given even number into prime numbers, as opposed to the problem of adding prime numbers.) The interpretivist is entitled to guess anything, but not to present his guesses (hypotheses) as true unless they have passed the suitable empirical tests. The imputation of intentions is not only dicey: it is also insufficient, because intentions, even if known, may explain success but not failure. The social constraints upon agency, and the reactions of other people to one's actions, must be envisaged too. That is, individuals must be placed in their systems.

3.3 Scientism: Gather Data and Craft Theory Consistent with Data

Scientism is the thesis that the scientific approach is the best of all approaches to cognitive problems of all kinds in all fields. Scientism should not be mistaken for naturalism, or the thesis that the social world is a fragment of nature, and consequently social research should be conducted in exactly the same manner as the study of nature. One may admit that everything social is made, while holding that, once made, a social item is out there, along with rivers and butterflies. That is, social reality is constructed, but not by the knower. And it is changeable, but not because the knower changes their viewpoint. Scientism does not involve the denial of the specificity and irreducibility of the social. It only holds that the scientific method is applicable across all the disciplinary barriers, hence that it is advisable to trespass them whenever they are artificial. In the case of sociology, scientism favors close relations with all its sister disciplines, particularly economics, politology, and historiography. Scientism also promotes the proliferation of social indicators, the production and statistical processing of data, and the crafting of empirically testable theories—in particular mathematical models.

Hundreds of social indicators have been invented, measured and used since the mid-1960s. However, their very nature is still somewhat unclear, due to insufficient philosophical investigation. A social indicator bridges the observed to the unobserved, effects to causes, symptoms to mechanisms, and data to hypotheses. However, it does so ambiguously unless it can be shown that no other unobserved trait or event could possibly account for the data. For example, the popularity of low-cost merchandise may measure either consumer satisfaction or poverty; and high church attendance may measure either religiosity or the need for social integration (or for respectability). Ambiguity is typical of empirical indicators. By contrast, the indicators used in the more advanced sciences are unambiguous because they are backed by theories. For example, pH is a reliable measure of acidity because it is an index of proton concentration, and theory defines acids as proton donors. The moral for sociology is that the reliability of a social indicator can be increased either by grounding it in a theory, or by using it jointly with other indicators of the same hidden trait.

Values and morals would seem to defy scientific realism. After all, Weber held that science ought to be value-free and morally neutral because he wished to preserve objectivity as well as the difference between science and ideology. Now, it is certainly correct to distinguish value judgments from factual statements. But not all values are subjective: some, such as peace, welfare, and truth, are not a matter of taste. Moreover, it is possible to investigate scientifically how values and moral norms emerge, and why some of them have become obsolete. It may even be argued that there are moral facts, such as misery and torture, and consequently that some moral judgments can be justified scientifically. Example: 'Anomie is wrong because it is personally and socially destructive.' It is also correct to distinguish science from ideology. Social scientists endeavor to understand social reality, not to alter it.

However, some of their findings can be used by social activists, politicians and managers to alter social conditions in a rational fashion rather than through costly improvisation. That is, a scientific ideology—one based on social science and empirically testable—is not out of the question.

4. The Sociology–Epistemology Connection

The traditional view of the relation between science and philosophy is that they are disjoint or even mutually incompatible. This view is mistaken, because science teems with philosophical concepts, such as those of reality, law, and knowledge, and because scientific research presupposes the reality and knowability of the world—a philosophical thesis. In short, philosophy and science, in particular social science, overlap partially. This overlap is only partial because only philosophers analyze philosophical constructs, and only scientists are equipped to study social facts.

However, not all philosophies are congenial with science. Whereas some philosophies are extraneous to science, others are relevant to it. For example, phenomenology is extraneous to science because it rejects the scientific method and consists in egology, or the self-study of the self. Existentialism is even more alien, because it rejects rationality and does not deal at all with problems of knowledge. The philosophies congenial with science examine, among others, the problems, concepts, hypotheses, and methods common to science and epistemology. Hence, they can be judged to be adequate to the extent that they propose true accounts of actual scientific practice and help advance science. For example, Popper's philosophy is congenial with science because of its rationalism and objectivism. But his devaluation of confirmation is incompatible with the search for truth, since a hypothesis can only be said to be true to some extent if it has been well confirmed.

5. Sociology of Epistemology

The sociology of philosophy is only embryonic, and mostly speculative. In particular, little is known about the social roots of the various epistemologies of sociology. For one thing, it is not true that they are motivated by class interests. Nor is it true that all idealists are reactionary and all materialists progressive. For example, Hegel's followers split into a left-wing and a right-wing. The second Comte inspired both the Mexican conservatives led by Porfirio Díaz, and their contemporary Brazilian progressives.

What is true is that, once crafted for whatever reasons, some philosophical views favor certain social groups rather than others. For instance, radical skepticism, even while revolting against the establishment, objectively favors the latter in that it discourages scientific social research and therefore reasoned and well-organized opposition. Individualist philosophies favor anarchism and liberalism. By contrast, holistic philosophies jibe with communitarianism and totalitarianism. In short, some philosophies, particularly if fuzzy, can be craftily interpreted to suit anyone's social interests. But the more abstract philosophical ideas—in particular the logical and semantical ones—are socially neutral. Thus, neither the logical calculi nor the theories of (semantic) meaning and truth refer to social facts, whence they cannot support any social ideology. However, they are useful to examine the cogency of any views whatsoever, and to this extent they have a subversive potential.

Sociology, History of

The standard way in which surveys of the history of sociology are written and taught still lags behind actual developments in the field itself. The writing and teaching of the history of sociology continue to be strongly dominated by the tradition of the history of ideas. Only recently have some major attempts been made to view the history of sociology from a sociological angle, using sociological concepts, methods, and theories.

In the absence of a standard sociological survey of the development of sociology, we shall in this outline mainly follow the familiar textbook trajectory. This approach inevitably implies distortions. It suggests a pattern of Whig history, in which the history of sociology is made into a neat succession of successes.

To balance that bias, the reader should bear in mind that the development of sociology itself has been a social and cultural process, consisting of a multitude of short-term planned actions and interactions with aggregate results that in the long term have not been planned by any single individual. This process took place, moreover, as a part of wider social and cultural developments.

The context was primarily European and, since the second half of the nineteenth century, North American; yet, as Europe and North America belonged to a more encompassing global constellation, we should also consider the relevance of the processes of colonization and decolonization affecting nineteenth and twentieth century society and culture all over the world (Connell 1997, Collins 1997).

Sociology, furthermore, was one of the social sciences amidst other intellectual disciplines: academic disciplines ranging from physics and biology to history and philosophy, as well as nonacademic disciplines including journalism, political debate, and literature. Sociology took on an articulate form in continuous dialog with those other disciplines, sometimes borrowing ideas from them, sometimes opposing them. Most of the controversies within sociology itself reflected its relations to the larger field of intellectual activities. This would be true of the moral or political views informing sociological theories as well as of the preference for either quantitative, 'scientific' methods or a qualitative, 'hermeneutic' approach (Lepenies 1988).

In addition to the differentiation into (a) theoretical and methodological orientations, sociology has also become differentiated according to (b) empirical specializations, and (c) national traditions. These various forms of differentiation are respectively related to (a) the prevailing orientation to other intellectual disciplines including science, philosophy, literature, and journalism; (b) the general process of differentiation of functions in society at large; and (c) international relations. While the variety of empirical specializations and national traditions is easily visible, this is not so clearly the case with the way the national traditions are 'nested' in an evolving international constellation characterized by specific hierarchies, loyalties, and corresponding intellectual interests.

We shall not continuously refer to the more general conditions affecting sociology in the following account which, because of its encyclopedic format, is written in accordance with standard practice. The reader should realize, however, that these conditions are relevant to each of the five major stages into which the development of sociology can conveniently be divided:

(a) A long 'predisciplinary' stage up to 1830, marked by what in retrospect may be recognized as 'protosociologies.'

(b) The formation of an intellectual discipline, 1830–1890.

(c) The formation of an academic discipline with diverging national traditions, 1890–1930.

(d) The establishment as a fully fledged academic discipline with autonomous degrees, departments, and research facilities and an emerging international hierarchy, 1930–1970.

(e) A period of crisis, fragmentation, and attempts at new synthesis, 1970–2000.

In discussing the successive stages we shall have to observe a basic rule of 'phaseology' (Goudsblom 1996): when a later phase begins, new elements are added to the previous constellation; but most of the elements which were already present in the earlier phase will continue to exist, albeit in a modified guise.

1. *The Predisciplinary Stage*

By a discipline we mean a 'unit of teaching, research and professional organization' (Heilbron 1995). There is a body of knowledge, recognized as such under a generally accepted name, set down in textbooks and discussed in professional journals by practitioners.

All of these elements were absent from the field of sociology prior to the nineteenth century. And yet we can list many names of people who may, arguably, be regarded as predecessors, 'protosociologists': people who reflected about social phenomena, collected data

about social life, or tried to find patterns in human history. Some individual contributors to these traditions have gained great renown in their own cultures. Thus, from ancient Greece, the names of such men as Herodotus, Plato, Thucydides, and Aristotle stand out. Although they have been 'appropriated' as founding fathers by the practitioners of the established academic disciplines of philosophy and history, many of the problems they addressed lay in the area of what was later to become sociology. Chinese, Indian, and Arab culture have similar intellectual traditions; here, too, a few individuals have become the famous exponents of those traditions (Collins 1998).

In this brief survey, we shall be able to pursue only the Western line leading up to the emergence of sociology as an intellectual discipline in Western Europe and North America in the nineteenth and twentieth centuries. Since the Middle Ages, there was, on the one hand, a strong tradition of philosophizing about human social life, mainly in theological and moral-legal terms, and, on the other hand, an increasingly strong tradition of collecting facts, most often related to state matters and focused on knowledge of the population and its resources, both at home and abroad (as reported by explorers and travellers). By and large, the two traditions stood apart.

The transition from the predisciplinary stage to the actual conception of sociology as an intellectual discipline in its own right occurred in the eighteenth and nineteenth centuries. The shift consisted partly in conscious attempts to bridge the gap between theory and practice, between philosophical reflection and the collection of facts about social life. The leading intellectual model, furthermore, was sought no longer in theology or metaphysics but in empirical science. And, in so far as the focus had been either on the political realm or on more 'private' moral issues, it now moved to the structure and development of 'society' at large. This threefold shift in orientation was pioneered by the groups which have become known as the French *philosophes* and the Scottish moral philosophers. Their work was developed in different directions during the last decades of the eighteenth and the first decades of the nineteenth century.

Among the *philosophes*, Montesquieu was one of the first and most influential. He demonstrated that types of government are to be understood in relation to their moral and physical infrastructure. For an understanding of such connections, a recognition of the 'general spirit' of a nation is central. This 'spirit' or 'common character' results from the combined effect of various causes, including climate, religion, and commerce. Instead of drawing deductions from an original principle such as a political or social contract, Montesquieu thus started to unravel the complex interdependencies of human society.

While Montesquieu pioneered the study of what Auguste Comte later was to call 'social statics,' his younger contemporary, the future statesman Turgot, pointed to the possibility of also viewing human society from a developmental perspective, in other words, in terms of 'social dynamics.' That idea was further elaborated in theories of successive stages or phases by such writers as Condorcet and Henri de Saint-Simon.

In a kindred spirit, the Scottish moral philosopher David Hume proposed introducing 'the experimental method of reasoning into moral subjects.' Hume and his younger friend Adam Smith rejected theories based on an assumed state of nature. Such reasoning had characterized the natural law tradition—the predominant framework for early modern theories of government and moral obligation (Grotius, Hobbes, Locke, Pufendorf). For Hume, the state of nature was a hypothetical construct, incompatible with the precepts of empirical science. To consider states as the result of an original voluntary act of agreement was illusory and contrary to scientific procedure. Social institutions, in Adam Ferguson's famous phrase, 'are the result of human actions, but not the execution of any human design.' From this perspective, morality would have to be studied historically and comparatively, tracing its development through the successive stages of hunting, shepherding, agriculture, and commerce.

As the idea of a general social science gained ground, various attempts were made to connect that idea to existing scholarly disciplines. Some groups, particularly in France, pursued the ideal of a social science modeled after the natural sciences. Thus, by applying probability theory to voting procedures and judicial decision making, mathematicians such as Condorcet and Laplace proposed a 'social mathematics.'

British liberal thinkers such as Jeremy Bentham and James Mill somewhat similarly tried to build a social and political theory upon the idea of a moral arithmetic. Individuals and governments alike should promote the amount of happiness and reduce the amount of pain. Their 'felicific calculus,' aimed at the greatest happiness of the greatest number, provided the means for assessing the utility of public institutions. Others, such as Saint-Simon, couched their analysis of early industrial society in a medical idiom, advocating a 'social physiology.' Conservative social theorists such as Edmund Burke, Joseph de Maistre and Louis de Bonald, by contrast, while recognizing the reality of 'social relations' and 'society,' opposed the notion of a natural science of society, and rather sought inspiration in theology, philosophy, and history.

2. *The Formation of an Intellectual Discipline, 1830–90*

In the course of the nineteenth century empirical social research became a regular and organized endeavor. Most of it was centered on the 'social question' and intimately linked with governmental agencies and

reform movements. Besides a multitude of local initiatives, national associations arose for the coordination of these efforts: the French Académie des sciences morales et politiques (1832), the British National Association for the Promotion of Social Science (1857), the US Social Science Association (1867), the German Verein für Socialpolitik (1873). More theoretically informed work made use of the research findings, but was carried out mainly by individual scholars who either possessed private means or made a living by writing and lecturing. Thus Auguste Comte, John Stuart Mill and Herbert Spencer were for most of their professional lives publicists, men of letters with a strong interest in the sciences. All three contributed significantly to the formation of sociology as an emerging discipline, but none of them was a regular academic or was actively involved in social research.

Other writers, such as Alexis de Tocqueville, Karl Marx and Adolphe Quetelet, shared similar interests, but consciously avoided the term sociology. Marx and Tocqueville have been incorporated in the canon of the discipline only after 1945. While Tocqueville called for a 'new political science for a new world,' Marx's critique of political economy resulted in a theory of capitalism and class domination. The Belgian astronomer and statistical entrepeneur Quetelet continued the efforts of Condorcet and Laplace. He considered the ever growing body of statistics to be the proper basis for a 'social physics.'

When Comte introduced the term 'sociology,' he was likewise concerned with the idea of a fundamental science of human society. At the time, Comte had no interest in applied knowledge, rejected premature specialization, and wanted to construct an appropriate foundation for social science. The term sociology captured all of these ambitions quite well. It conveyed the idea of a positive science, suggesting both a high level of generality and a great degree of independence from the natural sciences. For Comte sociology was to become an uncompromising positive science which, however, should not be conceived of in terms of either physics or physiology. Sociology was to biology what biology was to physics: a relatively autonomous science with its own subject matter and methods.

In the *Cours de philosophie positive* (1830–42) Comte explained that different methods prevail in the various sciences: the experimental method in physics, the comparative method in biology, the historical method in sociology. Sociology had to be founded on a historical law. Since human beings specifically have the capacity to learn, the development of knowledge is the core of human development, and Comte considered his law of the three stages in the development of knowledge as the proper beginning of sociology.

Comte's plea for sociology as the general social science was well received in the UK, first in the circle of John Stuart Mill, then by Herbert Spencer. Mill rejected Comte's criticisms of psychology and political economy, but admired his philosophy of science and embraced the idea of sociology. Yet, like the French followers of Comte, Mill never wrote a properly sociological study. One of the first sociological treatises appeared in the 1870s and was written by Spencer—the most widely read sociologist of the nineteenth century.

For Spencer, progressive change was the common denominator of all natural processes. From the maturation of an embryo to the evolution of life in general, all living things evolve from the simple to the complex through successive differentiation and integration. Evolution is the natural process of change from incoherent homogeneity to coherent heterogeneity. Human societies are no exception: they too develop through differentiation, a process steadily accompanied by higher levels of integration and coordination.

Spencer's view of evolution was thus broader in scope than both Comte's sociological and Darwin's biological theory. Combining a laissez-faire view borrowed from economics with an embryological model of growth, Spencer gave the evolutionary principle the status of a universal law and made it the core of his all-embracing system of synthetic philosophy. As stated in his influential essay 'The Social Organism' (1860), Spencer's sociology was cast in the organic idiom, while carefully maintaining an individualist perspective. In *Principles of Sociology* (1876–97) he elaborated his analysis, emphasizing the passage from 'militant' to 'industrial society.' In the latter, social integration is no longer imposed from a controlling center, but the spontaneous result of individuals who cooperate on the basis of a division of labor. Spencer strongly favored a laissez-faire stance, opposing state politics (in matters of welfare as well as in colonial expansion), and inspired what was—inaccurately—called social Darwinism.

His position as a freelance writer and lecturer allowed Spencer to make virtually unlimited claims for the scope of sociology. While he was most outspoken and influential in articulating the idea of sociology as an intellectual superstructure sustained by an evolutionary perspective and overarching all the other social sciences, that idea was shared by several other leading advocates of sociology in Europe and the USA.

3. *The Formation of an Academic Discipline, 1890–1930*

Sociology as an academic discipline emerged between 1890 and 1930. The first courses and chairs were established, sociological journals appeared as the primary outlet for research, and sociological associations were founded for furthering intellectual exchange and professional interest. France, the UK, Germany, and the USA were the core countries. In all

of these countries, distinct national traditions took shape, with the curious effect that some of the academic pioneers, most notably Durkheim and Weber, never referred to each other.

Emile Durkheim was the pivotal figure in French sociology. He taught his first course in 1887, wrote classic works on the division of labor, suicide, and the rules of sociological method in the 1890s, and organized a network of highly productive scholars around his journal, the *Année sociologique* (1898–1912). By proclaiming that social facts had to be explained by other social facts, Durkheim broke away from the predominant biologistic and purely psychological approaches. His explanation for variations in the suicide rate was a paradigmatic example. The social realm was a reality *sui generis* with its own structure and regularities. Systems of collective representations are an essential part of social life, not merely when studying religion or morality, but also for understanding the economy and political institutions. Following this line of argument, Durkheim and his collaborators (Marcel Mauss, Henri Hubert, Marcel Granet, Maurice Halbwachs, François Simiand) worked on a wide range of topics, contributing to many fields outside of sociology proper.

In the UK sociology did not gain a proper entry into the university system until well after World War II. The rich tradition of factual inquiry was continued by government officials and wealthy individuals (Charles Booth, B. S. Rowntree), but remained almost entirely separated from academia. Despite the existence of a sociological journal and a professional association, the British academic establishment did not show much interest in sociology. The only chair for a long time had been established in 1907 at the London School of Economics for L. T. Hobhouse, who, in 1929, was succeeded by his pupil Morris Ginsburg. Both men maintained a cautious evolutionary perspective but neither one built up a network of productive scholars. Whereas British academics showed little interest in studying their own society, they had no such inhibition about studying the exotic regions of the British Empire. Social anthropology became a respected academic discipline and partly served as a substitute for sociological concerns.

Sociology in Germany emerged later than in France and England; a professional association was founded in 1910, a first chair in 1917, a journal in 1921. The academic pioneers in Germany, men like Ferdinand Tönnies, Georg Simmel and Max Weber, faced two powerful indigenous traditions. The oldest was that of the *Staatswissenschaften*. The proponents of these disciplines (law, economics, administration) consistently subsumed civil society to the various functions of the state. This mode of thinking had its roots in the eighteenth-century system of centralized political administration and economic policy known as cameralism and was refashioned in the nineteenth century by idealist philosophers such as Hegel. After the founding of the German Empire, the members of the *Verein für Socialpolitik* maintained much of this conception of social science. They were opposed by liberal economists like Carl Menger during the first *Methodenstreit*, and by Max Weber and others during the second *Methodenstreit*. An important aim in Weber's argument about the value-freedom of scientific inquiry was to create a greater distance from the practice of the state sciences.

The other tradition with which German sociologists grappled radically opposed the natural to the cultural sciences: the first were supposed to be concerned with causal explanation, the second with interpretative understanding. Early sociologists such as Comte and Spencer had often been rejected in Germany as representatives of an inadequately naturalistic conception of the human sciences. Reflecting on these epistemological issues, Max Weber proposed to transcend the dichotomy by ingeniously defining sociology as the science of social action, which by interpretative understanding seeks to explain its course and consequences.

Weber was nominated for a chair in sociology shortly before his death in 1920. His achievements and those of others of his generation (Simmel, Alfred Vierkandt, Werner Sombart, Franz Oppenheimer) contributed to the recognition of sociology as an academic discipline during the Weimar Republic (1919–33). Sociology expanded rapidly, opening opportunities for a generation of young scholars including Max Horkheimer, Theodor Adorno, Theodor Geiger, Karl Mannheim, and Norbert Elias. Although these men had initially received a training in different academic fields, they were ready for brilliant careers in sociology. However, the seizure of state power by the National Socialist Party in 1933 made an abrupt end to the favorable outlook for German sociology, forcing all these men, along with many of their colleagues, into exile.

Sociology's most rapid expansion took place in the USA. The first courses were taught in the 1870s and 1880s, while the expansion of higher education in the 1890s produced rapid institutionalization. Within two decades sociology was taught in most colleges and universities; textbooks standardized the concepts and methods of the new discipline. US sociology developed primarily on the basis of empirical research into social problems. The main topics were the issues which were widely debated by politicians, religious leaders, and social reformers: massive immigration, urban problems, industrialization, local communities, social (dis)integration, ethnic and race relations. Empirical studies proliferated, based either on statistical material or on actual fieldwork.

By the 1920s the sociology department in Chicago, founded by Albion Small in 1893, had become the predominant center. Small also played a key-role in the *American Journal of Sociology* (1895) and—together with George E. Vincent—wrote the most widely

used textbook, *An Introduction to the Study of Society* (1894). The work of the Chicago School was founded on qualitative case studies, using observations, interviews, and life histories. Exemplary were William I. Thomas and Florian Znaniecki's *The Polish Peasant* (1918) and the collective volume on *The City* (1925).

4. *Establishment as an Academic Discipline, 1930–70*

Between 1930 and 1970, sociology became established as an academic field at most universities in the Western world. The number of practitioners and students greatly increased, and there was a proliferation of specialisms in research and teaching. Far from being an even process of growth all over, however, these trends were marked by far-reaching structural changes: a forcible break in the development of sociology in Europe, and a concomitant shift of intellectual leadership in the field from Europe to the USA.

That shift, which strongly affected the development of sociology, was illustrated strikingly by two historical introductions to the discipline written toward the end of this period: *The Sociological Tradition* by Robert A. Nisbet (1966) and *The Origins of Scientific Sociology* by John Madge (1962). Nisbet's book celebrated the formative era of the second and third stages, which he designated as 'the golden age of sociology.' Here was a US scholar revering the 'titans' of nineteenth-century sociology: a small pantheon of authors whose highly personal visions provided the basic ideas and concepts for their more pedestrian successors in the twentieth century. Almost inevitably, all the heroes of Nisbet's great sociological tradition were Europeans.

Madge's book radiated a very different atmosphere. Madge was an Englishman, proudly hailing the achievements of scientific sociology in the twentieth century. He discussed 12 pieces of empirical research; with the only exception of Durkheim's *Suicide*, they all belonged to the fourth stage in the development of sociology. Many of the studies selected by Madge were published under joint authorship, and, again except for *Suicide*, they were all carried out in the USA.

The leaders of the first generation of US academic sociologists all acknowledged an intellectual debt to European masters. Even in the early 1920s, it was still not uncommon for promising US social scientists to start their career with a European apprenticeship, as did Talcott Parsons who went to London and Heidelberg. At the time, however, the westward exodus of sociologists from Eastern Europe was already underway, as the communist regime in the USSR and the fascist regime in Hungary tightened their grip, greatly restricting the margins for sociological inquiry and reflection. 1933 brought the decisive rupture: the seizure of power by the Nazis in Germany put an end to the flourishing sociology of the Weimar Republic, and forced a great number of prominent and promising sociologists into exile, mostly to the USA.

In contrast to Europe, sociology in the USA suffered no drastic interruptions in the years between 1933 and 1945. It remained a subject in most college curricula, with textbooks such as Park and Burgess's *Introduction to the Science of Society* (1924) continuing to supply an authoritative framework of concepts and ideas. At the same time, practically oriented research in areas of social problems and social policy was stimulated by increasingly generous funding from both government and private foundations (Platt 1996). Empirical research received a powerful boost after 1941, when social scientists were recruited for the war effort and commissioned to study factors fostering the morale of the Armed Forces.

After 1945, the USA emerged as the major political, economic, and cultural power in the world. In the social sciences, including sociology, US examples were virtually unrivaled in setting an international standard of competence in method and theory. An impoverished Europe lacked the resources for challenging the US ascendency. The relatively autonomous sociological traditions in Germany and Italy were virtually destroyed. Sociology in the UK had only a minor position at the London School of Economics. In France the Durkheimian tradition continued to exert considerable intellectual influence among anthropologists and historians, but the actual institutional basis for sociology as an academic discipline was very weak.

Thus the scene was set for US dominance. The sociology departments at Harvard and Columbia University in particular gained international reknown. At Harvard, Talcott Parsons developed a new synthesis of sociological theory, mainly derived from European predecessors, which he presented as a 'general theory of action'—although in its worldwide reception it became known as 'structural functionalism' or simply 'functionalism.' Still, Parsons' generally recognized status as the world's leading sociological theorist did not imply that his ideas put a mark on the entire discipline. There were some influential rival theorists, including his Harvard colleague George Homans who advocated a strictly scientistic 'exchange theory' inspired by the model of *homo economicus*. At Columbia, Parsons' former student Robert Merton propagated a more modest ideal of 'theories of the middle range,' which proved to be very well compatible with the work of his colleague Paul Lazarsfeld, an immigrant from Austria who specialized in the organizational and methodological aspects of social research.

The years between 1955 and 1975 in particular spelled a boom period for American sociology (Turner and Turner 1990). The successful launching of Sputnik

by the USSR in 1957 inaugurated an era of unprecededly high government funding of scientific research in the United States, which also benefited sociology. In the 1960s, a combination of demographic trends (the postwar baby boom) and political discontent made for a dramatic increase in student enrollments. Professional self-confidence, which had been clearly mounting since the early 1940s, surged to new heights. The auspices were favorable for manifold activities in the realm of academic sociology: systematic elaboration of theoretical ideas in the Parsonian fashion; exploration of the possibilities of rival theories presented under such labels as exchange theory or symbolic interactionism; empirical research, conducted in many forms from intensive 'qualitative' case studies to extensive quantitative surveys, and applied to a broad range of social phenomena. Sociologists in most other capitalist-democratic countries outside the USA adopted similarly diverse programs for teaching and research. As the meetings of the International Sociological Association testified, by the end of the 1960s sociology was a blooming pluralistic discipline, with a tacitly accepted hierarchy of prestige headed by US sociologists whose ideas set the agenda for the discipline at large. Unintentionally, the publication of the *International Encyclopedia of the Social Sciences* in 1968 spelled the ending of that era.

5. *Crisis, Fragmentation and Attempts at New Synthesis, from 1970*

If the years around 1970 formed a watershed in the development of sociology, the tendencies that then became manifest had been at work for some time. By the time that readers all over the world pored over Alvin Gouldner's (1970) *The Coming Crisis of Western Sociology*, that crisis actually was in full swing. As Gouldner pointed out, mainstream academic sociology as represented by the combination of functionalist theory and survey research was rapidly losing its appeal to a new and vociferously critical generation. With much programmatic gusto, new 'paradigms' were launched, highly diverse in their implications, but all radiating the same radical spirit. Inspired by political protest movements, a culture of dissent arose in sociology, criticizing the intellectual canon and the professional stance of the discipline. The short-term result of this turmoil was the demise of functionalism as the leading theoretical perspective, and a flurry of controversies about a mixture of ideological, epistemological, and methodological issues. In the longer term, after the controversies receded, a state of fragmentation ensued to which most practitioners tacitly accomodated.

Fragmentation took many forms. The most obvious and least contested form was the proliferation of subdisciplines around an unsystematic array of specific research areas such as the sociology of the family, religion, organizations, etc. Then, equally noticeable but far more controversial, there was a plurality of theoretical orientations, often with corresponding methodological presumptions. Some theories were primarily attuned to specific forms of microsociology, marked by an affinity to various philosophic schools ranging from phenomenology (embraced by ethnomethodologists), through pragmatism (preferred by symbolic interactionists), to neopositivism (for rational choice theorists). At the level of macrosociology, functionalism as a perspective gave way to new approaches influenced by Marxism and emphasizing social conflict and long-term social transformations. Fragmentation was further enhanced by a weakening of the hierarchy in the international sociological community and an increased articulation of national traditions.

None of these changes came out of the blue, but together they produced an almost revolutionary shock to the world of sociology. Whereas the most famous sociologists of the previous generation had all been from the USA, now European names again came to the fore: Jürgen Habermas, Pierre Bourdieu, Anthony Giddens. During the early 1970s, while many older sociologists deplored the patent end to the illusion of consensus in the discipline, there was also a widespread sense of excitement over new intellectual possibilities and career opportunities. Ideological debates around many current topics, from race relations to the reform of psychiatry, were saturated with sociological references. In his critique of sociology, Alvin Gouldner (1970) did not present himself as a prophet of doom, but rather as a pioneer in 'reflexive sociology' who was able to point at new ways of fulfilling what C. Wright Mills earlier called 'the promise of sociology.'

The later 1970s saw a dramatic reversal in this mood of confidence. General public interest turned away from sociology, student enrollments dropped rapidly, research funds shrank–the only sediment of the earlier high tide that remained was internal fragmentation, pluralism. The general stagnation at first reinforced the tendencies toward fragmentation, as established subdisciplines tried to maintain their position in the face of diminishing institutional support for, and intellectual vigor of the sociological discipline as a whole. However, the 1980s and 1990s also brought new attempts towards a synthesis. Thus, in historical and comparative sociology the orthodox Marxist approach tended to be softened by combining it with a more liberal Weberian perspective. 'World systems' theory as originally developed by Andre Gunder Frank and Immanuel Wallerstein helped to break away from the implicit nation-centeredness that characterized most sociological work during the fourth stage. Making the international order, conceived either as a world system, or alternatively as 'transnational society,' or in terms of a process of

globalization, into the centerpiece for sociological study gave counterweight to the tendencies toward national parochalism.

Other ventures in historical and comparative sociology sought synthesis in a different direction. During the 1980s and 1990s, Randall Collins (1997) valiantly subjected a wide range of long-term cultural trends (including religion and philosophy as well as technology) to sociological analysis, while Jack Goldstone and Charles Tilly brought sophisticated techniques of statistical analysis to bear on huge sets of historical data. Meanwhile Norbert Elias's work, aiming at a thorough integration of sociology with history and psychoanalysis, was gaining influence inside and beyond the discipline.

These promising signs cannot hide the fact, however, that after the decades of rapid growth in the 1960s and 1970s, sociology had entered a period of far less favorable circumstances. The welfare state came under siege in many Western countries, and neoliberal policies in favor of deregulating and extending markets gained the upper hand. Even if the collapse of the USSR and the termination of the Cold War have not spelled 'the end of history,' these events have reduced interest in ideological matters and theories of society. A theoretical perspective that commands much public interest seems to be sociobiology—which, as the anthropologist Marvin Harris observes, may well constitute the most provocative challenge to the social sciences.

At the universities, the established social science disciplines (economics, sociology, anthropology, social science) have faced increasing competition from new, often multidisciplinary fields of study which are more immediately focused on policy needs (organizational studies, management, business) or the demands of particular student groups ('Black studies', gender studies). The strains of the present situation are also conducive to a revival of the old polarity between 'scientistic' and 'humanistic' approaches. The scientistic posture has given a great deal of prestige to 'rational choice' models by means of which some sociologists are applying assumptions and methods derived from economics to a wide array of non-economic relations. Others fear that the economic models thus adopted may have the effect of a Trojan horse, undermining sociology at its very center. Ironically, the humanistic approach is posing a similar risk: embracing culturalistic and postmodern ideas, drawn mainly from current anthropology, literary studies, and hermeneutic philosophy, may also detract sociologists from the core of their discipline—the study of social processes and social structures.

The opposing social currents at work in the world today, as well as the more directly felt institutional pressures and intellectual challenges are confronting sociology with a variety of contradictory claims. Recognizing the many sources of confusion is a first requisite in order to arrive at a balanced response to this situation. Equally important is a continuous reconsideration of the history of the discipline.

Sociology: Overview

The institutionalization of sociology has followed a long and nonlinear path.

The word sociology was created by Auguste Comte and became established once it was institutionalized in periodicals. Meanwhile, the existence of sociology was recognized in an implicit fashion. When Tocqueville ([1856], 1986) writes in the very first sentence of his book on *The Old Regime and the Revolution* 'This book is not a book of history,' he meant that it dealt with what we would call today 'comparative sociology.' But he could not use a word which was not yet common and probably considered Comte as an eccentric figure. Max Weber expressed doubts as to whether his work should be qualified as belonging to sociology. The institutionalization of the word and of the discipline owes much to Durkheim and later to the Chicago school of sociology.

