1.1 *From No-place to the Earth and Beyond*

The Platonic tradition which conceived good societies as necessarily small has been resumed by Thomas More and countless other writers who placed their utopia on imaginary islands or some similar remote sites, waiting to be visited by admiring travelers from the outside world who have been shipwrecked on their shores. With Mercier's *L'An 2440* (1971) the discovery is made through a lengthy process of sleep and reawakening, Rip van Winkle-style, in the utopian future of a whole nation-state, namely France's 700 years ahead, a narrative convention which has been used in countless utopias. With the passage of time the scope of utopias has become more embracing, to include developed post-capitalist nations in Marxist utopias, the whole Earth complete with a single world government and English as universal language in some H. G. Wells writings, and eventually the solar system through the space colonies as has been anticipated by Freeman Dyson (see Carey 1999, p. 463).

1.2 *Not Everybody (nor Everything) is Allowed into Utopia*

Radical utopian change is primarily aimed at faulty social institutions but as books are the repository of wrong beliefs and/or immoral fictions, they also can be fated to destruction as is the case for poetry in Plato's *Republic* (1941, Book X), in Mercier's twenty fifth century France or in Cabet's communist *Icaria*. Some utopias even provide for the destruction and renewal of much of the urban structures of the past, as in the Boston of Bellamy's *Looking Backward* (1951, chap. 5) or the big murky places which were, as we know, the centres of manufacture in England in *News from Nowhere* by William Morris (1970, chap. 10).

The admittedly extreme case of Wells' *In the Days of the Comet*, where several of the world's big cities are obliterated by a comet whose green vapors simultaneously induce a hypnotic slumber which alters human nature beyond recognition, would suggest that the actual aim of these beneficial disasters is less the physical structures than the human beings, for the latter have to change too in order to deserve the benefits of life in utopia. These changes concern either the existing population or its newborn component.

A first requirement, it seems, is that the raw human material has to be cleansed, either biologically or socially. More's Utopians secretly hope that all the Swiss they use as mercenaries will eventually be 'wiped off the face of the earth completely' as they are unfit to live. A much more significant case is provided by Wells, who considered that in the world state he anticipated, 'people who cannot live happily and freely in the world without spoiling the lives of others are better out of it,' a prescription made in 1901 which, most unfortunately, was taken deadly seriously some 40 years later. An as yet uncommon variant concerns gender cleansing, which aims at a deliberate change in the sex ratio. According to Wells, genetic engineering will allow 'if woman is too much for us, [to] reduce her to a minority' (Carey 1999, p. 371). More radically, but with here again some pretence of scientific veneer, feminist utopianism deals with this value-laden issue by, unsurprisingly, anticipating an all-woman community based on parthenogenesis (Gilman, in Carey 1999, p. 382), or a flower children paradise where some technology has been used to allow men (if that is the right word) to grow breasts and to suckle babies (Piercy, in Carey 1999, p. 475).

However, social cleansing of class opponents, while massively performed during and after the 1920s, is a most rare occurrence in the utopian literature except as a thought experiment performed by the French

utopian Saint-Simon (what if the leading nobles and officials of the bureaucracy died?, the answer being: no impact in social welfare terms), or as an aside in the Marxian literature dealing with the 'dictature of the proletariat.'

Beyond taking care of the initial stock, selective breeding is of great concern in some utopias, with a variety of patterns such as state control and astrological supervision of matings in Campanella's *The City of the Sun* (Carey 1999, p. 61) on the one hand, and reliance on unhindered sexual free market as a means toward race purification in *Looking Backward*, on the other. Once again H. G. Wells is quite clear that in his world utopia nonprocreational sex is all right, but parentage shall be subject to strictly enforced age, health, education, and income standards.

1.3 The Rules of the Utopian Game: A Difficult Tradeoff Between Equality, Compulsion, and Welfare

One crucial commonality underlying all utopian designs, fictional or otherwise, is that the source of what goes wrong in human affairs lies not in the original sin, which nobody can do about, but to faulty social institutions which can be dealt with by human agency. The 'fault' in social institutions lies in their giving free rein to the worst instincts of humankind, such as greed, aggressiveness, and jealousy and/or in stifling its best inborn instincts. Then, the right social arrangements are those that promote maximum equality among members of the relevant community. In the words of one typical exponent, the French revolutionary Babeuf (Carey 1999, p. 177), 'society must be made to operate in such a way that it eradicates once and for all the desire of a man to become richer, or wiser, or more powerful than others.' The positive fallout to be expected from this equality maximizing purpose are the usual ones of plummeting crime rates, eradication of (relative) poverty, and a stronger social fabric. As for the negative aspects, such as drabness and enregimentation in daily life, they figure quite explicitly in some works including *Utopia* ('when you have seen one town, you have seen them all') or Cabet's *Icaria* ('everything concerning food has been regulated by the law [which] accepts or rejects any type of nourishment').

Interestingly enough, perfectly consistent egalitarian utopias are in a minority, as Kolakowski (1990) points out. The majority is made of inconsistent schemes which allow having one's utopian cake and eating it by mixing egalitarianism with other, qualitatively different elements. Saint-Simon and Marx (in his infrequent utopian moments), Bellamy and, incredibly enough, even Cabet, are all evidence of such a compromise, with its unfailing reference to the utmost development of individual potentialities, to the concomitant productive efficiency of the economic infrastructure which allows egalitarianism to coexist with an unlikely upper-middle class affluence, but very little mention of what happens to delinquent or work-shy members of the community.

On the whole, there are few utopias which succeed in convincingly combining (a) a fair amount of equality, (b) minimal state coercion, and (c) nonascetic lifestyles. *News from Nowhere* (Morris 1970) is strong on the first two counts but unconvincing on the third, as all pastoral fairyland are. Huxley's *Island* (1962) is another case of equality *cum* small government, but a very short-lived one, whose indisputable ascetism is moreover counterpoised by a tropical paradise-type environment and recurrent use of mind-changing pills. The aforesaid feminist utopias are too clearly conceived for a restricted female readership to deserve discussion except as one curious brand of science fiction among others. However, Fourier deserves a special mention for the quite imaginative trade-off he devised between the three poles of the (a), (b), (c) triad for he is, as he rightfully argued, 'the only reformer who has rallied round human nature by accepting it as it is and devising the means of utilizing it with all the defects which are inseparable from man' (Manuel 1965, p. 207). Unfortunately, in spite of his efforts, neither the Russian Czar nor the Rothschilds accepted to invest some seed-money to check whether Fourier was right in claiming that all the passions created by God could work in harmony when afforded maximum expression in Fourierist phalansters. As for those experimental utopian communities created in North America by some followers of Fourier, Cabet, or Owen, they were at best honorable failures.

2. Utopias Appraised

2.1 The Birth of Utopias: A Well-kept Secret

Each utopia is in itself a permanent paradox: how an ideal society can be established by a gathering of hopelessly imperfect individuals? As has been shown above, makers of utopias are generally quite willing to let us know how their pet ideal society was discovered; they are also tireless in the description of their commendable arrangements. However, how a given utopia came into being looks like a well-kept secret (Ferns 1999). In most cases the problem is just swept under the carpet. Utopias, as Chesterton (1905) sarcastically pointed out, 'first assume that no man will want more than his share, and then they are very ingenious in explaining whether this share will be delivered by motor car or balloon.' The implicit reasoning seems to be that the merits of the 'nowhere' are vastly more important than the account of how it came about. There are also some cases, especially in the nineteenth century, where utopian changes were vindicated as the obvious response to the necessary laws of historical development which move the world, but except some evasive references from the Marxist

side to the inevitable transition through a dictatorship of the proletariat, William Morris was the only anticapitalist utopian to acknowledge that the new imagined society did not come about peacefully: 'it was war from beginning to end, bitter war.' As for Wells he found a third way of explaining away the emergence of a world utopia by ascribing it to the destabilizing impact of a disaster, either natural (the above-mentioned comet) or human-made (a nuclear war in *The World Set Free*, Wells, 1914).

2.2 Are Utopias Such a Good Place?

While many people have adhered to, and would still subscribe to Oscar Wilde's dictum that 'progress is the realization of Utopias,' reaction against utopia's blandishments is visible from the very beginning, as evinced by Aristophanes (1924), whose *The Parliament of Women*, with its satire of 'utopian' sexual relations, was contemporaneous with Plato's *Republic*. Very often the word 'dystopia' is used to convey the idea of a utopia turned sour. Unfortunately, it is too often applied to any kind of work, fictional or otherwise, which anticipates a dismal future for some existing society or for the world at large. If one agrees with the statement that 'to count as a utopia, an imaginary place must be an expression of desire. To count as a dystopia, it must be an expression of fear' (Carey 1999, p. xi), a case can be made for a distinction between two kinds of fear.

The first one, which is as old as the prophets of doom (with Malthus as its first modern voice) concerns the downfall which humankind might be heading for given its underlying, presumably lethal logic, a message for which the phrase 'disaster scenario' suggested by Carey seems quite appropriate. The second fear has been voiced by the Russian philosopher Berdiaev as quoted in the epigraph to Huxley's *Brave New World* (1963): 'Utopias seem much more realizable than once was thought. We find ourselves faced today with a problem distressing in a very different way: how can we prevent their realization? Utopias are realizable, and towards utopias we are moving. But it is possible that a new age is already beginning, in which cultured and intelligent people will dream of ways to avoid ideal states and to get back to a non utopian society, less 'perfect' and more free.' Dystopia, etymologically 'a bad place,' which makes it a kind of mirror image of utopia, can thereby serve to characterize those anticipations which seek to warn their readers that the world is evolving dangerously closer to utopia, the latter being then no more a solution but the problem.

In some of the dystopias, the target is clearly identified: socialist egalitarian utopias Bellamy-style in the first, and quite funny, example known (Jerome 1891, see Beauchamp 1983); the revulsion against Bellamy and his 'cockney paradise' was a source of inspiration for *News from Nowhere* (Morris 1970), *The Machine Stops* (Forster 1965) was written as a 'counterblast' against *A Modern Utopia* (Wells 1987), while *Men Like Gods*, a utopian novel by the same Wells provoked Huxley into writing a parody famously known as *Brave New World* (1963).

Unsurprisingly, one finds in the 'patented' dystopias from Jerome's prototype on, all the major features that are typical of mainstream utopias, but with reversed connotations: what was described in the typical utopian package as benevolent government care, strong social ties, true equality, and full development of individual potentialities is now disclosed as just the opposite, namely constant public scrutiny, compulsory uniformity, and lack of privacy; in other words the embodiment of the rule that 'everything is allowed for the sake of the society,' an 'unholy maxim' designed, Tocqueville said, 'to legitimize all the oppressions to come.'

If the typical dystopia is utopia taken upside down (so much so that it is sometimes unfairly interpreted as just a pro-Establishment reassertion of reactionary values), *Brave New World* (Huxley 1963) is on the other hand remarkably difficult to classify. As Carey put it, 'medical science has eliminated virtually all diseases, together with the debilitating effects of old age. There is no pain, no hunger, no want. [*Brave New World*] can be read as an ambivalent text, dystopian from one angle, utopian from another.' Hence the society described therein holds more attraction for readers today (particularly young ones) than Huxley expected (Jennings 1996); small wonder that the dystopian human hatchery in *Brave New World* (Huxley 1963) appears as a major positive highlight in Marge Piercy's feminist community (Carey 1999, p. 476). Oddly enough, the same ambivalence has been detected in *Utopia* (More 1965) which can be read, its modern, progressive features notwithstanding, as an ultimately dystopian admonition against relying on economic and social arrangements that are functionally efficient but at odds with a Christian and humanist set of values (Abrash 1977).

3. Some Concluding Remarks

Is there a future for utopias? If the latter are meant as comprehensive and hopefully feasible institutional schemes where happiness prevails once for all through consensual equality, the answer is probably 'none.' However, one can bet on the resilience of a special brand of utopian mentality, which did not leave any book worth remembering and whose followers literally believe in the imminent coming of paradise on earth after a cataclysmic confrontation between the true believers, generally under the guidance of a Messiah, and the forces of evil (Campion 1994). In addition, even if large-scale utopias seem to be a thing of the past, one should not forget the persistence of partial

utopias, namely the widespread conviction that in some specific areas of human endeavor, some ultimate state of (bounded) perfection is attainable, health being the most obvious candidate.

As far as dystopias are concerned, they may be threatened with obsolescence by the vanishing of non-millenarian utopian constructs but, after all, *Nineteen Eighty-Four*, Orwell's dystopian masterwork (1983), was not aimed at a specific utopian fiction but at a too real target. Above all, one must keep in mind that the key *raison d'être* of dystopias is to be a reminder of the ubiquitousness of unintended (dismal) effects of presumably well-intended social action (Boudon 1982). Hence, there is some reason to expect that the major issues on the dystopian agenda might include the dual threats of (a) the subversion from weapon-rich, single-minded millenarian groups; and (b) the disruption of the social fabric through human genetic re-engineering brought on, not by some benevolent Big Brother as in conventional utopias (and dystopias), but through decentralized parental decision making (Silver 1998, in Carey 1999, pp. 514–17).

V

Valency and Argument Structure in Syntax

The purpose of this article is to describe the valency and argument structure of the verb or predicate. The notion of argument is known to have been adapted from mathematics. In mathematics, a function may take one or more arguments, which will be used to determine the value of that function. In linguistics, argument is used as a technical term for syntactic elements that combine obligatorily with the verb (or the predicate as the verb is usually referred to in relation to arguments). For instance, the English verb *die* must take at least one syntactic element, e.g., *the mayor*, to form sentences, e.g., *The mayor died*. This syntactic element is taken to be the (sole) argument of the predicate *die*. The verb *kill*, on the other hand, requires two arguments to form sentences, one representing the killer (*the man*) and the other the person killed (*the mayor*), as in *The man killed the mayor*. The number of arguments that are required by a predicate is then specified in the argument structure of that predicate. Additional syntactic elements, e.g., *in the office* or *in 1878*, can also potentially combine with the predicate *die*, e.g., *The mayor died in the office, The mayor died in 1878*, or *The mayor died in the office in 1878*. But these are regarded only as optional, because their absence has no bearing upon the grammaticality of the 'minimal' sentence, *The mayor died*. Such optional syntactic elements are referred to as adjuncts. The distinction between arguments and adjuncts, albeit not always easy to make, is a useful one (see Comrie 1993 for discussion as to how arguments and adjuncts should be distinguished).

The argument structure also contains information concerning the relation between the predicate and its argument(s). For instance, in the sentence *The man killed the mayor*, the predicate *kill* and its arguments *the man* and *the mayor* have logical (or grammatical) relationships between them with the effect that *the man* is the actor (or the subject) who carried out the killing, and *the mayor* is the undergoer (or the direct object) who was affected by the actor's killing (see *Grammatical Relations*). Adjuncts, e.g., *in the office* in *The mayor died in the office*, also bear logical (or grammatical) relationships, e.g., location (or oblique), with the predicate. Information on adjuncts, however, is not included in the argument structure of the predicate itself.

The term valency (or valence in the USA) is said to have been borrowed from chemistry into syntax. In chemistry, the valency of a chemical element is defined as the capacity of that element for combining with a fixed number of atoms of another element, for instance, two hydrogen atoms combining with an atom of oxygen in the case of water (i.e., H_2O). The notion of valency, when applied to verbs, refers to the number of arguments that are required for a given verb to form sentences. For example, the verb *die* is regarded as having a valency structure of a single argument. Thus, verbs such as *die* are characterized as one-place (or monovalent) verbs. The verb *kill*, on the other hand, is a two-place (or divalent) verb, because it requires two arguments.

The rest of the article is concerned principally with illustrating how argument structure can be altered or manipulated with or without a concomitant change of valency. How languages may keep the valency of the derived verb from exceeding that of the basic verb by manipulating argument structure will also be illustrated (see *Morphology in Linguistics* for derivation). Finally, how valency-changing operations are handled in current grammatical theories will be discussed briefly.

1. Change of Argument Structure with Change of Valency

There are two main mechanisms through which the argument structure of the predicate can be altered, together with a change of valency: argument reduction, and argument addition. In argument reduction, one of the arguments of the basic predicate may be demoted to adjunct status. In argument addition, on the other hand, adjuncts may be promoted to argument status, or new arguments may be introduced into the argument structure. There are five important grammatical devices utilized in argument reduction or argument addition: passivization, antipassivization, noun incorporation, advancement, and causativization. The first three belong to argument reduction, whereas the last two fall under argument addition. (But for examples of noun incorporation consisting of argument reduction and addition, see Mithun 1984, and Sect. 2 for causativization involving both argument addition and reduction.)

1.1 Passivization

In the passive clause, one of the arguments of the basic two-place predicate (i.e., the actor) is demoted to an adjunct with the other argument (i.e., the undergoer) retaining its argument status (but being promoted to the subject of the passive clause). This operation is referred to as passivization (Siewierska 1984). The number of arguments of the basic predicate is thus reduced from two (i.e., the actor and undergoer) to one (i.e., the undergoer) in the corresponding passive clause. This is substantiated by the fact that it is possible to omit the newly created adjunct. This change of valency (or valency decreasing) is signaled on the verb either by a verbal affix or by a periphrastic element in the verb phrase. Korean provides a good example of the passive:

(1) Korean
cuin-i totuk-lil cap-əss-ta
owner-NOM thief-ACC catch-PST-IND
'The owner caught the thief.'

(2) Korean
totuk-i (cuin-eke) cap-hi-əss-ta
thief-NOM (owner-by) catch-PASS-PST-IND
'The thief was caught (by the owner).'

[Abbreviations used to gloss the data: ABS = Absolutive; ACC = Accusative; APASS = Antipassive; APPL = Applicative; ASP = Aspect; CS = Causative Suffix; DAT = Dative; DO = Direct Object; ERG = Ergative; F = Feminine; FUT = Future; IND = Indicative; INTR = Intransitive; IO = Indirect Object; LOC = Locative; M = Masculine; NFUT = Non-Future; NOM = Nominative; PASS = Passive; PERF = Perfective; PRS = Present; PST = Past; TR = Transitive.]

1.2 Antipassivization

Antipassivization is often regarded as the counterpart of passivization in languages with the ergative–absolutive case system. But it should not be inferred from this that the passive is never found in languages with the ergative–absolutive system; both the passive and the antipassive may occur in the same language. In the antipassive, the actor argument of the basic two-place predicate remains the (sole) argument of the corresponding antipassive (albeit marked by the absolutive case), with the undergoer argument demoted to adjunct status or, optionally, omitted. If and when expressed, however, the undergoer is marked accordingly by an oblique case. This suggests that the antipassive is as much intransitive or detransitivized as is the passive: a decrease in valency from two (i.e., the actor and undergoer) to one (i.e., the actor) argument. The verb in the antipassive also bears an affix as a marker of valency decreasing. Dyirbal provides a good example of the antipassive:

(3) Dyirbal
balan $d_y$ugumbil baŋgul yaṛa-ŋgu
F-ABS woman-ABS M-ERG man-ERG
balga-n
hit-NFUT
'The man is hitting the woman.'

(4) Dyirbal
bayi yaṛa bagun $d_y$ugumbil-gu
M-ABS man-ABS F-DAT woman-DAT
balgal-ŋa-n_yu
hit-APASS-NFUT
'The man is hitting the woman.'

1.3 Noun Incorporation

Noun incorporation is another type of valency-changing operation found in some languages of the world, whereby one of the arguments of the predicate becomes part of the predicate, thereby losing its argument status (Mithun 1984). The resulting predicate may function as a single word. In Chukchi, for instance, vowels of incorporated nouns must participate in word-internal vowel harmony in conjunction with host verbs:

(5) Chukchi
tumg-e na-ntəwat-ən kupre-n
friends-ERG set-TR net-ABS
'The friends set the net.'

(6) Chukchi
tumg-ət kopra-ntəwat-gʔ at
friend-NOM net-set-INTR
'The friends set nets.'

Note that, with the undergoer incorporated into the predicate, the actor argument of the basic two-place predicate in (5) loses its ergative marking, and is instead marked by the nominative case in (6). In Chukchi, noun incorporation also motivates the verb to shed its transitive marking in favor of the intransitive marking. These changes indicate that noun incorporation involves reduction of two arguments of the basic predicate to one (i.e., valency decreasing).

1.4 Advancement of Adjuncts to Arguments

So far, argument reduction has been illustrated. In many languages, it is also possible to do the opposite, that is, to increase the valency of the basic verb by promoting an adjunct to argument status. In order to signal such promotion or advancement, the verb is normally marked by a so-called applicative affix. In Kinyarwanda, for instance, instrumental adjuncts can be promoted optionally to argument or direct object status. Compare the following two sentences:

(7) Kinyarwanda
úmwáalímu a-ra-andik-a íbárúwa
teacher he-PRS-write-ASP letter
n'ííkárámu

with-pen
'The teacher is writing a letter with the pen.'

(8) Kinyarwanda
úmwáalímu a-ra-andik-iish-a íbárúwa
teacher he-PRS-write-APPL-ASP letter
íkárámu
pen
'The teacher is writing a letter with the pen.'

The instrumental adjunct in (7) is promoted to direct object in (8), evidence for which can be adduced from the fact that the instrumental nominal, which is marked by the instrumental prefix in (7), appears as a bare nominal (i.e., no case marking) in (8). This advancement must also be registered on the verb by the applicative suffix-*iish*, as in (8). Both the old direct object and the newly created direct object in (8) exhibit grammatical properties of objecthood. This suggests that the valency of the derived verb in (8) is greater by one argument than that of the basic verb in (7) (see Sect. 3). In (7), there are two arguments (i.e., *teacher*, and *letter*) and one adjunct (i.e., *pen*). In (8), on the other hand, there are three arguments (i.e., *teacher*, *letter*, and *pen*). Moreover, the argument structure of the predicate in (7) specifies the relation between the actor and the undergoer, and the argument structure of the derived predicate in (8) the relation between the actor, the undergoer, and the instrument. To put it differently, (7) without the instrumental phrase *n'ííkárámu*, will remain grammatical, whereas (8), with *íkárámu* deleted, will be rendered ungrammatical.

1.5 Causativization

In common with advancement of adjuncts, causativization adds an argument to the argument structure of the basic predicate. However, it does so not by converting an existing adjunct into an argument, but by introducing a completely new argument into the argument structure. This new argument is the causer argument. Thus, if the basic verb is a one-place verb, the corresponding causative verb will be a two-place verb (the newly added causer argument and the sole argument of the original basic verb). If the basic verb is a two-place verb, the corresponding causative verb will be a three-place verb (three arguments including the causer argument). This is illustrated by the following pair of Turkish sentences. As opposed to the basic predicate in (9), the causative predicate in (10), with the causative suffix -*t*, has the causer argument, *dişçi*.

(9) Turkish
müdür mektub-u imzala-dı
director letter-DO sign-PST
'The director signed the letter.'

(10) Turkish
dişçi mektub-u müdür-e imzala-t-tı
dentist letter-DO director-IO sign-CS-PST
'The dentist made the director sign the letter.'

The valency of the causative verb thus exceeds that of the basic verb by one argument as can be neatly expressed in:

(11) NONCAUSATIVE: n/CAUSATIVE: $n+1$
[n: number of arguments]

The formula in (11) indicates that causativization is a case of argument addition, with the status of the argument(s) of the basic predicate remaining intact. This may indeed be true of one-place verbs; causativization only increases the valency of the basic one-place verb from one to two arguments. Causativization of two or three-place (or trivalent) verbs, on the other hand, would give rise to three or four arguments, respectively, more than many languages can cope with—regardless of whether verbs are basic or derived. Indeed, there is much cross-linguistic variation in causativization of two- or three-place verbs. For instance, there are languages which derive causative verbs only from one-place verbs (Song 2001, Dixon and Aikhenvald 1997, Dixon 2000). Moreover, in many languages, argument structure is manipulated in such a way that the valency of the derived verb is prevented from exceeding that of the basic verb (Comrie 1989, Song 1996, Dixon 2000).

2. Change of Argument Structure without Change of Valency

There are languages which introduce a new argument into the argument structure of the causative verb, only if one of the arguments of the basic two- or three-place verb is demoted to an adjunct, or omitted completely. In other words, causativization of the basic two- or three-place verb in such languages results in no increase in valency, contrary to the formula in (11), bur rather the valency of the derived causative verb is equal to that of the basic verb. In Babungo, for instance, when the causative suffix -*s* is added to two-place verbs, the direct object of the basic verb must be omitted or expressed as an adjunct. Thus, the direct object in (12) appears as an optional prepositional phrase in (13).

(12) Babungo
ŋwɔ́ fɛ̀e zɔ̃
he fear-PERF snake
'He was afraid of a snake.'

(13) Babungo
mə̀ fɛ̀sə ŋwə (nə̀ zɔ̃)
I fear-CS-PERF him (with snake)
'I frightened him with a snake.'

This phenomenon suggests that, regardless of whether the predicate is basic or derived, languages allow only a certain number of arguments per predicate (i.e., two or three) (Song 1996, Kemmer and Verhagen 1994 from a cognitive–linguistic perspective). Other devices drawn upon in causativization for this purpose include antipassivization and noun incorporation. The net effect of the use of these devices, in conjunction with

causativization, is no change of valency, although there may be a change of argument structure between the basic predicate and the derived predicate: addition of the causer argument offset by demotion to adjunct status (or omission) of one of the arguments of the basic predicate.

3. Doubling of Grammatical Relations

One theoretical issue in argument addition concerns the question of whether or not identical coding of nominals entails doubling of grammatical relations. In some languages, two nominals in the causative construction may be coded identically, for instance. In Kinyarwanda causatives, both the actor argument (or subject) and the undergoer argument (or direct object) of the basic predicate are coded identically as objects. Comrie (1989) interprets such identical coding to be indicative of doubling of the direct object. This position, however, has been challenged by Polinsky (1994), who demonstrates that the two identically-coded nominals in Kinyarwanda causatives behave differently in terms of syntactic properties. In fact, only one of the identically-coded 'direct objects' is syntactically a direct object, the other being an indirect object, identical coding notwithstanding. Kozinsky and Polinsky (1993) describe more or less the same situation in Korean and Dutch causatives. Similarly, the old direct object and the newly created direct object in the Kinyarwanda applicative sentence (8) are bare nominals (that is, coded identically). Moreover, both nominals exhibit grammatical properties of objecthood. This also led to a controversy as to whether or not (8), as opposed to (7), has two direct objects, i.e., doubling of the direct object. Gary and Keenan (1977) take the view that (8) has two direct objects. Perlmutter and Postal (1983), on the other hand, argue that (8) does not have two direct objects, but rather one direct object and one indirect object. Further evidence against doubling of direct object in Kinyarwanda applicative constructions is provided by Dryer (1983) and Polinsky (1994).

4. Theoretical Approaches to Valency-changing Operations

Current grammatical theories have proposed different approaches to representation of valency-changing operations; more than one approach may also be possible within one and the same grammatical theory (Brown and Miller 1996). These approaches can be characterized broadly as lexical or syntactic. Lexical Functional Grammar regards valency-changing operations as productive lexical processes giving rise to alternative assignments of grammatical functions (or grammatical relations) to arguments. In mainstream Government and Binding Theory, valency-changing operations are treated as syntactic. In causativization, for instance, the basic verb undergoes movement to combine with the causative affix at an abstract syntactic level. This movement is then claimed to comply with the same principles that are obeyed by other movements in syntax. Relational Grammar invokes revaluation rules to handle valency-changing operations. These revaluation rules are regarded as syntactic, because they operate on grammatical relations between initial and noninitial strata (or different syntactic levels) of the relational structure.

Value of Life, Economics of

The economics of the value of life is about what individuals and societies are willing to sacrifice to get longer expected lifetimes. Value of life is about private choices that individuals make implicitly and explicitly about their own health and safety. Value of life is also about collective, public choices that societies make concerning tax and expenditure programs which affect expected lifetimes and regulations that shape the environment in which individual decisions are made. Inferences from individual choices inform public decisions and expert-based public policy is offered to improve the quality of individual decisions and consequences.

1. The Term 'Value of Life'

Value of life typically refers to an amount of money an individual is willing to trade for a small change in his or her own probability of survival. This definition is typical because this situation is typically what individuals face in life and what decision makers face in public policy. Exceptions exist, of course, and they will be addressed below.

1.1 Value of a Statistical Life

The typical situation is illustrated by thinking about an individual who is one of a group of 10,000 people. Everyone in the group is identical and knows that during the next year nine people in the group will die. Everyone also knows that the number of people who are going to die could be reduced to eight if sufficient funds can be raised. If somehow it is known that each individual is willing to pay \$500 for the reduction of one death in the group, then the value of life is \$500 per person times 10,000 people, or \$5 million. Sometimes this amount is referred to as the 'value of a statistical life' because the identity of the individual who would have been the ninth death, yet lives, is unknown at the beginning of the period when the decision is made.

1.2 Value of a Change in Mortality Risk

The numerical example illustrates another way of interpreting value of life. The reduction in the number of deaths implies that the probability of death faced by each individual decreases from 0.0009 to 0.0008. The \$500 that the individual is willing to pay reduces the probability of his or her death by 0.0001. Because information is available from similar situations with small changes in the risk of death, but the changes are not exactly the same, for convenience, the value is standardized to a unit change (1 to 0). The standardized 'value of a change in mortality risk' is \$500 times the 10,000 needed to standardize 0.0001 to 1, or \$5 million. Both the 'value of a statistical life' and the standardized 'value of a change in mortality risk' represent what is typically meant by value of life. For further illustration, see Viscusi et al. (1995, Chap. 20).

2. Characteristics of Value of Life

The nature of value of life as defined above can be described further by considering a simple equation of individual expected utility. Let

$$E(U) = PU(C) \tag{1}$$

where $E(U)$ is expected lifetime utility for an individual. U is a well-behaved utility function with marginal utility $U' > 0$ and diminishing marginal utility $U'' < 0$. C is consumption and P is the probability of survival. Differentiating Eqn. (1) keeping the individual at the same level of $E(U)$, and solving for $\mathrm{d}C/\mathrm{d}P$ yields the rate at which the individual is willing to trade off current consumption for a small change in the probability of survival:

$$\mathrm{d}C/\mathrm{d}P = -U(C)/PU' \tag{2}$$

Equation (2) says that the rate at which an individual is willing to trade consumption for a small change in mortality risk equals (the negative of) the utility of consumption divided by the expected marginal utility of consumption. The negative sign indicates a tradeoff, i.e., less C for more P. If consumption were expressed in monetary terms, U' would be the marginal utility of income, and PU' would be expected marginal utility of income. This would mean that the value of a change in mortality risk, $\mathrm{d}C/\mathrm{d}P$, would be the expected monetary value of the utility of consumption. It is the willingness to pay for risk reductions.

While the simple equation above captures the essence of the risk-dollar tradeoff, formal models of consumer and worker behavior include budget constraints, behavior which affects the probability of survival, insurance, workers' compensation, bequests, multiple periods, and multiple risks. For additional reading, see the book by Jones-Lee (1976), article by Rosen (1981), review by Jones-Lee (1985) and comprehensive book chapters by Cropper and Freeman (1991, pp. 165–211) and Freeman (1993, pp. 314–66).

2.1 Relationship with Earnings

Within the context of intense interest in economic growth and national income accounting and from an emphasis on manufacturing and machinery following World War II grew an appreciation for the potentially high returns from investment in human beings. In a special conference issue of the *Journal of Political Economy* in 1962, Mushkin (1962) articulated the case for investment in human beings through promoting better health. She argued that the return

would be through future increases in labor earnings. If one more person were to live because of an investment in health, then national income would be greater by the amount that person would earn in the labor market. Expected future or forgone labor earnings became a standard measure of the value of life. Notwithstanding the fundamental contribution made by establishing human health as an important factor in economic growth, reference back to Eqn. (2) yields no clear, precise connection between the value of life and labor earnings. P may be close to 1, and C may be positively related to labor earnings, but the primary difference is that the value of $U(C)$ is not likely to equal C. No allowance is made for consumption which occurs outside the formal market, and no allowance is made for the value of living. Schelling (1968, pp. 127–76) clearly distinguished between earnings, which he referred to as livelihood, and value of life or living. What matters is the value of the statistical life, or value of change in mortality risk, *to the individual who is affected*. The value to the individual influences individual behavior and should be the starting value for public decisions which affect risks to the individual's life. This point is a reminder that either gross national product, or national income measured with traditional accounting, is a highly imperfect and sometimes misleading indicator of well being.

2.2 Costs of Illness

In valuing investments in health, Mushkin (1962) added to earnings the saving of future health expenditures. The sum of these health expenditures saved (direct costs) and the labor earnings not forgone (indirect costs) became known as the 'cost of illness' avoided. Cost of illness was used extensively because of the wide acceptance of the importance of investment in human beings and because estimation was manageable. The shortcoming that homemakers would be valued at zero was overcome by estimating the value of the services performed or the amount of earnings the person would have had if the individual had worked in the labor market. The low values for infants whose future earnings were heavily discounted and zero values for retirees who are not in the market were troublesome. The most troublesome aspect of cost of illness, however, is the lack of a theoretical basis which includes the individual's own value of living. Further discussion can be found in Tolley et al. (1994), who provide a comparison of the cost of illness and the value of life based on an individual's willingness to trade money and risk.

2.3 No Single Value

Equation (2) is useful for demonstrating that there is no single value of life which applies to all individuals in all circumstances. The amount an individual is willing to trade for a small change in his or her probability of survival depends on P, the base level of the probability. Because P is in the denominator, the value of life can be expected to increase as P decreases. For example, adult aging reduces the probability of survival and can be expected to increase the value of life, holding constant consumption. Automobile drivers who must travel alone at night on winding roads covered with snow and ice can be expected to have higher values of life than at other times.

The value of life depends on idiosyncratic factors that are reflected in the utility function. $U(C)$ can vary among individuals with the same measured consumption, C, owing to differences in family or environment. Individuals enjoying close, supportive family relationships and living in clean, ecologically rich natural environments and societies with high-quality civil institutions and public services can be expected to have higher values of life.

Lastly, from Eqn. (2) the value of life depends upon C. Since C can be expected to increase with income, $U(C)$, and the value of life will be higher with higher income and consumption.

2.4 Ex Ante and Unidentifiable

Equation (2) displays another characteristic which is inherent in the situations illustrating the value of life. The situations for the value of a statistical life with one fewer person of 10,000 people dying and the value of reduction in mortality risk by 0.0001 share an *ex ante* perspective. The situation is confronted, the life lottery must be played, but the outcome is not yet known. The identity of the individual who would have been the ninth death among the 10,000 is not known. Or, whether the individual facing a lower probability of death survives or dies is not known. Decisions which must be made by individuals and by societies about risks to their health, safety, and environment are often made in a similar manner.

Situations in which the individual is identifiable are inherently different. If the individual is thrust into a life-threatening situation by an unforeseen natural event, such as a tornado which causes entrapment in a collapsed building, the individual and society will often spend whatever is available or do whatever is possible to save the life. The situation involves a potentially large change in survival for a known individual. Saving the individual's life from almost certain death is usually valued very highly. If the trapped person is saved, all may end well. If the person cannot be found in the collapsed building after some time, then the probability of saving the person becomes small and the rescue effort decision is transformed into one involving the more typical value of a change in mortality risk. Medical situations involving identifiable patients with known diagnoses have some similarities and are considered below.

Court cases involving wrongful death of a specific individual are also inherently different because they too are *ex post*. Nothing can change the fact that the individual is dead. Nothing can be done to compensate the deceased for death. The value relevant to forensic decisions is the amount that can compensate the survivors or the estate for the individual's death. The value depends on the deceased individual's contribution to the well being of the other members of the family, an amount that is related to labor market earnings. The amount that fully compensates the family for loss of a loved one can be practically infinitely large. From an efficiency perspective, the value relevant for forensic situations should consider generating sufficient incentive to influence future decision makers who deal with similar risks. The typical value of life may well be relevant, but the differences between the values in court cases and the values in benefit–cost analysis tend to be large (see Jones-Lee's (1982) book). The value of life in wrongful death cases is likely to be an area of great interest in future research. Experiences in natural resource damages assessment under Superfund in the USA could be relevant. They too are values for *ex post* compensation. See Kopp and Smith (1993) for issues involving damage assessment.

2.5 *Willingness to Pay and Willingness to Accept*

In contrast to the court cases about *ex post* wrongful death of a specific individual, Eqn. (2) shows the tradeoff an individual is willing to make between consumption and a small change in mortality risk. For small changes Eqn. (2) suggests that it makes no difference whether the individual is paying for small reductions in mortality risk or accepting compensation for small additions to mortality risk. For example, for small, equal (and opposite) changes in mortality risk, the amount the individual is willing to pay for a slightly safer job is approximately the same as the amount the individual is willing to accept for a job which is slightly riskier.

3. *Criticisms of a Value of Life Based on Individual Willingness to Trade Off*

A value of life based on individual preferences as defined above is not without criticism. Criticism ranges from the ethical to the technical.

3.1 *Deontology*

One saying goes that economists know the price of everything and the value of nothing. In this spirit, one objection to the value of life as defined above is that it is vulgar and ethically wrong to place a monetary value on human life. A deontologist is one such as Plato or Kant whose moral theory is based on obligate moral rules independent of the desirability of the consequences of acting on the rules. If it is morally wrong that people are exposed to risks of death, then it is wrong to construct a value of life to be used to guide decisions involving risks of death. Systematic choices involving risk are practically impossible.

In contrast, a teleologist such as Bentham or Mill whose moral theory is based on the goodness of the consequences is highly interested in a value of life which might guide decisions so as to generate the greatest good for the greatest number. While strident deontology can lead to paralysis in decision making when faced with risky situations, ardent teleology can produce policy recommendations, such as euthanasia, which a majority often deems morally wrong. Because teleology is the ethical basis of benefit–cost analysis which uses the value of life, its criticism by deontologists is understandable. For more on a deontological objection, see Brandt-Rauf and Brandt-Rauf (1980), who analyze the ethical conflict over occupational safety and health.

3.2 *Ex Ante Becomes Ex Post*

Another ethical criticism is that neither *ex ante* nor *ex post* willingness to pay is acceptable because at some time the lottery is played the individual knows what is going to happen and will either pay everything to avoid death or demand an infinitely large amount in compensation for death. This situation, Broome (1978) argues, is morally unacceptable. Broome's criticism is complex, but it seems to have a deontological dimension to it. While this may be a quandary, the fact individuals frequently make decisions in which they are tradeoff risk suggests that the tradeoffs are not completely reprehensible to individuals.

3.3 *Murdering Statistical Lives*

Recall that there is no single value of life and that one factor which determines the value is the base level of the probability of survival, P. As P decreases, reflecting the increased risk of death faced by the individual, the value of a specified amount of risk increases. If decision makers for public health and safety programs use the values of the individuals as a guide, then programs will be directed at individuals in high risk situations. With a fixed budget for managing risks, the prospect of spending everything on a few high-risk individuals at the expense of numerous individuals facing lower risks is unattractive. This murdering of statistical lives is something that Linnerooth (1982, pp. 229–61) believes should be made explicit in social decisions which affect the distribution of mortality risk in society. She argues that society should care about the distribution of risk just as it cares about the distribution of income. Another concern about too little attention to low-risk situations is based not on ethics, but on perceptions. If individuals perceive risk and changes in risk less accurately when faced with

low risk of death, then they will not make efficient decisions about their own health and safety. It follows that public programs which target reductions in risk for low-risk situations would be especially important for improving the well being of society. Jones-Lee (1985) provides a review of these and other criticisms of value of life defined as the amount of money an individual is willing to trade for a small change in his or her own probability of survival.

4. Estimates of Value of Life

Value of life is about private choices that individuals make implicitly and explicitly about their own health and safety. Bland, healthy diets are traded for tasty food and drink which increase blood pressure and cholesterol levels. Comfortable, safe dwellings are left for skiing and rock climbing. Jaywalking is done to save valuable time. Time and sweat are spent exercising to improve physical condition. Travel is postponed in order to avoid treacherous conditions and increase the chances of a safe trip. Jobs are given up to pursue a safer, healthier lifestyle. If the changes in risk and the values of whatever is traded are known by the individuals and can be known by researchers, then values of life can be estimated.

Values of life are implied by observable behavior. If realistic risk tradeoff scenarios can be constructed, then values of life can be elicited directly. Values of life have been estimated using these approaches at least since the early 1970s. The models upon which the estimation is based typically use a utility function which in some way resembles the one shown in Eqn. (1), make P endogenous so that individuals can change the probability of survival through their behavior, and finally introduce a resource constraint to reflect limited money and time. An implication of these models is that individuals will engage in risk-changing activity to the extent that the marginal value of the activity equals the marginal cost. Letting V be the value of life as defined in Eqn. (2), P' the change in the probability of survival, and K the cost of changing P, the condition of interest is

$$VP' = K \tag{3}$$

If P', the change in risk, and K, the cost of changing P, can be determined, then V, the value of life implied by individual behavior, can be estimated. For comprehensive presentations of models for estimation of the value of life, see Cropper and Freeman (1991), Freeman (1993), Johansson (1995) and Johannesson (1996).

4.1 Risk-compensating Wages

The labor market has proven to be a fertile area for producing estimates of individuals' willingness to trade off safety and money. Faced with an array of jobs with different characteristics, workers will choose jobs that suit them best. If two identical workers are confronted with two jobs which are identical except for risk of death associated with the job and pay, then equilibrium implies that the worker who chooses the riskier job must be compensated by a higher wage. This risk-compensating wage difference implies a value of life. In Viscusi's (1992) survey of the literature on the value of risks to life and health, he lists 24 studies which report estimates of the value of life based on analysis of labor markets. The studies use data from various years from 1967 to 1986 and from several countries including the USA, UK, Canada, Australia and Japan. The risk variables are based on actuarial data, industry and occupation data collected by the Bureau of Labor Statistics, and worker assessments. He judges that the most reasonable estimates of value of life are clustered in the \$4–9 million range, in 1999 dollars.

Several concerns exist about the reliability of these estimates. The fatality rates used to measure risk may not reflect actual risks on the job. Worker information about the risks may be lacking or worker perception of the risks may not reflect actual risks. Risks of nonfatal injury risks may be correlated with fatality risks and may not be measured well or at all. Unmeasured and omitted job disamenities may be correlated with fatality risks. Estimates of values of life may not be representative because of self-selection of more adept or less risk averse individuals into risky jobs.

4.2 Risk Tradeoffs in Consumption

Markets other than the labor market and activities other than work have also produced estimates of individuals' willingness to trade off safety and other things they value. By estimating the effect of air quality on housing values and isolating the effect of air quality on mortality risks, the value of life implicit in the housing market can be estimated. By estimating the effect of the occupant fatality rate on the prices of automobiles, the value of life implicit in the automobile market can be estimated. These situations match well with Eqn. (3) in that numerous options are available from which the consumer can choose. Other consumption decisions are less continuous, but still imply values of life. Wearing a seat belt while driving in a motor vehicle involves a tradeoff between the gain in safety versus the time and discomfort associated with belt use. Installing smoke detectors involves a tradeoff between a reduction in risk of a fatal fire and installation costs. The value of life estimates from consumption studies tend to be less than the estimates from the labor market and fall in the range of \$1–5 million.

The concerns about the reliability of these estimates are similar to the estimates from the labor market. Some concerns can be readily addressed. For example,

if risks are misperceived according to known relationships, the implied values of life can be adjusted. Two other concerns may not be addressed as easily. One is about the ability to separate the risk of fatality from other characteristics of the product. The other is the ability to estimate the value of disutility associated with the consumption.

4.3 Contingent Market Values

Early in the emergence of value of life based on individual willingness to pay, Mishan (1971, p. 174) encouraged economists to employ a questionnaire method to estimate values of life rather than rely upon the forgone earnings or cost of illness measures. Since Mishan's exhortation, economists working primarily in environmental, safety, and health economics have developed the contingent valuation method. Mitchell and Carson's (1989) book on using surveys to value public goods presents the method after 18 years of development. This method elicits the tradeoff choice through direct questioning of the individual. The hypothetical setting or market is described, the choice is presented, and information about the respondent is collected. The survey might be in person, by mail, by phone, or some combination. Individuals have been presented with more rapid-response ambulance service for higher taxes, changes in risk on the job for compensating changes in wages, safer highway travel for more money, and safer medications for more out-of-pocket expense. Risk–dollar, risk–risk, and hybrid risk–risk and risk–dollar tradeoffs have been designed to elicit values of life. Contingent valuation estimates tend to fall in the range of the estimates from the labor market.

A great advantage of contingent valuation is the ability to provide information and describe the tradeoff precisely. Concerns exist about the reliability of estimates based on contingent valuation, and they are debated in the symposium in the Fall 1994 issue of the *Journal of Economic Perspectives*. Two of the most worrisome for estimating the value of life is the hypothetical bias due to not actually having to pay and the insufficient sensitivity of values to the scale of the change in risk. Future research on 'cheap talk' and statements of intensity of commitment to pay and research on ways to communicate risk may increase confidence in these estimates.

5. Policy Considerations Beyond the Typical Values of Life

5.1 Values for Various Types of Individuals

Benefit–cost analysis of environmental, health, and safety proposals value anticipated changes in mortality risks using the average of values of life for all members of society. In this way the values which individuals place on their own lives inform public policy. For public policies such as improvements in traffic safety which have broad effects across many types of individuals in society, average values of life are appropriate. However, some policies primarily affect specific types of individuals who may have values of life which differ from the typical individual. Whether it is socially acceptable to value lives differently is a sensitive issue. A consensus seems to be emerging that it is unacceptable to use different values for groups which differ by income; an average value of life across all of society is normally used. While no consensus exists yet, there is interest in estimating values of life for vulnerable groups such as the elderly and children. Future research is likely to focus on values of life for types of individuals who get special attention in health, safety, and environmental policy. Related is the question about discounting changes in risk which occur in the future. Discounting future risks can be relevant to people of all ages, but it can matter greatly for the very young and old. Contingent valuation studies in the USA and Sweden which address age and discounting find lower values of life for the elderly and that future changes in mortality risks are discounted substantially (see Cropper et al. (1994), Johannesson et al. 1997).

5.2 Values of Others' Lives—Altruism

Values which individuals place on changes in their own probabilities of survival may be less than the value to all of society because the values that others place on the individual's life are not counted. The strongest case for including others' values is within the individual's immediate family. Since people sort themselves into households based on mutual caring it makes sense that interdependencies are greatest within the household. Bonds within the household are thought to be strong enough that decision making is sometimes modeled at the household level and transfers are made within the household. Differences between individual value and a household value are likely to be dominated by the other factors which influence estimates of the value of life and not produce much change in the range of values relevant for public policy.

Beyond the household it is not clear that the values others have for an individual's change in the probability of survival should be included in benefit–cost analysis. In a general model of a society constrained by limited resources, it can be demonstrated that the value of a statistical life is the same with universal pure altruism with caring about the overall well being of others and universal pure self-interest with no caring at all for others. In other words, the individual's value of his or her change in risk need not be supplemented

for benefit–cost analysis. This result follows from the recognition that adding others' values causes the individual to consume more health and safety and less of other desirable things than the individual would choose to consume. The individual's value is sufficient as long as there is not substantial concern with the distribution of income. With impure, safety-focused, paternalistic altruism, however, it can be appropriate to augment the individual's value by others' willingness to pay. Future research is likely to explore ways in which safety-focused altruism should augment individuals' values of their own lives. For further readings, see Jones-Lee (1992) and Johansson (1995).

5.3 Fiscal Externalities and Burden

Another reason for considering adjusting the individual value of life is the impact that an individual's death has on others through public tax and expenditure programs. In Martin Bailey's (1980) influential policy book, he advocated the use of individual value of life for guiding policy decisions. One adjustment he made was for the individual's contribution to the public tax and insurance system. The amount of adjustment is potentially greater the more extensive is the welfare state in the society of which the individual is a part. A topic for future research is whether the adjustments average out to zero for individuals living in a society with a balanced budget constraint where net contributions are presumably zero.

More recently, the idea of fiscal externalities has motivated something which might be called social burden analysis. The fiscal impact on others of individuals who smoke cigarettes, drink heavily, or have sedentary lifestyles has been estimated to quantify the costs which individuals who do these things impose on others. The motivation for calculating such costs is that they are potential pecuniary benefits of policies which reduce these activities. Interestingly, if this adjustment were made to individual values of life for benefit–cost analysis of, say, environmental programs which reduce the risks of individuals who engage in these activities, they would have lower than average values of life and the benefits of the environmental program would be less than if it affected groups with healthier lifestyles. However, the fiscal burden adjustment is rarely used this way. Also interesting is the variance in fiscal consequences which are included in the burden analysis. For example, a RAND Corp. study estimates that smokers, roughly speaking, pay their own way because of the excise taxes they pay on cigarettes and the amounts they bequeath to survivors through net contributions to pension plans. Others who do burden analysis, including those who determine what is admissible in court, are more selective in what they are willing to accept as relevant. They will count increases in some medical costs financed by others such as those associated with hospitalization but exclude other medical costs which would be saved, such as costs of long-term care. Social burden analysis awaits a theoretical grounding to put it on equal footing with benefit–cost analysis. For further reading on burden analysis, see Manning et al. (1991).

5.4 Quality-adjusted Life Years

Early evaluation of medical outcomes was in terms of life years added. The demand to recognize quality of life lead to the development of adjusting a life year added by a quality weight to yield quality adjusted life years, or QALY. The quality weight for a health state associated with an illness (or injury) can be determined by a direct questioning method. The questioning may be as straightforward as picking a point representing the health state on a straight-line scale between death and full health. It might be deciding what probability of full health in a standard gamble with full health and death as the possible outcomes is equivalent to the health state. QALYs place a value on the expected number of years of life.

QALYs emerged to be used in cost utility, or cost effectiveness in evaluating medical interventions for several reasons. One reason was the deontological repugnance to health professionals of putting a monetary value on changes in health and, especially, life. Another was the relative paucity and suspected unreliability of estimates of individual willingness to pay in the 1980s when QALYs were being developed. With the continued development of value of life estimation and the emergence of the contingent valuation method, future practice is likely to be a blending of values of life, QALYs, and related measures. For further reading, see Gold et al. (1996), Johannesson (1996), Sloan (1996) and Drummond et al. (1997).

6. What is Known

What may seem on the surface to be impossible, place a value on life, for practical purposes is straightforward. People, individually and collectively, make choices all the time in which they implicitly make tradeoffs between changes in their probability of survival and valuable time and money. Estimates of these values of statistical lives, or, alternatively, values of changes in mortality risks, come from analysis of jobs with different wages and risks, consumption decisions involving changes in risk and time and money, and from direct questioning involving risk-money tradeoffs in constructed markets. The evidence from a large number and variety of studies suggests the typical value of life falls in a range from $1 million to $9 million. The values from the consumption decisions tend to be in the lower end of the range and the best estimate of an average value is $5 million. Studies which compare values of life with expected changes in labor earnings (or cost of illness) invariably find the

value of life is greater. Clearly, value of life estimates based on willingness to pay are considerably more reliable than in the 1980s and a growing number of decision makers are finding values of life which are reliable enough for benefit–cost analysis and regulatory impact analysis.

Questions about risk information, perception, econometric estimation, contingent valuation, and the values of life estimates remain. Risk–risk analysis developed as an alternative to benefit–cost analysis in analysis of regulations. The central relationship is the connection between changes in disposable income and individual mortality. Valuing life directly is avoided. For examples, see the collection of studies by Graham and Wiener (1995) or the special issue of the *Journal of Risk and Uncertainty* in January 1997. As long as there are concerns about the ethical propriety of valuing life and about the reliability of value of life estimates, the incentive to develop alternatives to benefit–cost analysis based on values of life exists. As long as progress continues to be made in estimating values of life, their use in making policy will grow.

Value Pluralism

'Value pluralism' has traditionally been understood as a metaphysical thesis about what values there ultimately are: there are many values that cannot be 'reduced' to a single supervalue. Although value monism has an impressive pedigree of proponents (e.g., Bentham, Mill, and, arguably, Aristotle and Nietzsche among others), it is now widely assumed to be false. The arguments for value pluralism, however, are surprisingly inconclusive. Indeed, they critically depend on the resolution of a neglected question in value theory: how are values properly individuated?

The metaphysical plurality of values has been thought to be important in two main ways. First, if values are plural, any theory that relies on value

monism is mistaken. So, for example, hedonistic utilitarianism and most forms of preference-utilitarianism must be rejected. Second, the plurality of values is thought to raise problems for rational choice. If justice, for instance, is irreducibly distinct from mercy, how can there be rational choice between them? Without reduction, it seems there is no common ground that justifies choosing one value over another.

On closer inspection, however, it turns out that metaphysical or 'reductive' value pluralism does not have the implications for rational choice that many have supposed. A charitable interpretation of value pluralist writings suggests a second, 'nonreductive,' form of value pluralism. Nonreductive pluralism is neutral on the metaphysical question of plurality but insists that in the context of choice, there are differences between values—whether or not those values reduce to a single supervalue—that have important implications for rational choice. Since the differences claimed to hold between values vary from author to author, nonreductive value pluralism is not itself a particular view about values but merely a convenient rubric under which a loose collection of different views about values may be grouped.

This article examines the main arguments for reductive value pluralism, argues that reductive value pluralism does not have certain implications it is widely thought to have, and outlines three forms of nonreductive value pluralism.

1. *Reductive Value Pluralism*

Value pluralists maintain that whatever values are, there are ultimately many of them: they do not all *reduce* to a single ultimate value. Exactly how this metaphysical thesis is to be understood depends on how the notion of reduction is to be understood.

Reduction in the context of values is best understood as an explanatory relation: if one value reduces to another, what it is to bear the one value is fully explained by what it is to bear, promote, or respect the other value. This reduction is neutral on the general ontological question of whether there 'really' are any values at all. The pluralist maintains only that there are many values, whether or not they are to be regarded as entities in their own right.

Two paradigmatic relations of explanatory reduction are 'is merely instrumental to' and 'is wholly constituted by.' (Others include 'is merely symbolic of,' 'is merely contributory to,' 'is merely a part of'). If one value is merely instrumental to another, there is nothing more to having the one value than promoting the value it is a means to. For example, if beauty is merely instrumental to pleasure, what it is to be beautiful is fully explained by the pleasure it brings. If one value is wholly constituted by another, there is nothing more to having the one value than being a way in which the other value is borne. For example, if the evening's pleasure is wholly constituted by the thrill at the gaming tables, what it is to have the evening's pleasure is fully explained by the thrill it is constituted by.

If all values reduce to a single value, that value is the only ultimate value, and value monism is correct. If however there is something more to two or more values than the values they are instrumental to, constituted by, etc., then those values are irreducibly distinct, and value pluralism is correct.

2. *Three Arguments for Reductive Value Pluralism*

Although there has been no agreement on which is the one value to which all others reduce, the view that there is such a value has two main attractions. If all values reduce to one, then values can be neatly systematized as instruments to, constituted by, etc., a single supervalue. Value monism appears to ensure a simple and elegant axiology, with a supervalue at the trunk of a structure that branches out to the other values that each derive from the supervalue in some way.

Moreover, if value monism holds, it seems that all conflicts between values are only apparent. For if there is ultimately only one value, then options for choice can be tidily arrayed according to how much of the supervalue they bear, promote, or respect. Any evaluative choice would ultimately be a choice between two amounts of the supervalue. Choosing between values would always be like choosing between two lumps of coal or three. Thus, value monism seems to dissolve the threats to practical rationality posed by tragic choices, moral dilemmas, and 'incommensurable' options.

Despite these attractions, most contemporary value theorists assume that value pluralism is true. There are three main arguments for pluralism. First is the intuitive implausibility of value monism: given the apparent diversity of values, how could there be a single value 'common to' all valuable items? Second is the thought that *akrasia* can be explained only if values are plural: how can it make sense for someone to choose something that she believes is worse overall unless there is something attractive about the worse option that is not 'included' in the better one? A closely related third argument maintains that some choice situations involve unavoidable loss: no matter which alternative one chooses, something valuable will be forgone, and thus, there must be plural values at stake in the choice.

2.1 *Ordinary Intuition*

Value monism seems to run afoul of common sense. Two intuitions suggest that any monistic account will

be vulnerable to counterexample. First, how could there be just one value that runs through valuable items as diverse as, for example, achieving philosophical insight and eating a slice of delicious cheesecake? While perhaps the value of both options is instrumental to or constituted by some value (e.g., pleasure), it is hard to believe that bearing, promoting, or respecting that value is ultimately all there is to their being valuable. Second, if there were a single value that exhausted the value of all valuable things, the evaluative difference between things could always be given by some *amount* of the supervalue. But how could the difference in value between achieving philosophical insight and eating delicious cheesecake be a matter of quantity of some one thing? It is incredible to think that evaluative differences among diverse goods are just a matter of more or less of a single value.

To these charges, monists offer two replies. The first is to suggest that the troublesome intuitions rely on an uncharitable view of monism, one according to which what it is to bear the supervalue is to bear or bring about a kind of feeling or experience like pleasure or happiness. It is, indeed, hard to believe that all valuable things involve having or producing a pleasurable or happy experience. But monism need not be so crude. Some monists propose instead that the ultimate value is given by the satisfaction of one's 'fully-informed' or 'rational' desires or preferences. The one property that runs through all valuable items, then, is the property of satisfying constrained desires, and it is the value of *that* that is the supervalue. Evaluative differences between items are a matter of the strength or number of desires they satisfy.

Whether desire-satisfaction accounts of the supervalue are plausible depends on what it is for a desire to be 'fully-informed' or 'rational.' 'Full-information' is usually understood as 'having all the relevant facts and being free from logical error.' 'Rational' desires might be procedurally rational (passing certain evaluatively-neutral tests) or substantively rational (passing certain evaluative tests). Insofar as 'full-information' or 'rational' is a value-neutral constraint, there is no guarantee that such constrained desires or their strengths will track what is intuitively valuable or more valuable: it is perfectly possible that everyone have fully-informed or procedurally rational desires to perform evil and malicious deeds, and that the desires for those deeds be stronger than desires for angelic ones. If, in an effort to secure this tracking, one places evaluative constraints on desires, as one might do by insisting that desires be substantively rational, then one must give up monism. For the values that operate as constraints on desires must be distinct from the value they constrain, and so there are ultimately many values, not one.

Monists have a second, more promising, reply. This reply was introduced by Mill in an effort to defend utilitarianism against counterintuitive consequences of Bentham's quantitative hedonism. There are, Mill insisted, not only different *quantities* of pleasure, but different *qualities* of pleasure. The pleasure of philosophical insight is a 'higher' pleasure than the pleasure of eating delicious cheesecake. Thus, while there is ultimately only one value, there are different qualities of it that explain the seeming diversity of values. Moreover, the evaluative differences between valuable items are not simply given by some *amount* of the supervalue; achieving philosophical insight and eating cheesecake may differ in the *quality* of the supervalue they bear or instantiate—one pleasure is 'higher.'

This reply gets to the heart of the dispute between monists and pluralists. The monist insists that the common-sense belief in multiple values is in fact a belief about different qualities or aspects of a single value. Whether this position is plausible depends on how values are to be individuated. What makes two considerations two distinct values as opposed to two qualities or aspects of a single value? Unfortunately, this question has received almost no philosophical attention. Until the question of how values are to be individuated is settled, ordinary intuitions cannot provide good reasons for thinking value pluralism is true.

2.2 Akrasia

Some philosophers (Wiggins 1978, Nussbaum 1986) have argued that for *akrasia* to be explained as a coherent phenomenon, plural values are required, and since *akrasia* is a coherent phenomenon, it follows that there are plural values. This argument is often presented as establishing the 'incommensurability' of values, but 'incommensurability' is used as synonymous with or as entailing plurality.

If one judges that one has most reason to choose one alternative but instead chooses the other, one is weak of will. Suppose one must choose between going to a party and staying home to work. Although one believes that staying home to work has the greater value—and therefore that one has most reason to stay home—one chooses to go to the party. How can such a choice be explained? If monism is correct, it seems that weakness of will must be an incoherent phenomenon. For suppose that there is a single ultimate value, say, pleasure. It seems, then, that there is nothing about the lesser option that could possibly attract one to it. For everything the lesser option has going for it—a certain amount of pleasure X—is included in what the greater option has going for it—X plus more pleasure to boot. One cannot choose to stay home for a reason, no matter how bad, for there is no reason for choosing the one option that is not already a reason for choosing the other.

The argument, however, does not succeed in establishing value pluralism. For akratic choice can be explained simply by attributing to the akrates a *belief* that there are plural values at stake; there need not

actually *be* plural values. One might mistakenly believe that the value of going to the party is irreducibly distinct from the value of staying home and thus be attracted by the allure of the former. One's reason for going to the party, while based on a false belief, could nevertheless be a reason that makes one's weakness of will coherent.

But perhaps for *akrasia* to be coherent in an 'objective' sense, that is, coherent for agents with, *inter alia*, relevant beliefs that are true, plural values *are* required. This version, however, also fails. One possible difficulty is that what grounds the akrates' attraction to the lesser option may be not the plurality of the values at stake but rather some contingent feature of the circumstances in which the value of the lesser option is instantiated or realized. So, for example, although there might ultimately be only pleasure at stake, the fact that the lesser pleasure of going to the party occurs in a seedy part of town has a special allure for the akrates. There are arguably no plural values here, only circumstances extrinsic to the supervalue whose special appeal to the agent might provide a reason for choosing the lesser option.

A more significant problem is the fact that attraction to the lesser option can be explained by appeal to different qualities or aspects of the supervalue. Take, for example, a choice between two glasses of wine, one laced with pepper and one not (Stocker 1990). Although one judges that the unadulterated wine will provide the greater pleasure, one is charmed by the particular pleasure of the wine laced with pepper and so chooses the lesser pleasure for the reason given by its particular charm. Similarly, one might choose to go to the party while judging that staying home is better for the reason that the party option provides a particular quality of the supervalue which staying at home lacks.

The success of this reply depends on an account of the individuation of values. Is what attracts about the lesser option a value distinct from the value of the greater option or some distinctive quality of an ultimate supervalue?

2.3 Unavoidable Loss

In some choice situations, it seems that no matter which alternative one chooses, something valuable will be lost. If, for example, one must choose between attending a lecture on Kant's ethics and having cheesecake with friends, one is bound to lose out on value no matter which alternative one chooses—and not simply because one cannot have both. If one chooses to attend the lecture, one will forgo the gustatory pleasure of eating cheesecake; if one chooses to go out for cheesecae, one will forgo the philosophical insight one would have gained at the lecture. The fact that any choice in such situations entails value loss shows that the choice involves a conflict between distinct values. Therefore, there are plural values. (Essentially the same argument is sometimes put in terms of the possibility of rational regret over having foregone a lesser good.)

Monism, it seems, must deny that such cases exist. For if monism were true, then choice would always be a matter of choosing more or less of a single value. If one chooses the option with more value, there is no value loss. If one chooses the option with the lesser value, then there is value loss, but it is not unavoidable.

Both the argument from *akrasia* in its 'objective' form and the argument from unavoidable loss rely on the conviction that values are sometimes *incompatible* with one another: pursuit of (respect for, instantiation of, etc.) one excludes pursuit of (etc.) the other. It is the incompatibility of values that grounds the akrates' attraction to the lesser option and that ensures that no matter which value one chooses, there will be value loss. This incompatibility of values might be conceptual, as Isaiah Berlin believed was true of value concepts like *justice* and *mercy*, or an intrinsic feature of values given the circumstances in which they arise. If values are incompatible, it seems that they cannot be reduced to a common value.

The monist reply here is already familiar from the previous two arguments. Sophisticated monists of the Millian variety might insist that there can be incompatibilities among different *qualities* or aspects of a single value. In cases of unavoidable loss, there need not be more than one ultimate value. The languorous pleasure of basking in the sun might be incompatible with the piquant pleasure of hearing unexpected good news: having the one pleasure now rules out having the other now though they are nevertheless instances of a single value, pleasure (cf. Stocker 1990). Similarly, the qualitative value of achieving philosophical insight may be incompatible with the qualitative value of eating delicious cheesecake. Choosing between the lecture and the cheesecake involves a loss in value no matter how one chooses, but there is only one ultimate value.

All three arguments for value pluralism crucially depend on the answer to the question, How are values properly individuated? The fundamental idea behind the common monist response to pluralist arguments is that there is a *nonultimate* sense of 'value' according to which it can be true that there are distinct 'values' and yet those values cannot be values in the robust sense implied by the claim that there are two distinct *ultimate* values.

Exactly how this is to be worked out remains to be seen. Hurka (1996) has suggested that one pleasure is not a different ultimate value from another pleasure if it does not differ in any of its 'intrinsic' features. In explaining what it is for a feature to be intrinsic to a value, Hurka urges that the location of a value is *ex*trinsic to it. Thus, John's pleasure and Joanna's pleasure are two instances of the same value, pleasure. Stocker (1990), however, has suggested that if pleasure

is located in different people, there are different ultimate values: there is the pleasure-for-John and the pleasure-for-Joanna. Stocker (1990, 1997) maintains that if it is rational to care about any difference between two evaluative considerations, it follows that those considerations are different ultimate values. Thus, there is sharp disagreement about how values are properly individuated.

Monism, if it is to be plausible, must hold that the correct account of value individuation leaves room for a tenable notion of a value quality or aspect that serves to undermine intuitions that values are plural, accounts for weakness of will, and explains away choices that seem to involve unavoidable loss. If there is such a notion, then value monism may yet win the day. But any such victory for monism may be hollow. For if monism is to be cluttered with complex relations among value qualities or aspects, the two chief attractions of monism—in short, the tidiness and simplicity it seemed to offer—fall by the wayside. In the end, then, the debate between value pluralists and value monists may be much ado about nothing.

3. *Implications of Reductive Value Pluralism*

Assuming that there are ultimately many values, what, if anything, of interest follows? There are two main implications that are thought to be important.

First, if reductive value pluralism is true, then reductive value monism and any theory that relies on it must be rejected. So, for example, Benthamite utilitarianism has to go. Perhaps more significant is the result that preference utilitarianism, or, more generally, desire-satisfaction theories of value must go. (This is not to say that desire-satisfaction theories of what it is for something *to be* a value must be rejected. One might hold that every value must satisfy some or other desire to be a value while denying that all values reduce to the value of desire satisfaction.) Many economists and some philosophers favor desire-satisfaction accounts of value, and their accounts at the very least require modification if value pluralism is true. Economists who model rational choice on satisfaction of preferences, for example, must relinquish any claim that *goodness* is a matter of satisfaction of one's preferences and instead maintain only that the rationality of choice depends on one's preferences conforming to certain axioms (cf. Broome 1991). Philosophers who think that individual well-being is the only value there is and that what makes one's life go best is satisfaction of one's desires must give up either the claim that well-being is the only value there is or the claim that well-being is simply a matter of desire-satisfaction.

Some have thought that value pluralism shows that any form of utilitarianism is mistaken. But what is essential to utilitarianism is compatible with value pluralism (Sen 1981). Others have thought that value pluralism is the foundation of political liberalism: if values are metaphysically plural, then liberalism is the correct theory of justice. But the metaphysical plurality of values is plausibly neutral between liberalism and nonliberalism. The fact that there are ultimately many values does not entail that a state should not compel its citizens to pursue one value over others, nor does monism entail that a state should not protect its citizens' choices to pursue nonultimate values in ways that do not best promote or respect the supervalue. As some political theorists have pointed out, liberalism itself might be understood as monistic about value: the ultimate value is the value of permitting people to pursue different nonultimate values. Whether there is, in the end, some indirect way in which value pluralism supports liberalism remains an open question.

Value pluralism has been thought to have a second implication. If value pluralism is correct, then difficulties supposedly follow for rational choice. The difficulties alleged are various, but the reason for thinking that none follows from value pluralism is the same. Many have supposed, for example, that alternatives for choice bearing plural values are *incomparable*. How can the option of respecting someone's right to free speech be compared with an option that doubles everyone's pleasure? Insofar as the value of a right to free speech is irreducibly distinct from the value of pleasure, it seems that there is no common basis on which to make a comparison between their bearers. The argument goes, if options for choice bearing plural values are incomparable, rational choice between them is precluded.

There is good reason, however, to think that the plurality of values does not entail the incomparability of options that bear them. Take any two putatively ultimate values such as the value of the right to free speech and the value of pleasure. One can always imagine some option that bears the one value in a notable way that can be compared with another option that bears the other value in a nominal way. So, for instance, an option that involves violating everyone's right to free speech is worse than an option that involves reducing one person's pleasure by a small amount. Given any two putatively irreducibly distinct values, there will always be some comparison between a notable bearer of the one value with a nominal bearer of the other value. The existence of 'nominal-notable' comparisons demonstrates that if alternatives are incomparable, it is not the plurality of values *per se* that entails their incomparability (Chang 1997). Assuming that rational choice depends on the comparability of alternatives, the plurality of values, then, does not preclude rational choice in this way.

Although value pluralism does not entail incomparability, perhaps the issue of value pluralism is important because if value monism is true, complete comparability follows. If there is ultimately only one value, evaluative differences between items must al-

ways reduce to differences in amount or quality of the supervalue, and quantities or qualities of the same thing can always be compared. On some views, if alternatives are comparable, the existence of a rational choice is assured. Thus, monism seems to guarantee that there is a rational choice in every choice situation, no matter how intractable the conflict may seem.

The inference from monism to comparability, however, is mistaken. It is not clear that different qualities of a single value can be compared. How can one compare the luxurious, wallowing pleasure of lying in the sun and the intense, sharp pleasure of quenching a fierce thirst? Making the case for comparability is arguably just as hard under the assumption of monism as it is under the assumption of pluralism. Moreover, even assuming that the supervalue does not admit of different qualities, it is a mistake to assume that all *quantities* of a single supervalue are comparable. Pleasure can be greater in amount without the value of that pleasure being thereby greater. The five-course feast that ends with petit fours involves a larger quantity of pleasure than the five-course feast without, for the petit fours add a quantity of pleasure to the pleasure already had. But the additional quantity of pleasure may make the meal less valuable with respect to pleasure—the petit fours induce pleasure 'overkill.' Since a larger quantity of pleasure is not always better with respect to pleasure, it seems possible in principle that different quantities of a single value are incomparable. Assuming that there are such genuine cases of monistic conflict, the issue of value pluralism cuts across the question of whether bearers of value are comparable or incomparable.

4. 'Nonreductive' Value Pluralism

In general, the question of how many ultimate values there are is irrelevant to the question of how conflicts between them are to be resolved. What matters in conflict resolution is how the values relate to one another in the context of choice, not how they stand to one another metaphysically. As already suggested, a monist might happily allow conflicts between value qualities, while insisting that, as a metaphysical matter, there is ultimately only one value.

Given that reductive value pluralism does not have the implications for practical reason that many value pluralists seem to think it has, it is natural to think that there is some other notion of value pluralism besides the metaphysical one. There is, however, no single specific idea that would account for the concerns of all value pluralists who think the 'plurality of values' has implications for rational choice. At best, the cluster of views can be generally characterized as holding that there is some or other difference among values—something apart from mere metaphysical numerical difference—that has important implications for rational choice. The loose collection of views about the ways in which differences between values can have practical implications might be called 'nonreductive' value pluralism.

Nonreductive value pluralism comes in many different varieties, but there are three leading kinds (for general discussion see Griffin 1997). First is the view that some values are *incompatible*, that they cannot be pursued (instantiated, etc.) together. The incompatibility of values raises the possibility of unavoidable loss of value and, more alarmingly, the specter of moral dilemmas in which the unavoidable loss of value is expressed by a moral requirement.

Second is the view that some values are so different that they—and therefore their bearers—are *incomparable*. Suppose you must choose between a career as a clarinetist and one as a lawyer (Raz 1986). If the values of those careers are incomparable, and if their incomparability precludes rational choice between them, it seems that whichever career one chooses, the choice cannot be rational. Thus, this kind of nonreductive value pluralism has important implications for practical reasons. It suggests that there is perhaps a wide swathe of choices that are beyond the scope of practical reason.

A third view is that some values are so different that their bearers cannot be measured by the same cardinal scale of value (cf. Sunstein 1994, Anderson 1993, 1997). Suppose you must choose between guns and butter. Since there is no cardinal scale along which the value of guns and butter can be measured, the alternatives are *incommensurable*. Many pluralists have thought that rational choice between incommensurable options is impossible. But it is clear that the lack of cardinal comparability does not preclude rational choice. One alternative might be better than another though there is no cardinal scale according to which it is better. Lexically superior options, for instance, cannot be measured on the same cardinal scale as the options they are lexically superior to, but they are nevertheless better. Moreover, the failure of *precise* cardinal comparability need not entail incomparability. Items may be *imprecisely* comparable (Parfit 1984, Griffin 1986). Although incommensurable options do not preclude rational choice, the fact that they are incommensurable entails that any justification for choosing one over another cannot appeal to the idea that there is some amount of one that provides the equivalent *measure* of some amount of the other.

Values, Anthropology of

The importance of values in anthropology was recognized by the mid-twentieth century by the designation of two chapters on this topic in Alfred Kroeber's *Anthropology Today: An Encyclopedic Inventory* (1952). Both chapters were written by philosophers, F. S. C. Northrop and David Bidney, rather than practicing anthropologists, which perhaps suggests a sense that the topic should be grounded in a humanistic tradition. Both authors trace philosophical underpinnings while also discussing issues still current such as the debate between cultural relativism and human rights. While the present essay is much briefer than the two noted, they serve as a baseline against which we can note new developments.

Values, in the sense of 'conceptions of the desirable,' (Kluckhohn 1951) definitions of the good, the moral, enter anthropology both as an object of study and as an aspect of the anthropologist's own experience. Treating values as the object of study, anthropologists have taken either a cultural or a sociological approach, either emphasizing the patterning of values in themselves, and the power of values as cultural conceptions which shape experience or, *mutatis mutandis*, emphasizing the interrelationship between values and the sociological context.

Examples of the first approach come largely from cultural anthropology in the American tradition (which has philosophical roots in German idealism). Early examples are based on configurationalism: that is, holistic analysis of values which define broad themes of a particular culture. Benedict (1934), *Patterns of Culture*, is the classic example. She distinguished Appolonian and Dionysian values among plains compared with pueblo Indians. Later, during and following World War II, Benedict, Mead and others applied the same approach to whole nations, depicting dominant values and psychological patterns of Japan, Germany, and Russia; thus was created the national-character school in anthropology. Recognizing the somewhat undisciplined, sweeping holism of these anthropological studies, Kluckhohn, Vogt, and Albert (1966), Kluckhohn and Strodbeck (Kluckhohn 1951, Kluckhohn and Strodbeck 1961) refined the approach, explicitly centering on values, defining dimensions for comparison (for example, past vs. future orientation in relation to time or dominant vs. submissive attitudes toward nature) and made systematic comparisons of particular ethnic or regional groups within America. Clifford Geertz adopted a Parsonsian definition of culture (values, symbols, and ideas) that further refined the older configurationalistic notion, then pursued a Weberian project in his *Religion of Java* (1960) where he distinguished the major divisions within a complex culture according to distinctive values. *Habits of the Heart* (Bellah 1985) applied this approach to America, producing an influential critique of American individualism and calling for a return to earlier values that recognized societal responsibility. As with the early configurationalists, German influences remained important in these later, Weberian-inspired works; *the leitmotif* is that values, as a manifestation of culture, have meaning and significance not reducible to any societal context.

The second approach gives more importance to the societal context, which is viewed as a crucial source

and ground of values. Examples of the second approach come classically from the British social anthropological tradition which had philosophical roots in France especially Emile Durkheim. In *Elementary Forms of Religious Life* (1915), he argued that thought generally, including religious belief and values, derive from society in both its normative and experiential aspects. An excellent application of this thesis is Campbell (1964), *Honour, Family, and Patronage*. Campbell demonstrates cogently how bilateral family patterns explained conceptions of honor expressed by the Sarakatsani of Greece. Honor is an ultimate value, for which the Sarakatsani man will sacrifice his life. Yet honor is grounded in kinship; in this society where seven out of ten name a kinsman as best friend, and a bastard child, lacking kin, is left on the mule path to die, one's honor depends on one's kin. The values derive from and sustain the family. Campbell's analysis is one of the best in showing the intricate functional integration of value, and social organization. Building on this particular analysis Pitt-Rivers (1983), Peristiany (1992), and others also showed how the concept of honor can be seen as a Middle Eastern and southern European value, somewhat transcending particularities of social organization but also grounded in a regional cultural and social pattern they termed 'Mediterranean.'

An effort to reduce the first approach to the second was Douglas' *Cultural Bias* (1978). Douglas distinguishes two dimensions of social life, group and grid, which (though varying in definition) pertain to setting boundaries between in-group and out-group, and defining the inner networks and classifications internal to a group (grid). Utilizing her social variables grid/group, Douglas argues that many cultural values—conceptions of time, of health and disease, of nature—depend on which particular social configuration is dominant. Thus, by knowing the social pattern, one can predict which cultural value will dominate; the societal explains cultural values.

Since the peak of the cultural and social anthropological structural-functionalist approaches to value, anthropology has developed in a myriad of directions. One is pursuing the nature of human rationality (see Overing *Reason and Morality* (1985)) and even returning to questions about human cognition (as with Quinn and Holland (1987)). Further exemplifying the sociological emphasis, but with a Marxist twist, one anthropological approach treats political economy as the driving force of culture. This approach tends to diminish the role of values. Values are treated as false consciousness, as ideological constructions motivated by class interests or a drive to power and profit. Studies of colonialism and postcolonialism illustrate this approach, for example, Comaroff's *Body of Power, Spirit of Resistance* (1985), where religious movements and their accompanying values are contextualized within a colonial and postcolonial framework in South Africa.

Studies of transnationalism and globalism likewise tend to ignore or diminish the place of values, emphasizing the capitalistic and corporate forces that construct global culture. However, human-rights formulations of value loom as one of the crucial forces tempering the global market process that has exploded since the Cold War.

While anthropologists who emphasize political economy moved values from center stage, the topic has migrated to other disciplines, especially those concerned with globalism and international relations. Huntington's *The Clash of Civilizations* (1996), for example, reifies certain value configurations, notably the Islamic and the Western, then foresees the clash between them, replacing the ideological conflict during the Cold War. Scott's *Seeing Like a State* (1998) also focuses on the power of values, notably rationalization, when coupled with the state, to shape human life and thought.