1. Sociology: A Unique or Multiple Discipline?

Sociology, commonly defined as the scientific study of social relations,social institutions, and societies, has nevertheless displayed a great diversity of ways of conceiving its objectives, uses, styles, and methods. Durkheim never quoted Weber nor Weber Durkheim, although they were contemporary and could read one another. Nisbet (1966) maintains though that, beyond the differences, a common inspiration can be detected in the works notably of Tocqueville, Marx, Simmel, Weber, Pareto, or Durkheim. All would have seen that the rational utopian theory of society developed by the Enlightenment was unacceptable. For this reason, they all insisted on the social functions of religion, of the hierarchical distinctions between social statuses, on the role of traditions, or on the distinction between 'community' and 'society.'

Describing the identity of classical, and still more of modern, sociology can be harder though than Nisbet states, for both classical and modern sociologists endorse diverse main views as to the uses of sociology and to the ways it should be conducted.

1.1 Three Types of Objectives

A first type of sociologist sees sociology as having a mainly *informative* function: Its role would consist in producing data and proposing analyses implicitly and explicitly oriented toward decision makers. Thus, Le Play in his *Les ouvriers européens* (1855) produced a survey of the conditions of life of European workers, with the final objective of improving the social policies of the time. While workers themselves know the way they live, this local knowledge is not directly available at the level of societal decision makers. Collecting statistical data on crime is another illustration of this informative function: Such data are crucial to the determination of crime policy. Tarde became a sociologist because, as a judge and later as the head of the French Bureau of Statistics on Crime, he was concerned with the increase of crime rates. Schumpeter qualified this informative dimension of the social sciences as 'cameral' (*Kameralwissenschaften*). In the seventies, Lazarsfeld et al. (1967) produced an overview of the production of this 'cameral' sociology in their *Uses of Sociology*.

A second type of sociologist sees the function of sociology rather as *critical*: Sociologists should mainly aim at identifying the defects of actual societies and devising remedies to correct them. Saint-Simon, Proudhon, or Owen can be considered as examples among the pioneers of this type of sociology. The members of the Frankfurt School provide a modern illustration of 'critical' sociology.

A third type of sociologist sees sociology as having the same main objective as other scientific disciplines: explaining social phenomena which appear at first glance as enigmatic. Thus, Max Weber wonders why peasants appear as more attracted by polytheistic than monotheistic religions and Durkheim why all religions include the notion of 'soul' in one form or another. In such cases, the interests of sociologists are essentially of a *cognitive* character.

These three basic orientations can appear in combination. Marx is concerned both with explaining social mechanisms and with changing society. Durkheim gathered data on suicide with the objective of explaining the variations of suicide rates, but he considered them also as indicators of the general state of modern society. But Tocqueville, Weber, or Durkheim have reached the status of 'classics' essentially because they have proposed scientifically valid explanations of puzzling social phenomena, rather than by their diagnoses of the society of their time. Durkheim considered that sociology could be socially useful only if it was scientifically solid, in other words that good criticism can derive only from valid explanation. By contrast with Durkheim or Weber, the Frankfurt School is known more for its criticism of modern societies than because it would have proposed convincing explanations of puzzling phenomena.

The three orientations characterize modern and contemporary as well as classical sociology. Foucault's *Supervise and Punish* is generally recognized rather as a 'critical' than as a 'scientific' contribution (Foucault 1975). The 'labeling theory' teaches that some features of individual A can be interpreted as a 'label' by observer B and can structure B's behavior and expectations toward A. This has been known for ever, though, so the theory does not bring additional knowledge. Its 'critical' function is more undebatable than its cognitive function. So, the 'labeling theory' is not a theory in the scientific sense. But, as Foucault's

theory, it notably had an influence on our views and on the views of public officials as to the way prisoners should be considered and treated.

1.2 Several Types of Orientations

But sociology is perceived as a discipline with a weak identity, not only because of the existence of these three basic distinct goals, but also because the sociologists who consider that the main goal of sociology is to produce valid new knowledge on social phenomena endorse a variety of methodological and theoretical orientations. Thus, Weber's work is considered as illustrating a particular style of sociology, 'comprehensive' sociology, which is currently opposed to the 'positivist' conception of sociology. The former proposes to analyze social phenomena as the outcome of comprehensible individual actions; the latter to analyze the relations between social phenomena. Weber himself saw his own version of 'comprehensive' sociology as very different from others, and talked currently of 'comprehensive sociology in my sense (*in meinem Sinne*).' In the 1960s, 'quantitative' and 'qualitative' sociology were perceived as irreconcilable competitors: the former saw collecting standardized data able to be subjected to statistical analysis as the most effective research procedure, while the latter insisted that it would produce biased findings and proposed to use much more flexible methods. Merton's 'middle range theory,' that aimed at explaining specific social phenomena, was seen as the proper alternative to the type of general theory illustrated by Parsons, which C. Wright Mills had polemically called 'Grand Theory,' the object of which was 'society' as a whole. These notions label some of the main conceptions of sociology that can be distinguished and appear as more or less permanent.

This diversity in the basic theoretical orientations of sociology is also a lasting feature of sociology, observable in contemporary as well as classical sociology. At the beginning of the twentieth century, a first 'methodological quarrel' opposed those who thought that sociology should follow the path of other scientific disciplines, to those who, like Rickert, maintained that, while the goal of natural sciences is 'explanation,' the goal of the social sciences would be 'interpretation.' In the 1960s, the quarrel was reopened, opposing the 'positivists,' as their challengers called them, to those—the 'hermeneuticians'—who, once again, saw sociology as in charge of disentangling the 'meaning' of social phenomena—of 'interpreting' them—rather than identifying their causes, i.e. 'explaining' them. Adorno and Popper were respectively the main protagonists of the 'antipositivist' and of the 'positivist' group (Adorno et al. [1969] 1972). In various forms, this 'quarrel' reappears almost permanently. Thus, not long ago, ethnomethodologists claimed that the idea of producing an objective social knowledge would be self-contradictory, for social phenomena would be understandable only from the inside of a social group: one could interpret, not explain them.

Weber's sociology is particularly important, for it defines a third way between 'positivism' and 'antipositivism.' Explaining a phenomenon means to Weber finding its causes. The causes of any social phenomenon reside in the set of individual actions, beliefs, or attitudes of individual people responsible for it. So the sociologist has to make these individuals actions, beliefs, or attitudes 'understandable.' But understanding an individual action means finding out the meaning of the action for the actor, in other words the motivations and reasons that have inspired it. For Weber this operation amounts to building a theory of the motivations of social actors subject to the ordinary criteria any scientific theory should meet. Thus, when I see somebody cutting wood in his yard, I would reject the theory according to which he would cut wood because he is cold, if this action takes place on a hot summer day. On the whole, to Weber, 'understanding' is a crucial moment in the 'explanation' of any social phenomenon.

So, the sociologists mainly interested in the 'cognitive' function of their discipline, namely in its capacity to produce valid new knowledge, can be classified along a first main dimension, according to whether they see it as able to produce '*explanations*,' as in other scientific disciplines, or as rather entitled to produce '*interpretations*' with an unavoidably subjective character. But a secondary distinction should be introduced. It opposes those who, like the Durkheim of the *Rules*, believe that the subjectivity of social actors should be ignored by sociologists (Durkheim 1895) and those who, like Weber (1951) consider on the contrary that it is essential to sociological knowledge and in no way incompatible with a scientific ambition.

The latter distinction is correlated with another one: to some sociologists, individuals are considered as the atoms of any sociological analysis, while, to others, sociology should ignore individuals and rather be concerned with analyzing the associations between social phenomena and variables. The former follow the principles that Schumpeter called '*methodological individualism*,' the latter '*methodological holism*.' Weber declared explicitly that, to him, individuals are the atoms of any sociological analysis and that sociology should be 'individualistic as far as its method is concerned' (Mommsen 1965). Durkheim, by contrast, saw sociology rather as devoted to the analysis of the associations between observable social variables. He defends this viewpoint theoretically in his *Rules* (1895) and practically, for instance, in his *Suicide* (Durkheim 1897).

It suffices to evoke a few modern sociological schools to see that the above distinctions, along which classical sociological works can be classified, can also be used in the case of modern works. Thus, 'struc-

turalism' can be ranked on the side of positivism: It proposes to identify the stable relations prevailing between social variables; it claims to be hard science; on the other hand, it is holistic, since it treats individuals as being merely the products or reflections of 'structures.' 'Rational choice theorists' for their part propose to analyze social phenomena as the effects of individual actions; they believe firmly that sociology can be as objective and scientific as any other discipline, but under the condition that it respects the postulate that social phenomena are the outcome of individual actions led by individual interests. 'Ethnomethodologists' believe that sociology is an interpretative rather than explanatory discipline, but are mainly concerned with the interpretations given by individuals of the social setting they are embedded in. Holistic sociologists of history, such as Elias or Wallerstein, following the footsteps of a Burckhardt or a Braudel, are concerned with detecting diffuse orientations in the course of historical and social processes. They worry rather about interpreting than explaining social phenomena and are interested mainly in identifying global macroscopic trends.

The fact that the various conceptions of sociology emerging from the above typologies are lasting explains why sociology appears as a less unitary discipline than others. Moreover, the relative popularity of each of these conceptions tends to follow an 'oscillatory' process, as Pareto would have said. In many circles, structuralism was considered in the 1960s as the orientation which would make the social sciences genuinely scientific. But it was sharply criticized and became obsolete. Being 'positivist' and 'holistic,' it was replaced by antipositivist and individualistic currents, such as ethnomethodology or 'phenomenology' in the sociological sense.

2. *A Few Genuine Achievements*

The most effective way to refute the skepticism toward sociology that develops as a consequence of its diversity is to mention a few genuine achievements in some of the branches of the typologies outlined above.

Durkheim's *Suicide* (1897) is a classical example of the holistic-positivist type of sociology. The work consists in a systematic analysis of correlations between rates of suicides and a number of independent variables, such as sex, living in cities vs. living in the countryside, religious affiliation (Protestant, Catholic, Jew), and so forth. Thus, Durkheim found that, when anomie grows, rates of suicide become higher. Other things being equal, professionals are for instance more exposed to anomie than peasants, so that the rates of suicide of the former are higher. Anomie is greater in periods of economic boom, for expectations tend to be overoptimistic then, opening the way to disillusion and making the rates of suicide higher. Durkheim's *Suicide* provides a methodological model which has inspired many writers. Cusson (1990) wonders for instance why the rates of criminality are characterized by similar trends in most Western countries, with the two exceptions of Japan and Switzerland. He maintains that this exception is due to the fact that primary social control is more developed in these two countries than in others, because, even in large cities, Japanese and Swiss societies have, for historical reasons, maintained networks of interpersonal relations characteristic of traditional societies.

It should be noted, however, that, while such analyses are explicitly holistic, they implicitly consider individual motivations. Thus, in his *Suicide*, Durkheim contends that periods of political crises should be associated with a decline in the rates of suicide and that, other things being equal, they were effectively lower during the major political crises in France in the last two decades of the nineteenth century, as well as during the crisis between Prussia and Austria in the mid-1860s. As elsewhere in *Suicide*, the theory predicts an association between two variables defined at the societal level, and is in that sense holistic. However, the theory rests implicitly on the 'psychological' assumption that in periods of serious political crises, people cannot feel exclusively concerned with their own private worries. The same could be said of most analyses developed in Durkheim's *Suicide*. Thus, the activity of professionals is much less routinized than the activity of peasants; they cannot be content with following day after day the same rules of behavior, and must on the contrary always devise new rules, objectives, procedures, or ideas. This higher uncertainty generates a higher anxiety. So, implicitly, in spite of his official opposition to any psychological explanation of social facts and of the recommendation formulated in the *Rules* always to 'explain social facts by social facts,' 'understanding' in Weber's sense is implicitly conducted in the analyses of *Suicide*. Thus, in the nineteenth century, women had lower suicide rates than men because, being more exposed to social control, they were, according to Durkheim, more guided by routinized rules and norms and thus less exposed to the anxiety generated by uncertainty.

So, the contrast between the antipsychological holistic sociology of Durkheim and Weber's individualistic approach is less marked than is sometimes contended. Weber is as interested as Durkheim in macroscopic relations. Thus, in his *Essays in the Sociology of Religion*, he notes that Mithraism developed essentially among Roman civil servants before reaching other strata (Weber 1920–1). His explanation is that Mithraism was more palatable to civil servants than the old traditional Roman religion, because it could be perceived as a symbolic expression of the political philosophy which grounded the Roman bureaucracy. Roman civil servants were hierarchized in a number of grades associated with specific functions; admission to the bureaucracy and promotion from one grade to the higher was determined by

impersonal procedures; the whole system was placed under the authority of the Emperor, but the latter was held rather as the incarnation of the impersonal rules codified in the Roman Right. Now, Mithraism was a religion placed under the auspices of a God symbolizing impersonal rules; as in the case of Freemasonry, the believers were admitted and promoted through a scale of grades with the help of impersonal procedures. Here, Weber solves a macroscopic question—why are such and such strata more receptive toward a religious doctrine?— in an explicitly 'individualistic' fashion, by showing that Roman civil servants had strong reasons for perceiving Mithraism as more attractive than the old Roman religion, which was born in the context of a purely agrarian society. For the same type of reasons, Freemasonry in Prussia has attracted civil servants more than other strata.

The Weberian vein is noticeable in many modern analyses. Thus, Merton's classical analysis of the anti-Black attitudes of the white American workers in the time of the Great Depression of the 1930s rests upon the assumption that white unionists had strong reasons to believe that black workers, coming from the paternalist big farms of the South, would be less prepared to be faithful to the unions than the white workers from the North (Merton 1949). Bergeron (1999) wondered why methadone programs were rejected in France, while they were adopted in the Netherlands and Switzerland. His answer is that Lacanian theories, very influent among French psychiatrists, led psychiatrists to the diagnosis that drug addiction results from a disruption of social relations. Hence they drew the conclusion that drug addicts should be cured by a methodical restoration of their social relations. By contrast, the Swiss or Dutch psychiatrists did not think they had at their disposal a theory from which effective remedies against drug addiction could be drawn. As they did not feel able to cure drug addiction, they believed that their main duty was, to protect people, notably against the threat of AIDS involved in drug addiction. The French had strong reasons to stress that their role was to cure; the Dutch and Swiss to believe that their role was to protect, since they did not know how to cure. In an analysis such as this one, one retrieves the very flexible theory of rationality used by individualist sociologists following the Weberian tradition.

2.1 A Particular Version of the Individualistic Tradition: The Rational Choice Model

Contemporary sociology has developed a particular version of the individualistic tradition. Instead of the Weberian open theory of rationality, it proposes to use the theory of rationality developed by economics. According to this theory, social actors are supposed to be moved essentially by their interests and to be able to pick up the best means to follow their ends. This model—called the 'rational choice model'—the inspiration of which goes back to Bentham, is very useful. It has produced many fruitful theories in several fields: notably the sociology of crime, of education, of organizations. These achievements have motivated some sociologists, such as James Coleman, to contend that the 'rational choice model' could play in sociology the role of a general theory able to integrate heterogeneous findings. But this model cannot be considered as a realistic theory of behavior in all circumstances. Olson (1965) has stressed that his own theory of collective action, which applies literally the postulates of neoclassical economics, can explain that collective action does not occur as long as its axioms can be considered as realistic. But, he adds, in many circumstances, they cannot, simply because people can be moved and mobilized, not only by their interests, but also by their beliefs. Now, beliefs can seldom be satisfactorily explained merely by the interests of social actors. On the whole, the 'rational choice model' has produced many convincing theories, but it cannot be considered as a general theory, neither actually nor potentially.

The styles of research illustrated by the previous examples have in common that they provide explanations of social phenomena that follow the criteria generally used in all scientific disciplines. In that sense, they belong to the 'positivist' category of the previous typology.

3. Interpretation vs. Explanation

In his book on the methodology of the social sciences, *Problems of the Philosophy of History*, Simmel (1892) made the important point that history, as well as the social sciences, raises naturally two types of questions which respectively can and cannot be given a unique scientifically controlled answer. In Rickert's vocabulary, some questions raised by sociologists aim at 'explaining,' others at 'interpreting' social phenomena. Thus, Simmel (1900) himself proposed in his *Philosophy of Money* an *explanatory* theory of the decline of feudalism: From the moment when the peasants of the Middle Ages could pay their rents in money rather than in kind, they could decide what they would grow, they started to be in a position to create and sell surpluses, and were eager to participate in collective actions against landowners, so that on the whole this apparently minor institutional innovation generated a chain reaction which powerfully eroded the feudal organization of society.

But other questions call for '*interpretation*' (or '*description*') rather than 'explanation': what are the main features of modernity? Is the twenty-first century going to be characterized by a religious revival? What does it mean to be poor in an affluent society? How do

people live in poor suburban areas? Of course, such questions cannot be answered only in one way. There are many ways of describing the conditions of life in a poor suburban area. In other words, the answers to such questions are doomed—by the very nature of the questions—to be for one part subjective. Actually, as Simmel states, such questions can be answered in an interesting fashion, only if analysts are able to inject their own sensibility in their description or interpretation. Answering such questions requires on the whole a type of ability that makes sociologists close to artists. A good biographer, for instance, cannot follow exclusively the criteria defining a scientific work. He or she must also be able to give a unity to the numerous observations which have been collected by witnesses on the biography's subject, to that person's behavior and decisions in innumerable circumstances. A number of sociological works are faced with the same type of questions. Giddens's (1984) work on postmodern society, as earlier Burckhardt's work on the *Kultur der Renaissance in Italien* ([1860], 1952), are examples of works aiming at characterizing the main features of historical eras or identifying broad historical trends. Other works dealing, not with societies as wholes, but with local phenomena, belong also to the interpretative-descriptive category rather than to the explanatory one; though they deal with social reality, they evoke the procedures of novelists. Oscar Lewis' *The Children of Sanchez* (1961) is a classical illustration of this 'literary' sociology. The anthropologist Clifford Geertz (1973) has coined the expression 'thick description' to characterize the methodology of this type of work. Runciman (1983–97) has developed methodological considerations which can be considered as elaborating on Simmel's insights.

4. *A Complex Identity*

In summary, all the types of sociology which can be derived by the combination of the three main ideal-typical objectives (explaining, informing, criticizing) and of the four types generated by the combination of the binary variables holism vs. individualism and 'positivism' vs. 'hermeneutics' can be illustrated as easily by examples taken from contemporary as from classical sociology. This shows perhaps that all the types are legitimate and fruitful. The cost of this heterogeneity lies in the difficulty of perceiving the identity of sociology, its benefit in the fact that it makes sociology able to fill the gaps that other social sciences, such as economics, more devoted to a single paradigm, are unable to fill.

Solidarity: History of the Concept

The concept of solidarity epitomizes the total process through which sociology established itself among the social sciences. An originally juridical concept, per-

taining to the character of legal obligations, was given a new social and political meaning which made it tantamount to the theoretical conditions of possibility for the constitution of sociology as such. In order to do this, the concept of solidarity had to take a distance from other close concepts, such as compassion and fraternity, and to develop the specific features which would ensure its role. Throughout the nineteenth century, it expressed the search for a new articulation between individualism and collectivism which was at the origins of crucial transformations, in social theory as well as in social policies.

1. Compassion, Fraternity, Solidarity

Compassion had inspired the treatment of the poor in the Old Regime society, through private charity mixed with police repression. The inadequacy of such a treatment to a modern liberal order, from the vantage point of equality of rights as well as of a new way of production requiring the active participation of everybody, became clear in the early stages of the French Revolution (Procacci 1993). Against the fortuitous nature of private charity, solidarity openly marked its own public vocation. Instead of relying upon an occasional feeling or the practice of a religious piety, it was to become the principle of a secular organization framing the competition of individual interests according to the needs of the common good.

'Fraternity' was one of the key-words of the revolutionary tradition in France, together with equality and liberty, but proved to be much more difficult to fix in normative terms. Moreover, during the new 1848 revolution, fraternity inspired popular claims for a social and economic reform, engaging with the socialist tradition. Its revolutionary implications made more and more clear that, although fraternity was an integral part of the new legal system, it could not offer guidelines for public action—a role rather played by solidarity (Borgetto 1992). Solidarity presented the advantage of being a more 'scientific,' positive notion, interpreting more effectively a concern about social order. Fraternity had offered the first foundation to solidarity, well before the latter, toward the end of the nineteenth century, met the idea of social interdependence developed by sociology. Nevertheless, in French public law it eventually became restricted to the link among members of the nation, while solidarity was rather entrusted to regulate a system of mutual rights and duties organized by the state.

As a matter of fact, the concept of solidarity inherited the same political space covered by fraternity, having to respond to the need of governing the persistence of inequality within a society of equals. Solidarity took its social meaning within a general framework deeply marked by the establishment of modern individual rights—the process of liberal individualism. Individual rights entering into the new social reality, through a twofold process of emancipation, juridical and economic, did not offer criteria for organizing the life of the collectivity. Freed from the revolutionary echo resounding through fraternity, solidarity pointed at that sort of third way between liberal individualism and socialist collectivism that offered the proper room for the rise of sociology. The concept promised to reconcile individual independence and social cohesion, and on this promise built its own fortune.

2. Rights and Duties

Robert Nisbet (1966) correctly highlighted the contribution of conservative antirevolutionary authors to the social concept of solidarity, through the emphasis they put upon communitarian ties. De Bonald, for instance, denounced the revolution for having destroyed any collective order and therefore any possibility for solidarity. While sharing his insistence on the need for a systematic doctrine about the bases of social order, Saint-Simon fundamentally disagreed with his attempt to ground solidarity within religious thought. The recovery of social unity in a modern society required a new attitude, and foundations were to be searched within science. In fact, with Saint-Simon and Comte the reflection about solidarity clearly engaged in a criticism of the difficulty that legal and economic individualism opened to solidarity. From this point of view, the rise of sociology marked a discontinuity with respect to patterns of solidarity belonging to the past.

For Auguste Comte ([1830–42] 1975) the specific task of a social science was to oppose to the destructive strength of individualism a principle of social organization based on the authority of science. The revolution was the result of individualism's incapacity to provide criteria useful to organize any collective order; the only way to stop the revolution was to be able to remove its causes. To problems raised by the emancipation of individual rights, sociology must respond by providing concrete principles for social reorganization. Comte proposed to replace the emphasis on individual rights with a system of mutual duties, linking everybody to each other, therefore able to promote the solidarity of all parts within the social system. The concept of duty appeared to him directly social, in other words an organizer: It put at the forefront 'the intimate feeling of social solidarity,' the priority of common interest over individual ones. It was thus to become the key for a new politics, focused upon the search for the best way to combine the efforts of everybody, rather than upon the competition of interests. This was the meaning of 'order and liberty,' the motto of the *Société Positiviste* that Comte created as a response to the 1848 revolution. The imperative was to reorganize society, the essence of social

phenomena was organic; the concept of duty was to become the principle of an active morality, overcoming the opposition between individual and collective.

Along these lines, throughout the nineteenth century solidarity deepened its distance from fraternity. By the end of the century, the sociological definition of solidarity found the support of scientific discoveries: Microbiology and microphysics confirmed the interdependence of all parts of an organism under the form of a pathological contamination, giving to an old idea the new strength of a scientific evidence. If each single element depends upon the others, then their solidarity with the whole becomes a fact. Solidarity only refers to the whole, it concerns the community, and does not distinguish among categories of members. As such, solidarity designates a twofold bond, through the space within the community, and over time between generations.

3. *Organic Solidarity*

After the dramatic resurgence of revolution with the 1871 Commune, the concept of solidarity was at the core of the Third Republic political response to the conflict between two opposite views of the role of the state proposed by liberalism and socialism (Donzelot 1984). In the name of market economy, liberals opposed any intervention of the state in the solution of social problems, even at the risk of an objective alliance with conservatives' defense of the role of family and traditional groups. Socialists, in turn, regarded state intervention as necessary. Republicans stayed in between, but without any clear theory about the role of the state were forced to a negative position; solidarity offered them a positive principle for their politics, to the point of becoming an 'official philosophy' (Scott 1951).

It expressed a peculiar conception of social relations at the basis of a new social contract founded not merely on individual rights, but on the need for a collective reparation of social injustice. Alfred Fouillée (1885), the founder of the so-called *solidarist philosophy*, insisted on the Comtian description of society as a system of mutual obligations, as the source for an 'active repairing justice' more suitable to a democratic society than a liberal negative justice. His idea of a *contractual organism* found its theoretical foundation in the concept of solidarity and at the same time the key for a new set of concrete political measures transforming the system of social protection (Bec 1998).

Solidarity was not only the source of a philosophy, but became the core of scientific sociology with the seminal work of Emile Durkheim ([1893] 1978) on the division of labor. His attempt was to give a scientific foundation to the specific nature of social phenomena; solidarity conceptualized the principle of cohesion which only could transform a set of individuals into something like a society. Individual consensus could not explain society; it depended upon an objective cause underlying the characters of the social environment. Through his distinction between a mechanic, indifferentiated solidarity, and an *organic solidarity*, Durkheim defined the bases for a social organization where individual rights and state's ends did not exclude each other. From one model to another, the nature of solidarity changed, but it still worked as the foundational law of any society. A modern democratic society depended upon the level of division of labor: Individual functions must be specialized, but conversely their cooperation for a final end ought to be ensured. The division of labor was the pattern of the only kind of solidarity suitable to a differentiated society. Far deeper than individual freedom of contract, the organic solidarity organized functional interdependence of all parts with respect to the whole.

Durkheim was interested in the moral value of the division of labor and what consequences this would have from the point of view of society and individuals. It increased social dynamics and mutual dependence, but would it produce solidarity? If labor was badly distributed, then the priority of the whole over the individual would not be ensured. The intensity of social conflicts depended upon a lack of perception of solidarity: The problem thus was not in the structure, but in the representation of internal social bonds, and so was ultimately a political problem. This is the role of the modern democratic state: to organize solidarity through a right balance of social cohesion and individual liberty, constantly enhancing its perception.

The theory of solidarity established that societies live and change according to their own laws, they could neither be frozen in their past forms, nor be violated in their natural course. To acknowledge these laws became thus an indispensable step for politics, while promoting sociology's role. As such, solidarity offered the basis for grounding political reforms on the scientific knowledge of these laws, intentionally adopted by a *politics of solidarity*. From the 'natural fact' of interdependence, the principle of solidarity implied that everybody had to be guaranteed from some common risks, and reciprocally that all must do their part in financing common protection according to their means. On the idea of shared social risks, a whole set of solidarity techniques were developed, shaped above all on an insurance model (Ewald 1986). Welfare and pension laws followed at the beginning of the twentieth century in most European countries, based on the idea of a social debt toward the less privileged and their corresponding right to support. Techniques of solidarity were at the origins of modern welfare systems and of more general political strategies of socialization.

The very nature of solidarity, a concept born at the crossing point between liberal individualism and socialism, makes it particularly relevant today (Chevallier 1992), when we face again the need to

define a new balance between those two principles, not so differently from what gave substance more than a century ago to the concept of solidarity. The whole debate nowadays within social sciences on the future of welfare is there to prove it.

Solidarity, Sociology of

Solidarity refers to the binding, or melding, of individuals into a cohesive group or collectivity. As such, it is an emergent attribute of groups that facilitates social coordination and social order, and is a precondition to all nonspontanteous collective action.

Since social order and collective action are the alpha and omega of classical sociological theory, solidarity has always been a central concept in sociology. The concept came to the fore following the changes wrought by the development of industry and the rise of market economies. Although they were unjustified in doing so, most classical social theorists regarded the cohesion of agrarian communities as unproblematic. In their stylized view, such communities were technologically and demographically stagnant and uninvolved in long-distance trade.

Given these assumptions and barring exceptional circumstances—such as those resulting from wars or massive epidemics—social mobility would be minimal and most children would be destined to recapitulate the social lives of their parents. As agrarian communities tended to offer relatively little scope for individualism, the attainment of solidarity was viewed as relatively unproblematic. According to Ferdinand Tönnies (1887), such communities (which he termed *gemeinschaften*) were breeding grounds for social relations based on deep emotional, quasifamilial commitments. Emile Durkheim (Durkheim 1893) referred to the solidarity characteristic of this kind of society as 'mechanical,' implying thereby that it had a certain automatic quality. Mechanical solidarity rests on a set of common values, internalized norms, and beliefs (a *conscience collective*) engendered by physical co-presence, a common focus of attention, and a sense of mutual awareness. This kind of solidarity is often expressed in a religious credo.

Mechanical solidarity appeared to be threatened, however, by the rise of industry and the expansion of market economies in Western Europe, North America, Australasia and Japan beginning in the late eighteenth century. Among their many other effects, these transformations increased the size and scope of social networks, thereby affording many individuals greater options, ranging from marriage partners to occupations, in their daily lives. The growth of individualism and the concomitant decline of a *conscience collective* was the inevitable result (Simmel 1922). It was far from evident how groups, communities, and societies could maintain mechanical solidarity in the wake of this increasing individualism. Durkheim, the foremost early theorist of solidarity, initially argued that industrial societies were held together by individuals' mutual functional interdependence—a form of solidarity that he termed 'organic.' At the end of his life, however, he came to regard common values and norms as the basis for solidarity in all kinds of groups and societies (Parsons 1937).

Durkheim's insistence that solidarity requires compliance to a set of collective obligations based on particular values and norms has greatly influenced subsequent research. For example, a religious group is solidary only to the degree that its adherents comply fully with its obligations, both sacred (rites) and secular (tithing). Likewise, a working class is solidary only to the degree that individual workers regard themselves as members of a collectivity (e.g., the working class) with its own obligations, and refrain from engaging in activities—such as strikebreaking—that compromise or countermand these obligations.

Yet compliance to collective obligations can owe to causes other than solidarity. Consider the mobilization of labor in a profit-making firm. To attain maximum profit, firms demand that their employees perform to

the best of their ability and refrain from shirking. Employees usually comply with the firm's obligations, not out of a sense of solidarity but because they are compensated for doing so in wages or salaries. In contrast, the members of a religious group or a working class are not given pecuniary compensation to comply with their corporate obligations. On this account, it is likely that compliance in such groups is due to solidarity. Since compliance with corporate obligations can be attained via mechanisms other than solidarity, conducting empirical research on solidarity is inherently difficult.

This difficulty has not inhibited theorists, however. Theoretical perspectives on solidarity may usefully be divided into three distinct types. *Normative* perspectives suggest that solidarity arises from common values and norms, *structural* perspectives argue that it arises from common material interests, and *rational choice* perspectives hold that it arises from mutual interdependence.

1. *The Normative Perspective*

Normative theorists claim that solidarity is unlikely to result merely from the interaction of rational, self-interested individuals (Parsons 1951). This is because it is never in the interest of rational egoists to adhere to collective obligations if they can profit by ignoring them. In a world of rational egoists, the only means of assuring the requisite compliance is by sanctioning. Normative theorists hold that sanctioning is both too costly and too unreliable a means of assuring high levels of compliance, especially among large numbers of individuals. For them, values and internalized norms make individuals fit for social life by removing the conflict between the individual's interest and that of the relevant collectivity. If individuals adhere to the values and norms that underlie corporate obligations, they will tend to engage in the obligatory actions without the carrot of rewards or the stick of sanctions. According to normative theorists, socialization is the key to the attainment of solidarity. Solidarity therefore is most likely to emerge in socially homogeneous collectivities. It should be noted that the emergence of values and norms is exogenous to the theory, as are socialization processes. Moreover, although casual observation confirms that compliance with values and norms is never automatic, normative theory has been mute about the conditions under which the requisite compliance is likely to occur.

2. *The Structuralist Perspective*

Structural theorists typically, if implicitly, regard solidarity as an outcome of individually rational action. On their view, rational individuals form solidary collectivities principally by virtue of sharing common material interests. They discover their common interests in the course of mutual interaction, especially when they perceive themselves to be threatened by powerful antagonists (Marx 1972 [1845–46], p. 179). When mutual interaction occurs repeatedly, this may set the stage for the development of sentiments, or affective feelings, that further strengthen compliance to collective obligations (Collins and Hanneman 1998). However, the weaknesses of structural theories of solidarity are notable. Both commonality of interest and repeated interaction are insufficient causes of solidarity. Solidarity varies widely among workers and married couples, for example. Sometimes workers refuse to support striking colleagues, and the incidence of divorce has risen dramatically in nearly all industrial societies. Neither of these trends is easily accounted for by structural theories of solidarity. Further, if the individuals who share interests are rational egoists, as most structural theorists contend, then why would they ever join forces to pursue their common ends?

3. *The Rational Choice Perspective*

This question is the point of departure for rational choice perspectives of solidarity. Truly rational actors will *not* join a group to pursue common ends when, without participating, they can reap the benefit of other people's activity in obtaining them. Instead of contributing to the common weal, rational actors will free ride (Olson 1965) and behave individualistically when it is expedient. The upshot is minimal solidarity despite an extensive commonality of interest. The rational choice theory of solidarity (Hechter 1987) hinges on precluding free riding. In this theory, rational individuals form groups to obtain goods that they either cannot produce on their own, or that they cannot attain as economically. The ultimate motivation for group formation is held to be the individual's desire to gain access to jointly produced goods. These goods can only be produced if prospective members comply with the rules and obligations that are necessary to ensure production of the given joint goods. The more dependent individuals are on the group for access to valued goods, the greater its potential power over them. This dependence increases when the given goods are not readily available elsewhere, when members lack information about alternatives, when the costs of leaving the group are high, and when personal ties to other members are strong. Moreover, the greater the dependence of members on a group, the greater their willingness to comply with highly extensive obligations. Hence, dependence creates conditions not just for the emergence of corporate obligations, but for obligations that guide and regulate behavior to a high degree.