Turning to the place of values in anthropology and for the anthropologist, the basic debate is between engagement and objectivity. While Weber's 'value-free social science' concept converges with positivism to express at least an ideal of objectivity, his '*Verstehen*' converges with a Gadamerian postmodernism to acknowledge the role of values (what Gadamer terms 'prejudice') as projected by the analyst into the process of analysis. These Weberian nuances can still inform the anthropological debate (see for example, the debate between D'Andrade and Scheper-Hughes (1995)). Like Weber, anthropologists agree in acknowledging the role of values in their research and lives but they debate whether the analyst should attempt to control the influence of values, i.e., strive toward objectivity, or should embrace their influence, i.e., become engaged. Engagement means that the analyst should express rather than suppress values, whether those of one's informants, one's own, or others' (e.g., of some ideology or vision of the good). Objectivity means that the analyst should control or suppress expression of values (other than that of scientific or accurate description and analysis).

At an organizational level, two formulations by the American Anthropological Association (AAA), one on professional ethics, the other on human rights, illustrate the issue. The ethics statement boils down to a version of the Hippocratic oath 'Do no harm.' That is, above all else, do not endanger the people one studies. The Human Rights Declaration takes a more engaged and activist stance, calling for the anthropologist to intercede if human rights of a group are violated. In either instance, the anthropologist is engaged, but in the professional ethics statement the frame is set as within the research. Concern is especially with the group among whom one is doing fieldwork. With such a group of individuals, one has a 'covenental' relationship and an ethical commitment not to do harm to them as a result of carrying out the research. However, the ethics statement abstains from

a positive injuction 'Do good' or even from an activist call to 'prevent harm' to the group, in case they should come into harm's way.

As proposed by the AAA Committee on Human Rights for vote by the AAA membership, a more activist commitment is implied. The Declaration reads as follows:

> As a professional organization of anthropologists the AAA has long been and should continue to be concerned whenever human difference is made the basis for a denial of human rights, where 'human' is understood in its full range of cultural, social, linguistic, psychological, and biological senses.

The Committee further comments as follows:

> Support of the Declaration will allow anthropologists to participate more centrally in one of the most significant human-values debates of our time. Suppression of diversity by powerful states or factions with a claim to superior values has led to such horrors as ethnic cleansing and genocide. Yet, 'culture' has been used to justify not taking a stand on actions which human rights NGOs consider gross violations of human freedoms.

The history of the AAA attitude toward human rights intertwines with the history of the anthropology of values. In the mid-twentieth century when the Universal Declaration of Human Rights was being formulated, AAA declined to join the process of formulation on the ground that the ethics of human rights violated cultural relativism by claiming universal values. By the 1990s, AAA was re-engaging the conversation, acknowledging and affirming basic human rights while also emphasizing collective and cultural identities and their concomitant dangers e.g., genocide and ethnic cleansing.

While the complex issues of objectivity and engagement cannot be plumbed further here, this example illustrates part of the spectrum between a model of objectivity (analyst detached from object of research), a model of engagement (analyst obligated to intercede on behalf of endangered groups) and shades in between, illustrated by the 'do no harm,' injunction, which presumes a research objective tempered by an ethical constraint.

In the late twentieth century, efforts toward defining the place of values in the discipline of anthropology, display three major streams. The first affirms positivism and objectivity. The second affirms subjectivity, an interpretive, post-modernist stance leading toward reflexivity—explicit acknowledgement of one's values as part of one's analysis. The third also affirms the place of one's values, but leads not so much inward as outward, minimally toward ethical behavior in relation to those among whom one does research, maximally toward engagement and practice: a mission of reform and change of the world.

This debate about the proper place of values in the experience of the anthropologist is important within the discipline, but insofar as the debate is within the discipline, it is limited in its direct impact on the wider world. Arguably of greater impact is the first topic of this essay: the anthropological study of values as expressed by humankind.

Anthropology should count as one of its major contributions, to scholarship and to the world, the recognition of, study of, and affirmation of the worth of human values, both in their common aspects and in their distinctive emphasis by varied groups or cultures. This is an abiding contribution, worthy of perpetuation into the next epoch of the discipline.

Values, Development of

Values are patterns of regulation accepted as desirable by persons in a given culture or family environment and serve as guiding principles in their lives. Research on value development often centers around the concept of internalization which attempts to explain how values assumed to be initially external to an individual, become incorporated into the individual's thoughts and actions. This article describes four perspectives that guide current research on the development of values and three new research directions. Early research on value development was guided by psychoanalytic and social learning theories and did not distinguish among types of values (Grusec 1997).

Social learning studies, for instance, focused on single values such as obedience or altruism without considering connections or differences between types of values. This content-free approach to values implicitly assumed that the development of any values could be understood by very general learning or identification processes. There has been an increasing trend to study classifications of two or more values because it is thought that developmental, regulatory, and socialization processes differ depending on the content of a value. Distinctions have been made between individualistic vs. collectivistic values (Grolnick et al. 1997), the short-term (immediate compliance in parents' presence) vs. long-term nature (enduring compliance in parent's absence) of the parent's socialization goal (Kuczynski 1984), and the personal, conventional, moral, or prudential domain of the value (Smetana 1997). A comprehensive category system includes 10 values: stimulation, self-direction, universalism, benevolence, conformity, tradition, security, power, achievement, and hedonism (Schwartz 1992). These 10 values represent an integrated system that predicts how individual values may be compatible with and conflict with other values in the system. Such research on the content of values suggests that theories of value development will be contextualized increasingly in the future.

1. Four Theoretical Perspectives

Socialization perspectives emphasize the unidirectional transmission of values from an older generation to a younger generation. Older models are based on psychoanalytic (Hoffman 1970) and social learning (Bandura and Walters 1963) theories and generally are limited to an analysis of dyadic parent–child interactions. In general, this approach focused on the products of value socialization to the relative neglect of the process of value socialization. The focus on parents has been on pre-existing parental behaviors, traits, and styles that are conceptualized as antecedents of children's socialization. The focus on children has been on outcomes conceptualized as passive conformity with socialization pressures or internalization of values. Such models have been much criticized by psychologists and sociologists because of their static, homogenious assumptions concerning the nature of society, and the passive and overly conforming view of parents to the previous generation and of children to their parents (Wrong 1961). More recent socialization perspectives (Grusec and Goodnow 1994) retain a focus on the parental role in socialization, but incorporate an interest in how parents accommodate to child characteristics, abilities, and motives in designing flexible strategies for transmitting values to children.

The cognitive developmental perspectives of Piaget and Kohlberg represented early challenges to the socialization perspective. These theories emphasized children's cognitive construction of values and children's sequenced development of their capacity for moral judgement. The parent's authoritative role in teaching values was de-emphasized and a greater focus was placed on the superiority of egalitarian peer relations in promoting moral development. More recent social domain theory (Smetana 1997) balances an interest in the child's activity in constructing values in different environmental contexts with an interest in how parents, among others, provide contextually nuanced, affective, and cognitive material from which children can construct their understanding of value systems in their social environments.

Early socialization theories acknowledged the importance of a positive parent–child relationship context in such constructs as parental warmth and nurturance that were considered to enhance the effectiveness of a parent's socialization techniques. In recent relational perspectives, the long-term parent–child relationship moves to the foreground as a primary source of parental influence. Maccoby and Martin's (1983) review of the research on parent–child interaction presaged many elements of a relational perspective on socialization. In contrast to earlier

perspectives that emphasized parental discipline strategies they traced the origins of socialization to the beginnings of relationship formation during the first year of life. Research supporting the relational origins of children's co-operation include correlations with measures of maternal sensitivity during feeding, secure attachment, and measures of reciprocal parent–child responsiveness during play (Kuczynski and Hildebrandt 1997). The relational perspectives emphasize that far from having to be coerced into accepting parental values, children share a common relationship history with their caretakers that leads them to be receptive to parental influence and to adopt similar social goals.

Bilateral and coconstructionist perspectives are emerging integrative frameworks that incorporate concepts of bidirectional causality, agency of parent and child, and a changing cultural context into a comprehensive understanding of the process of value development (Kuczynski et al. 1997, Lawrence and Valsiner 1993). As with most new theories, these perspectives emphasize that values are actively constructed, or interpreted, by the child from the parental and cultural environment rather than transmitted passively unchanged from one generation to the other. What is distinctive is their explicit interest in the process of bidirectional socialization. For example, the bilateral model of parent–child relations (Kuczynski et al. 1999) focuses on relatively unexplored arenas of parent–child relations such as the constructions and strategic actions of both parents and children, power transactions, and relationship dynamics. These models also add complexity to the parental side of value development. They propose that the values that parents initially bring into the child rearing context also undergo change as the result of self-reflection, exposure to different and changing values outside the family, and the continual opportunities for problem solving and challenges that parents experience from their children during the lengthy process of childrearing.

2. *New Research Directions*

Older socialization perspectives focused on a small set of parental socialization strategies (modeling, punishment, reward, and reasoning). A generalization from this literature was that parents who had a warm relationship with their children, who were firm but not overly restrictive, and who used reasoning and persuasion more than power assertion are the most effective in enabling their children's internalization of values. Critiques of this literature are that it ignores impact of culture, and of a multitude of child characteristics (temperament, age, mood) on parental actions. It also is not consistent with findings that parents use different methods and adopt different goals depending on the varying demands of situations (Grusec and Goodnow 1994). Newer approaches that maintain a focus on socialization strategies of parents include an interest in parental flexible and responsive use of strategies and on an expanded range of socialization strategies. These are strategies that accommodate the agency of the child, attend to the construction, maintenance and repair of the relationship context of parenting interventions, and strategies that prevent or modify the impact of societal influences on children's socialization. There is a growing interest in the impact of unconscious, unplanned processes in the development of values (Bugental and Goodnow 1998). These include cultural practices in which values are learned in the doing of everyday routines and interactions. These practices are difficult to resist because they are taken for granted as 'the way things are' and are rarely open for examination or challenge. A second arena concerns the automatic processing of interactions where, for example, a parent's behavior during parent–child conflict occurs in a script-like, reactive manner, such as in mutually coercive interactions (Patterson 1997). When considered in the context of the conscious processes, a new question emerges: what aspects of value socialization develop from conscious vs. unconscious socialization processes? It is possible, for instance, that some cultural and familial values have nothing to do with specific parenting practices but are transmitted passively from parent to child as a consequence of everyday immersion in cultural practices. Other values may be inculcated by the deliberate activity of socializing agents. Conscious socialization might occur especially when parental values are not unambiguously supported by the surrounding culture or when parents deliberately prepare their children for a social context that differs substantially from the circumstances of their own socialization. Parents may also cycle through 'automatic' vs. conscious interactive processes during daily interchanges with their children (Kuczynski 1984). For example, parents may use unsophisticated power assertive strategies, such as unexplained commands and prohibitions during routine interactions when no more than a loose immediate control of a child's behavior is required. At other times, parents may shift to a more deliberate style of interacting, planning their communications or using effortful reasoning strategies, when the situation has implications for the child's long-term well being or invokes a strongly held parental value.

Most contemporary theories emphasize active, constructive processes of parents and children in value socialization and internalization. However, research is just beginning to describe these processes empirically. Research is needed on parental constructive processes concerning their own values. For instance, how do parents think about their socialization experiences and how do they select which values to pass on, abandon, or modify when they come to socialize their own children? Research is also required on children's

perspectives on their parent's socialization efforts. How do children interpret, resist, and negotiate parental messages? Lastly, the phenomenon of bidirectional influence needs to be better understood. This is because the processes underlying children's receptivity and resistance to parental influence and of parental receptivity and vulnerability to children's influence are still largely unexplored.

Values: Psychological Perspectives

1. Overview

This article asks the following questions: what are values and how are values distinguishable from related concepts like motives, goals and attitudes? Are values located within individuals or social structures?

Values are difficult to study and persistent questions arise as to whether they are 'real,' whether they actually can be shown to have causal influence on behavior. Yet much of everyday life is cast in terms of values—think of ethics, law, religion, politics, art, child rearing, and more. Abstract value judgments are embodied in seeming gut reactions that something is right, moral, or natural vs. wrong, immoral, or unnatural. Another way to 'see' values in action is to contrast cultures or subcultures in what seems right, natural, or moral. One of the great contributions of cultural and cross-cultural research is the way that it brings Western cultural values into sharp relief.

Americans are said to value life, liberty, and the pursuit of happiness. But what does value mean? Implicitly or explicitly we evaluate or assign value to everything—regarding things as good or bad, a truth or falsity, a virtue or a vice. How do we know? One important means is through values. Values can be thought of as priorities, internal compasses or springboards for action—moral imperatives. In this way, values or mores are implicit or explicit guides for action, general scripts framing what is sought after and what is to be avoided.

2. Definitions

Modern theories of values are grounded in the work of Kohn (class and values), Rokeach (general value systems), and Kluckhohn (group level). Values can be

conceptualized on the individual and group level. At the individual level, values are internalized social representations or moral beliefs that people appeal to as the ultimate rationale for their actions. Though individuals in a society are likely to differ in the relative importance assigned to a particular value; values are an internalization of sociocultural goals that provide a means of self-regulation of impulses that would otherwise bring individuals in conflict with the needs of the groups and structures within which they live. Thus, discussion of values is intimately tied with social life. At the group level, values are scripts or cultural ideals held in common by members of a group; the group's 'social mind.' Differences in these cultural ideals, especially those with a moral component, determine and distinguish different social systems. In this sense Weber's Protestant 'ethic' and 'spirit' of capitalism describe value systems.

Values, to which individuals feel they owe an allegiance as members of a particular group or society, are seen as the glue that makes social life possible within groups. Yet, they also set the stage for frictions and lack of consensual harmony in intergroup interactions. Values are thus at the heart of the human enterprise; embedded in social systems, they are what makes social order both possible and resistant to change. Values are not simply individual traits; they are social agreements about what is right, good, to be cherished.

What is common to all value phenomena? At the individual level, values contain cognitive and affective elements and have a selective or directional quality; they are internalized. Preference, judgment, and action are commonly explained in terms of values. Individuals take on values as part of socialization into a family, group and society. Once taken on, values are assumed relatively fixed over time (see *Values, Development of*). Indeed, values that are individually endorsed and highly accessible to the individual do predict that individual's behavior. Conversely, even personally endorsed values won't influence action when they are not made salient to the individual at the time of action. Moreover, in any given situation more than one personally endorsed value may apply, and the behavioral choice appropriate for one value may conflict with the behavioral choice appropriate to another value.

Values are codes or general principles guiding action, they are not the actions themselves nor are they specific checklists of what to do and when to do it. Thus, two societies can both value achievement but differ tremendously in their norms as to what to achieve, how to achieve, and when pursuing achievement is appropriate. Values underlie the sanctions for some behavioral choices and the rewards for others. A value system presents what is expected and hoped for, what is required and what is forbidden. It is not a report of actual behavior but a system of criteria by which behavior is judged and sanctions applied. Values scaffold likes and dislikes, what feels pleasant and unpleasant, and what is deemed a success or failure. Values and value systems are often evoked as rationales for action; for example, values of freedom and equality were evoked to elicit American support for the Civil Rights movements. Values differ from goals in that values provide a general rationale for more specific goals and motivate attainment of goals through particular methods.

3. *History and Current Developments*

Initially viewed with suspicion by Western social scientists as too subjective for scientific study, the concept of values found increasing use beginning with *The Polish Peasant in Europe and America* (Thomas and Znaniecki 1921). Impetus for the study of cultural values comes from the work of Alfred Kroeber, Clyde Kluckhohn, Talcott Parsons, Charles Morris, Robert Redfield, Ralph Linton, Raymond Firth, A. I. Hallowell, and more currently Milton Rokeach and Shalom Schwartz.

Kluckhohn and Strodtbeck (1961) proposed that cultural value systems are variations of a set of basic value orientations that flow from answers to basic questions about being: (a) What is human nature—evil, neutral, mixed, or good? (b) How do we relate to nature or supernatural—subjugation, harmony, or mastery? (c) What is the nature of time—past, present, future? (d) What is the nature of human activity—being, being-in-becoming, doing? (e) What is the nature of our relationship to others—are we joined vertically, horizontally or are we simply separate individuals? They also organized a system for comparing values in terms of their level of generalization and function in discourse and conduct, proposing that values fit into a pyramid of ascending generalization. For each society, a few central or focal values were proposed to constitute a mutually interdependent set of what makes for the 'good life.' These include the unquestioned, self-justifying premises of the value system and definitions of basic and general value terms; for example, happiness, virtue, beauty, and morality.

Since American researchers dominated values research, much early work focused on documenting American values. Need for achievement as an American value, and concern over decline in the centrality of this orientation appear as early as 1944 (Spates 1983). Values studies documented the influence of education, age, type of employment, and socioeconomic status on value preferences of Americans, adding to Weber's thesis of the influence of religion (Protestantism vs. Catholicism) on achievement and work values in Europe. Kohn (1977) was responsible for a number of important values surveys documenting that in various European countries and the US, parents of higher socioeconomic status value self-direction in their

children more than parents of lower educational and occupational levels. These findings have been verified cross-nationally in 122 societies.

Extending the documentation of American values, Rokeach (1973) validated empirically 36 values related to preferred end states and preferred ways of behaving. Using Rokeach's scale, value differences tied to class, age, race, subculture, and level of differences were documented in many countries. Building on Rokeach, Schwartz (1992) delineates values as ways of articulating universal requirements of human existence—to survive physically, have social interchange, and provide group continuity. For Schwartz, values represent operationalizations of these needs as goals that fit together in meaningful clusters (achievement, self-direction, stimulation, hedonism, universalism, benevolence, tradition, conformity, security, and power). Some clusters are compatible (e.g., stimulation and hedonism) and others compete (e.g., self-direction and conformity).

Using mostly data from teachers and college students in 20 primarily Western countries, Schwartz shows that, with the exception of China, specific values mostly do 'cluster' and 'compete' as expected. Thus, 'honest,' 'forgiving,' and 'helpful' cluster together as 'benevolence,' and 'self-direction,' and 'stimulation' cluster far from 'conformity,' 'tradition,' and 'security.' These data suggest important universality to how values are organized cross-culturally and that societies differ in which clusters of values predominate public life.

4. *Controversies*

Key tensions in the values literature focus on the conditions under which they may influence behavior, and the appropriate level of analyses for seeing values in action. Interest in values as a research focus has ebbed in the past as each paradigm for studying values has been criticized for lack of specificity of findings as due to values and not other social norms, attitudes or situational constraints. Current cultural psychology focuses attention on social structures as the repository of values such as personal freedom, group harmony, personal happiness, and duty or filial piety.

How do we know that values exist? A number of options are available: (a) Individual testimony—people say what values they hold.Yet, self-reports of values are subject to pronounced context effects (see *Attitudes and Behavior*). (b) Behavioral choices—either in naturalistic or laboratory settings, value differences may be imputed from behavior. Yet, behavior is influenced by many variables other than values. At the individual level, values themselves are assumed to link to behaviors via their influence on norms and attitudes, but people may infer their values from their behavior, reversing the causal relationship. (c) Cultural and social structures—expenditure of resources, time, energy and structuring of the natural environment; cultural products can be seen as concrete residues of value-based choices (see *Cross-cultural Psychology*; *Cultural Psychology*). (d) Social interchange—observation of behavior in situations of conflict, and more generally observation of what is rewarded or punished, praised or vilified provides data for identifying what is socially valued. Here, too, the question of appropriate evidence arises. To what extent is it appropriate to assume that differences in social structures and societies are evidence of value differences? Political and economic influences and simple inertia may set the stage for behaviors, without a causal influence of necessarily values.

5. *Future Directions*

Cross-cultural perspectives are currently becoming increasingly central to values discussion. For example Inglehart (1990) documented values and value change in a large multinational study, and a large number of two-nation comparison studies has emerged. Another important topic of research is the connection between values of individuals, values of subcultural groups, and values of larger cultural systems and methods for identifying and studying each of these. Perhaps in addition to identifying value vocabularies at each level, it is time to begin to ask whether values appropriately are studied as fixed traits of individuals or as embodied in groups, and to what extent values research is synonymous with cultural and cross-cultural research.

Given that any particular behavior importantly is influenced by context effects that make certain information salient at the moment of action, it is not surprising that the effects of individual value endorsements on behavior have a 'sometimes you see it, sometimes you don't' quality about them. But focusing on individual endorsement of values may miss much of the power of value systems to influence everyday life. That is, individuals may not need to personally endorse or have salient particular values in order for their influence to be felt. The most profound influence of values may be through the ways that they influence rules, norms, procedures within a society, and in this way structure the everyday life choices for individuals within a society.

Thus, whereas previous researchers have documented values using survey techniques in which individuals rated the extent to which various values were important to them, future assessment of values may need to consider more indirect approaches such as what services a society provides its members, what behaviors are rewarded or sanctioned and so on.

Values, Sociology of

Everything social actors appreciate, appraise, wish to obtain, recommend, set up or propose as an ideal, can be considered as a value. Ideas, emotions, moral deeds, acts, attitudes, institutions, material things, etc. may possess this special quality by virtue of which they are appraised, desired, or recommended. But what is attractive for some, can be repulsive to others. Thus, to values correspond countervalues which are underrated, disapproved, rejected. Nationalism and internationalism, private and public property, freedom and equality, etc., may be, according to diverse actors, values or countervalues.

1. *Dimensions of the Concept*

Four main dimensions of the concept can be distinguished:

(a) Each value has an *object*, i.e. what is valued, prized. The nation, Moslem faith, work, profit, instruction, leisure, honesty, the family, etc., may become values. Any element of social reality, of the spiritual and moral world, can have a 'value aspect' insofar it is praised or refused, advocated, or condemned.

(b) This object is qualified by a *judgment* as valuable or contemptible, as good or bad, as useful or useless, as true or false, as desirable or not, as beautiful or ugly, etc. The sentence expressed is a value judgment. One will say, e.g., that one's country is inviolable and its enemies are unkind, that Moslem faith is true and unbelievers are mistaken, that work is sacred and profits are unjust, that honesty is a virtue while robbery is dishonest, and so on. Value judgments answer to a large set of principles and criteria whereby opinions, beliefs, convictions are shaped, choices are made.

(c) Values become *norms* when they command and/or regulate conducts, prescribe a course of action. Norms tend to conform behavior and commitments to the values confessed. If your country is inviolable, you should defend it, if Islam is true, you must comply with its prescriptions, if profits are unjust, you must fight against them, if instruction is important, you must learn, if honesty is a virtue, you are not allowed to misappropriate funds. Values provide the grounds for accepting or rejecting particular norms, and norms are standards for actual conduct.

(d) The *value holders* are either individual or collective actors or social groups. Therefore one can speak of the values of such and such person, of the liberals, of the middle class, of the teenagers, of the Russians, or of Bantu culture.

The concept of value is inseparable from the notion of preference. To value one object rather than another (e.g. to prefer a party of cards to the theater) means that in a given situation the value inducing the choice was adopted or inculcated to the detriment of another.

2. *Value Systems: Definition*

The values of an individual or a collectivity do not appear as sharply separated and independent units. Instead, they are bound together, are interdependent, they form a *system*. When a new value is acquired or an old one is lost, when a value is weakening (lowering) or strengthening (rising), the whole system will be affected.

A system of values is hierarchically built up. It is also a scale of values. Often the difference between actors does not proceed from the content of their systems, but from their difference in ranking their values. For example, in the abortion debate, all participants may highly prize the value of life, but some will emphasize the conceived child's future while others will take into account the mother's decision.

The actor is more or less tied to certain values than to others. Values contain not only cognitive elements, they involve strong affective components too. The more a value is deeply rooted, the more it takes a central place in the system and the more it is lived intensely, arouses emotions, and mobilizes vehement energies. There are values men are ready to die for.

The mode of organizing a system of values varies from one culture to another. Its inner logic does not obey the same rules. This fact is undoubtedly the main reason why misunderstanding prevails between peoples pertaining to different cultures, each one interpreting the world in its own terms.

3. Harmony and Contradictions

At a first glance, the word 'system' suggests that the values upheld by the actors have their inner rationality and that their logic can be discovered. But a closer examination reveals that values are not necessarily clear and cannot be easily stated. A system is not perforce transparent. Often it comes to light only by action.

Moreover, values of the same actor can be in contradiction, i.e. push towards incompatible goals. The tension may remain covert if the actor is unconscious of this inconsistency, but overt contradiction in crucial matters may produce trouble of conscience, crisis, even anomy.

Another type of contradiction occurs when behavior and acts belie values. Criminals are likely to subscribe to principles and priorities similar to those of the man of the street. They only transgress a few of them by their deviant conduct. Ordinary people also regularly experience noticeable discrepancies between their fine words and their deeds.

Consequently, a set of values is a living system, very complex, open to seesaw motion and variations.

4. How Values are Acquired and Maintained

Values are shaped and built in, receive their meaning, and are structured primordially by the process of socialization whose main agents are the family, the school, the media, the peer-group, etc. Men progressively learn the rules of their society, their knowledge, their know-how, are educated, i.e. appropriate their 'cultural equipment.' Everybody confronts his/her life with the values which are accessible to him/her. Persons born in the same social milieu or at the same time (thus pertaining to the same generation) and having been socialized similarly are likely to embark upon their human destiny sharing the same values. Those who share the same values are likely to assemble and to act together.

If the system of values proves to be an efficient guide, a good map for the travel through life, there is no manifest reason to modify it. It is consolidated by experience. It is in congruity with the conditions of real existence.

Social approval or disapproval constitutes another way of reinforcing values. Opinions and behavior are socially controlled: conformity with the predominant values is rewarded, deviance is more or less severely penalized.

5. How Values Change

Nevertheless, a value system is a 'living concern' and it is regularly challenged by an evolving social environment. It responds by a slow, adaptive change, its main features persisting, but sometimes it undergoes more dramatic change, a complete upheaval.

Change has several meanings: some values are being upgraded or downgraded in the actor's value system; some values enter into the system, others exit; some gain in intensity, others weaken; values elicit greater or less commitment from their holders; some expand, the number of their adherents grows, others lose their attractiveness; the scope of validity of a value can vary (e.g. fraternity may be limited to the members of the family, but it may be extended to the nation or to mankind); etc.

Value changes can be induced by a large range of causal factors. It would be impossible to draw up a complete list. Some examples: value change may result from economic crisis or from prosperity, from demographic collapse or from a population explosion, from ecological alterations (such as pollution). Learning, knowledge, increased information are propitious to questioning values. External cultural influences may give rise to imitation or suggest that some institutions, customs, and ways of thinking are inadequate. Technological inventions play an important role: television has successfully replaced or diminished other leisure activities in the preference scale of citizens. If an organization is at odds with the surrounding world, it is challenged to change its mind, to introduce reforms or perish. The past and present of all political regimes or 2000 years of Christian history tend to show this.

Scarcity entails the rise of a value (in an anonymous world people are likely to cherish the value of conviviality). A durable conditioning by either advertisement or propaganda may provoke value shifts. Sometimes dormant values are awoken: generally solidarity is not very highly ranked in opinion polls, but some disaster may suddenly 'warm up' the value and mobilize people to help the victims.

In all these cases external pressure or influence initiate the process of value change. If change begins and continues in the same orientation, it can speed up and/or become cumulative. But the movement between values and the social environment is not unidirectional, as in the examples mentioned where values are dependent variables. Values are also independent variables. If, for example, technological inventions influence values through modifying ways of living, it is also true that valuing inventiveness, novelty, creativity, scientific research, will powerfully stimulate technological progress. The relation between values and economic, social, political, or cultural factors is governed by a dialectical swinging. Change is the product of the combined operation of the external world and the mental and psychic universe.

To explain dramatic value changes, reference must be made to a theory of social problems. In this perspective, as long as the itinerary of a society or a group, or the trajectory of an individual are unfolding without a major accident, there is no need for a change of course. But if suddenly a rupture happens (e.g. the

death of a beloved person, the loss of a job, a divorce … for the individual; deep dysfunctioning, a foreign attack, a revolutionary situation … for the society)—imbalance, disorganization, deadlock, frustration, alienation come about. The overall guiding capacity of the value system is cruelly put to the test.

It becomes rapidly apparent if the existing values are adapted or not to define the problem and suggest solutions. If this operation is successful, the value system of the actor will be consolidated. On the contrary, it may occur that the 'cultural equipment' of the actor is insufficient to recognize and evaluate the ins and outs of the situation. His/her perceptions, ways of thinking, and values which inform and command his/her feelings and reasoning lose grip on the reality. He/she seems to be culturally blind. He/she risks to succumb to a crisis or fall into anomy. At the macrolevel, whole civilizations may witness decline and final collapse.

Another eventuality is particularly interesting from the point of view of value change. The actor has perceived and formulated the problem, but he/she lacks means for tackling it. His/her value system is then submitted to a partial decomposition: the elements which do not respond to the requirements of the situation (i.e. to understand what is at stake and conceive a project) are dismantled, abandoned. For example, a society desirous to undertake economic development is forced to eliminate such values as conformity, respect for inherited hierarchies, or the acceptance of fatality.

A stage of recomposition is undertaken when the actor is trying to integrate new values able to suggest objectives and means for a suitable action. In this search, the total number of appropriate values is not infinite. Only those will be retained which offer a satisfactory solution to the original problem, correspond to the intimate aspirations of the actor, and can be bound up with other existing values. In the case of a development oriented society, entrepreneurship, the notion of exact time, or middle-term prevision will be values to be promoted.

The process described above is by no means a mechanical one, following a logical step-by-step operation or a fixed chronological order. It takes place in the very heart of the conscience, in the midst of impressions, reflexions, and hesitations; the values, as well as the project, which finally will prevail, will emerge from a more or less long incubation period. The path followed will of course differ in the case of an individual actor as for a collective one.

6. *Production of Values*

Values are not impersonal, everlasting principles, existing since the first mists of time, floating in the air. They are, in the last instance, shaped by historically situated outstanding figures or institutions. These latter can be called 'value producers,' 'standard setters,' 'sense makers.'

Who are they? Mostly, great moral personalities, prophets, philosophers, ideologists, intellectuals, scientists, artists, novelists, film directors, and institutions such as Churches, clubs, learned societies, research centers, universities, etc.

Their tasks consist of answering the society's existential questions, in giving a meaning to events, in elaborating systems of thought, in proposing new horizons. They supply society and the actors with ideas, objectives, programs, ethical principles, critical judgments, etc.

The expansion of values is assumed by 'value transmitters,' 'opinion leaders,' 'popularizers,' 'teachers,' etc. and takes the usual channels of cultural communication such as newspapers, radio, television and other media, books, music, the school system, etc.

Public opinion generally lags behind with regard to the value producers and the opinion leaders. The speed and the scale of the diffusion of a value depends on a complex interplay between the needs, the receptivity, and the resistance of the public and the powerholders, as well as the opportunities for innovation.

7. *Classifications*

Many typologies of values have been put forward. Here are some of the most significant and useful:

(a) The *core values* are those endorsed by the whole population. The *specific values* are shared by some segment of people: social class, age group, a region, an ethnic minority, etc. Social consensus is built upon the core values. They make sure that the members of a society can live together, understand each other, communicate and enjoy a minimal cohesion. Core values correspond to what are called the 'ethos of a civilization' or the 'dominant values' of a people.

(b) The *structuring values* are those in the center of a value system, ordering it, commanding the arrangement of the whole. They are the most important for the actor, explain his/her choices. They resist change while the *peripheral values* are more open to external influences. For some individuals, their structuring value is family, for others love or professional success or religion or soccer, etc., as well as any combination of two or three values.

(c) A similar distinction opposes *final* and *instrumental values*. The final values are at the top of the hierarchy in the system while the instrumental values are necessary to achieve them (like hard work as a means for professional success).

(d) *Global values* transcend the different spheres of social life, their area of validity embraces all human relations. For example, justice may be a requirement for the allotment of an inheritance, the fixing of a price, a legal verdict or the international relations.

Moral values are naturally global. *Sectorial values* are confined to a special sphere of society. Political, economic, religious etc. values like parliamentary democracy, competition, or piety, are sectorial.

(e) Totalitarian societies impose *unanimity* in the field of values. Many traditional communities tend to be unanimous. If constraint loosens, society becomes progressively *pluralistic*. The coexistence of divergent value systems calls for tolerance. But they can clash too. Value conflicts are sharper than conflicts of interests because values arouse emotions and passions. When values like nationalism or religion (or both) motivate the contenders and define their very identity, the struggle threatens with destruction and death.

8. *Place, Role, and Function of Values in Sociological Analysis*

Values are present practically in all social process and historical transformation. It would be impossible to list all situations and evolutions where they play an active role. To mention some of them must suffice.

Values assume the function of identity building. The individual aware of his/her values, can consider him/herself as a person, find his/her place in the world, feel confident, interpret and evaluate his/her environment. The group sees in its values one of the major reasons of its members' adhesion, the common denominator of the participants: to share the same values is cementing their union.

Values are constituents of the system of action of individual and collective actors. They motivate them, influence their needs and aspirations (for one strives to obtain what one is valuing), order their perceptions (for one looks on the world through the glasses of his/her values), provide criteria for their judgments on the society, their situation, on others, on themselves.

Values hold an intermediary position between the reality and the actor's will to preserve or to modify it. Indeed, values suggest projects. They command the selection of objectives: one goal is preferentially chosen because it is more attractive, more desirable, more appreciated. They help to determine the means: which one is better, cheaper, more appropriate, more efficient, etc.

Values supply the 'raw materials' of ideologies. Ideologies rationalize the values, the aspirations, and the interests of the actors. Values also intervene in any speech whose aim is to persuade or promote nourishing a more or less occult argumentation. They serve to justify unavowable initiatives, attitudes, or feelings: an aggression, e.g., will not be presented as such, but legitimated by values such as national security or the liberation of a neighboring country.

Values generate attitudes and steer behavior. The meaning of the patterns of behavior is not understandable without referring to the values of a given culture.

Values are often a mobilizing force for social change. Large-scale shifts like revolutions or reforms are generally preceded by transformations in the value systems and guided by new values. They are embodied by new symbols: flag, colors, emblems, statues, revered places or monuments, songs, etc.

Values contribute to maintain and regulate society, being the fundamentals of legitimacy, law, and social control. (Following the scientific ideal, it is claimed that social sciences must be value-free, which means that ideologies, doctrines, and beliefs can never impede, interfere with, or distort the impartiality and desirable objectivity of scientific method.)

9. *Study of Values: Methodological Devices*

Talleyrand said: 'God gave us the faculty to speak in order to conceal what we think.' This is the reason why it is so difficult to study values. Furthermore, even the most honest persons meet with difficulties in accounting for their values. A lot of these remain implicit, taken for granted. Another problem: how to identify values? They are embedded in verbal, behavioral, and situational contexts. We often have to infer them constructing indicators and being attentive to the signs which reveal them. This careful study requires a critical apparatus and a well-constructed method.

A large array of research instruments has been developed to recognize and index values. Allport, Vernon, and Lindzey used a values test. M. Rokeach listed 18 terminal values ('preferred end-states of existence') and 18 instrumental values ('preferred modes of behavior'). Respondents ranked the items by importance as guiding principles for daily life.

Interviews with standardized questionnaires are another path to follow. If they are conceived in an international comparative perspective, the selection of the vocabulary requires a preliminary contextual analysis. In case of free, nondirective interviews or autobiographies, the respondents choose their own words and produce a richer material, but less easy to generalize.

The researcher has at his/her disposal a great variety of sources: newspapers, magazines, advertisements, school textbooks, novels, doctrinal works, speeches, songs, pictures (photos, films), symbols, etc. He/she needs adapted content analysis or different kinds of semiological approaches to extract the values held by the authors and actors.

Values can also be observed in their natural setting focusing on men's activities and behavior which embody their motivations, desires, aspirations. In certain circumstances experimental designs and techniques are advisable.

The approach to adopt depends on several considerations: the nature of the values to be discovered, the seeking of rapidity of results, extensivity or

intensivity of the knowledge targeted, etc. A combination of procedures is always recommended, for none of the instruments covers the entire field alone.

10. Past and Recent Research

For philosophers and moralists, 'value' has been a familiar notion for a long time. For economists, from the outset, it was a central concept. The founding fathers of sociology approached the study of cultural phenomena without necessarily using the word 'value.' Tocqueville, for example, speaks of the 'spirit' of the Americans and attributes to religiosity the main characteristic of their society. For Karl Marx, ideas, feelings, ethics, law are superstructural facts determined by the infrastructure. According to Max Weber protestant ethics (values) play a central role in the birth of capitalism. With *The Polish Peasant in Europe and America* (1918–1921), W. Thomas and F. Znaniecki make of values an important factor.

Finally, the concept becomes the object of a book with C. Bouglé, one of Durkheim's followers (*Leçons de sociologie sur l'évolution des valeurs* 1922). Anthropologists were particularly well qualified at focusing their interests on field studies of cultural phenomena in small communities. Following their dominant values, Ruth Benedict divided Indian communities in the South-West of the US into Apollonians and Dionysians (*Patterns of Culture* 1934).

A new and decisive trend opens with the Cornell Values Study Group under the impulse of Clyde Kluckhohn (1949). It initiated a long-term comparative project which led to the theory of value orientations of Florence Kluckhohn and Fred Strodtbeck. These investigations owe much to Talcott Parsons' functionalism which places the actor and value guided action at the heart of the sociologists' interest. Seymour Lipset was inspired by Parsonian categories in comparing American values with those of other Anglo-Saxon societies (1963) and those of Latin America (1967).

In the meantime, the theory of development founded by economists was extended to the cultural field. Everett Hagen (1964) and others emphasized the decisive contribution of values to the transition towards economic growth.

At the end of the 1960s and the beginning of the 1970s, a deep cultural turmoil surprised the Western world. Old traditional values were refused and new ones adopted and diffused by osmosis. These profound and fast changes stimulated sociological research on values. The new era was baptized, following the authors, individualistic, narcissistic (Christopher Lasch), hedonistic, secularized, postindustrialist (Daniel Bell), postmaterialist, etc.

The postmaterialist hypothesis of Roland Inglehart (from 1971 on) opened a broad current of empirical investigations. Another pioneering effort was due to Milton Rokeach (1973).

In 1981 a first international comparative survey was launched by the *European Value Systems Study Group* headed by Jan Kerkhofs and Ruud de Moor, and covering 10 countries (the same questionnaire being used). Jean Stoetzel synthetized the results in his *Les valeurs du temps présent: une enquête européenne* (1983). A new wave of surveys took place in 1990 with all European countries as well as the US and Canada participating. The enterprise has become the largest research program ever carried out. It was decided to replicate the study at 10-year intervals. The 1999 survey encompassed 45 countries. A rich academic literature abounds around the investigations (between 1990 and 1997 alone, 194 recorded titles). A similar work was done by the European Union's *Eurobarometer*, publishing recurrent data on values too. More recent investigations have penetrated specific fields such as political values (Rezsohazy 1996).

Venture Capital

1. Introduction

Apparently, 'venture capital' was first used as a term in a public forum by Jean Witter in his presidential address to the 1939 Investment Bankers Association of America convention (Reiner 1989). Since then venture capital has evolved into a specialized form of finance supporting small privately owned companies judged to have the potential for fast growth. With few exceptions, the overriding goal of venture capitalists is to reap capital gains in excess of 10 times their original investment in less than seven years. A most strict definition of venture capital excludes buyouts, loans, and other financial transactions. Venture capitalists invest in equity in the form of common stock, or preferred stock, convertible debentures, or other financial instruments convertible into common stock when the small company is sold either through a merger or a public equity offering. At this liquidity event venture capitalists realize their profits in the form of capital gains.

2. The Venture Capital Industry

Since the 1950s a number of the fastest growing firms, particularly in the technology area, in the US economy received venture capital. These include Amazon.com, America Online, Amgen, Apple Computer, Cisco Systems, Compaq, DEC, Federal Express, Genentech, Intel, Lotus, Netscape, Oracle, Seagate, Sun Microsystems, 3Com, Yahoo!, and countless others. These and other venture capital-supported firms were responsible for the establishment of entirely new industries such as biotechnology, semiconductors, database software, the Internet, hard disk drives, minicomputers, workstations, and data communications. In this way venture capital became an important part of the US national system of innovation. Since the emergence of formal venture capital organizations there has been significant institutional experimentation seeking the best format to support venture investing. Not surprisingly, the organizational forms have varied through time. Though the independent private venture capital firm is the dominant organizational form, it is not the only one. Financial institutions particularly banks using their small business investment corporations (see below) have also been significant participants since the early 1960s. Industrial corporations have had significant venture capital operations since the mid-1960s. There have also been other formats including publicity-traded closed-end funds, other publicly traded vehicles, and family funds. In the early 1980s the private firms became the dominant format for venture investing. In the private firm the venture capitalists manage the limited partnership funds, each of which was denoted by a Roman numeral in increasing order. In these funds the venture capitalists were the general partners and investors were the limited partners. The investors included pension funds, foundations, endowments, corporations, wealthy individuals, and various other entities. The duration of a particular fund was typically between seven and ten years. During the first one to

three years the fund actively invests, then in the final years the fund harvests its investments. Compensation for the general partners has two components. The first component is an annual management fee paid by the limited partners; this can range from two to three percent of the limited partner's investment. These fees pay the costs of operating the firm and the salaries of all the employees including the venture capitalists. Very often, successful firms have two or more funds operating simultaneously, all of which provide management fees. The other component is the carried interest, which refers to the percentage of the capital gains the venture capitalists retain from the investments after reimbursing the initial investment of the limited partners. The carried interest varies by fund from 20 to 30 percent of the total returns. In the case of successful funds this can be very large.

3. *History*

Venture capital investing has always been cyclical, and largely governed by the receptivity of the stock market to new stock offerings. However, since the inception of formal venture capital investing in 1946 there has been a continuing growth in the amount of venture capital available. In 1965 venture capitalists invested less than $100 million in new ventures. In 1999 investments had increased to $48 billion (Venture Economics 1999). For centuries, wealthy individuals have invested in risky ventures in the hopes of securing an outsize return. Such investments can be traced back at least as far as the involvement of merchants in organizing consortia to finance long-distance trading ventures. The financing for firms participating in the Industrial Revolution came from merchants and other wealthy individuals willing to back entrepreneurs building manufacturing facilities or exploiting a new technology. These informal investors are now known as 'angels,' i.e., individuals who are not professional investors in startups.

During the 1930s in both the US and the UK there were discussions of the lack of investment capital for small businesses. In the UK the 1931 Macmillan Report identified a shortage of private sector funds for supporting small business. The report contributed to a contemporaneous debate in the US about how to provide funds for the small businesses severely affected by the Great Depression. There was little agreement about what types of small businesses should receive funding and the proper vehicles for providing financing. Prior to World War II, there were a few wealthy families, such as the Mellons, Phipps, Rockefellers, and Whitneys, investing in young ventures. Shortly after World War II in New York City these families established offices and hired professional managers to discover, evaluate, and invest in small companies with superior growth prospects. These were the first family venture capital funds. Though each of them changed many of their organizational characteristics, the Rockefeller (Venrock), Whitney (J. H. Whitney), and Phipps (Bessemer Ventures) funds continued to be active in 2000. The other significant private sector initiative was the establishment of American Research and Development (ARD) in Boston in 1946. ARD was important, not only because of the firms it funded, but also because of the Harvard Business School (HBS) faculty member, General Georges Doriot, who established it. Doriot influenced a number of HBS students who later became venture capitalists. As important, Doriot through his writing, speaking, and example defined many of the practices of venture investing. Finally, ARD's $70,000 investment in Digital Equipment Corporation in 1958 was worth $350 million in 1971—ample proof that significant return was possible. The role of the US government in the development of venture capital has been limited with a few important exceptions. In 1958 the US government passed legislation creating the Small Business Investment Corporations (SBICs) to encourage investment in small businesses. Despite being plagued by abuse during its first decade, the SBIC program made two important contributions to the development of the industry. The first contribution was its loan guarantees, which permitted participants to leverage their private funds. This made low-cost capital available to investors, a number of whom soon left the SBIC program and established important independent venture capital firms. The SBIC Act also loosened Depression-era laws forbidding banks from owning more than 5 percent equity in any company. By having an SBIC the banks were permitted to own large equity stakes in their venture-type investments. Particularly in the 1960s and 1970s banks were a significant source of venture capital. During the 1980s the independent firms displaced them.

There was other Federal legislation which had a significant impact on venture capital. The most important was a series of changes in employee pension fund laws during the 1970s. The first change was dramatic tightening by the Employment Retirement Investment Security Act of 1974, which operated to nearly cut off pension fund investment in venture capital. The legislation was gradually loosened from 1977 through 1982 and new pension fund monies flooded into the independent firms. The lowering of capital gains tax rates, may also have encouraged venture investing (Bygrave and Timmons 1992). With these exceptions the federal government has only had a limited role in creating the industry.

4. *Investment Process*

Venture capitalists are not passive investors. Because of their equity stake, they have an interest in the firm's success, which is defined in terms of a rapid increase in the firm's value. Invariably, one or more venture

capitalists 'lead investors' join the firm's board of directors. From this position they actively monitor the firm's progress. However, they do more than monitor. They often assist and counsel management. This involvement comes in many forms and is situationally dependent, but includes counseling on major strategic decisions, assisting in recruiting key personnel, providing contacts in the legal, investment banking, and other business service communities. Finally, the investment by a prestigious venture capital firm creates the perception that the small firm will be a success, an important asset for convincing customers and suppliers that the startup is viable and worthy of patronage.

Entrepreneurship depends on the structure of investment opportunities; in the typical venture capital investment scenario, an entrepreneur or entrepreneurial team approaches a venture capitalist with a business plan describing the firm, the management team, potential competitors, and the market (Martinelli 1994). Since venture capitalists receive hundreds of business plans per annum, though most receive at least a cursory examination, the plans recommended by someone the venture capitalist knows receive the greatest attention. If one of the venture capitalists is interested, then the entrepreneurial team is invited to present its business plan in person. Should the venture capitalist's interest continue, the entrepreneurs' references and others who might be able to speak of the candidate's qualifications, personal and technical, are contacted. If there are technological unknowns the venture capitalist gathers information on the project's feasibility from technical experts. They also interview prospective customers trying to gauge their need or desire for the product. In other words, they gather as much information as possible about the investment and its growth potential. If these hurdles are surmounted, then the team is invited to present the plan to a meeting of all of the partners. Should the partners agree, then a contract detailing the terms of an offer is extended to the entrepreneurs. Upon acceptance the venture capitalist invests the firm. With this investment the relationship between the entrepreneur changes as the venture capitalist now is committed to the success of the firm. Venture capital investments are staged, and, if the firm meets preset milestones, then it receives new investments at a higher valuation. Should the firm not meet its targets or the market changes at the next stage the firm's valuation can decrease. Usually, venture capitalists syndicate their investments with other venture capitalists, thereby spreading risk, providing multiple contacts and sources of advice for the startup firm, and a cross-check on the investment decision (Gompers and Lerner 1999). There are three exit strategies for venture investments: sale of the stock through an initial public offering, sale of the firm through a merger, or bankruptcy. Upon any of these liquidity events the proceeds are returned to the limited partners as either cash or marketable securities. As a rule of thumb, three or four investments are expected to fail at a near total loss. Another three of four neither fail nor are easily liquidated. These are termed the 'living dead' and are judged failures by the venture capitalists. For the successful funds it is the final two or three that determine the return. In these cases one or two investments provide returns of 10 to over 100 times the initial investment. It is these successes that compensate for the failures and complete the venture capital cycle.

5. *The Globalization of Venture Capital*

Venture capital as a formal institution was an US innovation. In other countries and other historical periods, merchant banks, governmental bodies, and even family networks performed some similar functions, especially with regard to money raising. Beginning in the late 1970s a few of the US funds looked abroad for funding opportunities; also, in other countries' governments, financial institutions, and individuals wishing to reproduce the US experience established funds targeting local opportunities. Most of these non-US efforts floundered because of a dearth of entrepreneurs, an inadequate institutional infrastructure to nurture and support entrepreneurship, and a lack of experienced venture capitalists. As a result, if these venture capital operations survived, it was, with only a few exceptions, by becoming what in the US would be called private equity capital firms concentrating upon management buyouts, bridge financing, purchase of equity in the stock market, and an occasional startup. The exceptions were a few firms in the UK, and notably, Israel, which became a center of venture capital-financed startups in the 1990s. In the late 1990s, due to the opportunities for new firm formation to exploit the Internet, there was a proliferation of venture capital firms in, not only Europe, but also Latin America and Asia.

The impressive returns achieved by US venture capitalists attracted investors from around the world. In some cases, these funds were routed through venture capital firms based in the US and managed by foreign professionals or corporate venture capital investment operations operated by foreign multinationals. More frequently, European and Asian funds were invested in US funds and in US startups. Despite these investments, non-US capital has only played a minor role in financing US venture capital.

6. *Conclusion*

There are continuing debates regarding the efficacy of a venture capital-based innovation system. There have been recurring criticisms of venture capitalists for encouraging the exodus of high-level managers and

even entire research teams from existing firms, thereby disrupting product development teams (Florida and Kenney 1990). In Europe some have seen in venture capital the harbinger of rampant individualism and greater income inequality and social differentiation. The emphasis on large capital gains is thought by some to bias the economic system against incremental process innovation and large-scale systems innovation such as, for example, in transportation systems. Despite these concerns, venture capital as an institution for supporting innovation has experienced a pattern of cyclical but massive secular growth since the 1940s.

Verbal Communication, Psychology of

Although linguists think of language as an abstract structure—a set of principles that specify the relations between a sequence of sounds and a sequence of meanings—to its users, what is most significant about language is its versatility as a medium for communication. The ability to communicate is vital to a species' survival, and all animal species communicate, some in ways that are impressively proficient. But none achieve the precision and flexibility that characterizes human communication, a capacity due in large part to the uniquely human ability to use language (Deacon 1997, Hauser 1996).

1. Elements of Communication Systems

All communication systems, regardless of how simple or complicated they may be, operate on the same principle: Signals transmit messages from a source to a destination. The distended belly of the female stickleback signals the male to initiate an elaborate courtship routine that culminates in fertilization of her eggs (Tinbergen 1952). Upon returning to its hive, a foraging honeybee communicates the direction and distance of a source of nectar by engaging in an elaborate waggle-dance (von Frisch 1967). Vervet monkeys (native to East Africa) have three distinctive vocal alarm calls that signal the presence of leopards, eagles, and snakes, their three main predators. Upon hearing one or another call, a Vervet will respond appropriately—climbing a tree in response to the leopard call, scanning the ground when the snake call is sounded (Seyfarth et al. 1980). Each of these systems represents the species' adaptation to the exigencies of a particular ecological niche in which communication facilitates survival. Language can be thought of as a similar sort of adaptation.

Communication systems use two kinds of signals: signs and symbols. Signs are signals that are causally related to the message they convey. We say that blushing means someone is embarrassed because we know that embarrassment is a cause of blushing. Symbols, on the other hand, are products of social conventions. Because of an implicit agreement among speakers of English, the sound pattern we recognize as the word *dog* denotes the familiar category of furry, four-legged creatures. There is no intrinsic reason that *dog*, rather than some other sound pattern, should convey that message, and in languages other than English, of course, very different sound patterns represent the concept DOG. Verbal communication often involves both signs and symbols. The tremulous voice that tells us a speaker is experiencing distress is a sign, i.e., a direct product of the distress it signals. But it is the symbolic content of verbal communication that accounts for its extraordinary effectiveness.

2. Semanticity, Generativity, and Displacement

Language is only one of the symbol systems humans use to communicate. The 'thumbs-up' gesture conveys the message of success, approval or hope; the wedding ring and the mourner's ribbon publicly proclaim the wearer's current status; a facial grimace in response to the question 'How did you like the movie?' symbolically and effectively expresses the person's assessment. Notwithstanding the utility of such symbolic displays, language endows human communication with three properties, semanticity, generativity, and displacement, that collectively distinguish it from other sorts of symbolic displays and from the forms of communication observed in other species.

Semanticity: In human communication, signals stand for things, which is to say that they have meaning. An overheated dog will pant to dissipate heat, and an astute observer may understand the panting to indicate that the dog is hot, but panting cannot be said to stand for overheatedness in the same way that the word 'overheated' does.

Generativity (sometimes called Productivity): All languages are capable of generating an infinite number of meaningful messages from a finite number of linguistic signals. Languages allow symbols to be combined and recombined in ways that yield novel meanings, and any competent language user will regularly produce and comprehend utterances that have never been uttered before, but are immediately comprehensible to all competent language users. Even so sophisticated a system as the Vervet's alarm calls is limited to a fixed set of messages, and lacks the ability to generate novel ones. For the Vervet, there is no way to signal the presence of predators other than eagles, leopards, or snakes.

Displacement: Language makes it possible to communicate about things that are remote in space or time, or indeed exist only in the imagination. Bertrand Russell once remarked that 'No matter how eloquently a dog may bark, he cannot tell you that his father was poor but honest.' Although the observation is self-evident, even banal, it points to a fundamental difference in the expressive capacities of language and other communication modalities. Vervets can signal the presence of a predatory eagle, but even the most articulate Vervet cannot refer to the eagle that attacked a week ago; their communication is limited to what is immediately present. Perhaps more than any other feature, it is the capacity of language to convey displaced messages that distinguishes it from other communication modalities.

The ability of language to generate an unlimited number of meaningful novel messages that are not bound to the here and now, combined with the cognitive capacity to exploit these properties, allows human communication to be extraordinarily effective and versatile. The full extent of this effectiveness and versatility is revealed by an examination of how communication systems work.

Regardless of the type of signal, all communication involves the transfer of information between a source and a destination. Anthropologists Daniel Sperber and Denise Wilson characterize it as:

> …a process involving two information-processing devices. One device modifies the physical environment of the other. As a result, the second device constructs representations similar to the representations already stored in the first device (Sperber and Wilson 1986 p. 1).

The description applies equally well to the transmissions of a fax machine, the gesticulations of a policeman directing traffic, or a conversation among intimates. In verbal communication the 'information-processing devices' are people, the 'representations' are mental representations or ideas, and the 'modifications of the physical environment' are the uniquely human disturbances of the acoustic surround called speech.

3. Four Communication Paradigms

Precisely how is language used to convey information? There are many characterizations of the ways language functions as a medium for communication, but the major ways are captured by four models or paradigms (Krauss and Fussell 1996). Each paradigm focuses on a different dimension of language use, and might be thought of as a necessary but incomplete description of the process. The four paradigms are: the encoding–decoding paradigm, the intentionalist paradigm, the perspective-taking paradigm, and the dialogic paradigm.

3.1 Encoding and Decoding

Language often is described as a code that uses words, phrases, and sentences to convey meanings. A code is a system that maps a set of signals onto a set of significates or meanings, and in the simplest kind of code, the mapping is one to one: for every signal there is one and only one meaning; for every meaning, there is one and only one signal. In Morse code, a familiar example of a simple code, the signals are sequences of short and long pulses (dots and dashes) and the significates are the 26 letters of the English alphabet, the digits 0–9, and certain punctuation marks. The encoding–decoding approach to language conceives of communication as a process in which speakers encode their ideas in words, phrases and sentences, and listeners decode these signals in order to recover the underlying ideas.

Words, phrases and sentences do convey meanings, of course, but viewing linguistic communication simply as encoding and decoding doesn't do justice to the subtlety of the process by which language communicates. In order to appreciate this, we need to consider the role of the speaker's communicative intention and how it is related to comprehension.

3.2 Communicative Intentions

In Morse code, the sequence · · · · designates the letter H, and only that letter, and the letter H is represented by the sequence · · · ·, and only that sequence. In contrast, a speaker who says 'Can you close the door?' might be understood to be: (1) requesting that the auditor shut the door; (2) asking whether the auditor is physically able to shut the door; (3) asking whether the door's physical condition is such that it could be shut; or (4) asking whether shutting the door is permitted. Typically, by saying 'Can you close the door?' the

speaker intends only one of those meanings to be understood. and in all likelihood that is the meaning that will be understood.

A listener who has understood an utterance has grasped the particular sense in which the speaker intended the words to be understood. Considering the number of meanings even the simplest utterance is potentially capable of conveying, the ability of addressees to identify the intended meanings of the vast majority of the utterances they encounter is truly remarkable. This ability is the foundation of human communication. As the linguist Stephen Levinson puts it: '…communication is a complex kind of intention that is achieved or satisfied just by being recognized' (Levinson 1983 p. 18).

There is abundant evidence to support an intentionalist view of language use. For example, bank clerks, when asked 'Can you tell me what the interest rate is?' are likely to respond to the utterance as a request ('Tell me the interest rate') rather than to its literal force ('Are you able to tell me the interest rate'). Listeners demonstrate considerable mental agility in divining speakers' communicative intentions. In one study, people were shown a picture of then-President Ronald Reagan seated alongside David Stockman (the not-well-known director of the Office Management and Budget), and asked one of two questions: 'You know who this man is, don't you?' or 'Do you have any idea at all who this man is?' As reflected in their answers, people asked the first question overwhelmingly assumed the question was about President Reagan, while none of those asked the second question did (Clark et al. 1983). That people strive to understand the communicative intention that underlies the utterance is not in doubt. What is less clear is how they go about doing so. Identifying another's communicative intention is not always a simple or straightforward matter, in part because people do not always perceive the world in the same way. This difficulty is usually formulated as a problem of Perspective-taking.

3.3 Perspective-taking

The meaning of even the most prosaic utterance is grounded in a set of implicit assumptions about what the communicators know, believe, feel, and think. People experience the world from different vantage points, and the totality of each individual's experience is unique to the particular vantage points he or she occupies. To accommodate discrepancies in perspective, communicators must take each other's perspectives into account when they formulate and interpret utterances. The process is most readily illustrated by spatial perspective-taking. Two people viewing the same layout of objects from opposite sides of a table will perceive the objects' spatial relations somewhat differently. The cream pitcher that is to the right of the sugar bowl for one person, will be to the left of it for the other. In talking about such things, or in giving directions, speakers tend to formulate spatial relations from the addressee's point of view ('It's the first door on your left'), even when it differs from their own (Schober 1993).

But even when they communicate about matters that lack spatial content, speakers must take others' perspectives into account. A statement like 'John is the fellow wearing the ugly tie' assumes that speaker and addressee share the same esthetic sensibility. For the utterance to communicate, the speaker must have in mind the addressee's conception of what constitutes an ugly tie. As the social psychologist Roger Brown put it, effective communication 'requires that the point of view of the auditor be realistically imagined' (Brown 1965).

However, the content of another's point of view is not always obvious. In his classic studies of childhood egocentrism, the Swiss developmental psychologist, Jean Piaget, demonstrated that the ability to apprehend others' perspectives represents a major milestone in the child's intellectual development. Young children are unable to detach themselves from their own points of view, and, in effect, seem to assume that the world appears to others as it does to them (Piaget 1952). This reduces their effectiveness as communicators (Krauss and Glucksberg 1977). Although adults do better, they are far from perfect, and like children their judgments of others' perspectives tend to be biased by their own points of view. Under time pressure or when preoccupied, adults are likely to formulate messages that neglect their addressees' perspectives (Keysar et al. 1998). Moreover, adults' perspective-taking efforts display an egocentric bias similar to that found in children. Asked to estimate the likelihood of someone identifying an individual pictured in a photograph, people who themselves recognized the person tended to overestimate his recognizability, while people who did not recognize him underestimated it (Fussell and Krauss 1991).

Such limitations in the ability to appreciate others' perspectives might make verbal communication considerably less effective than it is were it not for the fact that communication is a collaborative rather than an individual process. The collaborative nature of communication is the focus of the paradigm we call Dialogic.

3.4 Dialogism

The encoding-decoding, intentionalist, and perspective-taking paradigms all characterize communication in terms of individual acts of production and comprehension. In this view, participants are viewed as 'autonomous information processors' (Clark and Brennan 1991). The speaker must generate utterances that will convey a particular meaning; the addressee

must process those utterances, and by so doing identify the speaker's intended meaning. Communicative exchanges that relied exclusively on such an arrangement would impose a heavy cognitive burden on the participants. Probably because we do it so well, we seldom appreciate how complicated a process communication is. Producing spontaneous speech requires the speaker to perform two cognitively demanding tasks simultaneously: conceptualizing the information to be conveyed, and formulating a verbal message that is capable of conveying it. The number and complexity of the factors that must be taken into account is dauntingly large (Levelt 1989). The addressee's task is equally challenging. Speech is evanescent; once it has been articulated, it must be processed and comprehended in real time. Conversational speech is produced at a rate of about 2.5 words per second, often in noisy environments and with less-than-perfect articulation. Production and comprehension could pose formidable problems for two completely autonomous information processors. Yet participants typically come away from conversations believing they have communicated successfully, and objective evidence probably would indicate that they have.

One reason people are able to communicate as well as they do in such adverse circumstances is that the exquisite responsiveness of conversation (and similar highly interactive forms) permits them to formulate messages that are closely attuned to each others' immediate knowledge and perspectives, which reduces the cognitive demands of production and comprehension. The participant who at a given moment occupies the role of speaker can determine virtually instantaneously whether the addressee has identified his or her communicative intentions correctly. Simultaneously, the addressee can reveal the nature of his or her understanding as it develops, and in this manner guide the future production of the speaker.

As Herbert Clark and Susan Brennan (1991) have observed, certain activities by their very nature involve joint or collective action, and it makes little sense to think of participants' actions as individual events.

> It take two people working together to play a duet, shake hands, play chess, waltz, teach, or make love. To succeed, the two of them have to coordinate both the content and process of what they are doing…Communication, of course, is a collective activity of the first order.

Close examination of what actually is said in conversations reveals that it is seldom an orderly process in which participants alternate in the roles of speaker and listener. Rather, sentences often trail off inconclusively or are left dangling incomplete; listeners interrupt to ask questions, interject comments, and finish sentences; topics change abruptly and unpredictably; and what is left unsaid may convey more than what is explicitly stated. It would be a mistake to regard such conversational speech as a defective version of some ideal form. Rather, these apparent aberrations reflect the way conversation operates as a communicative process.

In the dialogic view, conversational speech is the model for communication, and a communicative exchange represents a joint accomplishment by the participants, who have collaborated to achieve some communicative goal. As a result, meaning is 'socially situated'—deriving from the particular circumstances of the interaction—and individual contributions are not fully meaningful apart from that situation.

4. *Future Directions*

Although language must have evolved in the setting of face-to-face communication, human inventiveness has long sought ways to transcend the limitations of time and space that physical co-presence imposes. The most important technological development in this quest was the invention of word-syllabic systems of writing, probably in Mesopotamia around 4,000 years ago. Phonogramic representational systems made it possible to transform the ephemera of speech into a tangible record that exists independent of the person who generated it—a development with profound consequences at both the individual and the societal level (Goody 1977).

Writing systems, combined with more recently invented technologies for recording, transmitting, and reproducing signals, make it possible to transmit a dizzying variety of materials (data, text, graphics, facsimile, to name only a few) over virtually limitless distances. Surely the enhanced communicative capacities that such technologies make possible have wide-ranging potential consequences for the way human life is constituted.

A species' survival depends critically upon its ability to communicate effectively, and the quality of its social life is determined in large measure by how and what it can communicate. Human social life as it is presently constituted is predicated upon an extraordinary level of communicative virtuosity—a level of virtuosity that the uniquely human ability to use language confers. Absent this, our lives would be quite different.

Verstehen and Erklären, Philosophy of

Verstehen (interpretative understanding) and *erklären* (law-governed explanation) are two ways to make scientifically respectable sense of a phenomenon. The scientist who engages in *erklären* tries to make explanatory sense of the phenomenon by finding the laws that govern it, whereas the scientist who engages in *verstehen* tries to make empathetic sense of the phenomenon by looking for the perspective from which the phenomenon appears to be meaningful and appropriate.

The originally German tradition of *verstehen* insists that the social sciences are unlike the natural sciences in that making merely *explanatory* sense of social phenomena can never lead to comprehensive knowledge of these phenomena, even if explanation would be enough, and indeed is all there is to comprehensive knowledge of natural phenomena. The reasons for this claim will be reviewed in this article. A first set of reasons, discussed in Sect. 1, derives from an investigation of the differences between natural and social phenomena. A second set, discussed in Sect. 2, derives from a survey of a number of controversies that are high on the agenda of those who assume that *verstehen* and *erklären* are incompatible methods, only one of which can be the proper method of the social sciences.

1. *The Autonomy of the Geisteswissenschaften*

The German verb *verstehen* is, from a philosopher's point of view, closely connected with Dilthey (1833–1911) and his concern to secure the autonomy of the *Geisteswissenschaften*. A salient feature of the development of German intellectual culture in the nineteenth century was a growing awareness of the fact that philosophy and metaphysics are themselves historical phenomena. An important consequence of this insight was that thoughts and ideas and such like came to be seen as part of the furniture of the world. Thoughts and ideas are not outside the world in some timeless conceptual realm; they are objects in the world that could, in principle, be studied by empirical science. Of course they are peculiar objects, these mental appearances ('*geistige Erscheinungen*'); they are objects with content, quite unlike natural phenomena, but are nonetheless empirical objects. An excellent example is a text printed in a book. That is obviously an empirical object—ink on paper—but is very unlike the ink spilled on blotting paper. Crucial to the text is that it means something, and this feature of the text is so important to its identity that we can easily make sense of the claim that a text which physically consists of nothing but ink on paper can still be numerically identical to a text which physically consists of sounds produced by a human voice, or even (as we now know) to a text which physically consists of a long series of bits on a computer disk.

The fact that the meaning of mental appearances such as texts is so fundamentally important to their identity motivated Dilthey to defend the view that there are two radically different kinds of empirical objects: natural and mental phenomena. According to Dilthey, this dualism within the empirical realm asks for and justifies a dualism on the level of scientific methods. Natural science already proved to be successful in making explanatory sense of natural phenomena by means of *erklären*. But the *Geistes-*

wissenschaften could not and should not try to make sense in a similar way (by *erklären*) of mental phenomena such as thoughts and ideas, even though it finally becomes commonsensical—or so Dilthey believed—that mental phenomena, like natural phenomena, are part of the furniture of the empirical world. If the *Geisteswissenschaften* were to be successful, Dilthey argued, they should not look for explanations in terms of covering laws, but should concentrate on the attempt to make empathetic sense of mental phenomena by means of *verstehen*. After all, the only way to acquire scientifically respectable knowledge of a phenomenon is to gain comprehensive insight into what is of crucial importance to the essence of the phenomenon; in the case of the mental phenomena, this means grasping their meaning.

In order to appreciate the relevance of this reasoning to the social sciences, it is important to point out how likely it is that one will take a second step after having pointed out the relevance of a distinction between mental and natural phenomena. This second step consists in claiming that what is crucial to social phenomena such as human actions is that they mean something, which makes them much more similar to mental appearances such as texts than to natural phenomena such as leaf-fall in autumn. It is relevant in this context to note that the twentieth-century French philosopher Ricoeur (1981, pp. 197–221) has argued that it is almost literally true that human actions are texts.

According to philosophers who defend the autonomy of the *Geisteswissenschaften* (e.g., Dilthey), the paradigmatic objects to be investigated by means of *verstehen* are the social and cultural manifestations of human life, characterized not only by being (a) meaningful, but also by being (b) purposive and (c) essentially relational. As will be shown in the remainder of this section, some of the details of the method of *verstehen* can be brought to the fore by discussing these three aspects of the manifestations of human life.

However, in this connection it should be stressed that although the distinction between *erklären* and *verstehen* was originally made in close connection with that between natural and mental phenomena as well as that between natural science and the *Geisteswissenschaften*, there is no need to accept these three distinctions as one package. That is, one can defend the view that there is a real and important distinction to be made between *erklären* and *verstehen*, independent of whether or not it is (a) plausible to defend that a neat split can be made between natural and mental phenomena, and (b) useful to divide the academic disciplines into the natural sciences and the *Geisteswissenschaften*. In the remainder of this article, it will be taken for granted that the social and behavioral sciences have no interest in making or accepting the latter two distinctions, although it is important for them to accept and take notice of the methodological distinction between *erklären* and *verstehen*.

1.1 Meaningfulness

Things have meaning (at least to a very large extent) in virtue of the fact that people ascribe meaning to them. These ascriptions can be diverse and numerous and can display a multitude of perspectives, motives, and biases. This has two consequences for the scientist engaged in *verstehen*. The first is that it is pretty absurd—if not impossible—to try to capture a phenomenon's meaning independent and irrespective of the meaning ascribed to it by all those people in whose life this phenomenon has a role to play. The meaning of, for example, a gesture such as a smile cannot be found if you start by excluding the meaning ascriptions of all the people involved. This should not, of course, mislead the scientist into thinking that a particular meaning ascription is as good as any other. Nor should he simply assume that particular persons (e.g., the author of a text) have a principled authority over the meanings to be ascribed. *Verstehen* is a delicate undertaking that requires careful attention. A scientist engaged in *verstehen* faces the important challenge of deciding on the relevance and import of each and every meaning ascription (see Schutz 1970).

The second consequence of the prominence of meaning ascriptions is that a double hermeneutics necessarily forms part and parcel of *verstehen*. Trying to grasp the meaning of a phenomenon is always a matter of trying to grasp the meaning of a pre-interpreted phenomenon. And it is one thing to grasp the meaning ascribed to the phenomenon by an earlier act of interpretation, but quite another to grasp the meaning this earlier act of interpretation attempted to grasp. This can lead to a conception of *verstehen* as a quest for the original meaning of a phenomenon, a conception that was dominant in the hermeneutic tradition of Dilthey. The German philosopher Gadamer (1960), however, argued that such a quest beyond all prejudices would be futile. A prejudice is an original meaning ascription, and—rather than blocking the road to empathetic understanding—these prejudices open up the very possibility of *verstehen*. There are no original meanings, according to Gadamer. There are only original meaning ascriptions. The intentions of the person who, for example, makes a gesture, share this character of being a prejudice (i.e., a meaning ascription) with the social scientist's attempt to make empathetic sense of this gesture. Meaning exists, in Gadamer's view, in the multifaceted meeting of different meaning ascriptions to the same phenomena. This leads to a conception of *verstehen* in which the growth of self-understanding is always as central to the scientific enterprise as is the growth in interpretative understanding of the phenomenon investigated.

1.2 Purposiveness

According to many, teleology—or purposiveness—is a distinctive feature of human action. Human actions take place *in order to* bring certain future states of affairs about, not merely *because* certain past states of affairs happened. I go to the hairdresser *in order to* have my hair cut, not merely *because* my hair has grown. This emphasis on goal-directedness and final causes in the description of human action is foreign to the spirit of modern science, which seems so successfully engaged in redescribing purposiveness in terms of functionality and functionality in terms of organizational structures that arise through natural selection. Human action seems to be a last vestige of teleology, and the adherents of the *verstehen* tradition took pains to defend it by arguing for a radical distinction between human behavior and all other natural events. *Erklären*, they argue, is a matter of making explanatory sense of natural events by citing their cause, but there is more to be done than just that in making sense of human actions. Part of what is needed in making sense of actions is to rationalize them, that is, to make empathetic sense of them by citing their reason. And reasons are essentially normative: if I were to try to explain my visit to the hairdresser by merely citing the fact that my hair has grown, I would fail to explain my action, unless I explicitly mention the implicit normativity, that is, that my hair has grown *too long*. The normativity that figures conspicuously in the rationalizing of actions is the tough nut to crack for those who wish to remove purposiveness from any description of such mental phenomena as human actions.

A lot of extremely interesting work done on the relation between explaining by citing causes and explaining by citing reasons can be found in the Anglo-American literature (Davidson 1980, Taylor 1964, Malcolm 1968, Wright 1971, Dennett 1973, Macdonald and Pettit 1981). This work, although mainly written without engaging with the tradition of *verstehen*, is very helpful in that it elucidates what it means to make empathetic sense of an action by looking for the reasons that make the action meaningful and appropriate.

1.3 Essential Relationality (Holism)

According to adherents of the *verstehen* tradition, we pick out natural and mental phenomena in very different ways. We can pick out, or individuate, natural phenomena without engaging in an attempt to make explanatory sense of them. That is precisely what creates the demand for natural science: here is a natural event (say the collapse of a bridge) and we can identify it in such a way that we know we are talking about this event, even though we have not the faintest idea of what caused it to happen. Thus, we can fail to understand a phenomenon we can describe quite accurately, and this is what motivates us to engage in *erklären*, that is, to look for causal and law-governed explanations.

We cannot, however, pick out mental phenomena in a similar way. Because their meaning is crucial to their identity, it is impossible to individuate a mental phenomenon without, by the same token, engaging quite seriously in an attempt to make empathetic sense of it. That is, the atomism that seems possible with respect to natural phenomena (each of which can be described in total isolation from the others) is completely foreign to the realm of mental phenomena. Getting acquainted with these phenomena requires holistic assumptions. In order to pick out such a mental phenomenon as a vote, for example, we need a tremendous amount of detailed knowledge about a whole background in which events could count as votes. This entails knowledge of institutions, of means to justify authority, of decision procedures, etc. This semantic background contains more than just the conceptual relations that make it possible for something to be a vote. It also contains the intentional relations that make it true that some bodily behavior constitutes a particular vote; the intentional relations that determine, for example, that this arm being raised at this particular moment counts as a vote for X, a vote that could also have been expressed by this particular option box being ticked, or by this name written down on this particular slip of paper, etc.

The holism that is essential to the individuation of mental phenomena has important consequences for the method called *verstehen*. Whereas it might be true that a law-governed explanation of a particular natural phenomenon urges us to completely revise our ordinary description of the phenomenon (e.g., contrary to what we always thought, we now know that solid bodies consist mainly of the void), it is inconceivable, according to adherents of the tradition of *verstehen*, that a scientifically respectable, interpretative understanding of the manifestations of human life could radically replace our ordinary understanding of them. The *Geisteswissenschaften*, it is claimed, are bound to elaborate on the conceptual scheme of common-sense (nowadays often labelled folk psychology), because they can only begin to make empathetic sense of mental phenomena such as human actions in virtue of accepting the commonsensically sound understanding of these actions implied by our means to pick them out in the first place.

This is known as the hermeneutic circle, or the inescapability of each individual's own traditional semantic horizon. It raises many of the most important questions discussed in the *verstehen* tradition, for example, how to understand the manifestations of a foreign culture, or texts written in bygone times.

The upshot of the discussion so far is that there is a useful distinction to be made between a scientific interest in the causal laws that govern phenomena and a scientific interest in the perspective from which

phenomena appear to be meaningful and appropriate. The former interest can be satisfied by engaging in *erklären*, the latter by engaging in *verstehen*. *Verstehen* involves (a) the careful assessment of the relevance of meaning ascriptions, (b) a double hermeneutics, (c) a concern for self-understanding, (d) a rationalization of phenomena by citing reasons, (e) a disclosure of implicit normativity, (f) an acceptance of semantic holism, (g) of the inseparability of description and interpretative understanding, and (h) of the inescapability of semantic horizons.

Whether or not these features disqualify *verstehen* as a scientific method, or force us radically to revise our conception of (social) science, has been the topic of serious controversies.

2. *Two Ways to Do Social Science? Some Controversies*

The German verbs *verstehen* and *erklären* almost immediately suggest the image of an opposition and, therefore, of a controversy. Although there were periods in nineteenth- and twentieth-century German intellectual life during which *verstehen* and *erklären* were conceived to coexist peacefully—the first being at home in the humanities, the second in the natural sciences—the most disturbing, and fruitful, interest in the concepts arose during two periods (the first and second *Methodenstreit*) in which people fought over which of the two methods would be most appropriate to the social sciences. During the first period (roughly 1900–30), neo-Kantians such as Rickert, Cassirer, and, most influentially, Weber tried to come to terms with the methodological dualism that seemed characteristic of the social sciences that emancipated at the time from philosophy. During the second period (roughly 1955–85), Wittgensteinians, phenomenologists, and critical social theorists mainly discussed the impact of the ontological commitments connected with a *verstehen* approach to social reality on our conception of (social) science.

In this section, four themes that were high on the agenda during those periods will be discussed. The discussion will be conceptual; no attempt will be made to provide a picture of the historical development of these themes (see *Hermeneutics, History of*).

2.1 *Unity of Science*

Positivism (see *Comte, Auguste (1798–1857)*; *Logical Positivism and Logical Empiricism*) followed in the wake of the natural sciences, endorsing the view that science is to be defined by the methodological procedures that enable us to explain and predict natural phenomena so successfully. If there are to be social sciences, the demand of the unity of science will imply that the method used in natural science (*erklären*) must also be applicable to human action. If human action allows for scientific knowledge this will mean, according to the positivist credo, that we can and should try to explain human actions by looking for the causal laws that govern them.

This bold statement evoked worries, misunderstandings, and refinements with respect to the place of *verstehen* in the social sciences. One plausible reaction (developed by neo-Kantians during the first *Methodenstreit*) is to defend the unity of science but deny the defining role of *erklären*. Science, one could say, is an attempt to make systematic and generally accessible sense of all phenomena. But there is more systematic and generally accessible sense to be made of what happens than merely explanatory sense. We can—and in the case of the manifestations of human life, should try to—make empathetic sense of what takes place by looking for the perspective from which these manifestations appear to be meaningful and appropriate.

Part of the positivistic project, however, was to show that there is no need and no place for empathetic sense in science. If the meaning and the appropriateness of human actions are to be accounted for by science in a systematic and generally accessible framework, this should be done, according to the positivists, by investigating objective patterns of behavior and not by telling stories about how these patterns look from the necessarily perspectivistic point of view of the people on the scene. The main problems with this line of reasoning are discussed under the three following subsections.

2.2 *Intentional Explanations*

According to the positivists, actions are to be explained by subsuming them under general, contingent, empirical, causal laws that connect mental states of individual agents (in particular, their beliefs and desires) to their actions, that is, their overt bodily movements. Acknowledging that reasons are in fact sets of beliefs and desires that function as causes is—according to the positivists (see *Hempel, Carl Gustav (1905–97)*)—the starting point for a social science that can make progress by engaging in *erklären*.

Opponents of this view argue, along three different lines, that one can make empathetic sense of human actions by producing intentional explanations (i.e., explanations citing beliefs and desires), but that such explanations are not a matter of *erklären*, because intentional explanations are neither causal nor nomothetic (involving laws).

First, a Wittgensteinian line of argument says that pointing out the relevance of the agent's beliefs and desires in order to explain the apparent appropriateness of an action is not a matter of citing its cause or of hinting at an underlying causal mechanism. Intentional explanations do nothing more than provide us with useful redescriptions of actions that surprise us (Taylor 1964, Winch 1958, Wright 1971).

Second, the Logical Connection argument says that intentional explanations cannot be causal, because the relation between the mental states of the agent and the action they are supposed to have caused is not contingent but logical. To correctly describe an action as, for example, a vote, logically requires ascribing to the agent the intention to vote. Entities that cannot really be distinct (e.g., actions and their accompanying intentions) cannot be related causally. This conclusion does not deprive intentional explanations of their role in science. Their import is not one of *erklären*, but of uncovering normative relations holding between the agents and institutions involved in the genesis of the phenomenon to be made sense of (Stoutland 1970).

A last line of argument concentrates on the nomothetic (or law-involving) character of *erklären*, arguing that things are different when explaining action: the principles of behavioral and attitudinal rationality that we use in intentional explanations do not function as contingent laws but as a priori principles. That is, *erklären* requires that we take pains to fill in the contingent, endlessly revisable details of the causal laws that govern the phenomena we investigate. *Verstehen*, however, requires us to take pains to redescribe occurring human phenomena over and over again until they make empathetic sense, and we can do this only if we accept the following principles as a priori true: agents tend to (a) act in accordance with what they believe and desire, and (b) believe what they have reason to believe to be true, and desire what they have reason to value (Davidson 1980, 1984, Macdonald and Pettit 1981).

2.3 Subjective Meanings

Many argue that one of the most important features of science is that it is a systematic attempt to transcend distorting effects of particular, biased, subjective points of view. That is, science aims at objectification, and this leaves absolutely no room for a necessarily perspectivistic *verstehen* approach.

The best reply to this line of thought from adherents of the *verstehen* tradition is to point out a problem science should have with subjective meanings, a problem one fails to recognize (let alone address) if one takes an *erklären* approach to human action. The problem was mentioned above in discussing the hermeneutic circle (Sect. 1.3). Subjective meanings are part and parcel of intentional phenomena. Part of what such phenomena are is what they are taken to be from the commonsensical point of view by those engaged in them. Understanding such phenomena requires us to investigate subjective meaning ascriptions (Sect. 1.1), being both a first step towards interpretative understanding (*verstehen*) and an essential building block of the manifestations of human life. The problem can be described as a paradox: is it possible to acquire scientific knowledge of subjective meanings if such knowledge requires transcendence of subjective points of view?

The point can also be stated in another way: to identify a phenomenon as an action implies reference to the contentful mental states (beliefs and desires) of the agent. These states must, according to the principles of behavioral and attitudinal rationality, be roughly in tune with the action and with what the agent believes to be true and desirable. We cannot change the last part of the previous sentence into 'with what *is* true and desirable,' as though this would be something radically independent of the agent's interpretation of it. That is, we cannot sidestep the attempts of agents to ascribe meaning to their actions. In speaking of actions we have to take seriously the commonsensical and folk-psychological interpretations of those involved in the actions. This does not, however, commit us to accept that the agent's interpretation of the action has a privileged authoritativeness. But neither has ours. It is in the careful and sensitive confrontation between the various ways of ascribing meanings that two things happen: (a) the manifestations of human life take shape, and (b) interpretative understanding (*verstehen*) becomes possible.

2.4 Deliberation

Rational choice theory (see *Rational Choice Theory: Cultural Concerns*) is the most serious attempt to fully acknowledge the normativity that is crucial to intentional explanation, and the subjective meanings that play their indispensable role in behavioral and attitudinal rationality, without giving up the aim of a unified science based on *erklären*. The hope of rational choice theory is to explain and predict human action in terms of laws that causally relate expected utility numbers and ensuing actions. The idea is that for an agent whose preferences conform to various constraints, it is possible to represent him as having a utility function and a probability function such that every action maximizes expected utility as computed by those functions (Eells 1982).

A strong reply is open to those favoring a *verstehen* approach. It starts from the observation that a choice is not merely an event that occurs, but is always also a decision made by an agent capable of deliberation. Consider a case where a couple wanders down the street, looking for a place to eat, and deciding to opt for that small Thai restaurant next to the popular pizzeria. It is quite likely that explanatory sense can be made of this choice in terms of the calculation of utility numbers and some additional game theoretic considerations about successful co-operation. But such a story is of no use in trying to make sense of their conversation as a matter of deliberation (Pettit 1991). If we want to make sense of the way in which the woman replies to a suggestion made by the man, and

vice versa, and of how this conversation is their way of making up their minds about where to eat, then we need something rational choice theory does not give us: interpretative understanding. That is, rational choice theory could perhaps make explanatory sense of events that we would ordinarily describe as choices, but making sense of them as choices, as decisions reached by agents who reason their way to these choices, is something that requires a *verstehen* approach. Making a choice or forming an intention is done by deliberative agents, capable of recognizing and responding to considerations of evidence ('Look! They serve Teriyaki!') and valuation ('Oh, you know, you always hate those crowded places.').

Agents capable of deliberation should be in epistemic contact with the normative import of the contents of their beliefs and desires. Deliberation requires an intelligibility related to the first-person perspective of a rule-follower. Deliberative agents must be able to exercise their care for the rationality of their beliefs—given what they have reason to believe to be true—as well as their care for the rationality of their desires—given what they have reason to value—and they must be able to decide what to do on the basis of the beliefs and desires they come to accept as rational. Deliberation is not something that looks like explaining and predicting what to do given the expected utility numbers one assigns to possible outcomes. In deliberation, one does not predict one's own actions. Of course, deliberation might involve the weighting of utility numbers, but if it does, it does not do so from the explaining and predictive standpoint of rational choice theory, but from the first-person standpoint of appreciating the normative import of these numbers as reasons on the basis of which one will choose to do what one does. This is so, even in those cases where habits seem to rule ('Yes, we always end up in this restaurant—but of course, we cannot discuss such predictions *as predictions*.').

If we are to think of choices and actions as events brought about by deliberating agents who care to be rational (i.e., who try to determine and follow the appropriate rules) and who ascribe meaning to what they do, we cannot do without *verstehen*. Although this does not rule out rational choice theory altogether, it does rule out the possibility of a completed social science based on merely an *erklären* approach.

Vestibular System

1. Introduction

Throughout the evolution of life on the planet Earth the phenomena of light and gravity have played a compelling role in the development of many biological

mechanisms. While the intensity of light changes from day to night, gravity remains constant and omnipresent at all times. For any being on Earth it remains impossible to escape from its influence for more than a few seconds. Indeed such transitions into weightlessness, or free-fall, provide pleasant sensational experiences as when the baby is thrown up in the air, the child playing on the swing or the more courageous who test their limits while bungee jumping or sky diving.

The gravitational force, which is directed to the Earth's center and is equivalent to an acceleration with a magnitude of $9.81\,\mathrm{m\,s^{-2}}$ corresponding to the acceleration of a formula I racing car with 700–900 hp, represents a unidirectional force for all biological organisms, no matter how primitive, and thus provides the fundamental reference for 'spatial orientation.' For the neurophysiological circuitry of the sensory-motor system, gravity may be considered as a constant background offset or bias signal.

2. *Anatomy of the Vestibular Organs*

Any movement in three-dimensional space involves accelerational components that are compounded with gravity. In order to cope with such continual reorientation, each organism requires adequate sensory organ to transduce the magnitude and direction of the concomitant acceleration. In single cell organisms and plants, this organ is situated within the cell, whereas in higher organisms more sophisticated sensory organs have been developed, namely the vestibular organs in the inner ear.

The basic principle for the measurement of acceleration is that of a heavy body, lying either on a sensitive surface, for example, the endolymphatic reticulum of the cell or the inner cell membrane, or embedded in a gelatinous membrane coupled with

Figure 1
Otoconial layer in a otolith organ of man

Figure 2
Schematic drawing of the inner ear of man with three semicircular canals, the two otolith organs and the cochlea (Baloh and Halmagyi 1996)

sensory hair bundles that are sensitive to flexion. The tip of a plant root possesses a relatively primitive sensory organ. This provides the root with information on the direction of gravity, enabling correct growth—usually deeper into the earth (a figure for such a type in a cress root can be found in Volkmann et al. 1986). More complex examples of sensory organs for the measurement of linear accelerations are the open systems, which employ foreign bodies (e.g., sand particles used by crabs), and sealed systems with self-made bodies, typically calcium carbonate crystal structures. In the fish these consist of single bodies (otoconia) in each organ, while birds and mammals usually have multiple particles (otoconia) embedded in a gelatinous membrane (Fig. 1).

While a sensory organ that signals linear acceleration (otolith organ) may be adequate for those organisms that move relatively slowly and in a linear fashion, for faster moving species and particularly those that utilise three-dimensional space the transduction of linear acceleration must be complemented with the measurement of rotation. Accordingly, in the vertebrates a system of three, approximately orthogonal, semicircular ducts or canals has evolved to signal rotations around any arbitrary axis (Fig. 2). These canals are filled with liquid, so-called endolymph, and are sealed in a domelike enlargement (the ampulla) by a membrane-like structure (the cupula) projecting from a sensory epithelium on a crest (crista ampullaris) into the cupular structure are a multitude of sensory hairs (Fig. 3). When the head is rotated the inertial moment is counteracted by the viscosity of the semicircular canal liquid, producing pressure on the cupula and thus causing the sensory hairs to be sheared in the opposite direction. This, in turn, results in

Figure 3
Schematic drawing of the ampulla and cupula of a semicircular duct

hyper- respectively hypoactivity of the sensory cell, according to the direction of hair deflection.

The human vestibular organs are embedded in a fluid-filled bony labyrinth in the temporal bone (Fig. 4) adjacent to the hearing organ, or cochlea. Common to both vestibular and hearing organs are two fluid compartments containing respectively the perilymph and the endolymph. The vestibular labyrinth consists of two organs for the transduction of linear acceleration, the macula utriculi and macula sacculi, and a set of three semicircular canals, namely the horizontal, anterior, and posterior, which function as sensors of rotation. In the upright position the macula utriculi is more or less aligned to transduce any linear acceleration in the horizontal plane while the macula sacculi is effectively aligned to the vertical plane.

The function of this part of the vestibular organ is not yet exactly defined; it may also be responsible for the sensory transduction of very low frequency sound waves. From an ontogenetic viewpoint, the cochlea is an evagination of the sacculus. In principle the sensory hair cells in the cochlea function identically to those of the vestibular organ, although the general structure is optimised for acoustic transduction.

The vestibular labyrinths in the right and left inner ear can be regarded as mirror images. While each labyrinth is able to measure all naturally occurring linear and angular accelerations, they are neurally interconnected to complement one another, to some extent analogous to a push-pull amplifier. While the head is stationary a steady signal of typically 80–100 impulses per second is present on the afferent nerve connecting the vestibular organ to the vestibular nuclei in the central nervous system. During a head rotation to the right, this impulse rate from the right labyrinth increases while the impulse rate from the left labyrinth

Figure 4
Mechanism of cupula stimulation and frequency modulation of signal transfer in the afferent nerve (push-pull) by rotation of the head (Scherer 1997)

decreases (i.e. pulse frequency modulation). This is illustrated in Fig. 4. This push-pull principle provides increased sensitivity and permits accurate bi-directional measurement.

Such information is transferred via the bipolar vestibular nerve to the central vestibular nuclei in the brainstem. The ganglion Scarpae of this nerve is situated within the inner auditory canal. Its peripheral branch synapses to the primary vestibular sensory cells, the central branch to the cells of the vestibular nuclei, where the information is relayed to many efferent fibers.

3. *Physiology of the Vestibular System*

The neural circuitry in the vestibular nuclei of the brainstem have three principal functions, namely the integration of vestibular information with that from

the visual and the proprioceptive systems related to motion in space, the stabilization of the visual field, and third, the stabilization of body posture and locomotion. All of these tasks function autonomously without the need of our conscious intervention. Only in those situations where there is a disorder in the sensory information, occurring through sensory mismatch or through disease, do we become aware by way of motion sickness or dizziness with symptoms such as ataxia or tendency to fall to one side, or disturbance of the visual field. In the following chapters the major physiological functions—and the associated dysfunctions—of the central vestibular system, and thereafter of the peripheral vestibular system, are described.

4. *Integration of Motion-related Sensory Information*

Several sensory systems—namely the visual, the vestibular, the proprioceptive, and the auditory—contribute to the maintenance of spatial orientation. In principle one can say that all stereo systems responding to motion in three-dimensional space are involved to some degree in the integrative process in the central vestibular nuclei. This multisensory flow of information is essential for coordinated motion in space. Afferent nerve fibres from each of the named sensory systems converge to the nerve cells in the vestibular nuclei. This means, for example, that motion perception in the vestibular area in the cortex (parieto-insular vestibular cortex, PIVC) is induced by real motion or by regarding a moving visual field.

One can play with this phenomenon by looking at a fast running river from a bridge, or by watching clouds on a windy day while lying on a meadow. It takes about 20 seconds until one has the impression that the water, respectively the clouds are standing still and the observer is moving. This effect is due to the fact that when different sensory information converge to a single cell there is no possibility at this level to distinguish a optical from a vestibular stimulation.

Visual, or optical, motion perception is mainly mediated from the peripheral retinal field. Thus, a stronger intensity is reached when the entire field-of-view is stimulated. For clinical testing a stripe pattern or other strongly contrasting presentation (e.g., large format projection of city skyline) moving at angular velocites of up to $90\,\mathrm{deg\,s^{-1}}$ is employed. This is known as 'optokinetic stimulation.'

In the human there is a second component of the optical system for motion perception which must be taken into account. This is mediated by the central area in the retina known as the fovea, which provides high-resolution focussed imaging. The afferent information from this area is relayed to the vestibular nuclei via separate pathways. Clinical stimulation of the fovea is performed with more slowly moving objects ($< 40\,\mathrm{deg\,s^{-1}}$), typically by means of visible point targets or a pendulum.

Brain diseases affecting any of the described systems generally produce disturbances in spatial perception or orientation.

Somatosensory perception of motion or gravity originates from receptors distributed throughout the body, even from the intestines. The neural information from these receptors is relayed either directly, or via mossy or climbing fibres to Purkinje cells in the cerebellum, and in turn via inhibitory connections, to the vestibular nuclei.

One feels gravity with the receptors of the plantar surface of the foot when standing upright, with the sensors in the back when lying down or when accelerated in a car. One can feel the change of gravity with the receptors in the intestinum, e.g. when a cable railway runs over a pillar.

The main sensory inputs converging to cells in the vestibular nuclei stem from the visual, vestibular and somatosensory receptors. When we move actively in our habitat all of these components are well matched and concur with a correct sensory perception. However, the situation can be very different during passive motion when the sensory inputs no longer necessarily match correctly, that is, a sensory mismatch occurs.

Such a sensory mismatch can be experienced by a car passenger who, while driving along a hilly and curved road, simultaneously reads a newspaper. The optical system will indicate that one is stationary (stable image of the newspaper) while the vestibular system, the somatosensory, and the acoustic systems will indicate the movement of the vehicle. The same situation occurs in an aircraft. The cabin compartment of the plane presents a stable optical environment for the passenger, but the vestibular organs transduce the plane's motion during curves and landing manoeuvres.

When such a sensory mismatch, or conflict, cannot be resolved quickly and correctly a crisis known as 'motion sickness' occurs, which is accompanied by a series of symptoms, namely paleness, tiredness with yawning, stomach awareness, outbreak of sweat, nausea, and vomiting.

The vestibular system uses nausea and vomiting as an emergency outlet instead of pain as is the case for all other sensory systems. The reason for this is unknown, but we do know that there would be no fairground machines if the vestibular system would elicit pain when being overstimulated.

Strictly speaking, to avoid motion sickness one must prevent the occurrence of the precipitative sensory mismatch. One should not make fast head movements while the whole body is subject to passive motion. The combination of fast active and passive motion is associated with the outbreak of motion sickness. There is also a wide interindividual variability in susceptibility to motion sickness within the same provocative situation.

J. W. v. Goethe was hypersensitive to motion sickness. He described his problems during his Italian journey on a ship cruise from Napoli to Palermo on the island of Sicily. He was very angry, not only because of his own motion sickness, but also about the fact that his companion was not affected and furthermore was enjoying his food.

One reason for this variability may lie in the difference in mass of otoconia between the right and left labyrinths, which lead to asymmetrical afferent input to the central vestibular nuclei.

Normally, during our active movement repertoire this difference is well-compensated on a neural level. However, during passive motion this asymmetry could potentially introduce a sensory mismatch and therefore play a role in the elicitation of motion sickness. While it has proved difficult to measure the effective mass of otoconia in mammals, it has been possible to measure the mass of the single otoconial stones in fish. In a measurement series performed with the trout, salmon, and xiphophoris Helleri right-to-left differences of up to 76 percent were found (Scherer et al. 1997).

In the case of a sensory conflict (mismatch) in the area of the central vestibular nuclei hierarchical structures of the brain come into play. As we know the visual system dominates over the vestibular and within the vestibular system the evolutionary older otolith organs dominate over the semicircular canals.

One can notice this hierarchical principle when sitting in a stationary train in the railway station. When a neighbouring train starts to move one immediately gets the impression that one's own train has started to move and that the other train is stationary. In this case of different sensory input (optical: moving; vestibular and somatosensory: stationary) the dominant visual system determines the percept.

5. *Stabilization of Upright Body Posture*

Together with the cerebellum, the vestibular system contributes substantially to the stabilisation of body posture during locomotion. The vestibulo-spinal tract emerges from the lateral vestibular nucleus in the brainstem and runs unilaterally to the spinal motoneurons of the extensor muscles (Fig. 5). When a person turns to the right, the stimulus to the right vestibular organ leads to an increase of the afferent firing rate on the nerve fibres leading to the vestibular nuclei; simultaneously the firing rate on the nerve fibres from the left vestibular organ decreases. At the same time the visual system signals the rotation of the surrounding, that is, to the left during a head turn to the right. The afferent signal from the retina converges with that from the vestibular organs and enhances their effect, that is, stimulating the right vestibular nuclei positively and the left negatively. Via the vestibulo-spinal tract the tonic signal to the extensor

Figure 5
Simplified diagram of the two reflex arcs involving the vestibular nuclei in the brain stem, the vestibulo-spinal and the vestibulo-ocular reflex (Brodal 1981). S, D, L, M = superior, descending, lateral, and medial nucleus, respectively

muscles on the right is increased, which has the effect of counteracting the increased body mass on this side during the turn. At the same time there is a corollary increase of tonus to the left flexor muscles.

When the function of one vestibular labyrinth (right or left) is suddenly reduced due to an accident, an infection, or an operation the person feels a tendency to fall to the injured, or diseased, side. However, this symptom lasts only for a number of days, even in those cases where the function of the diseased side does not recover. The reason for this recovery and for the similar reduction of other symptoms lies with the powerful self-reparatory capability, or adaptability, of the vestibular system. A major therapeutic approach to vestibular deficits is based on self-training. In the first weeks after the sudden loss of vestibular function the patient undergoes training involving general natural body movements; in the following weeks specific training of impaired functions and symptoms is necessary.

The phenomenon of height vertigo can also be explained within the context of sensory mismatch or conflict. This 'physiological vertigo syndrome' (Brandt

1991) occurs when a person stands on the top of a high tower or on the brink of a cliff. In every normal person a certain degree of random body sway can be measured during upright stance. This body sway is regulated by the multisensory convergence in the vestibular nuclei. In this context spatial vision plays a major role, particularly the perceptual relationship between foreground to background. While standing on the edge of a high tower or cliff the relative motion of the background—now located many metres distant in comparison to normal—is perceived visually as much greater. This discrepancy in visual perception destabilises the regulatory mechanism for postural stability and body sway increases. On continued exposure this 'positive feedback' can lead to serious instability. How this fundamentally physiological response is processed cognitively and psychologically can vary enormously among individuals, in some people leading to severe height anxiety with vegetative symptoms. Such physiological instability can be counteracted immediately by stepping back from the brink so that the discrepancy is resolved by viewing a normal foreground at foot level, or by providing more contact to the ground by grasping a handle or rail, sitting down or kneeling. Extreme forms of height vertigo can be cured by behavioural therapy.

J. W. v. Goethe treated his height vertigo by repeatedly climbing up the tower of Strasburg's Gothic cathedral and standing on exposed platforms (similar to contemporary 'flooding' therapy). Another kind of training of height anxiety is shown in Alfred Hitchcock's film *Psycho*.

6. *Stabilization of the Visual Field During Locomotion*

The stabilization of eye position in the head during locomotion is supported by the so-called vestibulo-ocular reflex. Afferent nerve fibres project from the ipsilateral superior and the contralateral medial nuclei upwards via the medial longitudinal fasciculus (MLF) to the oculomotor nuclei, which in turn govern the input to the motor neurons driving the eye muscles (Fig. 6). This reflex is described here briefly since it plays a major role in the diagnosis of vestibular disorders.

Again taking the example of a rotation to the right, the surrounding visual field rotates too the left. If the eyes were to remain fixed in the head during this rotation, the image of the surroundings would slip on the retina, causing a blurring of perception until the head was stationary. This would obviously deteriorate spatial orientation. A major purpose of the vestibulo-ocular reflex is to rotate the eyes compensatorily to the head movement, thus retaining a focussed image on the retina. Under normal conditions the vestibulo-ocular reflex facilitates compensatory eye movement equivalent to the concomitant head movement, regardless about which axis the head is rotated. In this manner, head movement in three-dimensional space is compensated for by appropriate reflex eye movement. However, the mechanical range of eye rotation is limited anatomically by the extraocular muscle and optical nerve structures. Thus, during a full head- and body-rotation, eye position is compensatory, but is regularly reset by means of a quick phase in the anticompensatory direction. This leads to a sawtooth pattern of eye movement, known as 'nystagmus,' during full body rotation. The nystagmus eye movement pattern is defined by the sawtooth pattern consisting of the vestibularly induced slow phase and the quick reset movement (Fig. 6). Such nystagmus patterns of eye movement are elicited by natural movements or by unilateral or bilateral stimulation of the vestibular organs. A similar pattern, known as optokinetic nystagmus, can also be elicited by rotation or translation of the visual field while the subject is held stationary.

Figure 6
Body movement (rotation) and compensatory sawtooth eye movement (nystagmus)

Optokinetic nystagmus can be seen easily when a person looks out of a train's window or out of the side window of a car. The moving optical pattern causes a slow deviation of the eye in the direction opposite to the train's motion with a fast phase in the direction of the train's motion.

Since the visual system is hierarchically superior to the vestibular system, visual fixation of a target point suppresses these nystagmus responses. A practical consequence is the fact that we are able to read during active or passive motion, although this may lead to a sensory mismatch which may cause motion sickness in sensitive individuals. On the other hand we have to prevent fixation in order to be able to measure nystagmus. This is done usually by means of thick lenses in a goggle (Frenzel glasses), by electric or

magnetic nystagmography or by videoimaging of the eyes in infrared light.

Observation and measurement of eye movements represents an important inroad for the examination of the function and dysfunction of the vestibular system, and therefore provides an important diagnostic tool for the clinician who has to deal with patients suffering from dizziness)

7. *Encyclopaedia of Typical Vestibular Disturbances*

7.1 *Peripheral Disturbances*

(a) Sudden unilateral loss of function of the vestibular organ.

Pathophysiology: unknown, virus infections of Scarpae's ganglion, disturbed blood supply, trophic disorders of the cupula in the ampullae of the semicircular canals (Helling et al. 2001, 2000) are discussed.

Symptoms: heavy turning sensations in the first days, the symptoms decline gradually.

(b) Meniere's disease.

Pathophysiology: osmotic disturbance within the two components of inner ear fluids, leading to a hydrops of the endolymphatic space and a sudden poisoning of nerve fibers with potassium.

Symptoms: sudden attacks of severe vertigo and vomiting in combination with low tone hearing loss and tinnitus in the affected ear.

(c) Benign paroxysmal positioning vertigo (BPPN).

Pathophysiology: aberrated otoconia from the otolith organs lying in the vertical semicircular canal initiating a unphysiologically endolyph wave.

Symptoms: heavy torsional sensation, which lasts for 10 to 20 seconds after performing a fast body motion.

(d) Acoustic neuroma.

Pathophysiology: benign tumor growing in the vestibular part of the eight cranial nerve in the inner auditory canal.

Symptoms: unilateral, slowly intensifying loss of vestibular and acoustic function. While the vestibular defect usually is well compensated and asymptomatic, the acoustic defect brings the patient to the doctor.

(e) Psychogenic (phobic) vertigo.

Vertigo is a frequent symptom of psychiatric illness (Brandt 1991). Alternatively, a transient labyrinthine dysfunction may initiate development of neurosis in which anxiety, panic attacks and depression are most common, and which typically preserves subjective vertigo and postural imbalance (Brandt 1991).

7.2 *Central Vestibular Disorders*

A lot of central disorders induce vertigo or postural instability. Most common disorders are mentioned (for details see Brandt 1991)

(a) Basilar artery migraine
(b) Vestibular epilepsy
(c) Down- or upbeat vertigo syndromes
(d) Central positional vertigo
(e) Posttraumatic vertigo (central or peripheral)
(f) Familial vertigo
(g) Drug vertigo (central or peripheral).

Vestibulo-ocular Reflex, Adaptation of the

The vestibulo-ocular reflex (VOR) produces eye movements in the direction opposite to head movement, thus serving to automatically stabilize vision relative to space. VOR displays a remarkable capability of adaptation. It modifies its dynamics so as to secure visual stability under any circumstance in which mismatched movements of the head and the visual surroundings impair visual stability. The major site of this adaptation has been shown to reside in evolutionarily the oldest area of the cerebellum, namely

the flocculus. In recent years, VOR has been studied extensively as a model system for investigating the learning mechanisms in the cerebellum.

1. *VOR*

The reflex arc for the VOR is a three-neuron pathway connecting the primary vestibular afferents arising from the semicircular canals, to the VOR relay neurons in vestibular nuclei, and finally to motoneurons innervating the extraocular muscles. VOR relay neurons are either excitatory or inhibitory in their synaptic action, and induce either contraction or relaxation of the extraocular muscles via excitation or inhibition of motoneurons. There are a number of parallel pathways connecting the three semicircular canals (horizontal, anterior, and posterior) and the two otolith organs (saccule and utricle) in each labyrinth to the six extraocular muscles in each eye (medial and lateral rectus, superior and inferior rectus, superior and inferior oblique). These pathways operate in concert under conditions of free head movement, but in an experimental setup they are stimulated separately by giving yaw, pitch, roll or linear acceleration.

The horizontal VOR is tested by sinusoidal or velocity-step head rotation on the horizontal plane, and the VOR gain is measured as the ratio of the attained eye velocity to the applied head velocity. Sinusoidal rotation is convenient for measuring the gain and phase of the VOR separately, while velocity steps enable us to separate the VOR responses, which arise with different latencies, into their constituent components. Measurement of the VOR is performed in the dark or with the eyes closed while the whole body is rotating.

2. *VOR Adaptation*

Long-term visuovestibular mismatching (for days to months) can be imposed in a subject (either animal or human) with the aid of a pair of prism or lens goggles. Short-term mismatching (1–4 hours) is created by combined rotation of the turntable on which the subject is positioned and a screen representing the visual surroundings. Both wearing of Dove prism goggles, which reverses the right–left axis of the visual field, or miniaturizing lenses which reduce the visual field, and in-phase rotation of the turntable and screen in the same direction, cause adaptive reduction of the horizontal VOR gain. Likewise, both wearing of 2x magnifying lenses and out-of-phase rotation of the turntable and screen in opposite directions cause adaptive increase of the horizontal VOR gain. These adaptive changes in VOR gain act to reduce the retinal slips that occur during the VOR, which otherwise are augmented by the imposed visuovestibular mismatching.

A cross-modal adaptation occurs between the horizontal and vertical VORs; when yaw rotation on the horizontal turntable is combined with vertical optokinetic motion, the VOR measured in the dark acquires a vertical component even when the head is rotated only horizontally.

3. *The Flocculus*

In rabbits and cats, the flocculus has five to six major folia, while in rats it usually has only one folium. In classic anatomical studies of the monkey cerebellum, ten folia have been described in the flocculus, but recent studies on neuronal connectivity have revealed that the rostral five folia belong to the ventral paraflocculus and not to the flocculus.

A proportion of Purkinje cells in the flocculus of either side supply inhibitory synapses to both excitatory and inhibitory relay neurons in the VOR arc arising from the ipsilateral semicircular canals. Purkinje cells related to the horizontal VOR arc are localized to a narrow zone (H-zone, about 1 mm across) in the flocculus. The H-zone is flanked by other zones related to vertical (V-zone) or rotatory (R-zone) VORs, and a simple method to identify these zones in physiological experiments is to apply local electrical stimulation to these zones, which induces distinct horizontal, vertical, or rotatory eye movements.

These microzones in the flocculus are also characterized by their climbing fiber inputs relayed by the inferior olive. Purkinje cells in the H-zone receive climbing fiber signals encoding retinal errors, that is, slips of the retinal images on the horizontal plane. Purkinje cells reported to receive climbing fiber signals encoding retinal slips approximately in the vertical and rotatory directions, may be located in the V- and R-zones, respectively.

Branches of mossy fibers arising from the semicircular canals are distributed throughout the flocculus. Canal signals could also be relayed to the flocculus via 4–6 mm-long parallel fiber axons of granule cells. Yet, in the H-zone Purkinje cells, simple spike discharges are modulated specifically in relation to the horizontal head velocity (see below).

4. *Flocculus Hypothesis for VOR Adaptation*

Based upon the abovementioned relationships between the flocculus and the VOR, it is suggested that the H-zone originally receives mossy fiber information from all directions, and through learning by referring to climbing fiber signals, canal-plane-specific simple spike responses are established. It is further suggested that the established simple spike response patterns are updated daily by learning, whenever retinal errors are sensed through the climbing fibers.

Learning in the flocculus would occur at the synapses formed between the axons of granule cells

relaying mossy fiber signals and Purkinje cells. This type of interaction was suggested in Marr's and Albus' theories of the cerebellar circuit proposed around 1970, later identified as long-term depression (LTD). LTD occurs in granule cell axon-to-Purkinje cell synapses, when these are conjointly activated with climbing fibers. These hypothetical views have been tested experimentally in recent decades, as reviewed below.

5. *Deprivation of Flocculus Function*

That the flocculus plays a role in VOR adaptation has been confirmed by showing that impairment of flocculus function results in abolition of VOR adaptation. Previously, surgical ablation of and injection of toxic amino acids in the flocculus were used. More recently, based upon newly acquired knowledge about LTD, various pharmacological reagents and genetic means have been used to block LTD in the flocculus. Injection of hemoglobin into the subdural space over the flocculus in rabbits and monkeys abolished VOR adaptation, presumably due to the scavenging action of hemoglobin on nitric oxide (NO) that is required for the induction of LTD. Injection of an inhibitor of NO synthase into goldfish cerebellum inhibited adaptive increase of VOR gain. Mice transfected with the gene of a pseudosubstrate inhibitor of protein kinase C (PKC), did not exhibit VOR adaptation, as expected from the well-known requirement of PKC for LTD induction.

6. *Behavior of Flocculus Purkinje Cells*

Whether the behavior of H-zone Purkinje cells is consistent with the flocculus hypothesis has also been examined by recording two types of spikes generated by the Purkinje cells: namely, simple spikes, reflecting their mossy fiber inputs, and complex spikes, evoked by climbing fiber inputs.

During sinusoidal head rotation, VOR relay neurons are driven by signals from the ipsilateral horizontal canal, which are modulated in phase with the head velocity (increased during ipsilateral rotation). In the H-zone, Purkinje cells exhibit modulation of simple spikes either in phase or out of phase (decreased during ipsilateral rotation). The in-phase-modulated inhibitory signals of Purkinje cells should depress VOR by canceling the effect of similarly modulated canal signals. On the other hand, the out-of-phase discharges of Purkinje cells should enhance VOR by adding inversely modulated inhibitory signals to the canal signals.

Under the condition that sustained visuovestibular mismatching enhances the VOR, the simple spike responses of H-zone Purkinje cells to head rotation became predominantly out of phase. Conversely, under the condition that sustained mismatching depresses the VOR, the simple spike response became predominantly in phase. These changes in simple spike responses can be interpreted as being causally related to the VOR gain changes.

The two types of simple spike discharges in H-zone Purkinje cells may be induced by mossy fiber inputs from the horizontal canals of the two sides. Signals from the ipsilateral canal would drive Purkinje cells in phase, while signals from the contralateral canal would drive Purkinje cells out of phase. The shift of dominance of the type of simple spike modulation during VOR adaptation can be explained as being caused by LTD, depressing either the ipsilateral or contralateral canal inputs to the Purkinje cells. The climbing fiber discharge patterns observed in H-zone Purkinje cells are consistent with this notion.

7. *Memory Site for VOR Adaptation*

No doubt, the flocculus plays a crucial role in the induction of VOR adaptation. However, there is a dichotomy of opinions regarding its role in retention of the memory of VOR adaptation. To determine whether or not the memory of VOR adaptation is retained in the flocculus, studies have been carried out on the effects of blocking of flocculus functions—either surgically or functionally—after VOR adaptation develops. In goldfish, no less than 30 percent of the altered VOR gain was still maintained after ablation of the cerebellum, suggesting that the cerebellum is the major, but not the sole, site responsible for the maintenance of VOR adaptation. Microdialysis of lidocaine into goldfish cerebellum, however, abolished both the induction and short-term maintenance of VOR adaptation, suggesting that the memory for VOR adaptation is retained at least for a few hours in the cerebellum.

Another strategy to determine whether the memory underlying VOR adaptation is retained in the brainstem or in the cerebellum is to analyze the component eye movements elicited by velocity-step head stimuli at different latencies. The measurements in goldfish indicated that adaptive changes occurred in the earliest component of the eye movement elicited by a stimulus with a latency of 18 milliseconds, which could be mediated via the three-neuron VOR arc. However, the measurements in monkeys remain inconclusive.

8. *Oculomotor Signals in the Flocculus*

A complication in the flocculus hypothesis arises from the possible existence of mossy fibers that relay information regarding oculomotor activities to the flocculus. The existence of such mossy fibers has frequently been assumed in modeling the flocculus–VOR system (Lisberger and Sejnowski 1992).

However, it is difficult to accurately estimate such mossy fiber signals in isolation from the vestibular or

retinal mossy fiber signals. In the previously used visual suppression method, the oculomotor signals were eliminated by training a monkey to fix its gaze on a spot moving with the head, and the resultant changes induced in the Purkinje cell behavior are assumed to represent the oculomotor signals. However, such gaze fixation is executed by central command signals, which would be a source of another mossy fiber input to the flocculus. Oculomotor signals in the flocculus have also been measured during nystagmic eye movements evoked by the stimulation of the optic tract. This measurement yielded a much smaller estimate of the oculomotor signals to the flocculus as compared with the visual fixation method.

It is notable that the simple spike responses of H-zone Purkinje cells to head rotation in the dark and those to screen rotation that evokes optokinetic eye movement responses varied independently of each other. Since oculomotor components should be shared between the two types of simple spike responses, this observation in rabbits favors the view that H-zone Purkinje cells receive few oculomotor signals.

The possibility so far overlooked is that learning forms simple spike responses reflecting oculomotor activities. Since retinal errors represent the deviations of actual eye movements from the ideal eye movements fully compensating for head movement, these should contain information regarding eye movements, which could be reflected in simple spike responses through the LTD mechanism.

Vietnamese Revolution, The

In one and a quarter century since the French conquest of southern Vietnam in the 1860s, Vietnam underwent a radical transformation from a Confucian monarchy to a Marxist–Leninist state. The Vietnamese revolution involved a violent clash with two major Western powers, France and the United States, as well as a fundamental transformation of the Vietnamese socio-economic system.

1. Historical Background

Citing the Vietnamese monarchy's persecution of Catholics and refusal of a trade request, France launched a series of attacks on Vietnam from 1858 onwards. By 1867, France had seized as a direct colony the frontier southern third of Vietnam (Cochin China or *Nam bo*) from the Vietnamese monarchy. By 1884, the northern and central Vietnam (respectively Tonkin or *Bac bo*, and Annam or *Trung bo*) had fallen under French control, although the Nguyen monarchy nominally still retained its direct administration of the latter.

In the aftermath of the French conquest, the resistance to French colonialism, mainly in the name of an 'Aid-the-King' movement, was led primarily by Confucian literati. It lasted the longest in central and northern Vietnam. By the time the Union of French Indochina was established in 1897, with Laos and Cambodia as the remaining two of the five components, the armed anticolonial resistance led by Confucian literati had virtually collapsed (see Marr 1971).

Many members of the Vietnamese elite collaborated with the French rulers, while a number of others searched for a more effective path of resistance, strongly influenced by Chinese reformist and revolutionary thoughts and inspired by the rise of Japan as an Asian power. At one end of the collaboration–resistance spectrum in the first quarter of the twentieth century was the Confucian scholar Phan Boi Chau, a native of northern Central Vietnam, who organized a movement of students to Japan and inspired isolated armed resistance against French colonialism (Marr 1971). In the context of a strong French repression, Thailand and southern China served as important bases for exiled resistance leaders (Goscha 1999). At the other end were many collaborators, such as the northern neo-traditionalist Pham Quynh, as well as many southerners who were rewarded with large tracts of land sold at low prices as the cultivated acreage in Cochin China increased five times from 1870 to 1920 thanks to the French water control work. Many of the latter acquired French citizenship, experimented with the more open politics in the direct French colony of Cochin China, or even played a role in the southern millenarian movements of Cao Dai and Hoa Hao (Tai 1983, 1992), co-opting many poor peasants in the sharply stratified Cochin Chinese society.

With the last Confucian examination being held in 1919, a new Western-educated elite began playing a salient role in the anticolonial resistance from 1925 onwards. The major uprisings took place in northern Vietnam in 1930 under the leadership of the Vietnamese Nationalist Party (VNP), and in central and

northern Vietnam in 1930–1 under the Indochinese Communist Party (ICP). The ICP-led movement in 1930–1 represented the most serious challenge to French colonialism since the Aid-the-King movement of the nineteenth century, as it involved the participation of half a million Vietnamese and threatened the colonial order in 25 provinces. At the peak of this movement, the colonial administrative apparatus virtually collapsed in many villages in the provinces of Nghe-An (birthplace of Ho Chi Minh) and Ha Tinh in northern central Vietnam. The ICP local leadership spontaneously seized village administrations, abolished taxes, reduced rents, and redistributed up to 8,500 acres of communal land in these two provinces alone.

In the short run, both the VNP and ICP-led movements in 1930–1 collapsed under the strong repressive measures by the French colonial regime with its superior military forces. Many revolutionary leaders were imprisoned, while Thailand and southern China again became important bases for exiled political activists, including Ho Chi Minh. It was not until the release of a number of political prisoners and the introduction of a more liberal political atmosphere in colonial Indochina under the Popular Front regime in the metropolis (1936–9) that revolutionary activism gained a significant momentum. In the context of the Japanese military advance into Indochina in September 1940 and the French colonial government's subsequent collaboration with Japanese military authorities, the Vietminh (abbreviation of *Viet Nam Doc Lap Dong Minh Hoi*, or Vietnam Independence Alliance League) under Ho Chi Minh began building a base of operation in northern mountainous areas, working with many members of ethnic minorities, against both the Japanese and Axis-aligned French colonial administration (Marr 1995, Chap. 3).

2. *Wars and Vietnamese Revolutionary Momentum*

The major turning point was 1945, when French colonial power was humiliated by the Japanese supported coup of March 9, 1945, and when in the context of a power vacuum with the Japanese surrender to Allied forces in August 1945, the Communist-led Vietminh organized the seizure of power throughout the country. The last Vietnamese monarch abdicated under revolutionary pressure. Ho Chi Minh's Declaration of Independence from France in September 1945 evoked a powerful nationalist sentiment from all social strata, and garnered widespread support for the first independent government of Vietnam (Marr 1995, 537–9). In the Vietnamese Marxist orthodox discourse, this seizure of power has been referred to as the August Revolution (*cach mang thang tam*). It was a revolution only in the narrowest sense of the term, that means, as a seizure of administrative power and official marking of the end of the monarchical era. However, even the maintenance of this administrative power in a territorially unified Vietnam came under a serious challenge by France's desire to regain its influence and control of Vietnam and the complications of post-WWII international politics with the post-WWII rise of US power and the Cold War. France's attempt to regain control of Vietnam and its underestimation of the support for Vietnamese independence led to the Franco-Vietnamese war from 1946 to 1954. The US's greater concern with Europe and Soviet influence after WWII, in combination with the Chinese communists' control of mainland China in 1949, shifted US policy towards a support for France and away from Franklin Roosevelt's support for the aspiration for independence of colonized peoples in Asia and Africa. The violent Franco-Vietnamese war ended in 1954, after the Vietminh defeated the French at Dien Bien Phu in the northern highlands. Vietnam was temporarily divided into two parts at the 17th parallel, with the north under Communist control, and the south under American influence.

Ho Chi Minh's vision of a unified Vietnam was not achieved until 1975, after a long and violent war which, in the context of the Cold War, involved a massive US ground involvement in South Vietnam and US bombing of the north and parts of Laos and Cambodia. The Vietnamese Communist Party began lending support to the armed resistance against the US-allied government in Saigon in 1959, helped to establish the National Liberation Front of South Vietnam in 1960, and increased the flow of personnel and arms from the north to the south from 1960 onwards (Cao van Luong et al. 1995, pp. 285ff.). The United States responded by increasing military advisers in South Vietnam to 15,000 by 1963, bombing North Vietnam from 1964 onwards, and introducing ground combat troops to South Vietnam in 1965. At its peak, the US had half a million of combat troops in South Vietnam. In the context of the Cold War, North Vietnam in turn received significant military and economic aid from the Soviet Union, China, Eastern Europe, and Cuba. The intense warfare led to the migration of millions of peasants to urban areas in South Vietnam, seriously damaged the South Vietnamese economy, and increased the dependence of the US-supported government in South Vietnam on US aid.

In the US, the draft system and the protracted warfare in Vietnam, exposed daily in the mass media, intensified the antiwar movement, especially among the young. This contributed to the US policy of handling the war to South Vietnamese troops, and to the withdrawal of US ground troops and the end of bombing of North Vietnam by 1973 in the aftermath of the Paris Peace Agreement. South Vietnam enjoyed no peace, as the Paris Agreement was violated by both

the Saigon-government troops on the one hand and the North Vietnamese troops and their southern allies on the other. The US-supported government in South Vietnam eventually collapsed in April 1975, under the attack of North Vietnamese troops and their southern allies.

Vietnamese Marxists' seizure of political control in the north by 1954 and in the entire country by 1975 strengthened the foundation for the enactment of their socioeconomic vision. In North Vietnam, the socioeconomic revolution accelerated throughout the 1950s under the Communist vision of a collectivized economy where the state played the dominant role in the industrial and agricultural production process, as well as in the distribution of raw materials and finished products. By 1965, the northern economy was based mostly on the state and cooperative sectors, and sustained by aid from the socialist bloc, as North Vietnam became directly involved in the war against the US and the American-supported government in Saigon. The Communist party's economic vision was imposed on the south after 1975. The economic crisis in the late 1970s, fueled by the resistance of peasants in the southern Mekong Delta to collectivization and the disenchantment of northern cooperative farmers, led to a gradual shift towards a market economy. This process of economic reforms (*doi moi*) started in agriculture in 1981. The economic reform was reaffirmed at the 1986 Communist Party Congress, and implemented in the rest of the economy by 1989. Cultivators consequently have long-term leases on land, and regain control over production and distribution processes. Private enterprises have been allowed to reemerge in industries and commerce, and foreign direct investments since 1988 have helped to fuel a generally strong economic growth in the 1990s.

3. *The Vietnamese Revolution: Theoretical Debates*

Many an important theoretical model on revolution has been constructed partly on the basis of the scholarly knowledge of the Vietnamese revolution. These models are embedded in the major traditions of contemporary Western social theory (John Stuart Mill, Karl Marx, and Emile Durkheim).

In the literature on revolution and agrarian unrest, the political scientist S. Popkin's rational choice model offers a good example of a theoretical model within the Millean tradition of inquiry (Popkin 1979). It considers the behavior of both the peasantry and the elite as the goal-directed acts of self-interested individuals. Popkin argues that modern revolutionary movements such as the Vietminh succeed because, as political entrepreneurs, their leaders can offer peasants concrete welfare improvements and effective organization against the marauding lords and notables of the old order. He emphatically rejects the view that modern agrarian movements involve defensive reactions to the violation of pre-capitalist normative structures by the colonial and capitalist order. In Popkin's argument, the incorporation of indigenous agriculture into the capitalistic world market, the establishment of the colonial regime, and the expansion of state power are not necessarily deleterious to peasant welfare. According to Popkin, colonialism brings vital stability and an improved communication system which keeps prices from fluctuating widely and thus keeps peasants alive in times of local famine.

Intriguing as it is, Popkin's model encounters its share of empirical anomalies in the Vietnamese case. For example, on which matrix of material costs and benefits did a large number of Vietnamese from different social strata volunteer for the Vietminh armed forces in the 1946–50 period, when Vietminh troops faced an enemy of overwhelmingly technological superiority, and before the poor recruits could foresee any substantial socioeconomic reforms in their favor?

In contrast to the Millean tradition of inquiry, the Marxist tradition seeks to situate economic transformation and revolutionary movements within the structure of conflict-ridden class relations. Both Western and Vietnamese Marxist analysts consider Western capitalist expansion as the root of the Vietnamese revolution. In this perspective, French colonialism in Vietnam as the representation of Western capitalist interests sought the maximal return on capital at the expense of the native working classes. The sociologist Martin Murray argues that capitalist exploitative measures included the concession of indigenous land to colonial settlers for the development of major cash crops; the introduction of direct and indirect taxes, and the conversion of tax payments from kind to cash to facilitate capitalist growth; and the oppressive appropriation of labor through the corvee system, the maintenance of rural labor reserves in Tonkin and Annam, and repressive labor laws to hold down labor costs for capitalist agro-mineral ventures.

Murray suggests that the impact of world capitalism was far from uniform in Vietnam. It was most striking in Cochin China which emerged as one of the top three rice exporting areas in the world, where approximately two-thirds of the rural population were separated from the means of agricultural production, where land and labor became strictly commodified, and where classes became increasingly differentiated. In contrast, in the north and center (Tonkin and Annam), although the rural population was increasingly drawn into market relations, the majority still tenaciously held on to their minuscule land holdings, buffered in many communities by their small shares of communal land. In North and Central Vietnam, the proportions of inalienable communal land averaged respectively 21 per cent and 25 per cent of the cultivated acreages.

Murray suggests that the persistence of communal land in the north and the center contributed to the formation of non-capitalist labor reserves for the plantations, mines, and factories within French Indochina and beyond, reserves where workers could rely on kinship and communal ties for survival in times of recession and during the pre-productive and post-productive periods (youth and old age). It has been suggested that the cost of capitalist production was consequently held down because capitalist firms had to pay only the cost of short-term labor reproduction (the cost to sustain workers physically during the period of employment), and not the cost of long-term labor renewal (the cost of replacing a physically debilitated work force with a new generation of laborers and of maintaining a temporarily idle work force during economic downturns). In the long run, Murray suggests, '[t]hese 'blockages' to the homogeneous spread and deepening of the extended reproduction of capital coincided with economic stagnation, declining productivity, and the vicious cycle of rural poverty associated with the 'underdeveloped' regions of the globe' (Murray 1980, p. x).

In the context of the capitalist world system, Marxist analysts consider the proletariat to be either largely located in the periphery of world capitalism, or composed of 'ethnicities' originating in the periphery; the bourgeoisie is heavily concentrated in, although by no means restricted to, the Western core. Within the Marxist world-system framework, class conflict takes on an international dimension, and revolution is seen as originating in the periphery where proletarian class interests emerge most clearly.

Within the same Marxist framework, the sociologist Jeffrey Paige suggests that 'The strength of colonial and imperial political controls long prevented the political expression of these conflicts, but with the decline of colonial power in the postwar era, the commercial export sectors of the underdeveloped world have become centers of revolutionary social movements' (Paige 1975, p. 3). Assuming inherent conflicts between agricultural producers and the dominant class, Paige attempts to construct an overall model of the forms which class conflict takes (Paige 1975, 1983). Paige deduces these actors' behavior patterns and the form of agrarian unrest from their income sources. More specifically, he proposes, on the one hand, that the economic base of the landed dominant class is narrower, more static, and less efficient than that of its commercial and industrial counterparts. The former's economic weakness gives rise to zero-sum class conflict as well as to its tyrannical political control of the means of production (both land and labor). On the other hand, the broader, more dynamic and efficient capital base of the commercial or industrial upper class can expand non-producers' resources. This factor facilitates the adoption of more compromising solutions by the dominant class. In this context, class conflict involves the economic distribution of goods and products rather than the political control of labor and land. Adopting Marx's theoretical arguments in his analysis of the French peasantry (Marx 1964), Paige further hypothesizes that cultivators' dependence on land as their main source of income gives rise to a conservative, competitive, and structurally dependent peasantry. In contrast, their dependence on wages would result in a more radical, solidary, and structurally interdependent cultivator class. In the Vietnamese case, Paige's model predicts that agrarian unrest will take the form of rebellion when both cultivators and non-cultivators derive their incomes from land, as is the case in North and Central Vietnam. Furthermore, in Cochin China, 'A combination of non-cultivators dependent on income from land and cultivators dependent on income from wages leads to revolution' (Paige 1975, p. 71, 1983, p. 706).

The Marxist framework has its share of empirical anomalies. First of all, the active resistance to French colonialism did gain support among numerous members of the native elite whose organizational efforts provided a crucial link among the rural communities. It is reflected in the necessity of the special category 'resistance-supporting landlord' in the land reform campaign in the north after independence. The active support of these members of the indigenous elite for anticolonial movements cannot be mechanically explained in terms of the struggle by the working classes of the periphery against the capitalists of the core. It is their nationalist aspirations that propelled towards a path of political activism (see also Woodside 1976, p. 303, Emerson 1960).

The regional variations in revolutionary strength and socioeconomic conditions in Vietnam present the Marxist models with a second major anomaly. In colonial Vietnam, the peasantry was most heavily dispossessed of the means of production in Cochin China (South Vietnam). However, from the mid-nineteenth century to 1975, the armed resistance to French colonialism and capitalism was generally more limited in the south than in the north and the center. With the sole exception of the 1940 armed insurrection in certain areas of Cochin China (Toan et al. 1985, pp. 318–9, cf. Paige 1975, pp. 323–4), at no point did the anti-colonial armed movement in the south exceed or even approach the intensity of the unrest in the center and the north. In the pre-World War II period, it was in Annam (Central Vietnam) that the 1930–1 unrest posed the greatest threat to the colonial order. During the first Indochinese war (1946–54), the French encountered considerably greater resistance in Annam and Tonkin. During the period of direct and massive American intervention (1964–75), it was not in the former Cochin China, but in the southern part of Central Vietnam that the National Liberation Front developed its strongest roots (Mitchell 1968, Paige 1975, pp. 326–32, Luong 1992, pp. 227–8). It is an historical fact that north and central Vietnam, despite the lesser degree of class polarization, constituted the

areas with both stronger resistance to Western intervention and greater socialist revolutionary potential.

While influenced to varying degrees by the Marxist approach, anthropological analyses of agrarian revolutions, and of historical events in general, have paid closer attention to the dynamic interplay between capitalism and indigenous non-capitalist social formations as sociocultural systems (Wolf 1969).

In James Scott's moral economy model, agrarian unrest is examined in terms of the reactive response of the peasantry in a pre-capitalist social formation to capitalism and colonialism. In the context of the world market and the colonial state, the pre-capitalist order's subsistence ethic, by which lords and the state are supposed to respect peasants' right to subsistence in exchange for legitimacy, is more often violated. The expansion of Western capitalism and the establishment of European colonies led to the violation of the subsistence ethic through the erosion of patron–client ties and the existing welfare mechanisms in the relation between cultivators and non-cultivators. Scott considers peasant movements quintessentially defensive reactions of a moral nature: defensive reactions against the violation of the subsistence ethic and the increasingly serious threat to peasants' survival during subsistence crises. Under this threat and violation, any significant natural or human induced disaster potentially sparks off agrarian unrest. The prominent role of Third Word peasants in twentieth-century political movements, Scott argues, involves this dynamic interplay between a pre-capitalist socio-cultural order on the one hand and colonialism and capitalism on the other. Unrest is thus defined, within the Durkheimian tradition of social thought, in terms of a breakdown of the normative framework during a period of transition.

In the context of the greater socialist revolutionary potential in north and central Vietnam, Luong hypothesizes that the pre-capitalist tradition of the north and the center provided stronger ideological and organizational resources for the active resistance to French colonialism in particular, and to capitalist imperialism in general. Despite considerable internal tension, this tradition nurtures values conducive to the growth of nationalism, to collectivism in a relatively mild form, and to a hierarchical organizational framework (Luong 1992).

On one level, the indigenous pre-capitalist framework was characterized by both class cleavages, and a male-oriented and kinship-centered hierarchy. Luong suggests that the hierarchical structure of the local tradition, maintained partly through the socialization process, accounts for numerous features in Vietnamese anticolonialism and the Vietnamese revolution: the male-centered elitism in the VNP recruitment and organizational methods, the Vietminh's reliance on male members of the intelligentsia for local leadership in the early period of anti-French resistance, and the male dominance in both domestic and public relations in postcolonial Marxist Vietnam.

On another level, the growth of nationalism and a collectivistic vision of political economy is facilitated by important communal institutions and corresponding conceptual categories in the local tradition of the north and the center. Northern and central villages maintained sharp boundaries through villagers' participation in the collective worship of tutelary deities, an extraordinary degree of village endogamy, the institution of communal land, and their nucleated settlement pattern. In contrast, group boundaries were considerably less rigid in southern Vietnamese communities where settlements were non-nucleated, and where there existed significant geographical mobility due to the frontier environment. Luong suggests that through a sharp distinction between insiders and outsiders in the native conceptualization of kinship, communality, ethnicity, and nationality, the northern and central tradition has intensified the negative reaction of many Vietnamese to any foreign intrusion on the indigenous landscape and to the French domination in the colonial racial diarchy. Luong also suggests that in northern and central Vietnam, the relatively strong institution of communal land in particular, and the subsistence ethic of the pre-colonial period in general, nurtured a collectivist vision of political economy even among many VNP members in the 1920s, well before their exposure to Marxism. The existence of communal lands and the subsistence ethic also facilitated the process of land collectivization in northern and central villages, in comparison to its slow progress in the south since 1975. Finally, within the bamboo hedges of the corporate rural community, the extensive kinship and communal ties facilitated the mobilization of resources by local revolutionary leaders, especially the generally well-regarded members of the native intelligentsia. Luong suggests that the indigenous non-capitalist tradition thus cannot be ignored in any analysis of the Vietnamese encounter with French colonialism in particular and the capitalist world system in general (see Marr 1971, Woodside 1976).

Violence and Effects on Children

1. Violence in America: History

The common dictionary definition of violence runs something like the following: 'exertion of physical force so as to injure or abuse.' The inclusion of 'abuse' in the definition is important, because it opens up the issues of force being used to induce negative psychological states and to violate basic human dignity. Thus, violence includes the range of behaviors that assault or batter, that induce fear or terror, and that demean and humiliate.

Understanding the effects of violence on children demands an interdisciplinary perspective, one that incorporates psychological, biological, sociological, anthropological, and historical insights within the context of a larger ecological model. Anchoring this issue is the fact that each year in the United States nearly 5,000 children and youth commit acts of lethal violence, half against others (murder) and half against themselves (suicide). The numbers of children and youth who commit potentially lethal acts is, of course, many times greater, what with the tens of thousands of 'serious assaults' and 'suicide attempts' that take place each year involving minors. For each of these kids, and for the families, communities and societies of which they are a part, this problem of violence constitutes a crisis.

The current crisis of these kids is not historically new, however. Writing in *Juvenile Justice Update* in 1997, Robert Shepherd points out that the *New York Times* 140 years ago editorially bemoaned the fact that 'the number of boy burglars, boy robbers and boy murderers is so astoundingly large as to alarm all good men.' He offered the following analysis from a child psychiatrist working in Manhattan for the Juvenile Court in the 1950s: 'At first it comes as a shock to meet youngsters under 16 who rob at the point of a gun, push dope, rape and kill. I've seen boys of 7 so small they could barely clear the desk who had sold themselves to sex perverts. Others had shot out kids eyes or had clubbed or knifed them, just for the fun of it.' And the statement is from an article entitled *Manhattan's Child Criminals Are My Job* in the *Saturday Evening Post* of March 27, 1954. Recall that in the mid-nineteenth century, the governor of New York had to call out the militia to deal with rampant youth gangs in New York City.

2. Violence in America: Today

While there are historical dimensions to the current situation, there are features of the contemporary situation that are distinctive as well. For one thing, we must recognize that the magnitude of the problem is different today. There has been a seven-fold increase in per capita aggravated assault rates among youth in the United States since 1956. Also, kids are being tried as adults and incarcerated correspondingly, in what seems like a macabre return to the medieval concepts of children as simply little adults. But the parallel is even more subject to documentation than that. The homicide rate in the city of Amsterdam in the year 1450 is estimated to have been 150 per hundred thousand. By 1850, when Amsterdam had been 'civilized,' the rate dropped to 2 per hundred thousand. This rate might be taken as a kind of base line for the minimum expectable homicide rate, the rate we find in most of the modern and relatively affluent countries in the world. But in the US we continue to find rates of 20 per hundred thousand and in the most oppressed social environments within our society we find rates of 160 per hundred thousand!

Homicide rates provide only an imprecise indicator of the overall problem of violence in the lives of American children and youth, however, for behind each murder stand many nonlethal assaults. This ratio varies as a function of both medical trauma technology (which prevents assaults from becoming homicides)

and weapons technology (which can increase or decrease the lethality of assaults). An example from Chicago illustrates this: the city's homicide rate in 1973 and 1993 was approximately the same, and yet the rate of serious assault had increased approximately 400 percent during that period. Thus, the ratio of assaults to homicides increased substantially—from 1:100 in 1973 to 1:400 in 1993 (Garbarino et al. 1992).

Class, race, and gender exert important influences on exposure to community violence. The odds of being a homicide victim range from 1:21 for Black males, to 1:369 for white females—with white males at 1:13 and Black females at 1:104 (Bell and Jenkins 1993). Being an American itself is a risk factor. As noted above, the US far exceeds all other modern industrialized nations in its youth homicide rate (even for young whites, where the rate of 11.2 per 100,000 is far more than the second place country, Scotland, with 5 per 100,000 (Richters and Martinez 1993).

3. *Exposure to Violence as an Influence on Development*

Having established this historical and social context, what next becomes clear is that understanding the effects of violence on children is very much a matter of recognizing the developmental links between early experiences of violence as a victim and later experiences of violence as a perpetrator. This developmental relationship exists both within the lives of individual children and across the generations in families. Research indicates that inside virtually every dangerously violent youth is an untreated traumatized child, a child with experiences of violent victimization, and that the there is substantial cross-generational continuity in violence within families.

Research by psychiatrists Perry et al. (1995) and van der Kolk (1996) has begun to illuminate the neurological processes that translate early trauma into later dangerous behavior through brain development and neurochemistry. Dodge et al. (1997) have further elaborated this link by documenting the adaptive processes that link the experience of violence as a young child to the development of a pattern of aggressive antisocial behavior as an elementary school-age child. Their research reveals that the problems comes when abused children develop four particular psychological adaptations (hypersensitivity to negative social cues, obliviousness to positive social cues, a readily accessible repertoire of aggressive behavior, and a belief that aggression is a successful strategy in social relations). Such children are seven times more likely than abused children who do not develop these patterns to end upon diagnosed with 'conduct disorder' (chronic aggressive and antisocial behavior). Abused children who do not develop these patterns are no more likely that children in general to develop conduct disorder.

4. *Children in War Zones*

This is highly significant because it is from the ranks of children with conduct disorder that most chronic violent delinquents come (about a third of such children emerge as chronic violent delinquents according to a variety of studies—cf. Loeber and Farrington 1997). Child abuse and community violence are rampant in the lives of kids who become violent youth. This is one of the most important effects of violence on children. My own research illuminates these links through intensive, multiple interviews with boys involved in lethal violence (Garbarino 1999), and highlights the importance of geographic concentrations of violence that create 'war zone' like settings for children. These are the social settings in which the rates of child victimization is highest (with child maltreatment rates many times higher than in other neighborhoods—Garbarino et al. 1992) and from which most lethal youth violence comes (Snyder and Sickmund 1999).

Children living in neighborhoods which simulate war zones are exposed to high levels of violence. A survey of sixth to 10th graders in New Haven, Connecticut, revealed that 40 percent had witnessed at least one incident of violent crime within the previous 12 months (Marans and Cohen 1993). In three high risk neighborhoods in Chicago, 17 percent of the elementary school age children had witnessed domestic violence, 31 percent had seen someone shot, and, 84 percent had seen someone beat up (Bell and Jenkins 1993).

Some 30 percent of the kids living in high crime neighborhoods of major metropolitan areas like Chicago have witnessed a homicide by the time they are 15 years old, and more than 70 percent have witnessed a serious assault. These figures are much more like the experience of kids in the war zones we have visited in other countries (Garbarino et al. 1991) than they are of what we should expect for children, living in 'peace.' Richters and Martinez (1993) have amplified these results. In their study, 43 percent of the fifth and sixth graders had witnessed a mugging in a 'moderately violent' neighborhood in Washington, DC. Other researchers echo these findings (e.g., Taylor et al. 1994).

5. *Children Adapt: For Better and For Worse*

Children adapt to their perception of community safety in many important ways. One is their view of the future. A Harris poll of sixth to 12th graders in 1992 revealed that 35 percent worried they would not live to old age because they would be shot (Harris et al. 1994). In our interviews with families living in public housing

projects in Chicago we learned that virtually all the children had first-hand experiences with shooting by the time they were five years old (Dubrow and Garbarino 1989). A six-year-old girl once said that her job was to find her two-year-old sister whenever the shooting started and get her to safety in the bathtub of their apartment. 'The bathroom is the safest place,' she said. Interviews with school-age children and youth confirm that the 'gun culture' is a potent factor in the life of children in diverse settings in the US (Garbarino 1995, 1999). Teen use of guns in homicides increased from 64 percent in 1987 to 78 percent in 1991. During the same period, teen arrests for crimes involving weapons increased 62 percent (Snyder and Sickmund 1995).

When children understand that adults cannot protect them they are left with what we might call juvenile vigilantism, the impulse to protect themselves, to take up weapons and relationships that substitute for adult protection. This is evident in comments from children and youth such as 'If I join a gang I'm 50 percent safe. If I don't join a gang I'm zero percent safe' (Garbarino 1999). Adults don't enter into the equation.

6. *Risk Accumulates*

The key to understanding the effects of living in a war zone is the recognition that these children do not simply face a single threat to development, a solitary risk factor. Rather, they face multiple risk factors, a fact of overarching importance in light of research by Sameroff et al. (1987) documenting the cumulative effect of risk factors. In Sameroff's study, while the presence of one or two risk factors was generally manageable for children, the presence of three or more risk factors was associated with significant developmental impairment. These are the children of greatest concern to us, the children who face major accumulations of risk factors, and who are thus most at risk for the psychological effects of trauma due to violence.

Tolan (1996) examined this phenomenon in detail in a study in a Chicago-based study in which he asked the question, 'What percent of kids are resilient if we measure resilience as neither requiring mental health intervention or remedial education?' When he asked that question of data from boys growing up in the most afflicted war zone neighborhoods of Chicago, living in abusive and impoverished families, contending with minority status in a racist society, and looked at this kids over a two-year period, the answer was zero percent. None of the children by age 15 were resilient in Tolan's terms. This testifies to the effects of violence when they occur within a larger context of social and psychological risk accumulation. The relentless pressure imposed on kids who come from that nexus of community violence, family disruption, and personal experience of trauma is uniformly overwhelming.

7. *Future Directions*

As research on the impact of violence on children matures it turns increasingly to studies of the conditions under which alternative pathways are taken by affected children. Why do some child victims become adolescent perpetrators while others do not? How can early intervention change these pathways? How significant are the neurobiological effects of early trauma? These and other questions will require many years of sustained research to address adequately. Unfortunately, the world shows no signs of preventing childhood exposure to violence, so these questions must be answered.

Violence and Media

Public and academic concern about media's contribution to real world violence are about as old as the mass media and the social sciences themselves (Wartella and Reeves 1985). Despite frequent framing of the matter as 'controversial,' extensive research—an estimated 3,000 (Donnerstein et al. 1994) to 3,500 (Wartella et al. 1998) studies in the United States alone—have examined the impact of media violence, and a number of recent major reviews (Huston et al. 1992, Murray 1994, see also Potter 1999, Paik and Comstock 1994, Comstock and Paik 1991), have concluded that media violence plays a measurable role in real-world violence. A variety of US agencies, including the Centers for Disease Control of the US Public Health Service (1991), and medical and public interest organizations, including the American Medical Association, the American Academy of Pediatrics, and the National Conference of Parent-Teacher Associations, have identified media violence as a public health problem. The review below focuses most heavily on US research and US media, most notably American television, primarily because a large majority of the published social science research on media and violence is US research on American audiovisual media. Potter (1999, pp. 44–5), for example, reports 42 published content analyses of US television since 1954, and just 19 from the rest of the world. Moreover, American media are among the world's most violent—and most exported—and real-world violence is a recurring public policy issue. Further, much of this literature concerns impacts of media violence on children and adolescents, for the inter-related reasons that young audiences are considered the most impressionable and most vulnerable. Adults are generally viewed to be more resistant to the deleterious influences of violence, and, as some would argue (cf. Huesmann 1997), violent behaviors in adulthood may be traced to media use during childhood.

1. *Theories of Effect*

Three models have been proposed to describe the process by which such learning and imitation of media violence occurs: social learning theory, priming effects theory, and a social developmental model of learning (Wartella et al. 1998).

First proposed by Albert Bandura in the 1960s, social learning theory is the best known theoretical account of violence effects. Bandura asserts that through observing television models, viewers come to learn behaviors which are appropriate, that is, which behaviors will be rewarded and which punished. In this way, viewers seek to attain rewards and therefore imitate these media models. When both children and adults are shown an aggressive model who is either rewarded or punished for their aggressive behavior, models who are positively reinforced influence imitation among the viewers. Even research in the field has demonstrated that aggression is learned at a young age and becomes more impervious to change as the child grows older. In a longitudinal study to examine the long-term effects of television violence on aggression and criminal behavior, Huesmann et al. (1984) studied a group of youth across 22 years, at ages 8, 18, and 30. For boys (and to a lesser, though still significant extent for girls), early television violence viewing correlated with self-reported aggression at age 30 and added significantly to the prediction of serious criminal arrests accumulated by age 30. These researchers find a longitudinal relationship between habitual childhood exposure to television violence and adult crime and suggest that approximately 10 percent of the variability in later criminal behavior can be attributed to television violence.

Priming effects theory serves to augment the more traditional social learning theory account of television violence effects. In the work of Leonard Berkowitz and his colleagues, this theoretical account asserts that many media effects are immediate, transitory, and short-term (Berkowitz 1984). Berkowitz suggests that when people watch television violence, it activates or 'primes' other semantically related thoughts which may influence how the person responds to the violence on television. Viewers who identify with the actors on television may imagine themselves like that character carrying out the aggressive actions of the character on television, and research evidence suggests that exposure to media aggression does indeed 'prime' other

aggressive thoughts, evaluations, and even behaviors such that violence viewers report a greater willingness to use violence in interpersonal situations.

Only Rowell Huesmann's (1986; see also Huesmann 1997) theoretical formulation of the social developmental model of violence effects offers a true reciprocal theoretical account of how viewers' interest in media violence, attention to such violence, and individual viewer characteristics may interact in a theory of media violence effects. Using ideas from social cognition theory he develops an elaborate cognitive mapping or script model. He argues that social behavior is controlled by 'programs' for behavior which are established during childhood. These 'programs' or 'scripts' are stored in memory and are used as guides to social behavior and problem solving. Huesmann and Miller (1994, p. 161) submit that 'a script suggests what events are to happen in the environment, how the person should behave in response to these events, and what the likely outcome to those behaviors would be.' Violence from television is 'encoded' in the cognitive map of viewers, and subsequent viewing of television violence helps to maintain these aggressive thoughts, ideas, and behaviors. Over time such continuing attention to television violence can thus influence people's attitudes toward violence and their maintenance and elaboration of aggressive scripts.

This theory suggests that while viewing violence may not cause aggressive behavior, it certainly has an impact on the formation of cognitive scripts for mapping how to behave in response to a violent event and what the outcome is most likely to be. Television portrayals, then, are among the media and personal sources that provide the text for the script which is maintained and expanded upon by continued exposure to scripts of violence.

Huesmann has demonstrated that there are key factors which are particularly important in maintaining the television viewing–aggression relationship for children: the child's intellectual achievement level, social popularity, identification with television characters, belief in the realism of the TV violence, and the amount of fantasizing about aggression. According to Huesmann, a heavy diet of television violence sets into motion a sequence of processes, based on these personal and interpersonal factors, that results in many viewers becoming not only more aggressive but also developing increased interest in seeing more television violence.

It must be emphasized that all serious scholars of the impacts of media on violence are careful to note that media are not the only, nor perhaps among the most important, contributors to real-world violence. Violent behavior is a complex, multivariable problem, formed of many influences. Racism, poverty, drug abuse, child abuse, alcoholism, illiteracy, gangs, guns, mental illness, a decline in family cohesion, a lack of deterrents, the failure of positive role models, among others, all interact to affect antisocial behavior. As Huesmann has argued, aggression is a syndrome, an enduring pattern of behavior that can persist through childhood into adulthood. The impact of media violence appears strongest as a predictor of real-world antisocial behavior as one facet of a 'culture of violence.'

2. *Types of Effects*

As Potter (1999, Chap. 9) notes, media-violence effects fall into five categories—physiological, emotional, cognitive, attitudinal, and behavioral—and both immediate or short- and long-term effects have been studied. While some attention has focused on direct, short-term imitative or modeling effects (cf. Phillips 1980, 1982, but see Hessler and Stipp 1985), more attention and public policy concern has focused on the long-term impact of repeated exposure to violence. More generally, three overarching categories of effect receive most attention: learning of aggression, desensitization to real-world violence, and the cultivation of fear in repeated exposure to media violence (Wilson et al. 1997).

Clearly, not all violent depictions should be treated equally, nor all viewers. The (US) National Television Violence Study (Wilson et al. 1997) identified several contextual factors within a representation that may influence audience reactions to media violence which include the following.

2.1 *The Nature of the Perpetrator*

Where individuals perceive perpetrators of violence as attractive, as heroes, and/or as similar to themselves, the likelihood of stimulating attention (Bandura 1986) and aggression (Paik and Comstock 1994) increases.

2.2 *The Nature of the Victim*

While the commission of violence on an attractive character with which an audience member identifies might serve to inhibit aggressive behavior, its principal impact would seem to be in arousing fear among the audience members.

2.3 *The Reason for the Violence*

Wilson et al. (1997, p. 24) note that violence viewed as justified likely heightens aggression, while violence viewed as unjustified arouses fear. The impact of justification has been documented with fictional as well as realistic programming (Meyer 1972), and with adult as well as child viewers (Liss et al. 1983). In fact, a recent meta-analysis of 217 media studies documents

that a justified portrayal of violence can enhance aggressive behavior among viewers (Paik and Comstock 1994).

2.4 The Presence of Weapons

A number of studies, including a meta-analysis of 56 published experiments (Carlson et al. 1990) have demonstrated that the presence of weapons, either pictorally or in the natural environment, can enhance aggression among subjects. While, for ethical reasons, the large majority of such research involves adult subjects, in at least one study (Frodi 1975) the presence of weapons enhanced aggression among adolescents. 'Conventional' weapons such as guns and knives are more likely than unconventional means for priming the effect, social learning theory would suggest, because their use as a means of aggression are stored in memory (Berkowitz 1990, Leyens and Parke 1975).

2.5 The Extent and Graphicness of the Violence

A review (Wilson et al. 1997) for the National Television Violence Study suggested that more research is needed, but several tentative conclusions about extent and graphicness could be reached: (a) extensiveness of violence *within* media presentations should be associated with increased desensitization to violence, at least in the short- to medium-term; (b) graphicness of violence should be associated with increased cultivation of fear; (c) longitudinal studies clearly suggest that extensiveness of *viewing*violent media presentations heightens the likelihood of engaging in aggressive behavior.

2.6 The Degree of Realism of the Violence

In brief, realistic violence has been found to induce aggressive behavior, and to induce fear, more than violence believed to be less realistic or more fantastic. An extremely important qualification deals with younger children, who may be unable to distinguish realistic from fantastic characters, behaviors, and situations. In one study, however, where *perceived realism* was manipulated for older children (9 to 11 in Feshbach 1972; 10 to 13 in Atkin 1983), those subjects who were led to believe that footage was realistic news were more likely subsequently to behave aggressively than those led to believe it was taken from an entertainment program.

2.7 Whether Violence is Rewarded or Punished

Rewarded violence is more likely to be imitated than violence which is punished. Significantly, and particularly for children (since, as we will show below, television programming most frequently presents violent actions that are neither rewarded nor punished), the absence of punishment may enhance imitation, even in the absence of explicit reward (Bandura 1965, Walters and Parke 1964). Paik and Comstock's meta-analysis (1994) suggests that rewarded violence stimulates aggression among both child and adult audiences. One study suggests that punishment of criminal violence decreases fear (Bryant et al. 1981).

2.8 Consequences of Violence

In general (and exceptions are noted in Wilson et al. 1997, p. 30), mediated depictions of violence which show either pain cues or other short- or longer-term negative effects or consequences of violence are likely to depress the learning of aggression. There is little research on the effects of pain cues or violence consequences on desensitization and the cultivation of fear.

2.9 Presence of Humor

As the National TV Violence Study review also noted, further research is needed here as well, but the present state of knowledge suggests, other things being equal, that violence coupled with humor is more likely to heighten aggression, and to increase desensitization, than violence without the presence of humor:

> Several mechanisms can be used to explain such a facilitative effect of humor on aggression. Humor might elevate a viewer's arousal level over that attained by violence alone, and increased arousal has been shown to facilitate aggression. … Humor could serve as a reinforcement or reward for violence, especially if the perpetrator is funny or admired or his or her wit. And humor may diminish the seriousness of the violence and therefore undermine the inhibiting effects of harm and pain cues in a scene. … However, we should underscore that our conclusion about the facilitative effect of humor on aggression is tentative until more systematic research … is undertaken (Wilson et al. 1997, p. 32).

3. Young Viewers

As noted, research indicates that certain factors may be processed differently by young viewers. First, children below about age 8 have more difficulty distinguishing reality from fantasy and often imitate superheros with magical powers such as the *Power Rangers* (Boyatzis et al. 1995). Second, young children may have difficulty connecting scenes and drawing inferences from the plot. Timing of punishments and rewards becomes important in this instance. In many programs, the crime or violent behavior may go unpunished until the end of the program. Young children may have difficulty connecting the ending punishment with the initial violent act and may, therefore, believe that the violence went unpunished (Wilson et al. 1997). Thus, learning of aggressive attitudes and behaviors from television varies by both the nature of the portrayals and the nature of the

viewers. The presence of contextual factors in the portrayals which may inhibit young children's social learning of aggression decreases the negative consequences of such portrayals and should be encouraged. Not all violent portrayals are the same and the context of violence is clearly quite important. Similarly, young children, those under the age of seven or eight, may be particularly susceptible to learning from exposure to television violence because of differences in how they make sense of television compared to adults.

4. *The Media Environment*

Television's role as the central mass medium in much of the world for the past half-century, and its ubiquity and ability to enter almost every home, often without parental supervision, has meant that more public and scholarly concern has focused on its contents than on any other medium's, and this concern has accompanied its diffusion into every corner of the earth.

Unfortunately, cumulative and comparative research on television's violent content is hampered by a lack of consistency in defining violence and especially defining the population and sampling frame in studies of television.

The most extensive single content study of US television was the 1994–7 National Television Violence Study (National Television Violence Study 1997, Center for Communication and Social Policy 1997, 1998). Examined were the 6 a.m.–11 p.m. contents of a multistage probability sample constructed sample week of programming on 23 network-station, independent-station, and basic-cable and premium-cable channels; thus about 8,000 programs were analyzed over the 1994–5, 1995–6, and 1996–7 television 'seasons.' Certain programs, including 'hard news,' religious shows, sporting events, quiz shows, and educational shows, were sampled but not analyzed. About three-fifths of the remaining programs contained some visual violence, a figure that like most summary statistics remained stable over the three years of the study. In descending order, premium cable, basic cable, independent-station, broadcast network station, and public broadcast stations' programming were likely to contain violence. By content genre, in decreasing order, movies, dramas, children's shows, music videos, and reality-based and comedy programs were likely to contain violence. Violence was far more prevalent during prime-time than during daytime hours.

Of signal concern to the NTVS researchers was the *context* of televised violence; it was often glamorized (more than a quarter of all violence was perpetrated by 'good' or attractive characters, and some 40 percent by characters with at least some good qualities); sanitized (about 7/8 of violent scenes show no blood and gore; almost half show no harm to victims of violence, although more than half of violent interactions show infliction of harm that would be lethal in 'real life,' and about half depict no pain cues in victims of violence); and unsanctioned (in a majority of scenes, violence perpetrators were neither rewarded nor punished ['punishment' was considered any noticeable sanction, including a perpetrator's oral expression of remorse], and among other scenes, rewards and punishments were about equally likely; in three-quarters of cases, characters perpetrating violence were either never punished, or were punished only at the program's conclusion). Moreover, only three percent of programs with violence had any antiviolence theme (Center for Communication and Social Policy 1998, Chaps. 3–4). Potter (1999) has an extensive discussion of definitions of media violence and the results of content analyses from a variety of studies.