Yet dependence is an insufficient cause of compliance. Children tend to be highly dependent on their parents, but this is no guarantee that they will routinely perform their chores, or study diligently in school. Dependence by itself is unlikely to resolve the free rider problem. Free riding can only be precluded when the given group has a high control capacity. This control capacity, in turn, is a function of monitoring and sanctioning. Monitoring is the process of detecting noncompliance to corporate obligations; sanctioning is the use of rewards and punishments to induce compliance. The theory therefore holds that compliance to corporate obligations—an indirect measure of solidarity in noncompensatory groups—is jointly a function of dependence and control mechanisms. That said, this theory remains incomplete because the sources of individual dependence are exogenous to it.

4. *Future Research*

The empirical study of solidarity has been hamstrung by a lack of agreement on definitions of the concept. Defining solidarity as an intersubjective state (as normative theorists do) poses a severe challenge for empirical research. This is because there are as yet no consensually accepted measures of individual values and internalized norms in social science; direct measures of the sentiments or feelings that may hold within collectivities perforce are unavailable. Most empirical research on solidarity therefore focuses on explaining variable compliance with corporate obligations. When this research fails to pay sufficient heed to the pitfalls of inferring an intersubjective state from behavior (see above), its results are questionable.

Future research on solidarity is likely to proceed along both methodological and substantive fronts. Methodologically, new measurement instruments some day may make it possible to gauge solidarity directly as an intersubjective state, rather than using behavioral compliance as a proxy. Substantively, there is much to learn about the interaction of solidary groups in wider social systems. Since solidarity is built around a set of normative obligations and enforcement mechanisms, it follows that the normative content of any given solidary group may be more or less congruent with that of its global social environment. Thus minority ethnic groups often espouse norms at variance with their host society. Adolescent peer groups evolve norms that are mutually inconsistent, and generally inconsistent with school norms. Factory workers can embrace output restriction norms that are at variance with their employers' expectations, and inner city gangs and organized crime groups establish norms that are at variance with those of the society at large. The effects of solidarity in such countercultural groups are a matter of dispute among both social scientists and political decision makers (see *Social Capital*). Further research is needed to clarify the mechanisms that are responsible for the emergence of such countercultural groups and the consequences these groups have on social order.

After a long period of dormancy, interest in solidarity has increased in several social science disciplines. The rational choice theory of solidarity has been used to explain variations in legislative party voting, the membership rules of friendly societies and mutual benefit associations, the survival of US intentional communities, cross-national crime rates (Hechter and Kanazawa 1993), social order in Japan and the United States (Miller and Kanazawa 2000), and the prevalence of nationalism in world history (Hechter 2000). Whether group solidarity incites or inhibits intergroup conflict is now the subject of lively debate (Bhavnani and Backer 2000, Fearon and Laitin 1996, Gould 1999). Legal theorists (Ellickson 1991, Posner 2000) are exploring group solidarity as an institutional alternative to law as a means of dispute resolution. Finally, a variety of mathematical models of solidarity recently have been proposed by a group of social and physical scientists (Doreian and Fararo 1998).

Somatoform Disorders

The history of somatization phenomena, the 'borderland between medicine and psychiatry' (Lipowski 1988), or in terms of neuroscience the problem of the 'body–brain-interface' (Guggenheim 2000), can be traced back to ancient Greek medicine, where the term 'hysteria' was used to describe patients' somatic complaints without the presence of somatic disease. Hysteria (from hystera = womb) was understood as a psychological problem in women, whose intrapsychic conflicts, resulting from the unfulfilled wish to bear a child, lead to somatic complaints (see *Hysteria*). Similar clinical observations by different European clinicians since the mid-nineteenth century (Briquet, Charcot, Janet, Breuer) were antecedents of the Freudian concept of conversion disorder. The psychodynamic etiology and psychoanalytic treatment approach to patients with conversion disorders, psychosomatic complaints, and hysteria was most influential to the 1970s. Nowadays, the term somatoform disorders replaces the traditionally used, but not precisely defined terms of hysteria, 'functional symptoms,' and 'masked depression,' etc., that were mainly confounded with etiological (psychoanalytical) assumptions. The current concept of somatoform disorders encompasses a heterogeneous group of psychiatric disorders that are characterized by four core features: (a) patients suffer from enduring or recurrent bodily complaints, symptoms and/or pain (e.g., palpitations, headache, fatigue, and dizziness), which are experienced as indicators of somatic illness, (b) mainly these complaints are not due to physical or organ dysfunction, (c) psychological and social factors—usually refused as influences by the patients—play a predominant role in the development and course of these disorders, and (d) patients experience a general preoccupation with bodily symptoms and health concerns.

This article describes the various somatoform disorders, their prevalence, and etiology. Critical aspects regarding diagnosis, treatment, and management of somatoform disorders in healthcare systems will be discussed.

1. *Classification and Epidemiology*

From a nosological perspective, somatoform disorders were grouped together in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-III*) in 1980 for the first time. However, this clustering was primarily based on clinical criteria and not on empirically derived or laboratory findings. The tenth edition of the *International Classification of Diseases* (*ICD-10*) includes most of the somatoform disorders of the recent *DSM-IV* (American Psychiatric Association 1994), except for conversion disorders that are grouped with the dissociative disorders. The main feature of these disorders is the 'repeated presentation of physical symptoms with persistent request for medical investigations, in spite of repeated negative findings and reassurances by doctors that these symptoms have no physical basis. If any somatic disorders are present, they do not explain the nature and the extent of the symptoms or the distress and preoccupations of the patient' (WHO 1991). For the diagnosis of all somatoform disorders the patients' symptoms have to be of sufficient severity to warrant clinical attention. The *ICD-10* differentiates between four main nosological entities (seven different diagnoses) which were characterized by different diagnostic criteria (see Table 1). Recurrent, multiple somatic complaints that are not associated with any physical disorder are the essential feature of somatization disorder. The diagnosis requires a history of many bodily symptoms of several years' duration with onset before the age of 30. In somatoform autonomic dysfunctions symptoms of autonomic arousal (e.g., palpitations, sweating, and stomach discomfort) are the main complaints of the patients. Chronic pain syndromes (duration > 6 months) like tension headache, lower back pain, and atypical facial are labeled as persistent somatoform pain disorder when emotional conflicts or psychosocial problems are involved as main influences. Psychological factors can play either a major role within a general medical condition (e.g., rheumatoid arthritis) or may be the only determinants of pain (e.g., not otherwise specified lower back pain). The pain in one or more anatomical sites is the main focus of clinical presentation.

Conversion disorder is mostly a transient disturbance of physical functions (typically occurring in stressful situations) which do not conform to current

Table 1
Somatoform disorders and their characteristics

Subtypes	Characteristics and (selected) main criteria (*ICD-10*)
Somatization disorder	• a history of at least 2 years of multiple and variable complaints which cannot be better explained by somatic factors or other psychiatric disorders (A) • preoccupation with the symptoms causes persistent distress and leads to seek repeated medical consultations (B) • persistent refusal to accept medical reassurance that there is no adequate physical cause (C) • a total of six or more enduring autonomous symptoms from different groups (gastrointestinal, cardiovascular, genitourinary system, skin and pain symptoms) (D)
Hypochondriasis	• a persistent belief of the presence of a serious physical disease (A1) • a persistent preoccupation with a presumed deformity or disfigurement (body dysmorphic disorder) (A2)
Somatoform autonomic dysfunction	• Symptoms of autonomic arousal attributed by the patient to a physical disorder (heart and cardiovascular system/upper and lower gastrointestinal tract/respiratory or genitourinary system) (A) • Two or more autonomic symptoms like palpitations, sweating, dry mouth, flushing or blushing, epigastric discomfort etc. (B)
Persistent somatoform pain disorder	• Persistence of severe and distressing pain for at least 6 months which cannot be explained adequately by a physiological process or physical disorder (A)

concepts of the anatomy and physiology of the nervous system. Many disorders seem to be neurological disorders (e.g., motor disorders or disturbances of sensory function), but do not show the usual pathological signs. Hypochondriasis is not exclusively a secondary phenomenon within affective, anxiety, or psychotic disorders but a diagnostic subgroup of its own. Patients are preoccupied with their belief of already suffering from a severe illness or the fear of becoming ill with a life threatening disease (e.g., cancer, stroke, or AIDS). The diagnostic congregation of body dysmorphic disorder—which is rarely seen as a full-blown syndrome—is different in the nosological systems. In the *ICD-10* it is a subgroup of hypochondriasis, with the preoccupation on a presumed deformity or body abnormality. Patients subjectively feel unattractive, ugly, and disfigured despite lacking evidence for major defects in appearance or stigmata. Positive feedback from significant others about normality in appearance has no corrective effects.

Somatoform disorders show high prevalence rates in the community, especially in the primary health care system. In industrialized societies up to 4–12 percent of all people suffer from somatoform disorders (Escobar et al. 1987, Simon and von Korff 1991). In medical outpatient and inpatient treatment, patients with the probable diagnosis of somatoform disorders are estimated at up to 25 to 30 percent. The onset is in adolescence or young adulthood, and the course in untreated cases is usually chronic with a waxing and waning of symptoms. Women, persons from lower social classes, and ethnic subgroups are more likely to develop somatoform disorder. Furthermore, somatization is more often seen after separation and divorce. Somatoform disorders are often associated with other psychiatric disorders, especially depression, anxiety disorders, substance abuse disorders, and personality disorders (see *Depression*, *Anxiety and Anxiety Disorders*, and *Personality Disorders*). Patients with somatoform disorders are often not correctly recognized by their doctors and therefore insufficiently treated. Also, the latency between onset of the disorder, the appropriate diagnosis, and the referral to adequate treatment is usually high. These factors lead to largely extended costs for medical and psychosocial services (nine-fold costs of care than media costs of all patients).

2. *Etiology and Course*

No single factor can explain the pathogenesis of somatoform disorders. Comparable with other psychiatric disorders, biological, psychological, and social factors interact in complex ways (see *Mental Illness, Etiology of*). Their impact probably varies over time within the same individual and between different patients resulting in a common final pathway. There is no general etiological model for somatization phenomena (Pilowsky 1997). However, interesting preliminary data demonstrate that patients with somatization disorder may have an abnormality in cortical and neuropsychological functioning, e.g., bifrontal impairment of the hemispheres, abnormal

Figure 1
Risk model for somatoform disorders (adapted from Rief and Hiller 1998)

auditory-evoked potentials, and elevated levels of cortisol (Guggenheim 2000, Rief and Nanke 1999). Several etiological conditions play a prominent role, especially in maintaining the process and can be considered as empirically derived risk factors for somatoform disorders (see Fig. 1).

(a) Genetic risks, e.g., higher rates of somatoform disorders for monozygot than for dizygot twins, and in first-degree relatives.

(b) Higher physiological reactivity which can lead to pervasive interoception of physiological signs. Unspecific bodily sensations are perceived and interpreted as symptoms of disease. The consequence is the intensification of the complaints and elevated attention to them.

(c) Biographic vulnerability, a high proportion of physical, sexual abuse (within the family), and traumatic experiences like war and natural catastrophes are over-represented in these patients. Furthermore, chronically ill parents or siblings, and learning by model within the family may influence the localization and types of somatoform symptoms.

(d) Personality traits, e.g., difficulties in the perception and expression of emotions with an inverse relationship of reduced emotional expressions and heightened psychophysiological arousal in stressful situations.

(e) Unrealistic health beliefs with a low tolerance for normal complaints, 'catastrophizing' ideas about physiological processes, and exaggerated expectations regarding effects of modern medicine to all kinds of complaints.

(f) Chronification factors like multiple diagnostic procedures, the overvaluation of normal variants through the caring physician (iatrogen factors) and positive (e.g., attention from others) or negative reinforcement (e.g., defense mechanism for negative emotions, advantages of the sick-role, withdrawal from responsibilities).

Which of these potential factors are important, and how much impact they have in the individual patient have to be determined within the diagnostic and psychotherapeutic process (see *Mental Illness, Etiology of*).

3. Diagnostic Process

The diagnostic process follows a sequence starting with a careful monitoring of all presented bodily complaints and ending up with a reliable and valid diagnosis of a special subtype of somatoform disorder and its severity. Knowledge of base rates for somatoform disorders and the potential medical disorders which have to be ruled out, age of the patients and their presentation style, history of other bodily complaints and excessive visits to other doctors might be hints for the assumption of the diagnosis.

The physician is confronted with the dilemma of possible false decisions: (a) they might diagnose somatoform disorder although the symptoms are better explained by a somatic disease which has to be treated by medical guidelines (type-1 error, 'false positive'); (b) the diagnosis of a somatic disease/dysfunction is assumed although the patient suffers from a somatoform disorder (type-2 error; 'false negative'). In most cases doctors and patients judge the risk of missing the correct somatic diagnosis as more adverse and therefore try to minimize it. However, this is one of the major factors maintaining somatoform disorders. A pragmatic rule for diagnosis is 'to have somatic diagnostic efforts as much as necessary but as less as possible.' Thorough, but not excessive or indefinite, medical examinations have to rule out organic disease and dysfunctions that might be causing the symptoms (e.g., hyperparathyroidism, multiple sclerosis, or brain tumor). It has to be supported by adequate and plausible procedures (e.g., physical and neurological examination, laboratory examination). Results and documents from other doctors should be revised in order to prevent repeated examination without relevance. A precise mental health examination for a complete overview of previous severe psychiatric disorders and minor complaints and the current psychopathological status is necessary. In single cases it can be difficult to decide whether the symptoms can better be explained by affective, anxiety, and personality disorders or whether they are real comorbid states. The sequence over time and the severity of symptoms are helpful in finding the correct hierarchy. Symptoms, pathological illness behavior, course, and consequence of the complaints will allow one to find the adequate nosological diagnoses along with the diagnostic criteria of *DSM-IV* or *ICD-10*. This diagnosis within the group of somatoform disorder has the status of a working hypothesis and is helpful for further treatment planning. If the patient visits a mental health specialist he or she will gather specific information regarding nosological diagnosis. A sophisticated analysis of all relevant information concerning the individual development, learning and predisposing factors, the onset, and further course of the symptoms, which is based on a life-chart interview, and information about actual psychosocial conditions, conflicts and traumata is inevitable. Of course it partly depends on the theoretical assumptions and models of the different psychotherapeutic schools (see *Differential Diagnosis in Psychiatry*).

4. Treatment

Since psychological factors are most influential in the development and course of somatoform disorders they have to be addressed in every effective treatment. Of course the setting, intensity, and content of psychological interventions can vary depending on factors like severity of symptoms, comorbidity, insight, and motivation of the patient and availability of psychotherapy. In a step-by-step approach the primary care physician should start with short-term verbal interventions. Acute and isolated somatoform symptoms may respond to psycho-education and counseling within the usual medical visits. Counseling and advice for general and easy-to-administer methods of symptom monitoring and management can be helpful. The physician should know the pitfalls in the treatment of patients with somatoform disorders and avoid procedures, which might reinforce the patients' pathological illness behaviors (e.g., no medical tests or laboratory examinations without clear indication). Information about and motivation for more specific forms of psychotherapy are essential if these basic interventions within the primary care system fail. For the more severe patients a referral to mental health experts is needed, for chronic and therapy-refractory cases even psychiatric or psychosomatic inpatient treatment may be necessary. Unspecific factors, which are important in any psychotherapy (e.g., therapeutic alliance, expectations of being helped, enhancing the sense of mastery, etc.) can be differentiated from specific therapeutic techniques and be adapted to relevant pathological processes in somatoform disorders (see below). Multimodal and multidisciplinary treatment approaches seem to be more effective than single treatment approaches.

A validating, accepting, and (especially in the beginning) nonconfronting patient–therapist relationship is a prerequisite for active participation in therapy. It is also the basis for the development of an alternative model of illness and the motivation to change. Self-monitoring diaries aim at a precise identification of symptoms in relation to external or interoceptive stimuli, events, and their positive and negative consequences in concrete situations. Psychoeducation and cognitive therapy are essential for a critical discussion and revision of inadequate concepts about health and disease and a better understanding of ongoing mechanisms. For example, the hypochondriac patient may realize the effects of a feedback loop leading to a vicious circle as is the case in increased autonomic arousal through anxious thoughts and worries about illness. In a collaborative way the therapist tries to convey a more realistic and helpful

paradigm of body–mind interactions which aims at a better understanding and mastery of symptoms. Relaxation training is provided as a method for an active reduction of tension, arousal, and apprehension. The patient is motivated to reduce maladaptive illness behaviors like body scanning and checking, excessive medical visits, seeking reassurance, and social withdrawal. Cooperation with physicians and family members is warranted so that they can avoid inadequate reactions to the patients' illness behaviors. Alternative behaviors, e.g., exercises, sports, and positive activities have to replace the symptomatic ones and can help to re-experience bodily functions in a more positive way. Stress management, social competence, and problem-solving interventions can be used optionally to improve coping with stress, conflicts, and interpersonal problems. Furthermore, therapy has to prevent relapses and enhance a more balanced life style. As some of the symptoms might resist the described interventions or take a longer time to be effective, patients have to learn how to 'live with the residual complaints as best as possible' and to regain a better quality of life instead of waiting for complete remission.

Up to now there is no empirically validated form of specific pharmacological therapy. Clinical experience shows that in some cases tricyclic antidepressants and selective-serotonin-inhibitors might be helpful, especially in patients with comorbid depression, anxiety disorders, and pain. However, without concomitant psychotherapy the risk of relapse is usually high. Benzodiazepines and low-potency neuroleptics should not be given because of the risks of long-term intake, especially abuse and dependency in benzodiazepines and tardive dyskinesia in neuroleptics.

Compared to other psychiatric disorders the empirical evidence for effective treatments is low in somatoform disorders. But there is a growing number of controlled outcome studies since the syndromes were clearly defined in 1980. These studies have to face the fact that most of these patients are not treated within mental health services but in the primary care system or in consultation and liaison services. Additional difficulties arise from the complexity of recent approaches, which can only be evaluated as 'total treatment packages' (see *Antidepressant Drugs*; *Behavior Therapy: Psychiatric Aspects*).

5. *Summary and Outlook*

The clear operationalization of diagnoses within *DSM* and *ICD* classification systems stimulated a lot of empirical studies concerning the epidemiology, etiology, pathogenesis, and treatment of somatoform disorders in the 1980s and 1990s. Medical and mental health services have realized the clinical relevance of these disorders and the need for early recognition and multidisciplinary intervention programs. Clinical observations and outcome studies have challenged the former statement, that patients with somatoform disorders in general have a poor prognosis. The acceptance of psychotherapeutic and psychiatric interventions can be enhanced if their positive effects are transparent to the patient. Convincing models for a better explanation and understanding of symptoms, the definition of limited and concrete goals, and the provision of successful experiences in symptom reduction and improving coping abilities may have the function of a 'positive vicious circle' and convey a sense of mastery.

However, patients and their caregivers have to overcome a series of obstacles:

(a) The first step is the correct recognition and early diagnosis by the primary care physician.

(b) Divergent health belief systems of patient and physician may burden the relationship and cooperation between them, so that it is difficult to realize psychological interventions.

(c) Although psychological treatment is indicated, physicians often avoid time-consuming verbal interventions or are not adequately trained for their application. However, it is not clear whether psychotherapeutic interventions, which are proven within a psychotherapeutic context, can be adopted by general practitioners without diminishing their efficacy.

(d) If physicians try to refer to mental health experts a lot of patients refuse this referral or are not motivated for psychotherapy.

(e) Since empirical validation of different treatment approaches for somatoform disorders is still rare, the selection of therapeutic methods mainly depends on local availability and personal preferences rather than on evidence-based criteria.

Each of these items is a challenge for clinical and research efforts as well as for a better dissemination of existing knowledge and competence to different health professionals who are involved in the treatment of somatoform patients.

There is also an ongoing debate concerning the psychiatric nosological congregation in somatoform, related disorders and their diagnostic criteria (Rief and Hiller 1999). High rates of mutual comorbidity between anxiety, affective, substance abuse, and somatoform disorders have challenged the usefulness of the concept of discrete and stable nosological entities and different treatment needs. Some clinicians propose a concept of spectrum disorders with more transient borderlines between different, but obviously linked, clusters of psychopathology and their courses in a long-term perspective. Specifically the relevance of subclinical forms of disorders as precursors and remaining psychopathological states after partial remission is stressed. Furthermore, the congregation within the somatoform disorders is questioned, e.g., for hypochondriasis, where parallels to anxiety disorders are obvious. Etiologic and pathogenetic models of panic and obsessive compulsive disorder seem to be

of value for a better understanding and effective modification of health anxieties in somatization syndromes, too. Some new candidates are thought to be potentially affiliated as psychiatric diseases with apparent parallels to somatoform disorders. Chronic fatigue syndrome, fibromyalgia, and multiple chemistry sensitivity, etc. are syndromes with bodily complaints of unknown etiology and pathogenesis. Their treatment might profit from adopting interventions, which have been successfully applied in somatoform disorders.

Somatosensation

The somatosensory system provides both some of our most immediate and compelling sensations—e.g., toothache, orgasm, and the urge to urinate—and those which, almost unnoticed, guide our movements as we write a letter, button a shirt, knead bread dough, use a screwdriver, or simply walk across the room. Under the rubric of somatosensation we include not a single modality, but several distinct submodalities: touch, proprioception, thermoception, and nociception, each served by characteristic receptor types, and conveyed to the brain by distinct neural pathways. Unlike vision or hearing, receptors for somatosensation are not localized in one place—like the retina or cochlea—but scattered throughout the body: in skin, muscle, and viscera (Gardner et al. 2000).

The sensitivity of those receptor systems is astonishing. Using active touch of the fingertip, we can distinguish a raised dot .006 mm high and 0.04 mm wide (smaller than Braille) from a smooth surface. This high degree of spatial resolution is matched by a temporal resolution that enables a Braille reader to process up to 100 characters per minute (Phillips et al. 1990). Conversely, as a probe is moved stepwise across the skin, we can identify, with great precision, not just the location of the probe, but the direction and speed of its movement and the duration of its contact. Similarly, variations in the angle of the knee joint can be detected with a resolution of 0.5°. Note that all of these feats of discriminative somatosensation involve movement: either movement of a limb with respect to the body, movement of a body surface with respect to the stimulus, or of a stimulus with respect to the body surface. These examples highlight several key features of the somatosensory system; its multimodal nature, its close association with movement—in proprioception and active touch—and the topographic (i.e., somatotopic) mapping of sensory inputs with respect to the body image.

Although the somatosensory system processes both pain and temperature, this review will focus on its role in mechanoreception. Progress in this area over the past few decades has involved a continuing interaction between studies of somatosensory psychophysics in human and animals, especially primates (Talbot et al. 1968). The development of methods for single-unit recording and controlled presentation of tactile stimuli to awake primate preparations has made it possible to

study, at the cellular level, neuronal activity correlated with performance on somatosensory discrimination tasks (Gardner and Kandel 2000).

As with any sensory system, we begin with the initial elements of the system—the receptors and primary afferent fibers—characterizing their receptive field properties, and considering their putative contribution to the encoding of specific sensations or sensory attributes. We identify the ascending neural pathways that convey the encoded information to the spinal and cranial divisions of the CNS (central nervous system), and thence to the thalamus and somatosensory cortex. The somatotopic and physiological organization of somatosensory cortical regions is reviewed, with a focus on the manner in which information about modality and topography are integrated at the cortical level to provide functionally significant outputs. In the final section we examine processing within somatosensory cortex and between the 'primary' sensory areas and adjacent cortical 'association' and 'motor' areas involved in the generation of 'percepts' and the control of movement.

1. *Receptors, Receptive Field Properties and Encoding of Somatosensory Properties*

Human skin contains several classes of mechanoreceptors—Merkel disks, Meissner's, Ruffini, and Paccinian corpuscles—whose differential stimulus selectivity is associated with a distinctive morphology. All four are capable of transducing stimulus energy into peripheral neural activity via the generation of receptor potentials. Their associated afferent fibers may be classified with respect to receptor location (cutaneous vs. deep), receptive field size (small vs. large), and adaptation to maintained stimulation (slowly vs. rapidly adapting). In humans, a given receptor type is uniquely associated with a specific type of conscious sensation (e.g., light touch\pressure, flutter\vibration, stimulus movement). In addition to these tactile receptors, muscles and joints are endowed with a variety of proprioceptors (e.g., muscle spindles, Golgi tendon organs) activated by limb displacement. This ensemble of mechanoreceptors and their associated afferents mediate the extraordinarily rich array of sensations that accompany contact with the skin and movement of the limbs.

By combining analysis of single primary afferent responses to controlled mechanical stimulation in monkeys, with psychophysical measurements in humans it has been possible to assess the differential contribution of different receptor classes to the encoding of tactile stimulus properties. Such studies suggest that spatial properties of tactile stimuli (form, texture) are best preserved in the discharge of slowly adapting cutaneous receptors; their temporal properties (flutter, vibration, slip) by the discharge of rapidly adapting afferents. However, natural stimuli do not engage a single receptor, but a population of receptors of different types. Thus, complex movements like grasping, lifting, and manipulating objects are guided by a continuous flow of afference from slowly and rapidly adapting receptors of several types, while information about the static position and movements of limbs involves a combination of muscle, joint, and cutaneous inputs (Johnson and Hsiao 1992, Valbo et al. 1984).

2. *Ascending Neural Pathways: Modality Segregation and Somatotopic Organization in the Lemniscal System*

Each of the receptor types discussed above is associated with a primary afferent fiber arising from a peripheral ganglion cell in the spinal or cranial divisions of the somatosensory system and conveying inputs from, respectively the body or head, to higher levels of the system. The ascending somatosensory pathways are organized according to the principle of modality segregation, which insures that information from each type of receptor is conveyed along a separate 'labeled' line, to terminate in a unique collection of cells in the CNS. This insures that, at least at early stages of processing, information about e.g., light touch, vibration, or proprioception is kept separate and processed in parallel within a 'lemniscal' pathway. Moreover, pain and temperature inputs are conveyed and processed by a distinctly different—anterolateral—pathway.

Information from the different mechanoreceptor types projects to 'higher' brain regions via a series of sensory 'relay' nuclei at brainstem and thalamic levels. The organization of this 'lemniscal' projection reflects not only modality segregation but an initial dissociation of inputs from the body (spinal) and head (trigeminal) divisions into dorsal column-lemniscal and trigeminal lemniscal pathways, respectively. At each level of the pathway, the representations of head and body within a nucleus are somatotopically organized. For example, at lower brainstem levels (dorsal column nuclei: gracilis and cuneatus) the body representation (which is ipsilateral) is mapped so as to form a 'homunculus,' with the lower trunk, legs, and feet medial in the medulla, and the upper trunk, hands, and arms, lateral. The body and head representations travel in the medial and trigeminal lemnisci, which cross at medullary levels so that in the thalamic 'homunculus' the contralateral head and body are represented in medial, and lateral posterior subnuclei (VPM, VPL) respectively. The ventrobasal complex, in turn, relays this information to two cortical somatosensory areas: SI, located on the postcentral gyrus of the parietal lobe, and SII, on the banks of the lateral fissure. In addition to sharing a thalamic input, the two regions are linked by reciprocal connections within and between the two hemispheres (Gardner and Kandel 2000).

3. Somatosensory Cortex: Brain Maps and Sensory Function. Anatomical, Physiological and Functional Organization

SI occupies a cortical region divisible, by cytoarchitectonic criteria, into Brodmann's areas (3a, 3b, 1, and 2) and lying along an antero-posterior axis bounded rostrally by motor cortex and caudally by posterior parietal regions. Within the area defined as SI there are four somatotopically similar but physiologically distinct representations of the body surface (Nelson et al. 1980). These somatosensory maps are 'functional' rather than 'veridical.' All parts of the body are not equally represented since representation of a body part reflects its significance for the animal, not the actual space it occupies. The 'significance' of a body part is highly correlated with density of its receptor innervation. Thus the tail of the spider monkey, the whiskers of the rat, and the hand and tongue of humans occupy disproportionate amounts of the cortical map of those species. Moreover, the cortical map preserves the modality segregation inherent in the 'labeled line' processing of receptor inputs. The representation in each of the four areas is dominated by input from one mechanoreceptor submodality: in 3a it is primarily muscle stretch receptors; in 3b input from cutaneous receptors, in area 2 the dominant input is from deep pressure receptors, while in area 1 rapidly adapting cutaneous receptors predominate. Despite these differences in their predominant inputs, the various somatosensory representations within SI share a common physiological organization, evident in the results of single-unit studies. As an electrode advances downward from the cortical surface along a radial traverse through successive layers, all the neurons encountered in its path will respond to the same type of stimuli (cutaneous or deep, rapidly or slowly adapting, muscle or skin) originating from the same part of the body. This principle of 'columnar organization,' first encountered in SI, has proven to be an important principle of cortical organization across other sensory systems. For the somatosensory system, the mapping process results in an orthogonal relationship between modality and topography, such that a recording from any point on the map will generate information about both the nature of the peripheral sensory message and the part of the body from which it originates

4. Somatosensory Plasticity and the Phantom Limb Syndrome

The complexity and stereotypy of cortical maps suggested that such maps are a fixed and relatively immutable property of mammalian somatosensory cortex. However, it is now evident that the somatotopic maps defined by recording studies are modifiable, even in adult primates, by a variety of sensory and experiential manipulations, including deafferentation and behavioral training. Differential use of specific digits or portions of a single digit (in monkeys, or human Braille readers) may result in expansion of the map area devoted to the stimulated region (Recanzone et al. 1992). Deafferentation of specific portions of the map of the hand in primates produces a sequence of stages, in which the denervated area may initially be unresponsive, but then become gradually responsive to inputs, not from the originally innervated region, but from regions adjacent to it. It is as if the areas devoted to the adjacent regions expand into the region deprived of its original input by the deafferentation. This interpretation is supported by an experiment in which removal of a single middle digit (D3) is followed by expansion into its representation by the adjacent digits (D4 and D2). Similarly, after surgical fusion of two contiguous digits (D3, D4) the receptive fields of the two digits become continuous across the area of fusion, and this continuity remains even after the fusion is removed (Clark et al. 1988, Jones 2000). However, the most striking examples of such somatosensory 'plasticity' are seen after limb amputations, which result in expansion of the adjacent face representation into the area originally activated by inputs from the limb. Stimulation of the face in such animals activated neurons, not only in the face, but also in the denervated hand or arm areas. Anatomical tracing experiments have shown that these new patterns of excitation are correlated with the emergence (over time) of a widespread expansion of lateral connections in the affected cortical regions. These findings have prompted a reexamination of the 'phantom limb' phenomenon of human amputees, and the suggestion that it may reflect reorganization processes similar to those seen in denervated monkeys (Florence et al. 1997, Kaas et al. 1983, Ramachadran 1993).

5. From 'Somatosensation' to Somatosensorimotor Functions

Ablation studies of SI and SII have demonstrated a rough correlation between the physiological properties of anatomically discrete somatosensory cortical areas and the differential function of those subdivisions. Ablation studies of SI in primates are consistent with the physiological data. The differential effects of lesions of SI subdivisions upon tactile discriminations (texture, size, and shape) are correlated with the stimulus properties processed by that area. Lesions of SII, in addition to their effects upon texture and size discriminations, also disrupt the ability to transfer a tactile discrimination task from one hand to the other, an observation consistent with the presence, in SII, of a bilateral somatosensory representation, mediated by callosal connections (Carlson 1980).

However, the parallel processing of peripheral inputs to SI may represent only a first stage in the

transition from 'sensation' to perception and movement, i.e., from the identification of specific sensory attributes to the recognition of, or interaction with objects. The possibility of a serial, possibly 'hierarchical' mode of processing is suggested both by the intracortical connectivity patterns within SI and the increasing complexity of the receptive field properties of neurons encountered in penetrations along the anterior-posterior axis of the postcentral gyrus. The initial thalamic input to SI terminates primarily within layers III and IV of area 3b, which project, in turn, upon layer IV of more caudal areas 1 and 2. This connectivity pattern is accompanied by an increase in both the size and complexity of somatosensory receptive fields along the anterior posterior axis. Thus neurons recorded in area 3b tend to have relatively small, punctate fields involving only a single digit, and comparable with those recorded from primary afferent fibers. The receptive fields of posterior neurons (areas 2 and 1) are responsive across larger areas, including the palm and several digits, and respond to moving stimuli with distinct preferences for the direction or orientation of movement (Gardner et al. 1989). Such neurons would be relatively unresponsive to passive contact by small probe tips, or active contact of a smooth sheet of paper, but show increased discharge rate to edges and three-dimensional shapes. Such observations suggest a special role for areas 1 and 2 in the digital coordination involved in grasping and manipulation of objects. Reversible (pharmacological) disruptions of cortical activity centered on area 2 produced a marked impairment in such manipulative abilities in primates. Interestingly, ablations of specific finger regions of area 3a and 3b deactivate homologous digit areas in area 1, but not the reverse (Iwamura et al. 1991). Finally, lesion data also suggests that SI lesions which disrupt complex discriminative functions (such as categorizing the relative speed of a tactile stimulus) do not impair a simple stimulus detection task. These findings are consistent with serial processing mechanisms involving the convergence of processed inputs from areas 3b, 3a and 1 upon area 2. Evidence for an additional level of serial processing involving SII comes from observations that neurons in this region may have still more complex receptive fields, including bilateral representations, involvement in active touch and modulation (enhancement or suppression) of neuronal activity by attentional processes (Burton et al. 1995). The participation of such processes should not be surprising. In nature, animals seek out, attend to, and actively engage objects, using 'mobile sensors,' such as the human fingers, to generate movement patterns directed at surfaces and three-dimensional objects (Lederman and Klatsky 1987). Such 'haptic' scanning patterns are among the most complex movements mediated by the somatosensorimotor system. Their generation, sensory control and contribution to object recognition are likely to involve the interaction of SI and SII with contiguous frontal and parietal 'association' cortex (Gardner and Kandel 2000).

Somatotherapy, History of

1. Definition and Roots

In psychiatry, somatotherapy refers to a variety of treatments of mental illness by physical or chemical means. It also includes psychosurgery and operations practiced in the late nineteenth and early twentieth century, such as castration, or removal of the clitoris, tonsils, teeth, etc. (Kalinowsky and Hippius 1969).

The roots of physical therapies are in bloodletting, and in the use of emetics, and purgatives. The roots of chemical therapies are in soporifics which have been in use since ancient medicine. Poppy (opium) and Indian hemp (*Cannabis indica*) were known to the Egyptians, and mandrake (*Atropa mandragora*) to the Babylonians and Hebrews. Henbane (*Hyoscyamus*) and dewtry (*Datura stramonium*) were used by the Orientals and the Greeks. The roots of psychosurgery are in 'decompressive trephining' that had been practiced by the neolithic Gauls and the Bohemians (Garrison 1929).

2. Pharmacotherapy: Behavior Control

The developments, which led to pharmacotherapy in psychiatry, began with the isolation of morphine from opium in Germany by Serturner in 1806; the separation of bromine from the ashes of the seaweed in France by Balard in 1826; and the synthesis of chloral hydrate in Germany by Liebig in 1832. Morphine, for controlling agitation and aggression, and potassium bromide for relieving restlessness and anxiety, were introduced for clinical use in the late 1850s. Chloral hydrate for controlling insomnia became available about 10 years later. The judicious use of these three drugs provided the necessary means for day- and night-time sedation. It also allowed the replacement of physical restraint by pharmacological control (Lehmann and Ban 1970).

Isolation of hyoscine (scopolamine) from hyoscyamine and the preparation of paraldehyde during the 1880s provided alternative treatments. Subcutaneously administered combinations of morphine (or apomorphine) and scopolamine (hyoscine) became the prevailing treatment modality of excitement and agitation in psychiatry by the dawn of the twentieth century (Ban 1969).

The synthesis of malonylurea (barbituric acid) by von Baeyer in 1864 opened the path for the development of barbital (Veronal), the first barbiturate hypnotic introduced in 1903. Barbital, together with many other long-, intermediate-, short-, and ultra-short-acting barbiturates, dominated the treatment of insomnia for about 50 years (Lehmann 1993).

3. Beyond Behavioral Control

The first treatments in psychiatry which aimed beyond behavioral control were fever therapy and prolonged sleep (Shorter 1997).

3.1 Fever Therapy

The development, which led to fever therapy, began in the mid-1890s. It was triggered by Wagner-Jauregg's observation that one of his female patients, who contracted erysipelas, recovered from her psychosis after she developed a high fever.

Instrumental to further development was the preparation of the tuberculin vaccine in 1890 by Robert Koch and the demonstration of the presence of *Treponema* (Spirocheta) *Pallidum*in the brains of patients with syphilitic general paresis in 1905 by Moore. The recognition of the heat sensitivity of spirochetes was also important.

To follow up his observation, Wagner-Jauregg induced fever with the employment of the tuberculin vaccine in several of his patients with general paresis at the University of Vienna. In spite of the favorable results, he replaced the vaccine in 1917 by blood from patients with tertian malarial attacks, because malaria could be reliably terminated by quinine.

Treatment with malaria-induced fever was an overwhelming success. Six of the first nine patients treated with 'fever therapy' improved; three fully recovered (Wagner-Jauregg 1919). Wagner-Jauregg received the Nobel Prize in 1927 for introducing the first effective treatment for neurosyphilis.

Fever therapy had also been tried in psychiatric disorders other than general paresis, e.g., depression,

schizophrenia; and fever had been induced by means other than the tuberculin vaccine and malarial blood, e.g., typhoid vaccine, killed *Escherichia coli* suspension, sodium nucleinate, sulfur in oil, hot bath. But only in general paresis did 'malaria therapy' have a demonstrable therapeutic effect. Even in general paresis, only in one-third of the patients did it yield 'satisfactory' results (Pichot 1983).

3.2 Sleep Therapy

Sleep therapy can be defined as pharmacologically induced sleep for about 20 hours a day for an extended period, e.g., two weeks. It was first introduced in Shanghai with the employment of bromides ('bromide sleep') by Macleod for mania in 1900. Sleep therapy was also used by Wolff, with the employment of methylsulfonal one year later ('Trionalkur').

Sleep therapy was reintroduced as 'prolonged sleep' (*'l'ipnosi prolongata'*) with long acting barbiturates by Epifaneo in 1915 at the University of Turin. It was adopted by Klaesi for the treatment of schizophrenia in 1922 at the Burgholzli psychiatric clinic in Zurich. Klaesi referred to sleep therapy (prolonged sleep) as 'continuous narcosis' (*Dauernarkose*) (Klaesi 1922).

For about three decades, during the 1930s, 40s and 50s, 'sleep therapy' was used in conditions ranging from manic and catatonic excitement, through severe anxiety and depression, to various forms of schizophrenia. Various drug combinations had been employed to induce and sustain sleep. Klaesi himself used Somnifen, a barbiturate combination that contains in equal amounts diethyl and allylisopropyl barbituric acid. The Cloetta mixture was another frequently used combination. It contains paraldehyde, amylhydrate, chloral hydrate, alcohol, isopropyl-allyl-barbituric acid, digalene, and ephedrine.

Sleep therapy was of marginal benefit, but of considerable risk. In Klaesi's original sample of 26 schizophrenic patients, the improvement rate was about 30 percent, that is about 10 percent higher than the 20 percent spontaneous remission rate in a similar population. This relatively small gain was offset by a higher than 5 percent fatality from pneumonia and/or circulatory collapse. Nevertheless, 'sleep therapy' was lingering on, even after the introduction of new psychotropics—with the incorporation of drugs like chlorpromazine in some of the 'sleep mixtures'—before fading away in the 1960s.

In 1971, Pflug and Tolle, found sleep deprivation therapeutic in endogenous depression (Pflug and Tolle 1971). The findings are in keeping with neuropharmacological theory about the action mechanism of tricyclic antidepressants. Since the early 1970s sleep deprivation has been employed with success in the facilitation of the therapeutic effect of these drugs (see *Schizophrenia, Treatment of*).

4. Physical Therapies

Insulin-induced coma and electrically-induced convulsions were the first 'physical therapies' of schizophrenia with demonstrable therapeutic effectiveness without considerable risk (Sargant and Slater 1954).

4.1 Insulin Coma

Insulin was isolated from the pancreas by Banting and Best in 1921. Insulin is the hormone that regulates sugar metabolism and since 1922 it has been used as replacement therapy in diabetes mellitus, a disease caused by its deficiency. The first report on the successful treatment of symptomatic depression with insulin in diabetic patients was published in 1923.

Insulin, was introduced into psychiatry for stimulation of appetite and sedation in the late 1920s. Its indications were extended to the alleviation of the discomfort in morphine withdrawal in the early 1930s. Manfred Sakel's report in 1930 was one of the first on the therapeutic effect of insulin in morphine withdrawal.

The origin of insulin-coma therapy in schizophrenia was in Sakel's observation that some of his restless and agitated addicts who inadvertently slipped into coma became tranquil and accessible. By following up in schizophrenics, at the neuropsychiatric clinic of the University of Vienna, the observations he made in addicts at the Lichterfelde Sanatorium in the suburb of Berlin, Sakel established the effectiveness of insulin coma therapy in schizophrenia. He published his findings in a series of 13 papers in the *Wiener medizinische Wochenschrift* between November 1934 and February 1935 (Sakel 1935).

Insulin coma therapy fared favorably to all other therapies used in the treatment of schizophrenia in the 1940s. It was especially effective in recent cases. The spontaneous remission rate was doubled if the treatment was used within the first year of the illness. The risks with insulin-coma therapy were low. Of the 90 deaths reported out of the 12,000 patients treated with insulin coma therapy in the United States, only half could be attributed to the treatment. One British expert had only one fatality in over 1,000 cases (Mayer-Gross et al. 1960). Nevertheless, insulin-coma therapy was short-lived in the Western world. It was promptly abandoned after the introduction of new psychotropic drugs. This was not the case in the Soviet Union and China, where it remained one of the major forms of treatment of schizophrenia until the late 1980s.

4.2 Electroshock

Developments, which led to the introduction of electroconvulsive therapy in psychiatry, began in the

late 1920s with Nyiro and Jablonsky's clinical observation that epileptic patients improved if they developed schizophrenia. It continued with Laszlo Meduna's findings in autopsies that the neuroglia, which is the supporting tissue of the nerve cells, was very thick in epilepsy and very thin in schizophrenia, and postulation of an antagonism between epilepsy and schizophrenia.

To pursue matters further, Meduna induced convulsions for the first time in a schizophrenic patient by the intramuscular administration of camphor on January 23, 1934 at the National Psychiatric Hospital for Nervous and Mental Diseases in Budapest. Adopting the treatment schedule used in malarial therapy, he repeated the injection every third day. After the fifth injection he found the patient markedly improved.

In spite of the favorable findings in several patients, Meduna replaced camphor by intravenously administered Cardiazol (Metrazol, pentetrazol) because of the pain caused by the intramuscular injection, the delay in the onset of the convulsions, and the agonizing fear patients experienced during the delay (Meduna 1937).

Pharmacologically induced convulsions were replaced by Ugo Cerletti and Lucio Bini by electrically induced convulsions in the late 1930s. Electroshock (EST), originally referred to as electroconvulsive therapy (ECT), was first given to a schizophrenic patient on April 18, 1938 at the neuropsychiatric clinic of the University of Rome. It was administered through electrodes placed on both temples that Bini found safe in dogs. Cerletti and Bini reported their findings with EST to the Italian Academy of Medicine in Rome on May 28, 1938 (Cerletti and Bini 1938). The treatment was therapeutically effective and safe; the only drawbacks it had were fractures and memory disturbance.

The risk for memory disturbance with EST was greatly reduced by the use of 'brief-pulse currents' and moving the path of the current in the brain away from the memory centers by locating the electrodes on one side, or over the very front of the head. An added advantage of bifrontal electrode placement is that seizures are elicited at near threshold frequencies.

The risk for fractures was greatly reduced by pretreatment with a neuromuscular blocker. Bennett in the United States was first in 1940 to employ curare to relax the muscle (Bennett 1940). Curare, a substance that competes with acetylcholine at the neuromuscular junction, was replaced by succinylcholine, a safer drug, which prevents the action of acetylcholine by depolarizing the muscle end-plates.

To prevent the panic which is caused by not being able to breath, succinylcholine administration is preceded by the administration of a short acting barbiturate. ECT, administered under general anesthesia with continuous oxygenation and monitoring of the body's physiology during treatment, is the safest among the somatic therapies today. It offers specific advantages for the elderly, in pregnancy, and for patients with cardiac disease (Fink 2000, Kaplan and Sadock 1988).

The indications of ECT have been extended over the years from schizophrenia to include mania and depression. However, in mania and schizophrenia, it is used only in treatment failures or in patients with specific contraindications to drugs. In depression ECT is also used as primary treatment in delusional-psychotic patients and in patients perceived as suicidal risks (Abrams 1997, Fink 1979).

In the mid-1990s a new technique, high-energy transcranial magnetic stimulation (rTMS) of the brain, was introduced. Expectations were high that it could eventually replace ECT. This, however, was not to be the case. Compared with ECT, the physiological effects of rTMS are rather modest.

5. *Psychosurgery*

Development of psychosurgery began in the late nineteenth century in Switzerland with the removal of parts of the brain (topectomy, craniotomy) in six psychiatric patients by Burckhardt. The first operations were of questionable success; one patient died, one improved, two became 'quieter,' and two remained unchanged (Burckhardt 1891).

Progress in psychosurgery received a great impetus in 1935 by Jacobsen and Fulton's demonstration that removal (ablation) of the frontal lobe has a calming effect in the monkey. It was their report which prompted Egas Moniz, a Portuguese neurologist, to develop transcortical leukotomy, a method in which the white matter between the frontal lobes and the thalamus in the brain is severed through burr-holes cut in the cranium. The first transcortical leukotomies were conducted in 1935 by Moniz and Almeida Lima, a neurosurgeon, in schizophrenic patients from the Bombarda asylum, at the Santa Naria Hospital in Lisbon. The operation was a success. It reduced the severity of tension and psychotic symptoms in over 60 percent of the patients. (Moniz 1937). Moniz received the Nobel Prize in 1949 for his pioneering work in the new field and for his role in the development of psychosurgical techniques.

Psychosurgery was introduced in the United States by Walter Freeman, a Washington neurologist, in collaboration with James Watts, a neurosurgeon. The first prefrontal lobotomy was performed in Washington on a patient with agitated depression at George Washington University in 1936 (Freeman and Watts 1936). About 10 years later, in 1946, Freeman introduced transorbital lobotomy by approaching the brain through the eye socket with an ice pick.

Psychosurgery fell into disrepute during the 1950s and 1960s, because it deprived patients from their judgement and social skills. Demonstration of its effectiveness and safety with the introduction of improved stereotactic techniques, however, led to its

revival in the 1970s and 1980s. The new techniques allow the placement of discrete lesions in the brain, and also to make the actual lesions by radioactive implants, cyroprobes, electrical coagulation, proton beans, and ultrasound waves (Lehmann and Ban 1994).

Today, psychosurgery covers a wide range of operations which aim to reduce the severity of psychopathology by destroying specific regions (lobotomy) or connecting tracts (leukotomy, tractotomy) in the brain. Among the most frequently employed operations are cingulectomy in the treatment of refractory obsessive compulsives, and thalamotomy in the treatment of refractory depressions.

6. *Pharmacotherapy in the 1930s*

There was a steadily growing interest in pharmacotherapy during the 1930s. One of the targets was catatonic inhibition which by the mid-1930s had been transiently removed in some patients by the inhalation of a 30 percent carbondioxide and 70 percent oxygen mixture, and the administration of sodium amobarbital and apomorphine (Loevenhart et al. 1929).

Racemic amphetamine, a powerful stimulant, was introduced by Prinzmetal and Bloomberg in the treatment of narcolepsy in 1935 (Prinzmetal and Bloomberg 1935). Two years later, dextroamphetamine was first used by Charles Bradley for calming hyperexcitable–hyperactive children. These were the first neuropsychiatric applications of the amphetamines. The amphetamines are substances with a phenylpropylamine structure synthesized by Edeleano in 1887.

Amphetamines were also tried in the treatment of depression, but with little success. Although treatment with hematoporphyrin, a photosensitizing substance, and dinitrile succinate, seemed to offer some promise in the treatment of depression, tincture of opium, introduced during the first quarter of the century, remained the prevailing pharmacological treatment modality in depressive illness during the 1930s, 1940s, and early 1950s (Ban 1981).

7. *Causal Treatments: The 1940s*

The developments which led to causal treatments in phychiatry during the 1940s began with the isolation of nicotinic acid (vitamin B-3) by Funk in 1911, and the demonstration of its therapeutic effect in pellagra by Fouts and his associates in 1937. Pellagra is a disease which may cause delirium in the acute, depression in the subacute, and dementia in the chronic stages of the illness (Ban 1971). It continued with the discovery of penicillin by Fleming in 1929, and the establishment of its therapeutic effect in syphilitic general paralysis by Stokes and his associates in 1944. It culminated with the recognition of the link between the selective memory disturbance of Wernicke's encephalopathy, first described in 1881, and thiamine deficiency by de Wardener and Lennox in 1947.

The diagnostic distribution of patients in psychiatric hospitals drastically changed with the introduction of nicotinic acid, penicillin, and thiamin into psychiatry during the 1940s. Psychoses due to cerebral pellagra and dementia due to syphilitic general paralysis virtually disappeared by the 1950s in the western world, and the prevalence of dysmnesias markedly decreased. This was the state of art in the somatotherapy of mental illness immediately prior to the introduction of new psychotropic drugs.

8. *Psychotropic Drugs: 1950–2000*

Introduction of therapeutically effective psychotropic drugs in the treatment of mental illness began in 1949 and has continued since. The term psychotropic was introduced by Ralph Gerard, an American neurophysiologist, in 1957 for drugs with an effect of mental activity and human behavior.

The history of psychotropic drugs can be separated into three distinct periods. The first corresponds with the introduction of prototype drugs during the 1950s. The second, with the introduction of the first-generation psychotropics, identified on the basis of structural and/or pharmacological similarities to the prototypes, during the 1960s and 1970s. The third, ongoing period, with the introduction of the second generation of psychotropics, developed with consideration of theories about the pathomechanism of mental illness, derived from studies on the action mechanism of therapeutically effective drugs.

The first set of psychotropic drugs included lithium, chlorpromazine, reserpine, meprobamate, iproniazid, and imipramine. In a broad sense it also included chlorprothixene, haloperidol, and chlordiazepoxide. It consisted of four antipsychotics (neuroleptics, major tranquilizers), i.e., chlorpromazine, reserpine, chlorprothixene, and haloperidol; two antidepressants, i.e., imipramine and iproniazid; two anxiolytic sedatives, i.e., meprobamate and chlordiazepoxide; and one mood stabilizer, i.e., lithium. Antipsychotics are effective in controlling excitement and psychomotor agitation, in the treatment of schizophrenia and mania, and in the management of psychosis. Antidepressants are effective in the treatment of depressive illness and also in panic disorder and obsessive compulsive disease. Mood stabilizers are effective in both the manic and the depressive phases of manic depressive illness, and in the acute, maintenance, and prophylactic treatment of bipolar disease. Anxiolytic sedatives are effective in the treatment of generalized anxiety disorder. Anxiolytics alleviate anxiety and relieve tension.

The first set of psychotropic drugs was introduced within a period of about 10 years. Lithium, in 1949

was first, followed by chlorpromazine in 1952, reserpine in 1954, meprobamate in 1956, imipramine and iproniazid in 1957, chlorprothixene in 1958, haloperidol in 1959, and chlordiazepoxide in 1960 (see *Antidepressant Drugs*).

The introduction of each of these drugs into psychiatry has its own story. The discovery of the therapeutic effect of lithium in mania was the result of John Cade's recognition that the substance protected guinea pigs from the lethal effects of urea, responsible for the toxicity of manic urine. The discovery of the therapeutic effect of iproniazid in depression was triggered by clinical observations on the euphorizing effect of the substance when used in the treatment of tuberculosis. The origin of chlorpromazine, the first antipsychotic phenothiazine, was in research with antihistaminics. Its introduction into the treatment of schizophrenia and mania by Delay, Deniker, and Harl followed within two years of its synthesis by Paul Charpentier in 1950. The origin of reserpine was in research with Rauwolfia alkaloids. Its introduction in the treatment of psychosis by Delay, Deniker, Tardieu, and Lemperiere followed within two years of its isolation from the 'snake-root' plant by Muller, Schlittler, and Bein in 1952. Development of meprobamate, the first widely used propanediol in the treatment of anxiety, was in Frank Berger's research that aimed at developing antibiotics for Gram negative bacteria originally. Development of haloperidol, the first widely used antipsychotic butyrophenone, was in Paul Janssen's research which aimed at developing analgesics which are more potent than pethidine (meperidine) originally. Imipramine was the result of the search for structurally related drugs to chlorpromazine at Geigy; chlordiazepoxide, of the screening for pharmacologically related drugs to meprobamate at Roche; and chlorprothixene, of the effort to synthesize structurally and pharmacologically related drugs to chlorpromazine at Lundbeck (Ayd and Blackwell 1970, Ban et al. 1998, Ban and Ray 1996, Healy 1996, 1998).

Some of the prototype drugs had a major impact on psychotropic drug development and by the end of the 1970s, the number of psychotropic drugs available for clinical use in the treatment of mental illness increased to about 50. Today there are well over 20 antipsychotics, antidepressants, and anxiolytic sedatives, and at least three mood stabilizers employed in the treatment of mental illness. In addition, there are also a couple of cholinesterase inhibitors in clinical use for the treatment of Alzheimer type of senile dementia (see *Alzheimer's Disease: Antidementive Drugs*).

9. *Neuropsychopharmacology in Perspective*

The introduction of therapeutically effective psychotropic drugs and the spectrophotofluorimeter during the 1950s led to the development of neuropsychopharmacology.

The spectrophotofluorimeter is an instrument with the capability (resolution power) to measure the concentration of cerebral monoamines, and their metabolites, involved in neuronal transmission at the synaptic cleft. Prior to its introduction, research dealing with central nervous system acting drugs was restricted to behavioral pharmacology and neurophysiological measures. Spectrophotofluorimetry provided direct access to the detection of biochemical changes responsible for behavioral effects.

Employment of spectrophotofluorimetry in the mid-1950s led to the demonstration that iproniazid increased, whereas reserpine decreased, cerebral monoamines, i.e., serotonin (5-HT) and norepinephrine (NE). Since iproniazid, a monoamine oxidase inhibitor (MAOI), induced euphoria in some tubercular patients, and reserpine, dysphoria in some hypertensives, the possibility was raised that the mood changes were mediated by the changes in 5-HT and NE concentrations in the brain (Brodie et al. 1956). The postulation of a relationship between reserpine-induced depletion of monoamines and depression led to the introduction of the reserpine reversal test in the screening for potential antidepressants which, in turn, led to a substantial increase in imipramine-type antidepressants by the end of the 1970s. It also provided the rationale for the research which, with the employment of radioactive isotope labeling techniques, led to the finding that tricyclic antidepressants block the neuronal reuptake of NE and 5-HT (Glowinski and Axelrod 1964).

Employment of spectrophotofluorimetry in the early 1960s led to the demonstration that nialamid, an MAOI, induced an accumulation of the 3-*O*-methylated metabolites of dopamine and NE in chlorpromazine and haloperidol treated rats. The increase in the accumulation of 3-methoxytyramine and normetanephrine could be explained by a compensatory increase of tyrosine hydroxylase activity to the drug-induced blockade of catecholamine receptors (Carlsson and Lindquist 1963). Postulation of a relationship between dopamine receptor blockade and antipsychotic effect led to the introduction of tests based on dopamine antagonism in the screening for potential antipsychotics which in turn led to a substantial increase in the number of chlorpromazine-type antipsychotics by the end of the 1970s. It also provided the rationale for the research which, with the employment of X-ray crystallography led to the demonstration of dopamine receptor blockade with antipsychotics (Creese et al. 1975).

Development of receptor binding assays during the 1970s opened the path for the determination of NE and 5-HT reuptake blocking potency of antidepressants. Identification of receptor subtypes during the 1980s led to the determination of the dopamine-D2 and serotonin-5-HT2A blocking potency of antipsychotics, and to the delineation of the receptor profile of psychotropic drugs.

Separation of receptor subtypes was further refined during the 1980s by the introduction of genetic technology. With the employment of receptor cloning by the late 1990s five subtypes of the dopamine receptor, 14 subtypes of the serotonin receptor, and five subtypes of the muscarinic-cholinergic receptor had been identified (Lucas and Hen 1995, Richelson 1999).

The new genetic technology rendered the tailoring of psychotropic drugs to receptor affinities a distinct possibility. It opened up a new perspective in the somatotherapy of mental illness.

Sou

South America: Sociocultural Aspects

South America, the worlds fourth largest continent, is composed of 12 nation-states and one territory. The significant differences among these 13 countries are matched by great internal sociocultural and ethnic diversity. Contemporary neoliberal and authoritarian governments strive to centralize and homogenize their populations. Internal cultural, social, and political movements heighten diversity. The military often plays a strong role in centralizing efforts. The Roman Catholicism of European colonialism historically and culturally shapes pan-national and internal cultural unity of the 10 Iberian-derived nations. Diversity is especially strengthened by the striking polarization between the small wealthy minority and the large poor majority; by indigenous and Afro-Latin American movements of cultural and ethnic self-affirmation; by the presence of significant ethnic blocs resulting from European migrations since the two World Wars; by the struggles among leftist, rightist, and populist political parties; by the challenge of the twentieth century spread of protestantism; and by the liberal Catholicism of recent reforms.

1. Human and Topographic Diversity

The rapidly expanding population contains as wide a spectrum of phenotypic features found anywhere in the world. Its modern nation-states include Venezuela, Colombia, Ecuador, Peru, Bolivia, Chile, Uruguay, Paraguay, and Argentina, where Spanish is the official language; Brazil, where Portuguese dominates; Guyana where English is the national language; Suriname, where English, Dutch, and Sranan are prevalent; and Guyane, an administrative district (*département*) of France, where French is dominant. Many other languages are spoken in most of these countries.

Western South America is dominated by the mighty Andes mountains, with snow-coned active volcanoes that rise to 20,000 feet. They extend southward from the Caribbean Island of Trinidad to terminate in southern Argentina at Tierra del Fuego. In this region Venezuela, Colombia, and Ecuador are known as the northern Andes (and the former two as the Spanish Main); Peru and Bolivia constitute the central Andes, and Chile, Paraguay, Uruguay, and Argentina are called the Southern Cone. Eastern South America features the great Amazon Basin, epitomized by the Amazon itself, the 'Ocean Sea.' Toward the headwaters of the huge feeder rivers of the Amazon lie the mountainous Guiana Shield in the north, the Brazilian Shield in the south, and the Andean foothills or *montaña*, rimmed by the *ceja*, 'eyebrow,' in the west. Northwest and northeast of the Amazon regions, and west of the Guiana Shield, are the plains (*llanos*) of Colombia and Venezuela, which phase into the Orinoco Basin, and west of the Brazilian Shield are the *llanos de Mojos* of Bolivia. A subregion that combines elements of Amazonian and Andean systems is that of the North Pacific coast. From northern Ecuador through western Panama an Amazonian ecosystem prevails. From northern Peru southward, high aridity is characteristic.

2. Precolumbian People: Their Lands, Products, Societies, and Languages

Native South American cultures prior to 1492 represented a dynamic mosaic of languages, cultures, social systems, rituals, and power relationships. long-distance trade—sometimes extending for thousands of miles—combined with bi- and multilingualism and multiculturality. Such trade traversed some of the most rugged landscapes in the world, creating networks of native knowledge and imagery crosscutting great geographical differences. Antiquity of South American native peoples is highly controversial. In the east, and thence up the Amazon and Orinoco (the latter has its head waters in the Parima and Pacarima mountains of the Guiana Shield and flows west, then north, then east out into the Atlantic), evidence suggests antiquity of 12,000 years ago or earlier, but the routes of arrival are obscure. Neither transatlantic nor transpacific routes seem credible to scholars in 1999, though sporadic contacts in South America by the first Americans with Asian-Pacific and Euro-African peoples remain subjects of possibility. Plant domestication seems to begin in Amazonia and in the Andes by about 8,000 years ago.

The period beginning about 6,000 years ago and continuing until the European conquest and colonization marks the florescence of fine ceramics in Amazonia, and the development of textiles, gold, and silver work in the Andes and adjacent coastal regions. At the mouth of the Amazon, ceramics manufactured on Marajó Island, an area the size of Connecticut in

the USA, rivaled the quality of any ceramic wares found anywhere in the world in terms of their beauty of form and decoration.

By 4500 years ago great migrations from the lower and central Amazon region were underway, and regional consolidation in the Andes was occurring. People from coastal, Andean, and Amazonian regions were in contact with one another, and with the people of the Caribbean Islands, Central America, and Mesoamerica. People who belong to three language families—Arawak, Carib, and later Tupi—spread from the eastern and central Amazon to the Orinoco drainage and on to the Caribbean (Arawak), and to the base along the rim of the *montaña*. Other Amazonian language families of prominence include Tukano, Tukuna, Jívaro, Pano, and Gê; these languages spread in a general arc from northwest of the Amazon around the central Amazonian rim to the southwest. Andean languages were also highly diverse.

The Inca empire, radiating north and south out of its capital of Cuzco, in what is now Andean Peru, emerged in the fifteenth century to severely alter the cultural mosaic in the Andes, and set up political-economic and cultural shock waves that radiated eastward. This empire was in full conquest fervor by the time word arrived from the Caribbean and Central America of the pending Spanish advances down the Pacific Coast and up into the Andes. At the height of their expansion, the Inca controlled all Andean systems from central Chile to southern Colombia, and their north-south 3,416-mile parallel cobble stone roadway (one coastal, one Andean) through this vast territory (385,000 square miles) amazed the conquering Spaniards. Although the Inca never dominated the adjacent indigenous people of Upper Amazonia, there is ample evidence of extensive trade between Amazonia and Inca-dominated Andes and Coast. Quechua (a variant of which is Quichua) was the lingua franca used by the Inca in its conquest, and became the language of 12 million people throughout the empire, and beyond. Other prominent Andean languages include Chibcha in the north Andes, Aymara in the central Andes and Mapuche in the southern cone.

In the greater Amazonian areas east of the Andes people depended on maize and manioc cultivation for caloric intake, and on intensive fishing and reptile and amphibian collecting for protein and amino-acid balance. Hunting in the various ecosystems of the flooded forest, the upland forest, and the flood plains and riverine systems complemented the balance of fishing and horticulture. As time progressed manioc (*Manihot esculenta* Crantz) came to be the staple of the agricultural system, with maize sporadically and regionally grown and consumed. Fishing in rivers, estuaries, streams, and coast was of paramount importance, as were techniques for corralling turtles and other amphibians. Polities varied from well-developed chiefdoms and relatively small-scale states to more dispersed systems. Intermarriage between peoples at war with one another, and speaking different languages, seems fairly common.

In the Andean regions, the potato was the supreme crop, with beans, squash, maize, quinoa, and other grains providing a balanced diet when combined with animal protein. Approximately 240 species of potato were grown, harvested, and prepared in many ways. Llama (one of three Andean camilids), guinea pig, and much later the hairless dog, were the primary animals raised for food, and the llama was used as a beast of burden. Polities ranged from small-scale systems to states and the expansive Inca Empire.

3. *The European Conquest of Native Lands and People*

A new cultural system based on conquest and capitalism was violently created by the overseas empires of the Spanish and Portuguese after 1492 as they sought huge profits in gold, silver, spices, and slaves. In the Treaty of Tordesillas, signed in 1494, the Spanish and the Portuguese divided up their colonies long before they knew the vast extent of their respective territorial 'holdings.' From the terms of this treaty the Portuguese would lay claim to Brazil, and Spain would take the rest, including all of the Pacific regions from South America to the Philippines and Japan, all of the Andes, and a parts of Amazonia, a territory itself nearly the size of the USA. Portugal's interests first lay in the route around the horn of Africa to India, and only a bit later in its vast new colonies. In 1499, sailing (and/or writing) for Spain, Amerigo Vespucci signed his map of the 'New World' thereby creating the currently favored name for the entire continent. During the early to mid 1500s Spain set out to locate, conquer, and colonize its Amazonian, Andean, and coastal regions, and Brazil set out on the conquest of its Amazonian, coastal, and mountainous regions. The Spanish first brought sugar to the Americas and the Portuguese first brought the banana from India. Both of these overseas empires introduced cattle, sheep, goats, pigs, and chickens.

Everywhere they went the conquerors encountered native people. They subdued them by enslavement, trickery and trade, and they spread European and African diseases for which native resistance was low or nonexistent. Where possible they enlisted them in slaving activities, and they killed indigenous people with firearms, swords, spears, and arrows with steel points. In areas feasible for such warfare they sent their warhorses and war dogs to maim and kill them in their radical recolonization of the subcontinent. This brutal transformation resulted in 90 percent or greater depopulation of the native inhabitants throughout the continent. Trade and warfare, now with an escalating colonial need for indigenous chattel slaves in the lowlands, and indigenous landed slaves in the highlands, created a persistent poverty that endures into

the twenty-first century. Nonetheless, cultural creativity endured with local-level technical competence promoting subsistence and adaptations.

4. Blackness

The Spanish and Portuguese brought Black slaves from Africa and from Iberia with them. Many such people escaped to mountainous, forested, inaccessible areas, and created a myriad of free, fortified sites where Native American and African American people often collaborated, intermarried, and established powerful political systems on the fringe of the dominant Spanish and Portuguese territories. From these refuge sites, often called *palenques* in Spanish and *quilombos* in Portuguese, self-liberated residents established powerful political systems on the fringe of the dominant Iberian and colonial territories. They threatened the Crown political economies. In some regions such as western Ecuador, southwestern Colombia, western Venezuela, and the north of Brazil, active trade between runaway people, often called *cimarrones*, and the colonial planters ensued.