5. *Media Violence and Public Policy*

As noted, the consensus in the social scientific community regarding media violence is that it serves as a contributor to aggression in the real world, and virtually all public opinion surveys confirm that wider publics believe this as well. Nonetheless, such findings are 'controversial' in the media industries, and among a minority of academics (see, e.g. Fowles 1999 and sources cited therein). In the United States in particular, since the 1950s the media industries—television in particular, but also recorded music, motion pictures, pictorial comic books, and video games—have responded to public and governmental outcries against violent content by promises to reform under self-regulation. Motion pictures, video-games, and recorded music all list 'ratings' for their products which suggest age-groups for which the industry self-regulatory groups think the content for these products is appropriate. The US Telecommunications Act of 1996 mandated that the television networks create a 'voluntary' ratings system or face creation of one by the federal government. The system the broadcast industry has created suggests appropriate age categories and levels of sex, language, and violence to allow consumers and parents to make program choices. The same act mandated a 'v-chip' in newly manufactured television sets to allow parents to screen or filter out violent programs. There is to date insufficient research to indicate whether and what sorts of parents and other viewers are using either the ratings or the v-chip technology to screen violence. However, experimental research by Cantor and her colleagues (Cantor and Nathanson 1998, Cantor et al. 1997) suggests that young children may use aged-based ratings systems to shield themselves from violent content while for older children and adolescents, there may be a boomerang or 'forbidden fruit' effect whereby ratings *attract* them to more 'adult' violent or sexually explicit material. In the United States Congress, a moratorium on discussion of television violence is in effect, pending further information on the effects of ratings and the v-chip, but the legislature is

focusing its attention on violent video-games, the target of significant public criticism in the wake of a number of firearms murders in public schools.

6. Conclusion

It is clear that where children and television violence are concerned, the question that remains is not whether media violence has an effect, but rather how important that effect is in comparison with other factors in bringing about the current level of crime in the United States and other industrialized nations. Future research should also aim to establish who precisely is most susceptible to media violence, and, most importantly, what sorts of intervention might help diminish its influence. At the same time, any interventions that help establish policies and practices to reduce the socially inappropriate ways of portraying violence and increase the socially responsible ways (such as using violence to assert antiviolence messages) should be encouraged as well. Long-term solutions to problems caused by violence in the real world, however, will require attention to a much wider variety of causal agents.

C. Whitney and E. Wartella

Violence as a Problem of Health

In the early 1990s, many policy makers and social scientists related the problem of community violence to neighborhoods trapped in struggles among gangs competing to sell and distribute illegal drugs, especially cocaine and crack cocaine. From this perspective, the challenge for communities was to locate and restrain perpetrators and respond to victims. Gradually, it has been recognized that community violence, however it began, affects many segments of the population. Seemingly clear distinctions between victim and perpetrator seem to have faded. Heightened exposure to violence is assumed to increase acts of aggression in anticipation of violence from another. Effectively, the timing rather than the nature of an act may differentiate victim from victimizer. In such an environment, the sense of unease may seem constant, the need for vigilance continuous, and suspicion of others required. That state may, in turn, disrupt sleep, upset vegetative functions, impair interpersonal relationships, and disable effective concentration on work and studies. Together, these characteristics produce an environment marked by 'pervasive community violence' (PCV), an ecological situation with significant impact on emotional, behavioral, and psychological health.

PCV, therefore, negatively alters the essence of community life, broadly disrupts its functioning and presumably thereby impairs residents' general health. The potential for such broad impact must be appreciated and respected *before* one can enlist communities to join in investigating PCV's nature and consequences. Investigators who do not appreciate that quality may be surprised by the reluctance of community leaders (e.g., school administrators, county health officer, and representatives of the mayor's office) to participate in its study. The leaders may deny the problem's extent or hesitate to make public the negative quality of their neighborhood or community. For them genuine partnerships require time accumulated through historical involvement and future commitment. History enables disclosure and trust. Intimate aspects of a community are rarely shared with strangers. Assurance that the investigator will be there in the future (even after external funds are gone) is important, given community leaders' appreciation of the intransigence of social problems and the fickleness of social scientists. Thus, from the outset it must be appreciated that to study and alter the nature and consequence of PCV requires a genuine and long-term partnership between communities and social scientists.

1. *Definition of Terms*

As one reviews the growing PCV literature, the need for defining relevant terms becomes apparent. *Violence* refers to both acts and consequences of the *intentional* use or threat of use of force to cause injury, harm, or death to another. The qualifier 'intentional' excludes unintended or accidental acts and consequences. Determining intent represents an as yet unresolved methodological challenge. For PCV, the *consequences of violent acts* refer to the rippling health and mental health effects experienced by: (a) individuals directly victimized by an act or threat of violence; (b) indivi-

duals indirectly victimized as a bystander, witness, acquaintance, or loved one of a direct victim; and (c) individuals indirectly victimized by their awareness of, and anxiety about, the occurrence of acts or threats of violence. *Community violence* locates the acts and their consequences in a geographic setting (e.g., a neighborhood or a school), an identifiable social grouping (e.g., a grade cohort, a gang, a nuclear or extended family) or both. *Pervasive community violence* (*PCV*) refers to the chronic and widespread occurrence of acts or threats of violence within such settings or social groups.

Thus, PCV exists when *substantial* acts and consequences of violence are encountered across *multiple* settings and circumstances over *extended* time. To investigate PCV systematically, the qualifiers 'substantial,' 'multiple,' and 'extended' must be operationally defined and rigorously measured. Information must be gathered about a community's rate of violent acts and about rates of individual encounters with violent acts. For methodological and political reasons, PCV measures vary in their consideration of violence occurring within or outside of the home. The majority of such measures limit their focus to outside encounters. Yet, by definition, PCV implies cross-setting exposure. At its most extreme, PCV represents the absence of any sanctuary or setting in which relief and a sense of safety is possible. Thus, the most serious impacts on physical and psychological health are likely to be observed in those exposed at home, at work or school, and en route between the two.

In a series of papers and chapters, I have proposed consideration of *PCV as an environmental contaminant* with measurable effects on health and mental health (Cooley-Quille and Lorion 1999, Lorion 1998, 1999, 2001, Lorion et al. 1998, Lorion and Saltzman 1993). From that perspective, PCV contaminates settings and thereby the actions and interactions of at least some inhabitants. *Contamination* refers to the corrosive or pathogenic effect of PCV exposure on community climate. Slowly investigators are documenting PCV's negative effects on: (a) individual assumptions about the threatening quality of others, (b) the need to limit one's contact with others, and (c) the urgency of responding aggressively to actual or anticipated attacks. This ecological contamination appears to vary in its pace as well as intensity across individuals, situations, and settings. Understanding the determinants and mechanisms of such patterns and their malleability within and across individuals should inform the design of interventions to limit PCV exposure and reduce its consequences.

2. *Measuring PCV*

Investigation of PCV's environmental influence requires the availability of measures to estimate its presence and to confirm its impacts. Applying a common measurement approach across diverse populations and settings, Richters and associates (Lorion and Saltzman 1993, Martinez and Richters 1993, Osofsky et al. 1993, Richters and Martinez 1993) scientifically documented the extent of children's exposure to violence. They also provided early evidence of the relationship between PCV exposure and children's emotional and behavioral functioning. Subsequent investigations of such relationships (e.g., Hill and Madhere 1996, Singer et al. 1995) confirmed the seriousness of such links.

Measures of exposure to community violence share many similarities with the Survey of Children's Exposure to Community Violence (Richters and Saltzman 1990). Instructed explicitly *not* to include media exposure (i.e., what was seen or heard about on radio, television, or in movies), respondents indicate along a five-point Likert scale (from 0 = *never* to 4 = *a lot of the time*) how often they have been victimized by, heard about, or witnessed violent events or related activities (e.g., shooting, stabbing, mugging, seeing a dead body). For each instance of reported exposure, respondents provide information about: (a) where the exposure occurred (i.e., in or near school, in or near home, in the neighborhood); (b) who perpetrated the violence (e.g., a stranger, a family member); (c) who, if not the respondent, was victimized (e.g., a stranger, a family member); and (d) when the incident occurred (e.g., one week ago, five years ago).

Variations of this measure were applied by Martinez and Richters (1993) and Osofsky et al. (1993) in studies of mothers of elementary graders and by Richters and Martinez (1993) and Saltzman (1992) in their studies of fifth and sixth graders. A cartoon-based version of this measure was designed by Richters and Martinez (i.e., Things I Have Seen and Heard, 1990) to assess PCV exposure in primary graders. Test–retest reliability was a most acceptable $r = 0.81$. A second cartoon-based measure, Levonn, assessed distress symptoms associated with exposure (Richters et al. 1990). Subsequently, Fox and Leavitt (1995) developed the Violence Exposure Scale for Children (VEX-R) as a cartoon-based measure of PCV exposure in children from preschool through the elementary grades. Using this measure, Shahinfar et al. (2000) documented PCV's impact on preschoolers. The negative behavioral consequences of such exposure was confirmed in a sample of Israeli elementary school children by Raviv et al. (2001).

A further variation of the Richters and Saltzman (1990) measure was applied by Saltzman (1995) to examine PCV exposure's link to adolescent involvement in antisocial and delinquent behaviors. Building on these variations, Singer et al. (1995) designed the Recent Exposure to Physical Violence and the Past Exposure to Violence surveys to obtain adolescent reports of exposure during the prior 12 months or 'while growing up, not including the past year,' respectively. The acts of violence surveyed by Singer et

al. included threats, slapping, hitting, punching, beatings, knife attacks, and shootings. Separate reports for each (other than knife attacks and shootings) were obtained for home, school, and neighborhood. Respondents were also asked how often they had witnessed someone else victimized at each of the aforementioned sites. Two additional items inquired about respondents' having been 'made to do a sexual act' or having witnessed someone else 'being made to do a sexual act.' Overall, measurement efforts to date support the conclusion that psychometrically acceptable reports of PCV exposure can be obtained from youth ranging in age from preschoolers to adolescents.

In addition to the above work, Jenkins and associates (Bell et al. 1988, Jenkins and Thompson 1986) designed and conducted qualitative studies of African-American children's encounters with violence. Results from four studies are summarized in Bell and Jenkins (1993). Using related measures, Jenkins and colleagues obtained information about youth's exposure in terms of: (a) knowing someone who was a victim of violence; (b) having witnessed violent events *in real life*; (c) having been a victim of a violent incident; and (d) having perpetrated a violent act. Comparable to the work mentioned above, information about such forms of exposure was obtained from students enrolled in grades 2 through 12.

Although not a universal experience, victimization occurs at levels approaching 50 percent for threats and 40 percent for forced entry into their home. Indirect victimization (e.g., being a witness to a violent act) levels were consistently higher for incidents ranging from drug use to shootings, stabbings, and muggings. Reports of seeing a dead body in the neighborhood ranged from 24 to 40 percent. Using an extension of the Richters and Saltzman measure, Singer and colleagues (Singer et al. 1995, Song et al. 1998) validated these reports in their surveys of high-school students ($N = 3{,}735$). As expected, considerable variability is present across settings. Nevertheless, levels of victimization and witnessing (both at home and in school) justify recognition of PCV as a major environmental contaminant. Apfel and Simon's (1996) description of communal violence as referring to settings in 'which every child has witnessed or expects to witness violence and has been or expects to be violated' (pp. 4–5), seems to apply to many of the nation's neighborhoods and schools.

3. *Assessing PCV's Health Impact*

The aforementioned studies also report on PCV's toxicity. Saltzman (1992), for example, observed significantly higher levels of generalized emotional distress in PCV-exposed fifth and sixth graders. This pattern is also reported by Richters and Martinez (1993), Martinez and Richters (1993), Osofsky et al. (1993), and Bell and Jenkins (1993). Across these studies of preadolescents, PCV exposure relates positively to affective and vegetative signs of depression and indices of stress-related disorders. With both preadolescents and adolescents, Singer et al. (1994) linked PCV exposure and increased aggression, conduct disorder, running away, and decreases in self-esteem and social competence. Support for the link between PCV exposure and involvement in violent acts is reported by Saltzman (1995). In Saltzman's study, PCV exposure significantly related to adolescent involvement in antisocial and violent acts independent of peer, familial, and other recognized predictors of aggression during that developmental period. Rubinetti (1996) linked PCV exposure and violent activity most strongly in youth with decreased empathy, hopefulness, and self-esteem. Provocatively, Song et al.'s (1998) findings suggest that indirect victims are more likely than direct victims to aggress *in anticipation of* violent acts. Although further study is needed, PCV may create interpersonal distance among the residents of an affected setting, desensitize them to the consequences of violence on others, while heightening the need to defend oneself against assault. Overall, there appears to be substantial evidence that heightened exposure to PCV increases the likelihood that one will engage in violence. In turn, the resulting acts of violence increase levels of PCV exposure, providing a mechanism for a continuing cycle.

Two recent studies (Cooley-Quille and Lorion 1999, Scarpa et al. 2000) have begun to examine the physical impacts of PCV exposure. Each study found physiological concomitants of PCV exposure, including increased heart rate, respiration, and cortisol levels, long-established indices of heightened stress and arousal. Cooley-Quille and Lorion (1999) also reported preliminary evidence of a link between PCV and sleep disorders. Anecdotal reports from youth living in PCV-heightened neighborhoods report difficulty falling asleep, repeatedly waking up in response to gunshots, loud noises, and police activity and, generally, only rarely sleeping throughout the night. If these reports are confirmed along with further information about the vegetative effects of PCV exposure, new understandings may emerge which change existing assumptions about the lack of impulse control and academic failure, often associated with urban poverty, from attributions about personal failure to questions about environmental toxicity. Thus, although examination of the physiological consequences of living or working within settings characterized by high PCV levels is just beginning, preliminary results suggests that these impacts are real, extensive, and potential triggers for further pathogenesis across multiple parameters of functioning.

Such findings support the hypothesized toxicity of PCV exposure which appears to impair cognitive, emotional, behavioral, and biological functioning simultaneously, sequentially, or synergistically. As yet

unexamined systematically, however, is the breadth of these 'PCV-consequences' (assuming they are causally linked) within settings and communities. In essence, we have yet to study how the toxin spreads and the transmission routes by which the occurrence of violent events (presumably their nature, frequency, and intensity would influence the spread of effects) contaminates the environment. Longitudinal information is necessary to causally link exposure and its observed concomitants. It is also necessary to determine at what point interventions can be introduced to protect against or, if necessary, to treat such effects.

It should be recognized that what is presently known about PCV relates almost entirely to school-aged youth. We know little about the effect of maternal PCV exposure on neonates, of exposure on toddlers and preschoolers, and even less about the nature, extent, and consequences of exposure on adults. What of the parents, grandparents, and others who live in such neighborhoods? Within schools, what of the staff and teachers who may live in such neighborhoods, travel through such neighborhoods, or hear the tales of their students? Work reported to date pays little attention to these members of exposed communities, except perhaps to suggest that they could buffer youth against the impacts of PCV. Whether we can assume the capacity of exposed adults to do so merits careful examination.

We must therefore examine exposure across the entirety of a community's population and settings. Anecdotal reports, informal focus groups, and clinical encounters suggest that exposure reduces the quality of teachers' instructional effectiveness, capacity to apply classroom management strategies, and availability to students before or after the school day. Reasonably, one might expect that PCV similarly disrupts parent–child, parent–teacher, and teacher–teacher interactions. As reported above, Song et al. (1998) found a significant link between indirect exposure and anticipatory aggression. Ambiguous interpersonal cues may be interpreted by youth (and perhaps adults?) as threatening, leading to what is assumed by the perceiver as a defensive act. Presumably (although we do not really know), when self-defense seems unlikely to succeed, ambiguity leads to retreat, avoidance, or perhaps acquiescence with stated or unstated demands.

If this explanation of Singer's finding is valid, would it not extend to adult interactions within and across generations? Might it not explain, at least in part, what from the outside appears as hypersensitivity to insult or disrespect, the immediacy with which one asserts one's right, or the reluctance to give way, lest courtesy be mistaken for weakness or fear? Might it not explain urban parents' use of physical discipline or its reverse, that is, seeming inability or unwillingness to control their children's behavior? What of neighborhoods in which the elderly limit, and the young have limited, time outside of the home because of concerns about danger and vulnerability? Would not isolated streets facilitate violence with immunity? Would not the biological concomitants related to stress, sleep deprivation, and concentration impair adults' (be they teachers, storekeepers, bus drivers, or neighbors) capacity to interact comfortably with each other and to neutralize or at least dilute PCV's toxicity and thereby protect youth? To ignore the status of adults in such settings implies that they are unaffected by PCV or other community toxins.

Albeit at levels of concern, PCV is linked to increased but not universal pathology. Not only does a majority of those exposed not manifest pathology, but most residents do not report exposure. PCV exposure appears to relate not only to the occurrences of violent acts, but also to awareness of those occurrences. Somehow, many exposed are seemingly unaware of that and, potentially, for them there is some bliss in ignorance. What individual and ecological factors determine sensitivity remains to be investigated. That such differences exist, however, argues for attending to issues of adaptation, coping, and wellness. As noted recently:

> By implication it seems reasonable to view wellness as representing the outcome of normative developmental processes, in programming terms, as the default option. In the absence of that relatively rare combination of individual and situational circumstances, individual development appears to proceed within socially expected and appropriate boundaries reflecting the general capacity to adapt to situational demands and cope with stressful events. Just as canalization accounts for the limits within which genetic processes emerge within species (Gottlieb 1992), an analogous process may account for the human capacity to adapt to a multitude of settings and circumstances, and to cope with seemingly debilitating and pathogenic stressors. (Lorion 2000, pp. 13–14)

If wellness, adaptation, and adjustment represent the default option in human development, and individuals, families, neighborhoods, schools, and communities in general cope with PCV, economic (dis)advantage, familial instability, critical life events, inadequate school budgets, etc. (the length of one's list merely underscores the point), understanding those mechanisms may inform the design of interventions to protect those who cannot cope. Answers to questions about how to optimize development and coping must be out there, in the homes, the schools, the classrooms, and the neighborhoods. To find those answers, we in the social sciences must enter the communities to observe, inquire, and learn. I propose we go not as experts bringing esoteric knowledge, but as students and collaborators, hopefully bringing tools and perspectives whose utility will be determined relative to what already exists, and what can be sustained over time and across levels of resources.

R. P. Lorion

Violence, History of

Violence in its various forms has been an aspect of historical descriptions since Thucydides, but to this day there is no independent specialty in historical research on violence. The history of violence is thus written as part of military and war history, of research on revolution and protest, and of the history of gender and the body. In Europe and elsewhere, it cuts across the institutional and disciplinary logic of the study of history. This lack of independence has two consequences for historical research on violence. First, it is always interdisciplinary and includes approaches

proper to political science and social history, as well as issues of cultural history. Second, it cannot look back on a unified development, but on disparate traditions in the individual disciplines. While revolutionary violence, for example, is discussed primarily in the context of the French Revolution, research on social protest has developed under the influence of 1950s Anglo-American social history and of the reactions to the 1960s urban riots in the USA. The historiography of research on violence is thus many-stranded and international.

1. Definitions of Violence

The definitions of violence are as varied as its manifestations. The term itself takes on disparate coloring in the context of each respective national language. English, French, and Italian reflect the Latin and emphasize the injuries caused by violence and its violation of corporal integrity. By comparison, the German term '*Gewalt*' is less negatively charged, also being used as a synonym for 'power' or '*pouvoir*'. Only its extension '*Gewalttätigkeit*' captures the injurious character of the Anglo-American term. A comparative examination of the history of terms is a desideratum for research.

The spectrum of scholarly definitions of violence is broad. The distinctions between direct and indirect, collective and individual, legitimate and illegitimate, concrete and structural, physical and psychological, and manifest and symbolic violence reflect varying accents in the discussion. Depending on the definition, the focus can be on the manifestations, the justifications, or the effects of violence. The term has been specified further in accordance with its intended use for qualitative or quantitative studies. Modern research on protest sees collective violence when at least 20 persons take part in acts in which persons or objects are damaged.

In the current discussion among historians, violence is widely understood as injury to people's physical integrity, caused by various historical actors in various contexts. Here, violence is not seen as an anthropological constant, nor as a universal historical trait held in common, but tied to the actions of specific groups and conditions that are subject to change in various national societies and epochs. The German sociologist, Heinrich Popitz, has advanced this view (Popitz 1986). He sees violence as 'an act of power that leads to the intentional bodily injury of others'. In this view, corporality distinguishes violence from other means of domination, such as orders, though it contributes to their effect.

Since violence injures bodily integrity, it possesses a massive potential for threat and evokes fears. These can contribute to the avoidance of acts of violence, but can also amplify them. The pair of terms 'physical' and 'psychological' violence touch on this connection. Not only does the experience of physical violence, such as torture or rape, have psychological consequences; psychological violence, such as brainwashing, can also have physical effects. Popitz' definition also points to the concept of power. It thus designates the content of violent conflicts as an often unequal structural situation of victims and perpetrators. This underscores that the history of violence is also always a part of societal processes in which the distribution and resources of power are up for discussion.

Beyond its physical core, the term violence has taken on various meanings in the course of the modern age.

(a) In the process of forming states, legitimate violence is distinguished from illegitimate private violence, independent of whether the latter is wielded in revolutions or in defense of the status quo. The state has defended and extended its monopoly on violence as a constituting component of being a state since early modern times. This monopoly prevailed through the disarmament of the feudal rulers. With the army and (since the eighteenth, and especially the nineteenth, centuries) the police, state organs exercised the monopoly on legitimate violence. This monopoly required justification in its form and degree, but not in its existence. Lindenberger and Lüdtke saw the hallmark of modernity in the network of relationships between physically suffered violence, on the one hand, and the state monopoly on violence, on the other (Lindenberger and Lüdtke 1995). Thus they not only claim an increase in the state's practice of control and repression, but also touch upon the everyday experience of violence. In the modern age, citizens can come into conflict with state regulations and sanctions, which in turn provoke violent actions. In modern protest research, Charles Tilly, among others, has held state reactions to unrest responsible for the extent of counterviolence (Tilly 1975).

(b) The experiences of dependency and inequality between the centers of power, colonies, and the so-called 'Third World' led the Norwegian social scientist, Johan Galtung, to develop the concept of 'structural violence' (Galtung 1975). From the perspective of peace politics, he drew attention to a discrepancy. He saw a chasm between the existing potential for development based on technology and available societal wealth, on the one hand, and the respective levels of development of disadvantaged groups and countries, on the other. His concept emphasizes, not individual perpetrators, but social structures, and not primarily physically-experienced violence, but poverty and exploitation. He was not so much concerned with legitimating counterviolence, as vehemently defended by the Algerian sociologist, Frantz Fanon, but with social peace, which he thought would be secured for all through equality and opportunities for development (Fanon 1961).

The term 'structural violence' flourished in the 1970s, but also met criticism. It was accused not only

of failing to define 'structure,' but also for lacking specificity in its analysis of violence. 'By tendentiously deciphering all relations as relations of violence, these relations are leveled,' wrote Wolf-Dieter Narr (1973); i.e., the analyses of violence and of society are indistinguishable. Galtung was able to demonstrate that the term 'violence' can be applied meaningfully in the analysis of acts in the context of the forcible relations effective in acts of exchange, in inculcating literacy, and in migrations.

(c) The concept of symbolic violence is beset with similar problems of distinction. Pierre Bourdieu and Claude Passeron used it in their theoretical analysis of the French school system and thus designated 'that form of violence' that 'is exercised against a social actor with the complicity of this "actor"' (Bourdieu and Passeron 1970). The experience is violent in that the actors are subjected to a code of language and behavior alien to them; it is symbolic through the verbal and semiotic form of its mechanisms. These shape the school's demands and enable or prevent scholastic careers. According to Bourdieu, by accepting this code, the actors contribute to the lasting legitimation of the scholastic system of selection. This term rightly touches on the linguistic and semiotic dimension of violence, but expands it to the point that it no longer has clear contours.

(d) In the course of the development of gender history in the 1990s, the concept of violence has been extended to private forms of violence within the family. Feminist literature has used the term 'sexual violence'. This refers to actions that appear in a form tying societies to sexuality. They are carried out against the will of persons who do not have the same power resources as the perpetrators. Sexual violence is thus analyzed as part of the inequality effective in the relationship between the sexes. It shifts from an exceptional phenomenon to one in terms of which the paradigmatically prevailing ideas of power relations and sexuality, and the experiences of women and girls can be grasped. This extension of the concept of violence not only opens new fields to scientific research, but, since the 1980s, has also been taken up in the penal codes of individual societies.

2. *Historical Research on Violence*

In the past, experience with violence was subsumed again and again in theoretical sketches. Among them, the theories of Thomas Hobbes, Max Webber, and Hannah Arendt were doubtless the most influential, though they arose under disparate conditions (Hobbes 1914, Weber 1919, Arendt 1970). But, especially since the 1950s, their influence on historical research on violence has been superseded by that of Norbert Elias, Michel Foucault, and most recently Clifford Geertz (Elias 1976, Foucault 1975, Geertz 1973).

Thomas Hobbes was the primary inspirer of historical research on violence (Hobbes 1914). In seventeenth-century English society, which was no longer integrated by religion, he demonstrated in terms of contract theory the necessity of the state's use of violence. Hobbes postulated that, to pacify an English society composed of private persons hostile to each other, these persons relinquished their rights to the Leviathan state, i.e., in the English case, to the absolute monarch. In return, they received protection from hostile others and the guarantee of societal peace. The double function of the state's monopoly on violence—on the one hand, to protect the interests of individuals, and on the other, to limit their possibilities of self-realization and their rights—has become the common possession of most analyses of violence since Hobbes. The individual's relationship to state violence thus often develops from his specific experiences either with the state's protection or with its limitation of his freedom.

Norbert Elias has provided important stimuli for historical research on violence (Elias 1976). Elias described European history since the Middle Ages as a history of civilization. This hypothesis is based on two central assumptions. First, Elias says that, in the course of the expansion of the trades, commerce, transportation, and the activity of the state, the interaction among members of society became more frequent and more dense. To the degree that they competed for influence and shares of power, agreements on behavior, and behavioral norms were required. In this process, civilized manners prevailed. On the other hand, the state monopoly exercised an increased external compulsion over the behavior of the members of a society. This found its most complete form in courtly society. In the realm regulated by courtly etiquette, the individual's success depended on new civilized modes of behavior. To the degree that peoples' definition of themselves conformed to this framework, forms of self-compulsion and control of feelings resulted. Violent structures of interpersonal societal relations receded as the model of civilized and inner-directed acting spread from the upper strata to the rest of society. Elias' historical periodization has been criticized by Hans-Peter Duerr, but his secular-based hypothesis has nonetheless been very fruitful for research (Duerr 1988–96).

Michel Foucault emphasized the shift in form and content in state practices of punishment, which shaped both societal reality and the individual's life practice lastingly (Foucault 1975). In his view, the practices of domination targeting the body have shifted since 1800 to strategies targeting the mind. The disciplinary measures carried out on the human body in clinics, psychiatric facilities, and prisons took on a more total character in the modern age. As in Jeremy Bentham's 'Panoptikum,' the individual is now subjected to control by institutions and the effects of techniques of power, which in turn are provided by the fields of

study that dominate discourses (Bentham 1787). In Foucault's model, the direct violence of the exercise of power made way for the violence of discourses—at least after the threshold between the epochs, which he locates around 1800. Historical studies have relativized this hypothesis and made it more specific, as they did with Elias' theories, but it too has retained its importance as a challenge to detailed studies.

While Elias and Foucault locate the changing use of bodily violence in epochal contexts and societal macrosituations, cultural anthropological studies have gained importance over the years, and they are no longer devoted to the causes, but to the forms of violence. Attention to the 'how' of the practice of violence, a maximum of 'dense description' of constellations of violence, and even an 'ethics of precision' (von Trotha 1997) is demanded for the description and explanation of acts of violence and their results. In referring to Clifford Geertz, recourse is taken to anthropological approaches or variants of symbolic interactionism are tested (Geertz 1973).

3. *Emphases and New Fields in Historical Research on Violence*

3.1 *An International Comparison of Violence*

Historical research on violence has so far privileged the national context and has seldom conducted international comparisons. This concentration on the nation state suggested itself, since the state monopoly on violence stood in the center of research on violence. But there are still some comparative works, based partly on national research or inspired by the latter's questions. Among these is the long-term comparison of the period from the thirteenth to the nineteenth centuries, in which P. Spierenberg describes behavior toward victims, the weak, and animals to demonstrate a general increase of empathy in Europe (Spierenburg 1991). Charles Tilly formulated a typology of collective violence in Europe, in which he names the parochial conflicts—the feuds between geographical communities (Tilly 1975). He uses the term 'reactive violence' to designate resistance against state interference in the citizens' way of life. According to Tilly, proactive violence is exercised within those organizations that acquire, and seek to defend, their political power.

All these investigations face the problem of having to work with unequal and incomplete national data. Since forms of protest and criminality take different cultural shapes in different societies, views of reality are often grasped as reality itself. In comparative research on revolution, violence has often not been accorded central importance. The only exception is Arno Mayer's study that contrasts the violence of the French and the Russian Revolutions (Mayer 2000). Finally, research on totalitarianism has pinpointed state terror as a central instrument of totalitarian systems. Dietrich Beyrau has presented a critical, detailed analysis contrasting and comparing violent state measures (Beyrau 2000). It elaborates the similarities as well as the differences between the violence of the National Socialist and that of the Stalinist systems of rule. Comparative studies permit discussion of the charged question of modern research on violence: whether private and public violence dwindles in or is compatible with the functioning of modern society.

3.2 *Collective Violence as Social Protest*

Research on protest is one of the most flourishing branches of research on violence. The extent and significance of acts of violence are examined in it. It has taken on new contours since the 1950s, under the influence of English, often Marxist-inspired social history and of the 1960s American research on urban riots. Insight into the inherent logic of popular action has supplanted the condemnation of rage-blinded, aggressive mob and crowd activity. Their violent nature has been interpreted less as a defining characteristic than as an aspect of social protests and less as irrational than as a rational strategy. Georges Rudé and Edward P. Thompson in particular have carried out this revision (Rudé 1964, Thompson 1971). Thompson has also drawn attention to the 'moral economy'. With this term, he designates the model of violence as a fitting behavior by peasants, artisans, and workers in response to the markets in times of economic crisis or famine. Acts of popular violence in Great Britain during the transition from the eighteenth to the nineteenth centuries are set in relation to this model and contrasted as a traditional alternative to the developing market society. Thompson's continuing hypotheses that these protests were directed against the gentry have meanwhile been revised. Nevertheless, building on Thompson, attention has shifted to the significance of violent protests in a strategy based primarily on negotiating and compromising with the authorities. In this context, John Bohstedt speaks of a 'protocol of riot' that the protesters strictly adhered to, in order to initiate negotiations, rather than destructive activities (Bohstedt 1988). When violence was nonetheless employed, its form was often borrowed from traditional rituals or it was applied symbolically against objects. Between 1770 and 1850 in Great Britain, France, and Germany, the majority of protests against famine, tax revolts, and resistance against conscription were usually conducted nonviolently. Following the American urban unrest, Graham and Gurr later questioned this hypothesis of violence's positive significance for negotiating processes (Graham and Gurr 1969). They underscored that violence is, as a rule, unproductive, while in Charles Tilly's interpretation of violent means as part of power struggles, they can indeed be successfully employed (Tilly 1975).

Since the mid-1980s, this still influential view of protest has been accused of attributing too much rationality to it and of denuding it of its emotionality. Alain Corbin in particular has pointed out the degree to which fears, hopes, and rumors have been responsible for acts of violence (Corbin 1990). George Lefebvre already traced plundering and acts of violence against the landed nobility in France in 1789 to the effects of alarming news and fears in the rural population (Lefebvre 1970). For his part, Corbin describes how, on a market day in August 1870, a crowd of 300–800 people tormented a young noble and then burned him alive. He had been accused of being a Prussian and of calling out 'Vive la République.' These acts, like the Grande Peur in the French Revolution, can be traced to the spread of rumors, but that does not explain their cruelty. For historical research on protest, this finding suggests that violent activity should be understood as part of a history of the emotions.

The investigation of the history of violence has not been limited to the extent and significance of acts of violence, but has also asked about its instigators and causes. The mass psychologist Gustav Le Bon has attributed mass violence primarily to women (Le Bon 1908). Historical research on protest has shown that women have taken part in acts of violence. But women remained in the minority and were more intensely active when the well-being of the family was at stake than, for example, in conflicts with the military. Beyond that, the social profile of people arrested for manifestations of violence has been worked out. They usually do not come from the 'Lumpenproletariat,' but are rural and urban wage-earners, sometimes from tradesmen milieus. The people, more than the mob, carried out these actions. Bohstedt, in particular, has pointed to disturbed societal relations as one of the causes of violence in Britain, especially where social contact and dependencies between the upper classes and the masses were attenuated (Bohstedt 1988). But this hypothesis cannot be confirmed for other protests. Whether acts of violence always followed social disintegration, and whether rituals of violence do not in turn presuppose relatively unified communities is a question for additional research. In the past, historical research on protest has concerned itself most with the phase in which civic society was formed, but now it is also examining the period between the world wars of the twentieth century and is including the problem of political violence to a greater degree. Its approaches and methods must now prove themselves in this field.

3.3 Historical Research on Violence as Crime

Violent crime in its long-term historical development, societal distribution, and meaning has been investigated primarily in terms of Europe in the Middle Ages and early Modern Age, and in terms of the twentieth-century USA. Modern historical studies of crime that also address nineteenth- and twentieth-century Europe are rare. Quantitative international comparative studies of violent crime often exhibit methodological deficiencies, because the data base in the individual countries and through time is uneven, and above all because the prevalence of recorded acts of violence determined also depends on the strength and severity of prosecuting authorities. Additionally, Eastern and Central Europe have been almost completely omitted from almost all long-term studies, due to the lack of research there or to language barriers. Nevertheless, trend analyses from a bird's-eye perspective can provide hypotheses that can then be worked out in detail or modified by historical microresearch. Spierenberg hypothesized a drop in the rate of homicide in Europe before 1850 (Spierenberg 1991); in contrast, studies of Western Europe and the USA from 1800 to the beginning of the twentieth century by Gurr and Lane find a rising rate of crime and homicide (Gurr et al. 1977, Lane 1997). These rates allegedly fell in the century from 1840 to 1940, only to rise again in the middle or end of the 1950s, but individual studies of crime in discrete nation states or cities do not confirm this chronology. American research has confirmed the hypothesis that the USA was, and remains, the most violent nation among the Western democracies. But it is still debated whether this can be traced primarily to 'frontier violence' (Hollon 1974) and its consequences.

Modern research on crime focuses on the relationship between delinquents, the penal system, and prosecution. Social history concerns itself with the social origin and situation of criminals; legal history and sociology investigate penal 'labeling,' which criminalizes specific behaviors; and institutional and political history is devoted to the construction of prosecuting bodies. Nicole Castan and Gerd Schwerhoff, among others, have conducted historical studies of cities or regions, examining premodern societies' approach to violent delinquency (Castan 1980, Schwerhoff 1991). The following general finding resulted. Until the early modern age, even homicide was an infraction that was not punished automatically by death, but it could be atoned for and expiated through rituals and payments of money. In sixteenth-century Germany, laws called for more severe punishments, but court practice was orientated more toward requiring expiatory measures benefiting the surviving relatives than toward retaliation. This assessment of violence was not surprising in a time that still accepted it as a definite part of societal practices and rituals in the premodern period. Among youth, villagers, and journeymen and masters in trades, not only were conflicts resolved by violence; initiation rites were also organized around violence.

The criminalization and limitation of violence is a process that began in the early modern age, but did not fully prevail until the full-blown modern age. For

France, and based on the discourse of elites, Muchembled reports on rapid advance of the process of civilization, locating the criminalization of homicide in the eighteenth century (Muchembled 1988). But even for the eighteenth century, doubts have been raised whether the draconian penalties prescribed can be regarded as an indicator that more severe norms prevailed, or if these penalties were intended to compensate for the weakness of prosecuting authorities. For it has been pointed out that, precisely in premodern times, legal jurisdiction and police control had not thoroughly penetrated into rural communities in a number of European societies. For the nineteenth century, Peter Gay has advocated the hypothesis that, despite the criminalization of violence, it was indeed tolerated in specific societal areas, to the degree that it remained limited to and ritualized in them (Gay 1993). He adduces the examples of the duel and students' fencing to gain scars, corporal punishment in schools and the army, and violence within marriage. The question of when which practices were prosecuted judicially and considered illegitimate violence has not yet been investigated adequately in international comparison.

3.4 Recent Approaches of Historical Research on Violence

Historical research on violence has taken on new dimensions in the newer style of the history of war and the military. The latter is concerned with military perpetrators of violence that exceeds normal military action: participation in mass executions, acts of annihilation, torture, or rape. Browning and Bartov have been exemplary in pursuing this approach in studying National Socialist police troops and the *Wehrmacht* on the Eastern front respectively (Browning 1992, Bartov 1985). Concentrating on military perpetrators opens up the analysis of wars that accompany decolonization, the Vietnam War, and warlike conflicts accompanying the collapse of the bipolar world order. Beyond the discovery of formerly unknown or repressed atrocities committed by soldiers and officers, attention has focused on analyzing the causes of such inhumane behavior. Current discussion addresses the question of whether specific images of community and/or group cohesion motivate the perpetrators.

Beyond soldiers' and officers' motivation, interaction, and acts, research is also concerned with how they deal with experiences with violence. To the degree that interest in the history of memory and experience increased, the effects of violence on postwar societies has also been researched. World War I has been more thoroughly considered than World War II. Even today, it is becoming clear that societal discourse on wars and on the legitimacy of the violence exercised in them has as large a role as direct experience of violence in dealing with the past. It turns out that there is a need to correct the one-dimensional assumptions that experiences on the front are transformed directly into a brutalization of postwar behavior.

Since violence is defined as physical injury, its analysis is also part of the history of the body. The experience of pain is not historically constant and unchanging, but is influenced by respectively specific bodily experiences and views of the body. The conditioning of the human body by the military, prisons, and insane asylums, whose importance has been underscored above all by Foucault, as well as the feelings felt and expressed thereby, are relevant as parts of the history of violence (Foucault 1975). Just as the awareness of the body, its integrity, and its injuries are interpreted culturally, the views and assessments of violent intrusions into the body—such as bodily injury, homicide, rape, or torture—depend on the respective common cultural patterns. In the future, these must be examined not only in terms of their shaping in specific epochs and by gender, but also in terms of their disparate shaping in different cultures.

All this already indicates the degree to which research on violence has profited in the late twentieth century from interest in questions of cultural history. In this context, simple attributions have become problematical. The taboo against violence is no longer seen as the dominant characteristic of the modern age, whose ambivalence Baumann has underscored (Baumann 1991). The media's conveying and staging, which depicts and overemphasizes acts of violence, have contributed to this ambivalence of the modern age. These connections are often mentioned in current diagnoses, but there is a lack of comparative historical research devoted to the respective cultures of violence in various milieus and at various times. For most epochs, not even the discursive boundaries between violence and nonviolence are well enough known. Special attention should be paid to the degree to which state authorities and the upper strata of societies have intervened in the justification of forms of violence and in its condemnation. For the respective concepts of violence all have a mediating link between the state monopoly on violence and everyday experience.

H.-G. Haupt

Violence in Anthropology

Across the Cold War and the collapse of great-power socialism, anthropological studies of violence have focused on international patterns of revolution, counterinsurgency warfare, state terrorism, militant ethnic nationalism, communal violence, and organized crime (Wolf 1969, Das et al. 2000). The field has also reconsidered the violence of Western colonialism, the epistemic violence of states that marginalize devalued groups, and the structural violence inherent in systems of inequality that consign great numbers of people to unstable incomes and life-threatening poverty, hunger, and preventable disease (Schepper-Hughes 1992, Bourgois 1995).

This array of issues contrasts with social anthropology's earlier functionalist focus on the internal regulation of social tensions, leadership transitions, and intergroup hostilities in lineage-based societies, imagined as isolates. The turn to examining the interplay of local communities and state politics, and the political consequences of globalization has revitalized the subfield of political anthropology.

Although the discipline has appropriated issues from political science and comparative sociology

throughout this scholarly transformation, it has also critiqued central assumptions in these fields and reasserted the importance of cultural issues in the study of violence. As a result, anthropology is contributing to a rethinking of the state in the context of globalization, and reconsidering the interface between state and civilian populations. Most importantly, it has taken on the cross-cutting question of how communities in different political situations cope with their own patterns of internalized violence.

The scope of the anthropological project has grown as researchers questioned the conventional social science emphasis on violence as the state's monopoly over the use of legitimate force by the armed forces, police, and judicial systems (Giddens 1987). By contrast, cultural anthropology has chosen not to privilege uniquely formal institutions or physical harm in its studies, but rather additionally to examine the social fragmentation and suffering created by organized, but often informally instituted, structures of violence generated in situations of civil war, state terrorism, fragmented states, and globalized economies.

In Latin America, Asia, and Europe, a central issue has been the ways in which local communities both resist and become complicit with state violence. In regions of weak states where alternative power structures have assumed state functions, as in the case of the former USSR and sub-Saharan Africa, a major issue is tracing the growing significance of illicit trading networks and mafias.

Anthropology has embraced notions of culture that include the diverse discursive practices that states have used to legitimize the use of violent force by portraying others as inherently violent or not fully human, and thus deserving of preemptive control rather than full citizenship. The discipline has examined alternative forms of resistance to state violence, the politicization of ethnicity, and the impact of counterinsurgency states on civil populations. It has also begun to analyze popular representations of violence in the media.

1. *Violence and Resistance*

Rather than ignoring those without power and status, one well-established anthropological approach examines patterns of cultural resistance to domination and oppression. As has become clear in this literature, resistance in oppressive circumstances takes many highly coded forms. Resistance perspectives examine the way groups configure ideologies and political actions to reject the terms established for subordinates by state authorities and regional power brokers, even in extreme circumstances when they are political prisoners (Aretxaga 1997). A tactical dual consciousness allows submissive subordinates to feign submission yet hold subversive beliefs in their behind-the-scenes 'hidden transcripts' (Scott 1990).

This approach is especially concerned with cultural forms through which local populations keep their veiled social critiques alive: such as oral histories of martyrdom, ritual parodies of power structures, and political art. These cultural forms assert alternative moralities, unveil abuses of power, and describe forms of militancy, great and small. Such codes of resistance cannot be read from afar, that is without knowledge of particular cultural circumstances and access to how people rework cultural forms to deal with the particular existential dilemmas they face.

2. *Violence and Leadership: A Critique of Rational Choice Reductionism*

Another line of analysis, influenced by political science, pursues the motivation of rivals for state power, particularly those who defy political systems and seek to undermine the integrity of the state by organizing separatist rebellions. Researchers have sought to understand political violence in these circumstances by using rational choice theory, and studying the competition of groups for resources and the self-interests of political leaders. Analysts now routinely question political leaders' self-declarations, and unmask opportunists willing to politicize ethnicity and inflame populations to their personal advantage. Leaders exhibit a willingness, sometimes a frightening eagerness, to promote the radical fracturing of society into antagonistic groups with the goal of unifying their own group through strategic antagonisms.

Anthropology suggests that violence and conflict should not be seen as exceptional moments of crisis and rebellion, or simply as the consequences of competitions over resources, but as integral parts of a social fabric already fragmented in innumerable ways. Ethnographic research shows how important it is to comprehend people's understandings of the contradictory tensions, and the heterogeneous personal and collective interests in their lives. Struggles over memory and history, the importance of culturally specific narratives for the expression of grievances, and the local constructions of 'choice,' 'competition,' and 'opportunism,' are all doorways to a fuller cultural analysis. At issue in moments of crisis are the intensification and redirection by leaders of what is already there—the systems of meaning that actively generate cultural understandings.

The mix of opportunism and resistance approaches chosen for interpreting a particular violent conflict depends on a range of factors, including the historically and politically conditioned gaze of researchers working in regional studies traditions. With its long colonial history, decades of military rule from the 1950s to the 1980s, anti-imperialist guerrilla movements that sought to topple elite-driven states, revolutionary socialist experiments, and current strug-

gle to institutionalize democracy, Latin America has drawn the attention of a variety of analysts.

In these contexts, ethnic identities have been shaped by racially inflected modes of stratification, deep cultural resistance, and political mobilization that has had complex relations and tensions with capitalist and socialist ideologies (Hale 1994). In the case of the Zapatista uprising in Mexico—which protested entrenched regional violence and the subsistence shocks of the 1994 neoliberal trade agreements between the USA and Mexico that established the North American Free Trade Agreement (NAFTA)—politicized indigenous identity has been the source of alternative visions of social justice, combining international human rights discourses with the communal politics of Maya communities (Nash 2001). It is hard to find the reductionist explanations of rational choice theory convincing in these complex circumstances.

3. *Death Squads*

Government-mandated counterinsurgency violence that seeks to extinguish political opposition is often an unstable solution to social conflict, yet it has been the common practice of regimes across the political spectrum. Violent states have persisted in labeling wide ranges of their citizens as dangerous and undeserving of full rights. Nationalisms have been crafted by political elites not only to create an imagined community for their country's citizens but additionally to rationalize mass repression much wider in scope than any immediate uprising.

Anthropologists have documented an often hidden and always denied aspect of violent states: death squads operate at the margins, engaging in torture, kidnap, rape, and assassination outside the rule of law. Paramilitary groups specialize in what the police and armed forces officially appear to eschew: the extrajudicial torture and killing of dissenters, the disappearances of local leaders, students, and journalists, and the retaliatory abuse of activists' families, including the rape of women to humiliate their parents and to pollute family lines. The political goal is to silence critics and intimidate the general public through preemptive violence, while maintaining plausible deniability of government involvements in violence against civilians. Some militaries have instituted community-based civil patrols, forced to engage in death squad activities and community surveillance, all in the name of self-defense. There are many variations of this violent mode of control, responding to the particular political and cultural histories of countries as diverse as Northern Ireland, Spain, India, Indonesia, Argentina, and Guatemala (Montejo 1999, Sluka 2000).

It is clear from these studies that the police and army are not bounded institutions set apart from society. Rather, the state, armed forces, paramilitaries, insurgents, and civil society form interpenetrating social fields. Civilians fill the ranks of armed forces on all sides and, often as forced recruits, experience state-centered indoctrination to fight these wars. The general population, whatever its sympathies, frequently finds no feasible exit from the conflict between insurgents and the state (Stoll 1993). Individuals become complicit in state violence by informing on the activities and putative alliances of their neighbors. Whether coerced, offered in exchange for personal gain, or solicited to enhance one's power at the expense of others, these complicities involve betrayals that splinter family and community trust, and create situations of internalized violence that add new tensions to old divisions (Warren 1993, Das et al. 2000). These dynamics create powerful existential dilemmas for people who must endure heightened insecurity over long periods of time. As E. Scary (1985) observed, the deeper cost of violence is not its physical harm but its capacity to 'unmake the world.'

In the face of state terrorism, anticolonial opposition movements pose particular challenges for anthropologists. In instances where cultural minorities or grassroots movements are repressed by overwhelming state power, it has been difficult for anthropologists not to sympathize with those who denounce and resist injustice. For some researchers, the fact of war justifies counterviolence, whatever form it takes. For others, the issue is how repression potentially recreates a sense of common purpose and unites resistance across ethnic, geographic, and class lines.

For still other analysts, resistance to repression involves a painful blurring of motives and allegiances over time, with individuals betraying their established loyalties rather than bridging them, sometimes voluntarily or in other circumstances to put off their own death sentences. Anthropologists have traced the contradictions, ironies, and the mimesis of state violence in anticolonial separatist movements. As Ortner (1995) argues in her critique of resistance approaches, anthropologists are called upon to contextualize and historicize (rather than ignore) the contradictory impulses of such social movements. A return to richer ethnographic portrayals has become necessary to counteract the earlier tendency to idealize opposition movements by focusing on their activities as exemplars of resistance.

Beyond the horror of state violence, there is no neutral subject position from which to narrate these histories. That counternationalisms can generate their own authoritarianism, death squads, and corruption-mirroring state power as they critique it—and that grassroots insurgents may lose rather than gain civilian support over time create special challenges for anthropological writing in politically charged situations. Another compelling issue is the criminalization of former combatants where peace processes have not coped with the extreme social fragmentation that accompanies protracted violence. Former com-

batants, death squad members, civil patrollers, and families displaced by violence need new sources of employment and community involvement if they are not to continue patterns of predatory behavior.

Perhaps the triumphalist discourse of democratic modernity—especially the post Cold War end-of-history variant of this discourse—has inhibited closer examinations of violence in democratic societies. Tambiah (1996) argues that paramilitary violence may be much more intrinsic to democratic states than is usually suspected. In practice, democracy channels intense competition for power through electoral politics which is often accompanied by occult violence. Thus, in India, groups frequently provoke riots at election time for their own political ends. Echoing these patterns, elections in Guatemala and Colombia bring waves of assassinations of candidates for local and national office. Although these riots and cyclic killings are condemned, electoral violence becomes an anticipated event in these political landscapes. The underside of democracy includes spaces of violence that are integral aspects of state politics, even as they are, in effect, public secrets.

4. *Interpenetrating Explanations of Violence*

How does anthropology weight the factors ultimately accountable for contemporary violence? First of all, it is important to consider international influences such as the highly volatile global economy and neoliberal economic policies promulgated by the international development community as part of democratic modernity that creates and tolerates dramatic gaps between prosperous and impoverished citizens. Policies and investment decisions at great distance from their effects continue to bring subsistence shocks that threaten the lives of the poor. The Asian financial crisis of 1997, for example, which began in the realm of international currency speculation, precipitated the collapse of several national currencies and generated riots and continuing ethnic tensions in Indonesia.

Political transnationalism would be another issue. Counterinsurgency and insurgency training, and the sale of arms and surveillance equipment have long been global industries that are increasingly decentralized in practice. The School of the Americas, a US-based training center for Latin American military officers who have been implicated in many human rights abuses in their own countries, has been the conduit for techniques of violent control developed over the longer history of Western colonialism. Strategies first developed in colonial Asia were brought to Latin America in the 1950s, redeployed in Vietnam during the war, and later put back into circulation in Latin America, moving in the last decade from Guatemala to Mexico, where they have been used most recently against the Zapatistas. British colonial models of control developed in Kenya and Malaya have been redeployed in Northern Ireland. The post Cold War repositioning of militaries as partners in national development has left unchallenged the discourses of 'national security,' in which state terrorism can be used to combat whatever is discursively defined as a political threat.

Another crucial element for the explanation of violence is the national institutions and political actors who, for their own reasons and interests, seek to foster authoritarian, militarized solutions to social conflicts. Finally, it is important to include the interplay of local and national formations of violence to trace the intimate interplay of transcommunity organized violence with community conflicts.

To neglect any of these arenas, or to locate the moral or causal explanation of death squads in particular international arenas so that it displaces all other considerations, would appear to be a serious misreading of a complex political field of actors and institutions. Nevertheless, it is clear that the study of patterns of violence shows the direct linkage of very local events with wider power structures and globalized currents of change. Capitalist economics, which has led to the search for ever cheaper sources of labor without wider obligations for workers' social welfare, and the transnational sex trade, which transforms adults and children into commodities, exemplify the social costs of globalization.

5. *Violence and Media Representation*

Current research challenges the usefulness of media accounts of 'ancient ethnic hatreds' to explain conflicts leading to the fragmentation of states. There is a consensus now that Western media and official media elsewhere promote dangerously simplified ethnic readings of conflicts, ones that reinforce primordialist readings of 'the other.' Such presentations in mass media deflect attention from the reality that the West has been directly involved in many 'localized' conflicts through economic and political interventions in the internal affairs of other nations (Allen and Seaton 1999).

In contrast to the overdetermined language of ethnic antagonism, recent research in anthropology demonstrates that many social systems involve the coexistence of diverse groups and hybrid identifications, and that politics in various parts of the world cross-cuts ethnic, religious, and linguistic difference. An important deconstruction of ethnicity as a fixed or essential entity is occurring across these analyses. The classical critique has been to discredit ethnicity in order to uphold class as the prime factor to explain social conflict. A more recent countertrend is to widen the field of identities and identifications under consideration, and to understand class as a creation of particular cultural and historical circumstance, rather than a preestablished or transcultural set of categories.

A fuller cultural analysis, which pursues the multiplicity of identities and the flow of ideas and signs across borders, is central to interpreting conflict and the directions it takes. The issue is not just meanings that mediate reality, but the images that make imagination—in this case violence, fragmentation, and/or coexistence—possible. Instead of assuming that people internalize the ethnic hatred and opportunist politics sold by corrupt leaders and the media—an assumption left unchallenged in US journalism by repeated photographs of armed mobs without any sense of people's reasons for their participation—it is important to understand the playing out of contradictory consciousness in people's daily lives, and the political consequences of these understandings. To make sense of low-intensity peace or nationalist crises, one must historicize and contextualize the forms of violence and its denial.

Culturally informed analyses call for an array of strategies for studying representation, control, resistance, and complicity—the violence within and without. Significantly, these same strategies can be used to explore unexpected alliances and unexpected avenues for negotiation that might successfully challenge violence and its grammar of oppositions.

Violence: Public

Visibly violent social processes simultaneously attract and repel analysts of human behavior. War, rape, genocide, assassination, assault, football, looting, official execution, collective suicide, mutual flagellation, automobile collisions, airline crashes, gang fights, and struggles pitting police against demonstrators all qualify by some definitions as public violence. Most of them regularly attract headlines when they occur—the more extensive, public and grisly their consequences the bigger the headlines. Violence makes the news.

In these circumstances, reporters and readers commonly turn to very simple explanations: some humans are violent in nature, others peaceable, so violent events occur when violent people congregate and enjoy free rein. Unfortunately for that sort of explanation, the boundary between violent and peaceable people actually blurs badly. Even individuals who participate energetically in violent events generally spend most of their time and energy on nonviolent activities. Meanwhile persons who live mostly peaceful lives occasionally get involved in organizing or perpetrating violent activities, for example, by doing military service, serving on juries, or engaging in contact sports. Other people who flee violent interactions in their daily routines nevertheless support one variety of public violence or another in the proper circumstances, for example, by voting for candidates who favor the death penalty, by cheering one group of nationalists in their competition with rivals or by cooperating in what they call a just war. Indeed, most citizens of most states distinguish sharply between coercive acts committed lawfully by duly constituted

agents of their own states (legitimate force) and similar acts committed by other people (illegitimate violence). Nonviolence is a beguiling principle, but one honored more in the breach than in the observance.

In general discussions of the subject, three competing views of violence prevail: as propensity-driven behavior, as instrumental interaction, and as cultural form. Treatments of violence as propensity-driven behavior locate its causes within the actor, calling attention to genetic, emotional, or cognitive peculiarities that incline a given individual, group or category of persons, to damaging behavior more than others. Portrayals of violence as instrumental interaction characterize everything from petty assaults to all-out warfare as means (however inefficient and self-defeating) to power, wealth, prestige, or other ends. To call violence a cultural form—as in the claim that because of the frontier, slavery, or capitalist competition the USA has an exceptionally violent culture—argues that the ready availability of certain ideas, practices, models, and beliefs itself promotes violent action.

The three views suggest very different approaches to inhibiting or promoting violence. Propensity-driven violence calls for the alteration or inhibition of motives, instrumental violence for shifts of incentives and outcomes, cultural violence for teaching new ideas, practices, models, and beliefs. Alas, none of these three broad approaches to violence has yet yielded systematic explanations of the genesis, trajectory, outcome, or sheer variety of public violence as a whole. Perhaps we await the social scientific Isaac Newton who will detect underlying regularities in all the diverse phenomena people call violent. More likely the notion of violence resembles such other widespread but diffuse terms as disorder and goodness: morally powerful categories that do not refer to any causally coherent domain.

In any case, the word 'violence' almost always arrives with baggage of disapproval. The distinction of violent from nonviolent social interactions usually depends on a moral boundary, or at least activates one. Precisely because of that moral charge, advocates of one cause or another frequently extend the term 'violence' to varieties of harm far outside the range of direct, short-term infliction of physical damage on one person by another. They label hate speech, pornography, poverty, unemployment, malnutrition, and other ills as forms of violence. To call a phenomenon virtual violence is to condemn it, to claim that it damages something valuable even if it produces no physical destruction in the short run. As a consequence, every social scientific attempt to delimit, describe, classify and explain public violence generates controversy. This attempt will be no exception.

We can nevertheless discipline the inquiry by adopting a restrictive definition of the phenomenon under analysis. Public violence, for present purposes, refers to episodic social interaction that:

Figure 1
Crude typology of public violence

immediately inflicts physical damage on persons and/or objects

results at least in part from coordination among persons who perform the damaging acts

occurs at least partly in publicly accessible spaces.

(The ensuing discussion will, however, extend 'physical damage' to forcible seizure of persons or objects over restraint or resistance.) At one edge, such a definition excludes strictly individual, private, impulsive, and/or accidental damage to persons or objects. At the other, it excludes long-term, incremental damage such as communication of infectious disease, cumulative wear and tear, exposure to toxic substances, and death hastened by neglect or social pressure. Nevertheless, it includes an immense range of social interactions, from minor scuffles among rival groups of voters to wholesale civil war. Despite a century or more of effort, social scientists have not so far assembled any reliable, important and systematic body of knowledge that applies to the whole range thus defined.

We therefore have no choice but to differentiate, reviewing analyses of narrower phenomena that bear some family resemblance to each other, probably share some causal processes, and have attracted sustained scholarly attention. Assuming episodic interaction in publicly accessible space, at least a little communication among actors, and some minimum of physical damage to persons or objects, Fig. 1 combines the extent of coordination among damage-doers and the salience of damage in the overall pattern of interaction to produce a crude typology of public violence. ('Low' coordination means individualized action with little collective planning and signaling, while 'High' coordination means activation of differentiated and bounded organizational structure with extensive planning and signaling. 'Low' salience of violence means that most of the social interaction involved produces no short-term physical damage,

while 'High' salience means interaction strongly concentrated on damage.)

Other distinctions come immediately to mind. Separation of symmetrical from asymmetrical interaction, for example, usefully distinguishes relatively even contests from situations in which a gang or an oppressor visits violence on a victim having no means of retaliation. Whether agents of a constituted government participate in public violence, as we shall see, significantly affects its character; thus we might also classify public violence by the presence or absence of governmental agents. Again, public violence probably incorporates scale effects, so that damaging interaction involving just two or three people differs qualitatively from otherwise similar interaction involving thousands of people at a time. The present classification gives priority to coordination and salience on the hunch that those two dimensions capture a significant part of the systematic variation about which social scientists have produced useful ideas and findings.

Within the coordination–salience space we can conveniently distinguish five locations:

(a) organizational outcomes: various forms of collective action generate resistance or rivalry to which one or more parties respond by actions that damage persons and/or objects; examples include demonstrations, protection rackets, governmental repression, and military coups, all of which frequently occur with no more than threats of violence, but sometimes produce physical damage;

(b) coordinated destruction: persons or organizations specialized in the deployment of coercive means undertake a program of damage to persons and/or objects; examples include war, genocide, collective self-immolation, and some kinds of terrorism;

(c) opportunism: as a consequence of shielding from routine surveillance and repression, individuals or clusters of individuals use immediately damaging means to pursue generally forbidden ends; examples include looting, gang rape, revenge killing, and some sorts of military pillage;

(d) fragmented resistance: in the course of widespread small-scale and generally nonviolent interaction, a number of participants respond to obstacles, challenges, or restraints by means of damaging acts; examples include sabotage, clandestine attacks on symbolic objects or places, assaults of governmental agents, and the more immediately damaging forms of what James Scott (1985) calls 'weapons of the weak';

(e) violent games: two or more relatively well-defined and coordinated groups follow a known interaction script entailing the infliction of damage on others as they compete for priority within a recognized arena; examples include gang rivalries, contact sports, some election battles, and some struggles among supporters of teams or stars.

Of course these crude types overlap, for example in the activities of the South Asian thugs who sometimes act as enforcers for landlords in disputes with squatters (organizational outcomes) but at other times follow their patrons in large-scale raids on their caste, religious, or political enemies (coordinated destruction). Similarly, the various actions known as terrorism show up in all four corners of Fig. 1—as clandestine resistance, as a by-product of peaceful claim-making in highly repressive regimes, as part of genocide, and as opportunistic elimination of old enemies. It is nevertheless useful to retain the five-part division, because within each area thus delineated social scientists have accumulated at least a modicum of systematic knowledge. Let us therefore review them one by one. The following discussion gives extensive attention to organizational outcomes and coordinated destruction, then uses analogies and comparisons with the first two as it treats opportunism, fragmented resistance, and violent games much more summarily.

Organizational outcomes. A significant share of public violence occurs in the course of organized social processes that are not in themselves intrinsically violent. That is notably the case in collective political struggle. Political regimes differ dramatically in the scope they allow for nonviolent collective making of claims, for example by petitioning, shaming, marching, voting, boycotting, striking, forming special-interest associations and issuing public messages. On the whole, democratic regimes tolerate such claim-making more readily than do their undemocratic neighbors; that is one way we recognize a regime as democratic. Even in democratic regimes, nevertheless, such forms of collective claim-making occasionally generate open violence. That occurs for three main reasons.

First, every regime empowers agents—police, troops, headmen, posses, sheriffs, and others—to monitor, contain and, on occasion, repress collective claim-making. Those agents always have some means of collective coercion at their disposal, and always enjoy some discretion in the use of those means. In one common sequence, claimants challenge repressive agents, occupy forbidden premises, attack symbolically significant objects, or seize property, then agents reply with force. Because variants on that sequence frequently occur, when repressive agents are at hand they actually perform the great bulk of the killing and wounding that occurs in public violence.

Second, collective claim-making often concerns issues that sharply divide claimants from regimes, from powerful groups allied with regimes, or from rival groups; examples are campaigns to stop current wars, outlaw abortion or expel immigrants. In these circumstances, offended parties often respond with counterclaims backed by force, whether governmental or nongovernmental.

Third, in relatively democratic regimes an important share of collective action centers not on specific programs but on identity claims: the public assertion that a group or a constituency it represents is worthy, united, numerous, and committed (WUNC). Asser-

tions of WUNC include marches, demonstrations, mass meetings, occupations of plants or public buildings, vigils, and hunger strikes. Even when the means they adopt are currently legal, all such assertions entail implicit threats to direct WUNC energy toward disruptive action, implicit claims to recognition as valid political actors, and implicit devaluation of other political actors within the same issue area. These features sometimes stimulate counter-action by rivals, objects of claims, or authorities, with public violence the outcome.

Organizational outcomes also include some encounters that do not begin with concerted making of claims. Border guards, tax collectors, military recruiters, census-takers, and other governmental agents, for example, sometimes generate intense resistance on the part of whole communities as they attempt to impose an unpopular measure. Similarly, audiences at theatrical performances, public ceremonies, or executions occasionally respond collectively to actions of the central figures by attacking those figures, unpopular persons who happen to be present or symbolically charged objects. By and large, organizational outcomes connect with issues over which groups are also currently contending in nonviolent ways.

One subclass of organizational outcome, however, displays a rather different pattern. Some organizations specialize in controlling coercive means, threatening to use those means if necessary, but seeking compliance without violence if possible. Examples include not only established agents of repression but also *mafiosi*, racketeers, extortionists, paramilitary forces, and perpetrators of military coups. When such specialists in coercive means encounter or anticipate resistance, they commonly mount ostentatious but selective displays of violence. Their strategy resembles that of many Old Regime European rulers, who lacked the capacity for continuous surveillance and control of their subject populations, but often responded to popular rebellion with exemplary punishment—rounding up a few supposed ringleaders, subjecting them to hideous public executions and thus warning other potential rebels of what might befall them. The strategy is most successful, ironically, when specialists in coercion never actually have to deploy their violent means.

Coordinated destruction differs in precisely that regard. It refers to those cases where persons or organizations specialized in the deployment of coercive means undertake a program of actions that damage persons and/or objects. Coordinated destruc tion overlaps with organizational outcomes because specialists in coercion participate in both and because threats of force sometimes escalate into struggles between coercive organizations. Here, however, the organizations' strategies center, however temporarily, on the production of damage. Examples include war, genocide, collective self-destruction, public penance, and government-backed terror. The major distinctions separate (a) lethal contests, (b) campaigns of annihilation, and (c) ritual harm.

In lethal contests, at least two organized groups of specialists in coercion confront each other, each one using harm to reduce or contain the others' capacity to inflict harm. War is the most general label for this class of coordinated destruction, but different variants go by the names of civil war, guerrilla, low-intensity conflict, and conquest. Although lethal contests of various sorts stretch back as far as humanity's historical record runs, the standard image of two or more disciplined national armies engaged in destroying each other within generally accepted rules of combat only applies to a very small historical segment: roughly 1650 to 1950 for Europe, a few much earlier periods for China, even rarer intervals elsewhere in the world. Outside of those exceptional moments, autonomous raiding parties, temporary feudal levies, mercenary assemblages, bandits, pirates, nomads doubling as cavalry, mobilized villages, and similar conglomerate or part-time forces have fought most historical wars.

Lethal contests shade over into campaigns of annihilation when one contestant wields overwhelming force or the object of attack is not an organization specialized in the deployment of coercive means. Analysts have employed the term genocide for those campaigns in which attackers define their victims in terms of shared heritage and politicide for those in which victims belong to a common political category; so far no commonly accepted term has emerged for similar campaigns aimed at members of religious or regional categories. The usual stakes in campaigns of annihilation are collective survival, on one side, and recognition as the sole party with the right to territorial control, on the other. Because of those stakes, such struggles tend to generate vast mobilizations of support extending far beyond the specialists in coercion who initiate them.

Ritual harm plays a much smaller part in contemporary public violence than do lethal contests and campaigns of annihilation. At times, however, they have assumed considerable importance, for example in the potlatch (aggressive, competitive destruction of the performer's own symbolically charged property) that once marked struggles for precedence along America's northwest coast. Other well known instances include the processions of flagellants once organized regularly by Renaissance Italy's penitent confraternities. Today self-immolation, collective suicide, and hunger strikes occasionally occur as gestures of protest, serving chiefly to dramatize the positions of groups that lack other political resources.

Within the broad category of coordinated destruction, a remarkable change occurred during the half century following World War II. Where interstate wars among well-identified national armies had predominated for a century or more, shifts toward a much wider variety of coercive forces and toward campaigns of annihilation elevated civil war, broadly defined, to

the chief setting of coordinated destruction. Decolonization, expansion of world trade in arms and drugs, reappearance of mercenary forces, and the weakening of central state capacity in many world regions all contributed to that change.

Opportunism combines low levels of coordination with high salience of violence within the total interaction. Opportunism benefits from some of the same processes that have favored recent moves away from interstate war toward violent struggle within state boundaries. Looting, gang rape, revenge killing, and some sorts of military pillage all occur more frequently in interstices, peripheries, and lapses of central state control. In fact, opportunistic public violence often occurs as an outgrowth of coordinated destruction. Disbanded but still armed troops, for example, frequently use their arms to prey upon civilians. The destruction wrought by mercenaries during truces, marches, and aftermaths of wars made them the bane of European civilian life during the sixteenth and seventeenth century heyday of mercenary armies. Similarly, when major protests or disasters divert the attention of repressive forces, looters and killers often take advantage of relaxed control to pursue their own ends.

Fragmented resistance involves segmented or weakly coordinated damage to persons or objects in the course of interactions that are not predominantly violent. When governmental agents, landlords, employers, religious authorities, or other powerful people impose innovations, exactions or constraints on subject populations, members of those populations often resist indirectly and on the small scale. They engage in sabotage, ambushes, and clandestine attacks on symbolic objects or places, and temporary acts of resistance that either inflict damage on authorities or incite violent reprisals from authorities. Fragmented resistance differs from organizational outcomes chiefly in the balance of forces among parties and the scale of organization among the weaker parties. Otherwise, the same regularities that apply to organizational outcomes apply to fragmented resistance.

In its most stylized forms, such as the medieval tournament, coordinated destruction comes to resemble violent games. Likewise, such violent games as ritual fights between youths of neighboring villages edge over into coordinated destruction. Still, we can usefully distinguish a class of public violence in which two or more relatively well defined and coordinated groups follow a known interaction script entailing infliction of damage on others as they compete for priority within a recognized arena. Age grades of local youths, organized gangs, sports teams, supporters of powerful or popular figures, electoral factions and fraternal orders inducting new members all sometimes engage in violent games. Frequently the outcome of the contest produces confirmation or alteration of a rank order that in turn entitles winners and their followers to prestige or privilege. In that sense, violent games stand somewhere between (a) WUNC performances (whether violent or not) and (b) the public displays of wealth, power and patronage by which warlords, crime bosses, political magnates, heads of influential families, *caciques*, and entertainment stars maintain their credibility.

In all its forms, public violence interacts closely with nonviolent politics. Violence as organizational outcome or coordinated destruction clearly entails struggles for power and takes shape from the character of power struggles spanning violent and nonviolent action. Violence as opportunism and fragmented resistance often occurs as a by-product of grand political processes: state formation, revolution, war, military conscription, taxation, patron–client realignment. Violent games follow their own rules, but frequently intersect with or mutate into other forms of public violence. At first glance, violence may seem the antithesis of orderly public politics. At second glance, most public violence connects closely with politics in general.

Virtual Reality and Spatial Cognition

In its broadest sense the term virtual reality is currently being used to describe everything from three-dimensional photorealistic rendering through non-graphical simulation to artificial intelligence. In its narrower sense virtual reality is a technology that makes use of computer-generated interactive graphics which give the user the sensation of being in a virtual, that is, computer-generated world. Special hardware devices such as projection screens or head-mounted displays (HMDs) aid the perception of the synthetic world. Another important feature is the possibility to interact with this world through various devices, for example haptic devices to experience force feedback by the virtual world, bicycles to move through the world, or pointing devices.

In this article, we give an overview of applications of virtual reality in behavioral experiments on human cognition. We focus on spatial cognition, i.e., navigation and spatial memory.

1. Applications

The very first application of virtual reality was the training of air force pilots in flight simulators. The first computer-graphics based flight simulator was built in the 1970s. By the 1980s, with better software and hardware, the market for virtual reality technology had grown far beyond military use. As we enter the twenty-first century, virtual reality is a standard method for manipulating the action–perception cycle underlying normal behavior in all autonomous agents (see *Autonomous Agents*).

Contemporary virtual reality systems are widely used. Examples include:

1.1 Visualization

Visualization is of high importance for interpreting data for many technical or scientific applications. An excellent overview is given in vanDam et al. (2000). Examples come from the fields of art, medicine, architecture, and archaeology. For example, members of the Computer Science Department at Brown University have been collaborating with archaeologists to develop the Archave system which makes it possible to visualize the results of excavations. On the basis of this visualization, further analysis of the data is possible. Another example comes from the field of car design. In virtual realities car-designers and engineers are not only capable of presenting future models but can also examine functional aspects. For example in a packaging simulation, one can study the assembly of an engine or the possibility to dismantle single pieces of the engine for repair. Furthermore, crash tests can be observed from unusual perspectives: One can place a virtual camera right in the middle of the engine during a crash test.

1.2 Training and Education

There are many applications of virtual reality to training and education, especially in the field of medicine. For example, many practising surgeons completed their training before the so-called laparoscopic era of the 1990s. Laparoscopic or minimal invasive surgery has dramatically changed the way surgery is performed, which makes it necessary to teach even very experienced physicians. For this reason, there are many training simulations in the field of endoscopic surgery, for example of the knee (Muller et al. 2000). In this simulation students can act on virtual reality tendons and bones with realistic instruments.

A further application is the various driving simulators—for example, for aeroplanes, helicopters, motorcycles, trucks, and even wheelchairs. In the case of aeroplanes and helicopters, the purpose of training in a flight simulator is not to substitute for the training in the real world completely but to familiarize students, for example, with the handling of the cockpit, instrument displays, navigational tasks, or modifications of existing instruments.

1.3 Behavioral Experiments

Computer graphics has been used for many years in the generation of experimental stimuli to examine the visual system. With virtual reality, the sensory system and related behavior can be investigated, that is, it is possible to examine a whole action–perception cycle. If one focuses on perception alone, it is always hard to decide which feature of the measured sensor performance is responsible for a certain behavior. The following are easily measurable behaviors in virtual worlds: reaction-time measures, pointing direction, grasping behavior, eye movements, or navigation ability. For the experimenter, the advantage of the virtual world compared to the real world lies in the possibility of controlling the environment very strongly, in the flexibility and ease with which different environments can be constructed, and in the ease with which experimental data can be saved and visualized.

2. Spatial Cognition: Experiments in Virtual Reality

Many fruitful experiments in the field of spatial cognition have been performed with virtual reality. A comprehensive overview of the advantages and disadvantages of performing navigation experiments in a virtual world is given in Péruch et al. (1998). On the one hand, it is possible to build up totally new environments, which are unknown to subjects. Thus unbiased measurements of navigational ability are obtained. Mallot et al. (1998) describes a maze—like city called 'Hexatown,' where each junction is a connection of three streets, resulting in a hexagonal structure (Fig. 1). The regularity of the ground plane has the advantage that the structure of the city does not give the subject any cues in a navigational task. During the experiments the subjects sit in front of a computer screen and move through the town by pressing the buttons of a computer mouse. The results suggest that the subjects acquire a cognitive map during exploration even in the absence of physical motion. On the other hand, it is possible to reconstruct existing cities or buildings to investigate in virtual reality the spatial memory acquired in real environments or vice versa (Fig. 2).

Witmer et al. (1996) investigated the transfer of knowledge based on training in a virtual world to knowledge acquired in the real world. They concluded from their experiments that the resulting configuration knowledge is very similar.

As mentioned previously, one advantage of experiments in a virtual world is the high flexibility and controllability they provide. In older navigational studies the experimenters prepared videofilms or slide presentations in order to control the environment that the subjects had to explore. In other studies model towns were built using toy houses and the perspectives from within the town were caught in a camera drive. This latter method resembles the fashion in which virtual worlds are built up today. With software very similar to the computer-aided design (CAD) programs used by architects, the surroundings can be modeled. The interaction with a user resembles a camera drive moving through the model. Using this

Figure 1
Bird's eye view of the synthetic city called 'Hexatown' used in Mallot et al. (1998)

Figure 2
Single view of the virtual reconstruction of the historic centre of Tübingen used in Mallot et al. (1998), courtesy of H H Bülthoff

type of software it is much easier to make subtle changes. For example, it is possible to move objects during the experiments (Aginsky et al. 1997), to change the lighting conditions (Mallot et al. 1998), or to change the topography of the environment, for instance the slant (Mallot et al. 2000).

One set of navigational experiments has focused on the question of the comparability of the results obtained in the virtual world to results obtained in the real world. Ruddle and colleagues (1997) replicated a distance-estimation and pointing task in a virtual world that was originally carried out by Thorndyke and Hayes-Roth (1982) in the real world. The results turned out to be very similar. However, Péruch et al. (1997) found in a path-integration task that subjects in a virtual world made a different systematic error compared to subjects in the real world (Loomis et al. 1993). The latter tend to compress the range of actually produced turns and distances in such a way that large values are underestimated and small values are overestimated. Subjects in the virtual world underestimated all values. One has to keep in mind that the sensory input in the virtual world is different from the input in the real world. For instance, in the Loomis et al. (1993) study the subjects were blindfolded during the experiments, that is, perception was based on vestibular and proprioceptive input alone. On the other hand, in the Péruch et al. (1997) study the behavior was based only on visual input.

Recently, there have been efforts to combine the visual input in the navigation experiments with adequate proprioceptive and vestibular stimuli. Most of the studies carried out so far have taken place in 'desktop virtual reality,' where subjects sit in front of a computer screen or a projection wall and press the buttons of a computer mouse or move a joy stick. By doing this, they navigate through the virtual world. In a study of Chance et al. (1998) subjects performed a triangle-completion task in which they walked two sides of a triangle and were then requested to return to the starting point, completing the third side. During walking, the visual input was presented on a head-mounted display. The performance was better than in 'just turn' group. The latter could only physically turn and carried out translatory movements in the virtual world.

A very interesting paradigm is the combination of virtual reality with functional imaging studies (PET or

fMRI) to identify regions in the brain involved in spatial cognition. One exciting finding is that there is an activation of the *hippocampus* proper (besides several other regions in the brain), which has already been found in animal experiments. In studies of rat hippocampal pyramidal cells, so-called 'place cells' have been identified, that fire when the animal is in a specific location (O'Keefe and Dostrovsky 1971). In similar fashion, Maguire et al. (1998) found in a PET study with human subjects that the right hippocampal formation shows increased activity during exploration of a virtual town (see *Navigation in Virtual Space: Psychological and Neural Aspects*).

3. Simulation Sickness

A major problem with virtual reality is simulation sickness, which was initially documented in a helicopter flight simulator. The most common symptoms are: general discomfort, sweating, disorientation, nausea, and vomiting. Some people exhibit all of these signs whereas others exhibit only a few or even none. In an analysis of data from 10 US Navy and Marine Corps flight simulators, it was found that approximately 20 to 40 percent of the pilots experienced at least one of the symptoms (Kennedy et al. 1989). The main theory explaining simulation sickness is the 'Cue Conflict Theory,' which implies that the main causes are discrepancies between the senses concerning information about body orientation and motion.

Virtual Reality, Psychology of

The term 'virtual reality' refers to a computer program that gives its users the sense of being in a world that exists outside physical space. The experience may be created through visual images and/or text. In some virtual realities we are alone as we navigate virtual oceans, unravel virtual mysteries, and engineer virtual skyscrapers. In others, we are in the company of other people, all connected to the same program and to each other through the Internet, the rapidly expanding global system of networks that links millions of personal computer users together.

The psychology of virtual reality includes a broad set of questions, both because of the diversity of virtual environments (everything from video games to Internet chatrooms) and the wide range of psychological frameworks that may be brought to bear on their exploration. The field includes cognitive psychologists who study sensorimotor adaptation in immersive virtual environments, such as flight simulators, and clinical psychologists who study video game playing as a form of addiction. Current questions in the field include the role of simulated spaces on people's experience of the physical 'real.' This issue is

raised when a seven-year-old child looks at a seashore jellyfish and comments 'It looks so realistic.' It is raised when we compare a rafting trip down the Colorado River to an adolescent girl's use of an interactive CD-ROM to explore the same territory. And it is raised in the contemporary practice of science, highly dependent on simulation, and in science education. Some scientists are concerned that once students have seen an experiment unfold perfectly in a simulation, the messiness of a real experiment—the imperfections of measurement, the crack in the equipment that means you have to repeat it—can come to seem like a waste of time (Turkle 1995).

The perspective taken in this article necessarily narrows the field, focusing on the experience of the self in social virtual realities, environments where people interact with each other through their self-representation in computational worlds. The current practice of social virtual reality enables people to recast their notions of personal identity in more flexible terms, because they are able to use relationships in cyberspace to explore multiple aspects of self. Virtual reality is not the only factor that is moving our psychological culture in this direction (Gergen 1991; Lifton 1993), but it is one of the most potent.