5. Mestizaje, Cultural Practices and Ideologies of Racial Blending

The Spanish initiated an ideology of ethnic blending, called *mestizaje* (miscegenation) that excluded both indigenous people and people of African descent. Spanish administrators from the republic of Spaniards demarcated a republic of 'indios,' so named by Christopher Columbus who thought he was in India. There was no legal space for Black people, except what they themselves created. Those excluded from the Spanish-Mestizaje realm were sometimes referred to as *la mancha*, 'the (racial) stain.' From this viewpoint the dominant, European concept of hybridity prevailed in this hegemonic model of racial mixing: the White, civilizing genes and cultures were to mix with the savage or barbarian 'Indian' and 'Black' to form such intermediate categories as *mestizo* and *mulato* in Spanish. In Portuguese, *mestiço*, and *mulato* referred to White-Black hybridity.

Those people with hybridized 'racial' features, according to European and later Creole (New World born) ideologues, ranged up and down the scale from white-civilized-Iberian to dark-civilizing-Creole. These diverse *mestizos* were known as the *castas*. In some times in some places the number of their racialized categories ranged from a dozen named 'types' to hundreds. Indeed, there could be five or more such 'types' among the sons and daughters of one couple. They were constituted as those people somewhere betwixt and between the savage and the civilized, and legal and colloquial labels for some of them included such racialized concepts as 'wolf,' 'coyote,' 'throw back,' 'up in the air,' and even 'there you are!'

Black people (including slave, *bozal*, and free, *ladino*) and native people (usually divided into tame, *manso*, and fierce or wild, *bravo*), fell outside of the scheme of *castas*. Their own intermixture, often rendered in Spanish by the term *zambo*, was (and is) a category filled with racist ideas about danger and power, for here was a mixture without the civilizing affects of European-sponsored hybridity. An indigenous artist using European techniques in 1599 did the first oil painting in South America. His subject was that of the 'Zambos' of western Ecuador who, adorned in European princely clothes, wearing indigenous gold jewelry, and carrying spears with iron tips characteristic of Africa and Europe, walked from their free Republic on the coast of Ecuador to Quito to swear alliance to the Spanish Crown in the face of English encroachments.

Before the rise of nation-states, movements of self-liberation by Black people and indigenous people were common, and some were quite successful. Early revolts in the sixteenth century resulted in ethnic regions that endured into the era of nation-state emergence. In 1579 the Quijo and the Jívaro of Ecuadorian *montaña* revolted in attempts to unite Amazonian and Andean people. In Peru and Bolivia the revolts of Tupac Amaru and Tupac Katari later did the same. In the forested and mountainous coastal zone of Alagoas, Pernambuco, Brazil, Black and indigenous people formed the state of Palmares in the 1640s, and fought Portuguese and Dutch soldiers for a century. Black people in Suriname revolted in the mid-seventeenth century, and initiated a 100 year war against the Dutch and British, winning independence for six nations—Saramaka, Paramaka, Kwinti, Ndujka, Matawai, and Aluku—in the interior of this region. In neighboring Venezuela, the Carib-speaking Yekuana expelled the Spanish in 1767, and maintained their complete independence for 100 years until a brutal nationalist regime militarized the area for the purposes of exploiting wild rubber.

6. The Transformation from Colonies to Nation-states

Wars of nationalist Independence from Spanish and Portuguese colonial rule began in 1810 in areas of vast distances from one another, from what is now Mexico through northern South America to the southern cone. Those who achieved positions at the pinnacle of power in South America were *criollos*, 'Creoles,' who outnumbered those of Spanish descent. In turn, they were vastly outnumbered by their darker compatriots, those especially of African descent who fought in wars led by Simón Bolívar in the north, and by José San

Martín in the south. As the Creole nationalist wars moved through slave territories, slavery was abolished, but blackness and indigenousness were kept under rigid control by fears that the revolution would become an 'ethnic' one. The ethnically marginalized continued to be excluded from dominions of power. Both Bolívar and San Martín envisioned a united Spanish-speaking Creole nation, and lightness of phenotype within the ideology of *mestizaje* was clearly ascendant.

Such a continental nation did not materialize and, one by one, contemporary nations rapidly emerged from their previously liberated colonial regimes. By 1822 Spain had lost all of its territories in the Americas, and the Portuguese King lost his colony to a new Brazilian monarchy with its own New World Empire. By 1830 all of the republics of Spanish-speaking South America emerged, only to begin border wars, geopolitical vestiges of which last to the present day. Peru, for example, invaded Ecuador in 1941, claiming half the latter's territory, and these countries fought a war over a very small sector of disputed territory as recently as 1981 and 1995, both of them in indigenous Jivaroan-occupied sectors long serving as refuge areas due to the rugged, mountainous, Upper Amazonian topography.

African chattel slavery continued in the new states side by side with Black freedom, as various systems of oppression of indigenous people continued side by side with native revolts. The last country to abolish slavery, Brazil, did not do so until 1888, and in some states illegal slavery existed side by side with manumission legalities. Not until 1966 (Guyana) and 1975 (Suriname) would two of the three Guianas gain nation status from the British and the Dutch, respectively.

7. *The Fusion of Cultures*

The powers of Spanish and Portuguese Catholicism came to South America in the heyday of the Spanish Inquisition. Powerful priests and others sought out indigenous and African systems of thought and knowledge to be stigmatized as idolatry and Devil worship. An underlying fear of converted Jews permeated some middle ranks of conquest and colonialism. Those of humble Iberian origin sought alternative sources of inspiration for religion and magic from indigenous and Black people, thereby heightening the symbolic powers of the oppressed. Fusions of Iberian, African, and Indigenous belief systems and ways of knowing and 'seeing' became legion. All this occurred at micro-levels in macro-systems of Iberian Catholic missionization that gives almost all of South America its special 'Latin American' sociocultural character.

In the area of language, pidgins emerged out of African, Indigenous, and European imperfect syntheses, to become Creole languages. In medicine the humoral system from Mediterranean classical antiquity fused with African curing programs and indigenous shamanism. The result was hundreds, perhaps thousands, of highly regional systems of health and curing which, in turn, served as vehicles of communication with people in other regions who had experienced similar cultural fusions. Religious syncretisms became the *modus operandi* of colonizing curates and of indigenous and African specialists in esoteric and numinous thought and reflection. Even horrors of the conquest were syncretized into indigenous and Afro-Latin American cultures.

For example, The battle cry of the Spanish conquistadors, '*Santiago*!' came from Santiago de Matamoros (Santiago the Moor Killer) as the Moors were defeated during the Castillan *reconquista* that was concluded in 1492. It was used to mark Spanish territories in the Americas. After the reading of the 'Requirement' document informing all 'Indians' of their loss of rights to the Spanish, the conquerors yelled 'Santiago!' and attacked with firearms, war horses, and war dogs, often feeding parts of the dead natives to the dogs, and rendering fat from the same dead natives to rub on wounds of dogs and horses. Santiago underwent a ritual reversal in the Central Andes where this Saint became the patron icon of indigenous, Quechua-speaking peoples, and was called forth to resist the Spanish. Also in this region, and in parts of Amazonia, indigenous people say that some outsiders, whom they call *pishtaco* in Peru, seek 'Indian fat' for nefarious purposes. This may well be a modern reference to practices of the Spanish conquerors—an indigenous dimension of historical consciousness—though it is usually treated as an item of strange and curious native lore.

8. *Cultural Continuities*

In the face of radical transformations and syncretisms, continuities were also abundant. Amazonian languages such as Tupi, Arawak, Tukano, Tukuna, Jívaro, and Pano continued in their respective indigenous areas, with trade between different people also continuing, in spite of the efforts of the Catholic curates, first the Jesuits and Franciscans, and then others, to 'reduce' the populations to nucleated areas. Tupi itself, as Neenghatú, became the Lengua Geral of rural Brazil until replaced by Portuguese in the late nineteenth century, and the same language, as Guaraní, became the national language of Paraguay, where citizens spoke it along with Spanish. Quechua spread in the Andes to Argentina and in Upper Amazonia where it may have served as a language of trade. Today at least 13 million people speak Quechua, making it by far the greatest indigenous language family in the Americas. Many languages that defy classification with other known indigenous languages

continue to be spoken today, especially in the Andean nation-states with substantial Amazonian regions and in the eastern countries of Brazil and the Guianas.

Rich realms of story telling, often called mythology, are legion among native peoples, Afro-Latin American peoples, and people of 'mixed' descent, where they constitute sources of spirituality and historicity embedded in more than 100 languages. They convey rich information ranging from medicinal plants to healing procedures, to ways of thinking about humanity and society that confront the models of hierarchically organized and exploitative nation-state bureaucracies. Such telling of pasts motivates symbolically the development of political movements such as that of Pachakutik in Ecuador in the mid-1990s, and the Ecuadorian indigenous uprisings in that nation during the same decade.

Within the socioeconomic classes oriented toward national politics, which have long been articulated to the global economy, the figure of the *caudillo* has loomed large since the end of the colonial era. A caudillo is a powerful figure, usually a man but sometimes a woman, such as the late Eva Perón in Argentina, who emerges in a time of political-economic or sociocultural crisis, attracts followers from many sectors of national life, including radically opposed political parties and classes. One of the greatest caudillos of all time was the liberator Simón Bolívar. The caudillo rallies such followers to his or her own personal benefit, thereby often losing considerable influence, and even office, when the crises are over. It is to the benefit of the caudillo, then, to maintain an aura of crisis, which in South America today, and back through its tumultuous history, is not difficult to do. The caudillo is matched in the indigenous sector by the *cacique* (sometimes called *curaca*), who shares the qualities just described. (Cacique is also used for leaders in organized crime.) Both caudillos and caciques, as leaders in peripheral nations, depend in large part on economic gains to come from industrialized, wealthy nations. The cultural form of dependence of South American countries is closely tied to the developmental policies of the center nations, whose funding for externally designed projects often support *caudillismo* and *caciquismo*.

9. *Modernities and Alternative Modernities*

Modernity among the elite and middle classes of South America is tied to urbanity, whiteness, and Euro-North Americanized consumer culture. The doctrine of *mestizaje* serves these interests in the sense that the identity of mestizo underscores the processes of social whitening (*blanqueamiento*). Similarly, the representations as mestizo of those below the elite or middle classes refers to the darker complexions and stigmatized and racialized vulgarity of the common people, who in many nations constitute the vast majority. For people of indigenous and Afro-Latin American descent, and for others classed by the elite as 'mestizos,' modernity consists of passing back and forth among different systems of thought and behavior.

Passages themselves give rise to new dimensions of power politics in South American nations, just as they gave rise to the Creole imagined nationalities of the nineteenth century. The alternative modernities in the Euro-American dominated global economy that spawned earlier state nationalism are now sewing the seeds of ethnic nationalism, manifest in many countries by the self-conscious rise of new nationalities out of the symbolic transformations and continuities of syncretic formations. Public displays of collective selfhood by indigenous people tap significant financial resources through Non Governmental Organizations (NGOs) of Europe and North America, giving such social formations and movements a new articulation to economic resources. Black selfhood, however, does not attract significant financial resources.

The nations of South America vary greatly one from the other, and the salient characteristics of their respective modernities also vary. Twentieth century migration has changed the complexion of many countries, as Europeans (Jewish, Catholic, and Protestant), Middle Easterners (Jewish, Christian, and Islamic), and Asians (Chinese, Japanese, Korean, and Vietnamese) have become prominent actors in various class sectors. In the southern cone nations of Argentina, Chile, and Paraguay, live significant populations of German immigrants. The ex-President of Peru, Alberto Fujimori, is the son of Japanese immigrants, and the Ecuadorian ex-President, Jamil Mahuad Witt, is the son of Lebanese and German immigrants.

South American nationality is often expressed through public performances as crystalizations of 'authentic' local-level or regional cultures. Concepts of cultural hybridity and alternative modernity fold ethnic and cultural diversity into a unified national pride. Festive centralization is often matched by local-level and regional divergence, as people in many walks of life appropriate nationalist stereotypes about authenticity into their own self-presentations.

For example, indigenous people of Andean Ecuador have long performed individualized constructions of the European festival of Corpus Christi. Cultural images of rain-forest inhabitants are evoked in these performances. In response to both the politicized indigenous movements and the craving of foreign tourists for 'authentic' Incaic performative reproductions, some of these festivals have been renamed '*Inti Raymi*,' solstice of the sun. Performance of them becomes transformed to a nationalist, 'mestizo' rendition of Incaic authenticity and also an indigenous rendition of their increasing cultural spaces in the modern nation state.

In the late twentieth century, nationalist governments use their expanding military powers to stress

centralization and homogenization, and pan-Roman Catholicism continues to be a centripetal force at the beginning of the twenty-first century. Nonetheless, indigenous and Black movements of South America together with labor movements, feminist movements, and various cultural emphases promoting counter-hegemonic diversity work against the exclusive imagery of ethnic blending in their respective nation states and across national boundaries. New and dynamic cultural mosaics are constantly created out of the interplay of secular-sacred centralization, and ethnic-cultural diversity. The dynamic, transformative balance between centralization and diversity that began in early colonial times continues into the beginning of the twenty-first century.

South Asia, Archaeology of

The archaeology of South Asia, or the Indian subcontinent, is a very substantial topic, since there is a deep history in this land of diverse peoples and cultural traditions. Moreover, archaeological fieldwork is conducted on a substantial scale, with a dozen or more excavations each year, and widespread exploration. Since it is impossible to be comprehensive in an article such as this, the article will focus on four topics (the Palaeolithic, Early Village Farming Communities, the Indus Civilization, and the Early Iron Age) that are at least representative of the principal problems on which contemporary archaelogy has focused.

1. Palaeolithic

Unexpectedly early stone tools were found at Riwat, in the Soan Valley, about 6.2 miles (10 km) south-east of Rawalpindi between 1983 and 1988 (Allchin 1995) (see Fig. 1). Twenty-five pieces of flaked quartzite were recovered. Of these, only three are undeniably artifacts; that is, objects shaped by humans. Other pieces from Riwat might be the products of human activity, but they are so simple that this cannot be determined with certainty. Two of these artifacts are cores, the third is a flake. They are generally similar to the Oldowan industry of Africa, which dates to between two and three million years ago. The geological deposits of the artifacts at Riwat have reversed polarity and are therefore associated with the Matuyama Chron, between 780,000 and 2.60 million years ago. Volcanic ash immediately above the Riwat artifacts dated to c. 1.8 million years ago. The artifacts are therefore older than that; how much older is somewhat problematic. An excavation was undertaken in 1990 in the Pabbi Hills, to the south-east of Riwat. This excavation yielded tools in a deposit that was palaeomagnetically dated to 1.2 to 1.4 million years ago.

The Lower Palaeolithic (c. 1.5 million to 200,000 years ago) is represented in virtually all regions of India, but not Sri Lanka. It is a period of two major traditions of early tool making, the western core biface (hand axe/cleaver) tradition and the eastern chopper/chopping tool tradition. The line defined by Professor Hallam Movius that follows the foothills of the Himalaya mountains down the Ganges Valley, dividing these two traditions, is a concept that has returned favor. The distribution of these tool-making traditions

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

centralization and homogenization, and pan-Roman Catholicism continues to be a centripetal force at the beginning of the twenty-first century. Nonetheless, indigenous and Black movements of South America together with labor movements, feminist movements, and various cultural emphases promoting counter-hegemonic diversity work against the exclusive imagery of ethnic blending in their respective nation states and across national boundaries. New and dynamic cultural mosaics are constantly created out of the interplay of secular-sacred centralization, and ethnic-cultural diversity. The dynamic, transformative balance between centralization and diversity that began in early colonial times continues into the beginning of the twenty-first century.

South Asia, Archaeology of

The archaeology of South Asia, or the Indian subcontinent, is a very substantial topic, since there is a deep history in this land of diverse peoples and cultural traditions. Moreover, archaeological fieldwork is conducted on a substantial scale, with a dozen or more excavations each year, and widespread exploration. Since it is impossible to be comprehensive in an article such as this, the article will focus on four topics (the Palaeolithic, Early Village Farming Communities, the Indus Civilization, and the Early Iron Age) that are at least representative of the principal problems on which contemporary archaelogy has focused.

1. Palaeolithic

Unexpectedly early stone tools were found at Riwat, in the Soan Valley, about 6.2 miles (10 km) south-east of Rawalpindi between 1983 and 1988 (Allchin 1995) (see Fig. 1). Twenty-five pieces of flaked quartzite were recovered. Of these, only three are undeniably artifacts; that is, objects shaped by humans. Other pieces from Riwat might be the products of human activity, but they are so simple that this cannot be determined with certainty. Two of these artifacts are cores, the third is a flake. They are generally similar to the Oldowan industry of Africa, which dates to between two and three million years ago. The geological deposits of the artifacts at Riwat have reversed polarity and are therefore associated with the Matuyama Chron, between 780,000 and 2.60 million years ago. Volcanic ash immediately above the Riwat artifacts dated to c. 1.8 million years ago. The artifacts are therefore older than that; how much older is somewhat problematic. An excavation was undertaken in 1990 in the Pabbi Hills, to the south-east of Riwat. This excavation yielded tools in a deposit that was palaeomagnetically dated to 1.2 to 1.4 million years ago.

The Lower Palaeolithic (c. 1.5 million to 200,000 years ago) is represented in virtually all regions of India, but not Sri Lanka. It is a period of two major traditions of early tool making, the western core biface (hand axe/cleaver) tradition and the eastern chopper/chopping tool tradition. The line defined by Professor Hallam Movius that follows the foothills of the Himalaya mountains down the Ganges Valley, dividing these two traditions, is a concept that has returned favor. The distribution of these tool-making traditions

Figure 1
Sites and places mentioned in the text

seems to be coincident with the distribution of bamboo, which could have been a major source of tools in the Lower Palaeolithic.

A Middle Palaeolithic (250,000–30,000 years ago) stone-flake tool industry is widely distributed in India, Pakistan and Afghanistan. Some sites have evidence of the 'Levallois,' technique. The cave of Darra-i Kur in north-eastern Afghanistan produced a fossil that is anatomically a modern *Homo sapiens* dated to c. 30,000 BP (Kennedy 2000).

Sites with Upper Palaeolithic blade and burin tools are not well represented in the Indian subcontinent.

Establishing a chronology for such a tool-making tradition, and documenting its distribution and relationship with the Middle Palaeolithic and the development of microlithic technology, is one of the major challenges in the prehistory of South Asia.

The oldest fossil hominid in South Asia is an archaic *Homo sapiens* from Hathnora on the Narmada River, near the famous palaeolithic site at Hoshangabad (Kennedy 2000, pp. 1173–80). This find is not associated directly with stone tools, but the deposits from which it was derived are Upper Pleistocene and date from about 200,000 to 250,000 years ago. Representatives of anatomically modern *Homo sapiens* have been found in Sri Lanka in the caves of Fa Hien, Batadomba Lena and Beli Lena Kituigala (Kennedy 2000, pp. 180–8). Radiocarbon dates have shown that the Fa Hien specimens date to c. 33,000 BP and are associated with a non-geometric microlithic tool industry. The fossil humans from Batadomba Lena date to c. 28,000 BP and are associated with microliths, bone tools, and faunal and floral remains.

2. *Early Village Farming Communities*

Insights into the beginnings of food production in South Asia have been found at Mehrgarh (Jarrige et al. 1995), on the Kachi Plain of the Indus Valley. Period I is aceramic, with small rectangular houses, and interesting multiroomed buildings thought to have been storehouses or granaries. A new periodization of Mehrgarh emerged from the 1998 excavations there. Period I now has three phases: IA and IB, with habitation, and IC, during which the excavated area was used as a cemetery (Meadow 1998, p. 13).

The date for Period I at Mehrgarh has to be inferred, somewhat unsatisfactorily, from eight radiocarbon samples that range from c. 4000 BC to older than 8000 BC. The early ceramic Neolithic of Period IIA is reasonably well dated to c. 5300–4700 BC, by seven calibrated determinations, thus the beginnings of Mehrgarh IA at 7000 BC, is a reasonable estimate, given the 11 building levels there. More than 90 percent of the food grains recovered from Period I are naked six-row barley, along with domestic hulled six-row barley, and wild and domestic hulled two-row barley (Meadow 1998). The naked barley is probably cultivated and on its way toward full domestication in Period I. There are also three forms of domesticated wheat, including emmer, einkorn and a third, free-threshing, form.

The animals from Period I include wild forms of sheep, goats and gazelle, along with other ungulates that were never domesticated. Two burials of Period IC contain the remains of five kids in each, taken to indicate their domesticated status. This inference is corroborated by the remains of relatively small subadult or adult goats in trash deposits. After gazelle, goats were found to be the most common animal in the Period IA. Over the course of Period I, sheep and cattle rise in proportion to other animals; and by the end of Period IB cattle bones comprise over 50 percent of the remains. It is thought that increasing representation and decreasing body size 'strongly supports a hypothesis of local domestication. In addition, both osteological and figurine evidence indicate that zebu (humped) cattle (*Bos indicus*) were present and likely to have been the dominant form' (Meadow 1998, p. 16).

It is clear from the Mehrgarh data that cattle, sheep, and goats were domesticated locally. Wild barley has been found in the hills above Mehrgarh, and it too would therefore seem to have been part of the same process. The one remaining resource, wheat, has never been found in the wild on the eastern edge of the Iranian Plateau, but suggesting that it was 'imported' as part of an otherwise local process of domestication creates an untenable awkwardness in the interpretation of the Mehrgarh sequence.

It is also apparent that Mehrgarh does not document the beginnings of domestication, since both the plants and animals in the earliest levels there are either domesticated, or in the process of being so. The early beginnings of this process should be in the hills above Kachi, where the sheep, goats, and cattle as well as barley (and wheat?) would be found in the wild.

Pursuing this line of inference is one of the most exciting challenges of contemporary South Asian archaeology.

It was sites like Mehrgarh and their predecessors that laid the foundations in subsistence productivity that led to the beginnings of urbanization in the Indian subcontinent.

3. *The Indus Civilizaiton*

3.1 *Introduction*

South Asia's earliest cities were a part of the Indus, or Harappan, Civilization, which arose on the plains of the Greater Indus Valley of Pakistan and northwestern India in the middle of the third millennium (c. 2500–1900 BC). The Harappan peoples were, for the most part, farmers, herders, and skilled craftspeople who lived in the cities of Mohenjo-daro, Harappa, and Ganweriwala. The Harappan Civilization covers about one million square kilometers (Possehl 1999, Allchin and Allchin 1997; see Possehl 1999, pp. 38–154 for the story of its discovery).

The Indus Civilization can be defined by its ideology, which emerges as a grand act of creation. Some parts of older traditions survived, since it is clear that there was little change in subsistence, and in the sociocultural, economic and political balances between farmer and pastoralists. But Harappan ideology was based in nihilism. The new social order was founded in urbanization and sociocultural complexity.

Figure 2
Domains of the Harappan civilization

Water and 'cleanliness' were powerful forces in the Mature Harappan ideology. The Mature Harappans were technological innovators.

3.2 Geography

The ancient cities of the Indus were built in riverine settings, in the lower Indus River, the Ravi of the Punjab, and the ancient Sarasvati. The land was quite different in the third millennium, since the now-dry Sarasvati, or Ghaggar-Hakra, was an active stream, and the rolling uplands between the rivers of the Punjab were unirrigated scrub grasslands. Harappan peoples are evidenced from the Iranian border to the Aravalli Mountains, and the Arabian Sea to the Himalayas. There is a Harappan outlier site on the Amu Darya in northern Afghanistan known as Shortughai. In an effort to deal with the cultural geography of the Indus Civilization, their territory has been divided into 'domains'—geographical and cultural regions, possibly with political significance (see Fig. 2).

3.3 Urban Origins

The beginnings of the Harappan Civilization are still not well understood. There was an Early Harappan

Figure 3
Plan of Mohenjo-daro

period (c. 3200–2600 BC) of four roughly contemporaneous phases (Kot Dijian, Amri-Nal, Damb Sadaat, and Sothi-Siswal) without large settlements or strong signs of social stratification. Craft specialization during the Early Harappan was not developed to a marked degree. There was a Transitional Stage between the Early Harappan and Mature Harappan at about 2600–2500 BC, during which most of the complex sociocultural institutions of the Indus Civilization came together (Possehl 1999, pp. 713–23).

3.4 Major Settlements

The major excavated settlements of the Harappan Civilization are Mohenjo-daro and Harappa, each of about 100 hectares, with estimated ancient populations of about 20,000. The third city, Ganweriwala, in Cholistan, is unexcavated.

Mohenjo-daro is the best preserved of the Indus cities (see Fig. 3). It was a planned settlement from the start, and was probably built in the middle centuries of the third millennium BC. The majority of the buildings were constructed of burnt brick, which was served to preserve the site in an extraordinary way. A Lower Town was situated to the west, laid out in a grid, with major thoroughfares running north–south and east–west. Multiroom, and probably multistoried buildings line these streets. The private houses were generally provided with bathing facilities, which were connected to an integrated civic drainage system. These bathing facilities were not privies. To the west of the Lower Town was the Mound of the Great Bath, an artificial hill with a series of public edifices on it. The most important of these were a Great Bath, probably used by some portion of the elite population as a place of ritual ablution, and a warehouse, once thought of as a State Granary.

Other major sites are:

Kalibangan, a regional center of the Indus Civilization near the present border between India and Pakistan on the ancient Sarasvati. It documents the succession from the Early to the Mature Harappan (Thapar 1973).

Chanhu-daro, a former Harappan town, located 70 miles south of Mohenjo-daro. It is important for the presence of a bead- and seal-making workshop (Mackay 1943).

Dholavira, located in Kutch, is midway between Chanhu-daro and Lothal. This was an important way station between major Mature Harappan regions, and was 60 hectares in size. It was fortified, with important water storage and drainage facilities. There is a stratigraphic succession from the Early Harappan to the Mature Harappan and succeeding cultures (Bisht 1999).

Lothal, located in Gujarat at the head of the Gulf of Cambay, provides an understanding of Mature Harappan trade and craftsmanship, and the stratigraphic relationship between the Mature Harappan and the Posturban Harappan in the region. The large brick-lined enclosure at the site, once described as a dockyard, was probably a water storage facility (Rao 1979, 1985).

3.5 Writing

The Indus peoples mastered the art of writing, which was rendered in pictographic form on a range of physical objects. The best known of these are the Harappan stamp seals with writing and an animal device (see Fig. 4). In spite of many claims to the contrary, the Indus script remains undeciphered (Possehl 1996) and the names we use for their settlements are not likely to be those of the Indus peoples themselves.

3.6 Subsistence

Most of the Harappan peoples were farmers and herders who also hunted and fished, with some gathering mixed in. The chief food grains were barley and wheat. They also cultivated at least two forms of gram, the chickpea, field pea, mustard, sesame cotton, and dates. The evidence for the cultivation of rice during the Mature Harappan is ambiguous, but possible. The Harappans used grapes.

The peoples of the Indus Civilization were cattle keepers. Cattle remains are consistently above 50 percent of the faunal assemblage, and often much more. Cattle imagery is also prominent, and makes it clear that this was the most important animal in their culture as well as probably the principal form of wealth. The Harappans also kept water buffalo, sheep, goats, and pigs. Fish, both marine and freshwater, were traded over wide areas.

3.7 Craft and Trade

The Indus craftsmen plied their trades with great skill and had a mastery of pyrotechnology that was a model for its age. Their pottery was fashioned using a number of forming techniques, often in multiple parts that were welded together prior to firing. Bead making was an Indus forte, especially their long, barrel-shaped carnelian examples, sometimes etched. They were accomplished smiths, who smelted copper and tin, as well as arsenic to make bronze. They used gold, silver, electrum, lead, and antimony. Maritime shells, especially the conch, were formed into bangles, ladles, inlays, and other objects. Bangles and other objects were formed also from stoneware and faience, another of the Harappan specialties.

The Mature Harappan peoples were participants in the Middle Asian Interaction Sphere which linked the regions from the Indus to the Mediterranean and Bactria/Central Asia to the Arabian Gulf. This interaction sphere has deep roots and began much earlier than the Mature Harappan, but was at its peak during the second half of the third millennium BC. Maritime trade with Mesopotamia is well documented, both textually and archaeologically. Mature Harappan peoples were also in the Arabian Gulf. The merchandise that the Indus peoples supplied to Mesopotamia, according to the cuneiform texts, are: carnelian, lapis lazuli, pearls, woods, fresh dates, a bird, a form of dog, cats, copper, and gold. The products traded to Meluhha are not as clearly documented, but

Figure 4
A Harappan stamp seal

included food products, oils, cloth, and the like. There are many Harappan artifacts in Mesopotamia, including seals, etched carnelian beads, and ceramics. The Mesopotamian products found in Harappan contexts at Indus sites are very few and there is a considerable disparity in the archaeological record of this subject.

3.8 Religion

The central theme of Harappan religion is a male deity usually shown with bull or water-buffalo horns (see Fig. 5), matched by a number of different female images (Possehl in press). At times, notions of gender may be merged. The plant and animal imagery of the Indus Civilization can be seen as specific aspects of the great duality of the Harappan Great Tradition. The multiheaded animals, 'unicorns' with elephant trunks, perhaps 'unicorns' themselves, as in the terracotta figurines from Chanhu-daro, are all themes appropriate to zoolatry. So are the tigers with bull horns and half human-half quadrupeds seen on the seals, such as the cylinder from Kalibangan (see Thappar 1973, p. 29) (see Fig. 6).

There is widespread evidence for the place of animals in Harappan ideology. Two Indus sealings, in fact, show small animal figures carried above the crowd in a procession. This is just another minor observation that supports the idea that animals were a source of wealth for these people, and entered their ideological world as well. There are many portrayals of composite animals, some with three heads on one body, or tigers entwined, human torsos on four-legged bodies, 'minotaur-like,' tigers with horns, 'unicorns' with elephant trunks and 'unicorns' growing out of trees. There is no good evidence for fire-worship.

Two iconographic themes that appear on Harappan seals have parallels in Mesopotamian mythology, both related to the Gilgamesh epic. The first is shown on a seal from Mohenjo-daro with a half-human female half-bull monster attacking a horned tiger (see Fig. 7). This Harappan seal could be seen as portraying the story of the Mesopotamian goddess Aruru, who created Ebani or Enkidu as a bull–man monster to do combat with Gilgamesh, but who ultimately became his ally and fought with Gilgamesh against the wild animals. The second motif is the well documented Mesopotamian combat scene, with Gilgamesh fighting off rampant animals on either side.

F. R. Allchin sees in a seal from Chanhu-daro a representation of Heaven, (the Bull), who is at once the consort and the father of Earth; and of Earth, who is at the same time the consort of the Bull (Heaven),

Figure 5
The great Harappan male god, once called the 'Proto-Shiva'

Figure 6
Kalibangan cyclinder seal

Figure 7
A possible representation of the Mesopotamia goddess Aruru in combat with a tiger

and the mother of the Bull, her calf; and that these themes can be understood by reference to the Creation myths found in the *Rgveda* and *Atharvaveda* (Allchin 1985, p. 381). This is perhaps our best evidence for a connection between a belief in the Bronze Age being carried forward into historical India.

3.9 The Eclipse of the Ancient Cities of the Indus

Mohenjo-daro was largely abandoned at the end of the Mature Harappan (c. 1900 BC). Similar evidence is available at Harappa, although there is a small occupation there of the so-called 'Cemetery H people.' The situation at Ganweriwala is less clear, since there has been no excavation there, but surface prospecting indicates that the occupation was limited to Mature Harappan times.

Older theories which hold that the cities and civilization were destroyed by invading Aryan tribes, as depicted in the Rig Veda, make very little sense. This is in part because there is no evidence for the sacking of any of the Mature Harappan settlements. Nor is there good chronological agreement between the date of the Vedic texts and the changes seen so graphically at Mohenjo-daro and Harappa. The proposition that a natural dam formed across the Indus River in Sind and flooded out the civilization has been critiqued widely and is not a viable proposition (Raikes 1964, Wasson 1987).

The evidence from the three urban centers, as well as regional surveys, indicates that Sind and West Punjab experienced the widespread abandonment of Mature Harappan settlements at the opening of the second millennium BC. A summary table of the substantive data comparing Mature Harappan and Posturban archaeological assemblages by regions is given in Table 1.

These figures indicate that the 'eclipse of the Harappan Civilization' might hold for Sindh and Baluchistan, but in other regions, notably in the east and to a lesser degree in Gujarat, the course of culture change was different. In these areas there were strong lines of continuity through the early centuries of the second millennium with little, if any, of the 'trauma' that effected Sindh. The stark image one has for Baluchistan in the second millennium BC represents a clear challenge for field archaeology, because it would not seem reasonable to presume that the entire area was deserted at that time. Excavation and exploration are needed to give a more realistic sense of the culture history at that time (Possehl 1997).