1. *Virtual Personae*

A key element of the psychological impact of on-line life is the possibility of creating and projecting constructed personae into virtual space. This can be done through the use of visual materials (virtual worlds may allow users to design their own virtual 'bodies') as well as through textual description. In cyberspace one's constructed identity can diverge from physical realities: the obese can present themselves as slender, the beautiful can present themselves as plain. And text-based on-line 'conversations' allow time to reflect upon and edit one's 'composition.' This makes it easier for the shy to be outgoing, the 'nerdy' sophisticated. The relative anonymity of Internet identities—in most virtual settings, one has the choice of being known only by one's chosen 'handle,' or on-line name—gives people the chance to express often unexplored aspects of the self. The simplest form of this multiplication of selves takes place in the simple act of naming oneself when people take out multiple e-mail accounts on the web or multiple names or 'handles' on their on-line service. It is not unusual for one person to have three accounts such as, for example, armani_boy@hotmail.com, motorcycle_man@hotmail.com, pinstripe_guy@hotmail.com. It is not unusual for one person to be in one chatroom as MrSensitive, a second as RollingStone, and a third as GayPal. And, of course, it is possible for the physical person behind armani_boy or MrSensitive to be a woman rather than a man.

The on-line exercise of playing with identity and trying out new ones is perhaps most explicit in role-playing virtual communities and in massively multi-player games, where participation begins with the creation of a persona (or several), but it is by no means confined to these somewhat exotic locations. In bulletin boards, newsgroups, and chatrooms, the creation of personae may be less explicit, but it is no less psychologically real.

The creation of site-specific on-line personae is not only dependent on adopting a new name. Personae-shifting happens with a change of virtual place. Cycling through virtual environments is made possible by the existence of what have come to be called 'windows' in modern computing environments. Windows are a way of working with a computer that makes it possible for the machine to place you in several contexts at the same time. As a user, you are attentive to only one of the windows on your screen at any given moment, but in a certain sense, you are a presence in all of them at all times. Your identity on the computer is the sum of your distributed presence.

Technology has always provided psychology with metaphors for mind; perhaps the best-known example is Freud's use of hydraulics to represent the play of forces in the psyche. In our time, the computer has become a model of mind in the academic world (Dennett 1991) and in everyday practice, the windows technology that we use when visiting cyberspace provides a potent metaphor for thinking about the self as a multiple, distributed, 'time-sharing' system. The self is no longer simply playing different roles in different settings—something that people experience when, for example, one wakes up as a lover, makes breakfast as a mother, and drives to work as a lawyer. The windows metaphor suggests a distributed self that exists in many worlds and plays many roles at the same time. It suggests a life experience in which one 'cycles through' and is able to experiment with different 'aspects of self.'

2. *Identity, Moratoria, and Play*

Cyberspace, like all complex phenomena, has a range of psychological effects. For some people, it is a place to act out unresolved conflicts, to play and replay characterological difficulties on a new and exotic stage. For others, it provides an opportunity to work through significant personal issues, to use the new materials of cybersociality to reach for new resolutions. These more positive identity effects follow from the fact that, for some, cyberspace provides what Erik Erikson (1963) would have called a 'psychosocial moratorium,' a central element in how Erikson thought about identity development in adolescence. Although the term 'moratorium' implies a 'time-out,' what Erikson had in mind was not withdrawal. On the contrary, the adolescent moratorium is a time of intense social and intellectual activity. It is a time of

passionate friendships and experimentation. The adolescent falls in and out of love with people and ideas. Erikson's notion of the moratorium was not a hold on significant experiences but on their consequences. It is a time during which one's actions are, in a certain sense, not counted as they will be later in life. They are not given as much weight, not given the force of full judgment. In this context, experimentation can become the norm rather than a brave departure. Relatively consequence-free experimentation facilitates the development of a 'core self,' a personal sense of what gives life meaning that Erikson called 'identity.'

Erikson developed these ideas about the importance of a moratorium during the late 1950s and early 1960s. At that time, the notion corresponded to a common understanding of what 'the college years' were about. Today, the idea of the college years as a consequence-free time-out seems of another era. College is pre-professional, and AIDS has made consequence-free sexual experimentation an impossibility. The years associated with adolescence no longer seem a time out. But if our culture no longer offers an adolescent moratorium, the possibility of a virtual life often does. This is part of what gives virtual reality its psychological holding power.

Erikson's ideas about the importance of a psychosocial moratorium for successful identity development were part of a larger theory of the stages of the lifecycle. Erikson's ideas about stages did not suggest rigid sequences. His stages describe what people need to achieve before they can move ahead easily to another developmental task. For example, Erikson pointed out that successful intimacy in young adulthood is difficult if one does not come to it with a sense of who one is, the challenge of adolescent identity building. In real life, however, people usually have to move on in their lives with significant deficits. With incompletely resolved 'stages,' they simply do the best they can. They use whatever materials they have at hand to get as much as they can of what they have missed. Now virtual social life plays an important role in these dramas of self-reparation. Time in cyberspace reworks the notion of the moratorium, because it may now exist in an always-available 'window.'

3. *Virtual Reality and the Psychology of Everyday Life*

Recent psychological theory has stressed the importance of appreciating multiplicity or 'decentering' as a cornerstone of identity (Bromberg 1994, Dennett 1991, Gergen 1991, Lifton 1993). But despite the prevalence of such critiques of traditional, unitary notions of 'the ego' or 'identity,' it is usually difficult for people to make a personal connection with these ideas—hard, for example, to accept a challenge to the idea of an autonomous ego. The normal requirements of everyday life exert strong pressure on individuals to take responsibility for their actions and to see themselves as unitary actors. And our very language gives us a unified self in our first-person assertions: 'I do,' 'I want,' I desire.' This disjuncture between theory (the unitary self is an illusion) and lived experience (the unitary self is the most basic reality) is an important reason why, in the history of psychology, multiple and decentered theories have been slow to catch on—or when they do, why we tend to settle back quickly into older, centralized ways of looking at things. But today, the everyday practice of people using personal computers and modems to participate in on-line life provides experiences that bring theories of multiple selves 'down to earth.' When virtual reality enables an individual to construct multiple personae that can explore different aspects of the self, the notion of a decentered identity is concretized. In this way, cyberspace becomes an 'object to think with' for thinking about identity.

The popular appropriation of Freudian ideas had little to do with scientific demonstrations of their validity. Freudian ideas passed into the popular culture because they offered robust and down-to-earth objects-to-think-with (Turkle 1992). The objects were not physical but almost-tangible ideas, such as dreams and slips of the tongue. People were able to play with such Freudian 'objects.' They became used to looking for them and manipulating them, both seriously and not so seriously. And as they did so, the idea that slips and dreams betray an unconscious started to feel natural. In Freud's work, dreams and slips of the tongue carried the theory.

Today, virtual reality—life on the computer screen—carries psychological theory. People decide that they want to interact with others on a computer network. They get an account on a commercial service. They think that this will provide them with new access to people and information, and it does. But it does more. When they log on, they may find themselves playing multiple roles; they may find themselves playing characters of the opposite sex. In this way they are swept up by experiences that enable them to explore previously unexamined aspects of their sexuality or that challenge their ideas about a unitary self. To use the psychologist Philip Bromberg's (1994) language, on-line life may enable people to 'stand in the spaces between selves and still feel one, to see the multiplicity and still feel a unity.' To use the computer scientist Marvin Minsky's (1986) language, on-line life may enable people to experience themselves as cycling through their 'society of mind,' a notion of identity as distributed and heterogeneous.

4. *A Heightening of Projection*

The psychological power of virtual reality is enhanced by the fact that phenomena associated with projection and transference are heightened in virtual space. As in

Thomas Mann's *The Magic Mountain*, which takes place in the isolation of a sanitarium, relationships in cyberspace become intense very quickly because the participants feel themselves to be in a remote and unfamiliar world with its own rules. Electronic meeting places breed an easy intimacy. In the first phase of electronic friendships, people describe the excitement of a rapidly deepening relationship and the sense that time itself is speeding up. In virtual encounters, the lack of information about the physically real person to whom one is talking, the silence into which one types, the absence of visual cues, all encourage projection. This can lead to disappointment when, in a second stage of friendship, people who have had only virtual encounters move to bring them into the physical 'real.' However, it also has a positive side. Virtual reality offers a new tool for self-reflection. In close virtual friendships, it is not unusual to 'log' one's interaction with an intimate. It is possible to compare the text of the 'relationship' with the depth of feeling it has evoked. Very often, the gap between the two provides a rough but potentially useful approximation of the 'transference.' More frequently, people do not have an actual transcript of an on-line relationship to work with, but as they become more experienced in virtual social interaction, they are in a good position to notice recurrent patterns of on-line behavior. In this sense, it is possible to use the virtual to reflect constructively on the real. Otherwise put: people who make the most of their lives on the screen are usually those who are capable of approaching it in a spirit of self-reflection; they examine what they are doing on-line and ask themselves what it says about their desires, perhaps unmet, about their needs for connection, perhaps unfulfilled. They make efforts to use what they learn in virtual reality to improve the quality of their lives in the physical 'real.'

The study of the psychology of on-line life requires a better understanding about how to instill and nurture this discipline of self-reflection. Among psychologists, this enterprise has met some resistance by a movement to label the medium 'addicting' and requiring control much as one would control a drug (Young 1998, Greenfield 1999). There is a lively debate among psychologists (Young 1999) about the usefulness of the concept of Internet addiction. For some, the analogy is justified by the compelling hold of virtual life and computer games and by the fact that the term 'addiction' is employed by many who are drawn to chatrooms, on-line communities, and computer games and who find themselves spending more and more time using them. For others, the addiction analogy seems misplaced (Turkle 1995, Grohol 1999). The argument against the addiction metaphor is that it closes down the important psychological questions that discriminate among computer users and the use to which they put virtual reality. Cyberspace may be compelling, but it is only a medium and can be used for 'acting out' or 'working through' for both constructive and destructive psychological ends. From this point of view, a parent whose child is on heroin needs to help the child stop taking the drug, whereas a parent whose child is on-line needs to be curious about what he or she is doing there. Is the child forming on-line relationships that are serving important developmental purposes? Are the specific on-line experiences likely to serve as stepping-stones for important emotional or intellectual growth? From this perspective, when we try to understand the psychological state of a person at a networked computer, it is most constructive to think of the Internet and its virtual spaces as a Rorschach, rather than as a narcotic.

5. *Future Directions*

Early writings about virtual reality stressed the possibilities of fully immersive environments, as well as the possibilities of full-body suits that would open up erotic possibilities for long-distance sexual activity and, less sensational but equally exotic, experiences for world exploration (Rheingold 1993). One could thrash one's way through a Brazilian rain forest and feel the thickness of the brush or walk through the Latin Quarter of virtual Paris and feel the roughness of the cobblestones under one's feet. These possibilities may well be in the future. But it is significant to note that the most robust applications of virtual reality, even after more than a decade of technical progress, remain some version of role-playing community creation. When hundreds of thousands of people join on-line gaming communities, they appreciate the technical innovations that make their 'worlds' increasingly well rendered. But what keeps them engaged is the way they become taken up by roles in which they can be somewhat 'other' and play on teams, where they can socialize with other players. Sociality and the pleasures of talking to other real people remains the 'killer application' for the virtual.

In on-line games set in virtual medieval landscapes, players do not only make friends and have romances, they join guilds, develop strategic alliances, and have political disagreements that lead to the formation of political parties and the drafting of political constitutions and bylaws. But it is one thing to raise a virtual child in a simulation game and quite another to confront the problems of real children, who so often face lives without adequate parenting or schooling, or health care or hope.

I have interviewed 20- to 30-year-olds who consider themselves politically active in virtual communities but who do not bother to vote in local or national elections. They say that they feel more powerful in their virtual communities than in the politics of the physical world, which they see as cynical and unresponsive. One might fear that virtual reality, to borrow a concept from Marx, is like religion, a kind of opiate. It is important to confront the seductions of simu-

lation: our real communities need us badly, and we can ill afford to abandon them for virtual citizenships, no matter how gratifying. This essay began with the thought that having literally written our on-line personae into existence, they can be a kind of Rorschach. We can use them to become more aware of who we are and what still feel we need. The same can be true of our lives in virtual communities. Hopefully, the future will bring greater emphasis on learning how to use the virtual to reflect constructively on the physical real.

Virtue Ethics

1. Definition

It has often been said that the development of virtue ethics (in modern dress) is in its infancy. For this reason, though virtue ethics is a type of substantive normative ethical theory opposed to consequentialism and Kantian ethics, it resists definition. The problem of definition is compounded by the fact that though much contemporary virtue ethics is neo-Aristotelian, it need not be, and has not always been. Increasingly, David Hume is being read in a way more sympathetic to virtue ethics, Nietzschean virtue ethics is developing, and Plato and Martineau have inspired 'agent-based' virtue ethics. Virtue ethicists, then, need not, and do not agree on such central questions as the definition of right action, and what makes a trait of character a virtue. Common to virtue ethicists, however, is the view that character rather than the motive of duty, rules, or consequences is central to ethics. This is not to say that rules, consequences, and the motive of duty are not important, but a character-based ethics will produce virtue-centered conceptions of moral rightness, objectivity in ethics, impartiality, demandingness or stringency of ethics, and practice, which reconfigure the moral universe.

The major source of inspiration for the development of modern virtue ethics is Aristotle (1955), particularly his *Nicomachean Ethics*. Two central features of his view have influenced definitions of modern virtue ethics. The first is his idea that the judgment of a virtuous agent is the rule and the measure of the right. This feature has spawned the view that virtue ethics is opposed to moral rules and principles, and that these must be entirely replaced by the judgment of a qualified judge (a virtuous agent). However there are 'virtue-rules' such as requirements to be kind, considerate, fair, courageous, and so on: rules which we use to educate our children into the moral life, and which we may use in morally charged situations where we might ask for example 'What would be the kind or tactful thing to do here?' Virtue ethicists, however, follow Anscombe (1958) in believing that moral rules should be couched in the 'thick' virtue concepts.

The second feature sometimes thought to be defining of virtue ethics is Aristotle's view that virtues

are essentially connected with the flourishing of their possessor. David Hume, however, thought that there are four potential grounds for status as a virtue: agreeableness and usefulness to self and agreeableness and usefulness to others. What constitutes right action and what gives status as a virtue are points of disagreement among virtue ethicists, so particular conceptions of right action and virtue status should not be employed to define virtue ethics as such.

2. *Intellectual Content of Virtue Ethics*

Discussion of the intellectual content of virtue ethics can center usefully on three issues: (a) virtue ethical conceptions of moral rightness of action, (b) the nature of virtue in virtue ethics, and (c) different conceptions of what makes a trait of character a virtue, within virtue ethics.

2.1 *Virtue Ethical Conceptions of the Right*

It is often thought that the virtue ethical conception of rightness, indeed one that is defining of virtue ethics is the following. (a) An act is right if and only if it is what a virtuous agent would characteristically (i.e., acting in character) do in the circumstances (Hursthouse 1996). However, other possibilities within virtue ethics exist, and have been canvassed. According to 'agent-based' virtue ethics rightness is understood thus. (b) An act is right if and only if it exhibits good motivation (Slote 1996). Statman (1997) alludes to another possibility. (c) An act is right if and only if it is expressive of virtuous character.

Finally, we might say (d) an act is right if and only if it is overall virtuous, and (d) differs from (a) in that it is possible for a virtuous agent acting in character to do in the circumstances something which is wrong according to (d). For example, according to (d), an act expressive of a benevolent disposition, and benevolently motivated, may fail to be a benevolent act. For a virtuous agent, though endowed with practical wisdom, is not omniscient, and the act may turn out to be extremely harmful. For the same reason (d) differs from (b) and (c). Furthermore, virtuous acts, as opposed to actions from or expressive of a state of virtue, need not possess all the features required for action from a virtuous state (as Aristotle recognized). In certain contexts, they may not express fine character or even good motives. In short a virtue ethicist may share the common conception of right action as one that is successful in hitting its target. Where virtue ethicists who share this view differ from, for example, consequentialists, is in their conception of 'hitting the target.' The target is set not by consequentialist criteria of promoting the most good, but by the ends of the various virtues. These ends will of course differ from virtue to virtue, so unless one subscribes to a strong doctrine of the unity of the virtues, virtue ethicists will possess a pluralistic view of rightness of action.

Where a virtue ethicist does not require fine inner states for rightness (as opposed to goodness) of actions, they may distinguish between rightness and excellence of acts, where the criteria for the latter are more stringent than those for the former.

2.2 *The Nature of Virtue in Virtue Ethics*

A virtue is an excellence of character. It is a disposition of acknowledging or responding to items in the field of the virtue in an excellent way. According to virtue ethical conceptions of virtue, the standards of excellence point to states inside the agent, as well as to the world outside the agent. In short, for a virtue ethicist, the realization of the end of a virtue must express fine inner states, if that realization is to display virtue.

Virtues have a specialized focus, that is, they have a field. The field of a virtue may be human beings in general, one's children, property, friends, honors, pleasure, the natural world, cultural and artistic objects, money, abstract objects such as knowledge, and states of affairs such as dangerous situations, interpersonal conflict, and so on. There is a wide variety of virtues which focus on different fields or domains—virtues such as friendship, courage, justice, environmental virtues, appropriate assertiveness, honesty, politeness and tact, liberality, generosity, thrift. Some virtues are universal such as courage, temperance, and justice, while others are relative to roles, such as professional virtues and virtues of parenthood. Yet others are relative to situation, for example, according to Aristotle, virtues whose field concerns (the expenditure of) money vary according to how much money one has, and range from thrift to 'magnificence.'

Insofar as 'virtue' is a success word, the form of acknowledgment of items in the field of a virtue required by a virtue must be appropriate or successful. What constitutes success or appropriateness will vary according to two types of things: first, according to the different kinds of morally significant feature in those items which it is the end of the virtue to recognize, sustain, further, or bring about (such as their value or status), and second according to the differing forms or modes of moral acknowledgment of items required by the various virtues (such as promoting (value or good) or respecting individuals in ways befitting their status). Virtue ethicists will differ on what are the basic morally significant features in the items acknowledged, and what are the basic forms of moral acknowledgment inherent in virtue. The former may include value, status, bonds, and good; the latter promotion, honoring (Pettit 1997), respect, love, appreciation,

and creativity. The important point is that the criteria of success in meeting the various ends of the different virtues will vary, depending on which forms of moral acknowledgment are involved in their exercise. We may ask, for example, whether such virtues as justice, benevolence and friendship are centrally concerned with all, or some of, the following: the promotion of good, the promotion of value, the honoring of value, respect for individuals in ways befitting their status, or love for individuals in virtue of bonds between those individuals and the agent.

According to virtue ethicists, an exercise or manifestation of virtue requires the successful expression of fine inner states, that is, in displaying virtue, the agent must both have fine inner states and successfully express them in her behavior. For example, virtuous creativity does not merely involve meeting the standards for success in the external manifestation of creativity that confers artistic merit in the created product. The creative response must also be expressive of fine inner states, such as the expression of artistic passion, a desire to create something of value to society or of high artistic quality, practical wisdom in the production of value, originality, a desire to create something novel, interesting, or original. Similarly, love as a virtuous response or form of moral acknowledgment is not merely the promotion of the good of an individual, or the inculcation of a belief in the beloved that she is loved. Virtuous love is expressive of genuinely caring motivation: motivation that is not pathological, such as passively or morbidly dependent. Again, respect for status as a virtuous response is not merely the formal trappings of respect according to societal convention.

Though virtue ethicists share the view that virtue requires excellence of inner states, what kinds of inner states need to be excellent for virtue to be displayed is a matter of some controversy. Neo-Aristotelians emphasize the necessity of practical wisdom, but this view has been challenged by work on so-called 'virtues of ignorance' (Driver 1989), by those who emphasize the sufficiency of admirable motivation for virtue (Slote 1996), and by those who emphasize the pivotal role of passion in the life of virtue (Solomon 1998). Say, for example, that benevolence as a virtue is concerned centrally with promoting the good of individuals, we still need to know answers to the following questions. Is it enough for benevolence to be displayed that the agents display good motives in her attempt to promote good? Is it necessary that she display practical wisdom? Is it sufficient that she display practical wisdom or is she also required to display knowledge in cases where there is large-scale ignorance concerning good? To what extent does virtue require rising above the general ignorance of a population or culture?

Some progress on the issue of what constitutes excellence in inner states appropriate to human beings may be secured if Nietzsche's emphasis on excellence in depth psychological states is followed up. For Nietzsche, virtuous action is action expressive of fine depth states, and this view enables him to draw a distinction between virtuous and nonvirtuous altruism, virtuous and nonvirtuous asceticism, and so on. Forms of beneficence, sublimation, and self-discipline, which are expressive of self-contempt and resentment lack virtue, for Nietzsche. Post-Nietzschean analytic-oriented psychologists also distinguish virtue and vice on the basis of depth states expressed in habitual behavior. For example, genuine and passive dependent or 'morbid' dependent love is distinguished on that basis by, for example, Horney (1951). Fromm (1977) too, distinguishes between healthy (benign) and unhealthy (malignant) forms of aggression. Rather than aggressiveness being simply characterized as a vice, Fromm's account distinguishes between malignant and benign forms based on the human's characterological orientation to the satisfaction of basic needs such as the needs for excitation or stimulation, and relatedness.

2.3 *What Makes a Trait of Character a Virtue*

On the issue of what makes a trait of character a virtue, virtue ethics can be divided into eudaimonistic and noneudaimonistic forms.

2.3.1 Eudaimonism. According to eudaimonistic virtue ethics, which characterizes Greek and neo-Aristotelian virtue ethics in its modern form, virtue is at least partially constitutive of the flourishing of the possessor of the virtues. Common to all versions of eudaimonistic virtue ethics is the view that what constitutes the flourishing of the agent cannot be understood entirely independently from the idea of virtue itself. That is, in determining what the virtues are, we cannot simply ask, first, what is good for a person, and then define the virtues in terms of traits that promote that good. For example, according to Aristotle, fineness of character is the greatest good for a person. Pleasure without temperance, wealth without justice, the possession of friends without the virtue of friendship is not good for an individual, that is, does not benefit an individual. However, unlike the Stoics, Aristotle did not believe that virtue is sufficient for eudaimonia or flourishing: a modicum of good fortune and money, and children that do not disgrace one, are also necessary.

Due to the fact that eudaimonistic virtue ethics has been the dominant form of virtue ethics, it has been the main target of opponents of virtue ethics. The most important of their criticisms are the following. Because eudaimonism does not understand flourishing to be characterizable wholly independently of virtue, it has been accused of circularity. However, a coherentist

epistemology, which is indeed adopted by Aristotle and many neo-Aristotelians, may remove the sting from this criticism. It does so provided the network of concepts and background theories of human nature in which conceptions of virtue and flourishing are embedded, is sufficiently rich, informed by the social sciences, and broad-ranging, and does not rely on a problematically narrow, prejudiced, and uninformed set of intuitions. A second important criticism is the charge of egoism occasioned by the belief that, according to eudaimonism, the rationale for the virtues is their benefiting the possessor of the virtues. This criticism is met by the claim that virtuous action need not be, and is not standardly, motivated by the self-interest of the possessor of the virtue. This reply in turn begets the criticism of indirection, namely the criticism that a paradoxical and unmotivated dissonance opens up between the rationale for status of a trait as a virtue and the motivation and rationale of virtuous action.

2.3.2 Noneudaimonistic virtue ethics. Criticisms such as these have motivated, at least in part, the development of noneudaimonistic vrtue ethics, which does not require that status of a trait as a virtue is grounded in the flourishing of the possessor of the virtues. Two noneudaimonistic forms are currently being explored.

(a) Agent-based virtue ethics. According to 'agent-based' views, developed by Slote (1996, 1998a) and inspired by Plato and Martineau (1891), a virtue is a trait that is admirable, and its admirability need not be based on its contribution to further value, such as the welfare of human agents or the environment generally. Nor need a virtue be even partially constitutive of the flourishing of a human agent. Such a view relies for its development on aretaic intuitions about admirability, rather than the more standardly appealed to axiological intuitions about what is valuable.

(b) Response views. Although all virtues are dispositions of appropriate responsiveness to or acknowledgment of items within their fields, according to response views this feature is what makes a trait of character a virtue. It is not also necessary that a virtue characteristically constitute (in part) the flourishing of the agent. Response views may be more or less pluralistic about both the bases of moral acknowledgment (such as bond, value, status, and good) and the forms of moral acknowledgment (such as promotion, honoring, love, respect, appreciation, and creativity). Response views may allow that some goods and states (such as pleasure, money, friends) cannot be understood as goods entirely independently of virtue, but some theorists, such as Hurka (1992) require that there be base-level valuable states to which virtues are responses and which must be defined wholly independently of virtue.

3. *Intellectual Context of Modern Virtue Ethics*

Two main concerns have motivated the rise of virtue ethics in recent times:

(a) increasing emphasis on the importance of good character and character education for a healthy society, and

(b) dissatisfaction with rival moral theories—particularly consequentialism and Kantianism.

The emphasis on character, and the character training of children is increasingly thought to be important, indeed central, for an ethically sound society. Moral rules, where important, need to be made, interpreted, and applied in complex situations, and in ways that are not distorted by such vices as greed, impatience, cowardice, lack of perseverance, racism and other forms of hostility, callousness, oversensitivity, lack of concern for or over-concern with, fairness, and so on. A difficulty for a reorientation of ethical thought towards virtue ethics, in line with the above concern, is the apparent linkage of virtue ethics with social conservatism. This view, however, is based on several misunderstandings. First, virtue ethics as such is open as to how we delineate the virtues. Specific versions of virtue ethics will differ on this question. Second, though it would be agreed by all that it is imperative to bring up children to possess character traits which are not personally and socially destructive, virtue ethics as such is open as to whether a correct version of virtue ethics provides a monistic or pluralistic answer to the question 'What is a good life for a human being?' Third, it is sometimes thought that virtue ethics is too 'individualistic' and fails to appreciate the limitations of a virtuous agent, and her embeddedness in society. However, a virtue ethicist could agree that even a virtuous human agent necessarily has limited experience, possesses limited perspectives, and has limited expertise and knowledge. Accordingly, it is open to a virtue ethicist to adopt a dialogical view of virtues of practice, and moral epistemology generally.

The philosophical/theoretic push to virtue ethics has been driven by several factors, including the following. One factor is dissatisfaction with the lack of emphasis on, or a denigration of, the 'inner'—feelings, emotions, passions, and practical wisdom—in the life of the moral agent. Virtue ethicists emphasize the importance of outer action as expressive of inner states: benevolence, for example, is not just a matter of promoting value or good. Fine emotions, for example, are important for the situational appreciation required by practical wisdom. Emphasis on the emotions also brings into view forms of moral acknowledgment not sufficiently emphasized in analytic philosophical ethics, such as (virtuous) caring and love. It also highlights the centrality in ethics of certain partialistic virtues such as parental love and friendship.

A second factor in the intellectual context of modern virtue ethics is its objection to decontextualized under-

standings of moral theory. For example, for a virtue ethicist, ethics is neither essentially impartial nor essentially partial. Rather there are both virtues and vices of impartiality, and virtues and vices of partiality relative to different fields. An understanding of partialistic vices, such as nepotism and favoritism (towards one of one's children, for example), and impartialistic vices (such as dispositions to seriously neglect near and dear in the interests of 'the common good'), requires a highly nuanced and contextualized understanding of the boundaries between these vices and allied virtues.

Related to the above feature of virtue ethics is a third and much-emphasized factor: skepticism about the codifiability of ethics. Virtue ethicists favor a conception of ethical expertise that emphasizes experience and practical wisdom. Because of their emphasis on detail, particularity, and complexity, they recognize that moral expertise, which relies on knowledge of, for example, medicine, business, educational, and other practices, does not generalize to all contexts.

A fourth factor is a desire to make the concept of living well central to moral evaluation. Commonly for virtue ethicists, the supposed gap between the good life and the moral life is reduced via the desideratum of living a virtuous life. Living a virtuous life reduces this gap primarily through a reconfiguration of the contrast between altruism and self-interest. A virtuous agent, characteristically and in normal circumstances, enjoys the moral life as Aristotle points out, because her capacities for strength, love, concern, respect, and lack of resentment, enable her to see her own concerns as not sharply in contrast with the interests of others.

4. *Virtue Ethics and Applied Ethics*

The application of virtue ethics to social practice raises the question of an epistemology suitable for virtue ethics. Such an epistemology may be monological or dialogical. Commonly it is thought that virtue ethics is inherently monological because the arbiter of rightness of action is thought to be the (or a) virtuous agent, that is, an agent of good moral character, practical wisdom, fine sensibilities, and the ability to appreciate a situation and context in fine detail. Nonvirtuous agents simply emulate virtuous ones. However, even virtuous agents are necessarily limited because of their human condition (e.g., a virtuous man cannot have the experiences of women who are contemplating an abortion). Arguably, a suitable virtue ethical epistemology for the world of practice, for example, education, medicine, business, aid work, family relations, must be properly socially grounded. Participants in a practice, recognizing their epistemic and other limitations, exercise the moral/epistemic virtues of practice, which include the dialogical virtues. These of course are legion, including imaginative deliberation, insight, perseverance, respect in various forms, open-mindedness, facilitativeness, and an absence of those vices which distort practical wisdom and communication, for example, cowardice, rigidity, hostility, callousness, excessive love of power, squeamishness, and lack of concern for or excessive concern for fairness. For a virtue ethicist, determining whether a participant is, for example, excessively concerned with fairness or insufficiently concerned with fairness is often a matter of fine judgment applied in contexts where many values are at stake, and knowledge and appreciation of relevant facts, including the feelings, preferences and so forth of affected parties, commonly is gleaned only through well-conducted dialogue.

5. *Skepticism About Character*

One of the most interesting recent criticisms of virtue ethics derives from the social sciences, specifically 'situationist' psychology (Ross and Nisbett 1991). According to some philosophers who make use of this psychology, virtue ethics is inadequate because it is based on a characterological psychology that is empirically inadequate. According to situationist psychology:

> Behavioral variation across a population owes more to situational differences than dispositional differences among persons. Individual dispositional differences are not as strongly behaviorally individuating as we might have supposed … (Doris 1998, p. 507)

The claim that experiments such as Milgram's (1963) demonstrate the empirical inadequacy of virtue ethics because there is a lack of cross-situational consistency in behavior, betrays a lack of understanding of the virtue ethicist's concept of virtue. For a virtue ethicist, a virtue is not simply a disposition to perform acts of a certain type (e.g., beneficent acts). The possession of virtue requires also the possession of fine inner states. Admittedly, Milgram's experiments show that a remarkable number of subjects administer electric shocks of considerable severity, in experimental situations of a certain type. The tendency to perform beneficent acts is arguably not as robust as one might hope. However, there was considerable variation in the mental states of those prepared to administer such shocks, and these differences may point to character traits of, for example, compassion, benevolence, respect for authority and commitments, which manifest themselves in various ways in dilemmatic situations. According to Milgram, the subjects differed markedly in their emotional reactions to increasingly pressuring requests to administer shocks. Milgram claims that an unanticipated effect 'was the extraordinary tension generated by the procedures.' He says: 'One might suppose that a subject would simply break off or continue as his conscience dictated. Yet this is far from what happened. There were striking reactions of tension and emotional strain.' While some subjects reported and manifested intense strain and

anguish, however, 'some subjects (who had administered maximum shocks) had remained calm throughout the experiment, and displayed only minimal signs of tension from beginning to end' (Milgram 1963, p. 376).

For the virtue ethicist, emotional reactions are crucial for the attribution of virtue and vice, and the mark of the virtuous is the propensity to violate a 'virtue-rule' such as 'Be benevolent' only with reluctance, anguish, distress. The degree to which these emotions are present will vary according to the circumstances. Furthermore, it is clear from Milgram's account that the anguished saw themselves as operating under a rather severe virtue-dilemma. A benevolent agent may also possess the virtues of respect for authority, trust, honoring commitments, and appreciation of (the value of) knowledge. All of these virtues were in play during the experiment (1963). Subjects rightfully assessed the experimental situation as warranting trust, the honoring of a commitment, and as promoting a worthy objective. Now where virtues of, for example, trust and fidelity appeared in acute dilemmatic relation to another—nonmaleficence—most subjects arguably gave insufficient weight to the latter. But virtue ethicists are not committed to the view that many actual agents are capable of resolving such dilemmas correctly when under severe stress. The degree of virtue in agents is however able to be determined by their emotional reactions to their admittedly faulty resolutions of dilemma (e.g., reactions of anguish or indifference). And those differences were evident. It is open to the virtue ethicist to argue that while trust was not misplaced, and though obedience to authority is a virtue, in this case most subjects displayed this virtue to excess. Arguably, this failure hindered the exercise of the virtue of nonmaleficence present in those who suffered anguish.

According to virtue ethicists, good character is a centrally important component of the good life for an individual in society, and virtue ethics is a philosophically rich and fruitful approach to moral theory. The further development of this theory requires cooperation with the social sciences, if a richer understanding of virtue, as an excellence of character in human beings, is to be obtained.

Vision for Action: Neural Mechanisms

Sensory input received by the visual receptors from an object in space results in a complex pattern of excitation from which object properties relevant to different functions have to be extracted. This selection is the basis for a specific mechanism called visuomotor transformation, the shaping of the motor effectors into configurations precisely adapted to capturing, manipulating, using, and transforming visual objects. In primates, the remarkable evolution of the hand into a grasping apparatus represents an ultimate acquisition for skilled interaction with objects and use of tools. This article will focus on anatomical and functional analysis of neural mechanisms involved in visuomotor transformation.

Beginning in the 1970s, the anatomical description of cortical visual pathways in the monkey has led to the formulation of the 'two visual systems' model (Ungerleider and Mishkin 1982). According to this model, the primary visual cortex in the occipital lobe projects along two main streams that reach, respectively, the posterior parietal lobe (the dorsal pathway) and the inferotemporal cortex (the ventral pathway). Although the two pathways are densely interconnected with each other, they are now viewed as relatively independent functional entities.

Figure 1
Lateral view of the left hemisphere of a monkey brain. Two of the main sulci have been opened to show the 'buried' areas: the intraparietal sulcus (IPs) and the lateral sulcus (Ls, which separates the parietal lobe from the temporal lobe). The other main sulci are the central sulcus (Cs) which separates the parietal lobe from the frontal lobe, the arcuate sulcus (As) and the principal sulcus (Ps) within the frontal lobe, and the superior temporal sulcus (STs) within the temporal lobe. The anterior part of the parietal lobe, which includes somatosensory areas SI and SII (in the upper bank of the lateral sulcus), is not concerned with visuomotor transformation. The posterior part of the parietal lobe includes areas 7 and 5 on the cortical surface, and the intraparietal areas (medial, lateral, ventral, anterior intraparietal areas, respectively). The motor strip of the frontal lobe includes the primary motor cortex (MI, the command area), and the dorsal and ventral premotor cortex (PMd, PMv, respectively).

The dorsal pathway, which will be under scrutiny in this article, was once considered as a space channel. Indeed, its experimental destruction in the monkey produced spatial disorientation of the animal. Later on, a more complete description of the anatomical organization of the posterior parietal cortex, which is outlined in Fig. 1, led to a new conception of its functional role. First, a number a specialized areas, many of them located in the intraparietal sulcus (e.g., LIP, MIP, AIP), were added to the classical cytoarchitectonic areas (e.g., areas 7 and 5). Second, these newly described areas were found to be connected with motor regions of the frontal cortex. These connections appear to be selectively organized: parietal area MIP is preferentially connected with the upper part of the premotor cortex (PMd in Fig. 1), whereas AIP is preferentially connected with its lower part (PMv).

Both PMd and PMv project to the motor cortex itself, where the commands to the relevant muscles are generated. Thus, the dorsal pathway, whereby visual information is transferred from the primary visual cortex to the premotor and motor cortex, can better be conceived as a pathway specialized for visuomotor transformation.

1. A Mechanism for Reaching Objects in Visual Extrapersonal Space

Reaching for a visual object requires that the set of coordinates in which the object-oriented movement is computed must have its origin on the agent's body (egocentric coordinates). This constraint stems from the fact that object position in space must be reconstructed by adding signals from eye, head, and body positions for the arm to be ultimately directed at the proper location. Determining object position in space by computing its retinal position alone would be inappropriate, because this locus in space would correspond to different retinal positions according to respective eye, head, and body positions (Jeannerod 1988). The following paragraphs describe some of the mechanisms which have been identified in recent experiments in monkeys and which could account for transforming retinal (eye centered) coordinates into (body centered) egocentric coordinates. These mechanisms are primarily located in the intraparietal sulcus.

An influential hypothesis proposes that the basic information about where to reach for an object is the motor command sent to the eyes to move in its direction (the eye position signal). Neurons in area 7a have been shown to encode visual stimuli for a specific position of the eye in the orbit, i.e., they fire preferentially when the object stimulates a given location on the retina (the neuron's receptive field), and when the gaze is fixating in that direction (Andersen and Mountcastle 1983). These neurons would provide a representation of visual space that could subsequently be projected to the premotor cortex for guiding the arm reach. This mechanism is apparently compatible with the organization of visuomotor behavior: the gaze systematically moves first to the location of the desired stimulus, followed by the arm movement within about 150 ms. A closer look, however, shows that, because the motor command to the arm muscles anticipates arm displacement by about the same amount, the motor commands to the eye and to the arm are in fact more or less synchronous (Biguer et al. 1982). Duhamel and his colleagues found the solution to that enigma. They discovered in area LIP neurons which fire in response to a stimulus briefly presented, not within their receptive field, but within the area of space where their receptive field will project after an eye movement is made. This effect begins some 80 ms before the eye movement starts (Duhamel et al. 1992). The retinal position of receptive fields is thus modified prior to the occurrence of an eye movement. This remapping of the representation of space in the parietal cortex accounts for perceptual stability of the visual scene during eye movements. In addition, the existence of this mechanism demonstrates that signals related to the intended eye position are available to the motor cortex. In area VIP, neuron discharges testify to a different form of remapping. Their receptive fields remain in the same spatial position irrespective of eye position in the orbit. In this case, therefore, the receptive fields appear to be anchored, not to the eye, but to the head, i.e., the receptive fields move across the retina when the eyes move (Duhamel et al. 1997).

Eye and head position signals, however, should not be sufficient in themselves for generating a directional signal for guiding the arm. Besides the position of the stimulus on the retina and the position of the eye in the orbit, the position of the arm with respect to the body must also be available to the arm motor command. This function is achieved by neurons presenting receptive fields in two sensory modalities. Neurons in area MIP, for example, respond to both a localized visual stimulus and a cutaneous stimulation applied to one of their hands. These bimodal neurons are strongly activated when the monkey reaches with that hand to the visual target within their receptive field (see Andersen et al. 1997, Colby 1998).

Neurons located in motor areas outside the parietal cortex also present bimodal activation. Graziano and his colleagues found bimodal neurons in the ventral premotor cortex: these neurons, which in addition encode the direction of arm movements, have tactile receptive fields and visual receptive fields that extend from the tactile area into adjacent space. For those neurons which have their tactile receptive field on the arm, the visual receptive field moves when the arm is displaced (Graziano et al. 1994). These visual receptive fields anchored to the arm encode visual stimulus location in body (arm) coordinates and thus may provide a solution for directional coding of reaching. In what way does this premotor mechanism relate to parietal mechanisms? What is the role of connections between parietal areas and the premotor cortex? These points remain unclear. It is likely that, instead of a single directional signal used for all purposes, multiple transformations and multiple spatial maps are generated and adapted to each purpose: guiding the eye, guiding the arm, stabilizing the visual world, etc.

Data from single cell recordings are supported by experimental data in human studies which clearly point to the parietal lobe as the site of visuomotor transformation for reaching. Although human data are less direct than monkey data, they provide deeper insight into the function due to the unique human ability to execute tasks without having to learn them. Functions like visually guided reaching can be examined in more naturalistic situations. Observation of patients with focal posterior parietal lesions in one

hemisphere show deep alterations of reaching movements, usually limited to the hand contralateral to the lesion: kinematics are altered, and large reaching errors are observed. This misreaching is more marked in the condition where the visual target is presented outside the fixation point and increases when the target distance from the fixation point increases (e.g., Milner et al. 1999). These clinical findings are corroborated by brain imaging studies (based on changes in localized cerebral blood flow) in normal subjects during pointing at visual targets. The activated area, in the parietal lobe contralateral to the pointing hand, corresponds closely to the location of lesions that produce misreaching (Faillenot et al. 1997). Finally, the involvement of the posterior parietal cortex in visuomotor control is confirmed by transcranial magnetic stimulation (TMS). This technique allows the application, via magnetic induction, of very brief single shocks to a given cortical zone. When TMS was applied to posterior parietal cortex shortly after onset of a reaching movement directed to a visual target, it prevented online corrections needed to reach the target. TMS only affected the arm contralateral to the stimulated cortex, which excludes the possibility that the stimulation perturbed visual processing of target location: only the adaptation of the motor command to the visual position of the target was perturbed (Desmurget et al. 1999).

2. *The Case of Hand and Finger Movements*

Grasping is often the ultimate achievement of reaching. For this reason, the two functions can hardly be dissociated. Grasping, however, relies on a quite different system than reaching: it involves distal segments, multiple degrees of freedom, and a high degree of reliance on tactile function. It is an ensemble of visuomotor transformations which preshape the hand while it is transported to the object location. Preshaping deals with object features which are not relevant to reaching, like object size, shape, or orientation (Jeannerod et al. 1995).

Indeed, anatomical data suggest that the cortical pathway connecting posterior parietal and premotor finger areas and controlling grasping is separate from the pathway controlling reaching. Hand movement-related neurons were disclosed by Sakata and his colleagues (1995) in a small zone within the anterior part of intraparietal sulcus, corresponding to an area (AIP) closely connected with the ventral part of the premotor cortex (PMv in Fig. 1). Neurons from AIP were recorded in monkeys trained to manipulate various types of objects, which elicited from the animal different motor configurations of the hand: most of them were selective for grasping objects of a given shape. Task-related neurons were classified as 'motor dominant' or 'visual dominant' according to whether their discharge related more to the action of grasping or to the inspection of the object. Most importantly, neuron activity was not influenced by changing the position of the object in space, which suggests that they were related to distal hand and finger movements (for which spatial position is irrelevant) rather than to proximal (reaching) movements of the arm (Sakata et al. 1995). Finally, a distinct population of neurons sensitive to the 3-D orientation of the longitudinal axis of visual stimuli was found in the caudal part of the intraparietal sulcus. It is therefore likely that these neurons process the 3-D characteristics of the object and that the output of this processing is sent to AIP.

Transient inactivation of the AIP region, by locally injecting a GABA agonist (muscimol), produces a subtle change in the performance of visually guided movements during grasping. Lack of preshaping and grasping errors are observed in tasks requiring a precision grip. In addition, there is a clear-cut dissociation of the muscimol effects on grasping, which is altered, and reaching, which is preserved. These results (Gallese et al. 1994) support the view that these parietal neurons play a specific role in the visual guidance of grasping.

In humans, clinical observations also stress the role of the posterior parietal cortex as a structure controlling the visuomotor action of grasping. During prehension of objects, parietal lesioned patients show little or no preshaping with their contralateral hand; they tend to open their finger grip too wide with respect to object size and to close it only when their fingers come into contact with the object; the opposition axis (the axis which passes through the two opposing fingertips and the center of gravity of the object) is improperly oriented, which results in misplacement of fingertips on the object surface (Jeannerod et al. 1994). In normal subjects, the above brain imaging study (Faillenot et al. 1997) revealed an area specifically involved in grasping, at the ventral extremity of the intraparietal sulcus, also including part of the somatosensory area S II. It is likely that this cortical zone includes the human homologue of the monkey AIP area.

An intriguing question thus remains to be discussed: in which system of coordinates are finger movements during grasping coded? The main aspect of grasping, grip formation, has been described using parameters such as grip size, orientation of opposition axis, number of fingers involved, etc., which, arguably, should not depend on the object position in space. This is also the case for another aspect of grasping, the encoding of grasp and lift forces: these parameters depend on visual cues for object weight, for which object location is irrelevant. There are limits to this reasoning, however. Reaching and grasping cannot be considered in isolation, as they represent two aspects of the same action, reaching to grasp an object. The need for coordination between these two aspects becomes apparent when measuring the orientation of the opposition axis during grasping. The position of

the fingertips on the object surface should only be determined by object shape and 3-D characteristics in order to achieve a stable grasp. Paulignan et al. (1997), however, using upright cylinders as targets (e.g., objects affording multiple possible positions for the fingertips) showed that orientation of the opposition axis changed as a function of the cylinder position in the workspace. This result indicates that the action of grasping must encode not only finger movements but also movements of the proximal joints: due to biomechanical limitations of the arm, the configuration of the upper limb cannot be the same for grasping the same object at two different locations.

Even though reaching and grasping cannot be considered as functionally independent (in spite of segregation of their anatomical pathways), they process different types of information and operate at different rates. Experiments using visual 'perturbations' synchronized with movement onset clearly demonstrate this difference (Paulignan et al. 1991a, 1991b). If, for example, the target object to be reached by the subject jumps (by means of an optical device) by 10 degrees to the right as the subject starts reaching in its direction, a corrective movement is produced so that the new target is adequately reached: the first kinematic evidence for correction occurs around 100 ms following the perturbation. If, in another experiment, the object keeps the same location, but changes size (e.g., increases) as the subject starts to move, it takes at least 300 ms for the finger grip to adjust to the changing object size. This sharp contrast between the timing of the two types of corrections accounts for the functional differences between the two components of the action. Although fast execution during reaching has an obvious adaptive value (e.g., for localizing and catching moving targets), this is not the case for grasping, the function of which is to prepare fine manipulation of the object once it has been caught.

3. Conclusion

Posterior parietal cortex thus appears as a critical zone for organizing object-oriented action, whether movements are executed by the proximal or the distal channels. The specialization of the dorsal visual pathway for visuomotor transformation is complementary with that of other brain regions, mostly located within the ventral pathway, and specialized for object identification and recognition. This suggests the existence of a dual mode of processing for object properties like spatial location, orientation, shape, or size. Perception requires that object properties are processed within an allocentric frame of reference, that is, independent from the perceiver and where the relationships between objects within the visual array are preserved. Action, by contrast, as has been shown in this article, requires that information is processed within an egocentric frame of reference where everything in the visual array that is not the target for the movement is ignored.

Vision, High-level Theory of

The concept of 'high-level vision' is used to denote aspects of vision that are influenced by information stored in memory such as an object's identity, its name, or the context in which it belongs. It is usually distinguished from low-level visual processing, which is driven primarily by the visual input. High-level vision involves functions such as object recognition, face perception, mental imagery, picture naming, visual categorization, or scene perception.

1. *Background*

In hierarchical models of vision (e.g., Marr 1982, see also *Marr*, *David* (1945–80)), higher levels of visual processing operate on the building blocks delivered by more primitive visual mechanisms. In Marr's approach to perception, each stage has its own algorithms and its own format of representing processing output. The primal sketch represents the basic features and their spatial relations (low-level vision) and the 2,5-D sketch represents surfaces and shapes from the observer's viewpoint (intermediate-level vision). Recognition, that is, matching of object descriptions stored in visual memory with visual input, Marr believed only possible when the full 3-D structure of an object and its components is represented in a so-called 3-D object model (high-level vision).

Marr's approach has been highly influential as a framework to integrate disparate work on the processing of, among others, luminance, texture, shading, color, stereo, or motion (see Palmer 1999). However, his assumption of strictly bottom-up processing in sequential stages has gradually lost attraction. One reason for this theoretical evolution has been the increased popularity in the 1980s of so-called interactive activation models in which different levels of processing interact with one another (see also *Connectionist Approaches*; *Artificial Neural Networks*: *Neurocomputation*): Partial outputs from lower-level processes initiate higher-level processes and the outputs of higher-level processes feed back into the lower-level processes.

When different levels are distinguished in more recent theories, great care is taken to avoid the assumption of strict sequential processing. However, the issue of where early vision ends, where high-level vision starts, and how to demarcate the two has remained important in current theorizing. Pylyshyn (1999) has proposed the notion of cognitive impenetrability as the major criterion for separating early (or low-level) vision from later (or higher-level) vision. Early visual processes run autonomously; they cannot be influenced by what we know about the world or expect in a specific situation. Most aspects of visual processing which seem cognitive (e.g., recovering unique 3-D percepts from ambiguous 2-D inputs) are attributed to embodied natural constraints derived from principles of optics and projective geometry, internal to the visual mechanisms themselves. Only effects of object-specific beliefs on earlier visual processing would count as cognitive penetration. A large number of so-called 'top-down effects' of higher-level processes on early vision are then explained as effects of attention (preceding early vision) or as post-perceptual effects on the decision stage based on the perceptual output. For example, perceptual learning, perceptual expertise and effects of categorization on discrimination might be attributed to learning to focus attention to the important features or attributes of a stimulus. Semantic effects of the context of the whole scene (e.g., a kitchen) on the identification of the objects embedded within the scene (e.g., bread) have been shown to result from response bias rather than from genuine perceptual effects (e.g., Henderson and Hollingworth 1999).

Implicit in Pylyshyn's (1999) effort to delineate early vision from cognitive influences is his belief—perhaps shared by many vision scientists—that real scientific progress is possible only in early vision. Arguably, however, in recent years considerable progress has been made in the area of high-level vision as well (e.g., Edelman 1999, Ullman 1996). Most of this progress has been made in object recognition, and, thus, this topic will be covered predominantly (see also *Binocular Space Perception Models*).

2. *Object Recognition*

2.1 *Biederman (1987)*

Object recognition concerns the identification of an object as a specific entity (i.e., semantic recognition) or the ability to tell that one has seen the object before (i.e., episodic recognition). Interest in object recognition is at least partly caused by the development of a new theory of human object recognition by Biederman (1987). Building on Marr's recognition ideas, where perceptually derived 3-D volumetric descriptions are matched to those stored in memory, Biederman in addition incorporated Gestalt principles of perceptual

grouping and some newer ideas from computer vision into his theory.

Biederman proposed that objects are identified at their entry level on the basis of a structural description of their components and their spatial relations. All object parts are modeled by a limited number of simple primitives called 'geons,' a specific subset of generalized cones. A generalized cone is the volume swept out by a cross section moving along an axis. Geons are defined by the categorical attributes on the following dimensions: the axis (straight or curved), the shape of the cross-section (straight or curved, symmetric or asymmetric), and the size of the cross-section (constant, expanded, or expanded and contracted).

One major claim in Biederman's Recognition-by-Components (RBC) theory is that geons themselves are viewpoint-invariant because the underlying dimensions can be distinguished on the basis of so-called 'nonaccidental properties' or NAPs (a notion developed in computer vision). These are special features in the image (such as collinearity, curvilinearity, cotermination, parallelism, and symmetry) that are reliable in the sense that they are most likely caused by similar characteristics in 3-D space (under the assumption of a general viewpoint). For example, rarely do nonparallel structures in 3-D space project to parallel structures in the image. Biederman argues that Gestalt principles of grouping support the extraction of these NAPs and that they are thus detected fast and reliably enough to support bottom-up identification of geons.

The spatial relations between object components also have to be specified by a number of parameters and in later versions of the theory, a few coarse metric attributes of the geons themselves must be specified too. The combinatorial possibilities of even only two or three geons are then enormous. This allows Biederman to argue that the recovery of two or three geons is enough to recognize complex objects quickly even when they are occluded, rotated in depth, degraded, or lacking color or texture.

This claim is supported empirically by experiments in which parts of objects (in fact, line drawings of objects) were deleted until only two or three parts were left. For most moderately complex objects consisting of six or nine parts (e.g., an airplane, an elephant) three parts were still enough to recognize the object. Other supporting evidence comes from recognition of contour-deleted line drawings (which is possible as long as the geons are recoverable), priming with contour-deleted pictures (which is situated at the level of the parts, not the image fragments and not the whole picture), and viewpoint-invariance of 3-D object recognition (under certain limited conditions).

While Biederman and his associates were accumulating evidence for his RBC theory, others were accumulating evidence for strong effects of viewpoint changes on 3-D object recognition (see, e.g., Bülthoff et al. 1995). This has given rise to a lot of controversy between viewpoint-dependent and independent theories of object recognition, often centered around the relevance of specific types of objects used as experimental stimuli (e.g., line drawings vs. rendered 3-D objects, all sorts of novel objects such as paperclips, amoebas, and 'greebles') or specific types of experimental tasks (e.g., matching, naming, priming). Because the focus in this review is on theory instead of empirical results, this debate will not be reviewed here (but see also *Binocular Space Perception Models*). Instead, two promising new theoretical developments will be highlighted.

2.2 *Ullman (1996)*

Ullman's (1996) book *High-level vision: Object recognition and visual cognition*, brings together his achievements in three diverse sub-domains of high-level vision: (a) object recognition (alignment, combination of views), (b) visual cognition (classification, visual routines), and (c) sequence-seeking and counter-streams.

In the area of object recognition, Ullman proposed two different theories. According to his alignment theory, object recognition consists of a search for a particular object model in memory, M_i, and a particular transformation, T_{ij}, that will maximize the fit between (M_i, T_{ij}) and the viewed object, V. The set of the allowed transformations, such as changes in scale, position, or 3-D orientation, can be applied either to the incoming image (more bottom-up) or to the stored model (more top-down). The simplest version of this theory works well for simple, rigid objects. Because the set of relevant transformations is restricted in that case, only three points are needed to be able to establish a correspondence between the image and the model. This so-called 'three-point alignment scheme' explicitly uses 3-D models but works well only when the features that are used for alignment are visible from different views. For all other cases, his second theory, recognition by the combination of views, works better. This does not explicitly use 3-D models but a representation of 3-D objects as a small collection of 2-D views. Object recognition then consists of matching the viewed object against a linear combination of these 2-D views. Extensions of this method can even handle cases with partial views due to occlusion and cases with nonrigid transformations.

Object recognition is concerned with specific shapes undergoing well-defined transformations, which are relatively easy to specify and compensate for. Object classification, on the other hand, is more difficult because it is not obvious what the critical shape features of object classes like 'dog' or 'chair' are. Ullman demonstrated that relatively simple pictorial comparisons based on extensions of the alignment method can begin to achieve useful classification. Another contribution of Ullman in the domain of

visual cognition concerns the visual analysis of shape properties and spatial relations. For example, judging whether an *X* lies inside or outside a closed arbitrary curved shape, which of two ellipses is most elongated, whether two dots lie on a common curve, etc., is notoriously difficult for artificial vision systems, while humans can make such judgments remarkably well. Ullman believes that the flexibility of human spatial perception and cognition depends on so-called 'visual routines,' efficient sequences of basic operations that are hardwired into the visual system. For different spatial tasks, different visual routines are compiled consisting of different sequences of the same basic operations such as shifting the processing focus, boundary tracing, and marking.

Ullman's most general contribution to the theory of high-level vision is his proposal for a general model of information flow in the visual cortex. At the heart of the model are a process (called 'sequence-seeking') and a structure (called 'counter-streams'). Sequence seeking is a search for a sequence of transformations that link an input image with a stored object description. It works in two directions, bottom-up as well as top-down, and it explores a large number of alternative sequences in parallel. Counter-streams are two complimentary pathways, an ascending one from low- to high-level visual areas and a descending one from high- to low-level visual areas. The basic idea is that bottom-up processing (starting from the input image) is performed in the ascending pathway and that top-down processing (starting from the stored models) is performed in the descending pathway. The interactions between the two complementary pathways support the integration of bottom-up and top-down processing.

With this model it is possible to match images and models by simultaneously exploring multiple alternatives instead of testing them sequentially. The model also does justice to many well-know anatomical and physiological facts about the visual cortex. For example, the visual cortex has a massively parallel architecture and descending or feedback projections are equally abundant as their ascending or feed forward counterparts. Finally, Ullman's model offers a detailed account of many well-known psychological findings such as priming, context effects, and perceptual learning.

2.3 Edelman (1999)

Another important theoretical step forward in high-level vision is Edelman's (1999) book on *Representation and recognition in vision*. Edelman argues that the attempt to base recognition on geometrically reconstructed representations of distal objects (like Marr's 2,5-D sketch) suffers from serious theoretical and practical problems. First, it would lead to the homunculus problem and, more pragmatically, it appears, at least up till now, not to work, not even when using the most sophisticated computer vision techniques. The major reason for this failure might be that previous approaches have tried to achieve veridicality of object representation by aiming for isomorphisms between objects in the world and their corresponding internal representations (i.e., first-order isomorphism or representation *by* similarity). Instead, Edelman proposes to aim for the formally just as good isomorphism between the relations among several external objects and the relations among their corresponding internal representations (i.e., second-order isomorphism or representation *of* similarity).

Edelman then introduces the notion of a shape space, a formalism borrowed from mathematical statistics. Shape space is a metric space in which each point corresponds to a particular shape and in which geometric similarity between shapes can be defined rigorously as proximity, a quantity inversely related to distance. Edelman argues that shape similarity can be made not to suffer from the objections commonly raised against a metric-space approach to similarity (e.g., arbitrary choice of features, context dependence, and asymmetries of comparisons; see also *Categorization and Similarity Models*). Although a large number of parameters is needed to represent distal shape space fully, fewer may be sufficient if, as in second-order isomorphism, only relations between objects must be represented (e.g., a blending coefficient when morphing the shape of a cow and a pig).

A novel shape (or a novel view of a previously seen shape) can be localized in shape space based on its similarity to known objects (or stored views of known objects). A tuned unit (or module of units) that responds optimally to some shape (i.e., the landmark) and progressively less to progressively less similar shapes is enough to implement this mechanism. Edelman uses a radial basis function approximation network that can be trained (see also *Artificial Neural Networks: Neurocomputation*) and generalizes its response from a series of given views of an object to other views of that object. As a byproduct of this learning, the network will also respond progressively less to progressively less similar objects, precisely what is needed for it to work as an active landmark in internal shape space. This scheme not only works for known objects but also for novel objects. The trick is that a new object must be represented by a vector of proximities to several reference shapes or landmarks. For example, even if one has never seen a giraffe before, it is possible to compute the proximities to known animals such as a camel, a goat, a pig, or even a leopard.

Edelman calls this system a 'Chorus of Prototypes' to stress that the prototypical landmarks act together in representing shape, in contrast to a winner-take-all scheme such as Selfridge's Pandemonium (see also *Statistical Pattern Recognition*). Initial simulation results with this system are encouraging, especially in

light of the wide variety of tasks: identification of novel views of familiar objects, categorization of novel object views, discrimination among views of novel objects, local viewpoint invariance for novel objects, recovery of a standard view and of pose for novel objects, prediction of a novel view for a novel object, etc. None of its theoretical competitors (Biederman's RBC, Ullman's alignment) can deal with this variety of tasks.

There is also considerable neurobiological and psychophysical evidence that is compatible with Edelman's system. In terms of neurobiology, Edelman discusses properties of the receptive fields at lower levels of processing (broad tuning and graded response) and at higher levels of processing such as inferotemporal cortex (for a review, see Logothetis and Sheinberg 1996): selectivity to objects, ensemble encoding (i.e., sparse distributed representations) selective invariance, plasticity and learning, and speed of processing (which is important because Chorus is essentially a feed forward model). In terms of psychophysics, Edelman discusses the evidence for the well-known effects of viewpoint on object recognition (see Sect. 2.1).

3. *Other Topics*

A number of other topics could be covered under the umbrella notion of 'high-level vision' but some are addressed more extensively elsewhere in this encyclopedia. Because faces are 'objects' with special significance, face perception has become a research topic of its own, somewhat isolated from more general object perception (see also *Face Recognition Models*). Indeed, some argue that faces are processed differently, even in a separate area in the brain (i.e., the so-called 'fusiform face area'), and subject to a specific disorder, prosopagnosia, after brain damage to this and surrounding regions (see also *Face Recognition: Psychological and Neural Aspects*).

A second topic of special interest, which could be regarded as belonging to high-level vision, is mental imagery, the ability to create mental images and operate on them in tasks requiring visual or spatial judgments in the absence of visual input (see also *Mental Imagery*, *Psychology of*). In his *Image and Brain*, Kosslyn (1994) has defended the analogue nature of mental images and the use of visual processing mechanisms in mental imagery tasks on the basis of classic psychological experiments and more recent neuroimaging evidence obtained with Positron Emission Tomography (PET) and functional Magnetic Resonance Imaging (fMRI). In addition, he has developed a detailed psychological and neuroanatomical theory of high-level vision, consisting of seven major subsystems: visual buffer, attention window, encoding of object properties, encoding of spatial properties, associative memory, information look-up, and attention shifting. Each of these components is worked out further into its more detailed operations and then localized neuroanatomically on the basis of neuropsychological case studies of brain-damaged patients with specific deficits and available evidence from PET and fMRI studies.

Two other topics of high-level vision, not addressed elsewhere in this encyclopedia, are picture naming and inattentional blindness. Picture naming has always been an interesting task for cognitive psychology because it obviously involves a number of distinct representations and processes. Traditional cognitive theories have proposed different so-called 'box-and-arrow' models to chart the intermediate representations and information flow between them, and traditional experimental methods have been used to test hypotheses derived from these models on the basis of performance measures like error rates and response times. More recently, as with mental imagery, the models have become more detailed and neuroanatomically specific thanks to neuroimaging and patient work (e.g., Humphreys et al. 1999).

In the typical experimental paradigm to study inattentional blindness (e.g., Mack and Rock 2000), subjects receive a rather demanding task at fixation (e.g., reading a small letter) while other visual stimuli are present in the visual field. When asked about the irrelevant (distractor) stimuli afterwards, subjects recall very little about them, except perhaps some basic features like color or orientation. In a more spectacular demonstration along the same lines, sudden changes to even large and central parts of a rich visual display like a colored picture of a scene, go unnoticed when attention is drawn away from the change. This so-called 'change blindness,' as well as the other forms of inattentional blindness, suggest that our conscious visual experience of the world is really quite limited, despite the illusion that it is rich and visually detailed. These phenomena constitute interesting examples of how visual attention, visual perception, visual memory, and visual consciousness interact with one another in everyday circumstances, but little theoretical progress has been made in understanding this intricate interplay of separate psychological functions.

4. *Conclusion and Future Directions*

In the area of high-level vision a number of trends emerge. One is the application of computational methods (previously applied with some success to lower-level visual processing) to higher-level visual processing. A second trend is the increased consideration of the neural basis of high-level vision. Theories about high-level vision should be constrained by what we know about their possible implementation in the brain on the basis of monkey work, neuropsychological studies with brain-damaged patients, and neuroimaging studies with healthy subjects.

High-level vision is an active area of interdisciplinary research and much progress may be expected yet.

Vision, Low-level Theory of

1. Introduction

The primate visual system comprises over 30 cortical areas in addition to the retina and other subcortical structures. To model the lower levels of form vision or motion perception, it therefore becomes necessary to develop neural network theories of retinal, striate, and extrastriate cortical function that are consistent with known anatomy and physiology and that are capable of predicting relevant psychophysical data. The mathematical techniques necessary for this enterprise include convolution and 'nonlinear dynamical systems' theory (see also *Self-organizing Dynamical Systems*). This article will review current theories of retinal and striate cortical function followed by a discussion of neural models related to areas 'V2' and 'V4' in the form vision hierarchy.

2. Theories of Retinal Function

Retinal neurons transform the optical image in order to extract biologically relevant visual information concerning light intensity changes in space (i.e. contours and edges), changes in time, and chromaticity. Furthermore, the retina must shift its operating point so as to signal useful information over more than a brightness range, a process termed light adaptation. These transformations are carried out by networks comprising at least five different types of neurons: photoreceptors, bipolar cells, horizontal cells, amacrine cells, and ganglion cells (see Wässle and Boycott 1991). As the extraction of color information is covered elsewhere (see *Color Vision Theory*), let us focus here on light adaptation and the extraction of contours.

Light intensities in natural scenes cover more than a 10^6 range, yet the ganglion cells providing the retinal output to the brain can only respond over about a 300:1 range. Thus, the retina must compute the mean level of illumination at any given time and adjust the circuitry to respond to about a 300:1 range around that operating point. Key experiments on retinal light adaptation have demonstrated that there are two major processes involved: one subtractive and one divisive (see Hood 1998). The direct path through the retina involves photoreceptors activating bipolar cells, which in turn activate ganglion cells. In addition the retina incorporates two major feedback loops: (a) from photoreceptors to horizontal cells then back to photoreceptors, and (b) from bipolars to amacrine cells back to bipolars. A recent retinal model has tentatively identified each of these loops with one of the light adaptation processes (Wilson 1997). In particular, loop (a) was conjectured to provide subtractive feedback, while loop (b) was suggested to be the site of divisive feedback. In a subtractive loop, the feedback signal is subtracted from the loop input, while in a divisive loop, the feedback signal divides the loop input signal thus reducing its gain. (More likely, each feedback loop incorporates both subtraction and division, suggesting a somewhat more complex formulation.) It is significant that both horizontal cells and the amacrine cells, the key units in these two feedback loops, have a relatively broad horizontal spread across the retinal surface and thus provide

feedback that is averaged over an extended area. Subtractive feedback is well understood in the context of linear systems theory, but divisive feedback moves into the realm of 'nonlinear dynamics'. Designating the bipolar cell response as B, the amacrine feedback response as A, and the light-derived signal received from the photoreceptors as L, the simplest divisive feedback equations are of the form (Wilson 1997):

$$\frac{\mathrm{d}B}{\mathrm{d}t} = -B + \frac{L}{1+A}$$
$$\frac{\mathrm{d}A}{\mathrm{d}t} = -A + B^N \qquad (1)$$

These equations may be analyzed using standard techniques (Wilson 1999) of nonlinear dynamical systems theory. In particular, one can solve for the steady state or equilibrium value at which $\mathrm{d}B/\mathrm{d}t = 0$ and $\mathrm{d}A/\mathrm{d}t = 0$. The results for very small and very large values of L are approximately:

$$B \approx L \quad \text{for} \quad L \leqslant 1$$
$$B \approx L^{1/(N+1)} \quad \text{for} \quad L \gg 1 \qquad (2)$$

Thus, at very low light intensity levels the bipolar response B is approximately equal to its input, so there is no attenuation of weak signals. At high light intensity levels, however, B is compressed to approximately the $(N+1)$ root of L. For $N = 2$, a physiologically plausible figure, the divisive feedback loop in Eqn. (1) will compress an $L = 10^6$ input into a $B = 100$ output, easily compatible with the response range of the ganglion cells. A further property of Eqn. (1) is that the temporal response becomes more transient as L increases (Wilson 1999), and this change is well documented in the literature on flicker sensitivity and light adaptation (Wilson 1997).

As is well known, retinal receptive fields have an excitatory center and inhibitory surround (or vice versa) spatial profile (see *Visual Perception, Neural Basis of*). Direct bipolar input to the ganglion cells produces the receptive field center, while the lateral spread of both horizontal and amacrine cells creates the antagonistic surround. Thus, the neurons engaged in light adaptation via feedback also produce the spatial surround of ganglion cell receptive fields. As is evident from the discussion above, divisive feedback has almost no effect at low light levels (Eqn. (2)), so one would expect receptive field surrounds to be very weak at low luminances but much stronger at higher luminances, and this has been demonstrated experimentally. For some simulation purposes the spatial characteristics of retinal receptive fields may be approximated as a circularly symmetric difference of Gaussians:

$$G(R) = A\exp(-R^2/\sigma_c^2) - B(L)\exp(-R^2/\sigma_s^2) \qquad (3)$$

where R is radius, and σ_c and σ_s are the space constants of the center and surround, respectively. The inhibitory gain $B(L)$ would vary from $B(0) \approx 0$ to $B(L) \approx A\sigma_c/\sigma_s$ for $L \gg 0$, which makes the integral of the receptive field $\int G\,\mathrm{d}R = 0$. For further discussion of retinal models see Wilson (1997) and Hood (1998).

3. *Theories of Striate Cortical Function*

Hubel and Wiesel (1968) categorized striate (V1) cortical cells as simple or complex (see also *Visual System in the Brain* and *Visual Perception, Neural Basis of*). Both of these cell types show a preference for a particular orientation and also for a range of spatial frequencies. The now classical model for a simple cell receptive field (RF) is just an oriented linear filter with parallel excitatory and inhibitory zones defined by horizontal (x) and vertical (y) coordinates:

$$RF(x, y) = A\left\{\exp(-x^2/\sigma_c^2) - \frac{\sigma_c}{\sigma_s}\exp(-x^2/\sigma_s^2)\right\} \times \exp(-y^2/\sigma_y^2) \qquad (4)$$

Equation (4) describes a vertically oriented receptive field, but other orientations (varying in about 15° increments between 0° and 180°) can be produced by coordinate rotation. Based on physiological data, $\sigma_y \approx 3.2\sigma_c$ produces appropriate orientation bandwidths. The activation $R(x, y)$ of a cortical array of simple cell receptive fields is produced by convolution:

$$R(x, y) = \iint_{-\infty}^{\infty} RF(x-x', y-y')\, I(x', y')\, \mathrm{d}x'\mathrm{d}y' \qquad (5)$$

where $I(x', y')$ represents the distribution of light in the image. Simulated neural responses are then produced by passing the results of Eqn. (5) through a nonlinear function exhibiting both a threshold and saturation such as the Naka–Rushton function

$$S(R) = \left\{\begin{array}{ll} \dfrac{MR^N}{\beta^N + R^N} & \text{for} \quad R \geqslant 0 \\ 0 & \text{for} \quad R < 0 \end{array}\right\} \qquad (6)$$

where M is the maximum response level and N $\approx$ 2–3 for cortical neurons. As $S(R) = M/2$ when $R = \beta$, β is referred to as the semisaturation constant. Dynamics may now be added to this formulation as follows (Wilson 1999):

$$\tau\frac{\mathrm{d}E}{\mathrm{d}t} = -E + S(R) \qquad (7)$$

where E is the excitatory firing rate and τ is the time constant for the rate of exponential approach to the asymptotic firing rate.

The simple cell model in Eqns. (4)–(7) can be used to generate complex networks of interconnected model neurons for simulations of cortical function (Wilson 1999). However, contemporary research indicates that orientation selectivity is more complex than this. In particular, the linear filtering in Eqn. (4) suggests that orientation tuning originates entirely from a linear superposition of nonoriented lateral geniculate (LGN) filters similar to that in Eqn. (3). While this was Hubel and Wiesel's (1968) original suggestion for orientation selectivity, the preponderance of evidence now supports additional factors in orientation tuning. First, convergence of as few as two nonoriented LGN filters conveys a modest orientation bias on cortical neurons. This very broad orientation bias is then sharpened considerably by two operations occurring in neural networks at the cortical level: contrast gain control and collinear facilitation (Sompolinski and Shapley 1997).

Contrast gain controls were first modeled by Heeger (1991) as divisive feedback operations. He suggested that the summed activity of many different oriented units provided a divisive feedback signal to each of the units in turn. The divisive feedback loop in Eqn. (1) can be altered to function as a cortical gain control as follows:

$$\tau \frac{\mathrm{d}E_\theta}{\mathrm{d}t} = -E_\theta + S\left(\frac{R_\theta}{1+A}\right) = \frac{MR_\theta^N}{\beta_\theta^N(1+A)^N + R_\theta^N}$$
$$\frac{\mathrm{d}A}{\mathrm{d}t} = -A + \sum_\theta E_\theta \qquad (8)$$

where θ designates the preferred orientation of each unit. Substitution of the Naka–Rushton function S from Eqn. (6) and rearrangement shows that this cortical divisive feedback circuit has the effect of scaling β by $(1+A)$. This network has been implemented and shown to sharpen cortical orientation tuning (Wilson 1993). Due to the dynamics of the network, this orientation sharpening evolves over time as the divisive feedback takes effect, and this has recently been shown to occur in most cortical neurons (Sompolinsky and Shapley 1997).

The final contribution to cortical orientation selectivity is provided by collinear facilitation (Sompolinsky and Shapley 1997). Recent evidence indicates that neurons with the same preferred orientation are interconnected if their receptive fields are situated on a common line defined by their preferred orientation. Such reciprocally linked receptive fields are typically separated by 1–2 receptive field lengths so that their mutual facilitation will only be triggered by stimulus edges of sufficient length. The excitatory connections are probably mediated by NMDA receptors so that both cells in a collinear pair must be independently activated by the stimulus for facilitation to occur. Obviously, collinear facilitation will sharpen orientation tuning when measured with extended lines or gratings. The function of collinear facilitation is to enhance the salience of extended contours, thus making them prominent candidates for further processing.

4. *Global Processes in Extrastriate Form Vision*

The complex cells of Hubel and Wiesel can be readily modeled by spatial pooling of simple cells with the same preferred orientation. More interesting are end-stopped complex cells, which are sensitive to both contour length and curvature. As illustrated in Fig. 1(a), an end-stopped complex cell can be modeled by full-wave rectification of simple cell responses followed by second-stage pooling using a 2–3 times larger version of the oriented filter defined by Eqn. (4). Full-wave rectification is mathematically equivalent to summing responses from both on-center and off-center simple cells that have the same spatial location and preferred orientation. The first- and second-stage filters in this filter–rectify–filter sequence usually have different preferred orientations, with the orthogonal case being illustrated in Fig. 1(a). The optimal line stimulus for this end-stopped unit will obviously be a horizontal line with length equal to the width of the second filter's excitatory zone as shown superimposed on the diagram. In addition to lines of fixed length, end-stopped cells will respond well to curves that are tangent to the preferred orientation of the first-stage simple cells, and they respond well to the orientation of texture boundaries (Wilson 1993). Although Hubel and Wiesel (1968) reported the presence of end-stopped neurons in V1, subsequent work by von der Heydt and Peterhans (1989) indicates that they predominate in the second visual area, V2.

Following V1 and V2 the cortical form vision pathway projects to V4, and finally to inferior temporal cortex (IT). Mean receptive field dimensions increase by a factor of approximately 2.5–3 from area to area within this pathway, reaching diameters of 10°–30° in IT. It was noted above that the receptive fields of end-stopped neurons must be approximately 2–3 times larger in each dimension than the simple cell receptive fields that provide their inputs in order to function optimally. Thus, the increasing receptive field size throughout the form vision pathway indicates that pooling operations are combining information over increasingly large areas. The nature of pooling in V4 was first investigated by Gallant et al. (1993). They studied macaque V4 responses to concentric and radial gratings as well as to conventional sine wave gratings. One subclass of neurons responded best to concentric gratings, while a second subclass responded best to radial gratings. Although many neurons responded to conventional sine wave gratings, few were optimized for these patterns.

Figure 1
Models of (a) an end-stopped complex cell and (b) a V4 concentric unit. The end-stopped cell (a) is produced by oriented simple cell filtering followed by rectification and subsequent filtering at a different orientation. The optimal bar length and orientation for stimulation of this unit is shown. The V4 concentric model in (b) builds upon the hierarchical theme in (a) by adding a final stage of configural pooling in which responses of a concentric array of end-stopped units are summed. The three stages of the V4 model are hypothesized to occur in V1, V2, and V4

Humans are extremely good at detecting concentric structure in glass patterns, and this results from concentric summation of orientation information over considerable regions (Wilson et al. 1997). A glass pattern is produced by randomly positioning pairs of signal dots such that each pair is oriented tangentially to the desired concentric structure. This produces a random dot pattern appearing to contain concentric swirls of dots. Furthermore, fMRI studies have shown that human V4 is more sensitive to concentric or radial gratings than to conventional gratings (Wilkinson et al. 2000). A quantitative model for V4 concentric receptive fields is depicted in Fig. 1(b) (Wilson et al. 1997). The initial two stages of the model are oriented simple cells followed by rectification and orthogonal second stage filtering. As mentioned above, these model end-stopped complex cells map onto V1 and V2 physiology, and they respond to curved contours that are locally tangential to the orientation of the simple cell filter. The final stage of the V4 model consists of linear summation ($\sum$) of concentrically arranged curvature information from V2. This represents an example of configural pooling, as each curvature response is pooled only if it arises in a spatial subregion of the receptive field consistent with the concentric global pattern. The final V4 receptive field size is approximately three times the diameter of its V2 subunits, thus conforming to the observed receptive field size increase in the form vision pathway. Similar V4 configural pooling models may be constructed to extract radial and other structures from the stimulus, and one challenge to future research will be an enumeration of configural pooling mechanisms.

What might be the function of V4 concentric units? Several observations suggest that they may be involved in the perception of faces and other ellipsoidal shapes. First, computer simulations have shown that model V4 units can detect faces in complex scenes (Wilson et

al. 2000). Second, fMRI studies have shown that the face-selective area in the fusiform gyrus responds not only to faces but also to circular or ellipsoidal contours (Wilkinson et al. 2000), thus supporting the hypothesis that analysis of head shape is a major ingredient in face perception.

5. *Perceptual Oscillations*

There are many instances of instabilities resulting in perceptual oscillations, two of the most common being the Necker cube and binocular rivalry. A third example is the Marroquin illusion in which a static, periodic dot pattern triggers the percept of flashing illusory circles (see Wilson et al. 2000). A Marroquin pattern is constructed by superimposing three square grids of dots, each rotated $\pm 60°$ with respect to one another. It is natural to conjecture that competitive interactions among V4 concentric units might be the cause of the illusory circles triggered by this stimulus. Indeed, there is physiological evidence that competition among V4 neurons forms a basis for spatial and object based selective attention (Reynolds et al. 1999).

A neural network model incorporating spatially regional competitive interactions among V4 concentric units can explain the illusory flashing Marroquin circles (Wilson et al. 2000). In this simulation V4 neural responses were represented by a variant of Eqn. (7):

$$\tau_E \frac{\mathrm{d}E_n}{\mathrm{d}t} = -E_n + \frac{100\, P_+^2}{(\beta + H_n)^2 + P_+^2}$$

where

$$P = S_{Marroquin} - k \sum_{n \neq k} I_k \exp\left(-R_{nk}^5/\sigma^5\right) \qquad (9)$$

$$\tau_I \frac{\mathrm{d}I_n}{\mathrm{d}t} = -I_n + E_n$$

$$\tau_H \frac{\mathrm{d}H_n}{\mathrm{d}t} = -H_n + g E_n$$

In these equations the input P to each neuron is the response of the V4 model in Fig. 1(b) to the Marroquin pattern, $S_{\mathrm{Marroquin}}$ minus a spatially weighted sum of inhibitory activity I_k generated by neighboring V4 neurons, the inhibitory neurons being driven by the E cells as described by the second equation. Parameters k and σ are respectively the gain and space constant of the inhibitory region. Mathematical analysis of equations such as these shows that one further ingredient is necessary for the network to produce limit cycle oscillations: the firing rate of active excitatory neurons must decline over time (Wilson 1999). Excitatory cortical neurons are known to contain slow hyperpolarizing currents that cause the firing rate to drop about threefold over the course of several hundred milliseconds, and this is incorporated into the mathematical model via the H or hyperpolarizing variable (Wilson 1999). The effect of this variable, governed by g, is to increase the semisaturation constant of any active E neuron, thereby reducing the firing rate. Simulations of this network provide a good quantitative explanation of the illusory flashing circles generated by Marroquin patterns (Wilson et al. 2000). Extensions of this work suggest that models analogous to Eqn. (9) can also explain oscillations and traveling wave phenomena in binocular rivalry.

6. *Conclusions and Future Directions*

The low-level vision theories developed here are based on nonlinear differential equations describing firing rates (rather than individual spikes) of retinal and cortical neurons. Large-scale neural networks incorporating these principles can now be used to simulate visual processing from the retina up to V4. Although this approach certainly represents but a first-order approximation to the underlying neural activity, it nevertheless provides a solid foundation for further progress.

Many issues, of course, remain to be addressed. Key among these is the ubiquitous cortical feedback: IT back to V4, V4 back to V2, etc. One conjecture is that these connections mediate a rapid dynamical optimization of the processing circuitry based upon initial feed-forward estimates of the stimulus being analyzed: a sophisticated example of a self-organizing system (see also *Self-organizing Dynamical Systems*). A second likelihood is that this feedback mediates both top-down influences on selective attention and figure-ground segmentation, which appears to involve extrastriate feedback to V1 (Lamme and Roelfsema 2000). The future promises a cooperative interaction between theory and experiment in elucidating these and many other exciting issues.

H. R. Wilson

Vision, Psychology of

Vision research began more than 100 years before experimental psychology was founded. Over the past 50 years there have been four major developments that have greatly increased our understanding of how vision works. The first was the appreciation of the role that internal noise and uncertainty plays in limiting visual performance. The second was the resolution of a century-long conflict between two theories of color vision. The third was the discovery that vision, like audition, performs a frequency analysis of the visual stimulus. And the fourth was the realization that there are many parallel streams of visual processing being carried out simultaneously and that different characteristics of the stimulus are analyzed by different modular mechanisms.

The purpose of vision is to provide us with information about objects in the world around us. This information is obtained from photons radiated from objects. When these photons enter the eye and are absorbed by photopigments in the photoreceptors, the resulting photoreceptor signals influence the activity of many processes, ultimately giving rise to the experience of seeing. Providing an incontrovertible definition of 'seeing' is not so easy. *Seeing* usually refers to the generation of conscious experiences through stimulation of the visual system by light. But visual experiences can also be generated as a result of direct electrical or chemical stimulation in the eye and at many locations in the brain. Conscious experiences are taken to mean experiences that can be verbally reported, although some experts find this definition too restrictive, and some find it too broad. Disagreement occurs because there is no clear definition of 'conscious' and 'consciousness.'

Vision involves four realms of human knowledge: the realm of physics (energy and matter); the realm of physiology, and especially neurophysiology (the behavior of the nervous system); the realm of overt behavior (what people say and do); and the realm of the mind and subjective experience. A complete understanding of vision necessarily involves the understanding of these realms and their interactions. In this essay, however, we will focus on the psychological mechanisms that make up the mind. The characteristics of these mechanisms cannot be determined by direct observation but must be inferred from the outcome of appropriately designed experiments.

1. The Role of Uncertainty

1.1 Physical Nature of Light

Light is electromagnetic radiation. It exists in discrete packets of energy called quanta, or photons. Quanta cannot be subdivided, and consequently light always consists of an integer number of quanta. Quanta differ from each other in the amount of energy they contain. Quanta may also be quantified by two other properties that are directly related to the energy: frequency and wavelength. The energy, frequency, and wavelength of a quantum are interrelated by two fundamental equations: $E = h\nu$ and $c = \lambda\nu$, where E is the energy in Joules, h is Planck's constant, ν is frequency in cycles per second (Hertz), λ is wavelength in meters, and c is the speed of light in a vacuum. A single quantum therefore has only one unique characteristic, which may be described as energy, frequency, or wavelength.

Light sources are characterized by the distribution of quanta that they produce. Hot sources produce broad spectral distributions, while some sources (lasers, for example) produce only a single wavelength. When a quantum from a source strikes matter (gas, liquid, or solid), one of three things occurs to the quantum: it is reflected from the surface; it passes through the medium; or it is absorbed and its energy is transformed into heat. The probability that a quantum is reflected, transmitted, or absorbed depends on the energy of the quantum and the physical properties of the material. The distribution of quantal energy from a source is therefore modified by the material with

which it interacts. The human eye takes in quanta from sources, and quanta reflected from or transmitted through objects, and forms an optical image on the retina at the back of the eye.

1.2 Beginnings of Vision

Vision begins when photoreceptors in the retina absorb quanta of light and generate electrochemical signals. Collectively, the human photoreceptors can absorb quanta in the narrow range of wavelengths from approximately 400 to 700 nm ($1\,\text{nm} = 10^{-9}$ meter). The probability that a photoreceptor will absorb a quantum varies as a function of quantal wavelength, with a maximum probability occurring at a specific wavelength, λ_{max}. There are four types of receptors: one rod and three cones. The receptor types differ in their absolute sensitivity (rods are more sensitive than cones), and in their relative sensitivity, to different wavelengths. Rods have a λ_{max} at 510 nm, while the three cone types have a λ_{max} at approximately 420 nm (S-cones), 530 nm (M-cones), and 560 nm (L-cones). The normalized sensitivity of each receptor is plotted as a function of wavelength in the upper panel of Fig. 1.

Photoreceptors signal the rate at which quanta are being absorbed. They do not and cannot signal the wavelength of the quanta that are absorbed. The voltage change that occurs in a receptor when a quantum is absorbed is independent of the wavelength of the quantum. This important principle is known as the 'Principle of Univariance.' The visual system operates over a physical intensity range of 10^{12}. The upper limit of 10^6 is equivalent to a white cumulus cloud illuminated by the noonday sun. The range from 10^6 to 10^{-2} is handled by the cone receptors and is called photopic vision. The lower part of the whole range, from 10^{-2} to 10^{-6} is handled by the rod receptors and is called scotopic vision. The intensity of 10^{-2}, the boundary between photopic and scotopic vision, corresponds to the illumination provided by the full moon. The lowest level at which rods function is about 100 quanta of 510 nm light striking the front of the eye. The minimum amount of energy for detecting each wavelength with the scotopic and photopic systems is plotted in the lower panel of Fig. 1. The difference between the energy needed for photopic detection and that needed for scotopic detection is called the photochromatic interval. At short wavelengths, scotopic vision is much more sensitive than photopic vision, but at long wavelengths the two systems are equally sensitive.

1.3 Internal Representation

The component of the mind called 'the sensory processes' builds internal representations of the external world by transforming physical stimulation into internal activity. This activity plays an important role in shaping the final representation, but memory, attention, and motivation also influence the final outcome. The internal representation is not simply the physical stimulus in a new form. To equate the stimulus with the sensation that it produces is to make the so-called *stimulus error*. Light, as a physical phenomenon, has no color: it has wavelength distribution and intensity. Color is produced by chromatic mechanisms in the sensory processes, and there are many wavelength combinations that give the same color (see Sect. 1.4).

1.4 Uncertainty

Internal representations are characterized by uncertainty. This uncertainty derives from many sources but originates in the quantum nature of matter and energy. If short flashes of weak light are used in a vision experiment, it is not possible to know exactly how many photons of light are delivered to the eye on each trial. This uncertainty stems from the random nature of photon generation. The probability of obtaining a specific number of quanta on a flash can be computed using the Poisson probability distribution if we know the average number of quanta delivered to the eye on each flash:

$$p(x) = \frac{e^{-\lambda}\lambda^x}{x!} \tag{1}$$

where x is an integer number ranging from 0 to infinity and λ is the mean number of photons per flash. On some presentations of these stimuli there will be many photons, and on some there will be few, and on some there will actually be zero photons. This uncertainty in the physical stimulus combines with the inherent uncertainty of the many neural synapses and processes involved in constructing internal representations. The result is that the internal representation is not a fixed quantity but fluctuates with time. It is therefore necessary to represent internal representations by probability distributions rather than fixed quantities. The most common one is the Gaussian probability distribution, which is specified by a mean, μ, and a standard deviation, σ:

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-0.5((x-\mu)/\sigma)^2} \tag{2}$$

The use of Gaussian probability distributions to describe internal representations has a long history that began with Gustav Theodor Fechner's landmark book *Die Elemente der Psychophysik* in 1860. It was

Figure 1
The normalized absorption functions of the rod and three cone photopigments (upper panel), and the minimum stimulus intensity for detection by the scotopic (rod) visual system and for the photopic (cones) visual system (lower panel)

Figure 2
Five psychometric functions from the three authors of the classic 1942 experiment by Hecht, Shlaer, and Pirenne. The smooth functions on the left are the psychometric functions predicted by assuming that internal representations of the stimuli are Poisson probability distributions and that the observer needs a fixed number of quanta or more in order to say 'yes'

assumed by Galton when he introduced percentile analysis in 1885 and became more widespread in the early twentieth century through the writings of Thurstone and Urban. Signal detection theory, developed in the 1950s, has introduced this use of probability distributions to a much wider range of applications.

1.5 Psychometric Function

The most immediate consequence of noisy internal representations is that there is no single stimulus intensity above which one will always see a stimulus and below which one will not see it. Rather, as stimulus intensity is increased, the probability that an observer will say that the stimulus is visible increases. This relationship between the probability of a response and the stimulus intensity is called a *psychometric function*. Psychometric functions are S-shaped (ogive) when stimulus intensity is plotted on a logarithmic axis, as is illustrated at the right side of Fig. 2.

The psychometric function is a powerful tool for inferring the properties of the sensory process and the internal representation. In 1942, Hecht, Shlaer, and Pirenne sought to answer the question 'how many quanta have to be absorbed by rod receptors in order to say "yes, I saw the stimulus"?' Since the processes of generating quanta and of absorbing quanta are described by Poisson probability distributions, and since the theoretical Poisson psychometric functions have shapes that depend on the number of quanta required to 'see' (smooth curves on the left side of Fig. 2), and since only a fraction of the quanta striking the cornea of the eye get absorbed by photoreceptors (quantum efficiency), both the number of quanta required for seeing and the quantum efficiency may be estimated by finding the theoretical psychometric function that best fits the observed psychometric functions. In Fig. 2, the data of Hecht, Shlaer, and Pirenne have been shifted to the left by an amount corresponding to the quantum efficiency of each observer so that the data coincide as well as possible with a Poisson psychometric function. Each set of data fits extremely well with one, and only one, of the theoretical Poisson functions. It is concluded that from four to 10 quanta are needed, and that the quantum efficiency is about 5 percent.

How one interprets the probability distributions depends on the model of the detection process one adopts. All models of detection have a sensory process and a decision process. One widely held, but now thoroughly discredited, model of the sensory process is the high threshold model, in which the sensory process has a threshold that must be exceeded by the stimulus before the sensory process generates an internal representation of the stimulus. With such a model, the psychometric function represents the integral of the underlying probability distribution of the fluctuating threshold values.

The decision process of the high threshold model says 'yes' on test trials where an internal representation was generated and says 'yes' when no representation was generated by guessing some of the time. In order to estimate the guessing rate, experimenters introduced two types of detection trials: those in which a stimulus was presented (signal trials) and those without any stimulus (blank trials). Performance on such a detection task requires two measures to characterize it fully: the hit rate (probability of saying 'yes' when the signal is present); and the false alarm rate (probability of saying 'yes' when the signal was absent). The relationship between the hit rate and the false alarm

Figure 3
Three variations of the dual-Gaussian, variable-criterion signal detection model. The Gaussian distributions are the internal representations generated by the sensory process. The vertical lines are the decision criteria used by the decision process to generate responses. Upper panel: single criterion generates two detection responses. The insert shows the receiver operating characteristic (ROC). Middle panel: four decision criteria generate five responses expressing confidence that the signal was present. Lower panel: four decision criteria and five different stimuli

rate as the decision process changes its decision strategy is called the receiver operating characteristic (ROC). The high threshold model predicts that the ROC will be a straight line, illustrated on the ROC inserted in the upper panel of Fig. 3. Hit rate–false alarm rate pairs from actual experiments in which decision strategy is manipulated form a bow-shaped ROC, shown in the upper panel of Fig. 3 by the nine filled circles. The fact that the high threshold model fails to predict the correct ROC is one reason it has been rejected as a viable model of the sensory process.

The widely accepted replacement for the high threshold model is the signal detection model. The sensory process of this model has no sensory threshold

Figure 4
Two forms of the psychometric function of the sensory process derived from the signal detection model. The upper panel shows that stimulus detectability increases as a linear function of log stimulus intensity. The lower panel shows that the classic S-shaped psychometric function is obtained when the area under the ROC is used to characterize the sensory process. The inserts show the ROC for each stimulus intensity

and is always generating an output even with no stimulus: any nonzero stimulus adds to this output. The decision process uses one or more decision criteria to decide what response to generate. The ROC predicted by the dual-Gaussian, variable-criterion signal detection model is plotted as the smooth curved line in the insert in the upper panel of Fig. 3 and provides an excellent fit to the data.

Three variations of the Gaussian model are illustrated in Fig. 3. Two measures of sensory process sensitivity are widely used: the distance between the mean of the no-signal distribution and the mean of the signal distribution, d_a, and the area under the ROC generated by the two distributions, A_z. The model in the bottom panel of Fig. 3 describes detection data from an experiment in which on each trial an observer was presented with one of five visual targets, each of different intensity, or no stimulus at all. The observer rated their confidence that a visual target had been presented. The ROCs for detecting these stimuli are shown in the inserts on the graphs of Fig. 4. As stimulus intensity increases, the ROC for that target becomes increasingly bowed. The psychometric function of the sensory process is formed using either d_a or A_z (Fig. 4), since in the model they represent the sensitivity of the sensory process to the stimuli. The variability contributed by the decision process to actual performance is effectively removed.

In the past 20 years, the application of the signal detection model of noisy internal representations has been expanded well outside its humble beginnings as a model of the sensory and decision processes of vision and audition. Fields in which this model has been shown to provide extremely good descriptions of observed data include recognition memory, medical diagnosis, weather forecasting, lie detection, clinical evaluation, drug detection, releasing prisoners on parole, and computer-guided decision making.

2. *Color Vision*

The field of color vision has been marked by controversy and conflict that began with Isaac Newton's discoveries about the nature of light and of color mixing published in his *Opticks* (1704). By the end of the nineteenth century, two theoretical camps had formed: one based on the ideas of Thomas Young and Hermann von Helmholtz; and the other grounded on the ideas of Ewald Hering and Johann Wolfgang von Goethe. Helmholtz argued that colors are created by the pattern of activity of three types of photoreceptors, each generating a specific color: red, green, and violet (the trichromatic theory). The Hering camp held that there were three processes that generated opponent pairs of colors: red–green, yellow–blue, and black–white (opponent process theory). These two seemingly incompatible theories coexisted for almost 100 years.

The simple resolution came in the late 1960s with the demonstration that each theory described only part of the color vision process. A complete theory of color vision having a Helmholtz component and a Hering component was published by Hans Vos and Pieter Walraven in 1972. To understand the resolution of this conflict, one must carefully distinguish between color matching and color appearance.

Two colors form a metameric match when, in spite of different wavelength composition, they appear identical and indistinguishable in a side-by-side comparison. For people with normal color vision, all colors can be matched by mixing three suitably chosen primary lights. There are many possible primaries: the only constraint is that each of the three primaries cannot be matched by a mixture of the other two. This restriction means that one of the primaries will be reddish, one will be greenish, and one will be bluish. All colors can be specified by the amounts of the three primaries that are needed to match them. The specifications based on one set of three primaries can be changed into any other set of three primaries by simple linear transformation.

When lights are mixed, the amount of the three primaries required to match the mixture is the sum of the amounts of the primaries required to match the individual components of the mixture. This linearity of color matching is remarkable and occurs because the receptors act like quantum counters. Two lights will match if the S-, M-, and L-cones absorb exactly the same number of quanta per second when exposed to the one light as they do when exposed to the others. The three receptors form the Helmholtz zone and govern color matching.

In the above discussion of color matching, no mention was made about the color *appearance* of the match. This omission is deliberate, because color appearance is not caused directly by cone activity. Visual sensations vary along three fundamental dimensions: hue, saturation, and brightness.

Brightness and saturation are so-called *prothetic* dimensions: they can be rank ordered from least to greatest (Stevens 1951). For example, white is brighter than gray, which is brighter than black. Hue is a *metathetic* dimension: different hues cannot be rank ordered from least to greatest; one cannot say that red is greater than green, it is just different. Color appearance is generated by the activity of two chromatic opponent mechanisms and one luminance mechanism. Each of these mechanisms receives input from the three cone types. The red–green chromatic mechanism can generate red or green experiences but not both at the same time. The yellow–blue chromatic mechanism can generate yellow or blue experiences but not both at the same time. In normal color vision, the hue and saturation of a color experience is determined by the joint activity of these two chromatic mechanisms. A color can be reddish-blue but not reddish-green. A color can be yellow-green but not yellow-blue.

The chromatic mechanisms function by comparing the weighted activity of one cone type with the weighted activity of the other two cone types. The cones' connection to the chromatic mechanisms and to luminance are estimated to be (from the work of John Werner and Billy Wooton (1979a, 1979b):

$$(+r-g) = 1.89\ LCone - 2.79\ MCone + 0.45\ SCone$$

$$(+y-b) = (0.94\ LCone + 0.21\ MCone)^{1.65} - 1.65\ SCone$$

$$Luminance = 0.85\ LCone + 0.15\ MCone + 0.015\ SCone$$

There are two important points to be noted: the S-cones make almost no contribution to luminance and to the red–green chromatic mechanism; and the yellow–blue mechanism is nonlinear. The activity of the chromatic mechanisms in one part of the visual field is altered and influenced by the activity of the mechanisms in spatially adjacent areas. A 'neutral gray' test patch will appear greenish when surrounded by a red field.

It is common to read in introductory textbooks that the color opponent processes are located in the ganglion cells of the retina. A careful analysis of the chromatic properties of chromatically sensitive ganglion cells, however, reveals that although many retinal ganglion cells show opponent characteristics by inhibiting their activity to some wavelengths and exciting their activity to other wavelengths, their actual properties do not match those required for the Hering zone chromatic mechanisms. The way the brain actually creates the chromatic mechanisms involves both retinal and cortical mechanisms.

3. Spatial and Spatial Frequency Analysis

Visual stimuli may be described quantitatively in two quite different but interchangeable ways: in terms of spatial features, or spatial frequency content. Simple spatial features are, for example, the diameter or height and width of a target, typically measured in degrees of visual angle on the retina of the eye. Description of more complex stimuli, such as letters of the alphabet or human faces, have feature sets to measure the properties of these stimuli. In the early 1950s, the powerful engineering methods of linear systems analysis were introduced into vision. Linear systems analysis characterizes systems by the degree to which sine wave stimuli of various frequencies are passed through it: the modulation transfer function (MTF). In vision, a physical stimulus does not pass through the observer but is transformed into an internal representation; but by finding the amplitude of a sine wave frequency that will give rise to a constant internal effect (a constant level of detectability, for example) investigators approximated the MTF of the human visual system using the modulation sensitivity function (MSF), or equivalently, the contrast sensitivity function (CSF). A typical photopic contrast sensitivity function is plotted in Fig. 5.

Figure 5
Contrast sensitivity function. Sensitivity is the reciprocal of the contrast required to detect a sine wave pattern at a fixed level of sensory process detection performance, $d_a = 1.0$. The individual solid lines show the sensitivity of underlying Gabor mechanisms tuned to subsets of the whole spatial frequency range to which the human visual system is sensitive

In the late 1960s, Fergus Campbell and colleagues at Cambridge University reported in two landmark papers that visual detection of complex grating patterns was better predicted by their spatial frequency properties than by their spatial properties (e.g., Campbell and Robson 1968). There ensued an intense period of research investigating the spatial frequency properties of stimuli (as computed by means of the Fourier theorem and transform) and their relationship to various aspects of visual perception. There was also intense debate about whether the visual system carried out a spatial analysis or a spatial frequency analysis of the retinal image.

The controversy was resolved in 1980, when John Daugman (1980) and Stephan Marcelja (1980) pointed out that cells in the visual cortex had spatial-response properties that closely resembled so-called Gabor functions. Denis Gabor had proved in 1946 that products of Gaussian envelopes and sine and cosine waves were optimal for minimizing the joint uncertainty of specifying location in space and spatial frequency simultaneously. Numerous experiments that followed these two papers found that the visual

system carries out a simultaneous spatial and spatial-frequency analysis of visual input by means of mechanisms that are like Gabor functions. Thus, the visual system has developed an optimal way of carrying out a spatial analysis and a spatial-frequency analysis simultaneously.

4. Modular Processing

The second discovery of the landmark Campbell papers was that the entire span of spatial frequencies to which the visual system responds (see Fig. 5) is handled by numerous mechanisms, each tuned to a different and smaller subrange of spatial frequencies. The mechanisms that detect high spatial frequencies act independently from the mechanisms that detect lower spatial frequencies. The spatial-frequency tuning properties of a few of these mechanisms are also shown in Fig. 5. Each of these mechanisms is also tuned to a narrow range of contour orientation. To cover the range of spatial frequencies and orientations to which we are sensitive requires approximately 90 different mechanisms at each area of the retinal image, each tuned to a specific range of frequency and orientation.

The idea of modularity of visual processing, with different mechanisms analyzing different properties of the visual input, is at the heart of our current concept of the visual system. In fact, based on both anatomical and psychophysical evidence, we seem to have two visual systems, the M-pathway and the P-pathway (named after the magno- and parvo-cellular layers of the lateral geniculate nucleus). These two systems carry quite different kinds of information from the retina to the brain. The M-pathway, the older of the two, has high-contrast sensitivity but low spatial resolution. It carries no color information but does carry information about motion and depth and responds rapidly to visual stimulation. The P-pathway has high spatial resolution, but responds slowly and has lower spatial resolution. The P-pathway carries color information encoded in an opponent-process manner.

5. Summary

A complete understanding of vision involves an understanding of physics, physiology, behavior, and the mind. At its simplest, the mind contains a sensory process that converts external physical stimuli into an internal representation and a decision process that uses information available in the internal representation to make decisions about what to say and what to do.

Four major advances in the psychology of vision took place in the last half of the twentieth century. The first is the recognition that the internal representation is noisy and unreliable, which has led to the development of powerful models and methods to deal with the resulting uncertainty. The second has been a resolution of the battle between two conflicting theories of color vision by combining both into a single unified theory. The third development has been the discovery that vision, like audition, carries out a frequency analysis on the visual input. Unlike audition, however, it carries out a simultaneous spatial analysis and does it in the theoretically most efficient way. The final advance has been the appreciation that in the early stages of visual processing different types of information are handled by different types of mechanisms, producing a modularity of visual processing.

Visual Anthropology

1. Definitions

No short phrase will catch the two main streams of thought and practices which 'visual anthropology' implies. One sense refers to attempts to communicate anthropological observations and insights through photography, film, and video. In this sense, many early anthropologists who used these media were practicing forms of visual anthropology before the approach had been made explicit. Margaret Mead and Gregory Bateson used cine film and still photography as central to their studies of culture and personality, and later Jean Rouch and Timothy Asch both filmed extensively and argued for the recognition of film in anthropology. John Collier did the same for photography, as did Paul Hockings, for both mediums, working to formalize the importance of such contributions to academic and humanistic anthropology.

The second definitional approach to visual anthropology is more recent and is concerned with the understanding of visual systems in cultures and societies. It shares common concerns with the *anthropology of art* and with *technology and material culture*. By convention, the subject of literacy and its significance has not been prominently included within visual anthropology, but is normally discussed in wider debates about the transition from the neolithic to large-scale states and empires, and debates about power, hierarchy, and authority. Although visual anthropology is of increasing interest to students, and younger academics, it as yet shows few signs of making serious inroads into the hegemony of classical political economy and other mainstream concerns. The approach claims that special attention to visual systems may lead to reassessment of mainstream assumptions and analytic givens. 'Understanding visual systems' can be broken up into three related elements.

First, the study of the significance of visual perception in human cognition, generally: how far do humans, as a species rely on what is seen, and how do they integrate what they see into their deeper and wider understandings and practices? Psychologists have studied the dominance of one sense over another in experimental situations; anthropologists are increasingly interested in nonlinguistic and prelinguistic cognition, some of which depends in part on visual perception, and are more interested in psychological work than they have been for many years. In any specific society, how great a part do visual symbols, signals, emblems, and sign systems play in the construction of social order? Traffic lights, national flags, systems of body modification, ritual objects, house styles, animal and plant classifications are clearly all necessarily dependent on visual information. How important is this? Do systems of visual signification have any autonomy from the cultural and international systems in which they are necessarily situated?

The second element in this approach concerns the significance of the visual in any particular society or civilization and, related to this, how a given history affects the use made of a visual technology, such as photography. Do some societies place a much greater emphasis on the visual communication of knowledge,

and religious truths than do others? It has been suggested, for example, that in particular societies, the young learn how to do things, particularly artisanal production, by watching experts at work, rather than by explicit verbal and conceptual instruction. How far are singing, dance styles, facial expressions, body postures, clothing forms and usages, the whole range of physically performed elements of cultural behavior, deeply and implicitly shaped by visually led cultural learning? Are there austerely 'unvisual' societies in which speech 'leads' and visibly performed action is less strongly marked? Once, industrial societies relied on reading, memorizing, classroom and radio listening for knowledge transfer, but now television and digital memory storage are major inputs into many lives. What difference does this shift in culturally packaged techno-learning make?

The third element concerns what is broadly termed issues of (visual) representation. The word *represent* has several senses—to bring something into existence, to make visible, to exhibit or reproduce an action, or a person, as upon the stage, to take the place of something, and to stand as an example of something. French anthropology, through the work of Durkheim and Mauss promoted the idea of rituals as 'collective representations,' but the term influenced visual anthropology more through Edward Said's *Orientalism*: 'The idea of representation is a theatrical one: the Orient is the stage on which the whole East is confined. On this stage will appear figures whose role it is to present the larger whole from which they emanate. The Orient then seems to be not an unlimited extension beyond the familiar European world, but rather a closed field, a theatrical stage affixed to Europe' (Said 1978, p. 63). The paragraph goes on to list some of the stock characters on this stage including the Sphinx, Cleopatra, Babylon, Babel and Mahomet. Said's deeper concern is with the production of reductive, and often negative stereotypes of peoples and cultures. Simply put, then, the issue of representation in visual anthropology has become a many-sided discussion of how far a painting, a postcard, a photograph, a film, a video, can be understood to have reasonably and sensitively portrayed the persons or issues with which they are concerned. A good starting point is Roland Barthes' account of his difficulty in finding a photograph of his mother which really did justice to his memories of her. A sensitive discussion of more impersonal representation issues in film-making appears in Ruby (1991): ownership, collaboration, informed consent, censorship, and the right to make representations of other people are searchingly discussed.

2. *Intellectual Contexts*

Visual anthropology can be said to begin when, in the middle of the nineteenth century, photographs are first used as ethnological records of human diversity, as images of colonized peoples for the appreciation of metropolitan publics, and, before long, for portraiture by all, metropolitan or colonial, who had access to the technologies. We discuss these issues in more detail below. However, in the modernist sense, visual anthropology could, and perhaps should, begin with a consideration of all visual systems employed in depicting human action, before photography became a dominant mode. This implies a discussion of the cave drawings, etchings, woodcuts, lithographs, paintings, and many other forms of image employed in early African, Arab, Chinese, European, Hindu, Japanese, Moghul, and many other sources, whenever faced with the task of communication of cultural differences. As yet, such interests are mainly pursued by archeologists and historians of art, but their preoccupations are inevitably somewhat different from those of anthropologists. Not only would illustrations in texts be of interest, but so would objects used in ritual, and the decorations of objects in daily use.

Visual anthropology has in fact developed differently. First, there has been the practical use of photographs from 1860 to the twenty-first century at first untheorized, taken-for-granted as unproblematic additional field research tools. The second component has been an interest in the use of film as a scientific recording medium. In the 1950s and 1960s, articles started to appear which argued forcefully for the importance of 'ethnographic film' as a complementary field research tool for mainstream anthropology. This approach was summarized in Hockings (1995). In the spirit of recording for posterity, several large collections of ethnographic film were created (see below). The third major development, in the 1980s, was a growth of intellectual interest in how photography had been used by anthropologists in the colonial period. In the 1990s, visual anthropology includes many new areas for inquiry, and there is increasing boldness in its claims to raise questions ignored by visually nonliterate, concept-fixated anthropologists.

3. *Photography*

The first great achievement of scholars engaging with photography has been to reverse the truism that 'Every picture tells a story' so that it reads 'Every picture needs its history.' An example is H. L. Seneviratne's essay on a photograph taken at the Temple of the Tooth, Kandy, Sri Lanka (then Ceylon), at some point between 1870 and 1900. The photograph shows the Temple building, with three monks in the top right-hand corner, looking down upon a circle of some 30 persons, many of whom are monks in positions for formal reverence grouped around a table, at a lower level. The author argues that what is visually central in the photograph is in fact politically and semantically peripheral. The author is able to identify the 'central'

figures as numerous Burmese monks, and the three elevated ones as Sri Lankan monks, dressed relatively casually. The fact that an electric light fitting is visible helps date the picture. However, the analysis raises serious doubts about the probability that the object on the 'central' table is the Sacred Tooth relic which the ritual postures of the 'central' monks seems to imply. Three reasons are offered: first, a lack of supporting attendants; second, the relative simplicity and austerity of the table on which the objects are displayed; and third, the Relic is never brought down from the higher level of the building. Seneviratne concludes 'The occasion of the picture thus represents a variety of possibilities, the more so for want of precise information' (Edwards 1992, p. 156). It should be noted that this analysis depends on significant historical knowledge external to the photograph itself: every photograph is historical from the moment it has been taken, and every photograph needs its historian.

The second achievement has been to question implicit realist assumptions about how photography 'works.' That the camera permitted 'stern fidelity' and 'penetrating certainty' (Pinney 1997) was a dominant assumption of many European colonial photographers. Pinney suggests that one use of the camera in colonial India was linked to the task of ethnological classification: photographs were taken of exemplary 'representatives' of cultural groups. Faces, clothes, hair-styles, and adornments were held to characterize named castes and ethnic groups decisively. Foucault's concern with definitive classification and state surveillance helps us see that the evidential fingerprint and the police arrest photograph are inherently realist, too. However, Pinney also describes the enthusiasm with which elite Indians under British rule took up this European invention and developed it for their own purposes, at first employing European conventions of formal portraiture. He also shows how some early British photographers in India used portraiture in a more sensitive way than Foucault's focus would allow, with empathic regard for the qualities of the person portrayed.

The third achievement is to identify specific 'ways of seeing.' Pinney's account of how contemporary Indian villagers in Nagda, Madhya Pradesh, use photographs is illuminating. They opt for portrayals of persons not 'as they are,' spontaneous, informal, and unadorned, but rather 'formalized and theatrically staged images … are most desired.' This may include adorning a photographic image with watercolors, the juxtaposition of a villager with a famous film star, palaces or temples as backgrounds, or wearing special clothes as if a rajah, a bandit, a warrior, or a princess. The 'Indian Eye' is not primarily a naturalistic eye but is concerned to make 'traces of the person endure, and to construct the world in a more perfect form than is possible to achieve in the hectic flow of the everyday' (Pinney 1997, p. 149) (see also the film by David and Judith MacDougall, *Photowallahs*, 1991).

4. *Ethnographic Film*

Film was used by ethnologists as early as 1898, and although travelers and ethnologists continued to make filmed records of native peoples, such material hardly received serious anthropological attention until the 1950s. Enthusiasts for film tended to stress its assumed objectivity and its capacity for contributing to anthropology as a behavioral science, and fitness for tasks of ethnographic salvage, conserving records of rituals, techniques, and practices among peoples threatened with extinction or radical transformation. Certain film makers in the naturalistic documentary tradition undertook large-scale filming projects among particular peoples, such as Ian Dunlop's work with members of the Mandjindjara and Ngadajara groups in the Australian Western Desert, and his subsequent work with the Baruya of East Highlands, Papua New Guinea, Timothy Asch's collaboration with Napoleon Chagnon, among the Yanomami, Christopher Curling and Melissa Llewelyn-Davies' work among the Loita Maasai in Kenya, David Turton and Leslie Woodhead's films among the Mursi of southwest Ethiopia, and some of Jean Rouch's work among the Dogon and Songhay of West Africa.

Such attempts to film naturalistically and objectively, for the historical or archival record, were soon challenged by a different approach, in which the aims were not scientific, but more exploratory, celebratory, observational filming without authoritative commentary, and with a sense of intimacy between film makers and subjects. This has been described as 'participatory' or 'collaborative' cinema (MacDougall 1998) in which the film maker's aim was to allow the personal qualities of individuals to be conveyed, as well as characteristic themes and emphases from the particular society in which they lived. It also encourages what has been termed 'reflexivity' (Ruby 1980), in which the film maker made the intellectual premises on which the film was being made transparent to the audience.

This approach required a decisive break with any suggestion that films were made by detached, all-seeing, and all-knowing scientists presenting 'objective truths' about those filmed. 'Reflexivity' was sometimes understood superficially to mean that the film-makers should introduce themselves and the filming project as the framework within which the film developed. While some anthropological film-makers still work in the observational tradition, more experimental forms of narrative are gaining adherents.

5. *Changes in Emphasis and Future Developments*

Visual anthropology has been influenced by the wider theoretical changes which have affected mainstream anthropology in North America, and Europe—skepticism about objectivity, successive impacts of French structuralism, Marxism, feminism, and post-modernism upon choice of subjects and their treat-

ment. The simplest way to sum up the current state of thinking is to say that visual anthropology, like mainstream anthropology itself, is becoming ever more inclusive, in several different senses.

First, there is an inclusiveness of subjects for description and analysis. As the world continues to change under the impact of global technology transfer and market forces, so new social relations and new social issues emerge, and classical assumptions need reconsideration. Labor migrations and the formation of diaspora communities who keep in touch with their recent origins by cheap air travel, the telephone, and the internet are examples. The wedding video, enthusiastically adopted in India, as in Europe, represents a new field of study, and the styles, the emphases, the inclusions and exclusions, and the contexts of use and reuse are being described and analyzed. The consumption of media products, particularly television soap operas, and national cinema productions are attractive to visual anthropologists because they tend to miniaturize and bring into relief deep cultural themes, and this is doubly the case when the diffusion, both positive flows and negative obstructions, can be included. For example, Greek Cypriots who in the 1970s were likely to watch Greek and Turkish fiction films and US-originated soap operas, in the 1980s started to favor a Mexican soap. In the UK, Australian soaps aimed at teenagers are now more successful than US ones. In Africa, Hindi films were once much viewed, and Australian Aboriginal peoples have enjoyed Kung-Fu films.

Second, the inclusiveness involves what has come to be termed 'indigenous media' activity. This takes several forms. First, there are broadcasting systems run by and for ethnic minorities. Australia and Canada have led the way in these matters, with aboriginal peoples producing local materials in their own languages, to celebrate cultural survival and resistance to national cultural impositions of uniformity. Indigenous media may show films by ethnic minorities to promote their political interests in the face of national systems. Thus films about land rights and the connection between a group and their territory through ancestral religious cults are prominent, as are films celebrating the tribal past, documenting the tribulations of previous generations, and movements for revitalization.

Third, indigenous visual anthropologists came forward to 'speak about' (make films about) cultures with which they are intimately connected by various links. Such work may implicitly or explicitly challenge the expertise of the 'outside' observer. Once there was a widespread assumption (underpinned by ideas about the necessity of scholarly detachment) that the best anthropology had to be done in a society to which the anthropologist came as a cultural outsider. Most scholars would now say that as anthropology has shifted from being primarily a Euro-American discipline to being a more international one, it has become clear that it is the nature of the intellectual training and not the anthropologist's originating culture which makes illuminating cultural analysis possible. Visual anthropology has been at the cutting edge in these matters.

The major claim from postmodern visual anthropology which has yet to be accepted by mainstream practitioners is that a great intellectual role for 'the visual' will challenge conventional thinking, and refresh it (Devereaux and Hillman 1995, Banks and Morphy 1997, MacDougall 1998). Since all postmodern anthropology questions all taken-for-granted classifications, hierarchies, and orthodoxies, the pro-visual anthropologists are unlikely to 'come to power' intellectually, but rather 'the visual' will probably be quietly and painlessly incorporated into mainstream anthropology courses. There will be little resistance to proposals to think freshly about 'visual systems,' although there will always be scholars who continue to argue in support of writing as the best mode of intellectual communication and the written ethnography as superior to any other form of discourse (see, for example, Hastrup in Crawford and Turton 1992). However, just as the ethnographic museum can be reconfigured to become a place which makes us think actively about history, power, tolerance, creativity, and core values, so too can a photograph, a Benin bronze, a fish trap, an MTV pop video, a British imitation of a Japanese garden, and a set of 'dirty' postcards be appropriately re-presented and freshly analyzed.

Visual Development: Infant

Immediately after birth, the visual system (see *Visual System in the Brain*) has access to structured visual input from the environment that could be used to guide behavior in, and perception of, the external world. Developmental events prior to birth establish rudimentary neural mechanisms that enable some limited perceptual capacities, but further neural developments as well as interactions with the visual environment lead to substantial improvements in these capacities after birth. This article covers the emergence of these perceptual capacities during the early postnatal period in human infants (see also recent monographs by Atkinson 2000, Daw 1995, Kellman and Arterberry 1998, Simons 1993). After considering methods that have been used to assess infant vision, the most fundamental aspects of visual development will be reviewed.

1. *Methods for Assessing Infant Vision*

Prior to 1960, most anecdotal and published accounts of the visual capacities of human newborns concluded that they were blind or, at best, severely visually impaired. These assessments, however, were based largely on insensitive methods, such as moving a single, small spot of light to elicit from the newborn a change in eye alignment (an ocular following or tracking response). Four methodological breakthroughs (see Gottlieb and Krasnegor 1985) occurred in the early 1960s which revealed that the visual capacities of young infants, although considerably less mature than in adults, were nevertheless quite sophisticated.

1.1 *Preferential Looking*

In the late 1950s, Robert Fantz revolutionized the study of infant vision by modifying a two-alternative preference technique originally developed for testing visual sensitivity in chickens. Fantz substituted the infant's looking response for the chicken's pecking response and presented infants with two side-by-side stimulus locations, only one of which contained a set of black-and-white stripes. Even newborns have a natural tendency to fixate (look at) the side of the display containing the stripes over the side of the display devoid of stripes. An observer viewing the infant's eyes, and estimating the direction of gaze through a peephole in the stimulus display, judges which of the two stimulus locations is fixated more often or for a longer duration. To guard against bias, the observer is 'blind' (i.e., unaware of the location) of the stripes. By systematically varying the width of the stripes, the smallest stripe-width that is just barely resolvable (significantly greater than chance, or 50 percent) can be determined across a series of trials in which the location of the stripes is randomly varied.

Teller (1979) established rigorous standards for using infant looking preferences to assess stimulus *detection* (a choice between a stimulus and no-stimulus). Teller coined the term forced-choice preferential looking (FPL) to describe this technique. FPL can also be used to assess stimulus *discrimination* by presenting two stimuli simultaneously. Evidence of a significant preference allows for the conclusion that infants can discriminate the difference between the two stimuli. However, the absence of a significant preference is ambiguous because the two stimuli may be discriminable but fail to elicit a clear preference in looking behavior.

1.2 *Visual Evoked Potentials*

Surface electrodes attached to the skull can record small changes in synchronized electrical activity from various brain regions. The amplitude and latency of several peaks and troughs in the visual evoked potential (VEP) vary with the size and intensity of a visual stimulus. As with preferential looking, VEPs can be used to assess the smallest stripe-width that is just detectable. VEPs can also be used to assess visual discrimination by measuring the averaged response to a change from one stimulus to a different stimulus and comparing it to the averaged response to no-change control trials.

1.3 *Fixations and Eye-movement Scanpaths*

Newborns show poor evidence of steady and consistent fixations of a small visual target, and their ability to track (follow) a small moving target is very poor. They will, however, follow a set of moving stripes. This following response is called optokinetic

nystagmus (OKN) because it consists of alternations between a smooth tracking response in the direction of stripe movement and a rapid saccadic eye movement in the direction opposite to stripe movement (as the eyes move from one extreme orbital position to the other). As with FPL and VEP, OKN can be used to assess the smallest stripe-width that is just detectable. OKN can be measured by direct observation or by one of a variety of eye-tracking devices, such as electro-oculography (EOG) or video-based images of the pupil and reflections on the front surface (cornea) of the eye. These latter corneal reflection techniques were developed by William Kessen and his colleagues (see Haith 1980) and provided the first detailed assessments of moment-to-moment sequences of visual fixations (scanpaths) by newborns as they viewed a simple visual stimulus.

1.4 Habituation

Fantz noted in his early studies of preferential looking that when the same two stimuli were presented side by side, fixation durations declined across repeated trials. This decrement in looking duration is called *habituation* and indicates that the infant has processed and retained some information about the stimulus across time. Subsequent elaborations on the use of habituation as a measure of visual discrimination (Bornstein 1985) have resulted in an 'industry standard' that consists of two phases: habituation and test. During habituation, a single visual stimulus is presented and an observer records how long the infant sustains fixation (interrupted by no more than two seconds of distraction) to that stimulus on a given trial. Identical trials are repeated, tallying fixation duration until there is a preset decrement (typically 50 percent) from the initial level of looking on the first several trials. When this criterion of habituation has been met, the infant enters a test phase in which the same habituation stimulus and a novel stimulus are presented on alternating trials. Continued low levels of looking to the habituation stimulus and significant increases (recovery) of looking to the novel stimulus are taken as evidence of discriminating the habituation (familiar) from the novel stimulus.

2. Resolving Fine Detail

2.1 Acuity

Perhaps the most basic question one could ask about infant vision is how well they can see small objects. This ability to resolve fine detail, called visual acuity, is what is assessed by an ophthalmologist or optometrist using an eye chart. Because infants cannot verbally report the smallest letter-size on an eye chart, one of the foregoing non-verbal techniques must be used to estimate their visual acuity.

Figure 1
Schematized contrast sensitivity functions for one-month-old and three-month-old infants and for normal adults. The x-axis represents stimulus size (e.g., the number of black-and-white stripes per degree of visual angle) and the y-axis represents sensitivity to contrast.

FPL, VEP, and OKN have been used to assess visual acuity in young infants. In each case, black-and-white stripes (or checks) are systematically varied in size to determine the smallest size that elicits a reliable response. Although there are some differences in estimates of visual acuity using these three methods, two facts are quite clear. First, visual acuity in newborns is approximately five octaves (an octave is a doubling) worse than in normal adults. Using the Snellen notation, where 20/20 refers to normal visual acuity (average performance at a viewing distance of 20 feet), newborn visual acuity is approximately 20/640. This means that a newborn can see at 20 feet what a normal adult can see at 640 feet. Alternatively, a newborn must be five times closer to a visual stimulus than an adult (7.5 inches vs. 20 feet) to resolve it equally well. Second, there is a rapid improvement in visual acuity between birth and six months of age, with average acuity rising to 20/40 within this postnatal period (Norcia and Tyler 1985).

2.2 Contrast Sensitivity

Most objects are not composed of features at the limit of resolution, but rather contain features sufficiently large to be well above the acuity threshold. For these features, size is less important than contrast. Contrast refers to the difference in luminance between adjacent object features. For example, a pair of black-and-

white stripes has very high contrast because the luminance difference is large. As luminance is added to the black stripe and subtracted from the white stripe, the stripes become different shades of gray and have lower contrast. At the limit, when the stripes are equal shades of gray, contrast is zero and the stripes are no longer visible. Thus, for any feature above the acuity threshold, visibility is determined by sensitivity to contrast.

Figure 1 illustrates a typical contrast sensitivity function (CSF) obtained from an adult, as well as CSFs obtained from young infants (Kellman and Banks 1998, Norcia et al. 1990). Notice that the adult CSF peaks at features with medium size and falls off for both smaller and larger sizes. The point on the far right of the CSF, where size is smallest and contrast sensitivity is least (i.e., stimulus contrast is maximal), is the estimate of visual acuity. The lower heights of the infant CSFs indicate that they are much less sensitive to contrast than adults at all feature sizes, and of course at maximal stimulus contrast visual acuity is far poorer. Importantly, even at medium feature sizes where both infants and adults can resolve a stimulus at high contrast, infants require much more contrast for minimal detection of that stimulus. Because many features of objects have low contrast, these features are invisible to the infant's visual system.

2.3 Limiting Factors

The two most obvious limitations on acuity and contrast sensitivity in early infancy are optical quality and neural immaturity. Adults with an optical error requiring spectacles or contact lenses show deficits in both acuity and contrast sensitivity when they fail to wear their correction. Although a small proportion of infants have optical errors (myopia: nearsightedness; hyperopia: farsightness; astigmatism: errors that vary by stimulus orientation), the five-fold deficit in newborn acuity cannot be accounted for by optical errors (Banks and Bennett 1988). Another potential contributor to optical quality is accommodation (change in shape) of the lens in the eye, which optimizes the focus of the retinal image for different viewing distances. Although newborns show poor accommodative control, this deficit is the product of poor visual acuity; that is, the immature visual system is unable to detect subtle changes in stimulus blur that trigger an accommodative response (Kellman and Banks 1998).

These results suggest that the fundamental limitation on acuity and contrast sensitivity is neural, not optical. Classic data on the developmental anatomy of the visual cortex in human infants (Conel 1939) documented substantial elaborations of neural structures (e.g., density of synapses) during the first two postnatal years. However, more recent data on the developmental anatomy of the retina suggest that much of the five-fold improvement in acuity can be accounted for by the increasing density of photoreceptors in the center (fovea) of the retinas and the inefficiency of photoreceptors (the outer segments) in capturing light (Banks and Bennett 1988).

Both maturational and experiential factors influence the development of acuity. The timecourse of developmental improvement in acuity is more closely linked to the infant's age post-conception than to its age post-birth, suggesting that normal visual experience after birth plays a relatively minor role in this developmental process. However, the absence of normal visual experience after birth leads to substantial deficits in acuity. Visual deprivation in the form of cataracts (opacities in the eye that prevent a clear retinal image) slows down the timecourse and eventual level of acuity unless the cataract is removed very early in infancy (Maurer and Lewis 1993).

3. Color

Chromatic discrimination requires at least two classes of photoreceptors (cones) that are sensitive to slightly different wavelengths of light (see article *Color Vision*). FPL, VEP, and OKN assessments confirm that the medium-wavelength (green) and long-wavelength (red) photopigments are functional by two months of age. However, the immaturity of the photoreceptor outer segments (see Sect. 2.3) limits the number of different hues that young infants can discriminate (Banks and Bennett 1988). Clear evidence that infants are trichromats (i.e., have the red, green, and short-wavelength sensitive blue cones required for normal color vision) is not present until four months of age (Teller and Bornstein 1987). Color constancy, the ability of infants to perceive the correct hue despite variations in lighting (e.g., ignoring the reddish tint at sunset), emerges between two and five months of age (Dannemiller 1989).

4. Motion

Moving stimuli are more effective at capturing infants' attention than stationary stimuli. This natural bias to attend to moving stimuli has been used in preferential looking studies to estimate motion thresholds: the minimum stimulus speed required to discriminate a moving from an otherwise identical stationary stimulus. Motion thresholds improve dramatically in early infancy despite nearly adultlike temporal sensitivity at birth, suggesting that these improvements in motion sensitivity rely critically on improvements in spatial resolution (Roessler and Dannemiller 1997).

Discrimination of different directions of motion is the definitive test of a motion mechanism because the responses of single neurons in primary visual cortex and many extrastriate cortical areas in the dorsal visual pathway (see *Neural Plasticity*) have a preferred direction of stimulus motion. However, both FPL and habituation techniques have failed to demonstrate

infants' discrimination of opposite directions of stimulus motion until two months of age. This is surprising because even newborns show directionally appropriate eye movements to stripe motion during OKN. Asymmetries in the direction of OKN (temporalward stripe motion is ineffective in eliciting monocular OKN in newborns) are mirrored in the VEP. Thus, the processing of motion direction appears to be mediated by at least two different neural mechanisms (see *Motion Perception: Psychological and Neural Aspects*). One of these mechanisms is presumably subcortical and is capable of controlling directional eye movements (i.e., OKN) in newborns, whereas the other mechanism is presumably cortical and does not support direction discrimination until several weeks after birth (Banton and Bertenthal 1997).

5. *Orientation and Vernier Acuity*

Another fundamental property of neurons in the visual cortex is orientation sensitivity, and this property is present in rudimentary form in newborn cats and monkeys. Human newborns are also sensitive to orientation, but only for gross differences (e.g., horizontal vs. vertical stripes). A VEP masking technique suggests that orientation sensitivity continues to improve throughout the first postnatal year (Skoczenski 2001).

Vernier or displacement acuity refers to the ability to discriminate the spatial misalignment of two line segments that are abutted end to end. In adults, vernier acuity is far superior to grating (stripe-width) acuity, whereas in infants prior to four months of age vernier acuity is poorer than grating acuity. This developmental difference in the relation between vernier and grating acuity has been documented using both FPL and VEPs (Skoczenski 2001). One potential cue for solving a vernier acuity task is the presence of a slight orientation change at the point where the two line segments meet. Thus, the protracted development of orientation sensitivity may acount for the developmental crossover in the relation between vernier and grating acuity.

6. *Depth and Binocular Rivalry*

The relative distance (depth) of objects can be appreciated using three different sources of information: motion, retinal disparity, and pictorial cues. A rapidly approaching (looming) stimulus elicits a blink response in one-month-olds, and motion parallax (more rapid image speed for near than for far objects) enables three-month-olds to discriminate small differences in object distance. Thus, sensitivity to depth from motion is present in very early infancy and does not require the use of both eyes (Kellman and Arterberry 1998).

Retinal disparity refers to the subtle differences in the images projected to the two retinas from an object at near (less than five meters) viewing distances. FPL and VEP studies have demonstrated that sensitivity to retinal disparity does not emerge until three to four months after birth. Moreover, the smallest retinal disparity that is just discriminable by infants improves very rapidly between three and five months of age, progressing from no sensitivity to nearly adult values (less than one minute of arc) in this age range (Birch et al. 1985).

During this same age range, infants become sensitive to binocular rivalry: the perceptual conflict induced by presenting grossly different images to the two retinas (e.g., horizontal stripes in one eye and vertical stripes in the other). Binocular rivalry occurs when the discrepant retinal images cannot be fused into a single percept. Prior to three months of age, infants appear to have a much greater tolerance for fusing discrepant images than adults, perhaps because of their poor acuity and contrast sensitivity (Birch et al. 1985).

In adults, failure to align both foveas onto a stimulus typically leads to binocular rivalry and prevents stereopsis (the appreciation of depth from retinal disparity). Some individuals, including some infants, have an ocular misalignment (strabismus) that eliminates fusion and stereopsis. If uncorrected in infancy, this misalignment can result in a permanent loss of the capacity for stereopsis, even if the eyes are surgically realigned in childhood (Banks et al. 1975). Thus, there is a sensitive period during which a normally developing neural mechanism for stereopsis, present by four months of age, can be permanently disabled by subsequent abnormal binocular experience (strabismus). These same processes were earlier demonstrated in the visual cortex of cats and monkeys (see *Neural Plasticity in Visual Cortex*), and subsequently confirmed behaviorally.

Pictorial cues to depth are contained in flat (two-dimensional) representations of actual (three-dimensional) scenes. These cues include shading, occlusion, and linear perspective (e.g., receding railroad tracks that converge in the picture plane). A preferential reaching technique was developed by Albert Yonas to determine, under monocular viewing conditions, whether infants perceive the depth information in pictures. At approximately seven months of age, infants under these testing conditions become sensitive to a variety of pictorial cues to depth, as indicated by their reliable reaching for the *apparently* nearer picture (Yonas and Granrud 1985).

7. *Object Perception*

As visual stimuli, objects are bounded three-dimensional collections of features. Even newborns fixate contours (high-contrast edges), suggesting that they can segregate a rudimentary object from its background. However, many objects are comprised of embedded sets of features, such as faces which have external (e.g., hairline) and internal (e.g., eyes) con-

tours. Newborns fail to fixate small, stationary internal contours of embedded-feature objects such as faces, presumably because of limitations in acuity and contrast sensitivity. After two months of age, infants both fixate and discriminate (as indicated by habituation studies) internal and external features, and often prefer to fixate internal features (Maurer and Salapatek 1976; see *Cognitive Control (Executive Functions): Role of Prefrontal Cortex*).

Objects can be extracted from a camouflaged background using differences in texture or motion. While adults can easily extract a single discrepant target element from an array of background elements, infants require highly salient element differences for such texture segregation, including target motion or multiple discrepant target elements (Sireteanu 2000). Orientation differences are particularly difficult for infants to use in texture segregation, consistent with the evidence (see Sect. 5) that sensitivity to orientation has a lengthy developmental timecourse.

By three months of age, the two-dimensional shape of an object can be extracted from coherent motion of a group of elements in a background of identical, but incoherently moving, elements. The three-dimensional shape of a rigid object can be extracted by four months of age from rotational motion that reveals the hidden perspectives of stationary views of the object. And the three-dimensional shape of non-rigid objects can be extracted by five months of age from displays consisting solely of disconnected points undergoing relative motion that simulates a human walker (Bertenthal 1993).

The actual size and shape of an object must be derived from properties of the retinal image and from object distance. For example, the retinal image of a familiar object (e.g., a dollar bill) varies in size when viewed at arms length or across a room, and in shape when viewed directly or from an oblique angle. Yet in all these cases we perceive the dollar bill to retain a constant physical size and shape. Size and shape constancy have been demonstrated in infants as young as newborns, suggesting that mechanisms for combining retinal image properties and object distance (presumably from motion cues) are functional with little or no postnatal experience (Kellman and Arterberry 1998).

Objects are often partially occluded by other objects, yet adults perceive objects as 'complete' despite the absence of various parts behind the occluder. Newborns do not appear to have an intact mechanism for perceptual completion, whereas four-month-olds do (Johnson 2000). Two-month-olds show perceptual completion, but only when given additional information for the continuity of the occluded object (e.g., a smaller occluder or one with gaps in it). And four-month-olds fail to show perceptual completion when the occluded object is stationary, suggesting that coherent motion of the visible object-parts binds them together into a single object.

8. Developmental Mechanisms

The development of mature visual perception during early infancy is influenced by both maturational and experiential mechanisms. Maturational factors include neural developments, such as the migration of photoreceptors (increasing the packing density of cones in the fovea), the elongation of cone outer-segments, and cell death (apoptosis). One result of such maturational factors is a reduction in the intrinsic neural noise that limits stimulus detection and discrimination (Skoczenski 2001). Experiential factors include periods of susceptibility to altered visual input. Although the range of visual inputs sufficient to enable 'normal' visual development is quite broad, visual deprivation (e.g., cataracts or strabismus) during a sensitive period can lead to permanent deficits in visual development.

Visual Imagery, Neural Basis of

Human thought makes use of different forms of mental representation; some language-like and some more visual or spatial. The term 'mental imagery' refers to the latter. It plays a central role in many cognitive abilities, from creative problem solving to strategies for improving memory. This article will review the current state of knowledge on the neural bases of mental imagery, beginning with the controversies in cognitive psychology that motivated the neuroscience research.

1. *Imagery, Verbal Thought, and Perception*

Much of the early history of imagery research was devoted to discriminating imagery from verbal thought, and characterizing some of its differences in functional information-processing terms. Allan Paivio (e.g., 1971) addressed these issues within the context of memory research. He demonstrated that, in ostensibly verbal learning tasks, imagery affected memory encoding. Though a program of research in which subjects learned words, which either lent themselves to concrete images or not (e.g., banana vs. vacation), with or without imagery instructions, he gathered evidence in support of a 'dual coding hypothesis.' According to this hypothesis, imagery and language are two distinct forms of mental representation. Imagery was therefore helpful in verbal memory tasks because, in effect, it doubled the number of representations being stored.

A challenge to this view came from Zenon Pylyshyn (1973), who questioned the computational feasibility of storing visual images, and raised a number of issues concerning the role of imagery phenomenology in the information processing that underlies thought. This challenge brought an empirical response from Stephen Kosslyn (e.g., 1978), who devised experimental tasks in which the visual-spatial properties of images could be shown to affect subjects' information processing. For example, when subjects focus their attention on one location within an image, and then shift to a different location, the time taken to shift is directly proportional to the imagined distance (Kosslyn et al. 1978). Findings from the laboratory of Roger Shepard also supported the visual-spatial nature of imagery. In mental image rotation experiments, images took more time to rotate through larger angles (Cooper and Shepard 1973).

As evidence accumulated that imagery is a distinct form of mental representation from linguistic or propositional thought, the question of its relation to visual perception came to force. Early work on this topic was pioneered by Ron Finke (e.g., 1980), who demonstrated many detailed and striking similarities between mental images and percepts. For example, he reported that mental images had similar-shaped fields of resolution to the perceptual visual field.

2. *Image Representation: Insights from Neuroscience*

The relation between imagery and perception can also be assessed in terms of their respective neural substrates. Indeed, many of the alternative interpretations that plagued the purely behavioral approaches to

Figure 1
A map of the Piazza Del Duomo in Milan. When patients with left neglect were asked to imagine themselves standing at point A looking toward the cathedral, and to report what they saw in their 'mind's eye,' the locations they mentioned were those marked with 'a.' When they repeated the procedure from the vantage point B, they then mentioned the locations marked with a 'b.' (Source: Farah M J 1999 The neural basis of mental imagery. In: Gazzaniga M S (ed.) *The New Cognitive Neurosciences*. MIT Press, Cambridge, MA.)

mental imagery did not apply to the neural data. An initial review of the literature on imagery and the brain, motivated by the need for more decisive evidence concerning the imagery–perception relation, uncovered a variety of relevant findings (Farah 1988). These included numerous findings of parallel impairments of imagery and perception after brain damage, which suggest that the same underlying representations are needed for both.

In one of the best-known demonstrations of parallel impairments in imagery and perception. Bisiach and Luzzatti (1978) found that patients with hemispatial neglect for visual stimuli also neglected the contralesional sides of their mental images (that is, the side of their image opposite the side of their brain lesion). Their two right-parietal-damaged patients were asked to imagine a well-known square in Milan, shown in Fig. 1. When they were asked to describe the scene from vantage point A on the map, they tended to name more landmarks on the cast side of the square (marked with lower case a's in the figure); that is, they named the landmarks on the right side of the imagined scene. When they were then asked to imagine the square from the opposite vantage point, marked B on the map, they reported many of the landmarks previously omitted (because these were now on the right side of

Figure 2
Depiction of the effects of unilateral occipital lobectomy on the visual angle of the mind's eye. (Source: Farah M J 1999 The neural basis of mental imagery. In: Gazzaniga M S (ed.) *The New Cognitive Neurosciences*. MIT Press, Cambridge, MA.)

the image) and omitted some of those previously reported.

Imagery and perception also share representations at relatively early stages of visual processing. This point was demonstrated by a patient with blindness in half of her visual field following occipital resection (Farah et al. 1992). If mental imagery consists of activating representations in the occipital lobe, then it should be impossible to form images in regions of the visual field that are blind due to occipital lobe destruction. This predicts a reduced maximum image size, or visual angle of the mind's eye, in this patient. By asking her to report the distance of imagined objects such as a horse, breadbox, or ruler when they are visualized as close as possible without 'overflowing' her imaginal visual field, one could compute the visual angle of that field before and after her surgery. It was found that the size of her biggest possible image was reduced after surgery, as represented in Fig. 2. Furthermore, the separate measurement of maximal image size in the vertical and horizontal dimensions showed that only the horizontal dimension of her imagery field was reduced significantly. These results provide strong evidence for the use of occipital visual representations during imagery.

The results of functional neuroimaging studies in normal subjects have been, on the whole, supportive of shared representations for visual mental images and percepts. Early studies with event-related potentials (e.g., Farah et al. 1989) and SPECT (e.g., Goldenberg et al. 1989) implicated a cortical visual locus and, as newer methods allowed better localization, it has been possible to test far more specific hypotheses concerning the precise areas within visual cortex that are recruited for mental imagery (Kosslyn and Ochsner 1994; Roland and Gulyas 1994).

3. Brain Systems for Image Generation

If imagery consists of activating some of the same cortical visual areas used for perception, this raises the question of how these representations become activated in the absence of a stimulus. Whereas one cannot see a familiar object without recognizing it, one can think about familiar objects without inexorably calling to mind a visual mental image. This suggests that the activation of visual representations in imagery is a separate voluntary process, needed for image generation but not for visual perception and object recognition.

Neuropsychological evidence for such a process comes from patients whose perception and general memory are preserved, but who cannot visualize objects or scenes from memory. This is the profile of abilities that would be expected given an impairment of image generation *per se*. A number of such cases have been reported in the neurological literature, with lesions generally being located in the posterior left hemisphere. In one such case (Farah et al. 1988), the imagery impairment was demonstrated in a number of ways, including a sentence verification task developed by Eddy and Glass (1981). Half of the sentences required the use of visual imagery to verify them (e.g., 'A grapefruit is larger than a cantaloupe'), and half did not (e.g., 'The US government functions under a two-party system'). Eddy and Glass had shown that normal subjects find the two sets of questions to be of equal difficulty (as did right-hemisphere-damaged control subjects tested by Farah et al. 1988), and that performance on the imagery questions was impaired selectively by visual interference, thus validating them as imagery questions. RM showed a selective deficit for imagery on this validated task: He performed virtually perfectly on the nonimagery questions, and performed significantly worse on the imagery questions.

RM was also tested on imagery for the colors of objects, using black and white drawings of characteristically-colored objects (e.g., a cactus, an ear of corn) for which he was to select the appropriate colored pencil. His imagery was further tested with drawing tasks. By these measures, too, his imagery was poor, despite adequate color perception and object recognition ability.

In subsequent years, a small number of additional cases of image generation deficit have been reported (e.g., Goldenberg 1992, Grossi et al. 1986, Riddoch 1991), as well as similar but weaker dissociations in subgroups of patients in group studies (Bowers et al. 1991, Goldenberg 1989, Goldenberg and Artner 1991, Stangalino et al. 1995).

What parts of the brain carry out image generation? This question has evoked controversy. Although mental imagery was for many years assumed to be a function of the right hemisphere, Ehrlichman and Barrett (1983) pointed out that there was no direct evidence for this assumption. Most of the patient-based research supports a left-hemisphere basis for image generation (see Tippett 1992, Trojano and Grossi 1994 for reviews; see Sergent 1990 for a different position). However, for questions of localization, we can also turn to functional neuroimaging.

Not all neuroimaging studies of visual imagery are appropriate for localizing image generation *per se*. The study must be designed in a way that can isolate this process, separated from perceptual and memory processing more generally. A large number of studies do meet this criterion, including those done with ERP, SPECT, PET and fMRI (see Farah 1999 for a review); in most cases, but not all, foci of activity are observed in the left inferior temporo-occipital region.

Although the bulk of evidence favors a left-hemisphere superiority for image generation, it also suggests that in most individuals both hemispheres possess some image generation ability. This hypothesis explains both the rarity of cases of image generation deficit after brain damage, as well as the asymmetries observed in neuroimaging studies, and the fact that when impairments are observed after damage, the left or dominant hemisphere is implicated.

Visual Images in the Media

Effects in the media of the visual image (i.e., a reproduced sight) are central to a debate which typically contrasts the properties of image and word. Here, that debate is tracked across three key areas: child literacy and education, commercial and political persuasion, and issues surrounding news.

1. *Visual Images vs. the Word*

The world is filled with visual images. Images appear on television and movie screens, billboards, posters, magazines, newspapers, and computer monitors. Increasingly, it is argued that the word, once the dominant medium, is being supplanted by the image. Civilization has taken, in Mitchell's phrase, a 'pictorial turn' (Mitchell 1994).

The visual image has been the subject of research across a range of academic disciplines. In recent years, the emphasis has moved away from theories of art towards a psychosocial perspective that draws on research from semiotics, branches of psychology, sociology and communications, and cultural theory (see *Semiotics*; *Mass Media: Introduction and Schools of Thought*; *Media Effects*; *British Cultural Studies*).

In part, this research has been driven by a long-standing debate over the social implications of the image. Often, this has centered on controversies that surround certain visual media; most prominently, racial and gender stereotyping, sexually-explicit material, and violence as depicted on television, film, and in computer games (see *Mass Media, Representations in*; *Pornography*; *Violence and Media*; *Media Effects*; *Computers and Society*). However, this debate has also been advanced as an opposition between the qualities and social effects of the word or text, and those of the image, with the former typically being privileged over the latter.

1.1 *History of the Debate*

The premise on which this debate turns is the superiority of text over image, a bias informed by an intellectual tradition that stretches back centuries (for a detailed discussion, see Stephens 1998). The Bible, in associating the Word with creation in Genesis, while forbidding the production of the 'graven image or any likeness', has long been used to support this presumption. Even as the image has established itself at the center of Western culture, writers and philosophers from Plato to contemporary thinkers have remained critical of the qualities and effects of the image compared with those of the word.

This intellectual antipathy is prompted by a series of overlapping concerns. Partly, it is founded on a long-standing suspicion of verisimilitude. In one view, such a capturing of likeness evokes a high degree of 'truth.' It is this perspective that typically reflects a traditional, although now contested, history of art as the progress of visual reproduction towards an ever more accurate reflection of the natural world, an ideal established by the Romans, and one that finds its most perfect expression in the photographic process.

However, verisimilitude has also driven a more negative perspective; that what the visual image offers is not truth but seductive illusion. A painter, Plato

wrote, can deceive 'children and fools' with the 'imitation of appearance', instead of bringing 'truth' or 'real things' (1956, p. 463). Substantively, this argument remains the root of one strain of criticism laid against television and movies, that their illusionary realism may offer an ideal vehicle for propaganda.

A second charge leveled against the visual image is that, with the growth of technical reproduction, images devalue the objects they represent. The uniqueness of the original is lost in the deluge of visual copies. This argument is perhaps most acute when what is being reproduced are images of cherished buildings, statues, and landmarks, and most especially, works of art. When the Mona Lisa becomes a common sight in the everyday world beyond the *Louvre*—for example, on T-shirts and advertising hoardings—the 'quality of its presence,' in the words of Benjamin is 'always depreciated' (1968, p. 221).

A third charge involves the long-held belief that the image speaks more directly to the emotions than to the logical mind. Aquinas argued that images 'excite the emotions more effectively aroused by things seen than by things heard' (cited in Freedberg 1989, p. 162). This rousing of emotions is seen as making the problems surrounding pornography and the visual depiction of violence all the more acute. Finally, the image's accessibility may distract the populace from the more cerebral merits of the word, be it the religious tract, improving essay, or newspaper text. It is a view that remains popular today, with some thinkers warning that the reach of words will shrink and that the era of the book is passing (see Nunberg 1996). Such a trend, however, has been difficult to substantiate, with sales of books in the US, for example, steadily increasing since 1998 after a slight fall in the mid-1990s (Schwartz 2000). Evidence for the decline of newspaper readership is more substantial, however. Daily circulations in the US fell yearly between 1987 and 1999, losing nearly 7 million in sales (Newspaper Association of America 2000).

2. *Visual Images and Child Literacy*

If there is unease that the image is replacing the word for society in general, this concern is heightened in debates over child literacy. At different times, anxiety has centered on the presumed ill-effects on children's reading abilities and habits of a series of visual media, including movies and comic books. However, most commonly criticized is television. Beentjes and van der Voort (1989) and Neuman (1995) are among researchers who have offered a number of hypotheses concerning the effects of television on child literacy, and weighed the empirical evidence for each.

A stimulation hypothesis argues that there is no conflict between images on television and words in print because watching television stimulates or improves reading in the young. This theory, although not widely held, rests largely on studies concerned with the reading of a book based on a television show after watching the program, or more generally, on children being prompted by television to research an interest. However, in a study of the juvenile book market, only 4 percent of children reported reading a book on the basis of seeing or hearing of it through television (Book Industry Study Group 1984). Similarly, the findings from other studies imply that any interests that are aroused by television tend to be short-lived (see Schramm 1961).

More systematically studied are variations of a reduction hypothesis, where the consumption of television is predicted to have a negative impact on reading. There are five common variations of this hypothesis. First, a displacement hypothesis argues that television viewing takes time away from reading. However, studies have shown no conclusive evidence of this, indicating instead that time given to reading, although always scant, has remained remarkably stable.

The passivity hypothesis argues that television viewing causes children to become mentally indolent and so less inclined to read. Although studies have shown that television does require less mental effort than reading, it is argued that synthesizing visual and audio information engages children in a process that is active, not passive. The retardation hypothesis, an associated theory that argues television viewing deteriorates the brain, is seen as implausible for the same reason.

A fourth variety of reduction hypothesis is concentration deterioration, which suggests that a child's ability to concentrate is weakened by television. This too, although popular among critics, has found little scientific support.

Finally, anti-school hypotheses argue that children come to expect school to be as entertaining and immediately gratifying as television programs like 'Sesame Street,' and when it fails to meet these expectations, pupils lose motivation (Cohen and Rudolph 1977, Trelease 1982). Once more, the evidence is inconclusive.

2.1 *Visual Images in Education*

In contrast to the attribution of negative effects to television viewing, some educationalists have called for the visual image to play a larger role in school curriculums which, traditionally, have been dominated by the word.

This move, in part, expresses a belief in the benefits of acquiring what is termed 'visual literacy.' The view is that irrespective of content, engagement with visual media may lead to the development of mental skills applicable beyond the understanding of the medium itself. To some extent, this argument is predicated on the widely influential work of Howard Gardner who, in developing a theory of 'multiple intelligences,'

argued that different modes of communication are beneficial to the development of different types of intelligence.

However, the theory that visual imagery may encourage both specific cognitive development and a distinctive worldview is more generally a reflection of similar beliefs regarding textual and verbal communication, as expressed, most notably, by linguists Edward Sapir and Benjamin Lee Whorf. The perspective may also be traced to theories associated with Marshall McLuhan, who links cognition to the technical characteristics of varying media.

In this view, it has been suggested that television-based teaching may have a positive effect on a number of areas of cognition, including the formation of a distinctive worldview, analytic reasoning, and spatial intelligence: the ability to envision mentally, for example, what a shape might look like from various angles. It is also suggested that exposure to certain visual media, such as advertisements that employ metaphors, may encourage and develop abstractive and analogical thinking.

However, it is argued that as images primarily function as analogs of reality and are so less inclined to divide the perceived world into particular categories in the manner characteristic of language, the development of a specific worldview through exposure to visual imagery appears unlikely. (This is not to say that the *uses* to which the visual image may be put, e.g., to depict violence on television, may not have a significant impact on one's worldview.)

Similarly, it is judged improbable that engagement with visual forms will enhance a viewer's skills in analytic thinking, since images lack many of the propositional elements of language (e.g., it is difficult to make statements in the negative through images, e.g., 'there is no ice-cream'). While a stronger case may be made for the connection between visual imagery and spatial intelligence, evidence for these benefits is also weak. Finally, it is argued that aspects of abstractive or analogical thinking may indeed profit from viewing certain visual material, although the argument remains controversial (see Messaris 1994 for a full discussion.)

More generally, there is a growing body of opinion that, rather than teaching new cognitive skills, the representational conventions of images are founded on informational cues that people learn routinely to interpret through their visual experiences in real-life. This calls into the question the very existence of a distinctive 'visual literacy' based on cognitive abilities acquired through exposure to mediated imagery.

3. *Properties of Visual Images*

Overall, there is scant evidence then, that visual images—most typically in the form of television—are either detrimental to child literacy, or significantly contribute to distinctive cognitive development.

However, it is clear that the image does possess distinctive qualities. Peirce's classification of signs into iconic, indexical, and symbolic (Peirce 1991) is seen as an important key to these properties. Images that bear a resemblance to some aspect of reality are examples of iconic signs. At the same time, the photograph may be defined as an index; a sign that has some physical connection to the object or event to which it refers, (such as fingerprints or footprints) since it is produced by the physical effect of reflected light on photographic emulsion.

These features clearly set the image apart from the word. Iconic signs have little role in language, and indexicality is entirely absent. Conversely, the visual image would normally not rely on the type of arbitrary conventions that link signifier (representation) with signified (what is represented) in the manner that constitutes the symbolic mode most characteristic of language.

Another crucial distinction can be made between words and visual images. Whereas verbal communication possesses detailed conventions governing word order (or syntax) that facilitate the linking of concepts, there is no such formal convention for combining images into larger meanings, although those who work with images, such as artists, may develop their own. Images exhibit what is termed 'syntactic indeterminacy' that increases their ambiguity as carriers of meaning (Messaris 1997). These distinct features have important consequences for the roles that the visual image plays within society. While it is difficult for images to convey precise statements about the objects they represent, (e.g., 'the man no longer enjoys sarcasm'), still the image's iconicity, together with less pronounced but flexible symbolic properties, have allowed the medium to convey information on physical characteristics with a precision and accessibility unmatched by words. For example, a range of scientific fields have been advanced through the use of detailed depictions and diagrams.

Equally, the visual image has been a boon in the development of user-friendly computers, where iconic representations, such as scissors and folders, have been used to replace lines of text. At the same time, photographic indexicality has become a vital component in the creation of historical records. However, these properties may also have troubling consequences.

3.1 *Visual Images and Persuasion*

Iconicity, indexicality, and syntactic indeterminacy bring distinctive properties to visual persuasion, be it set to commercial or political purposes. In an extensive study of these issues, Messaris (1997) offers a broad range of devices through which the advertising image may engage attention and mold attitudes. Iconic representations of physical appearance and interpersonal behavior may reproduce real-world visual

cues associated with a series of emotional responses; including sexual interest and excitement. This prompting of emotion is central to advertising strategies that seek to associate positive feelings with the possession or consumption of products (see, e.g., Williamson 1978). Further, iconic devices that manipulate the viewer's point of view (such as close-ups or high and low angles) can incite a series of other responses, including curiosity and trust.

The ability of iconicity to communicate information quickly and with relatively little mental effort may contribute to another advantage the image may have in persuasion. Some cognitive psychologists believe that visual images are typically processed peripherally—rather than centrally—in ways that may decrease the likelihood of viewers engaging their full critical and analytical faculties, especially when the speed of the message leaves little time for reflection (see Petty and Cacioppo 1986).

The 'truthfulness' implied by indexicality is also a critical ingredient in visual persuasion whenever a photographic image is offered as proof of an advertiser's claims. However, visual images may readily be made to lie through the application of a wide range of techniques, from the staging of photographs to airbrushing to improve appearances. Moreover, digital technology has become a powerful aid to those who would practice such visual deception.

Finally, the syntactic indeterminacy of the image may also have important consequences that make it more useful in persuasion than the explicit meanings offered by words. For example, advertisers may take advantage of this property to imply associations or statements that they would be unwise to state verbally (such as the association of cigarette smoking with healthy activity).

3.2 *Visual Images and Politics*

Television has been accused of having a number of detrimental consequences for the political process. These include, in a political equivalent to the displacement theory associated with child literacy (see above), distracting the populace from civic involvement. However, the area of most concern with regard to the visual image is its effect within political advertising and televisual campaigning.

Political advertisements use many of the same visual strategies as their commercial counterparts, although often exhibiting a strong reliance on iconic visual effects. Patriotic appeals are common in the political advertisement or campaign, and the use of certain visual symbols—including the national flag—has been found to be especially prevalent. Equally, the use of family imagery, such as images of spouses and of children, remains common.

The iconicity of visual imagery has been held responsible for other political strategies that accentuate appearance over content. These make extensive use of devices that appear to be modeled on people's real-world experiences of interpersonal space (see Meyrowitz 1986). For example, politicians interviewed on television will typically turn towards the camera, and therefore towards the viewer, in order to imitate the real-world appearance of a direct and candid approach.

The potency of the visual image in political persuasion is thought to have been most graphically displayed through a debate between Richard Nixon and John F. Kennedy. It is reported that the majority of those who saw the 1960 debate on television judged Kennedy the victor, while most who listened on radio thought Nixon had won. Typically, this result has been taken to indicate that the more attractive image that Kennedy presented was the deciding factor. However, there may be a number of reasons for such an outcome, including the possibility that it was radio that may have favored Nixon's patterns of delivery, while exaggerating Kennedy's Boston accent in a manner that repelled listeners (Schudson 1995). This and other uncertainties surrounding the visual effects of television has led some thinkers to argue that the persuasive power of the medium has been overstated.

4. *Visual Images and the News*

Equally controversial has been the influence of the visual image on news. The entry of the image into an arena that traditionally had been the province of the word was viewed with consternation, both by journalists and by many outside of the profession, as the use of visual material developed from artwork through wood-cut engraving to early photographs. Visual images continued to be regarded as a medium that bypassed the reasoning mind and, as such, appeared to threaten journalism's Enlightenment heritage. While the photograph was held in higher esteem in the picture magazine, this had little impact on its critics.

Yet at the same time, the photographic record, as metaphor as well as in practice, came to underpin the journalistic enterprise. By the mid-nineteenth century, there was widespread typification of the newspaper as a 'daguerreotype' of the social and natural world, with the indexicality of the process being used to exemplify, and give credence to, claims of journalistic objectivity (see Zelizer 1998). More recently, however, scholars have pointed to the use of photographs, in both print and broadcast news, as being a practice based on ideological values, as well to the connotative properties inherent in the practice itself. Barthes (1977) has argued that the photograph fulfills not only a denotative (or referential) but also a connotative (or interpretive) function, which undermines its claim to be unmediated truth. Moreover, by embedding the photograph within the narratives characteristic of

news, it is argued, its meaning is colored by that association. In this way, the news-photograph, be it on the page or in broadcast film, may be far from being either 'neutral' or 'objective.'

5. *Visual Images and the Word: Future Prospects*

Much consideration has been given here to the way the cultural impact of the visual image has been traditionally expressed through a rhetorical opposition favoring the 'rationality' of word over visual image. Yet many of the presumed negative effects of the image have little basis in scientific fact, while critical linguists and others have shown that the multiple levels of implicit meaning generated by text can make the word equally suspect.