Archaeological documentation supports the notion that the locus of culture change for the transformation of the Indus Civilization was urban, those physical settings and institutions most closely associated with sociocultural complexity, and the Mature Harappan ideology. In some places thought of as a part of the Harappan Civilization, this transformation went almost undocumented, as in Saurashtra and the Eastern Domain. There are also strong lines of cultural continuity that link the Harappan Civilization with the early Iron Age and historical South Asia. The

Table 1
Site counts and settled area for the mature and posturban Harappan

	Site count	Average site size (hectares)	Settled area (hectares)
Sindh			
Mature Harappan	86	8.0	688
Posturban	6	5.6	34
Cholistan			
Mature Harappan	174	5.6	974
Posturban	41	5.1	209
Baluchistan			
Kulli-Quetta/Harappan	129	5.8	748
Posturban	0	0	0
Saurashtra			
Sorath Harappan	310	5.4	1674
Posturban	198	4.3	815
East			
Mature Harappan	218	13.5	2943
Posturban	853	3.5	2985

reasons behind the transformation of the Harappan Civilization are still not understood, but it is quite possible that the ideology on which it was based had lost its strength. This might be documented archaeologically by the abandonment of the Great Bath at Mohenjo-daro 200, or even 300, years prior to the abandonment of the city by 1900 BC. It should also be noted that the locus of change during the transformation was urban, and thus centered on Mature Harappan ideology.

4. *The Early Iron Age*

Four archaeological assemblages document the Early Iron Age in South Asia: the Painted Grey Ware Assemblage, the Gandharan Grave Culture, the Pirak Assemblage, and the Megalithic Complex (Possehl and Gullapalli 1999).

4.1 *The Painted Grey Ware Assemblage*

The Painted Grey Ware Assemblage is quite different from that of the Harappan and Post-urban Harappan that preceded it in Northern India and Pakistan. This difference, and the association with iron, tended to set the Painted Grey Ware apart, causing some archaeologists to think of it as intrusive, even foreign to the Indian subcontinent. But archaeologists from the Archaeological Survey of India have done much to dispel this impression through their explorations and excavations in the Indian Punjab. Their excavations at Bhagwanpura and Dadheri have found evidence for Post-urban Harappan occupations followed by an overlap between the Post-urban Harappan and the Painted Grey Ware (Joshi 1993). Thus the culture-historical gap that once separated the Early Iron Age from the preceding Bronze Age in Northern India and Pakistan has now been closed and there is good evidence for cultural continuity between the two periods. Radiocarbon dates indicate that Painted Grey Ware begins around 1000 BC and persists to the middle of the first millennium BC, possibly to 300 BC.

Iron is widely associated with Painted Grey Ware, at times in considerable quantity. At Atranjikhera in the Ganges Valley, iron objects occurred in profusion, along with furnaces, slag, and tools used by smiths, suggesting that iron goods were manufactured at the site, along with smelting. About 500 Painted Grey Ware sites have been discovered. They extend from the Bahawalpur region of Pakistan east across the Punjab into Uttar Pradesh in India. The largest Painted Grey Ware site is Satwadi in Pakistani Cholistan at 13.7 hectares, far from what one would expect for a city. Most of these sites are in the one- to two-hectare range. Since iron is not mentioned in the Rig Veda, the earliest text of South Asia, there is little or no chance that the peoples who occupied the Painted Grey Ware sites were the Vedic Aryans.

4.2 *The Gandharan Grave Culture*

A series of cemeteries and associated habitation sites in northern Pakistan have produced evidence for Late Bronze Age and Early Iron Age life in the eastern portion of ancient Gandhara. Most of the excavations have been conducted at the cemetery site of Timargarha and the settlement of Balambat in northern Pakistan, and in Swat at places like Aligrama, Loebanr I, and Katelai. Other sites are distributed through the southern valleys of the Hindu Kush, and possibly Ladakh.

The earliest of the graves, Period 1 of the Gandharan Grave Culture can be assigned to the Late Bronze Age (c. 1500–1000 BC) and consist of pits lined and covered by stones. Flexed burials with hand-made red and gray pottery, and bronze artifacts were found at Timargarha, followed by evidence for cremation in Period II (1000–800 BC). The latest series of graves, Period III of the Gandharan Grave Culture (800–500 BC), contain iron as well as artifacts of other metals. At Timargarha, seven objects of iron are reported, including a spoon, spear head, and a nail, and, interestingly enough, an iron cheek piece from a snaffle bit that dated between the tenth and the sixth centuries BC.

4.3 The Pirak Assemblage

The site of Pirak is on the Kachi Plain 20 kilometers east of Mehrgarh. There are only four sites of this assemblage, with a few other small sherd scatters in Kachi. Excavations at Pirak took place between 1968 and 1974 (Jarrige and Santoni 1979, Enault 1979). Period I (c. 1750–1200 BC). The site has the characteristic Pirak pottery and well built houses. Stray sherds of Wet Ware, Faiz Mohammad Grey Ware, and other third millennium wares mark some continuity with the Harappan cultural tradition. A compartmented copper stamp seal of Period II does the same. The subsistence regime was based on rice, millets, and other cultivars. There is evidence for the Bactrian camel and an equid, possibly the domesticated horse, in the form of figurines.

Period II (c. 1200–1100 BC) has continuity with Period I, and is defined on the basis of new ceramic shapes and fabrics. Copper/bronze tools continue along with the original subsistence regime. Iron is introduced in Period III (1100–900 BC). Most of the iron was found in a large, basically quadrangular set of buildings constructed directly upon the remains of Period II. The iron artifacts, mostly points and 'bars' are complemented by the appearance of crucibles and iron slag, as well as copper/bronze, lead, silver, and gold artifacts. The appearance of certain gray wares in Period III is important in the definition of this phase of occupation.

4.4 The Megalithic Complex

The Megaliths of South Asia are an immense field of study, far too large to be covered adequately in this short survey. Burial monuments incorporating large stone constructions, associated with habitation sites, are known from prehistoric times in many regions of the Indian subcontinent, principally the north-western mountainous areas of Kashmir and Almora, the Vindhyas, the Deccan Plateau, and the deep south of Peninsular India. Aspects of this tradition may still be present in the subcontinent, as among the Nagas and Khasis of the north-east, and other tribes of the Chota Nagpur, and Bastar regions. The connections have not yet been sorted out for this complex, deep set of historical relationships. Archaeological stratigraphy, radiocarbon dates, and the study of associated materials indicates that the beginnings of Megaliths in south Asia is in the very late second millennium BC, and comes with the mass production of iron. The earliest iron implements associated with the Peninsular Indian Megalithic are simple things like arrow heads, daggers, and domestic vessels. They are also found in the transitional times between this cultural complex and the preceding South Indian Neolithic.

Megalithic burial monuments in South India include dolmenoid cists, slabbed cists, shallow-pit burials, deep-pit burials, umbrella-stones and hat-stones, hood-stones, multiple hood-stones, and menhirs. In excess of 1400 Megalithic sites are known in the Indian subcontinent, with 1116 of these in Peninsular India, about 240 of which have been excavated in some way. Most of these monuments contain human remains and associated burial furniture, sometimes in great quantity. Horses and vehicles are present, along with pottery and metal artifacts including tools, horse trappings, Roman coins, and other artifacts. Iron occurs in abundance. Human remains from the burials have been studied by Kennedy (2000, pp. 326–57).

South Asia: Sociocultural Aspects

1. Area and Population

The term 'South Asia' has come to stand for a group of seven countries: India, Pakistan, Bangladesh, Nepal, Bhutan, Sri Lanka, and the Maldives; and it is in that sense that it will be used in this article. These countries differ greatly in area and population, and in geographical aspect and location. India, with over a billion inhabitants, has the second largest population in the world; the Maldives have a population of only a few hundred thousand people. Nepal and Bhutan are entirely landlocked; Sri Lanka is an island in the Indian Ocean; and the Maldives comprise a chain of more than 1000 islands, most of them uninhabited.

The people of these countries have a shared past by which many of their present social and cultural characteristics have been shaped. Demographically, economically, and politically, India, Pakistan, and Bangladesh are the three most important countries of the region. Until 1947 they were one country. It was partitioned in that year, when India and Pakistan became separate and independent nations. Pakistan was in turn partitioned in 1971, leading to the creation of Bangladesh as a separate country. The first partition was occasioned by differences of religion, and the second by differences of language. In each case the partition was attended by considerable movements of population.

The Indian subcontinent, comprising India, Pakistan, and Bangladesh, was under British rule for a long time, as was also Sri Lanka. The two landlocked kingdoms of Nepal and Bhutan never came directly under British rule and remained relatively isolated from the economic and political forces released by it. Although many social and cultural changes have taken place in the region since the end of colonial rule in the middle of the twentieth century, large parts of it still remain economically backward.

The subcontinent is the home of a very ancient and distinct civilization that may be described as the 'pan-Indian' or the 'Indic' civilization. This civilization had its origin in the Indo–Gangetic plain in the second millennium BC, and it antedates the birth of both Christianity and Islam. Its characteristic bearers today are the Hindus. It has undergone many changes, and its influence has not only permeated throughout India and its neighboring countries but also extended to lands beyond the seas such as Indonesia, Cambodia, and Thailand. India is not only the home of Hinduism, it also gave birth to Buddhism which is the official religion of Bhutan and the predominant religion of Sri Lanka.

2. Religion and Language

Although Hinduism has had the longest and most pervasive influence on society and culture in the subcontinent, Islam too has a strong presence in it, including present-day India. Pakistan is an Islamic country; Bangladesh has a predominantly Muslim population; and although the Muslims are a minority in India, they are a very large minority. The medieval phase of Indian history was dominated by Muslim sultanates and empires; and the Muslim population of Bangladesh, Pakistan, and India taken together make up a considerable part of the Muslim population of the world as a whole.

In South Asia, the divisions of religion cut across those of state and nation, and the region as a whole may be viewed as a mosaic of religious communities, sects, and denominations. India provides an extreme example of co-existence of diverse religious faiths and practices. Although the Hindus predominate in the

country as a whole, there are districts in which Sikhs, Muslims, or Christians predominate. Again, Nepal is a predominantly Hindu country, but there are areas in which Buddhists predominate; in Sri Lanka it is the other way around.

South Asia is the home not only of many religions but also of innumerable languages, and, whether on the plane of cultural values or of social identity, language is as important as religion. Like the divisions of religion, those of language also cut across the boundaries of state and nation. The Punjabi-speaking community is divided between India and Pakistan; the Bengali-speaking community between India and Bangladesh; and the Tamil-speaking community between India and Sri Lanka. Sometimes, as in Sri Lanka, where the Sinhala-speakers are predominantly Buddhist and the Tamil-speakers predominantly Hindu, the divisions of language and religion follow the same line. But this is not always the case. It is common in the subcontinent, if not characteristic, for the divisions of language and religion to cut across each other; there are Muslims, Hindus, and Sikhs among the Punjabi-speakers in India and Pakistan, and Hindus and Muslims among the Bengali-speakers in India and Bangladesh.

Because of historical and demographic reasons India has the largest variety of languages among South Asian countries: it is indeed the most polyglot country in the world. There are more than a dozen literary languages, divided between the Indo–Aryan and the Dravidian families of language. In addition, there are numerous tribal languages and dialects belonging to the Austro–Asiatic, the Tibeto–Burman, and other families. In India, as in the subcontinent generally, the divisions of language correspond more closely to geographical divisions than do the divisions of religion; but here too, population movements through the centuries have led to a certain dispersal of language communities.

If the civilization of South Asia had a design, it was most clearly visible in the Indian subcontinent until its first partition in 1947. Visitors to the area from far and near have been for centuries struck by the distinctness and continuity of that design, and have commented on its influence on society and culture in the different countries of the region. Despite the changes and upheavals of the twentieth century, its distinctive features are still visible, most plainly in India, but elsewhere as well.

3. *Accommodation of Diversity*

A brief sketch of the design of the traditional civilization of the subcontinent will be provided as an aid to the understanding of the multitude of beliefs, practices, habits, customs, and manners prevalent in the region to this day. The first striking feature of this design is the accommodation of diversity. The rich ethnographic record available from the middle of the nineteenth century onward shows an endless, almost inexhaustible, variety in material culture, social arrangements, and religious beliefs and practices. Some of the variation in material traits, in matters such as food, dress, and habitation, may be explained by variations in geographical environment and natural resources. But the cultural variation is far in excess of what would be required by variations of natural environment. For instance, even where its basic ingredients are the same, food might be prepared and served differently among the different castes and communities in the same village.

Then there is the great diversity of social arrangements in matters relating to family, marriage, descent, inheritance, residence, and so on. What needs to be stressed is not simply the diversity of practices but also the diversity of rules; they were the despair of the colonial administrators of the nineteenth century who sought to codify the laws and customs of the subcontinent. There is finally the profusion of religious beliefs, doctrines, rituals, customs, and usages which have been mentioned.

The presence of diversity has been more than a matter of mere existence. In Indian society in particular and South Asian societies in general, it has been sustained by law, custom, and popular religion. Accommodation without assimilation has been a core value of Indian civilization until modern times. It has led to the co-existence of a large multiplicity of beliefs and practices as well as of social groups. Adding new components has not meant discarding old ones, and new and old components of the most heterogeneous kinds have existed cheek-by-jowl to a greater extent than in other civilizations. The Indian subcontinent has been and still largely remains a vast mosaic of tribes, clans, castes, sects, and communities, each with its own identity.

4. *Collective Identities*

The second distinctive feature of South Asian societies is the predominance of collective identities. In the past, what counted was not so much the individual as the group of which he was a member by birth, and this continues to a large extent even now. It has often been said that traditional Indian society was a society not of individuals but of castes and communities. As has been noted, there was a great multiplicity of groups, and this multiplicity was a feature even of small local communities. The members of a single village might observe different religious practices, speak more than one language, and belong to a dozen or more different castes and subcastes.

Collective identities were maintained by fidelity to the customs of one's ancestors and by rules for the regulation of marriage. In course of time, subtle differences developed in craft practices, dress, and

ornamentation, marriage rules and ritual observances between groups having the same origin. Each group and subgroup maintained its distinctive style of life and transmitted it from generation to generation. The group preserved a sense of its own identity despite changes in its social position. The high value placed on the accommodation of diversity allowed and indeed encouraged each group to retain a strong sense of its own identity.

The persistence of collective identities may be illustrated with two examples from the subcontinent. The first relates to what has been called 'the Hindu method of tribal absorption.' In the past, tribal groups which were relatively isolated from the wider society sometimes established relations with that society, discarding some old practices and acquiring some new ones. In this way, a tribe was often transformed into a caste but, despite a change of name and to some extent also of social position, it preserved its old collective identity. The second example relates to the survival of caste identities despite changes of religion. The census reports of British India show that in the Punjab, on both sides of the present international frontier, the same castes, such as Ahir, Jat, and Gujjar were present among Hindus, Muslims, and Sikhs. When a section of a Hindu caste embraced Islam or Sikhism, it adopted a new religion but did not abandon its old and distinct collective identity.

5. *Hierarchical Organization*

The accommodation of diversity did not mean that the tribes, clans, castes, sects, and communities that were allowed or even encouraged to maintain their distinctive identities were all placed on the same plane of equality. Diversity was organized on the basis of hierarchy and not of equality, and that is the third distinctive feature of the traditional civilization of South Asia. It is true that all communities were allowed or even encouraged to maintain their distinctive styles of life; but they were not all equally esteemed. While all premodern civilizations were hierarchical to a greater or lesser extent, the principle and practice of hierarchy were carried furthest on the Indian subcontinent, particularly among the Hindus.

Hierarchy is not simply a matter of inequality in the distribution of material resources or of life chances; it is above all a system of values according to which the division of the world into social groups deemed to be of unequal worth is a part of the natural scheme of things. The hierarchical conception of society found its fullest expression in the classical Hindu texts known as the *Dharmashastra* which provided the framework for Hindu law. Although the law has changed radically in the direction of equality, the bias of custom is still often in favor of hierarchy.

The Hindu caste system has been represented as the prototype of a hierarchical social order. But hierarchy extends beyond caste and permeates social relations and social institutions of the most diverse kinds among Hindus, Muslims, Buddhists, and others throughout the region. Despite the doctrine of equality characteristic of Islam, agrarian relations and gender relations are cast in a deeply hierarchical mould in Pakistan and to some extent also in Bangladesh.

6. *The Village*

Colonial administrators throughout the nineteenth century saw the subcontinent as essentially a land of villages. They have left behind memorable accounts of the unity, the self-sufficiency, and the continuity of the Indian village. A large number of village studies have been conducted in India by professional anthropologists and others since the country became independent in 1947. Similar studies have been conducted in Sri Lanka, Pakistan, Bangladesh, and Nepal. In the paragraphs below there follows a brief account of the broad social characteristics of the Indian village, many of which may also be found in villages in the other countries just mentioned.

In the past, the Indian village had a distinct physical identity which became particularly prominent during floods, famines, and other natural calamities. Most villages were nucleated although there were also dispersed villages, depending in part on the terrain. The life of the village was based on an economy of land and grain, and its rhythm was, and to a large extent still is, governed by the annual cycle of agricultural activities. The village also has an annual cycle of religious ceremonies and festivals, and the two cycles are related closely. With the development of transport and communication in the twentieth century, and particularly since the 1950s, the isolation of the village is becoming progressively reduced, although not at the same pace in all parts of the country or the region. The less isolated villages are now becoming urbanized, though in a highly uneven manner.

The social morphology of the village shows considerable variation in terms of size and internal differentiation. Irrigated villages in river valleys and close to the ancient and medieval centers of civilization tend to have an elaborate structure; 'dry' villages in the remote areas tend to be smaller and simpler in their structure. Only the latter may be described as communities of peasants. The former are often highly differentiated and stratified. They include noncultivating landowners, owner-cultivators, cultivating tenants, sharecroppers, and agricultural laborers, in addition to groups of families associated with various specialized crafts and services, usually on a hereditary or quasi-hereditary basis. Agrarian reform and the expansion of the market are changing some of this, although many of the older features remain.

Its relative isolation and self-sufficiency and its well-knit division of labor between agriculture, crafts, and

services gave the Indian village a certain unity. In the nineteenth century—and even later—it was often described as a 'little republic.' But it was not a republic of equals. In the larger irrigated villages the social boundaries between the superior, intermediate, and inferior sections of the community—landowners, tenants, agricultural laborers, priests, potters, and scavengers—were clearly maintained. If there was a certain unity in such villages, as indeed there was, it is best described as a 'vertical unity.' The unity of the village has been weakened in recent decades, but that does not mean that the inequalities have all disappeared.

While it is true that South Asia is a land of villages, one cannot ignore the presence of towns and cities in it. The subcontinent has cities going back to ancient and medieval times, and India had urban centers before most of Europe did. In the past, towns and cities grew around places of worship, the courts of kings and princes, and commercial and trading centers. Colonial rule led to the creation of a new kind of city, mainly along the coast, such as Calcutta, Madras, Colombo, Bombay, and Karachi. In the years since the end of colonial rule, industrialization has added to the population of existing cities and led to the creation of new ones. The urban middle class and the industrial working class are important factors in the economic and political life of contemporary India.

Returning briefly to the Indian village, a prominent place was occupied in it by caste. Indeed, caste may be viewed as the social basis of the division of labor in it, and the differentiation and stratification in the Indian village cannot be understood without taking caste into account.

7. *Caste*

Caste is an institution of great antiquity, and it has shown resilience in the face of the economic and political changes of the twentieth century. In its origin and fullest development, it is an institution of the Hindus, but near analogs of the Hindu caste system may be found among Sikhs, Muslims, and Christians on the subcontinent and among Buddhists in Sri Lanka; and it is of course very important in the predominantly Hindu population of Nepal. On the doctrinal plane, Hinduism, Buddhism, and Islam are different from each other; on the plane of everyday life at the local level, social divisions among Hindus, Muslims, and Buddhists act in broadly similar ways in most parts of South Asia.

The caste, the subcaste, and even the subsubcaste, to each of which the term *jati* may be applied, maintained its identity and continuity through the regulation of marriage. The most general rule was the rule of endogamy, and among Hindus this was supplemented by the rule of hypergamy. In the past, Hindu law prohibited intercaste marriage except under very specific conditions; the law has now changed, but the bias of custom is still in favor of endogamy among the Hindus, and to some extent also among the others.

Every caste or *jati* was in principle associated with a specific occupation, although agriculture was open to most if not all castes. The association between caste and occupation was stronger among the Hindus than among the others, but from the end of the nineteenth century, it began to weaken even among the former. A very important factor behind the weakening of the association has been the emergence, since the middle of the nineteenth century, of a large and increasing number of occupations that are 'caste-free' in the sense that they have grown outside the framework of the old division of labor based on caste.

The different castes are socially ranked; indeed, it is in the caste system that the principle of social ranking finds its most extreme and elaborate expression. In South Asia, castes are ranked among all religious groups, but the ranking is not as rigid or as exhaustive among the non-Hindus as it is among the Hindus. Caste ranking among the Hindus was expressed in the idiom of purity and pollution, but that idiom is now less pervasive than before, and new criteria of social ranking, having little to do with caste in the traditional sense, are becoming increasingly salient, particularly in the urban areas.

8. *Family, Kinship, and Marriage*

Given the great significance of the rules regulating marriage and in particular the rule of endogamy, it is not surprising that there is a close association between caste and kinship. Through repeated intermarriage from generation to generation, all the members of the local section of a caste or subcaste become related to each other by real or putative ties of kinship. This is generally true of all the major religious and linguistic divisions of South Asian society.

Much has been written about the prevalence of the joint family in the subcontinent and the changes it is undergoing as a result of urbanization, industrialization, and modernization. The Hindu undivided family had certain legal characteristics peculiar to itself, and some of these are still recognized by the law in India. One important feature of the family in the subcontinent, whether among Hindus, Sikhs, Muslims, or Christians, is that marriages are still to a large extent arranged by parents and older relatives, and the new couple generally lives in the parental home immediately after marriage even though it may set up a separate household after one or more children are born.

Reference has already been made to wide variations in the rules of descent, inheritance, and marriage across the many and diverse communities that inhabit the region. But through all these variations, kinship has a significant place in social life everywhere and

among all communities. Relatives are numerous and various, and the obligations of kinship are cherished and cannot be denied easily. The rules of endogamy act against the formation of real ties of kinship between members of different castes; but they do not prevent the formation of fictive ties of kinship between them. The idiom of kinship is used extensively in interpersonal relations across castes and communities in villages throughout the region.

Changes are undoubtedly taking place in the size and composition of the household, particularly in the rapidly growing cities. But even where nuclear households outnumber extended ones, the matrix of kinship within which they operate gives them a different character from their counterparts in the West. The boundaries between households are porous, and no household is secure against intrusion by cousins, uncles, aunts, nephews, nieces, and grandparents.

In discussing caste, kinship, and family it is impossible to ignore the subject of gender, although only a passing reference to it is possible here. Despite variations according to language, religion, and caste, and between patrilineal and matrilineal communities, women have since time immemorial occupied a subordinate position in South Asian societies. Polygamy was sanctioned by law among both Hindus and Muslims. In India it is now prohibited by law among Hindus but not among Muslims; it is permitted by law in Pakistan, and attempts to regulate polygamy by law have had little success among Muslims. The position of women is changing in all countries and among all communities in South Asia, although the change is highly uneven. Here, more important than the variations of language, religion and caste are those that arise from education, occupation, and income.

9. *New Institutions and Classes*

The first impediment against attempting a concise account of society and culture in South Asia arises from the problem of variation; the second impediment arises from the problem of change. Two important developments in the subcontinent since the middle of the nineteenth century have to be noted. These are, first, the growth of open and secular institutions such as schools, colleges, universities, libraries, laboratories, hospitals, law courts, and newspapers; and, second, the emergence of a new middle class based on a new educational system and a new occupational system. These two related developments have taken place everywhere, but most conspicuously in India where they are now a significant feature of the social and cultural landscape.

Open and secular institutions are sustained by norms and values that are very different from the norms and values by which the traditional institutions of South Asian societies have been sustained. The new institutions are often at odds with the old ones which exert various kinds of pressures on them and sometimes threaten their very survival. At the same time, and particularly in a country like India, they have grown to an extent that makes it difficult to dispense with them or to devise alternatives to them that are fully in harmony with the institutions of the past. As a result, the conflict of norms and values has become endemic in these societies.

The new middle class is both the creation and the creator of the open and secular institutions just referred to. The origins of the Indian middle class go back to the first half of the nineteenth century. Its first beginnings took place in the presidency capitals of Calcutta, Bombay, and Madras in each of which a new university was established in 1857. The graduates of these universities and of the others which came up in course of time became administrators, managers, lawyers, doctors, scientists, teachers, and clerks. The Indian middle class is now very large, at well over 100 million persons. Although it is still a relatively small proportion of the population of the country, it is among the largest and the most differentiated of the middle classes in the world.

The emergence of a new and increasingly dynamic middle class has not led to the effacement of the old identities and distinctions based on language, religion, and caste. Those still remain, although they are now coming to be organized in a different way. The middle class in turn is differentiated not only in terms of occupation, income, and education, but also in terms of language, religion, and caste. Caste and class reinforce each other in some respects and cut across each other in others. While there is some individual mobility, it does not lead to the equal distribution of all castes and communities among the different economic strata. The social mosaic is, thus, becoming in some sense even more complex than in the past.

South Asian Studies: Culture

This article discusses studies of culture in South Asia, from colonial times to the present, focusing on the changing meanings of the term, the contribution of various disciplines to research in culture, and recent developments in cultural studies proper. In the South Asian context, culture can mean the cultural heritage of the nation–states of the region, cultural practices or ways of life, community identities, as well as culture in the aesthetic sense, including literature and the arts.

1. Colonial Beginnings

The first elaboration of the idea of an Indian culture occurs in the colonial era, through the combined efforts of European Indologists and Indian nationalists. The Indologists' construction of an Indian tradition, based largely on textual sources, was picked up by the nationalists, who divided the cultural realm into 'two domains, the material and the spiritual,' conceding the West's superiority in the former, while claiming sovereignty over the 'spiritual' domain, which bore the 'essential' marks of 'cultural identity' (Chatterjee 1993). This realm was to be out of bounds for colonial reformers, but at the same time, as Chatterjee has argued, the nationalists had their own project 'to fashion a ''modern'' national culture that is nevertheless not Western.'

At this stage, however, terms like tradition and civilization were more prevalent, and the meaning of culture was not fixed. In 1910, during the era of *swadeshi* (the movement for the promotion of native industry), Ananda K. Coomaraswamy, a cultural nationalist and art historian who included even present-day Sri Lanka in his map of Indian culture, describes culture as a 'capacity for immediate and instinctive discrimination between good and bad workmanship' and a 'view of life essentially balanced.' Here culture is understood as a historically developed human attribute, an assimilated refinement of taste that goes with a certain settled, rooted way of life ('restlessness is essentially uncultured'), recalling the ideas of William Morris (Coomaraswamy 1994). It is this meaning that seems to have prevailed when the nationalists translated culture as *sanskriti*, a word now used in most of the major Indian languages, while Rabindranath Tagore's suggestion of *krishti*, which is closer to the English word in its derivation from *krishi* or cultivation, never gained acceptance even in his native Bengal, in spite of his being the most influential cultural figure of his time.

In its substantive definition, the national culture included the classical heritage in the arts, traditions of education (the *guru-sishya parampara*), family structure (the joint family was celebrated as quintessentially Indian), and the deep-rooted customs and practices of village India. The twentieth century witnessed a widespread campaign for the reform, rediscovery, and revival of the classical arts. Thus a traditional temple dance around which a system of 'courtesanship' had developed was taken and 'purified' to create 'Bharatanatyam,' one of the currently widely practiced national dance forms. The textual tradition was revisited in the light of Orientalist scholarship and selectively annexed to the national cause, with the *Bhagavadgita* emerging as a sort of national text, embodying the spiritual distinction of Indian civilization. The search for a 'living tradition' that would supplement the classical heritage led to the celebration and appropriation of folk arts and village crafts (Guha-Thakurta 1992). Early nationalist constructions of India's cultural heritage tended to focus exclusively on Hindu achievements, ignoring the Islamic heritage, on the basis of an ideological negation of Muslim rule as the cause of decline of Hindu civilization.

Intellectuals like Rabindranath Tagore and the progressives in the national movement on the other hand tried to construct a more inclusive cultural history, locating themselves in the modern present and acknowledging the irreversible re-making of Indian culture and society by colonial intervention. Jawaharlal Nehru, who became India's first prime minister, was a key figure in this project but it was a sociologist, D. P. Mukherjee, who produced the first extended reflection on the idea of a 'modern Indian culture.' In the 1940s, when Mukherjee wrote his book, the cultural climate seems not to have been very hospitable to such an idea, given the widespread preoccupation with the revival and preservation of the disappearing cultural heritage of the nation. Mukherjee's project in the book is to reflect on the contemporary cultural situation in the soon-to-be-independent nation, to inventory the cultural, social, and intellectual heritage and its effectiveness in the present, as well as to produce a concept of the present moment as constituted by a diversity of forces, traditions, and processes. Uncharacteristically for his time, Mukherjee, a partisan of a socialist future for India, distances himself from any approach to culture that privileges nationalism, and insists on a sociological account of culture as 'the whole social process' (Mukherjee 1979). Rejecting the idea of culture as heritage, he locates modern culture in a society marked by 'the artifice of an unreal class-structure.' He attacks the idea of India as a land prone to the mystic and the

spiritual, and is, throughout, preoccupied with the most pressing issue of the time: that of the coexistence of Hindus and Muslims, and other minorities, within a modern nation–state.

2. Tradition and Modernity

The 1940s and 1950s are a crucial period for the emergence of culture as an object of study. In this period we see the triumph of social anthropology over sociology as the disciplinary home of culture studies, and in consequence, the decline of Mukherjee's idea of a modern Indian culture as defined by contemporary struggles between social forces, whether traditional, entrenched, emergent, or imposed. The overwhelming sense of the contemporary, which favored a strictly sociological approach, was soon replaced by a more historicist approach, as the dualism of tradition and modernity, by far the most influential paradigm in South Asian cultural studies, took hold.

The key figures in this shift were M. N. Srinivas and Milton Singer, an associate of Robert Redfield. In 1952, Srinivas published *Religion and Society Among the Coorgs of South India*, a work which, Singer asserts, demonstrated how the social anthropological method could be applied to a Great tradition. It was Redfield who proposed, in his project for the study of civilizations at Chicago (Srinivas had been in California), the fundamental distinction between Great and Little Traditions, roughly equivalent to 'higher' and 'lower' orders of cultural practice, the former more reflective, more systematic, and textually elaborated, while the latter is considered to be more spontaneous, fragmented, primitive. Until then the anthropological method had only been employed in the study of the so-called primitive societies, but Redfield was proposing a research project of global sweep to study the cultural heritage of humanity. Singer undertook the Indian portion of the study, concentrating on the south Indian city of Madras, later published under the title *When a Great Tradition Modernizes: An Anthropological Approach to Indian Civilization*, with a foreword by M. N. Srinivas. Singer 1972, argued that the Indian Great tradition (the use of the singular was to attract criticism) 'was culturally continuous with the Little Traditions to be found in the diverse regions, villages, castes and tribes' and that therefore, 'even the acceptance of "modernizing" and "progress" ideologies does not result in linear forms of social and cultural change but may result in the "traditionalizing" of apparently "modern" innovations' (Singer 1972). The most significant element in this formulation is the suggestion that a civilization with a tradition evolved over the *longue duree* acquired the strength to assimilate ideas and changes coming from outside, and to convert them into organic elements of its own make-up.

One of the most influential and controversial concepts in this new disciplinary thrust was Srinivas's 'Sanskritization' that, together with 'Westernization' served to explain social change in modern India. Sanskritization, a process by which the lower orders of traditional caste society aspire for a higher social status by adopting the customs and manners of the upper castes, was seen as one of the ways in which the continuity of Little and Great Traditions was maintained. Singer's concept of 'cultural performance' illustrates both the notion of cultural continuity between Great and Little Traditions and that of the absorption of modern influences. Singer defines a cultural performance in the broadest possible manner, including within its ambit plays, concerts, and lectures, and the cinema and radio, as well as 'prayers, ritual readings and recitations, rites and ceremonies, festivals, and all those things we usually classify under religion and ritual rather than with the cultural and artistic' (Singer 1972). In other words, the anthropologist's, the Indologist's, and the aesthetician's definitions of culture have here been fused into one, to constitute a seamless continuum of culture, object of the new social anthropology. The disruptions and displacements brought about by colonial modernity, which were foregrounded in Mukherjee's sociology of the present, are now located as challenges which the Great Tradition takes in its stride. A. K. Ramanujan, a pioneer of Indian folklore studies, also based in Chicago, rejected the Great and Little Tradition dichotomy and asserted that 'cultural traditions in India are indissolubly plural' and organized according to the principles of context-sensitivity and reflexivity (Ramanujan 1999).