Moreover, in an era when media has long been multimodal, it is increasingly rare to encounter the visual image separate from the word. Consequentially, discussion has been moving beyond the opposition of the two modes to a consideration of how, when conjoined, words and visual image may work to fix, reinforce and subvert the meanings of one another, as well as to generate new meanings (see *Critical Inquiry* Spring 1980, special issue: Language and Image). Critics engaged in contesting photojournalism's appeal to the 'objectivity' of indexicality have long argued that photographs attain meaning only in relation to the settings in which they are encountered, which invariably include text. Similarly, those studying broadcast news have emphasized that viewing typically involves the simultaneous processing of words and images, with the voice-over commentary representing a particularly interactive relationship between the two modes. This interaction may be utilized to 'anchor' verbal discourse through a visual image, or vica versa, in ways that encourage viewers towards a particular reading of a depicted event (see, e.g., Hartley 1982).

The study of word and image combinations and their consequences has been given new emphasis with the advent of computer technology and the Internet. The ability to digitally combine and manipulate the two modes—in ways that may affect the credibility of both—means that many of the traditional arguments over word and images may soon be relegated to history. As Lester (2000, p. 306) puts it, the next decade promises to be 'known for the way that words and pictures are used together as equal partners in the communication process,' a new Information Age in which 'all forms of communication are included through the World Wide Web.'

Visual Memory, Psychology of

Human memory is not a single mental faculty or cognitive system; the cognitive processes which we collectively call memory are composed of a number of independent and specialized cognitive systems that encode and store information in different formats. Some of these memory systems express themselves directly in the form of conscious recollection of general knowledge and previous personal experiences, other systems express themselves indirectly in behavior. The concept of visual memory has two different, yet related, meanings.

1. *Visual Memory as the Channel of Communication*

In the most general textbook usage, visual memory refers to the storage of information transmitted through the visual system. According to this definition, it is a form of memory which may be compared with memory for information transmitted through other sensory systems such as auditory, tactile, or olfactory memory. The type of information that is processed (colors, music, smells) and which cannot be translated between modalities captures important characteristics of modality-specific memories. Differences between modalities in the organization of information in memory are also found. For example, when subjects are requested to remember a series of items presented in succession, in auditory presentation memory is better for the first and last items than the middle items (primacy and recency effects), whereas in visual presentation only the former effect is observed. While the basis for such modality effects is not known, they probably reflect differences in the way information is processed by the perceptual systems rather than characteristics of specific auditory and visual memory systems as such.

The channel-of-communication definition of visual memory misses the point that vision is a gate to many memory systems, and conversely that information in different sensory channels may be processed by the same amodal memory system.

2. *Visual Memory as a Code*

In a more restricted usage, visual memory refers to a code by which visual perceptions are inscribed and retrieved from memory in the form of images or sequences of images. According to this definition, visual memory is not a separate memory system but a representation of information that is processed by different memory systems. This definition also acknowledges that the channel of communication does not specify the memory format; what is viewed by the eye may be stored amodally, e.g., in memory systems relying on verbal codes.

2.1 *Object Recognition*

A direct expression of visual memory is the perceptual process itself, in the recognition of colors, textures, shapes, and objects in the world. This is achieved by some process by which on-line information from the visual system is matched to stored descriptions. Perceptual recognition is immediate, representing a fast, automatic and implicit (nonconscious) process (see *Implicit Memory*, *Cognitive Psychology of*), and it precedes semantic and episodic memory retrieval which deal with the identification of particular, familiar objects. The vast collection of memories that allow perceptual recognition is at least partly associated with a separate memory system, called the perceptual representation system (PRS) (Tulving and Schacter 1990). The PRS was formally proposed as a separate memory system in 1990, and is currently under intense investigation. It is believed to consist of several subsystems, one of which is a structural description system which stores descriptions of coherent or meaningful objects. A more recent theoretical proposal identifies a series of specialized memory processes at an earlier and more primitive level of representation, which stores information about elementary attributes of the visual world, such as the orientation, color, motion, and texture of visual patterns (Magnussen and Greenlee 1999). The function of this latter form of visual memory is not known but it might store information across fairly short time spans to help building permanent object representations.

2.2 *Visual Representation in Episodic and Semantic Memory*

Visual recognition goes beyond the recognition of classes of objects. The picture in the morning paper is not just a sidewalk café, it is the Deux Magots in Paris, and the person in the front row is not just a female figure, it is the movie star Catherine Deneuve. The conscious recognition of particulars is a visual expression of semantic memory—a memory system that stores information about general facts. And if you are a Parisian or happened to be a lucky tourist, you might also remember seeing Catherine Deneuve walking by as you were sitting outside the very same café, and you might remember her looks at that particular day. This production of a memory image to the 'inner eye' is a visual representation of episodic memory, a

memory system that stores information about personal facts and episodes.

Semantic and episodic memory represent declarative or explicit forms of memory. Both personal observation and experimental research testify to the human capacity for visual episodic memory. In a series of classical studies in cognitive psychology (Standing 1973) subjects viewed large numbers of black-and-white and color slides of natural scenes, objects, persons, interiors, and landscapes, and memory was later probed by presenting pairs of slides containing one previously seen and one novel picture and asking the subjects to pick from each pair the picture they remembered. Human subjects are amazingly good at this task. With a learning set of 2,500 pictures the score was on average 90% correct after a 36 h memory interval, and with a learning set of 10,000 pictures the score was 84% correct in the test trials. This easily outperforms the memory for words tested with similar methods (see *Recognition Memory, Psychology of*).

The excellent recollection of pictures and visual scenes has been explained in terms of the dual coding theory, which distinguishes between visual and verbal memory codes (Paivio 1995). Picture memory has an advantage because pictures are effectively coded in both memory systems whereas words are coded primarily, but not exclusively, in verbal systems. The effectiveness of dual coding is illustrated by memory-enhancing techniques, e.g., in the 'method of loci' where items to be remembered are attached to places in a visualized familiar environment and later retrieved by mentally traveling the same path in memory (see *Mnemonics, Psychology of*).

The distinction between visual and verbal coding systems is also central in theory of working memory. The working memory is a system for maintaining new information or information retrieved from long-term memory, and this maintenance of information is performed by two so-called slave systems, one of which is the 'visual–spatial sketch pad' a hypothetical rehearsal mechanism that keeps refreshing visual and spatial perceptual information (see *Working Memory, Psychology of*).

3. *Are Visual Codes Necessary?*

The necessity for postulating visual codes has been questioned by cognitive psychologists who favor a unitary memory system based on propositional, language-like codes. As an illustration, studies of memory expertise have shown that the memory of chess masters is vastly superior to that of ordinary players for real game positions, but not for random positions of chess pieces on the board (Chase and Simon 1973). The expertise memory is explained by the fact that masters have a long-term storage of a large number of visual 'chunks,' where a chunk is a constellation of actual game positions involving a few pieces, and the estimated number chunks is about 50,000, which is comparable to the number of words commanded by persons with a college education. Obviously, such chunks may be effectively represented either in terms of image codes or in terms of propositions—or in both (see *Mental Imagery, Psychology of*; *Expert Memory, Psychology of*).

The arguments for the existence of visual codes in memory may be summarized under four headings, as follows.

3.1 *Subhuman Primates Have Detailed Visual Memories*

Experiments with monkeys have shown that these animals can learn to discriminate between large numbers of complex abstract fractal or snow-flake type visual patterns, store these in long-term memory, and utilize the information in single-trial short-term memory tasks. Few, if any scientists have claimed elaborate propositional representation in monkeys.

3.2 *High-precision Storage of Sensory Information*

Experiments carried out in the 1990s have shown that sensory information, i.e., texture, orientation, motion, and similar attributes of the visual image, is extremely well retained in short-term memory. In fact, attributes such as motion and spatial frequency are represented in memory with the fidelity of the sensory image, at least for memory intervals of the order of minutes, but there is also some evidence for long-term storage of detailed sensory information. In one famous experiment, an eidetic subject was able to identify the three-dimensional figure hidden in random-dot stereograms when the left and right-eye patterns were viewed on different days (Stromeyer and Psotka 1970). Such high-fidelity images cannot reasonably be stored in terms of propositions.

Long-term memory changes in the form of perceptual learning are also well established. Subjects get better at performing fine discriminations between orientations or textures across large number of training sessions. The learning is specific for the training conditions and does not transfer to other conditions; for example, when subjects are trained in discriminating visual textures in one part of the visual field, the training effect does not transfer to other parts of the visual field (Karni and Sagi 1991). Some forms of visual memory must be due to local neural changes closely associated with the perceptual process itself.

3.3 *Dissociation Between Visual Memory and Other Forms of Memory*

Lesions of the brain which disturb semantic and episodic memory may leave the perceptual recognition

process intact. The patient's perception of the world is normal but he or she does not remember seeing these objects or persons before. Recognition memory may be demonstrated though perceptual priming (see *Priming*, *Cognitive Psychology of*): If the patient is shown a drawing of an object and at a later time is shown the same drawing again, there is a gain in the time required to identify and name drawings that were previously seen compared with novel drawings, and the gain is comparable for amnesic and normal subjects.

If, on the other hand, the link between visual memory representations and on-line perception is disrupted, amodal (verbal) episodic and semantic memory may be intact but the person can no longer recognize what he or she sees. In this condition of *visual agnosia* there may be nothing wrong with perceptual process *per se*, the person navigates safely in the geographic environment and may even copy diagrams and drawings, but the information which comes from vision is meaningless.

3.4 Visual Processing Areas of the Brain Are Recruited in Memory Tasks

Studies of memory processes in the human brain with modern brain imaging technology such as positron emission tomography (PET) and functional magnetic resonance tomography (fMRI) have shown that there is no special region of the brain where memories are stored. Memory involves widely distributed networks and all major regions of the cerebral cortex have been implicated in the various forms of memory. Since visual memory is a form of representation, a code rather than a system, one would expect it to share processing space with several memory systems, in addition to regions of the occipital lobe that are specific for the processing of visual signals.

Memory researchers now generally agree that memories may involve many of the neural ensembles that were involved in the processing of the information in the first place. In vision a close link between perception and memory is illustrated by the observation that certain forms of perceptual deficits due to local brain lesions appear to affect memory as well. For example, persons who lose their ability to see colors owing to bilateral lesions of a region of the occipital lobe known as V4 usually also lose their ability to remember or imagine colors.

The current debate on the neural mechanisms of visual memory does not consider whether sensory processing areas are recruited in memory, but how far down the processing hierarchy recruitment extends. Some brain imaging studies claim that the primary visual cortex (region V1), i.e., the very earliest level of sensory analysis receiving direct input from the eye, is activated in visual imagery tasks, but other studies do not find this activity (Cabeza and Nyberg 1997).

A logical argument may be directed against the involvement of early visual processing areas and a unification of visual perception and memory processes: Since memory images are normally much less vivid and detailed than perceptual images, and memory is rarely confused with perception, they must activate at least partly different neural circuits. The precise relationship between visual perception and visual memory is a major task for future research.

Visual Methods in the Social Sciences

Visual methods, relative to other methods, are underdeveloped in the social sciences. The probable explanation is that social science reasoning generally relies on the analysis of aggregate data, and photography and other visual methods locate their attention on the particular. Thus, it requires a reversal of typical social science reasoning to generalize from the particular, especially when the particular is a visual image.

The nature of visual evidence is also problematical for social science. Photographic (film or video) images

appear to represent the world 'objectively,' that is, without interpretation. At the same time, it is recognized that photographs are socially and technically constructed, thus embodying points of view and interpretive influences. The tension between the competing qualities of objectivity and subjectivity influence the use of visual images in the social sciences.

1. Forms of Visual Methods

1.1 Empirical Evidence

Photographs (or photos linked together in film or video) are the most common form of visual sociology. The most common use of visual images is to catalog aspects of material culture or social interaction (see Collier 1967), which was a common aspect of articles published in the first issues of the *American Journal of Sociology* (see Stassz 1979). In the first 20 volumes of the *American Journal of Sociology*, until 1916, sociologists used photographs to make arguments about the character of rural and urban life; the working conditions in offices and factories, and living conditions in industrializing cities. As sociology sought a more scientific posture, the visual research method (which was not well developed in these early examples) was largely abandoned.

Anthropologists, working in the first decades of the twentieth century, also used photography extensively (Edwards 1992). Anthropology's primary mission during its early eras was to document and classify human groups. Photography's ability to gather a large amount of information in a single document made it an important data-gathering method. As anthropology abandoned paradigms based on the taxonomic organization of racial classifications, photography became less important as a research method.

The full development of photography as part of ethnographic analysis is generally attributed to Gregory Bateson and Margaret Mead's (1942) study of Balinese culture. In this project, the researchers used 759 photographs (selected from more than 25,000 made during their fieldwork) to support and develop ethnographic observations and analysis. Bateson and Mead used sequences of photographs to show how the Balinese performed social rituals or engaged in routine behavior. These images typically record the unfolding of events, and thus are similar to short movie clips. The researchers also used images to survey material culture such as dwellings and agricultural techniques. This promising expansion and redefinition of visual anthropology has been followed by contemporary examples such as Danforth and Tsiaras' study of death rituals of Greek villagers (1982), and several other examples in sociology and anthropology.

Howard Becker was the first modern sociologist to suggest a link between photography and sociology (1974). Much of Backer's argument referred to the ability of photographs to record the world as observed. For example, Becker noted that photography and sociology, since their inception, had both been concerned with the critical examination of society. Becker noted that the early twentieth century photographers, such as Lewis Hine and Jacob Riis, were concerned with topics such as urbanization and industrialization, the exploitation of labor, and the conditions of immigrants, all of central concern to sociologists. Becker suggests that a modern visual sociology should emerge from documentary practice engaged with a sociological theory, and the sociological use of visual data developed in the context of common concerns with validity, reliability, and sampling. Becker's article, reprinted in several anthologies, is credited with the rebirth of visual sociology in the US.

In the meantime, sociologists have used photographs as evidence in the study of social change (Rieger 1996), in sociological classification of farmsteads (Harper 1997), and other topics that reflect conventional sociological research. Visual ethnography, however, remains a relatively small movement within the field methods tradition in sociology and anthropology.

1.2 Photos as Cultural Narratives

Anthropologists have used film and video (and, to a lesser extent, the 'photo essay') to communicate typical events of a cultural scene. This tradition is largely attributed to Robert Flaherty's seminal ethnographic film, *Nanook of the North*, completed during the 1920s (see Rotha 1980). The resulting film tradition in anthropology has both embraced and challenged the capacity of visual narrative format to communicate cultural information. Nevertheless, the use of film (and photography) to tell 'cultural stories' remains a viable part of visual anthropology, and constitutes the single most influential demonstration of visual methods in social research. In anthropology, ethnographic films are presented at professional meetings, scholarly film festivals, and as a part of normal pedagogy.

1.3 Photographs in the Research Process

Collier (1967) first described how researchers may employ photographs to elicit cultural information. The process, now referred to as 'photo-elicitation,' uses images to stimulate culturally relevant reflections in interviews. Researchers may take the photos prior to the interview, or the photographs may be from a personal collection or professional archive. Photo-elicitation has become a common method in visual sociology, used in a wide range of studies, including public responses to social problems (Faccioli and Zuccheri 1998), cultural definitions of an urban neighborhood (van der Does et al. 1992), the 'working knowledge' of a rural artisan (Harper 1987), and

ethnic recognition among Asian immigrants (Gold 1991). The promise of photo-elicitation lies in the understanding of how photographs communicate different meanings to the researcher and the subjects; thus the images become a basis of interviewing that explores the taken-for-granted assumptions of both researcher and subject.

Social science film-makers have integrated imagery into research in a different manner. Beginning in the early 1970s, anthropologists have taught cultural informants to use film and video cameras in order to make films that tell cultural stories from the vantage point of the informant. The first example of this method was Sol Worth and John Adair's research among the Navajo, which resulted in seven films made by native informants (described in Worth and Adair 1972). With the advent of easy to use video cameras, native-produced visual ethnography has become more common. While controversy continues to surround the redefinition of theoretical authority that native-produced films challenge, most visually oriented social scientists find the native-produced film or video a viable source of ethnographic information.

2. *Problems in Visual Methods*

2.1 *Ethics*

There are at least three aspects to the question of ethics and visual methods in research. The first concerns the matter of anonymity; the second concerns the matter of informed consent; and the third represents the burden of 'telling the visual truth.' These three issues are inter-related.

Because social science is generally concerned with the patterns of social behavior, individuals are represented by words, or more commonly, by responses they have made to a questionnaire. Thus the identity of individuals are protected. The protection of the privacy of subjects is, indeed, codified in the ethical canons of the social science disciplines. In the case of visual research, however, it is often impossible to protect the privacy of subjects. All discussion of ethics and visual methods rests on this fundamental fact; the photograph produces a likeness which is often identifiable.

Visual researchers thus face a more pronounced problem of informed consent. Subjects must be made aware of implications of publishing their likeness in social science research, and agreement to participate should be made in writing and prior to the research.

The matter of ethics in visual research is unique among research methods for one final reason. Because it is often possible to identify subjects in research images, visual researchers must be absolutely certain that these images 'tell the truth.' Visually oriented social scientists recognize that it is unethical to alter images to change their meaning, or to present an image that connotes a reality that was not consistent with the understood reality of a situation. Most visual researchers feel that the ethical considerations of visual research most separates it from that of their peers.

3. *Technology*

Like all social science methods, visual research depends upon technology. Like all technologies, visual technology makes it possible to record some types of information, but not others. Steiger (1995) detailed how specific cameras, lenses, film types, and camera settings create different kinds of filmic statements, which, in turn, make possible different types of sociological thinking. The specific connection between 'technologies of seeing' (whether relating to photography, film, video, or virtual reality) and social ideas remains an area of enormous potential and scant attention. Steiger's article raises the important point that to be a skilled researcher using visual methods is to master cameras, video and film cameras, and possibly photo printing. Now that many of these technologies have an electronic dimension, skilled visual researchers also need to become adept at software that catalogs visual images, that allows for the improved presentation of images, and that facilitates the production and distribution of images.

New methodologies, such as computer-based multimedia, the World Wide Web, CD publication, and virtual reality, all offer possibilities for the development of innovative visual methods. Each offers an approach for recording, analyzing, and participating in the visual dimensions of society. The future of visual methods in social research will depend, to a large extent, on how well these new technologies are integrated into social science methods and thinking.

4. *Publication: Organizational Basis*

In the past two decades, visual research in anthropology and sociology has been institutionalized in intellectual organizations such as the Society for Visual Anthropology, a part of the American Anthropological Association, and the International Visual Sociology Association, an independent scholarly organization with ties to several academic disciplines. Publication of visual methods requires special consideration, and the journals such as *Visual Anthropology* and *Visual Sociology* feature the presentation of images. The full development of visual methods in social research will require that the mainstream journals and books accept the publication of images as a normal part of social science research, no different than the publication of tables or graphs.

Visual Perception, Neural Basis of

Visual perception requires that patterns of light energy are encoded into neural signals in the retina of the eye, and that these signals are transformed as they pass through the neural network of the retina and are transmitted to a series of interconnected brain areas. These transformations create patterns of neural activity that can represent the visual information needed for recognizing objects, people, and events; for location in the environment; and for guiding actions.

1. *Structure of the Visual Pathway*

Encoding begins in the photoreceptor cells (rods and cones) in the retina, which signal the local light intensity falling on each receptor by their levels of electrical polarization. A network of horizontal, bipolar, and amacrine cells connect these receptors to the retinal ganglion cells. The axons of these cells form the optic nerve, and so the signals that they carry constitute the information that the eye sends to the brain; the nature of this information is discussed in Sect. 3. At the optic chiasm, these axons are routed so that signals from the two eyes can be transmitted to each side of the brain, making binocular integration at a higher level possible.

The lateral geniculate nucleus (LGN) of the thalamus provides a relay station where visual signals can be modulated, but the next major reorganization occurs when the signals arrive in the occipital lobe of the cerebral cortex (see *Cerebral Cortex: Organization and Function*). The primary receiving area, at the posterior pole of the brain, is known as striate cortex, or cortical area V1. It is surrounded by a series of extra-striate visual areas. These areas can be distinguished both by specializations of function (see Sect. 2.4) and by the fact that many of them form distinct, ordered maps of the visual field. Area V2 receives much of the input from V1, and sends information on to areas V3, V4, and V5. Pathways through these areas send information to the temporal and parietal lobes of the brain.

Within each cortical area, most connections between neurons are quite local. However, information is passed between cortical areas in fiber tracts, in an orderly way. Specific layers of the cortex receive input from areas at a lower hierarchical level, while other layers either transmit to higher levels, or receive feedback from higher levels. Thus, cortical areas are commonly thought of as a set of modules, each performing particular visual computations and passing the results of these computations to other modules.

A minority of fibers in the optic nerve transmit information not to the cerebral cortex, but to midbrain structures, in particular the superior colliculus which also incorporates a topographic map of the visual field. In lower vertebrates, the homologous structures provide the main central visual pathway, but in mammals, certainly in primates, this pathway serves the function of orienting to stimuli by eye movements rather than any complex analysis of the visual image, and probably does not contribute directly to conscious visual perception. However, there are connections running both ways between this subcortical visual pathway and the much more elaborate cortical network for visual information processing.

2. *Key Concepts of Neural Representation and their Evolution*

2.1 *Specific Nerve Energies and Place Coding*

In developing modern concepts of the neural basis of vision, an early key idea was that messages from the eye to the brain could convey distinct information according to which element of the nervous system carried them. Thomas Young, around 1800, proposed that different colors were represented according to the degree that three forms of 'sensitive filament' in the eye were stimulated, a view that in its essentials is accepted today. Developments of this idea in the nineteenth century were that each separate fiber in the optic nerve

is associated with a 'local sign' (*Lotze*)—that is, we can know which point in space stimulated our eyes from which particular fiber is active—and the 'doctrine of specific nerve energies' (*Müller*) that the quality of stimulation (e.g., sound versus light) is conveyed by which fibers convey a signal, not by any distinct quality in the signals themselves. This principle (sometimes called 'place coding' or 'labeled line') is now recognized as fundamental for understanding how visual information is represented within the brain, as well as in the sensory pathways leading to it.

2.2 Univariant Coding by Impulse Frequency

The work of Adrian in the 1920s established that sensory information is carried by a series of nerve impulses (action potentials). Since the impulses are identical all-or-none events, quantitative variations, e.g., in light contrast, have to be encoded by the rate at which impulses occur. In principle, more complex statistical properties of the train of impulses could carry rich information, but visual neurophysiology has not yet yielded convincing examples of this. Thus, the activity of a single neuron is univariant—it can encode only a single variable in the visual image. The classic example is in color vision: a particular receptor may respond relatively more strongly to green light than to red light. However, because its response is univariant, it can give indistinguishable responses to a dim green light and a bright red light. Thus, to represent even a single variable, within a multidimensional domain such as color, requires information to be combined or compared from two or more neural signals.

2.3 Receptive Fields and Tuned Filters

These principles of neural coding have been particularly applied in considering how the visual system represents spatial information. A concept which developed early was that each visual neuron had a receptive field—a region of the field of view within which light could influence the activity of the neuron. Further work showed that receptive fields had internal structure, such that a particular spatial pattern of light and dark within this region was optimal for activating a given neuron. This led to the idea that neurons could be 'feature detectors,' signaling the presence of a specific pattern element, such as a small black moving spot that might be a fly in the visual field of a frog. However, in the mammalian brain at least, it currently seems unlikely that any neuron on its own can provide such a signal; in all cases that have been investigated, the distribution of activity across some population of neurons would be needed to determine reliably the presence of a particular feature or object. This idea of population coding should not obscure the fact that, in visual brain areas, coding is sparse. That is, for any particular visual stimulus, only a small fraction of the available neurons are active, and so it is appropriate to think of particular subsets of neurons as being involved in representing particular visual attributes.

Neurophysiological and psychophysical studies in the 1960s and 1970s concentrated on how populations of neurons in V1 encoded particular visual properties, such as contour orientation. Each neuron was found to be a 'tuned filter,' which responded to a limited range of orientations. This makes it possible (a) to derive orientation information from the peak of activation across a distribution of differently tuned filters; and (b) to segregate visual information according to the local orientation, which may be valuable for segmenting and grouping the scene into distinct objects and surfaces. Cortical neurons also act as arrays of tuned filters for other properties, such as direction of motion and color.

2.4 The Hierarchy of Multiple Visual Areas

The finding, that neurons in area V1 were tuned to a range of stimulus properties, led to exploration of higher levels of cortical processing. Experiments with macaques, from the mid-1970s onwards, showed that there is a multiplicity of distinct visual areas beyond V1. As well as progressive transformations through a hierarchy of visual areas, there was found to be parallel processing by areas such as V4 and V5, which receive information from V1 in parallel via separate routes. These areas are specialized, so that, for example, V5 contains a high proportion of neurons tuned to specific directions of motion but few that are wavelength-tuned, while V4 shows the opposite balance. This has led to a picture of functional segregation, within the cortex, of representations which emphasize different aspects of visual information and which presumably serve distinct purposes.

It was recognized that this picture of functional segregation was consistent with findings in human patients who had localized brain damage; for instance, such damage could abolish color discrimination with little effect on other aspects of visual perception. In the 1990s new methods of functional brain imaging made it possible to explore localization of function in the normal human brain (see *Functional Brain Imaging*). These have confirmed the multiplicity of visual areas, each responding to particular stimulus properties and activated in different visual tasks. The fact that brain activation depends on the particular task the subject is set, and on his/her attention to the stimulus, indicates that vision cannot be thought of as a purely 'bottom-up' neural process, in which information originating in the receptors is progressively transformed. Rather, the results of high-level processes can modulate how low-level processes operate. An anatomical basis for this is provided by 'descending' connections from higher to

lower visual areas, which are at least as rich and complex as those transmitting information from lower to higher processing.

These concepts of neural information processing inform current research on all aspects of vision. In this article they are illustrated primarily with respect to the representation of pattern, shape, and spatial layout. They also underlie current understanding of other perceptual functions which, however, will not be developed here (see *Motion Perception: Psychological and Neural Aspects*; *Color Vision*).

3. Representation of Spatial Pattern and Shape

3.1 Receptive Field Structure and Specificity

The richness of vision as a source of information comes largely through the detailed pattern of light and dark that arises from the spatial structure of the environment. Encoding of this pattern begins in the retina. Receptive fields of retinal bipolar and ganglion cells have a center–surround opponent organization. In an 'on-center' cell, light in the receptive-field center activates the cell, but this is countered by inhibition from any light in the surround. Off-center cells show the opposite relationship. In either case, the activity of the cell signals the presence of spatial contrast, with little or no response to a uniform field of light covering the receptive field.

The signals leaving the retina in the optic nerve therefore highlight the field locations where spatial structure is present, but carry little explicit information about the nature of this structure. For instance, ganglion cell receptive fields are circular, and so respond equally to the contrast in an edge crossing the field whether it is horizontal, vertical, or oblique. Neurons in area V1 also respond to local contrast, but mostly have receptive fields with a preferred orientation. For example, if a vertical contour yields the maximum response, this response falls off sharply for a contour oriented 30° either side of vertical. Neurons with different preferred orientations ensure that contours at any angle around the clock are represented by activity within V1. Orientation seems to be a key organizing principle for V1, indicated by the layout of neurons in a semi-regular array of 'orientation stripes' across the cortical surface; presumably this provides the initial basis for the neural representation of shapes and textures.

A second important organizing principle is that of multi-scale representation. Some cortical neurons respond to very fine-scale spatial detail; others, covering the same region of space with larger receptive fields, respond to similar features on a much coarser scale. Mathematically, this scale variation has the effect of a local analysis in terms of component spatial frequencies of the image. Computational studies show that this is an efficient way to capture the significant structure of scenes.

3.2 From Measurements to Spatial Primitives

The multi-scale array of orientation-selective neurons in V1 can be considered as making a comprehensive set of measurements of the image. To develop a useful representation of scenes and objects, these measurements need to define primitives—elements of an 'alphabet' of spatial structure through which more complex entities can be represented. Thus, a measurement of contrast in a particular orientation and scale does not itself unambiguously define an edge segment; but in conjunction with nearby measurements at a range of scales, it can provide the basis for an assertion of a local edge-segment primitive. While such primitives are important in the computational description of what the visual system is doing, it is unclear whether neurons in visual cortex explicitly represent primitives, or rather whether they are implicit in the pattern of connections amongst V1 cells and from V1 to higher levels.

3.3 Grouping Processes

To yield descriptions of object shapes and bounded surfaces, local edge primitives must be grouped together to form extended contours and areas with a common texture—effects whose importance was first recognized by the Gestalt psychologists. A plausible neural basis for grouping exists in the horizontal connections between V1 cells tuned to a similar orientation. Contours, in turn, define the boundaries of surfaces and objects. Neurons have been reported in V2 which respond to the characteristic alignments of elements where one surface occludes a background surface. Local neural activity in V1 and V2 also reflects the key perceptual distinction between regions that form a distinct figure, and those that form the ground.

3.4 Recognition

One important end point of the processing of spatial pattern is the visual recognition of objects, faces, and scenes. Object recognition can be specifically impaired (agnosia) by damage to the temporal lobe of the brain, and a specific loss of the ability to recognize faces (prosopagnosia) may also occur. Functional imaging studies shows an area that is selectively activated during the processing of faces (the fusiform face area), and another that is active in visual recognition of locations (the parahippocampal place area). Human studies cannot show how individual neurons are responding, but in the temporal lobe of the monkey, single neurons are found to respond specifically to faces. The pattern of activation over a group of such cells conveys sufficient information to distinguish one individual from another. In the inferotemporal region, cells respond to features that can define different types of object. In both cases, the response shows position generalization; that is, it is selective for a particular

class of stimulus, irrespective of its position within a wide receptive field.

Thus, the principles of a sparse population code, found in the representation of local pattern in V1, appear to apply also to the higher level representation of visual identity. However, the hierarchy of neural transformations which connects the former with the latter is very poorly understood.

4. Spatial Location and Layout

As well as allowing the identification of objects and scenes, vision defines the space within which objects are located and are the targets of actions. Disturbances of spatial abilities are found with damage to the parietal lobe in both human and monkey brains. These disturbances are quite distinct from the impairment of object recognition, leading to the proposal of a broad division between a ventral stream of cortical visual processing, from V1 to temporal lobe and concerned with what we are looking at, versus a dorsal stream from V1 to parietal lobe which conveys the information needed to know where it is and how we can act upon it. Different specialized visual areas contribute to the two streams; in particular the motion area V5 (MT) sends information primarily via the dorsal stream (see *Visual Systems: Dorsal and Ventral*).

Spatial information requires a frame of reference. Area V1, and other early visual cortical areas, appear to be organized within a retinotopic frame—that is, the receptive fields, and their topographic arrangement across the cortex, are defined in terms of image locations on the retina. Since the eyes are constantly moving in the head, a stable representation of space requires more than retinotopic information. Eye direction must also be factored in, to establish a head-centered frame. Such combination of retinal and eye-direction information occurs in a number of parietal areas. However, the properties of cells in different parts of parietal cortex suggest that they are preparing visual information in an appropriate form for controlling different action systems—e.g., eye movements, reaching and grasping by the hands, and locomotion. Each of these may require a different frame of reference. An alternative frame of reference is allocentric, i.e., referred to the layout of the environment rather than any part of the body of the observer. It has been suggested that this is a feature of the ventral stream which has to identify objects independently of any particular viewpoint.

Parietal areas transmit information to motor-related areas of the frontal lobe, both directly and via the cerebellum. Comparison of cells in the parietal lobe with those in the premotor frontal areas to which they project emphasizes the difficulty of defining any boundary between visual and motor processing. For instance, activity in some parietal neurons is associated both with viewing a particular three-dimensional shape (e.g., cylinder) and with the grasping action required by that particular shape. 'Mirror neurons' in premotor cortex respond both in association with the hand action of the monkey, and when the monkey is passively viewing another hand executing the same action. It is best to think in terms of visuo–motor circuits which embody the spatial information needed to control and define a particular type of action. It must be recognized that the brain contains multiple circuits for different action types, each of which may work within a spatial frame of reference appropriate for its own requirements.

5. The Binding Problem

Research on visual neuroscience has emphasized the fragmentation of brain processing. Many different neurons are activated by any visual stimulus. Distinct brain areas and subsets of neurons process different attributes such as shape, color, and motion, and there are multiple spatial representations in different visuo–motor circuits. In contrast, our experience of the visual world appears unified, and the different attributes of a visual object are bound together—if a white cup and a green book are together on the table, we do not confuse which color belongs to which object. How perceptual unity arises from a fragmented neural representation is known as the binding problem (Treisman 1996).

Two, not necessarily incompatible, answers have been widely discussed. One is based on Anne Treisman's feature integration theory of attention. This theory, supported by evidence from visual search, proposes that a 'spotlight' of focal attention modulates processing within distinct 'feature maps' for different attributes, and so multiple feature attributes are accessed only for the object that is the current focus of attention. The second idea is that cortical neurons show oscillations in their activity at frequencies around 40 Hz, and that temporal coherence between these oscillations acts as a label for different signals contributing to the representation to a common object. Such coding by temporal synchrony has attractions; it could provide a basis for understanding how features at different locations within a single map can be linked or segregated in object-based representations, as well as how binding occurs across different maps. However, the evidence for it remains quite limited.

6. Neural Basis of Visual Sensitivity and Thresholds

Much detailed knowledge of vision comes from the analysis of psychophysical thresholds—measures of how sensitive the visual system is in making fine discriminations. If these data are to be integrated with knowledge from neurophysiology, the relation be-

tween psychophysical threshold and patterns of neural activity needs to be understood.

'Threshold' conveys the suggestion of a stimulus intensity below which no neural activity is elicited. However, in practice, neurons are rarely silent, and their activity, even with a fixed stimulus, shows variability or 'noise.' Thus, the ability to detect weak stimuli is determined by the statistical problem of distinguishing a stimulus-driven change in activity from those due to noise.

Several studies have determined the 'thresholds' of single neurons in monkey visual cortex, in terms of the stimulus level which achieves a statistically defined level of reliable response. These can be compared with behavioral performance in detection; in some cases behavioral and neural measures can be made simultaneously. The information carried by single neurons proves to be remarkably close to that implied by the behavioral responses. Remarkable, because the animal has the opportunity to pool the information from thousands of neurons, which would be expected to yield much more reliable information. The data can be reconciled by realizing that although large numbers of neurons may be involved, the random variations in their activity are correlated so the number of genuinely independent neural signals is much smaller (Newsome et al. 1995).

Whether a particular judgment depends on pooling activity in tens, hundreds, or thousands of neurons, there must be many more neurons in the same brain area whose activity is irrelevant because they do not respond selectively to the stimulus concerned. If activity of such neurons was included in the pooling process, it would introduce noise and degrade sensitivity. Thus sensitive discrimination, either in the laboratory or in real-life situations, must depend on selecting a small minority of neurons whose output is informative for the task in hand.

7. *Modulation of Neural Activity by Attention and Task Demands*

It could be conceived that neural activity, relevant to a particular task, was channeled to appropriate decision and response mechanisms through a purely 'bottom-up' process. However, Sect. 3 has mentioned the ample evidence for 'top-down' control of visual processing, modulating activity at many levels according to the central decisions about what is relevant. For instance: (a) neural activity, as early in the pathway as the LGN, is strongly modulated according to the sleeping–waking state of the organism; (b) the response of single neurons in areas such as V4 and V5 in monkeys can be changed radically according to whether the preferred stimulus of the neuron is behaviorally relevant or irrelevant on a particular occasion; (c) functional brain imaging shows that the overall activation of an area such as V5 in humans is enhanced by attention to the property that it analyses (in this case, motion), even if the stimulus is unchanged; and (d) within a topographically organized area such as V1, activation of a particular region is enhanced when attention is directed to the corresponding region of visual space (see *Attention, Neural Basis of*).

8. *Plasticity and Learning in Visual Neural Organization*

Section 7 discussed how the function of the visual system can be dynamically modulated from moment to moment. Visual neural function shows long-term adaptive changes, in response to the inputs it receives. For instance, if the input to visual cortex has an anomalous distribution across the retina (e.g., as a result of a congenital absence of cones in the central fovea) the usual retinotopic map in V1 is distorted to match this distribution. When the balance of input from the two eyes is disturbed (e.g., when the input of one eye is reduced in a critical period during early development) the cortex adjusts to receive less input from the less active eye. The plasticity seen in these abnormal cases must also play a role in normal development: development of the normal neural organization of visual brain areas must depend on the regularities and correlations in the visual input that these areas receive.

Visual abilities show strong learning effects; almost any visual discrimination becomes strikingly more sensitive with practice. This learning can be highly specific, for example showing improvement for stimuli only at the orientation that has been practiced, suggesting that changes occur at relatively low levels of visual processing such as V1. The discussion in Sect. 6 suggests that such learning may be based on establishing highly specific connections to decision mechanisms from the neurons most sensitive to the stimulus concerned. However, while changes with learning have been demonstrated in the responses of visual cortical neurons, the basis of these changes in modified connections is still speculative.

9. *The Neural Basis of Visual Awareness*

The detailed understanding of how visual information is represented in the nervous system does not answer the question: what aspect of neural activity corresponds to the conscious awareness of the subject? Many aspects of vision (for example, which eye received a monocular stimulus) are not accessible to consciousness, even though the relevant information exists within the nervous system. Is there some subset of visual neurons whose activity contributes specifically to awareness?

Individuals with damage to V1 report that they are blind in the region of the visual field corresponding to

the damage. They can sometimes make reliable responses to stimuli they do not report seeing. Thus there must be routes for visual information, probably through the superior colliculus in the midbrain, whose activity has no conscious correlate. However, it is not known whether V1 activity is itself a necessary correlate of conscious visual experience, or whether V1 simply serves as the only access route to higher processes that have such a correlate.

In binocular rivalry, discrepant patterns are presented to the two eyes, and alternate in perception. Neuronal activity can be monitored in monkeys who are also signaling which pattern is perceptually dominant. For some cortical neurons, activity fluctuates in correspondence with perceptual dominance, but for others there is no correlation. The proportion in the former group increases in going from lower to higher cortical areas (Logothetis 1998). These results suggest that awareness is not uniquely associated with particular cortical areas, but may emerge cumulatively as information is processed through the system. The true relation between brain and consciousness will remain speculative for many years, but visual processing is likely to provide the key test cases for this central problem of the human sciences (see *Consciousness, Neural Basis of*).

Visual Space, Geometry of

Human orientation in space is based primarily on vision: we are able to judge the size of an object even from a distance, its form and shape, and its egocentric distance. The set of all objects in the visual field together with the 'perceived' spatial relationships between them is called 'visual space.' To some extent, our perceptions are veridical. There are, however, marked and stable deviations from the physical relationships. This observation raises two questions: (a) are the regularities of perceived spatial relationships characterized by some particular geometry? and (b) if so, what are the psychological functions relating this geometry to the well-known Euclidean geometry of physical space? This article is only concerned with the first question (for the second one see *Binocular Space Perception Models*). It has four main parts. After some introductory and historical remarks on first observations and perceptual phenomena leading to the notion of non-Euclidean geometry of visual space in the early 1900s (Sect. 1) a formal characterization of what is meant by a geometry is given in Sect. 2. Section 3 presents a discussion of theoretical developments in the field of geometries for visual space, in particular the theory of Luneburg (1947). Section 4 reviews related empirical investigations and results.

1. Is Visual Space Non-Euclidean?

The question of whether visual space is Euclidean was not formulated explicitly until the beginning of the twentieth century. Answers to this question, however, can be traced back as far as the ancient Greek philosophers. Suppes (1997) presents a list of classical contributions to this problem, starting with Euclid's theory of perspective (rated as a 'Yes' answer). His list contains a majority of 'No' statements, some undecided cases rated as 'not sure,' and only a few 'Yes' conclusions, mainly from authors using philosophical arguments rather than empirical results. Strong evidence against Euclidean geometry as an appropriate description of the structure of visual space arose from observations in so-called alley experiments. Investigating the phenomenon of size constancy, Hillebrand (1902, cited in Lukas 1996) asked subjects to arrange small light points in the horizontal plane along two lines such that they should form an alley-like configuration, running from two fixed points towards the observer. He used two similar tasks but with different instructions. The first was to match the 'horizontal distances' of points to make sure that, perceptually, the width of the alley should be perceived as equal at any egocentric distance (D-alley).

The second was to pay attention to the alley's right and left border and make sure that they are perceived as 'parallel straight lines' (P-alley). To Hillebrand's

Figure 1
Classical setting for alley experiments. P and P′ are fixed points at eye level, L and R denote the observer's left and right eye, respectively. The subject adjusts movable points according to one of the criteria shown below (left: parallel alley, right: distance alley)

surprise, the two instructions led to different configurations. Both alley types were curved, with D-alleys consistently lying 'outside' the corresponding P-alleys (see Fig. 1). Blumenfeld (1913, cited in Lukas 1996) confirmed this finding and was the first to mention a far-reaching consequence: since in Euclidean geometry lines with constant distance everywhere are called parallel (and vice versa), visual space has to be non-Euclidean. Blumenfeld's geometric reasoning elicited a vivid discussion, but for more than 30 years thereafter, it was not worked out mathematically in any substantive way. Luneburg (1947) was the first to present both a complete geometrical framework for visual space, and explicit psychophysical functions that related physical and visual coordinates in order to explain the striking results of the alley experiments and other empirical facts in binocular space perception known at that time.

2. *Geometry as a Mathematical Language for Spatial Structure*

Within mathematics there are at least two different approaches to geometry, the 'synthetic' and the 'analytic'. In the spirit of Euclid's axiomatic approach, synthetic geometry is defined over a set of points and a set of straight lines as primitives by specifying a number of relations considered to be true. Over many centuries Euclid's axioms have been considered to be the only reasonable description for spatial relationships. They include incidence axioms (for example, any two distinct lines have at most one common point), order axioms, axioms concerning motion and congruity, metric axioms, and, finally, the famous parallel axiom stating that for any point P and any line g not containing P there is one and only one line g' through P parallel to (not intersecting) g. At the beginning of the nineteenth century, however, Gauss, Bolyai, and Lobachevski discovered independently that the parallel axiom can be replaced by the postulate that there exist at least two parallels, yielding a different type of geometry (later called 'hyperbolic'). Moreover it has been shown that even a third version of the parallel axiom, stating that any two lines have at least one point in common, is compatible with the remaining Euclidean axioms, and leads to an 'elliptic' geometry.

The properties of both types of non-Euclidean geometry are demonstrated easily by models that fulfill the respective set of axioms. A well-known model for an elliptic plane is the surface of a sphere in Euclidean space $I\mathbb{R}^3$, where the set of elliptic lines is defined as the set of all (Euclidean) great circles. Similarly, models for hyperbolic geometry can be constructed on surfaces with constant negative curvature in $I\mathbb{R}^3$ (for example, saddle-shaped surfaces). Hyperbolic geometry is therefore said to have constant negative curvature, whereas elliptic geometry is characterized by its constant positive curvature.

3. *Theories on the Geometry of Visual Space*

Let V be the set of all points in the three-dimensional physical space which a fixed observer can see without moving the head. If x, y, z denote the Euclidean coordinates in physical space, then V is a subset of the positive half space $y > 0$ right in front of the observer. The origin of the coordinate system is interpreted as

the egocenter of the observer and is assumed to lie in the closure of V, the x-axis denotes the direction from left to right, and the z-axis corresponds to the vertical axis. We restrict the following discussion to the horizontal plane $z = 0$ at eye level. The well-known Euclidean metric d_{phys} represents the physical distances in V.

In his famous attempt to represent the perceptual structure of binocular visual space geometrically, Luneburg (1947) starts out with the basic assumption that in addition to d_{phys} there exists some metric d_{vis} on V that represents the 'perceived' spatial structure. If γ and ϕ denote binocular parallax and bipolar latitude, respectively (see *Binocular Space Perception Models* for a definition), his theory can be summarized by the following basic hypotheses:

- LH1 There exists a Riemannian metric d_{vis} on the visual field V that represents perceived distances. The geodesics of d_{vis} are perceived as straight lines.
- LH2 The visual space (V, d_{vis}) has constant Gaussian curvature K.
- LH3 The perceived distance d_{vis} $(0, P)$ of point P to the observer is a function of the bipolar parallax only.
- LH4 The ϕ-translations $(\gamma, \phi) \to (\gamma, \phi + \text{const})$ are visual isometries (leave all perceived distances unchanged).
- LH5 The γ-translations $(\gamma, \phi) \to (\gamma + \text{const}, \phi)$ are angle-preserving.

Assumption LH1 provides the basis for the remaining assumptions: In a Riemannian metric space a coordinate system can be introduced that allows numerical representations for any geometrical objects such as lines, angles, triangles, or distances. LH2 restricts the discussion to geometries that are constantly curved everywhere. The remaining assumptions LH3 through LH5 define the psychophysical relationship between (physical) stimulus space and (perceptual) visual space. LH3 implies, for example, that points lying on a Vieth–Müller circle (a circle containing the nodal points of the observers eyes) are perceived as equidistant to the observer because they have the same bipolar parallax γ. These latter assumptions are explained and discussed extensively in *Binocular Space Perception Models*.

Eschenburg (1980) gave a complete proof of Luneburg's conjecture that LH1 through LH5 uniquely determine the metric d_{vis} by two parameters K and σ up to equivalence. More specifically, the line element of the metric is represented in terms of the bipolar coordinates ϕ and γ by

$$ds^2 = \frac{2\sigma^2(d\gamma^2 + d\phi^2)}{e^{\sigma\gamma} + Ke^{-\sigma\gamma}}$$

(Eschenburg 1980 p. 7). K denotes the Gaussian curvature of visual space, and σ is an individual scaling factor.

4. Empirical Results on Geometrical Structures of Visual Space

Whereas LH3 through LH5 are closely connected to the psychophysical relationship between physical and visual coordinates, LH1 and LH2 define the inner geometry of visual space. Empirical investigations have concentrated on two questions: (a) is K constant? (b) if so, is $K = 0$ indicating Euclidean geometry, or $K < 0$ (hyperbolic geometry) or $K > 0$ (elliptic space)? The early observations of distance alleys lying consistently outside the corresponding parallel alleys are only compatible with hyperbolic geometries (Indow and Watanabe 1984). Direct numerical estimates for K can be derived from alley experiments or from so-called 3- and 4-point experiments using double Vieth–Müllercircles (VMC) suggested by Luneburg (1947) (see Fig. 2). Using these methods K has mostly been found to be negative (Hardy, Blank, Boeder, Rand, and Rittler, 1953, cited in Lukas 1996). However, numerical estimates of K cannot always reliably be reproduced in repeated measurements, estimates resulting from 3- and 4-point experiments are not valid predictors for data obtained from alley experiments, and experiments over large egocentric distance ranges

Figure 2
Experimental procedure in 4-point experiments. P_1, P_2, and P_3 are fixed on the Vieth–Müller circles $\gamma = \gamma_1$ and $\gamma = \gamma_2$, respectively. P_4 is adjusted by an observer such that P_4P_3 matches P_1P_2 perceptually.

coincide qualitatively but not quantitatively (Indow 1991).

Moreover, for a test of LH 2, numerical estimates of K are only of limited utility, because they presuppose the psychophysical mapping functions. Several methods have been suggested to test LH 1 and LH 2 independently from the remaining assumptions. In the triangle method used by Blank (1961) subjects had to bisect two sides of a given triangle ABC. Six of a total of seven subjects gave judgments indicating a negative curvature. However, the results seem to depend on the size of the triangle. Using the same method, Higashiyama (1981) found strong variations in curvature depending on lateral positions of the triangles and their distance from the observer. Battro et al. (1976) used stakes to produce experimental alleys of variable size in large open fields in natural environments. The curvature of visual space did not show a negative constant value. In addition, the results of experiments with equidistant lines and visual triangles under these viewing conditions also invalidated the constant curvature assumption.

Luneburg (1947) used quite a different argument and referred to the fact that Riemannian spaces with constant curvature are often characterized geometrically by a property called free mobility (any configuration can be moved to any position in space without changing the shape). Eschenburg (1980) showed that, contrary to Luneburg's argumentation, the existence of visual isometries alone does not guarantee free mobility in a strict sense. In Blank's (1958, cited in Blank 1961) axiomatic version of Luneburg's theory, free mobility is guaranteed by an axiom that implies both the so-called Desarguesian property, and constant curvature in Riemannian spaces. Empirical consequences of this axiom have been tested successfully by Foley (1964, cited in Foley 1972). However, a much stronger test in subsequent experiments failed (Foley 1972). Lukas (1996) gave detailed arguments as to why the first test might have been too weak and the latter one unreasonably strong. From an empirical point of view Eschenburg (1980) provides the most powerful and sensitive test of the constant curvature hypothesis. He shows that an appropriate combination of the double VMC-experiments produces necessary and sufficient conditions for LH2. Experimental tests of these conditions reported in Lukas (1996) reflect a situation that seems to characterize most results in this field: the data are nicely fitted qualitatively by the predictions using constant curvature, yet there are numerically small, but statistically significant deviations.

Nevertheless, there are few models in the literature that try to generalize Luneburg's geometrical assumptions (contrary to his psychophysical assumptions, which have been relaxed in several attempts, see *Binocular Space Perception Models*). Yamazaki (1987) developed a concrete non-Riemannian geometry and suggested its application to visual space. Because this model does not use the concept of length, its utility for empirical research seems limited.

A different approach is reported in Lukas (1996). Starting out with an axiomatic analysis of size constancy, he defines 'apparent distance' in terms of modern measurement (see *Measurement*, *Representational Theory of*) and shows that a very weak invariance condition resembling Luneburg's iseiconic transformations (defined in LH 4 and LH 5) forces the geometric structure of visual space to be Euclidean.

5. *Conclusion and Future Directions*

Critical reviews of empirical results seem to indicate that there is little hope of characterizing visual space globally by one particular geometry. Suppes (1995) concludes that visual space is context-dependent and no reasonable simple set of axioms in the spirit of synthetic geometry can be given for the structure of visual space. This view seems to be supported by recent results from Zimmer (1998). In a series of experiments, subjects failed in a test of very basic requirement of 'betweenness' indicating that not even simple order structures on a straight line can be assumed to hold *a priori*. Nowadays, geometric models in visual perception are actively discussed almost exclusively in the context of mathematical psychology and foundational aspects of science. The main stream of research in vision has obviously shifted to computational models (see *Vision*, *Low-level Theory of*) and the analysis of cognitive processes underlying human performance in spatial perception.

Visual System in the Brain

The visual system in the brain refers to both subcortical and cortical neural structures. In primates and other mammals these structures include various targets of the retina in the midbrain and thalamus as well as a large number of cortical areas. Several parallel visual pathways can be identified that are based on the output of different types of ganglion cells in the retina. Visual cortex is comprised of a large number of cortical areas that can be distinguished by a number of criteria. The patterns of connections among these cortical areas allow them to be organized into a hierarchy of visual processing. Many of these cortical areas are organized into repeating modular subunits that appear to processing all the visual information within a small portion of visual space.

1. Subcortical Visual Structures

1.1 Midbrain Structures

The retina projects to a variety of nuclei in the midbrain that are involved in reflexive visual functions. These pathways are best understood in cats, but similar observations have been made in non-human primates. Specific classes of ganglion cells are known to project to the pretectum (PT-sparse and PT-others), where their information is used for the control of pupillary muscles (Rodieck and Watanabe 1993). Other ganglion cells project to the superior colliculus that supports reflexive movements of the eyes and head, especially in response to moving targets. In cats these ganglion cells are known as Y cells (alpha morphological type), but in macaque monkeys only a small proportion are parasol cells (similar to the Y cells of the cat), with the majority of cells coming from a diverse group with varying morphologies (Rodieck and Watanabe 1993).

The superior colliculus gives rise to pathways that ascend into the thalamus to innervate the pulvinar nucleus. In addition, the superior colliculus receives descending projections from a large number of visual cortical areas. These pathways linking the superior colliculus with extrastriate cortical areas describe a second cortical visual system that is distinct from the geniculo-striate system described later. This second pathway is thought to subserve the visual ability known as blindsight, where judgments about objects and especially motion can be made in the absence of true conscience experience.

1.2 Lateral Geniculate Nucleus

The vast majority of retinal ganglion cells project to the lateral geniculate nucleus of the thalamus. The lateral geniculate nucleus is a multilayered structure that receives input from both eyes to build a representation of the contralateral visual hemifield. The basic pattern of the LGN in primates consists of four layers, two each for each eye. The upper two layers become interleaved to form four layers, two each per eye. In primates, three or more anatomical classes of ganglion cells innervate the LGN. The parasol cells of the retina project to the lower two large cell containing layers, known as the magnocellular layers of the LGN. These ganglion cells and their LGN targets have large, concentrically organized receptive fields, lack color selectivity, have high contrast sensitivity, and give transient responses to stimuli. The midget ganglion cells of the retina project to the upper four small cell, or parvocellular layers of the LGN. These cells and their LGN targets have small receptive fields, which are organized with color opponent centers and surrounds, based largely on red and green cone inputs. These cells provide the majority of input to visual cortex, but their signals unambiguously represent stimulus color since different responses are observed for different size stimuli. The third class of ganglion cell that projects to the lateral geniculate nucleus is known as the bistratified cells which project to cells located in the intralaminar zones between the main LGN layers (Rodieck and Watanabe 1993). Physiological investigations have identified these cells to be of the blue/yellow type and their receptive fields are not concentrically organized. These cells project to distinct layers in striate cortex where they are though to subserve the beginning of a cortical color processing system.

1.3 Pulvinar Complex

The pulvinar is a collection of nuclei in the thalamus that are largely related to visual processing in higher

cortical areas. In phylogeny, the pulvinar nuclei have increased dramatically in size in parallel with the grown of these higher cortical areas. There remains some controversy about the number of nuclei within the visual pulvinar. On the basis of connections, a collicular recipient zone and a striate cortex recipient zone have been recognized. In addition, area MT projects to a distinct zone within the inferior pulvinar. The remaining subdivisions are less clear, but at least three subdivisions can be distinguished on the basis of their staining for the calcium binding protein parvalbumin (Cusick et al. 1993).

2. *Visual Cortical Areas in Nonhuman Primates*

2.1 *Criteria Used for the Characterization of Cortical Areas*

Visual cortex of all mammals consists of at least two and often a much larger number of distinct cortical areas. However, the specific criteria used to identify these areas vary considerably. The earliest views of visual cortical organization were based on anatomical criteria that compared the size and distribution of cell bodies and fibers across the cortical mantle. The most prominent of these architectonic studies were those performed by Brodmann (1909) and von Economo and Koskinas (1925) who subdivided the occipital cortex into three distinct zones. Primary visual cortex, also known as striate cortex, V1, area 17 of Brodmann, or area OC of von Economo and Koskinas has a very distinctive appearance, due largely to the sublamination of layer 4 and the presence of a dense fiber band in Brodmann's layer 4B, the stria of Gennari. Although the architectonic method allowed the identification of two additional belts of cortex surrounding striate cortex, subsequent studies have indicated that these belts contain more than one functional unit. More recent studies have used various histochemical and immunocytochemical markers to define distinctive anatomical features of several cortical areas.

The next most useful criterion for subdivision of cortical areas is the presence of a distinct topographic map of the contralateral hemifield. Typically, microelectrode mapping was used to define topographic maps of visual cortex and thus to delineate areas. Recently, functional imaging techniques have been used to define the topographic organization of visual areas, especially in humans. The third criterion used for the characterization of visual cortical areas has the specific pattern of intracortical and subcortical connections that a given field makes. These patterns studied through various pathway tracing techniques that label the origins or terminations of specific pathways following the intracortical injection of various tracers. The areas that are innervated and the specific laminar patterns of their connections thus help define specific cortical areas.

The next criterion used to identify cortical areas utilizes physiological methods to describe the functional properties of their neurons. Typically microelectrode recording techniques are used to study the receptive field properties of cells in a given area, which are then compared to other cortical areas. This approach has been most useful for the identification of area MT in primates, whose neurons are nearly all selective for the direction of object motion. Recently, functional imaging techniques have allowed physiological investigations in the visual cortex of humans. These studies first used positron emitted tomography (PET) and more recently functional magnetic resonance imaging (fMRI) has allowed the identification of human cortical areas specialized for motion processing (MT), color processing (V4 or V8), or for the processing of faces or objects.

The last criterion used to study the organization of visual cortex is distinctive behavioral deficits following localized lesions or transient inactivation. This criterion was first used to identify occipital cortex as the locus of visual processing. Subsequent studies have revealed specific deficits in motion or color processing following injury to area MT or ventral occipitotemporal cortex, respectively (Zeki 1990, 1991).

Although each of these criteria is useful for the identification of visual cortical areas, most areas have only been characterized by one or two criteria. Furthermore, the results of different studies have led to different conclusions, so some areas are better established than others. Therefore, the described organization of visual cortex should be considered a work in progress rather than the final word on visual cortex in primates.

2.2 *Cortical Areas in Macaque Monkeys*

Traditional views of the organization of visual cortex in monkeys and man were based on the idea of a primary visual area, V1 or area 17, which was surrounded by two belts containing visual association cortex and 'visual psychic cortex.' As additional anatomical and physiological criteria became utilized, it became clear that visual cortex occupies the whole of the occipital lobe and extends into the parietal, temporal, and frontal lobes. Figure 1 illustrates the location and extent of visual cortical areas of the macaque monkey displayed on an unfolded cortical map and on medial and lateral views of the cerebral hemisphere. As discussed above, many of these cortical areas, such as V1, V2, and MT are well characterized, appear in all primates, and are well accepted by the research community (Kaas 1997). Other areas are less well described and their precise borders and names remain somewhat controversial. As a whole, these visual areas occupy more than half of the surface area of the cerebral cortex of the macaque. They range in size from over 1100 mm^2 for areas V1 and V2 to less

Figure 1

Distributed hierarchical processing in the primate cerebral cortex. © Oxford University Press. Reproduced with permission

than 40 mm^2 for areas MSTd, MSTl, and V4t. Recent studies have extended this view of the organization of visual and visuo-motor areas in occipital parietal cortex (e.g., Lewis and Van Essen 2000). Specifically, this investigation used architectonic criteria to subdivide area LIP into LIPd and LIPv, VIP into VIPl and VIPm, and to redefine the extent of area PIP through the distinction of area LOP in its lateral margin.

Visual cortical areas vary in their functional specializations within perceptual and perceptual-motor categories. Overall, the visual cortex has been subdivided into dorsal and ventral processing streams (Ungerleider and Mishkin 1982). The dorsal stream begins in areas V1 and V2 and proceeds through area MT into parietal cortex. This functional stream, often called the 'where' stream, utilizes stereoscopic and direction specific signals in area MT to feed parietal areas that

are involved in the planning of eye and limb movements to visual targets. The ventral stream also begins in areas V1 and V2 and proceeds through area V4 into temporal cortex. This functional stream, often called the 'what' stream, utilizes color, shape, motion, and binocular disparity information to identify objects and to enable their encoding into visual memory. Although the dorsal and ventral streams are often described as separate and parallel processing streams, there are many interconnections between them that emphasize the interdependence of these various visual functions.

3. Hierarchical Organization of Visual Areas

Many of the visual areas described above have been identified primarily using their patterns of connections with other cortical areas. While earlier views of cortical pathways viewed each area as having a few inputs and a few outputs, current studies have greatly modified this view. Furthermore, cortical pathways differ in their laminar pattern of inputs and origin of outputs. Pathways that terminate in layer 4 of a cortical area are generally recognized to be of the feedforward type, characteristic of the thalamic input to primary visual cortex. In contrast, so-called feedback pathways tend to avoid layer 4 to terminate in layer 1 and 6. Finally, the lateral pathway has been observed which terminates in a column extending across all cortical layers. These different laminar patterns of terminations have been correlated with different laminar patterns of origin. Some feedforward pathways arise exclusively from cells located in the upper cortical layers, while some feedback pathways arise exclusively from the infragranular layers. Many pathways arise from cells located in both supragranular and infragranular layers and they may be of the feedforward, feedback, or lateral type.

A large number of cortical pathways have been identified interconnecting the 32 visual areas described in Fig. 1. As of 1990, more than 300 pathways had been recognized and since then additional areas and many additional pathways have been identified. By comparing the laminar patterns of inputs and outputs of these 32 areas it has been possible to derive an anatomical hierarchy of visual areas in the macaque (Felleman and Van Essen 1991, Maunsell and Van Essen 1983). In the hierarchy illustrated in Fig. 2, each visual area was assigned to a level based upon pairwise comparisons of each area with all other areas that it connects to. According to this scheme, nearly 90 percent of the cortical pathways can be unambiguously assigned as the feedforward, feedback, or lateral type. Most of the ambiguous connections are among visual areas making connections with frontal cortex. Although Felleman and Van Essen were able to derive a hierarchy based on the reported connections of a large number of visual areas, other investigators suggest that these data are not conclusive and thus it is not possible to derive a single cortical hierarchy (Hilgetag et al. 1996)

Recently, quantitative methods have been used to characterize the laminar patterns of origin for cortical pathways among the lower visual areas (Barone et al. 2000). This scheme introduces an anatomical distance metric between areas based on the proportion of supragranular cells in a given pathway. This analysis yields a hierarchy that in many ways is similar to the qualitative hierarchy described above, but differs in the assignment of a few areas. Future work will extend these quantitative studies to additional visual areas.

4. Modular Organization and Processing Streams in Visual Cortex

4.1 Modular Organization of Striate Cortex

A variety of anatomical and physiological evidence indicates that striate cortex is organized in modular fashion. The first module identified was that of ocular dominance columns. In macaque monkeys, inputs from the two eyes are segregated in layer 4 into ~ 0.5 mm wide zones that appear like zebra stripes when viewed tangentially. These stripes can be identified using anatomical methods using tracer transport or through histochemical staining for cytochrome oxidase following reduction in activity in one eye through disease or lid suture.

Histochemical staining for cytochrome oxidase reveals an array of dense, metabolically active blobs separated by pale, interblobs (see Fig. 3a). Anatomical studies have revealed that these metabolically active blobs are located in the centers of the ocular dominance stripes for each eye, and they are repeated across the cortical surface. Physiological investigations indicate that cells located within the blobs tend to lack orientation selectivity and tend to be color selective. In contrast, cells located in the interblobs are orientation selective and tend to lack color selectivity (Livingstone and Hubel 1984). Furthermore, orientation selectivity is organized in a specific pattern such that the preferred orientation of cells progresses systematically around a non-oriented blob center. Studies of circuitry from the thalamus and within V1 indicate that cells in the blobs receive a direct input from the konicellular (K) cells of the LGN and receive input from the parvocellular and magnocellular streams via inputs from layer 4Cβ and 4B, respectively. The region of cortex containing one blob and the corresponding orientation 'pin-wheel' that surrounds it has been described as a modular hypercolumn that contains all the processing elements for a small patch of visual space.

4.2 Modular Organization of Areas V2 and V4

Area V2 also contains a modular organization that can be revealed through staining for cytochrome

Figure 2
Hierarchy of visual areas in the macaque monkey. Anatomical hierarchy of the cortical areas illustrated in Fig. 1. This hierarchy reflects 305 feedforward, feedback, and lateral pathways among the 32 visual areas. Two subcortical stages are illustrated at the bottom corresponding to retinal ganglion cells (RGC) and the lateral geniculate nucleus (LGN). In general, occipital areas are located near the bottom of the hierarchy, parietal areas on the left, and temporal areas on the right. Felleman and Van Essen 1991. Figure 3
Cytochrome oxidase staining in visual cortex. A. Tangential section through the upper layers of area V1 illustrating the cytochrome oxidase dense blobs and pale interblobs. B. Tangential section through upper layers of area V2 illustrating the cytochrome oxidase dense stripes. Although not readily apparent in macaque monkeys, alternating thick and thin dense stripes receive input from layer 4B and the cytochrome oxidase blobs of V1, respectively

oxidase. Unlike the punctate blob-like staining seen in V1, area V2 is characterized by alternating thick and thin stripes of high metabolic activity separated by pale interstripes (see Fig. 3b). Furthermore, these V2 compartments have specific patterns of connections indicating that the parallel processing streams seen in V1 continue into V2. Thus, the magnocellular stream exits V1 from cells in layer 4B to terminate within the cytochrome oxidase thick stripes. Similarly, cells in the V1 blobs terminate in V2 thin stripes, while cell in the V1 interblobs terminate in V2 interstripes. Physiological investigations of receptive field properties using microelectrode and optical recording techniques have indicated that these different V2 compartments contain neurons with different receptive field properties. Thin stripes contain a high proportion of color selective cells that lack orientation selectivity, while thick stripes and pale stripes contain a regular organization of orientation selectivity. These three V2 compartments are repeated approximately 17 times within V2 of each hemisphere and thus each can be viewed as a modular subunit that contains the processing machinery for a small patch of visual space.

The parallel cortical processing streams that begin in V1 are maintained in V2 and continue through the projections to higher cortical areas. The magnocellular stream, exits V2 to continue on to areas V3 and MT. Both of these areas have a high proportion of cells selective for the speed and direction of object motion. These areas provide input to several parietal areas of the 'where' functional stream. The blob and interblob streams of V1 remain largely segregated in their projections to V2 thin stripes and interstripe compartments, respectively. Both of these compartments have

dense projections to area V4 (DeYoe and Van Essen 1985, DeYoe et al. 1994, Felleman et al. 1997). V4 does not contain a modular organization that can be revealed through cytochrome oxidase histochemistry. However, V2 thin stripes and interstripes project to segregated regions within V4 (Xiao et al. 1999). Furthermore, optical recording indicates that color selective and orientation selective cells are clustered in V4 in a pattern that is reminiscent of the segregated inputs from V2 cytochrome oxidase compartments (Ghose and Ts'o 1997).

5. *Topographic Organization of Human Visual Cortex*

Functional magnetic resonance imaging (fMRI) has been used to identify and map the representation of visual space in the occipital cortex of man (DeYoe et al. 1996, Sereno et al. 1995). The general strategy used in these studies was to present counter phased checkerboard stimuli at the vertical and horizontal meridia and different eccentricities, and to record the voxels that show maximum signals that are correlated with the visual stimulus. Since the visual cortex is highly convoluted in man, the visualization of activated voxels is facilitated greatly by mapping onto an unfolded cortical map. Using this approach topographically organized visual areas V1, V2, V3, VP, and V3A have been identified in human occipital cortex (see Fig. 4). As in macaque monkeys, V1 is a large area localized to the calcarine sulcus and its outer border is formed by the representation of the vertical meridian. Area V1 corresponds to area 17 of Brodmann or area OC of Von Economo and Koskinas. Area V2 adjoins V1 at the representation of the vertical meridan and nearly totally surrounds it, except perhaps at the anterior tip of the calcarine sulcus. Area V2 is split along the representation of the horizontal meridian and forms dorsal and ventral halves that represent the lower and upper fields, respectively. Area V2 only occupies the posterior portion of the architectonically defined area 18 of Brodmann. Thus, cytoarchitecture is insufficient and perhaps misleading, in the identification of area V2. Areas V3 and VP border dorsal and ventral V2, respectively, at the representation of the vertical meridian. Unlike macaque monkeys in which these areas are narrow, human V3 and VP are as large as area V2. Based on position, areas V2, V3, and VP together occupy the previously defined architectonic field, area 18. Area V3A is located anterior to V3 in dorsal extrastriate cortex and unlike the adjacent areas V2d and V3, contains a representation of the full visual field. In the ventral cortex, an additional area has been localized using topographic criteria. This area, V4v, is located anterior to area VP and adjoins VP at the representation of the vertical meridian. This region only contains a representation of the upper visual field and no corresponding lower field representation has been found in dorsal cortex, which would correspond to area V4d. It remains unclear whether this reflects a true dorsoventral difference in cortical processing, or whether area V4d has yet to be found. Finally, the human homologue of the MT complex (MT+) has been localized in the lateral occipital sulcus, anterior to area V3A. These studies thus identify a number of topographically organized areas in humans that appear homologous to those seen in macaque monkeys.

6. *Conclusion*

The visual system of the brain consists of a large number of subcortical and cortical components that contribute to different aspects of visual processing. Visual processing begins in the retina where specialized

Visual Systems: Dorsal and Ventral

1. Our Visual Inheritance

Evolution has provided primates with a complex patchwork of visual areas occupying the posterior 50 percent or so of the cerebral cortex. But despite the complexity of the interconnections among these different areas, two broad 'streams' of projections have been identified in the macaque monkey brain, each originating from the primary visual area (V1): a ventral stream projecting eventually to the inferior temporal cortex (ITC), and a dorsal stream projecting to the posterior parietal cortex (PPC). These regions also receive input from a number of subcortical visual structures, such as the superior colliculus (via the thalamus).

2. Evidence from Private Neuro-Behavioral Studies

In their seminal paper, Ungerleider and Mishkin (1982) argued that the two streams of visual processing play complementary roles in the perception of incoming visual information. According to their account, the ventral stream governs the recognition of objects, while the dorsal stream mediates the localization of those same objects. Apparent support for this idea came from work with monkeys. Lesions of ITC produced deficits in the animal's ability to discriminate visually between objects, but did not affect its performance on a task requiring it to judge the location of a 'landmark.' Conversely, lesions of the PPC produced deficits in performance on the landmark task, but did not affect object discrimination learning. Although the evidence available at the time was consistent with this proposal, recent research fits better with a distinction not between sub-domains of perception, but between

perception on the one hand and the guidance of action on the other (Jeannerod 1997, Milner and Goodale 1995).

3. *Evidence from Visual Neurons in the Ventral and Dorsal Streams*

Neurons in areas such as ITC are tuned to the features of objects, and many of them show remarkable categorical specificity; some of these cells maintain their selectivity irrespective of viewpoint, retinal image size, and even color. These neurons are affected little by the monkey's concurrent behavior, but many are affected by how often the visual stimulus has been presented, and by its association with reward. Evidently the ventral stream is more concerned with the enduring characteristics and significance of objects than with moment-to-moment changes in the visual array.

Neurons in the dorsal stream show quite different properties from those in the ventral stream. Neurons in the PPC are activated by visual stimuli according to the response the monkey makes to those stimuli. For example, some sells respond when the stimulus is the target of an arm reach; others when it is the object of a grasp response; others when it is the target of a saccadic eye movement; others when the stimulus is moving and elicits a slow pursuit eye movement; and still others when the stimulus is stationary and becomes the object of fixed gaze (Jeannerod 1997, Milner and Goodale 1995).

These findings can readily explain why posterior parietal lesions impair landmark task performance: the monkey simply fails to orient toward the landmark. They also explain one of the most striking effects of PPC lesions, namely an inability to accurately reach for a moving or stationary food morsel, and why they fail to shape and orient their hands and fingers appropriately to pick it up. Evidently visual networks in the dorsal stream compute more than just spatial location.

4. *Visuomotor Deficits Following Brain Damage in Humans*

The first systematic description of a patient with bilateral PPC damage was published by Bálint in 1909 (See Harvey 1995). Bálint's patient was unable to accurately reach toward objects with his right hand. In many respects, this disorder, which Bálint called optic ataxia, resembles the problems of the PPC-lesioned monkey. Patients with optic ataxia not only fail to reach in the right direction but also have difficulty orientating their hand and forming their grasp appropriately to pick up target objects (Perenin and Vighetto 1988). Often they are unable to use visual information to form their grip as they reach toward an object, and have to grope for it. For example, they make errors in hand rotation as they try to reach toward and through a large oriented slot. Also, they often fail to show the normal proportional opening of the hand when reaching out to grasp objects of different sizes. Yet despite their visuomotor failures, these patients have comparatively little difficulty in giving perceptual reports of the orientation and location of the very objects they fail to grasp.

5. *Perceptual Deficits following Brain Damage in Humans*

On the other side of the equation, an impairment of ventral stream function occurs in humans who suffer from the condition known as visual form agnosia. These patients not only fail to recognize faces or objects, they fail even to identify simple geometric shapes. One such patient, DF, has been extensively studied during the 1990s. The value of these studies depends on DF's uniquely fortuitous pattern of brain damage, which gives rise to severe visual form agnosia as an isolated symptom, in the absence of any motor impairment or mental deterioration. All other similar patients in the literature either have a less severe form agnosia, or an impaired ability to cooperate or to make precise limb and hand movements.

What DF can do is as important as what she can't. Her attempts to make a perceptual report of the orientation of an oriented slot show little relationship to its actual orientation, whether her reports are made verbally or by manual means. However, when she is asked to insert her hand or a hand-held card into the slot, she moves her hand or the card toward the slot in the correct orientation and inserts it accurately. Indeed her hand begins to rotate in the appropriate direction as soon as it leaves the start position. In short, although she cannot report the orientation of the slot, she can act upon it with considerable skill.

Similar dissociations between perceptual report and visuomotor control were also observed when DF was asked to deal with properties of objects such as their size and shape (Goodale et al. 1991). Thus, she showed excellent visual control of anticipatory hand posture when reaching out to pick up blocks of different sizes that she could not distinguish perceptually. Just like healthy subjects, DF adjusted her finger-thumb separation well in advance of contacting the object, in a perfectly normal and linear fashion in relation to the target width. Yet when she was asked to use her finger and thumb to give a perceptual indication of the object's width, her responses were unrelated to the actual stimulus dimensions, and showed high variation from trial to trial. Functional MRI data have shown that the ventral stream is severely disconnected from visual inputs in DF, so we infer that the calibration of these various residual visuomotor skills must depend on intact mechanisms within the dorsal stream.

Various studies of DF show that she is able to govern many of her actions using visual information of which she has no awareness. But it is clear that this is only true of actions that are directly targeted at the visual stimulus. She cannot successfully use the same visual information to guide an identical response but displaced to another location. Presumably the difference is that the displaced response is an arbitrary or symbolic one. DF seems to depend on a visual processing system dedicated to motor control, which will normally only come into play when she carries out natural goal-directed actions. She has no explicit awareness of the shapes and sizes that she is able to grasp using this system.

There are temporal as well as spatial limits on DF's ability to drive her motor behavior visually. In one study, DF was shown a rectangular block, which was then removed while her eyes were closed, and then she reached out and pretended to grasp it. The preparatory grip size of normal subjects still correlates well with object width even after a 30 second delay. In DF, however, all evidence of grip scaling during her reaches had evaporated even after a delay of 2 seconds. The problem seems to be that a delayed reach is not a natural movement, requiring subjects to imagine the object and then 'pantomime' an appropriate grasp. This strategy would not have been open to DF: she could not generate a visual image of something that she didn't perceive in the first place. Apparently her preserved visuomotor brain can only respond to present or imminent states of the visual world, and disregards past states that may no longer be relevant.

Recently, a complementary 'improvement' in both reaching and grasping accuracy has been recorded in two bilateral optic ataxic patients after a 5-second delay (Milner and Dijkerman 2001). Presumably these patients were able to throw off the dominance of the damaged dorsal stream under the delay condition, allowing them to make use of their better-preserved ventral system.

6. *Operation of the Two Streams in Normal Vision*

It may be that like DF, healthy observers also control their actions using visual information that is not present in their awareness. In providing such visual guidance the dorsal stream may act pretty much in isolation, and independently of any acquired 'knowledge base.' Our implicit assumptions about the perceptual stability and constancy of the world are based on such stored knowledge. These assumptions sometimes cause us to misjudge what we see, as when a shift in a large frame makes a stationary spot inside it seem to shift in the opposite direction. In contrast, the dorsal system, by and large, is not deceived by such spatial illusions. Instead, it directs our saccadic eye movements and hand movements to where a target really is, instead of where our perceptual system tells us it is (e.g., Bridgeman et al. 1997). Similarly, under appropriate circumstances geometric illusions can be seen to affect visually-guided reaching and grasping (Haffenden and Goodale 1998) far less than they affect perceptual judgments. In other words, you may perceive an object as bigger than it really is, but you open your finger-thumb grip correctly when reaching for it.

It seems that the processing accomplished by the ventral stream both generates, and is in turn informed by, stored abstract visual knowledge about objects and their spatial relationships. It may be that these 'top-down' influences are what render our perceptual representations accessible to awareness (Lamme and Roelfsema 2000). This would fit with the idea that coded descriptions of enduring object properties, rather than transitory egocentric views, are needed for mental manipulations like the planning of action sequences and the mental rehearsal of alternative courses of action.

7. *Integration of Visual Function*

Although the dorsal and ventral streams have separate functions, there are multiple connections between them, and indeed adaptive goal-directed behavior in humans and other primates must depend on a successful integration of their complementary contributions. Thus the execution of a goal-directed action might depend on dedicated control systems in the dorsal stream, but the selection of appropriate goal objects and the action to be performed depends on the perceptual machinery of the ventral stream. At the level of visual processing, however, the visuomotor modules in the primate PPC function quite independently from the ITC mechanisms generating perception-based knowledge of the world. Only this latter, perceptual, system can provide suitable raw materials for thought processes to act upon. In contrast, the other is designed to guide actions purely in the 'here and now,' and its products are consequently useless for later reference.

Visualization: Representation in Science

Scientific knowledge is represented in many forms: spoken and printed words, graphs, formulae, tables, drawings, engravings, diagrams, photographs, charts, maps, models, diorama, demonstrations, and many other more specialized renderings. Visual and graphic renderings are deployed at every stage of scientific production, from initial data collection through final publication. Often, diverse forms of rendering are combined in complex assemblages. For example, figures in scientific texts frequently incorporate mathematical, verbal, and pictorial expressions in a single frame, so that cross-referential relations are at least as significant as the particular graphic forms and formats. Since the mid-1970s, a growing body of research in science and technology studies (S&TS) has examined the production of visual evidence, and this has led to a radical revision of standard epistemological conceptions of observation and representation.

Two related senses of the term 'visual representation' are important for current historical, literary, and ethnographic studies of science. A passive or static sense of the word 'representation' refers to an image, inscription, or sign that depicts, signifies, or symbolizes something else. A large body of recent studies of the forms, interpretive meanings, and cultural implications of particular representations pursue this sense of the concept. A more active or dynamic sense of the word refers to the practice of making images and the action of doing representing. The term 'visualization' signals these more active connotations. Studies of visualization in laboratory and field science have contributed some of the most influential and challenging ideas in the S&TS literature, and these are emphasized in the remainder of this article.