3. Culture and Development

Around the 1960s, the dualism 'culture and development/modernization' begins to vie for space with its elder cousin Tradition/Modernity. Culture and development acquired wide currency at a more grassroots level, as development projects, undertaken by the nation–state and international agencies, began to transform the territory. While the Tradition/Modernity paradigm was prevalent among Indologists, anthropologists, and the nationalist intelligentsia, 'culture and development' rallies a wide range of social science disciplines including economics, political science, sociology, gender studies, as well as environmentalists and other grassroots activists and NGOs. 'Culture and development' the decolonizing, modernizing nation–state's version of Tradition/Modernity. Culture in this framework can be a hindrance to development, as in Amartya Sen's famous formulation about the 'missing women,' who are the victims of cultural constraints on women's access to food. Superstitions and prejudices nourished by entrenched cultural practices can come in the way of educating illiterate people in family planning, health, education,

hygiene, and other developmental concerns. Culture can also be a resource: traditional cultural forms can be usefully employed to spread developmental messages. Ecological debates have thrown up notions such as 'masculinist forestry' and turned to women as good agents in preserving the environment (Dietrich in Menon 1999). Thirdly, there is also the question of 'cultural survival,' cultural rights of minorities, tribes, and other groups, which come under threat from development's blind onward march and the imposition from above, of Western models of linear progress and development.

The most sustained critique of development and modernization from a point of view that affirmed the validity and continuity of Indian traditions was undertaken by Ashis Nandy. Recouping a Gandhian 'critical traditionalism,' Nandy attacked the deracinating effects of Western rationality, individualism, and other ideologies adopted by the Nehruvian state and the middle-class intelligentsia in its developmental campaign. Against the Western tendency to emphasize rupture as the precondition of change, Nandy, following Gandhi, emphasizes continuity. Against the rigid separation between male and female, between individual and individual, Nandy argues that fluid identities and ambiguous selves are more characteristically Indian. The imperative of cultural difference and diversity, of multiple rationalities, also gives rise to a critique of Western science and its hegemonic universalism, in the work of Nandy, Tariq Banuri, and others. The assertion of cultural specificity occurs in other fields of knowledge as well. Thus Sudhir Kakar, a psychoanalyst, has argued for a culture-sensitive psychoanalytic practice and has elaborated his own analytic picture of the Hindu psyche. There is a substantial body of psychoanalytic readings of South Asian culture, including the work of Girindrashekhar Bose, the first Indian analyst, Philip Spratt, Erik Erikson, Gananath Obeyesekere, and Nandy (see Vaidyanathan and Kripal 1999). There is sometimes a tendency to culturalism reduction in these writings, producing a domesticated psychoanalysis from which the fundamental alienation that psychoanalysis posits at the threshold of human subjectivity is wished away. More recently, Lacanian psychoanalysis has found favor among film studies scholars.

Nandy's rise to eminence as an ideologue of decolonization roughly coincides with the emergence of 'postcolonial studies,' galvanized by the publication of Edward Said's *Orientalism* in 1978. In India, Saidian postcolonial studies as well as studies of development undertaken in the social sciences were influenced by Nandy's discourse. Postcolonial theorists like Gayatri Chakravorty Spivak and Homi Bhabha also shared this space of the critique of colonial reason. Apart from this, another important development was the emergence of *Subaltern Studies*, a series of volumes to which mainly historians contributed, in which colonial and nationalist historiography was critiqued and a 'subaltern history,' of ordinary people, of tribal, and lower caste groups, during colonial rule and after, was undertaken. Culture plays a very important role in this project, especially when there is an emphasis on the spontaneity of 'peasant insurgency' and tribal uprising, and the question of the subaltern mentality. Postcolonial studies, the *Subaltern Studies* project, and the critique of development and modernization by Nandy and others, together constitute the legacy of cultural studies in the 1970s and 1980s.

4. *Globalization and Local Cultures*

In the 1990s, the terms shift again, as globalization arrives on the scene. In 'globalization and local cultures' we have the third and most recent version of the Tradition/Modernity paradigm, where again the emphasis is on questions of cultural survival in the face of globalization, the resilience of local cultures, and their ability to 'consume modernity' on their own terms. Arjun Appadurai has offered a comprehensive theory of globalization and the emergence of what he terms 'public culture.' Appadurai treats culture as 'the dimension of difference,' of identity based on difference, emerging after the rupture of globalization, in a world where he considers nation–states to be on their last legs. Global relations and movements, or 'flows,' have a more decisive bearing on human lives today than national identification. Others are less sanguine about the effects of globalization, and more skeptical about the nation–state's imminent demise. Appadurai is confident about the ability of societies to assimilate modernity, which is what globalization transports: although we have traveled far, we are still within Singer's paradigm where traditional societies respond to and assimilate modernity in their own ways.

The three variants of a paradigm that have been examined so far all share one thing in common: they approach the question of Indian culture on an international plane. In each case, one term in the opposition refers to a force, a process—modernity, development/modernization, globalization—which is of extraneous provenance, while the other term indicates the culture that is at the receiving end. None of them was developed with specific reference to India, which is only one of the sites to which they are applied. The concept of culture employed in all three variants is also predominantly anthropologically defined.

5. *National Culture*

Within India, other paradigms of cultural analysis have devoted themselves to reading and analyzing the stuff of national culture. Some of them emphasize a distinctive native culture with its own rationality, its sense of self, and strategies of survival. There are also attempts to forge an indigenous conceptual series for

the study of Indian culture, to reconnect with indigenous intellectual traditions after the 'amnesia' of colonialism. Beginning in the mid-1980s and throughout the 1990s, as questions of globalization assumed importance, the domestic politics of communalism, which resulted in popular mobilization and widespread violence against minorities, led to a fresh attempt to reexamine the past. As the Hindu nationalists put forth versions of history that supported their political activities, liberal and left intellectuals, particular historians, revisited the past to reassert the plurality and ineluctable syncretism and hybridity of India's cultural heritage (Thapar 2000). The question of multiculturalism, and of cultural rights, also became more urgent as cultural and ethnic conflict was seen as threatening the secular-democratic fabric of the nation–state.

Social anthropologists have noted the difficulty in the Indian instance, of separating a sphere of culture from those of religion, community, caste, etc. Caste has been a central category for understanding Indian society, from Dumont's notion of *homo hierarchicus* to more recent studies of caste conflict in a contemporary setting, where caste has more to do with cultural and political identity, than with social position. This shift to caste as identity brings it into the realm of culture, and various studies have asserted, against the idea of a universal dynamic of Sanskritization, that caste groups enjoy a measure of cultural autonomy and strive to maintain their cultural identity through the formation of networks across regional and language barriers. *Dalits'* (literally, 'the oppressed,' a term now used for the lowest castes in the caste hierarchy, especially the 'untouchables') struggles for social justice have included literary movements and other forms of cultural expression, as well as attempts, under the broad rubric of folklore studies, to record and study the traditional cultural forms prevalent among these groups.

Feminist scholarship has engaged with questions of culture at many levels (see Menon 1999, Thapan 1997). For nationalists woman was the guarantor of cultural identity and continuity. In the confrontations between the nationalists and the colonial government, and after independence, in the confrontations that arose between religious groups and the nation–state, women became the object of reformist attention and patriarchal protectionism. Two recent debates arising out of events in the 1980s that have had a lasting impact on the character of the national polity have posed a challenge to feminist scholarship, raising questions of the competing claims of women and minority cultural rights and the law, and of female agency in traditional practices that are offensive to a modern, secular outlook.

These relate to an incident of *sati* (self-immolation by a widow on her husband's funeral pyre, a practice that was thought to have died out) in a village of Rajasthan, and the case of Shah Bano, a divorced Muslim woman who filed a suit for maintenance from her former husband, leading to a debate about the competing claims of the state and the community's own institutions to handle such disputes. Using these incidents from the 1980s and the legislative moves that followed each, the anthropologist Veena Das has investigated how 'a web of creative or destructive tensions in the matter of cultural rights' determines relations between communities, the state, and the individual (in Menon 1999). Feminist scholarship has shown how communities deploy culture as a means to assert the supremacy of community rights over women's rights as citizens in a democratic polity. At the same time, on the Uniform Civil Code issue, which has been intensely debated in recent years, feminists have become more sensitive to community laws which, in certain instances, may be more beneficial to women, in opposition to the Hindu nationalist deployment of the discourse of citizenship to press for a civil code that will prevail over all other culturally specific laws (see Menon 1999).

The realm of Indian politics is also continuous with that of contemporary popular culture, in particular the culture of popular cinema. South Indian cinema culture has been the breeding ground of some of the most powerful political leaders to emerge in the states of Tamil Nadu, Andhra Pradesh, and Karnataka. Sociologists have studied the ways in which the unique film cultures of these regions have functioned as a platform for electoral politics. The fan clubs of these popular film stars are today an important feature of everyday political and social life, in some cases emerging as militant frontrunners in campaigns for a linguistic national identity.

Meanwhile, the impact of the Birmingham school of cultural studies and a reconstructed anthropology's search for new objects of research have spurred projects for cultural studies in India, notably studies of communities of reception for the popular film, popular cultures of photography, music, etc. Film has come to be seen as the emblematic cultural institution of modern India, and in recent years film studies have acquired legitimacy as a discipline, with a multidisciplinary resource base. The importance of globalization notwithstanding, there is a distinct national sphere of cultural studies, which draws upon many of the ideas and paradigms mentioned above, but locates its concerns within the national space. One instance is the study of aesthetic modernism. Postcolonial societies attract development and modernization approaches, where cultural issues are subsumed under sociological, economic, and political questions. Studies of modernism, on the other hand, are concerned with the emergence of artistic practices and ideologies that participate in the international modernist movement while speaking from within (though not only about) their own national space. Modern literature, cinema, theatre, architecture, painting, and other fine arts have been the object of this critical appreciation

(Kapur 2000), with the *Journal of Arts and Ideas* serving as an important forum for the theorization of an Indian modernism.

In the contemporary field of cultural studies, the traditional disciplines like anthropology are joined by new discourses like postcolonial studies, feminism, psychoanalysis, semiotics, post-structuralism, and postmodernism (see Niranjana et al. 1993, Spivak 1988). Ethnographies of cultural communities, including traditional ones as well as newer consumerist types of community, feminist critiques of gendered cultural forms and expressions, and of patriarchal ideologies, film and television studies, and studies of other modern, technology-dependent cultural forms, caste politics, popular religion, histories of modern and popular art, and political cultures are some of the types of cultural study being currently undertaken in India, by scholars belonging to a range of social science and humanities disciplines (see Manuel 1993, Niranjana et al. 1993, Thapan 1997, Vasudevan 2000). The concept of culture has undergone a definite shift of emphasis from ancient heritage and primitive ways of life to the more unstable and complex practices and processes of contemporary existence. The past coexists with the present, as it does in any social formation, but not in a historicist time-space. Cultural studies increasingly regard the present moment as a synchronic dimension, where all constituent elements, whether ancient or recent, foreign or indigenous, constitute a symbolic network with its own unique properties, making it radically contemporary (Dhareshwar 1995). Forging the tools for analyzing this complex cultural space is the task of the future.

South Asian Studies: Economics

South Asia is the sister that was all dressed up, but did not make it to the ball. At the time of independence at the close of the first half of the twentieth century, India, Pakistan and Sri Lanka (Ceylon at the time), the larger countries of the region, all seemed poised for successful development. Sri Lanka's per capita income was much higher than Korea's in 1950, and India and Pakistan were at income levels comparable to those of Korea. These South Asian countries had inherited a reasonable infrastructure, both physical and administrative, and, freed of colonial shackles, all truly seemed ready for the 'tryst with destiny' that Jawaharlal Nehru articulated for India.

Fifty years later, South Asia is far behind East and Southeast Asia in standards of living. While the region has made progress, the East Asian 'miracle' puts it to shame. The damning comparison is not just with the most successful developing countries;

> South Asia is fast emerging as the poorest, the most illiterate, the most malnourished the least gender-sensitive, indeed, the most deprived region in the world (Haq 1997, p.2).

What went wrong? This piece examines the economic development experience of South Asia and the lost

opportunities for the region's people. It touches on long-standing issues of growth vs. development, state vs. market, and agriculture vs. industry, as well as the more recent themes of political economy, decentralization, liberalization and reform. It discusses the role of economic ideas and of political ideologies and compulsions in shaping the course of economic policies and region's economies. The experience of the region's economies stands as a mirror of those ideas and ideologies: South Asia has been a laboratory for economic research on development.

1. India

We begin with objectives. Newly independent nations unambiguously wanted to catch up with the West that had ruled over them, to develop, to modernize, to industrialize—three somewhat different goals. Industrialization was the clear winner out of these. In India, the government was to occupy the 'commanding heights' of the economy, and engineer economic growth led by import-substituting heavy industrialization. The Soviet Union seemed an attractive model at the time, and formal planning exercises were launched in India and in Pakistan soon after independence. A Marxist view of an imperialist world economy, Fabian socialism, a colonial-trained elite, and an economy shaped by wartime controls, all met on common ground to define how India proceeded. The initial intellectual framework for Indian planning came from non-economists, but, at the time, the general approach of a vast, centralized resource optimization exercise was a common one in global thinking on economic development. Dissenting views to this model, accepted by most development researchers at the time, were rare, though not absent.

Through the nineteen-fifties, this model was reasonably successful. There were no purges, and no mass starvation (as economist Amartya Sen has suggested, these facts are connected by the constraints of a democratic polity). India did not break apart. And the economy grew steadily, at a rate much faster than in colonial times, 3.5 percent a year (later caricatured as 'the Hindu rate of growth'). Agriculture was not neglected, if not particularly favored. Land reform was legislated, but not really implemented, though it seemed to be called for on grounds of efficiency as well as equity. Agricultural pricing and food distribution also received attention from academics and policymakers, with the goals of increasing marketable surpluses and providing adequate food to the poor. Innumerable studies were performed on the productivity of Indian agriculture, using data collected through extensive surveys. What really wrought lasting change in agriculture, however, was the introduction of high-yielding varieties of wheat and rice. This 'green revolution' first took place in Punjab, where land holdings were relatively equal, and where the state government had created an infrastructure of market and rural roads. Central government irrigation projects also played a key role.

The Indian planning exercise was a peculiar one, in that the mechanisms for implementation were weak: this was not Soviet-style command planning. At the same time, the functioning of markets as resource allocation mechanisms was incredibly constrained, almost stifled: prices (for internal and external trade) as well as investment and production decisions were bureaucratically controlled and greatly distorted. Theoretically, these distortions were meant to promote equity (e.g., rationing basic foodstuffs) and efficiency (where social costs and benefits supposedly diverged from private ones). In practice, they did a little for the former, and impeded the latter. The government's 'license-permit-quota *raj*' epitomized the 'rent-seeking society,' where incentives for activities aimed at capturing a share of the current economic pie dominated those that would increase the pie itself. In fact, the experience of India seemed to inspire the coinage of the term 'rent-seeking society' by an economist, Anne Krueger (1974).

Compromise and consensus were viewed as necessary for India's continued unity, and this worsened the inefficiencies of the system. The nostalgic Gandhian ideal of a village-based *Ram Rajya* that rejected industrialization was accommodated through subsidies and protections for handlooms and small-scale industries in general: 'big business' could not encroach on their domain. A related populism that grew in the 1960s, as political competition greatly intensified, led to further restrictive polices. War, drought, and commodity price shocks worsened the performance of an economy hobbled by policies that led to inefficient capital use, despite increasing rates of savings and investment. Academic economists—a scattered few through the 1970s (Jagdish Bhagwati, Padma Desai, and T. N. Srinivasan being among the most prominent), then many more in the 1980s—pressed for economic reform, but ideology and vested interests in the economy and polity (as elegantly analyzed by Bardhan, 1984) engendered delay. A more pragmatic approach to economic policy-making made a halting entrance in the 1980s, and Indian economic growth picked up, to 5 percent along with a documented increase in productivity growth (Ahluwalia 1985, 1991, Goldar 1986). However, this took place in a manner that made India more vulnerable to external shocks. The balance of payments crisis of 1991 therefore ushered in a new wave of reform. The collapse of the Soviet Union and the success of East Asia demolished ideological barriers, and India considerably liberalized government controls on domestic and trade-related economic activities. The result has been a further improvement in India's economic growth rate.

Despite its relative economic failure, India has succeeded in building resilient political structures

during the five decades after independence. Its constitution was drafted expeditiously, and has stood the test of time. Fiscal and monetary institutions such as government budget processes and the central bank have remained transparent, accountable, and reasonably effective. In particular, the central bank has excelled in monetary management within its given constraints. Quasi-government bodies such as the Finance Commission that governs central-state fiscal transfers have developed expertise and reputation, and a slew of new regulatory bodies, such as the Securities and Exchange Board of India, promise to improve the quality of economic governance. Gandhian-inspired decentralization, after many half-hearted experiments that met with limited success, has taken root in a constitutional amendment strengthening local governments. If properly implemented, this decentralization may at last be the vehicle for effectively delivering health, education and social services to the bulk of India's poor, something that the planning process ultimately failed to do. The institutional developments in India again parallel broader research on the economic role of governance institutions (e.g., Williamson 1996): ideas help shape policy.

2. *Pakistan*

If consensus to the point of gridlock has often seemed to characterize India's development path, the word that describes Pakistan might be 'contradictions.' In many respects, policies followed in Pakistan were quite similar to those in India: import-substituting industrialization, controlled markets and prices, relative neglect of broad-based agricultural development and of health and education for the rural masses, and half-hearted attempts at land reform. This was part of the same economic development research consensus that shaped India's post-independence policies. At the same time, Pakistan diverged from India in significant ways. On the economic front, Pakistan was earlier in allowing the private sector freedom for industrial growth. It was able to squeeze resources for industrialization from the agricultural sector more effectively than India. It relied much more heavily on foreign aid and private remittances from overseas workers, and its domestic savings rate has been much lower than India's. Overall, as researchers would agree, the result was effectively a more efficient use of capital, and, up to the last decade or so, a higher growth rate than in India.

The starkest contrast with India, according to many analyses of Pakistan's economic performance, has been in the country's governance. Whereas India has evolved a robust, if still flawed, democratic system, Pakistan has essentially been an authoritarian state, where interludes of populism with the trappings of democracy can not disguise the essential nature of the system as a contest between three overlapping and related governing elites: the bureaucracy, the military, and the large landowners, with a small number of wealthy industrialist families acting as a background influence. Furthermore, ethnic divisions have sharpened this contest. While this sounds similar to Pranab Bardhan's (1984) analysis of India, the degrees of inequality and rent capture, and lack of political checks and balances in Pakistan have differentiated the two countries. When Pakistan was created in two parts, East and West, the East was more populous, but the West contained the bulk of the elite. Differences in language, culture and economic structure all stood against religion as the only common point. This cleavage heavily influenced the nation's political and economic development. Historians of the political economy of Pakistan, such as Omar Noman (1990) argue that real democracy was impossible for the Western elites to accept. Policies that squeezed the East's agriculture to benefit the West's industrial development exacerbated the divide. From this perspective, the country's split in 1971 was almost inevitable.

After the creation of Bangladesh from East Pakistan, the remainder of Pakistan faced further internal conflicts, reflecting a mix of class and ethnic divisions. The loss of the eastern wing sharpened the focus of these western conflicts. Society was further destabilized by the Soviet invasion of Afghanistan in 1979. This made Pakistan strategically more important, and led to greater foreign assistance, economic and military. This helped the economy in terms of overall growth, but exacerbated problems of governance, with a huge influx of arms into the region. When the Soviets withdrew, the problems for Pakistan remained, and persist. Around the same time, the decade-long oil boom in Persian Gulf wound down, curtailing the remittances from Pakistanis working there, and having a significant negative impact on the economy.

If we have described Pakistan's development path by its relation to that of India, this only reflects the consciousness of the nation. While those who govern India and determine its policies certainly are aware of Pakistan, India's larger neighbor to the north, China, is often more of a mental presence. The most popular view, typical for such a large nation, has probably been just one of insularity: 'India is different.' For Pakistan, however, India is the large neighbor, that helped to dismember it in 1971, and that, even after three wars and numerous skirmishes, maintains a firm grip on Muslim-majority Kashmir. Pakistan spends a much larger proportion of its GNP on defense than does India—as much as a third of its budget—and always must be aware of its giant neighbor.

However, Pakistan does not necessarily follow India in policy-making. Import substitution, bureaucratic control, and heavy industrialization at the expense of agriculture, all were chosen in Pakistan and in India because of their common history and a common understanding of the history and the possibilities of

development. Pakistan embarked on a path of economic reform shortly before India, in 1990, because of external pressures resulting from economic crisis—partly caused by external shocks, but ultimately reflecting the failure of the previous direction of policy. However, Pakistan may have a harder road ahead than India: its lead in per capita income has disappeared over the last few years, and it lags dramatically in human development indicators such as literacy and school enrollment, particularly for girls. Its population, too, is growing much more rapidly. Large inequalities and poor governance structures exacerbate the tensions inherent in its situation. Economists and political scientists would agree that this is not a promising situation for further economic development and growth.

3. *Bangladesh*

If Pakistan's prospects have dimmed recently, those of Bangladesh have grown brighter. When the nation was born, it had suffered from close to 25 years of economic stagnation as East Pakistan, and a devastating war of independence. Some observers dismissed it as basket case. It underwent the same cycles of military rule and authoritarian populism as Pakistan did after 1971. It also struggled with government-led development via Five Year Plans. While Bangladesh still trails India and Pakistan in measures of income, poverty and human development, it has shown progress in recent years, and has begun its demographic transition to a lower population growth rate, at income levels much lower than had been predicted by demographic research at that time.

Some researchers suggest that what distinguishes Bangladesh from its larger South Asian cousins is its relative societal homogeneity. Therefore, after initial conflicts among the elite, the nation seems to have settled into an approach that is delivering some broader-based human development. Agricultural production has improved substantially since independence, and the countryside has proved to be an impressive laboratory for nongovernmental organizations such as the Grameen Bank (rural microcredit) and the Bangladesh Rural Advancement Committee (community development for the poorest). This approach, drawing on the strengths of the nation's civil society, contrasts favorably with more centralized, government-led approaches in India and Pakistan. Of course each of these countries does have its own success stories, and building on them in the future will be important for sustained development. Not surprisingly, theoretical and empirical analyses of rural microcredit and targeted community development in South Asia have been very common (as documented, e.g., in the World Bank's annual World Development Reports).

Bangladesh also shares institutional problems with India and Pakistan: lack of systems that support widespread entrepreneurial attitudes, grossly inefficient formal financial sectors, and outmoded systems of taxation and tax administration. In each of these Bangladesh lags behind the other two nations, and its economic reforms in the last few years, where these institutional weaknesses are critical, make the reform process seem like pushing on a string, according to economists such as M. G. Quibria (1997) One thing that can potentially help Bangladesh is India's external liberalization—international trade within the region has been very low in general, despite the absence of the hostility that has limited trade between India and Pakistan. Bangladesh may also be in a position to move into export niches vacated by Southeast and East Asian countries moving up to more sophisticated manufacture. This possibility, and the importance of international trade in general, has been widely recognized by economists. In agriculture, also, India may matter: Bangladesh is a vast delta for rivers that flow from India. Controlling and using that water requires international cooperation that (as documented and analyzed by Crow and Singh, 2000) has only recently begun to develop.

4. *The Himalayan Nations*

International trade and water resource development also loom large for India's Himalayan neighbors, Nepal and Bhutan. The economic development of these small, land-locked nations has been, and will be, heavily influenced by India's own economic success, the openness of its economic regime, and its strategic concerns with respect to China. Nepal has had its own economic experiments with five year plans, and its own struggles with developing democracy. Its infrastructure is poor, but, in a more open regional economy, the potential of its natural resources is high.

5. *Sri Lanka*

Sri Lanka and the tiny Maldives are the island nations of South Asia. They are outliers in other respects too, with higher incomes and higher human development indices than their continental cousins. Yet Sri Lanka has undergone some of the same problems as the others. At independence, its economy was somewhat depleted by the costs imposed by World War II, but it was still relatively rich, with a strong base in exported cash crops. Post-independence policies that nurtured the population in terms of health, education and access to food gave the country a persistent lead over the continental region in broader human welfare, and all would agree with the position emphasized by Amartya Sen (1981) that these are significant achievements. Yet growth has been slow, and the lack of adequate economic growth has cost Sri Lanka heavily, by exacerbating ethnic conflict that has, proportionate to the nation's size, been the worst in the region.

The reasons for Sri Lanka's relative failure, as in the case of India and Pakistan, involve some themes that are familiar in analyses of the development of the region: populism, government policies overly restrictive of private entrepreneurship, direct government control through nationalization, failure to attract enough foreign investment bringing the right mix of capital and technological know-how, and severe distortions in the foreign trade regime. Both in the failure of its economic policies and of management of ethnic tensions, Sri Lanka's most striking comparison and contrast is with Malaysia, rather than the larger nations of South Asia. The economic policy mistakes of the 1950s and 1960s fed into austerity measures in the 1970s and the explosion of conflict between Tamils and Sinhalese in the1980s. This meant that, while reforms began earlier than in India or Pakistan, they have not been undertaken in the best conditions. Sri Lanka has managed to grow somewhat more rapidly recently, and to reduce the role of primary products by establishing labor-intensive manufacturing exports as a significant part of the economy, but the story remains one of lost time and lost opportunity.

6. *Prospects*

If all the major nations of South Asia, despite numerous differences in initial conditions and trajectories, made similar economic policy mistakes over the last five decades, can we lay the blame on common causes? The discipline of economics and its practitioners share some responsibility. The understanding of the workings of markets and entrepreneurship, and the roles played by information, incentives and innovation, was certainly incomplete when these countries embarked on their attempts at guided development. Economists who were skeptical of the abilities of government to be a guide or director of the economy were in a minority initially. Yet by the time economists began to be more forceful in their criticisms, policies had created entrenched interests, and reform has not come easily.

This is not to argue that the state has no role. Currently, economists agree that the issue is not simply 'state vs. market,' or the degree of state intervention along some one-dimensional conceptual continuum. There are many dimensions. The state does some things better than others. It may do nothing very well, but it may still be better than the market in some spheres of the economy. And, even if it does not 'govern the market' (to use Robert Wade's (1990) characterization of East Asia's experience), it certainly 'enables the market,' through the maintenance of law and order, and through a judicial system that enforces contracts. The state also provides safety nets for the unfortunate, physical infrastructure, and, sometimes, social-order-preserving redistribution, all through a system of taxation and expenditures. In all this, the state is itself the agent of interest groups and constituencies. Part of the lesson of South Asia's experiences of economic development is therefore a practical one: what does and does not work in economic policy, and the proper roles of state and market.

Returning to common causes for South Asia's relative failure, ideology, society and history all have their place—though not the catchall scapegoat of culture. The ideology of Marxism and its Soviet incarnation cast a long shadow, especially over India. Societal divisions have certainly made the tasks of governance and development enormously more difficult throughout the region, right from the partition that gave birth to Pakistan. Vertical cleavages have been as pernicious as horizontal ones, and the neglect of human development in South Asia may ultimately, perhaps, be blamed on the rule of an elite very different from any that exists in the social structures of Southeast and East Asia. Finally, history always matters, whether one begins with partition, or colonization, or even further back. While we have presented what might be termed the consensus of research on particular aspects of South Asia's experience, it is difficult to argue that overall agreement exists on the relative importance of the different factors that have shaped the region's development in the past half-century.

While history is always important, though, it sometimes becomes a fondly remembered golden past. For nationalistic politicians, 'In Search of Lost Time' has that Proustian relevance. In this case, however, the lost time is really that of midnight's children, the generations of South Asians who failed to realize the full promise of independence. Luckily, though, the ball does not end at midnight, and midnight's grandchildren may do much better than the previous generation. Perhaps economists have learned enough in the past few decades to help them.

South Asian Studies: Environment

Cultural traditions of ecological prudence evolve in sedentary societies inhabiting stable environments, when populations are close to resource saturation and technology is stagnant (Gadgil and Guha 1992). Accordingly, the emergence, maintenance, erosion, and restoration of ecologically prudent behavior in the south Asian region is examined here. Following sections sketch colonization of the subcontinent, evolution of agricultural society and resource partitioning amongst occupation-based caste groups, and environmental erosion triggered by the colonial conquest and the resultant industrial society. The concluding section discusses the implications of ongoing globalization and emergent environmental conflicts. Differing research perspectives on important issues, both within and beyond the subcontinent, are also examined.

1. *Colonization*

1.1 *Waves of Immigration*

The first major migration into south Asia was that of Austric-speaking, i.e., Australasian, peoples from the northeast about 65,000 years ago (Mountain et al. 1995). Subsequent numerous waves of immigrations were propelled by technological innovations outside the subcontinent, as underlined by Western-trained subcontinental researchers (Gadgil and Guha 1992). The farming of wheat, barley, cattle, and pigs in the Middle East around 10,000 years ago propelled several immigrations into south Asia of Dravidian-speakers approximately 6,000 years ago. Similarly, the farming of rice, buffalo, etc. in southeast Asia 8,000 years ago drove immigrations of Sino-Tibetan-speakers into the south Asian subcontinent about 6,000 years ago. Indo-Europeans dominated the latest immigrations around 4,000 years ago, following domestication of the horse in central Asia 6,000 years ago. Lastly, Europeans, pushed by resource scarcity following the 'Little Ice Age' and armed with superior ships and cannons, invaded India in the sixteenth century to control the spice trade.

These manifold invasions have shaped, genetically and culturally, the most diverse society of the world, as Western researchers have revealed (Mountain et al. 1995). This persistence of over 50,000 tribe-like endogamous groups, characterized by hunting–gathering/shifting cultivation cultures, in a complex agrarian and later industrial society, is very unusual. This situation has resulted from the peculiar regional tradition of subjugation and isolation, in contrast with the worldwide practice of elimination or assimilation of subordinated communities by dominant groups. This diversity is accompanied by extreme specialization of occupation, as subcontinental researchers emphasize (Gadgil and Guha 1992). The diversity of environmental regimes throughout the subcontinent, ranging from warm coastal mudflats to snow-clad mountain peaks, also nurtured the cultural diversity.

1.2 *Conservation Ethic*

In the relatively predictable tropical and subtropical environments, the primitive hunter–gatherer society evolved largely into sedentary, territorial tribes with populations close to carrying capacity. This promoted the evolution of cultural practices of ecological prudence, rationalized within a religious framework. Such traditions could have changed a little when hunters–gatherers advanced to the level of shifting cultivators, as is evident from the age-old practice of maintaining sacred groves (tree clumps protected against harvests by local people because of their religious significance), still followed in areas of shifting cultivation tracts such as the Himalayas. Harvests from such relict forest patches are prohibited or rigorously regulated by the local community. Even these communities showed some further occupational specialization by age and sex; such as shamans and traders of honey, shells, feathers, etc.

2. *Agricultural Civilization*

2.1 *Agricultural Evolution*

A sedentary agricultural civilization evolved gradually in favorable situations, employing paddy cultivation

in the river valleys and maintaining large cattle herds. The resultant surplus promoted the evolution of a predatory warrior social group, specializing in physical protection of the surplus and its usurpation as tax, as well as the expansion of territories. This accompanied the so-called Aryan invasion from west and central Asia, with horse chariots and iron axes easily clearing forest tracts for cultivation. Consequent deforestation in the Gangetic plains began around 1100 BC, proceeding to the southeastern end of the subcontinent by 600 BC (Gadgil and Guha 1992).

This new agricultural–pastoral society organized into sedentary, largely self-sufficient village communities seemingly nurtured many tribal practices of ecological prudence. The generation of a large surplus by agriculturists and herdsmen promoted the expansion of trade, including that in luxury goods such as spices, fine cloth and precious metal, which were exported to other continents. This strengthened the caste of traders, while tribal shamans evolved into the priestly caste claiming a monopoly over codified knowledge. The peasants and artisans constituted the lowest groups.

2.2 *Religious Evolution*

The hierarchical religion then practiced called for extensive sacrifice of animals, especially oxen. Such sacrificial ceremonies also necessitated extensive tree cutting for the holy fire. As the Gangetic plains became saturated with cultivation, woodlands and pastures shrank and oxen became a critical source of agricultural power and trade. As a result there was a strong protest from the peasants and traders against animal sacrifice and tree cutting, reflected in two new religions, Buddhism and Jainism, by the sixth century BC (Gadgil and Guha 1992). Respect for all forms of life and nonviolence was taken to extremes by Jainism, where one sect wears no clothes but for gauze over the nose to avoid trapping and killing insects. Jainism is strongest in the northwestern subcontinent, a region with a particularly fragile environment, where the dangers of overexploitation are acute.

2.3 *Resource Impoverishment*

Kautilya's Arthashastra, a manual of statecraft dating from the third century BC, near the peak of imperial expansion in the region, provides insights into the ecologically prudent practices of the rulers, such as maintaining royal hunting preserves (Gadgil and Guha 1992). Poaching wild elephants from forests along the boundary maintained for military purposes attracted the death penalty. Large empires began to disintegrate after the seventh century AD, probably due to the gradual decline of agricultural fertility over a millennium. This eroded the dominance of traders and their main religions Buddhism and Jainism by the tenth century. This resulted partly from a revival of Hinduism, through transformations such as the incorporation of several tribal deities, and the abandonment of ritual animal sacrifice and consequent meat consumption. This revival consolidated Hindu caste society, which now manifested rigid barriers of endogamy such as those found among the tribes.

2.4 *Resource Partitioning by Castes*

However, unlike the tribespeople, the Hindu castes do not occupy exclusive territories and have a specialized mode of subsistence, which used to be hereditary. In a small region, one caste specialized in catching fish, a second in herding buffaloes, a third in making salt from sea water. A fourth caste may have tapped liquor from palm trees, a fifth may have cultivated paddy, and so on. Thus, about 10 to 50 sedentary castes would coexist nearly independently within an area of about 1,000 square kilometers. The same area would also be visited by dozens of other nomadic castes of artisans, pastoralists, and entertainers. These nomadic castes also ranged over fixed areas. Traditionally, all these castes carried out barter with one another.

The most remarkable feature of the caste society was the regulation of competition for limited resources through the diversification of resource use (Gadgil and Guha 1992) with a biological perspective, such as the partitioning of food resources for organisms with differing ecological roles in an ecosystem. Resource regulations included intracaste and intercaste territoriality manifested in land ownership, livestock category, or grazing seasons. Besides resource use diversification, this caste society also exhibited traditions of regulated harvests, some of which continue even today. An example is the setting up of sacred ponds upstream to protect fish breeding pools and confining their extraction during, a particular season, so ensuring good harvests.

Besides religious motivation, villagers are also often aware of the direct benefits of sustainability practices, such as the utility of bird guano from protected village heronries as farm manure. Such understanding has manifested folk conservation practices beyond focal habitats to species protected by specific communities. For instance, the Bishnois, a sect of Hindus in the semiarid northwestern subcontinent, sacrificed several lives by hugging their sacred trees to prevent the soldiers of the local king from cutting down the trees for a lime kiln for the king's palace. Such strict religious protection has meant that even today Bishnoi villages are green islands with freely roaming peacocks, blackbucks, and blue bulls, amidst an otherwise desolate landscape. Incidentally, while the sacred trees are very useful to the Bishnois, their animals are protected and fed with stored grain despite the crop depredation they inflict.

Conservation practices amongst rulers continued, such as the moratorium on felling green trees, imposed by King Shivaji in western India in the seventeenth century. This king's navy established the first plantations of teak trees long before the celebrated British plantations in Malabar two centuries later. Conservation traditions were not confined to tribal peoples or Hindus, as evident from sacred ponds around Muslim shrines in Bangladesh (Gadgil and Guha 1992).

3. *Colonial Conquest*

While the subcontinental society responded to environmental constraints by resource specialization and cultural prudence, Europeans responded to resource scarcity by exploring new lands and technologies around the fifteenth century. The ensuing industrial revolution tilted the balance of power from landlords to traders and industrialists. The British government gradually whisked away the common property resources in the subcontinent and actively eroded the traditions of prudent communal management such as the sacred groves, condemned by Westerners as superstitious or obstacles to state control (Brandis 1884).

Subsequent to the British invasion, reckless hunting and timber harvesting took place. This denuded the forests and drove animals such as the Asiatic lion and cheetah nearly to extinction. The realization of the harm gradually promoted so-called scientific forestry, which nevertheless had to hire continental foresters, as Britain had no tradition of scientific forest management. Eventually the British granted protection to royal hunting preserves and established some new game preserves. Meanwhile the continued breakdown of the traditional economy and the solidarity of village communities forced the indiscriminate use of common property resources, now owned by the government but with usufruct privileges to local people. Indiscriminate grazing, tree cutting, fishing, hunting, and other destructive activities increased, further eroding the impoverished resource base. The forests reserved for the exclusive use of the government, for example to provide timber for the emerging railway network, did not fare well either as local people agitated for cultivation on this forest land and failed to cooperate in its management. Thus, beyond the decimation of the environment, the British period marked an erosion of the conditions that had fostered an ethos of ecological prudence.

4. *Industrialize and Perish?*

4.1 *Subsidized Profligacy*

The British looked at the subcontinent initially as a source of cheap raw material and, later, as a market for manufactured goods. In consequence, they deliberately destroyed traditional industries such as handicrafts and prevented industrialization from gathering pace. When several countries in the region became independent after World War II, they vigorously promoted mechanized industrialization as a remedy for the maladies of an impoverished resource base and growing population. The philosophy 'industrialize or perish' was quickly embraced by the urban elite, while farmers and artisans could hardly participate.

Unbridled industrialization opened the gates to mass exploitation of the natural resources at throw-away prices to industry. Highly subsidized land, water, and power, and unregulated pollution soon severely eroded the environment and resources. However, the resultant phenomenal profits posted by the industries far exceeded the output of the agricultural sector, allowing industries to shift the resource base. Such immunity promoted ecological profligacy and prudence was thrown out of the window. Concomitant elitist conservation initiatives were confined to the conversion and expansion of hunting reserves into wildlife sanctuaries and national parks, further cornering the resources of the dependent masses, triggering fresh ecological conflicts that haunt most large projects such as irrigation and power schemes even today.

4.2 *Grassroots Conservation*

This profligacy of the social groups that have a wide resource base and import goods from all over the world, termed 'biosphere people,' contrasts with the prudence inherited by the masses, termed as 'ecosystem people' (because they are dependent on the consumption and trade of immediately available resources from predominantly natural ecosystems). The latter group is dependent on protecting its neighboring resource catchment (Gadgil and Guha 1995). This is contradictory to the Western, Malthusian approach which attributes environmental degradation to population explosion of poor people (Ehrlich 1969). Regional researchers retort that the much higher resource consumption levels of the Western elite cause greater environmental degradation. Imposing the costs not only of environmental degradation but also of conservation by the elite on the masses was soon met with fierce resistance.

Ensuing social conflicts prompted many fresh initiatives of ecological prudence on the part of the masses, who were left with no option but to protect their resource base. For instance, northern Himalayan people were agitated to discover that besides encouraging ecological insecurity, the government was starving their cooperative forest-based industry for the benefit of distant private sector industries. This led to a tree-hugging protest by local people along the lines of the Bishnoi, mentioned above, with women in the forefront, against industrial tree felling. It became famous as the Chipko ('hugging') movement.

Chipko triggered unprecedented environmental awareness and mass conservation movements. The repercussions are socializing the government-sponsored afforestation drive, though enhancing the stake of villagers in managing existing forests is proving much slower.

Fishermen along the coast are agitating to prevent mechanized fishing trawlers from overfishing and destroying the spawning beds, ultimately eroding the fish stocks. This causes immense harm to traditional fishermen who avoid fishing during the breeding season and use nets with a large mesh size so that small fish can escape. The traditional fishermen are also opposing the aquaculture industry, as it promotes prawn cultures by landlords with heavy chemical inputs that ultimately pollute and destroy the estuarine fisheries which sustain small fishermen. In places, these conflicts have even assumed bloody dimensions. Often, multinational corporations (MNC) provide the finance for such environmentally damaging and socially inequitable projects.

5. *Globalization*

The global dimensions of even localized conservation conflicts became more evident after the recent ban by the USA of marine food imports from India. The USA has appealed to the World Trade Organization (WTO) to declare a multilateral ban. The ban was justified on the grounds that it would foster conservation, as the Indian trawlers lack expensive turtle-excluding devices, primarily used and sold by the developed countries. The WTO has ruled out a multilateral ban, acceding to India's request that environmental disputes be addressed at more appropriate platforms such as the international Convention on Biological Diversity (CBD). The threat to mass livelihoods from the global elite still looms large under the guise of environmental protection, with developed countries unsuccessfully trying to impose environment-related trade restrictions. This trend was seen at the Seattle millennium conference of the WTO in 2000. If the trawler ban was ever implemented, it would not only affect Indian trawler owners but also conservation-minded masses such as the traditional fishermen who eke out a living from fish exports.

Another example of an environmental conflict with the global elite is the transgenic cotton controversy in southern India (Gadgil and Utkarsh 1999). Here, cotton farmers were faced with disaster after crop failure due to extensive pest attacks in 1998. Not long afterwards, a multinational agro-corporation announced that it was carrying out ongoing field experiments prior to the likely release of a pest-resistant transgenic cotton variety. This prompted widespread protest from environmentalists and farmers, who feared not only that the transgenic strain might pose environmental hazards, but that if the MNC had a monopoly over the strain they might end up dependent upon it. Further, such transgenic crops might accelerate the erosion of traditional cultivars, thus undermining environmental efficiency and farmers' rights to their seeds.

The controversy about large dams on the River Narmada and consequent unfair widespread displacement is a rare case where unrelenting protest by the masses resulted in the withdrawal of an international investor, the World Bank. However, transnational investors do not generally display such restraint, especially if they are wooed by local governments unmindful of the environmental hazards and related protests by local people.

6. *The Future*

Future environmental conflicts may be glimpsed from the ongoing legislative reforms taking place in the south Asian region (Gadgil and Utkarsh 1999). For instance, the Indian biological diversity bill and patent act amendments intend to compel even foreign agencies to pay royalties for commercial applications based on Indian biological diversity and related folk knowledge. This might prevent cases like patenting of innovations based on Indian biodiversity and knowledge abroad, as in the infamous cases of Basmati rice and Neem-based pesticide where patents were obtained abroad on improved rice variety and process to stabilize volatile Neem extract, without sharing any profits with the original South Asian farmers. The bill proposes spending such funds on incentives for promoting grassroots conservation. It also buttresses people's resource rights, in theory, by requiring the consent of relevant village councils for any development or conservation project. Implementation of such intentions is awaited, but many national and international projects are already encouraging villagers' involvement in sustainable management of even government property, enthused by the success of village forest protection committees in Nepal and India or water users' associations in India. Other initiatives drawing on substantial information industry strengths in the region include registration of people's knowledge of biodiversity use, to prevent unfair patenting.

While social systems within the region are slowly adapting to resource conflicts, new international conflicts are emerging, such as that over the CBD biosafety protocol. This has implications for the competition between local cultivars and the largely foreign-controlled genetically modified organisms (GMOs). GMOs are feared for their likely environmental and social hazards.

Debate between the countries of the region and developed countries also concerns country contributions to the causes and mitigation of the global climate change. While developed country agencies fix the blame on deforestation and rice cultivation in the region (Anon 1992), regional researchers claim the opposite

(Achanta 1993). Regional cooperation unfortunately seems to be lacking, unlike the case in other tropical regions. For instance, SAARC (the South Asian Association for Regional Cooperation), is hardly cohesive and vocal in pushing its case at the CBD and climate change negotiations, whereas its east Asian, African and South American counterparts are very vocal and united, probably due to people's pressure in those regions.

The partitioning of the people's stake in the environment forms the focus of ongoing environmental research debate in the south Asian subcontinent. Those claiming to represent grassroots communities shun all that is modern and Western as environmentally destructive (Shiva 1993). Other Western-influenced regional researchers reject such categorization of conservation efforts (Gadgil and Utkarsh 1999), and advocate strategies to cope with globalization rather than to denounce it and presume that it is avoidable.

7. *Conclusion*

In future, conservation and livelihood conflicts might escalate both nationally and internationally. The evolution of cultural practices of ecological prudence has characterized much of the subcontinental society until now (Kothari et al. 2000). However, the emerging dominant social groups such as corporate industries are unlikely to inherit this traditional ecological prudence or to evolve an alternative paradigm. This stems from their ability to harness resources from many alternative locations, employing evolving technologies and measuring benefits solely in monetary terms. This profligate behavior is rationalized in the framework of economic growth and technological progress. The article emphasizes that ecological prudence might be maintained only through an innovative blend of the emergent corporate culture and the masses that inherit the conservation traditions.

South Asian Studies: Geography

The landscape of south Asia contains tremendous natural and cultural diversity, and the geographic study of the region exhibits an equally wide range of themes. During the last quarter of the twentieth century, geographers shifted focus from a regional studies approach, which provides general overviews of key geographic characteristics of the region, to a problem-oriented approach that highlights contemporary social and environmental issues confronting it. This article briefly introduces the regional geography of south Asia and then examines in detail the themes that inform contemporary geographic study of the region.

1. *Regional Geography of South Asia*

Many of the early regional geographies of Asia contain sections on south Asia and provide useful summaries of background information about society and the physical environment across the Indian subcontinent. An exclusive focus on the region developed in Asian regional geography after the 1947 partition of the subcontinent and the emergence of the newly independent countries of India and Pakistan. The early regional studies offered comprehensive overviews with selected coverage of specific geographic details, notably population and economy. In the 1960s, important studies of individual countries in the region appeared, which provided greater depth and attention to local scale geography (Karan 1963).

The regional approach to south Asian geography gained in sophistication during the 1970s, when geographers blended the study of regional patterns with a critical focus on process and on changes in society and the landscape. A study of the historical evolution of south Asian geopolitics appeared in the form of the monumental *A Historical Atlas of South Asia*, which offered new insights into the ebb and flow of imperial power and the design of regional landscapes (Schwartzberg 1978). The historical geography approach not only highlighted the magnificent periods of civilization in the region, but also showed how the contemporary organization of society and land owes its spatial origin in great part to the political past. The connection between history and modern times occupies a nexus of geographic study about south Asia. The historical perspective in regional geography was advanced further in the 1970s with studies that interpreted the spatial organization of the subcontinental economy according to the impact of colonialism. This work called specific attention to the role of the British in fundamentally altering not only the globalization of the regional economy, but also the administration of south Asian society and the usage of land and other natural resources. The regional geographies, including atlases of the subcontinent that have appeared since the 1970s, blend the comprehensive and historical approaches (Farmer 1983). Much of the contemporary study of south Asian geography, however, favors a problem-oriented approach over the regional perspective.

2. *Contemporary Themes of South Asian Geography*

The general issues of modern society drive the current study of south Asian geography. Prominent among these are the place of tradition in modern life, the function of the peasant economy amid globalization, the dilemma of development, territorial movements and ethnic conflict, and environmental change. The coverage of these thematic areas is distributed at varying scales across the region, from village-level study to international inquiry.

2.1 *The Place of Tradition in Modern Society*

The wealth of tradition in south Asia is one of its defining features and the subject of much study on the cultural geography of the region. The geography of India, for example, is commonly defined according to cultural practices, and the spatial organization of the landscape results in part from such complex traditions of culture as pilgrimage and sacred places (Bhardwaj 1973). The maintenance of traditional practices in contemporary life reflects their continued importance even while the material conditions of life rapidly change. Among the various roles of culture in the region is the importance of tradition in determining how people use the land to obtain their basic needs. Environmental outlooks, organized according to indigenous knowledge systems, remain significant features for the geographic study of local conservation strategies and people-based environmental movements. Modern agriculture and forestry initiatives in south Asia owe a great deal to the traditional systems of environmental management that obtain in specific localities, and, indeed, the latter define in many cases the prospectus for sustainable development in the region.

2.2 *The Function of the Peasant Economy*

The geographic study of peasant agriculture illuminates the place of culture in nature, as well as the social structures that organize village production systems. Farming systems research throughout southern Asia informs our knowledge about such farmer practices as crop type and rotation strategies, gender divisions of work, and the application of technologies in village economic systems. The harmonization of village agriculture with the vagaries of climate is the focus of much study, notably on the impacts of severe weather events and flooding on rural production systems in places such as Bangladesh, where natural events combine with human settlements to create potential hazards. Droughts and famine compelled early geographical studies on the nature of village farming systems, but the persistence of poverty within the peasant economy of south Asia is what drives much contemporary geographical inquiry into the function of the peasant economy. The contradictory nature of the green revolution and the political economic structures that determine how farmers participate in agricultural development programs are the focus of some important geographical studies that employ a social theory perspective.

Geographers working in the cultural ecology and political ecology traditions have successfully utilized a systems perspective to examine the linkages between environment and society within the peasant economy. In this perspective, the household is the nexus for material and energy exchanges between forests, pastures, and farm fields. The main contribution of this approach to peasant studies is its ability to analyze the interplay of a diverse set of environmental and societal arrangements, which collectively define the function of the village economy. Generally, the systems approach is utilized at the micro or village level, but it also has been applied successfully to the regional setting, for example in the Punjab, with the application of agricultural land-use models.

2.3 *The Dilemma of Development*

Geographical inquiry into south Asian development processes has a strong backing among both the early

regional geographies and the more recent thematic studies. In the former case, the various development indices (both economic and social) are applied on a country basis to map patterns of development, but generally such efforts are flawed because too little attention is given to explaining the geographic inequities that appear on the maps. The more recent development studies in south Asian geography take a very different tack. They examine foremost the processes that contribute to the overall low level of development in the region and to the unequal distribution of development successes within it.

The efforts of British geographers working with the Overseas Development Group at the University of East Anglia have led the way toward a political–economic explication of poverty in Nepal (Blaikie et al. 1980). Their work, guided by center–periphery relations theory, has contributed a great deal to our understanding of underdevelopment not only in the Himalayan kingdom of Nepal but throughout the subcontinent. The role of infrastructure in the development of spatial economies, the significance of land tenure relations for resource entitlement, and the geographic variation in wealth and poverty related to structural problems within national economies are the major foci for such studies.

Most recent south Asian development studies by geographers have adopted a critical perspective that views poverty as a social construction rather than a product of ineffective economic policy. It is argued in this case that poverty is a result of social histories wherein some segments of society (or indeed entire countries) are made dependent upon other societal elements (or countries). In this vein, the role of foreign assistance as a development vehicle is challenged on the basis that it mainly serves Western interests and simply promotes further dependency among the poor nations of south Asia (Shrestha 1997). Furthermore, the geography of development in south Asia is shown to reflect inequities in the distribution of foreign assistance as a result of poor planning, fiscal mismanagement, and official corruption. The social theory and critical perspectives found among recent development geographies of the region lend sophistication to the conventional, neoliberal interpretations of development that describe most early regional geographies of the region.

Development geography in south Asia pays considerable attention as well to urban and regional planning. Detailed analyses of urban systems show the role of cities as growth nodes for regional economic development and modernization. Micro-scale studies of south Asian cities examine such phenomena as urban migration and the development of fringe squatter settlements, the role of the informal economic sector in meeting the needs of the urban poor, and the environmental impacts of urban growth (Dutt 1994). In rural south Asia, especially in the northern mountains, geographers have examined closely infrastructures associated with regional development, mainly road alignments, and have shown how these make formerly remote areas more accessible to the influences of globalization and modernity. The rural development studies also consider the geographic role of tourism, which is shown to widely transform regions throughout south Asia with its impacts on society and the natural environment (Zurick 1995).

2.4 *Territorial Movements and Ethnic Conflict*

The fractious nature of the south Asian landscape derives in part from the tremendous cultural diversity of the region and the competing claims on territory by ethnic groups. The study of ethno-geographic zones and territorial aspirations of ethnic groups contributes to an understanding of peace and conflict in the region. Ongoing separatist movements are found throughout the subcontinent, from Kashmir in the northwest to Assam in the northeast, through the India plains where Sikh, Gorkhali, *adivasi*, and other ethnic groups claim regional autonomy or independence, and on to Sri Lanka, where Tamils and Sinhalese are embroiled in a civil war. The conflict potential of ethnic groups is viewed to be a function of such motivating conditions as government encroachment onto ethnic territories and socioeconomic discrimination, and such enabling conditions as group cohesiveness, population expansion, and access to infrastructure, foreign support and resources. Geographical analyses of territory-based ethnic conflict consider these factors as well as other historical circumstances of the conflict regions.

2.5 *Environmental Change*

The causes and consequences of environmental approaches used to study environmental change are diverse and include geo-technical monitoring in the Eastern Ghats of southern India, landscape assessment in Rajasthan, irrigation and water resource development in the Gangetic plain, and studies of the relations among subsistence economies, the natural environment, and political economy in the Himalaya (Zurick and Karan 1999). The geographic research on environmental trends generally subscribes to a fieldwork-based research model and is theoretically informed by cultural ecology, ecosystems research, and political ecology. Much environmental geography in south Asia centers on the Himalaya, where international research efforts span the mountains from Afghanistan to Burma.

Environmental research in the Himalaya is informed in part by a proposed 'Theory of Himalayan Environmental Degradation', which links land degradation to population growth and overuse of resources, and by various theories of global environmental and

social change. The work of German geographers in the upper Indus river valley in Pakistan follows the geoecology tradition, which centers upon the human exploitation of altitudinal-based environmental zones, and examines human alterations of the environment for subsistence purposes as well as for modernization along the Karakoram Highway. The UNESCO Man and Biosphere Project contains the work of geographers in Nepal who have examined such issues as land use change, hill slope stability, and natural hazards in the middle mountains region. Much of the contemporary geography in the Himalaya seeks to understand the human underpinnings of environmental change, distinguishing societal causes from natural ones, and to resolve environmental problems according to human needs (Ives and Messerli 1989).

The applied aspects of environmental geography in south Asia include such issues as forest regeneration, sustainable agriculture, geographic information systems (GIS)-based monitoring of environmental trends, and the reconciliation of societal aspirations with mountain carrying capacities. A great deal of applied geography is conducted under the auspices of the International Center for Integrated Mountain Development (ICIMOD) based in Kathmandu, Nepal. ICIMOD's critical program areas include the impacts of globalization on fragile environments, livelihood security, and natural hazards management. These efforts apply broadly across south Asia, linking the environmental and social conditions in the mountains to those in the densely settled plains.

Future geographic studies on the region will continue to engage scholars in the pressing issues of society and the natural environment. The regional perspective will benefit by considering the Indian subcontinent in terms of globalization trends and in respect to its potential role in the geographic alliances emerging within Asia. Among a set of related topics are the impacts of ethnic fragmentation on the evolution of national boundaries and on international relations among the south Asian countries. Attention on culture and environment will continue to consider the place of tradition as a guiding force toward sustainable practices related to economic development and the use of the natural environment. The overall economic transformation of the region will necessitate new geographic appraisals of the peasant economy, societal equity, and land management, linking these within new conceptions of environmental conservation, cultural survival, and sustainable development.

South Asian Studies: Health

1. Background

1.1 Common Heritage

For a proper appreciation of the status of the study of health in south Asia, it is important to underline certain facts pertaining to the character of the region and to health as a field of study. The seven countries in the region share a common cultural heritage as well as political history. Three of these countries—Bangladesh, India, and Pakistan—accounting for nearly 97 percent of the population of the region, were one country until 1947. The cultural and religious ties between India, Nepal, Bhutan, and Sri Lanka predate recorded history. This affinity and closeness have not only produced a similar mindset but also a largely common history of medicine and health.

Further, the story of health research in this region is almost as long as human history itself. This history is divided into four periods, each of which is marked by distinct characteristics regarding the nature and extent of health research.

2. Study of Health

2.1 The Pre-Islamic Period

The history of health in South Asia starts with the *Atharvaveda*, the last of the four Vedas—ancient

collection of sacred Hindu hymns, pages, and liturgical formulae. The *Atharvaveda*, which is said to date back to the second millennium BC, is the seminal source of Indian medicine. From it emerged the better known *ayurveda*, credited to Dhanvantari who supposedly received it from Brahma, the God of creation in the Hindu Trinity. The period between 800 BC and AD 1000 is regarded as the golden age of Indian medicine. During this period there was great advancement in knowledge about diseases, techniques of surgery, and the concept of health. Two very well-known medical treatises, *Charak Samhita* by Charak, a physician, and *Susruta Samhita* by a surgeon, Susruta, were also produced during this period. Although the exact dates of their writing are debatable, both these works are considered far older than any counterpart work produced in Greek medicine, giving rise to a claim for the priority of Indian scientific medicine. During this era, a sophisticated concept of health emerged, postulating interactive unity among soma, psyche, and soul (not too different from the modern concept of holistic medicine), an identification of water, food, physical and occupational environment, sanitation, hygiene and lifestyle, biological and karmic inheritance, and sociopolitical order as primary determinants of health.

Because of religious taboos on cutting bodies and killing animals for experimentation, deductive reasoning drove the study of medicine to a large extent. In this pursuit, the thinking about human anatomy and physiology was greatly influenced by the prevalent concept of universe; the human body was perceived as a reflection of the cosmos. However, there is some evidence to indicate a knowledge of germs and bacteria, disease etiology, and the use of empirical observations to determine the effectiveness of various treatments. There was detailed knowledge about a large number of diseases; the extensive *materia medica* included at least 760 medicinal plants, herbs, and spices, as well as a large number of minerals and animal remedies based on the milk of various animals, bones, dung, and urine. The list of surgical instruments invented and in use was equally impressive (Kutumbiah 1962, Zimmer 1948). But in later years there was a noticeable slowdown in the growth of medicine in this region, probably due to increased emphasis on the theory of 'karma' and wider prevalence of a medieval ethos characterized by feudatory attitudes and parochial concerns.

2.2 Islamic Period

The arrival of the Turks (around AD 1000) brought Indian medicine to a standstill because of the deterioration of traditional patronage. With the strengthening of Muslim hegemony, *unani* medicine (a mixture of Greek, Arab, Turkish, and Iranian medicines) gained the favor of the ruling class, and spread with the Muslim conquests. However, little documentary evidence is available regarding the state of medicine and health during this period, beyond the prevalence of epidemics and famines. Scholarship during this period seems to be concerned primarily with the importation of medical know-how from Iran, Turkey, and Arab countries.

2.3 The Colonial Period

The colonial period started on November 24, 1510, when Alfonso de Albuquerque captured Goa, and ended in 1948 when the British withdrew from Sri Lanka, after having withdrawn from India, Pakistan, and Bangladesh a year earlier.

During this period, the government by and large limited its attention to the healthcare of its employees, the military, and plantation workers. For this purpose, government health clinics and hospitals were built at most of the district headquarters, major cantonments, primary railway depots, and on tea and coffee plantations. (Due to the greater concentration of tea plantations in Sri Lanka, a proportionately larger health infrastructure was instituted there.)

Christian missionaries also built hospitals in major cities and established clinics in the tribal and backward areas. To staff these facilities doctors and nurses were initially imported from Britain, but later several medical colleges (the first of which was established in Madras in 1835) were set up to train local manpower. In 1921 a School of Tropical Medicine was established in Calcutta to train personnel for public health work. In 1932 it was upgraded to become the All India Institute of Hygiene and Public Health (Kumar 1998). A system of licensing the practitioners of allopathic medicine was introduced. However, the private practitioners of *ayurvedic* and *unani* medicine, who were not licensed, provided most of the medical services. Scholarship on health was largely limited to reports based on the decennial census introduced in 1872, and on vital statistics, although the latter were inaccurate due to a widespread failure to register births, deaths, and other vital events. Most of these studies, produced by Westerners, were part of larger sociopolitical concerns. These included official reports, travelogs, diaries, and the occasional book. (*Mother India* is an example of such a book, written by an American, Katherine Mayo, which became highly controversial due to its political overtones.)

In 1943, towards the end of the British rule in the region, an official committee under the chairmanship of Sir Joseph Bhore was appointed to produce a detailed report on health conditions in India (Pakistan and Bangladesh were then parts of India) and to make recommendations for improvement. The committee was called the Health Survey and Development Committee, and is popularly known as the Bhore Committee. This committee submitted its report in 1946, which is considered a seminal work on health-

care in this region insofar as it laid the basic foundation of scholarship as well as for political actions regarding the importance of health and the role of government in the provision of health services.

2.4 The Postcolonial Period

The basic character of the health system in South Asia was formed during colonial rule: the supremacy of allopathic medicine; an ambivalent concept of healthcare (human service vs. economic necessity); a high degree of dependence on the West for basic knowledge and know-how in all matters pertaining to health; a largely reactive role for the government, and a dependence on the government for health statistics.

Further, the deep-rooted cultural tendency to rely on deductive logic for problem-solving continued to be the hallmark of scholarship, placing high reliance on creative thinking over empirical proof. This is reflected in the fact that until recently the primary landmarks in the history of scholarship on healthcare in this region were a series of expert reports, starting with the Bhore Report.

The Bhore Committee, reversing the minimalist approach of the British government in India to the provision of healthcare, advocated that the government should take responsibility for ensuring universal access to preventive and curative health services because health was too important to be left to the vagaries of circumstances; it recommended the development of a nationwide network of primary health centers, the provision of integrated preventive and curative health services to all regardless of ability to pay, extensive health education to modernize the knowledge, beliefs and practices of the people, the training of needed health manpower, and the construction of necessary health facilities.

These recommendations reflected the mood of the time: the success of the Soviet Union in improving the health status of its population through central planning, the release of the Beveridge report in 1942 in Great Britain (recommending universal healthcare) which led to the passage of the National Health Services Act in 1946, and the high emphasis placed on social welfare by the leaders of the independence movement in the South Asian countries.

The Bhore Committee recommendations were incorporated in the first Five Year Plan of India (1951–6), and as a result a foundation was laid for the development of a nationwide network of primary health centers, as well as for the expansion of the training facilities to provide the necessary manpower. This foundation was built upon in each of the successive Five Year Plans, guided by a series of other expert committee reports: Health Survey and Development Committee (chaired by A. L. Mudaliar) 1961; committees on the integration of health services and family planning, 1963, 1968, and 1970; committee on multipurpose health workers, 1973; Joint Committee of Indian Council of Social Science Research and Indian Council of Medical Research, 1978, and so on. Other countries in the region also followed more or less a similar path and during this period expert committee reports remained the dominant focus of scholarship pertaining to health.

3. Recent Developments

3.1 Health Research

Since the early 1970s the study of health in this region has received increasing attention from international organizations (WHO, UNICEF, World Bank and USAID), other donor organizations, and American and British universities. This heightened attention is a result of a significant flow of foreign assistance to contain the burgeoning population and high saliency health problems. However, in-region scholarship is still in an early stage of development.

Earlier, it was noted that in this region deductive reasoning is a dominant scholarly tradition. This tradition persists despite the fact that the educational system is Western. But unlike those in the West, the institutions of higher learning in south Asia do not emphasize and reward empirical research. Instead, importance is given to the writing of treatises. This is reflected in the fact that while a Medline search covering the years 1980–2000 produced only 483 articles (around 25 articles per year, on average)—the majority of which reported biomedical research, advocated some policy posture or were descriptive in nature—the Sage India's summer 2000 list of books (covering the period 1998–2000) included 24 titles on various aspects of health and an additional 26 titles related to health. There are very few refereed journals published in south Asia that are concerned primarily with the study of health systems.

The *National Medical Journal of India* of the All India Institute of Medical Sciences, New Delhi, has been published since 1987. In recent years, three new journals have been established: *Journal of Health and Population in Developing Countries* (originally published in India by the University of North Carolina, but now moved to the USA), *Journal of Health Management* (published by the Indian Institute of Health Management and Research, Jaipur) and *Journal of Health, Population and Nutrition* (published by the International Centre for Diarrheal Diseases Research, Bangladesh). Funds for research also tend to be very scarce. The major sources of these funds are donor organizations, but they fund only those studies that meet their own needs. As a result, the researcher-initiated studies tend to be limited to doctoral dissertations, few of which are published.

The studies on health may be grouped as follows.

Table 1
Disability adjusted life expectancy (DALE) in South Asian countries, 1997

Country	DALE (years)	Ranking (184 countries)
Bangladesh	49.9	140
Bhutan	51.8	138
India	53.2	134
Maldives	53.9	130
Nepal	49.5	142
Pakistan	55.9	124
Sri Lanka	62.8	76

Source: WHO *The World Health Report* 2000, Annex Table 5 (for DALE scores); Annex Table 1 (for international ranking)
Note: DALE is calculated by subtracting the average number of expected years of disability due to illness and injury throughout life from the average expected years of life at birth

Table 2
Ranking of South Asian countries for health system performance, 1997 (191 countries)

Country	Performance on health level	Overall performance
Bangladesh	103	88
Bhutan	73	124
India	118	112
Maldives	147	147
Nepal	98	150
Pakistan	85	122
Sri Lanka	66	76

Source: WHO *The World Health Report* 2000, Annex Table 10
Note: Performance on health level is calculated by adjusting the DALE score for the efficiency of the health systems. Overall performance is a composite measure of achievement in the level of health, the distribution of health, responsiveness to people's concerns, fairness of financial contributions and managerial efficiency. For details, see *The World Health Report* 2000, explanatory notes, pp. 141–51

3.2 Health System Achievements

After 50 years of independence, the goal of universal access to preventive and curative health services in South Asia is far from fulfilled. This perception has been a catalyst for a number of studies typified by Qadeer and Sen (1998) and Wysocki et al. (1990).

A large number of studies prepared by the governments in this region describe progress made. For example, various reports produced by the Ministry of Health in India point out that a network of health centers, each serving 5,000–10,000 persons and staffed by auxiliary health workers, covers the country. In 1947, there were 26 medical colleges in India; by 2000 there were 146. Further, India is largely self-sufficient in drugs and medical supplies. A significant research infrastructure has been developed (some of the more prominent bodies include the All India Institute of Medical Sciences, National Institute of Communicable Diseases, National Institute of Health and Family Welfare, Haffkine Institute, Pasteur Institute, National Institute of Virology, and International Institute of Population Sciences). Two major social insurance programs provide medical care to targeted populations: the Employees State Insurance Corporation, established in 1948, provides healthcare to the employees of private industry and their dependents (nearly 3.5% of India's population); and the Central Government Health Insurance Scheme, which covers the employees of the central government and their families (more than 3 million people).

India's average life expectancy at birth rose from 41 years in 1951 to more than 60 years by 1995, and infant mortality rate fell from 146 infant deaths per 1,000 live births in 1951 to 71 per 1,000 live births in 1997. Other countries publish similar reports of progress.