1. *Representing and Visualizing*

The study of visual representation in science crystallizes lines of work from diverse academic disciplines. In the 1970s and early 1980s historians of science began to pay close attention to nonverbal representations and nonpropositional forms of reference (Rudwick 1976). At about the same time art historians took greater interest in the broad array of what Elkins (1995) calls 'images that are not art': pictures and models that are crafted as products and by-products of scientific and medical work, but which are rarely considered as art (Edgerton 1976, 1991, Alpers 1983). This led to a convergence of scholarly attention on the role of artisan skill, craft technique, and visual technology in the scientific revolution, and on the continuing place of visual arts and crafts in day to day laboratory work.

1.1 *Visual Representation*

Studies of visual representation in science include analyses of published and unpublished images, and of the historical crafts and technologies responsible for their production. Currently, there are numerous disciplinary and cross-disciplinary approaches to visual representation. Representation is simultaneously a philosophical, historical, and cultural concept. Social, cultural, and literary studies of science include a bewildering array of historicist, semiotic, feminist, cognitivist, epistemological, pragmatist and other lines of interpretation. All of these appear, often in combination, in studies of visual representations. As many cultural and literary studies have emphasized, visual representations do not simply resemble natural objects: they express normative assumptions about natural and cultural worlds; they incorporate historically and culturally specific artistic conventions; and they mediate political and cultural relations of patronage, commodity exchange, and subjugation (Newman 1996, Haraway 1997).

1.2 *Visualization*

When considered in a more active sense, representation includes a broad array of practices and technologies for making, producing, and shaping images and relations among images. In the S&TS literature, this active sense of representation is signaled by the term 'visualization' (Latour 1990). This means more than 'seeing' or 'depicting,' as it refers to any of the broad array of research tools and practices for making natural objects visible: practices for uncovering hidden

features; magnifying objects and enhancing analyzability; facilitating measurement and comparison; and making things publicly witnessable, intelligible, and accountable. Visualization includes efforts to convince as well as to exhibit. Consistent with a programmatic aim to investigate the content of natural science knowledge (Bloor 1976), ethnographers, ethnomethodologists, and social-historians closely examine the situated practices, inscription devices, and textual forms through which scientific data and pictorial representations are exhibited, analyzed, stabilized, objectified, and disseminated (Latour and Woolgar 1979, Shapin and Schaffer 1985, Lynch and Woolgar 1990). These studies stress the significance of visualization as a crucial aspect of a continuing scientific revolution. This revolution involves the incessant invention, adaptation, and use of novel instrumental and literary technologies for revealing invisible objects, expressing abstract relations, and disseminating knowledge.

Renaissance innovations in print and engraving technology, together with novel optical devices and artistic conventions, enabled natural philosophers to inscribe and reproduce 'faithful' representations of observational experience. Latour (1990) uses the expression 'immutable mobiles' to capture the dual sense of stability and mobility attributed to imprinted representations. Scientific matters of fact, while still controlled by those who had the means to purchase, build, and operate equipment like the telescope, microscope, and Robert Boyle's air pump were communicated widely in expanding networks of co-investigators, patrons, and other 'virtual witnesses' (Shapin 1984, Shapin and Schaffer 1985). In most cases, virtual witnesses who read Boyle's experimental reports were in no position to replicate the original experiments. Boyle tried to get around this communicative problem by composing prolix descriptions illustrated by engravings of observed phenomena and laboratory instruments. This literary technology enabled Boyle to disseminate experimental knowledge widely, while sparing all but a few well-equipped adepts from the difficulties and uncertainties involved in actually trying to replicate the experiments. The dissemination of printed and engraved representations facilitated, but did not guarantee, the stability (or 'immutability') of the knowledge in question, since printing, engraving, and publication compounded the contingencies of knowledge production, enlarging the circle of potential disputants as well as adherents. The stability and mobility of images were no better than the instruments and persons involved in their production and distribution. Instruments, like the microscope, and persons, like engravers, printers, and publishers, were subject to variable degrees of trust and distrust (Johns 1998). Consequently, whether located in a gradual historical process or in the temporal production of a late-modern laboratory project (Knorr-Cetina and Amann 1990), 'immutable mobiles' depend upon incessant efforts to control sources of distortion, disruption, and misinterpretation at every point of production and distribution.

2. *Image and Object*

Numerous S&TS works have examined the historical, conceptual, and interpretive problems associated with the production of visual images, and they have also described the communicative and community-building work facilitated by such images. By elucidating the practical handiwork and collective labor process hidden behind the grand polarity of image and object, these studies furnish detailed cases that challenge existing conceptions of the scientific image, the natural world, and the relations between image and object.

Studies of visualization address classic philosophical questions about observation, representation, and objectivity, but they give these questions an original twist. Instead of addressing these questions abstractly, S&TS researchers investigate specific cases in which scientists encounter practical dilemmas and devise provisional solutions. Hanson (1958, p.4) furnishes an ideal-typical version of such a dilemma:

> Consider two microbiologists. They look at a prepared slide. When asked what they see, they may give different answers. One sees in the cell before him a cluster of foreign matter: it is an artifact, a coagulum resulting from inadequate staining techniques. This clot has no more to do with the cell, in vivo, than the scars left on it by the archaeologist's spade have to do with the original shape of some Grecian urn.

In this example, the observational instrument is both a material thing and a transparent medium through which other things appear. Depending upon what the microscopist sees on the slide, the instrument will be judged a source of 'subjective' illusion or a means for revealing an 'objective' cellular structure. One of Hanson's microscopists sees an artifact, but in the particular research context it is less like an artifact uncovered at an archaeological site (a Grecian urn) and more like the unwanted traces on that artifact left by the spade that uncovered it. This example suggests that the distinction between objective structure and artifact can be contentious and difficult to resolve. In their restricted domain, the microscopists are faced with a standard philosophical question: 'How do you know that the image stands for a real object?' A nonstandard philosophical answer is given by Hacking (1983). Hacking rejects the picture of a static image standing for a natural object, and points to the practical interventions performed in the laboratory. These interventions include crosschecks, calibrations, and probes that compare and contrast the outputs from different instruments and techniques. Convictions about reality inform, and develop from, a microscopist's competent handling of the laboratory instruments and materials.

Hacking remains focused on the philosophical problem of knowing natural reality, but he places the solution in the competent hands of the microscopist. The classical confrontation between object and subject is supplemented and mediated by instruments and skills. They are part of the means of perception, and like our eyes and our minds they sometimes are deemed untrustworthy, as sources of 'subjective' illusion. In microscopy and other laboratory sciences, correct judgment involves a mastery of technique as much as clear eyes and an educated mind. A whole chain of preparatory actions precedes and sets up the dramatic confrontation between microscopist and cell. These preparatory practices include cell culture, fixation, staining, counterstaining, thin-sectioning, mounting on a slide, and many other techniques (Lynch 1985a). If the microscopist sees a 'foreign' body—an artifact—in the cell, one or another of the preparatory techniques may be held responsible for the illusion. What the microscopist sees (or does not see) is thus bound up with a labor process that includes much more than looking down the tube of the microscope and focusing the eyes on an object. Hacking treats instrumental design and technique as sources of practical solution to philosophical questions about the reality of 'invisible' entities, whereas ethnographers and social historians tend to defer the question of reality while examining situated practices for enhancing or undermining the credibility of visual evidence.

2.1 Chains of Industry and Credibility

The S&TS treatment of visualization as temporal, embodied, material labor opens up a domain of investigation that is not covered by mentalistic and perceptual accounts of scientific observation. It ties in with a sociological, rather than cognitive or idealist, legacy, by treating the appearance of the scientific object as being bound up in a temporal process, typically involving many hands in a division of labor. Marx famously credited Feuerbach with having stood Hegel on his feet, meaning that he placed Hegel's abstract dialectic on a firm footing in historical materialism. Less famously, Marx suggested a related way to bring history of science down to earth:

> …historiography pays regard to natural science only occasionally, as a factor of enlightenment and utility arising from individual great discoveries. But natural science has invaded and transformed human life all the more *practically* through the medium of industry; and has prepared human emancipation, however directly and much it has had to consummate dehumanization. *Industry* is the *actual*, historical relation of nature, and therefore of natural science, to man (Karl Marx, *Economic & Philosophic Manuscripts* 1844).

A further inversion from feet to hands can be inspired by studies of visualization in science. For Marx, industry, rather than history of ideas, embodies Western 'man's' actual, historical relation to natural science. For S&TS, natural science not simply the historical basis for modern industry and its relations of production. The laboratory's own labor process is itself a site of collective handiwork facilitated by instruments and exhibiting variable degrees of complexity, automation, and historical development. Marx speaks of the 'working up' of raw materials into the form of a product: an artifact that embodies human purposes and provides a résumé of the labor that produced it: 'The product is after all but the summary of the activity of production.' Among the products of laboratory work are data—carefully framed and emplotted observations and measurements which stand to nature much in the way that processed food does to raw ingredients. Scientists sometimes speak of 'raw data' collected in the field or from electronic instruments, and they distinguish such data from processed images that result from 'working up' the data into presentable form.

Likening the visualization of scientific data to a manufacturing process may seem to miss an essential point: that the object of scientific investigation is not an artifact, even though it may be difficult to establish the difference between the two in particular cases. Described in the vernacular of laboratory science, the object is found, or found out. It is not made, and it is distinguished from both deliberately constructed tools and inadvertently produced scratches, residues, and deformations. Close studies of day to day laboratory work have furnished many examples of how research materials are cultivated, handled, and reconfigured, but to conclude, for example, that all cellular structures are artifacts collapses a vernacular distinction that provides laboratory work with a fundamental task and tension. Such a conclusion also invites the sterile polarity and tired polemics of the realist–contructivist debate. Latour tries to avoid the polemics by devising a neologism that straddles the polarity. Where, according to Marx, the industrial product becomes a 'fetish'—a commodity whose exchange value hides the work of its production —according to Latour (1999, p. 272) the laboratory product becomes a 'factish'—a fact whose solidity and epistemic significance hides the day to day work of establishing and maintaining that solidity and significance. For Latour, the 'factish' is never independent of its manufacture, but this does not reduce it to an empty screen for projecting arbitrary beliefs. The robust credibility of 'fact' remains in place, not because it exists in an eternal space remote from human activity, but because of the way it is fashioned.

Latour's creative vocabulary is less instructive than his examples. In an ethnography of a Brazilian field project, Latour (1995) closely examined the series of practices through which a field site was made graphically analyzable. The project was concerned with a boundary between rainforest and savanna. The team

of researchers addressed the question of whether the forest was advancing into or retreating from the grassland. As scientific projects go, this one was simple. It involved only a few researchers, a down-to-earth problem, no complex equations, and relatively commonplace technology. Nevertheless, it involved a complicated series of representational practices for marking out a field site into a systematic grid, selecting and tagging plant specimens, collecting and analyzing soil samples, plotting data on paper graphs, and amassing files for every stage of the project. The field site, the tagged specimens, the binned and color-coded soil samples, and countless other materials used in the project were hybrid objects. None of these things were purely natural or artificial, concrete or abstract, material or symbolic, real or imaginary, but a great deal of care was taken to preserve selected aspects of specimens, keep track of identities, and cross-check measurements and records. The project resulted in a publication in which a graphic figure represented the forest–savanna boundary, and the data collected during the project were used to support conjectures about the movement in question. Again, this was not a massive or powerful project, and it resulted in tentative findings, but it served well enough to illustrate an important point about the credibility of the project's evidence. The researchers staked the credibility of their data on a complex network of accountability in which no single representation corresponded to an independent natural object, and yet all of their materials, in different ways, contained, encoded, traced, or preserved a tenuous relation to the natural field site. The credibility of the production was more like the strength of a rope, weaving together separate strands, and less like the compelling realism of a photographic image. Perhaps another example will help elucidate this point.

The police in the United States use the expression 'chain of custody' to refer to the continuity of evidence as it is collected and transported from one place to another. So, for example, blood evidence collected at a crime scene by a police employee or pathologist is placed in a tube and transported to one or more labs, where it is analyzed with DNA profiling methods. Such evidence typically travels a complicated route, and it is transformed and repackaged several times in the process. The potential consequences of such evidence, and the possibility of courtroom challenge, has led police organizations and forensic labs to use a whole series of administrative procedures for checking, cross-checking, and validating the identity of evidence samples. Standardized forms, tamper-evident bags, stickers with bar codes on them, automated scanners, filing systems, laboratory protocols for recording and 'witnessing' the movement and handling of evidence, and many other mundane bureaucratic artifacts create an administrative envelope that protects the credibility of evidence against courtroom challenge. In addition, courtroom presentations make use of some of the techniques of visualization that have been documented in scientific labs and field studies (Goodwin 1994). The credibility of DNA profile evidence stands only as long as the devices of visualization and their administrative envelope resists challenge. None of the forms, bar codes, and protocols that make up the chain of custody guarantee that it will resist adversary efforts to expose significant gaps. Even an elaborately documented and impressively consistent chain of custody does not guarantee the truth of the evidential result against all possibility of error, mishap, fraud, and conspiracy, but when the numerical indices, signatures, and analytic results tell a story consistent with public and judicial conceptions of good 'scientific' practice, they are more likely to resist adversary challenge (Lynch and Jasanoff 1998)

It often seems natural to employ metaphors of vision, perception, and cognition when discussing scientific observation and representation, but the analogy with an industrial labor process suggests a more material, and less ocular and mental, conception of visualization and its natural products. Consistent with the paradigm of the assembly line, a scientific project is organized into a chain of tasks performed by a series of technicians. Specimen materials are collected, selected, prepared, rendered, and reorganized to expose, enhance, and encode relevant features, to upgrade analyzability, and to frame data with instrumental and graphic fields (Lynch 1985b, Latour 1995, Knorr-Cetina 1999). Nature and culture pervade every link in the chain, and there is never a pure confrontation between and object and its representation.

Vocabulary Acquisition, Psychology of

1. Why Study Vocabulary Acquisition?

Having a vocabulary means knowing words: how to pronounce them, what they mean, the different forms they can take, and how they can be used in sentences. Children are phenomenal word learners—by the age of six, English-speaking children are estimated to have learned over 10,000 words; undoubtedly, children learning other languages are equally adept. This feat of rapid vocabulary acquisition is remarkable because it is not as straightforward as it might seem. Clearly children learn the words they hear in their environment, but they do not simply imitate everything they hear; imitation cannot explain how they extract words from the speech stream nor how they relate sounds (or signs) to meanings. Children often attain knowledge of a word piecemeal. They might know what kind of word it is (e.g., that it can take certain forms like -s or -ing or that it is allowed in certain sentence positions) before knowing what it means, or they might know its meaning without knowing how to pronounce it properly. Thus, studying how children acquire words—how they represent the sounds, meanings, and formal characteristics of words—is a part of the study not only of language development but also of the human ability to extract information from the environment over time, organize it, and use it. Because vocabulary acquisition is a life-long phenomenon, with estimates of adult vocabularies ranging over 100,000 words, the insights gained studying children's vocabulary acquisition may help in understanding why vocabulary knowledge remains a robust skill among the elderly, word-finding problems notwithstanding.

2. The Beginnings of Word Learning

By the time children start to use words, they have already exercised many of their inborn capacities in the service of language learning. Research shows that sensitivity to sound and memory for sound begin even before birth, and that the capacities needed to segment the speech stream are in place early (see Hoff 2001 for details).

2.1 What Infants Bring to Word Learning

Recent advances in assessing the capacities of infants have revealed remarkable abilities that are recruited to the task of vocabulary acquisition (see Werker and Tees 1999). Newborn infants can detect minimal differences between sounds, and the differences they detect most easily are those occurring in the sound systems of the world's languages. Newborns show remarkable sensitivity to the acoustic cues that specify word boundaries: they can discriminate between a two-syllable sequence extracted from a single word and such a sequence extracted from two separate words. Using acoustic cues, they also can discriminate the two basic kinds of words found in languages, i.e., content or 'open class' words like nouns and verbs and grammatical or 'closed class' words like prepositions and articles. Such sensitivities, plus an ability to keep track of statistical differences in the occurrence of different patterns of acoustic cues, enable infants by 8 months to segment a speech stream into words.

2.2 Experience and Development in Early Word Acquisition

During the first year, infants' general capacity to discriminate speech sounds becomes more attuned to the sound system of the specific language in their environment. By 10–12 months, infants discriminate best the syllabic sound differences of their native language. Shortly thereafter, they begin associating sound strings with meaning, but at the same time their ability to distinguish between words on the basis of sound becomes more holistic and in some sense less discriminating. First word productions are different from later ones in that the first words often label whole scenes or events, or they are used to make requests; one 10-month old would call, 'Dada mi(lk)' from his crib when he wanted his morning bottle.

There are many similarities across children in the first 50 or so words produced: toddlers have an array of labels for common items and familiar people in their environment, along with words like 'more,' 'up,' and 'all gone,' that indicate changes of state and place. About half of all children appear to undergo a vocabulary spurt around 18 months of age, learning words at a rapid rate. Other children may show a more gradual increase in the rate of their word acquisition or experience a later spurt.

Nouns predominate over verbs in the early vocabularies of children learning English. This tendency toward early noun predominance was thought to be universal on cognitive grounds: relating sounds to real-world objects should be easier than grasping the relational nature of verb meanings (Gentner 1982). Although this may be true, which languages caregivers speak and what they, as members of their culture, find important to talk about also play a role in early vocabulary. For example, children learning Asian languages that typically place verbs in perceptually salient sentence-final positions tend to have a higher ratio of verbs to nouns in their early vocabularies than do children learning languages like English (Tardif 1996).

3. Working on Words

By 2 years of age, children typically are adept word learners, using just about everything they know to help them map sounds to meaning. Given how rapidly vocabulary grows even in the early years, it is hard to see how it could be otherwise.

3.1 Constraints on Word Meaning

Because in language meaning is arbitrarily related to sound, there are an infinite number of hypotheses learners could make about the meaning of any string of sounds they hear. Vocabulary would never be acquired if the learner had no way of constraining possible meanings. Researchers have proposed various constraints that can be thought of as learning strategies or default hypotheses that children use to make first guesses at the mappings between sound and meaning. One strategy suggested for infants is that they expect speakers to be talking about what they are looking at. Beliefs that a new label should refer to a whole object and not part of an object, that objects should have only one label, and that objects with the same label are alike in some fundamental way are examples of other suggested strategies for toddlers. Moreover, there is considerable evidence that preschoolers use what they know about language structure to inform their word learning (see Bloom 1994 and Gleitman and Landau 1994 for details and discussions of these sorts of constraints).

3.2 Vocabulary Organization

The evidence that children use information about language structure to help them acquire word knowledge is consistent with other data suggesting that children consider word–word relations and not just word–world relations as they acquire vocabulary. For example, even before they know what a particular color term means, or even which perceptual dimension the word *color* refers to, they regularly answer questions about the color of objects with color terms, albeit incorrect ones (Shatz and Backscheider 1999). They show similar behavior with letter- and number-term categories. At least by the age of two, then, children are not just associating labels with objects or events, but they are relating words to one another, creating word categories based on common grammatical properties and on patterns of use in discourse.

3.3 Practice, Practice, Practice

The numerous reports of young children practicing their language skills (e.g., Kuczaj 1983) provide more evidence supporting the idea of early organization of word–word relations. One 20-month-old was observed reciting to himself a triad of antonym pairs, 'in-out, up-down, hi-bye.' At the age of 33 months, the same child, after talking to himself about family members' possessions, spewed out a string of pronouns, 'I, me, my, you, your, he, him, her, she, we, ours' (Shatz 1994). Thus, throughout their early years, children reveal in their private speech that they think about various kinds of word-word relations.

4. Vocabulary Acquisition Later in Life

4.1 Sources of Innovation

Vocabulary is the aspect of language that continues to show striking development beyond the early school years. This is because not only does an individual's

knowledge base grow, but there are many sources of vocabulary innovation in a speech community that an individual draws from throughout the life-span. New words or new meanings for old words are often introduced by groups such as adolescents eager to create a separate identity through language use, and the innovations often are adopted over time by the larger community. Other sources of vocabulary growth include borrowings from other languages, phrases used in public life or literature that take on idiomatic meaning and words created to describe new technologies. Little is known about how vocabulary grows throughout life, but it is likely that the patterns children display of partial knowledge about meaning organized along with facts about grammatical and discourse uses also characterize adult states of vocabulary knowledge as new words are acquired.

4.2 Vocabulary and the Brain

Although the rapid vocabulary growth of childhood undoubtedly slows over time, even seniors acquire new words, and vocabulary knowledge, like much linguistic knowledge, remains a robust skill among the elderly (Schum and Sivan 1997). Age-related difficulties in vocabulary use, such as word finding, word substitutions, and word loss can often be ascribed to particular brain insults like cerebral-vascular accidents resulting in area-specific brain damage. Others are likely related to decline in more general cognitive abilities like memory or speed-of-information processing (see Tun and Wingfield 1997). The occurrence of specific deficits for certain kinds of words (e.g., nouns) supports the view that words are indeed organized into a variety of categories, some of which are based on quite abstract characteristics.

5. Avenues of Future Research

Future research will build on the discoveries of infants' discrimination and segmentation abilities to address questions about the nature of early representations of sound-meaning relations. Why do children show decreased sensitivity to the specific sound characteristics of words just when they have recognized them as words? Why does a 2-year-old who has said 'crain' for *train* not register their own error but does so when an adult imitates 'crain'? Other questions about early vocabulary acquisition concern the development of word understanding and use. Given that early vocabulary use reveals some organization based on word–word relations, how do children integrate information about word–world and word–word relations over time into comprehensive representations?

Finally, future research must address important questions about the generality of the picture of vocabulary acquisition presented here. What is the relation between early and later vocabulary acquisitions? Can this view of vocabulary organization as one involving integrated aspects of sound, meaning, form, and use profitably be related to difficulties with word usage in aging or disordered populations? Second, can this account of vocabulary acquisition be appropriately applied to instances of acquisition in more agglutinative languages, i.e. those in which words themselves are made up of many more different pieces of meaning than they typically are in a language like English? The question of the generality of this account of vocabulary acquisition will undoubtedly require more than a one-word answer.

Vocational Education and Training

We define 'vocational education,' as any set of learning activities aimed at developing individuals for personally and socially significant life roles; and 'training' as a confined aspect of vocational education, namely

any set of learning activities aimed at equipping individuals with the knowledge needed for pre-defined tasks or roles. That is, vocational education and training is not just a particular sector of education, or particular activities preparing people for work, but also any other education, which recognizes explicitly the centrality of individuals' life purposes (including work) and their social significance in an individual's construction of meaning.

Our definition adopts Dewey's (1916) inclusive idea of *vocation*, as personally significant life activities. It is consonant with the Latin derivation of the term, *callings*, and the Greek idea that all people have a *telos*. Thus, a vocation might involve such disparate pursuits as motor mechanic, doctor, parent, rock-star, athlete, or street vendor. Some societies afford higher social status to some vocations, especially those taught in universities (e.g., medicine) and call them professions, leading to the professional/vocational distinction.

1. Classical Constructions of Vocational Knowledge

Differentiations of kinds of knowledge (and their acquisition) can be traced to the ancient Greeks who divided society into:

> … those who had to labor for a living [slaves, artisans and women] and those who were relieved from this necessity [free class worthy of liberal education] (Dewey 1916, p. 251).

Aristotle differentiated 'five ways in which the soul arrives at truth' (Thomson 1976, p. 206)—art or technical skill (*techne*); science or scientific knowledge (*episteme*); prudence or practical wisdom (*phronesis*); intelligence or intuition (*nous*); and wisdom (*sophia*). He regarded art and technical skill as concerned with *making* or *production*, but as essentially different from prudence or practical wisdom (*phronesis*), which is concerned with deliberating 'rightly' what is good and advantageous, thereby constituting *action* rather than production. Thus, vocational knowledge is often constructed in opposition to other knowledge, based on its supposed *technical* or *applied* nature. This segregation from 'general' knowledge reflects a social segregation of culture and utility, and of class. Separation of education for *techne* from more valued education (so-called general or 'liberal' education of the 'person') underlies the organization of education in Western industrial countries, with polarization of the constructions of liberal/academic, and vocational knowledge.

Based on classical Greek ideas, later authors have differentiated knowledge in two ways: (a) theoretical vs. applied knowledge, and (b) a knowledge that enables control over causes vs. knowledge that enables 'right' action (to secure what is appropriate or good).

1.1 Theoretical vs. Applied

This distinction is sometimes caricatured as a division of head and hand. Ryle (1949) cautioned against such conceptualizations of thinking that attributed to knowledge of 'how' a form and structure additional to its intrinsic nature, arguing that the capacity to demonstrate expertise was a single phenomenon, not driven by separate internal processes. Separation of the theoretical and the applied in vocational education is exemplified in formal college or school supplementation of on-the-job apprenticeship/traineeship training in Western society. However, the German Dual Apprenticeship system attempts to develop both theory and practice in both school and work settings. Institutional separation of vocational education from 'general' schools and universities also reflects this differentiation of theoretical and applied concerns or of culture and utility. Consider also the construction of educational pathways, which involve personal choice, but at the same time labor market segmentation and class allocation.

1.2 Technical Control vs. 'Right' Action

Critical theorists emphasize the distinction between 'technicist' knowledge for technical control and 'practical' knowledge for 'right' action. Such concepts can generate views of occupational roles as atheoretical and non-moral; and vocational education as separable from individual and societal needs. They help legitimate movements like competency-based training, which separates technical mastery and control for workplace performance from individual construction of meaning and the critical development of society.

Popkewitz (1998) has argued that both Dewey and Vygotsky were social constructivists bringing 'new democratic political rationalities into the governing of individual conduct' (p. 535). They, in a period of modernity, saw that 'social sciences [education] would not only provide a cognitive knowledge but also discipline the capabilities, values, dispositions, and sensitivities through which individuals problematized their participation in the world' (p. 537). They compared their 'problem-solving individual' with the images and constructions of social determinism (Popkewitz 1998) as the basis of state provision of vocational education and training, i.e., self-empowering education for democratic participation or technical/market control.

2. Psychological Ideas of Training

The psychological idea of training has its origins in early behaviorist research on classical and operant conditioning. Often training referred to the shaping of animal behavior, construing systematic mastery of

confined and pre-determined tasks. It places behavior in opposition to internal cognitive processes and externally determined goals in opposition to individual needs. This psychological idea of training has been extended to all work-related learning where learning goals are pre-determined, and individual behavior shaped towards those goals—hence workplace training, on-the-job training, etc. Moreover, the term has been further extended to any kind of learning for any kind of work e.g., teacher training, doctor training, presuming an equivalence between vocational learning and animal tricks.

Modern cognitive psychology views vocational knowledge in terms of expertise. These ideas challenge the separation of physical and intellectual skills, as both kinds of knowledge consist in the same kinds of cognitive representations. Routine action is accomplished through automatic execution of specific cognitive procedures, developed through extensive practice. Experts conceptualize unfamiliar situations in terms of principles, structured at various levels of abstraction, and linked to cognitive procedures, under the control of higher order cognitive procedures.

3. *Social Patterning of Vocational Knowledge*

Cognitive and anthropological studies indicate that knowledge is highly situated. The idea of situated knowledge also challenges the tradition that there is vocational and 'other' knowledge (e.g., knowledge derived from academic disciplines). Rather, as in the tradition of Vygotsky, all knowledge is regarded as socioculturally based, with patterning of concepts and procedures arising from social interactions and social contexts.

Sociocultural considerations impel the idea of normative judgement also challenging mechanistic notions of vocational knowledge. The idea of normative judgement helps to explain why some expected cases of transfer do not occur—transfer in the work place depends on normative judgements about what is appropriate in the setting.

4. *Life-span Centered Constructions of Vocational Education*

Career theory addresses vocational education and training in terms of personal traits, values and goals, with such personal meaning constructs embedded in sociohistorical contexts. For example, in World War II, women were recruited into manufacturing, and farming and transport, re-defining vocational pathways and self-definition.

Life-span approaches argue that understanding any part of a life requires reference to the whole life course—lives/vocations are constructed in a particular social and historical context. Vocation may involve several work and other social roles over the life-span, and the term 'life career' may better reflect such dynamic processes. A life-long learning philosophy of education and training has developed in recognition of changing contexts, individual aspirations and the potential of vocational education and training for human capital (see later) development.

Education is used as a precursor to vocational choice, and as a context for vocational orientation and training. Curriculum, streaming, assessment and various other processes allocate young people to vocational pathways and labor markets through credentials. This stresses the polarity of education for individual and social empowerment (democracy/equity) vs. education for production/class segregation (social differentiation). Vocational education and training become a form of state intervention in pursuit of economic goals. These state measures are evident in the contractual arrangements of apprenticeships and traineeships.

Adult learning theory can also emphasize humanist or socially critical perspectives on vocational education. In the first case, the learner determines the vocational nature of their own goals and the required knowledge. Critical theorists seek to empower learners in understanding how their vocations are constituted by society; how such forces can be oppressive, and how to take action. Thus, both constructions often see work-related discourses in opposition to the needs of the individuals or to society as a whole.

5. *Economistic Constructions of Vocational Education*

In competency-based education/training, learning goals are set against industrial standards. The economic goal is cost-effective use of resources in shaping learner behavior towards pre-determined learning outcomes (Stevenson 1993). This perspective is less concerned with individuals' callings, ways of constructing meaning, and socially appropriate practice, than with potential *human capital*.

Human Capital Theory assumes that education 'helps develop skills of work, that is, improves the capacity of the worker to be productive' (Sweetland 1996, p. 354). Such conceptualizations can confine human development to increasing workplace capital. The learning problem is human resource development, i.e., shaping individuals to increase their potential as economic resources. Such perspectives can separate work from life, reduce the time horizon of vocational education and training to immediate and predictable aspects of work, and give weight to those verbally expressible aspects of human capacities, which can be detailed in advance of learning activities.

6. Sociohistorical Influences on Constructing Vocational Education

The knowledge which counts as vocational differs across cultures and time. Where production consists in the application of knowledge handed down through generations (as in early agricultural economies or in contemporary non-western cultures), the knowledge is holistic and normative, and associated with forming one's cultural identity. Even in Ford's early factories, there was a sense of community, with housing provided for workers, just as in traditional Japanese enterprises. However, production assembly lines and associated boredom have produced a gulf between working and being human. This gulf extends to the requisite knowledge, giving rise to such confined vocational education curriculum development techniques as task analysis (Berryman 1993).

Social crises such as wars have seen recurring regressions to behaviorist/technicist notions of education (Stevenson 1996). These reversions have been resisted by humanist and socially critical movements, with distinctions being emphasized between educative processes and products, and between expressive, and other objectives. However, this resistance has not prevented the re-emergence of behaviorism in the 1980s in the form of outcomes-based education. Notwithstanding, the democratization of education is creating 'greater freedom of choice and a fight against the socio-cultural determinism which predestines some for management positions prepared for through academic training and others for operational tasks requiring vocational training' (Pair 1998, p. 23).

7. Contemporary Concerns

Contemporary concerns in conceptualizing vocational education and training arise from:

(a) (economic) changes in the nature of productive activity,

(b) (societal) changes in attitudes to the role of industrial development,

(c) (cognitive) changes in conceptualizations of knowledge,

(d) (philosophical) changes in views about different ways of knowing and rendering that knowledge, and

(e) (pedagogical policy) changes in the organization and conceptualizations of vocational education and training as programs of pathways evolving over the life-span, with the need for bridges.

Economic constructions of knowledge are moving from narrow short-term capacities to those more characteristic of dynamic workplaces. Socioeconomic needs challenge the separation of individual development from social development and from the capacity for productive work; or, to use cruder terms, of culture from utility. Work, in a knowledge-based society, is clearly reliant on thinking skills, innovation, and capacities to displace time, space, and financial constraints on design, production, delivery, marketing, and sales. A new terminology for productive capacities has emerged: intellective and connective skills; mobile knowledge workers, symbolic analysts (e.g., Harvey 1989). Work has become more continuous with other aspects of life. The OECD (1980) listed 'competencies' for working life, which have now been replaced by key/core competencies/skills/qualifications (see Hodgson and Spours 1997, Nijhof and Streumer 1998). Economic changes highlight further the arbitrariness of the separate denotation of high status vocations (e.g., medicine, law) as professions, simply because their preparation occurs in universities.

The idea that knowledge can be produced outside of 'intellectual' institutions has now also been advanced by Gibbons et al. (1994), who argue that ('Mode 2') knowledge exists within the situational and time characteristics of teams brought together to solve such problems as those generated in modern innovative workplaces

Social changes include increased participation of young people with plural characteristics, in schooling, creating the need to overcome pedagogical complexity in provision of education and learning pathways (Achtenhagen and Grubb 2001). Challenges also include renewed concerns about quality of life in and outside work, the environment, inter-personal relationships, and global harmony. These various social concerns call into question the ways in which educational provision is institutionally separated.

Concerns arising from cognitive psychological and anthropological research include understanding the relationships between tacit and expressible knowledge, situated and generic knowledge, dispositions, values and action, knowing and transferring, and apparently different kinds of intelligence. Philosophical movements challenging philosophical structuralism also challenge the hierarchy and polarization of knowledge developed from ancient Greek society.

8. Methodological Issues

In researching vocational education, an immediate problem is in defining the phenomenon. Discourses have traditionally polarized such ideas as knowledge and experience, theory and practice, life and work, and academic and vocational concerns. Such polarizations often confound knowledge with the capacity to render knowledge in verbal (declarative) form. This arises partly because declarative knowledge has uncriticized currency amongst researchers whose training comes from universities. For example, in researching vocational knowledge, due weight is not routinely given to nonverbalizable (undeclarable) knowledge conceptualized variously as knowing how, tacit knowledge, implicit knowledge, multiple intelligences, and

non-verbalizable intelligence; or to the plurality of representational encoding and memory systems. Nor is weight given to conceptualizing training structures and contexts as the interaction of many actors in sociohistorical time (employers, unions, people, communities, public authorities, training and education institutions) (Pair 1998).

Theories, concepts, research approaches and research tools developed from research into early human development, schools and universities are often applied unproblematically to research in vocational education and training. For example, a high value is automatically assumed for verbalizable propositional knowledge in relation to capacities for expert performance. Recognition that knowledge is not to be confounded with verbalizable renditions places an onus on researchers to re-conceptualize theoretical developments that have been based on tools and perspectives that privilege the verbalizable.

Immediate research goals include the epistemological ones of determining the nature of vocational knowledge and its relationship with other ways of knowing; the illumination of the relationships among epistemological frameworks, research tools and methods; and the development of new approaches that capture and give weight to plural ways of knowing and rendering that knowledge, as well as illuminating non-verbalizable knowledge. These methodological developments are fundamental to reconciling different perspectives on vocational education and training and in researching such matters as the relationships among learning, personal choice, work, social change, institutional structures and learning pathways. Ifn addition, more work is needed on teaching–learning processes within vocational education settings. The pathways concept (Raffe 1998), in particular, may be a tool for research and a metaphor for travel over the life-span. In particular the networks of interconnected pathways afforded by vocational and technical training, universities, and enterprises will be significant for innovation, flexibility and life-long-learning. How well various countries address such issues may well determine their economic competitiveness and their social democracies.

9. *Future Directions: Addressing Polarizations*

The directions of social, technological and economic change compel reconstructions of the ideas of the vocational and vocational education, in such a way as to reconnect ideas that have become polarized. Change will come from a number of sources: more continuities in the workplace between innovation and execution (e.g., flatter hierarchies, pace of change, working in teams); more continuities between being at work and other aspects of life (e.g., time and space displacement such as telecommuting); more continuities between the social regard for those in and out of work (fewer core jobs (Hirsch 1991)); greater continuities between industrial and wider societal needs (a resurgence of values for the environment, quality of life, global harmony); more pressure for innovation in training pathways and their interconnectedness (Pair 1998, Raffe 1998), and greater attention to socialization/exclusion through education and work (Poole 1992, Popkewitz 1998).

A view of knowing more connected with doing will arise also because few cases of doing will be confined to the routine execution of skills. The pace of change will highlight the necessity for the continuous construction and reconstruction of meaning based on changing experiences, reconnecting knowledge with the individual's developing sense of vocation, and with productive/generative activity, in pursuit of vocation. Reconnections will need to link the educational needs of individuals, the development of society, and productivity and generativity in industrial, and other vocations. These links will be contextual, changing over the life-span. We suggest that theoretical conceptualizations will increasingly inter-relate the ideas of knowing, doing, feeling, judging, across the Aristotelian divides, and across the derived academic/vocational divide. We also suggest that the idea of generative/productive activity in all societal roles will serve as a basis to build a bridge across the cultural and utility divide, and that vocational constructions will be social/contextual and dynamic across the life-span.

Vocational Interests, Values, and Preferences, Psychology of

This article describes how interests, values, and preferences are conceptualized in vocational psychology, how they are measured, and what reliable findings have been established by research using these measures. Such findings are the scientific basis for career counseling and career development.

Research in applied psychology has focused on two types of variables: ability and motivation. Psychologists succeeded early in developing measures of ability (e.g., *g*, verbal, numerical, spatial), drawing on the psychology of individual differences (DuBois 1970). Ability tests, *g* in particular, have been shown to be useful in a variety of school and work contexts (e.g., predicting grade-point average, job performance ratings).

Developing measures of motivation constructs proved to be more difficult. Many constructs were tried out and among the more successful ones were interests, values, and preferences. Research has since shown that interests, values, and preferences can contribute to the prediction of performance independently of the contribution of ability (Dawis 1991).

1. Definitions

Interest, value, and preference (and ability as well) belong to the class of constructs called 'dispositions.' Such constructs denote (typically stable) states of persons that indicate their behavioral tendencies. Thus, knowing the interests (or the values or preferences) of a person can indicate the likelihood that the person will engage in a particular activity given the opportunity.

Preference is the fundamental construct, interest and value at bottom involving preference. Preference means a more positive attitude ('leaning') toward one alternative over another (or other) alternative(s) expressed as the choice of the alternative over the other(s). Preference implies discrimination among the alternatives and judgment (or evaluation) of the alternatives. Preference implies comparative judgment, but it can also mean absolute judgment (requiring an absolute threshold for choice).

Interest and value are more complex constructs. Interest is manifested as sustained (long-term) attention involving cognition of the interest object and accompanying positive affect (pleasure). Interest can move beyond affective cognition to motor response (approach behavior or sustained activity), that is, interest can influence behaviour. Value is a similar construct, also involving cognition of the value-object and accompanying affect. It is manifested as affective valuation, and can also influence behavior. Both constructs are expressed as preferences, but they differ in their judgment basis.

When judgment in preference is based on liking (i.e., attraction), it is an interest. When the basis is importance (i.e., significance or meaning), the preference is a value. Liking and importance are differing dimensions of affective response as shown by the absence of empty cells in a two-way cross-classification (liked/important, not-liked/important, liked/not-important, not-liked/not-important).

The scaling of liking extends to its opposite, disliking; likewise, scaling importance extends to unimportance. Importance is readily conceptualized as one dimension, with unimportance as zero point. Liking can be conceptualized as one dimension (with disliking as the negative side of the scale) or as two dimensions (with disliking as a separate dimension, each dimension having 'indifference' as its zero point).

The remainder of this article will focus on liking preferences and importance preferences, that is, on interests and values. As described earlier, interests and values have a cognitive component (content, direction) as well as an affective component (intensity). Cognitive content can refer to persons, data, things, activities,

events, environmental conditions, and even internal conditions and events. In vocational psychology, measures of interests typically have work activities as their cognitive content. For values, the cognitive content is ends (goals or consequences of work) and means (instrumentalities) that have become ends in themselves. Such ends and means-ends are 'reinforcers' because, as behavioral consequences, they maintain behavior.

Besides having content, interests and values can be more, or less, intense. Measures of these constructs have to incorporate both direction (content) and intensity.

2. *Measurement*

Much of the research on vocational interests and values has been devoted to their measurement. Interests and values are commonly measured through self-report instruments (inventories, questionnaires). A typical self-report instrument consists of many items of varied content, with instructions on how to respond to the items. Response can take the form of a check-off (indicating what is liked or is important), a ranking of alternatives (sometimes in sets of pairs or triads), or a rating on a point scale (usually three or five points). All three types of response can be quantified by using any of several scaling methods (Dawis 2000).

Two kinds of scales are commonly used in interest and value instruments. Internally consistent scales are composed of highly intercorrelated items that measure the same principal component. Externally relevant scales consist of items that correlate with a variable external to the scale (the 'criterion variable'). The same interest or value instrument may include both internally consistent and externally relevant scales. Typically, many scales are included in an instrument in order to increase its usefulness.

Internally consistent scales are semantically comprehensible and thus are favored in theory-driven research. Scores on such scales are interpreted as reflecting intensity of interest or value. Externally relevant scales, by contrast, are often composed of items of heterogeneous content and may not 'make sense' theoretically, but are robust in their correlation with the criterion variables and hence are useful in professional practice. Scores on such scales are best interpreted as reflecting the similarity of the respondent to the 'criterion group' (representing the high pole on the criterion variable).

2.1 *Sample Measures*

Arguably the best-researched measure of vocational interests is the *Strong Interest Inventory* (*SII*; Harmon et al. 1994). It contains 320 items requiring response on a three-point, like–indifferent–dislike scale. The *SII* is scored on five sets of scales: general theme, basic interest, occupational, personal style, and administrative. Scores on the (externally relevant) occupational scales indicate the likelihood of a respondent's choosing an occupation (given the opportunity), and of remaining in the occupation (if entered). Such prediction is based solidly on numerous validity studies that demonstrate the occupational scales' usefulness in vocational counseling. Scores on the other sets of scales are useful in elaborating on and providing context for interpretation of the occupational scale scores.

The *Kuder Occupational Interest Survey* (*KOIS*; Kuder and Zytowski 1991) is another well-researched measure of vocational interests. It is composed of 100 items, each consisting of triads (three different activities) requiring a choice of 'most preferred' and 'least preferred.' The *KOIS* is scored on four sets of scales: dependability indices, vocational interest area estimates, occupational scales, and college major scales. Scores on the occupational and college major scales indicate similarity of interests with the corresponding referent group, which can then be the basis for career counseling.

The most researched measure of work values is the *Minnesota Importance Questionnaire* (*MIQ*; Rounds et al. 1981). The *MIQ* is a paired comparison questionnaire in which 20 'work needs' are compared, each with every other. Work needs are workers' requirements for work reinforcers (e.g., ability utilization, compensation, recognition), identified in studies of job satisfaction. Responses to the *MIQ* are scored for the 20 work needs and six work values. The *MIQ* is also scored by comparing a person's *MIQ* profile with commensurate measures for occupations (occupational reinforcer patterns, or ORPs). Where the *MIQ* indexes what work reinforcers are important to the person, the ORP indexes what work reinforcers are important to the occupation. How well the *MIQ* and ORP profiles match is predictive of occupational satisfaction.

Another measure of work values is the *Work Values Inventory* (*WVI*; Super 1970), which consists of 45 items, each requiring a response on a five-point importance scale. It is scored on 15 values (e.g., altruism, creativity, prestige, economic returns).

Two widely used measures of personal values are the *Study of Values* (Allport et al. 1960) and the *Value Survey* (Rokeach 1973). Both are used largely in descriptive studies.

2.2 *Structure of Content Domains*

The content domain of interests is best represented by the well-corroborated Holland (1997) model that uses a circular structure to organize six basic categories of interests: realistic, investigative, artistic, social, enterprising, and conventional. Numerous studies have

shown the circular order to be robust, with people's interests tending to be located in adjacent categories. This circular structure can be simplified by referring to two orthogonal axes: people vs. things, and ideas vs. data.

The content domain of values has not been studied as thoroughly as that of interests. One structure (Dawis and Lofquist 1984) proposes six categories organized by three bipolar orthogonal axes: achievement vs. comfort, status vs. altruism, and safety vs. autonomy.

2.3 Relations Among Interests, Values, and Other Disposition Variables

Interest and value scale scores correlate only marginally with each other, the largest correlations rarely exceeding 0.30. The highest correlations are between enterprising interests and status values, and between social interests and altruism values. Factor analysis yields separate interest and value factors.

Interest and value scales scores correlate slightly more with scores on personality trait scales. Correlations with personality trait scores reach and occasionally exceed 0.40. However, factor analysis shows that the three domains are relatively independent, with separate interest, value, and personality trait factors.

Even less related are abilities. Correlations of interest and value scores with ability scores rarely exceed 0.20. Interests correlate with abilities more than values do, but factor analysis shows separate ability, interest, and value factors. As currently measured, the content domains of ability and motivation are quite independent.

3. Research Findings

The reliable findings of research on vocational interests and values (as measured above) are reported below. More detail can be obtained from Dawis (1991).

3.1 Stability of Interests and Values

For most people, interests are relatively stable over long periods after age 25. Interests are unstable before adulthood (with notable exceptions), but they increase in stability after age 18. The exceptions are early childhood interests in mechanics, science, mathematics, art, and music, which tend to be rather stable. Twin studies show that interests have a significant heritable component—a likely determinant in the stability of interests.

Values are stable during adulthood, although not as much as interests. Little is known about the stability of values during the developmental years. However, twin studies also show that values have a significant heritable component.

3.2 Predicting Satisfaction and Satisfactoriness

Job satisfaction is best predicted by the degree to which the work reinforcers of the job match the incumbent's values. Close behind as a predictor is the degree to which the interests characteristic of the occupational group match the incumbent's interests. At a gross level, the higher the social status or intelligence status of an occupation, the higher is the job satisfaction of its incumbents—but also, the more likely its incumbents will have the appropriately matching values and interests.

The best predictor of worker satisfactoriness is still the degree to which the worker's abilities match the ability requirements of the job. Such prediction can be improved modestly by adding as predictors the degree to which the worker has the interests and values appropriate to the job.

3.3 Predicting Occupational Membership and Occupational Change

Follow-up studies (over 3- to 21-year intervals) of adults with interest measures have found that about half of them had appropriate interests, another fifth had nearly appropriate interests, and the remainder had inappropriate interests. This is the most reliable finding in research on interests, justifying the use of interest measurement in career counseling and career development. Similar results, though not as well documented, have been reported for values.

Studies of people who have changed their occupation have found that their interests and values tend to be more appropriate for the occupations to which they changed than the occupations from which they changed.

4. Problems and Future Directions

4.1 Research Problems

Practically all of the research on interests and values has used self-report instruments. The extent of bias in the findings that result from such use of a single method is unknown. Findings such as those reported above need validation by other methods.

Another problem with self-report measures is the assumption that scores on such measures index intensity of interests or values. By themselves, scores (number of items endorsed) index not intensity but rather, coverage of content domain. Often, intensity is 'built into' the rating scale anchors (e.g., 'Not Important,' 'Important,' 'Very Important'). The assumption that intensity is thereby measured requires validation.

Problems arise when an instrument has scales with the same names constructed by different methods (e.g., the SII). Studies of same-named scales in the same instrument, one internally consistent and the other

externally relevant, have found low correlations (median of 0.30) between the two. Examination of item overlap shows less than 50 percent commonality. Differing inferences from the two kinds of scales are therefore possible.

A similar problem arises for same-named scales in two different instruments. Studies show low correlations and loadings on separate factors in factor analyses even for scales constructed by the same method. Again, these can lead to differing, even contradictory, inferences. Items of such scales should be compared to see how similar they are in content.

4.2 Future Research Directions

The most important problem for future research is to examine how vocational interests, values, and preferences originate and develop. Such development is likely linked to emotional development (as well as cognitive development), involving both biological and cultural aspects. It is clear that vocational interests, values, and preferences are learned, but a more detailed account of how such learning takes place is needed.

However, in the near term, research will probably continue to focus on predictive validation studies using available or improved instruments as current professional practice requires more such research.

Voluntary Associations, Sociology of

The term voluntary association has a long history in sociology, reaching back to the founding period of the discipline. Although never at the core of sociological theorizing, the term has figured prominently in a number of approaches (see *Conflict Sociology*; *Institutions*). Moreover, it is an important concept in a number of sociological specialties. Prominent examples are organizational sociology, where voluntary associations are seen as one of the three basic forms next to the business firm and the government agency; urban sociology, where voluntary associations have been identified as vehicles of local integration and sources of community power (see *Community Sociology*); political sociology, where voluntary associations are related to social movements (see *Ethnic and Racial Social Movements*), interest groups and status politics (see *Political Sociology*); or the sociology of development, where voluntary associations play an important role in building a social infrastructure for economic growth by generating networks of mutual trust (see *Modernization, Sociological Theories of*).

1. Definition

Not surprisingly, given the different contexts in which voluntary associations figure in sociology, definitions vary somewhat by theory and field. However, while numerous definitions have been offered, they share a common core in the sense that voluntary associations are seen as private, membership-based organizations in which membership is noncompulsory. What is more, the organization should have identifiable boundaries to distinguish members from nonmembers, be self-governing, and noncommercial in objective and behavior (Salamon and Anheier 1997).

Definitions differ mostly in emphasis and 'at the margins,' i.e., along the demarcation lines to related forms such as business (partnerships, cooperatives, mutual organizations), compulsory organizations (guilds, bar associations, and, in some countries, chambers of commerce), political organizations (parties, political action committees, interest groups), and quasigovernmental institutions (mass membership organization in the former Soviet Union, state churches). Some of the definitional complexities arise from significant overlaps with related terms such as

nonprofit organization, nongovernmental organization or third sector organization. In contrast to these forms, voluntary organizations have a membership focus, whereas many nonprofit organizations like hospitals, social service agencies, or art museums may have a governing board but no broad membership base as such. The same applies to nongovernmental organizations like Oxfam or Save the Children, although some like Amnesty International, the Red Cross, or Greenpeace are membership-based.

2. *Development*

Classical sociological thought saw voluntary associations as an indicator of social evolution in the development of undifferentiated to differentiated societies and voluntary associations as expressions of development supplanting traditional forms of organizing such as the extended family or compulsory groups such as guilds and caste-type institutions. Maine's distinction of status vs. contract, Toennies' Gemeinschaft vs. Gesellschaft, and Durkheim's mechanical vs. organic solidarity are prominent exemplars of this type of thinking.

In traditional societies, voluntary organizations fulfilled a number of functions. They served as integrative mechanisms cross-cutting family and clan structures as well as age groups, thereby avoiding potential divisions within the community; they operated as alternative mobility strata in societies with rigid, often hereditary status systems; they were part of the division of labor and provided mutual assistance and economic benefit to members (farmers, craftsmen, traders); or they were in fact precursors of social classes grouping similar economic statuses, occupations, and property owners around a joint interest.

Researchers emphasized the contributions voluntary associations make to the integration of migrants and minorities. African village associations in urban areas facilitate the acculturation of rural–urban migrants from the same area by providing a buffer zone between village life and the more diverse city culture. Other examples along the same principle include ethnic associations among Italian, Greek, or German immigrants to the United States in the nineteenth century, or Turkish clubs in Germany the late twentieth century. Next to social integration, voluntary associations served a complementary economic function as well. They provided a mechanism for mutual self-help among marginal population groups. Savings and credit associations among the poor, cooperative-type organizations among small-scale farmers and small-scale producers etc. are examples of how excluded members of society pool resources to improve their economic well being.

Modern sociological thought about voluntary associations has its in roots de Tocqueville's *Democracy in America* (1990 [1840]) where he observed the importance of voluntary associations for the working of democracy at the local level. In modern, democratic societies, voluntary associations serve a dual function: they organize people from diverse backgrounds around a common purpose, thereby contributing to social cohesion; and they build an intermediary sphere between the political center of power and the electorate, thereby allowing for the expression of minority preferences against a potential 'tyranny of the majority.'

With de Tocqueville's work, the study of voluntary associations began to put more emphasis on state–society relations, the political system, and social structure. A brief comparison of France, Germany, and US may illustrate this central point.

Tocqueville's analysis of the US was meant as a critique of France and its postrevolutionary political order. France had been a centralized nation-state long before the revolution of 1789, and this very centralization made the revolution possible and facilitated its effectiveness in replacing the *ancien regime* with a new ruling class. In line with the highly individualistic and anticorporatist ideology of the revolution, the influential *Loi de Chapelier* decreed that no intermediary associations were allowed to exist between the individuals as *citoyens* and the state as their supreme and unambiguous representative. As a result, the legal and political space for voluntary association became very limited. Only in the twentieth century did voluntary associations gain momentum as their number increased significantly in the 1980s onwards, particularly in the field of leisure, recreation, and culture (Archambault 1996).

In the US, no French *Jacobin* tradition restricted the development of voluntary associations. Indeed, while both countries emphasized individualism over collectivism, the US remained quasi stateless for a prolonged period, developed both a strong pragmatic orientation in policy-making, and a general mistrust of centralized power. As a result, voluntary associations flourished, and soon created a complex network of social clubs, religious, and church-based organizations, and political, professional, and scholarly associations. Voluntary associations and charities continued to occupy a prominent place throughout US history: as service providers in the absence of a welfare state, as an important source of political mobilizations (e.g., civil rights), and as a platform for status competition in a formally egalitarian society (DiMaggio and Anheier 1990). Coser (1956) suggested that multiple memberships in voluntary associations created overlapping social circles and criss-crossing social conflicts, thereby avoiding the emergence of significant class cleavages and other fault lines that could potentially divide society into two antagonistic groups.

In contrast to 'state-based' France and 'association-based' US, Germany reveals a very different role of voluntary associations in political development. In the

absence of an antifeudal revolution, the German case is a series of compromises between a self-modernizing feudal system and an emerging, co-opted bourgeoisie (Seibel 1992).

When elements of a bourgeois culture and civil society first evolved in the form of literary societies, music clubs, and educational associations, the political system and state administration remained under aristocratic control. Moreover, there existed a widespread system of self-governing organizations, in particular the mediaeval system of guilds and unions, with their compulsory membership and comprehensive coverage, underwent a modernization push. In the early nineteenth century, the mandatory system of corporatist organizations was transformed into modern voluntary associations as part of a modernization policy championed by the state. As a result, the German voluntary associations were not seen as the antithesis to the state, as in France, nor did they develop parallel to it, as in the US, but in interaction with an emerging welfare state.

Characteristically, whereas religions in both France and the US are voluntary associations constitutionally separate from the state, the German Catholic and Protestant Churches in particular continue to enjoy the status of public institutions with their own legal system (canonical law), signifying the incomplete separation of religion and political power as a consequence of historical compromises.

3. Scope

Regardless of the strikingly different political and social contexts in which voluntary associations developed historically, recent decades have witnessed a significant expansion in the number of associations and memberships. The number of voluntary associations in the US is well over 1.5 million, with 57 percent of the population being members of at least one association. In France, an associational boom has increased the number of associations to 700,000–800,000, with 35 percent of the French population having at least one membership. Associational density in Germany has tripled since 1960, and nearly two-thirds of Germans belong to associations. Social democratic countries like Sweden have among the highest membership rates among developed societies, with over 80 percent. On average, about half of the adult population in developed countries belongs to at least one voluntary association.

In the developing world, this proportion is somewhat lower with regard to formal, i.e., registered associations. Estimates of membership in indigenous forms of associations are very incomplete, as many of these organizations are informal and not registered. Moreover the legacy of authoritarian rule in many developing countries over the last 50 years also contributed to somewhat lower membership rates in formal associations. At the same time, there are significant variations. India shows a very rich tapestry of associational forms, with estimates running over 2 million. By contrast, developing countries with prolonged histories of authoritarian rule and a tradition of restrictive laws have much lower rates of associations. Formal registered associations number about 800 in Ghana, 13,000 in Thailand, 20,000 in Egypt, and 200,000 in Brazil (Anheier and Salamon 1998).

In former state socialist countries, mass organization linked to political parties accounted for very high membership rates; in the transformation process, however, many have lost significant numbers of members or otherwise faced dissolution. As a result, the membership structure in such societies in reorganizing and remains at lower levels than in the West. At the same time, important differences exist across countries: in the Czech Republic, Hungary, and Poland, an association boom immediately after the initial regime transition signaled the emergence of new voluntary sector, whereas in other countries like Romania and Bulgaria, such processes are much slower, suggesting a continued underdevelopment of civil society.

4. Theoretical Approaches

Current approaches group voluntary associations frequently with other nonstate/nonmarket forms in an attempt to develop theories that explain the existence of a third sector in modern economies that is located between the market (first) and the state (second). Several such theories have been introduced.

The 'heterogeneity' theory is based on the notion of 'market failure/government failure' in economics. This line of thought assumes markets have an inherent limitation in producing 'public goods,' i.e. goods that are available to all whether or not they pay for them. This 'market failure' justifies the presence of government, which exists to satisfy the demand for goods left unsatisfied by the market system. In a democracy, government can perform this role only when a majority of voters support the production of a particular public good. Where considerable differences in voter preferences exist about which public goods to produce, and which ones not to produce, it may be difficult to generate such majority support, leaving unsatisfied demand for public goods as a consequence. Such 'government failure' is most likely where considerable heterogeneity (religious, linguistic, or ethnic) exists in a population. In such circumstances, the establishment of voluntary associations and other types of nonprofit organizations serves both as a vehicle of collective action in the formation of interests and as a mechanism to supply the public goods neither state nor market provide.

A related body of theory sees voluntary associations not only as a reflection of demand heterogeneity; instead, the theory emphasizes the role of social and political entrepreneurs who seek to maximize nonmonetary returns, i.e., followers, believers, or members (James 1989). According to this supply side theory, the presence of such entrepreneurs is most likely in societies with high levels of religious competition or basic ideological splits within the population. In such circumstances, activists have an incentive to form voluntary associations as a way to attract adherents to their cause by offering services that these potential adherents might find attractive, such as health care, education, or cultural events.

A third approach is based on the notion of information asymmetries in market economies (Hansmann 1996). In many transactions, consumers lack the information they need to judge the quality of the goods or services they are purchasing. This can occur because the purchaser is not the same person as the consumer (e.g., the purchase of nursing home care by children for an elderly parent), because the service in question is inherently complex and difficult to assess, or the inputs of some are difficult to match with the benefits procuring to many. In such cases, purchasers or members seek alternative bases for trust in leadership performance or the quality of the resulting service. Voluntary associations offer a solution to this trust dilemma. Because of the 'nondistribution constraint,' i.e. the prohibition on distribution of profits to owners, voluntary associations may be more trustworthy and more likely to serve client or member needs. Accordingly, the nonprofit status of voluntary associations functions as a proxy for the market, signaling trust in the quality of output.

A fourth approach emphasizes the embeddedness of voluntary associations in the social, economic, and political dynamics of societies (Salamon and Anheier 1999). As such, their evolution cannot be attributed to any single factor, such as the unsatisfied demand for public goods or the supply of social entrepreneurs. Rather, the emergence of voluntary associations in modern society is rooted in the broader structure of class and state–society relations. Salamon and Anheier (1997) suggest four regime types of voluntary sectors, each with a particular constellation of social forces, specifically the social and economic importance of the state, measured in terms of social welfare spending, and the overall scope of civil society, measured as the size of voluntary sector activity. The *statist* regime combines limited state activity and a weak voluntary sector. It is found in societies where the state assumes a controlling role, and where elites co-opt the middle class, thereby reducing the level of organizing outside state structure and the market, with Japan being the most prominent example. The *liberal* model characterized by limited state activity but a well-developed system of voluntary association is found in countries like the United States and Great Britain. By contrast, the *social democratic* pattern in countries like Sweden is characterized by relatively high levels of government social welfare spending and relatively small nonprofit sectors in economic terms, but with a very active voluntary component in terms of number of associations and memberships. Finally, in the *corporatist model* both the state and the voluntary sector work in cooperation with each other, whereby the state assumes the role of financier of activities offered by voluntary associations. A typical example is Germany, where a vast network of religious organizations helps implement government-funded programs.

5. *Future Directions*

Despite some progress, the study of voluntary association continues to face considerable methodological and theoretical challenges. In terms of methodology, the measurement of central variables, such as membership, voluntary activities, and formality/informality remains a problem because of significant cross-cultural variations in meaning. Moreover, the development of adequate databases remains underdeveloped because major economic and social statistical systems exclude nonmarket/nonstate activities from regular reporting. In terms of theory, research on voluntary associations will increase by addressing the emerging field of civil society studies (Keane 1998), the notion of social capital (Putnam 1993), and work in the field of world society (Meyer et al. 1997).

Voluntary Organizations

Voluntary organizations are groups within which individual members associate of their own volition with others in the pursuit of common objectives. Participation in such organizations is structured according to agreed norms and is normally intended for public benefit. Voluntary organizations engage in a wide range of activities: those that are most often associated with voluntary endeavor include healthcare, education, religion, the arts, sports, and a wide range of social welfare services.

Voluntary organizations are self-governing and are not controlled by government. In a particular jurisdiction, depending on the nature of charity law, a voluntary organization may be categorized as charitable, in which case it may be eligible for specified tax privileges. The work of voluntary organizations may be supported by contributions provided by individual donors, corporations, or philanthropic foundations. Unpaid board members normally govern voluntary organizations; their work, however, may be accomplished either by volunteers or paid staffers.

The main forms of voluntary organization activity include service philanthropy (helping others); social solidarity (helping self and others in the same situation); changing (altering the basis of society); mobilizing (rallying other people or resources to support a cause); creating (bringing something new into play); and intermediary (coordinating or organizing activity as research and development, provision of administrative service, or representation) (Knight 1993). Voluntary organizations are 'voluntary' in a dual sense: (a) much of their human resources are contributed by members as volunteers and (b) they are nongovernmental and not-for-profit (cf. Van Til 1988). Thus, voluntary organizations may be seen as mainstays within what is increasingly referred to as civil society (noncommercial, nongovernmental) and key components of what has come to be called society's 'third sector' (business and government being the other two sectors).

1. *Intellectual Antecedents and the Theory of the Third Sector*

Voluntary organizations are central to a number of important theoretical perspectives in social science (Sills 1968, Van Til 1988). Writing at the end of the nineteenth century, the French sociologist Emile Durkheim, following in the footsteps of his countryman Alexis de Tocqueville, gave a major role to associations in his studies of social solidarity, in turn giving birth to the influential theories of sociopolitical pluralism. The observations of Max Weber laid the basis for later neocorporatist thought, and the studies of Robert Michels illuminated aspects of elitism and populism within voluntary organizations. Karl Marx, although hardly an enthusiast for voluntarism, nevertheless relied upon the power of voluntary social movements to accomplish the revolutionary tasks he predicted and prescribed. And, in the twentieth century, social theorist Talcott Parsons envisaged voluntary organizations playing a major role in the 'integration' of societal institutions, a task extended by the contemporary communitarian theories of Amitai Etzioni, Roger Lohmann, and Jennifer Wolch.

Distinctions between formal and informal organizations, nonprofit and for-profit groups, and public and private purposes (the boundaries between each being often unclear or 'blurred') suggest that voluntary organizations may occupy space where they act very much in 'hybrid' or 'multi-sectoral' ways, as Victor Pestoff has demonstrated visually (in Kramer 1998). Voluntary organizations may assume specific characteristics of organizations in the other sectors. Rudolph Bauer has observed that volunteers tend to experience voluntary organizations as providers of charitable service, board members tend to see them as though they were political organizations, and staff may behave as though the same organization is primarily a business.

2. *Voluntary Organizations: Scope and Scale*

Around the world in diverse societies and in contrasting political cultures the final two decades of the twentieth century saw a remarkable growth in the range and number of voluntary organizations, leading some commentators to speak of a 'global associational revolution of extraordinary scope and dimensions' (Salamon 1995). This pace of development shows no sign of slowing. In the developing world and throughout Eastern Europe locally based voluntary organizations work in partnership with international agencies and philanthropic foundations whose policies increasingly stress empowerment and the participation of local people in development projects. Throughout the developed world the retrenchment of public welfare regimes and pressures on public funding have encouraged the formation of partnerships between public authorities and voluntary organizations to

deliver social welfare and other services with increased flexibility and less bureaucracy.

The development of close relations between government agencies and voluntary organizations has promoted concerns about the 'incorporation' of voluntary organizations by the state, and the danger that they would lose their role as advocates. Although generally represented as a part of a 'private' nongovernmental sector, many voluntary organizations increasingly are described as becoming 'interdependent' with government. This interdependence most often has been linked to the service provider role that voluntary organizations play under contract to government programs (Kramer 1998). Billis and Harris (1996) have identified the linkages created through voluntary organizations' roles as advocates for public policies and as representatives of special interests.

Prominent among the contemporary ranks of voluntary organizations in a number of Western nations stands a subcategory that is governmentally identified as exempt from corporate taxation. These are conventionally identified as 'nonprofit organizations,' that are certified to perform a wide range of functions in society, and in return for their exempt status are required to provide public accounting of their actions.

Contemporary estimates identify over 1.2 million nonprofit organizations in the United States, many of which employ paid staff as well as utilize volunteer employees and board members. In the United States approximately half the population engages in regular volunteering for the benefit of others outside their families; and nine percent of all meaningful employment (and seven percent of all salaries) emerge from the third sector (Hodgkinson et al. 1996). Much additional activity is conducted within grassroots associations, which need not be formally chartered, and whose number has been estimated at 7.5 million or more in the United States (Smith 2000).

3. *The Growth of Voluntary Action Research*

Since 1970, the study of voluntary organizations has become an increasingly active arena for scholarly research. Professional associations like ARNOVA (Association for Research on Nonprofit Organizations and Voluntary Action) and ISTR (International Society for Third Sector Research) have grown rapidly; scholarly journals like the *Nonprofit and Voluntary Sector Quarterly*, *Voluntas*, and *Nonprofit Management and Leadership* have emerged; and organizations like Independent Sector and CIVICUS have grown to play key roles in asserting the role of voluntary activity in society.

The phenomenon of global associational development has been charted in an extensive series of country studies under the aegis of The Comparative Nonprofit Sector Project directed at the Johns Hopkins University in the United States. These studies have established that the numbers of voluntary organizations and the importance of this sector are much greater than previously thought, both in the developed and developing world. Academic centers for the study of voluntary organizations now exist in many countries. In the United States there are many well-established academic research centers such as those at Indiana University (where the Nonprofit Academic Centers Council is located), and at Case Western Reserve, Duke, Harvard, Georgetown, and Yale Universities and the City University of New York. In the United Kingdom, academic centers exist at the London School of Economics, London's South Bank University, Aston University in Birmingham, and the University of Ulster. Elsewhere there are university research centers or academic research concentrations in many countries including Australia, Belgium, Brazil, Canada, Egypt, India, Israel, the Republic of Ireland, South Africa, and Spain.

4. *Challenges and Future Directions*

Most, but not all, voluntary organizations are benevolent or benign in their objectives. Whereas all voluntary organizations tend to feature common bonds of interest, solidarity, and commitment among their members, sometimes described as 'bonding social capital,' not all voluntary organizations generate or facilitate the building of 'bridging social capital,' which, by its nature is broad and reaches out to other groups. Bridging social capital encourages linkages with networks and tends to be tolerant of differences (Putnam 2000). In some organizations the common interest is either so narrowly cast or pursued by such dubious means that many members of the wider society find their actions inimical to the public good or even to be a danger to public safety. Members of ethnic minorities or groups which consider themselves to be oppressed may form voluntary organizations to pursue social and/or political objectives, sometimes using peaceful, legal, and nonviolent means, and at other times adopting paramilitary forms of organization and discipline and using violent methods (Gidron et al. 1999). The Middle East and Northern Ireland provide examples of violent political movements closely linked to voluntary welfare organizations established to provide much-needed social, cultural, and educational services to disadvantaged populations. Voluntary organizations thus serve two purposes: they respond to social need as they assist political movements in building and strengthening their constituencies. But the purposes of voluntary organizations can also be twisted into the service of those in governmental power, as was the case in Nazi Germany (Bauer 1990).

The increasing commercialization of modern life has affected nonprofit organizations, which have become increasingly dependent upon income from fees and, particularly in the case of hospitals and higher education institutions, have adopted many

'business-like' structures and practices (Powell 1986). Furthermore, in an era in which 'everything is for sale,' for-profit corporations often insist that their charitable donations must benefit themselves as well as others, by practicing what has been called 'cause-related marketing.' Philanthropic giving is itself encouraged by tax-deductibility, and individual programs are often required to support themselves as 'profit centers' within specific nonprofit organizations.

In the climate of resource uncertainty that prevails among many paid-staff voluntary organizations, fund-raising (increasingly referred to as 'development' or 'advancement') often becomes a central staff activity, and a high emphasis is paid to the quality of 'nonprofit management' credentials and skills, often provided by the many university centers that have emerged since 1980.

The futurist J Rifkin (1995) has argued that the twenty-first century is likely to see a continuing decline in the amount of paid work made available to individuals by both governments and corporations. This restructuring of economy and society will provide increasing scope, he contends, for participation in voluntary activity. By providing shadow wages (e.g., tax deductions) to support voluntary action and a social wage to facilitate volunteering by under-employed people, the social economy provided by the third sector may play an important role in maintaining social peace and order in an age threatened by the divisiveness of increasing socioeconomic inequality.

In such a time of change and challenge, it is important to recall that it is voluntary action that powers the third sector, and that the third sector is relied upon by society as a crucial developer of its distinctive goals. Voluntary organizations resemble, in part, businesses, governments, and families—and interact directly with all three of these organizational forms.

Voluntary organizations receive their unique stamp, however, from their shared value of advancing the common good by means of reflective and significant voluntary group activity. The core values of voluntary organizations distinguish these organizations from firms that operate in the marketplace and from other kinds of social service organization. These values should be reflected both in the objectives of the organizations and in their operational policies. For example, a typical volunteer or paid practitioner within a voluntary organization would likely consider as of central importance values such as caring, social justice, fairness, and the involvement of users in planning and delivery of services. Similarly, voluntary organizations normally will prioritize marginalized and minority individuals, people in need, and those who feel excluded or disadvantaged.

A particular challenge for voluntary organizations is to interpret and apply their values and to ensure that in their day-to-day work, management and care practices, and personnel and other policies, they are consistent with the values they say they stand for. When voluntary organizations succeed in defining their goals and meeting needs responsively, they can contribute significantly to the quality of life in modern society.

Volunteerism, Psychology of

Every year, millions of people volunteer substantial amounts of time and energy to helping others. Among other services, volunteers provide companionship to the lonely, tutoring to the illiterate, counseling to the

troubled, and health care to the sick. According to one estimate, 93 million adults in the USA engaged in some form of volunteerism during 1995, with their combined length of service totaling 20.3 billion hours. These 93 million volunteers represented 49% of the adult population, a quarter of whom devoted five or more hours per week to volunteering (Independent Sector 1996). Moreover, volunteerism is not limited to the USA and can be found in many other parts of the world (Curtis et al. 1992).

From a scientific perspective, the study of volunteerism provides opportunities for inquiring into the nature of helping and of prosocial action more generally. Two distinct traditions of research and theorizing in psychology can be identified, each investigating a specific form of helping and each focusing on issues relevant to that form of helping.

1. *Varieties of Helping and Prosocial Action*

One research tradition focuses on situations in which potential helpers are confronted with unexpected opportunities to help strangers (the classical example being 'bystander intervention,' e.g., Latané and Darley 1970). The help that occurs here is typically unplanned and spontaneous, is usually confined to relatively brief encounters, and generally entails neither prior contact nor future contact between helper and recipient. To answer the question of why this spontaneous helping occurs, some researchers have proposed that it reflects purely altruistic motives to benefit others (e.g., Batson 1998). Other answers involve claims that such helping reflects selfish concerns, such as to feel good about oneself (e.g., Cialdini et al. 1987).

A second research tradition focuses on people providing long-term care and support to those suffering with serious illness or chronic conditions. This research examines 'obligated' caregivers who, because of marital bond or blood relationship, provide assistance to a spouse, parent, child, or sibling suffering from ailments, including Alzheimer's disease, arthritis, or the aftermath of a stroke or serious accident (e.g., Thompson and Pitts 1992, Folkman et al. 1994). In such relationships, the impetus for assistance may reasonably be seen to flow from the legal, ethical, or familial obligations that tie the helper to the recipient, thereby rendering questions of personality and motivation all but moot. These helpers help because they have to, doing so for reasons related to moral, legal, or personal obligation. This literature has focused on the nature of such caregiving: it is difficult, demanding, and stressful, and may exact considerable psychological and even physical tolls on those who provide such ongoing, long-term care.

Although it shares many features with other forms of prosocial action, several features of volunteerism mark it as a distinctive form of helping (Piliavin and Charng 1990, Clary and Snyder 1991, Omoto and Snyder 1995). Rather than happening upon situations in which they are pressed to help, volunteers typically seek out opportunities to help, and may deliberate long and hard about the precise nature of their involvement; these features distinguish volunteerism from spontaneous helping. Volunteerism often entails commitments that extend over long periods of time and entail sizable personal costs; this feature of volunteerism is shared with the long-term helping of obligated caregivers. However, unlike obligated caregivers, volunteers typically do not know those they help in advance and have no prior bonds of obligation to help them; instead, volunteers often are matched with the recipients of their help by service organizations.

As a hybrid strain of helping, volunteerism engages many of the questions associated with the spontaneous helping and obligated caregiving traditions of research on helping. Volunteerism raises questions of personality (is it enacted only by individuals with altruistic dispositions?), of motivation (why, in the absence of obligation, do people ever volunteer?), and of mechanisms for sustaining it (in what ways do personal and social resources promote long-term helping?). At a theoretical level, then, understanding volunteerism requires broaching questions that are also of fundamental concern in other forms of helping.

However, in spite of its potential to engage a wide range of theoretical questions, there has been (until relatively recently) remarkably little psychological research on volunteerism (see Piliavin and Charng 1990, Clary and Snyder 1991). Also, because of its defining and characteristic features, volunteerism is something of a curious phenomenon. For a variety of reasons, it simply should not occur. Unlike the helping that occurs in response to emergencies, there is no press of circumstances. Unlike the helping that occurs in families and in existing relationships, there are no bonds of obligations. Volunteerism is effortful, time consuming, and involves opportunity costs to volunteers—all features that should serve as barriers to volunteering. Yet people do seek out opportunities to volunteer, and they do sustain their volunteer efforts over extended periods of time. The question is, 'Why?' Why do some people get involved in helping others as volunteers and in participating in society? What is it that moves people to seek out opportunities to help? What is it that guides them toward some helping opportunities and away from others? And what is it that sustains their efforts over time and through adversity?

2. *Motivational Foundations of Volunteerism*

The questions of why people volunteer to help others are fundamentally questions about motivation. Answering these questions in terms of the forces that move people to action and that guide and sustain

action is, therefore, to provide answers in terms of the processes of motivation. Theories of motivation are, by definition, concerned with what moves people to action, what channels their action in some directions rather than others, and what sustains their actions. One approach to understanding the motivations behind volunteerism is a 'functional' approach concerned with the needs being met, the motives being fulfilled, and the functions being served by engaging in volunteer service (e.g., Omoto and Snyder 1995, Snyder et al. 2000).

Several considerations recommend functionalist theorizing (Snyder and Cantor 1998). First, the functional approach is a motivational perspective that directs us to inquire about the personal and social processes that initiate, direct, and sustain action. Second, a core proposition of functionalist inquiry is that people can and do perform the same actions in the service of different psychological functions, with different people engaging in the same volunteer activity but doing so to fulfill different motives. Third, the functional approach suggests that important psychological events, such as embarking on a course of volunteer activities and then maintaining those activities over extended periods of time, depend on a matching of the motivational concerns of individuals with situations that can satisfy those concerns. Finally, research stimulated by motivationally oriented analyses of a wide variety of cognitive, affective, behavioral, and interpersonal processes supports key functionalist themes.

Guided by the broad directive provided by functionalist theorizing, researchers have sought to identify the precise motivations that can be fulfilled through volunteer service. Based on findings from diverse empirical investigations of volunteers involved in a wide variety of helping activities, it has been possible to identify and operationalize a diversity of personal and social functions served by volunteering (e.g., Omoto and Snyder 1995, Clary et al. 1998, Okun et al. 1998), including the expression of personal values, the quest for understanding, the desire for enhanced esteem, the strengthening of social relationships, the building of community ties, and the search for career advancement.

3. *The Processes of Volunteerism*

In their efforts to understand volunteerism as a form of sustained, ongoing prosocial action, researchers have examined the ways in which people construct agendas for voluntary action, identify their own motivations for volunteering, seek out and pursue service opportunities that they believe have the potential to fulfill their motivations, and sustain and maintain their involvement in these volunteer activities. Much of this research concerns helping and prosocial action as they occur in the real world, focusing on 'real' individuals involved in 'real' acts of volunteerism in 'real' world settings.

A guiding theme of research on volunteerism is that critical events in the 'life history' of a volunteer over the course of his or her volunteer service depend importantly on the match of that volunteer's motivations to the opportunities afforded by the environment in which volunteering occurs. Relevant to the conditions under which volunteerism is initiated, it has been found that persuasive messages motivate people to initiate volunteer service to the extent that the messages are tailored to the specific motivations important to individual recipients of the message (e.g., Clary et al. 1998). The importance of matching an individual's motivations to events in the situation does not end with recruitment. As participants in an ongoing and sustained activity, volunteers whose motivational concerns are served by their participation appear to derive greater satisfaction than those whose concerns are not met (e.g., Clary et al. 1998). Moreover, actual intentions to continue serving as volunteer helpers can also be linked to the matching of experiences with motivations such that volunteers who receive functionally-relevant benefits also express greater intentions to continue as volunteers, both in the short-term and in the long-term, than do volunteers who do not receive functionally relevant benefits or who receive functionally-irrelevant benefits (Clary et al. 1998). Finally, longitudinal investigations have found that fulfilling important motivations predicts actual commitment to volunteering (Omoto and Snyder 1995).

4. *Promoting Volunteerism*

Many societies view participation in volunteer activities as highly desirable, and people are encouraged to become volunteers. In fact, some American schools actually require students to participate in community service. However, requiring people to engage in community service may prove counterproductive in the long run, as there is considerable evidence that applying extrinsic pressures to perform an activity may actually undermine the motivation to continue to perform the activity once the pressure is removed (e.g., Lepper et al. 1973).

Stukas et al. (1999) examined this process in a 'mandatory volunteerism' program in which university students were required to perform community service. Of particular concern were students' intentions to continue to volunteer after the conclusion of the program, and the relation of these intentions to the students' preservice perceptions of control and prior volunteering experience. For those students who felt that their participation was under their own control (and thus perceived less external control to volunteer), greater future intentions were associated with greater previous experiences as a volunteer. However, for

those who felt external pressure to volunteer, their future intentions to volunteer were less than those who felt that they had retained personal control, and a slightly negative relationship between prior experience and intentions was observed.

Thus, volunteerism provides an opportunity to explore the empirical debate over the immediate and long-term impact of compelling people to act. Certainly, immediate volunteering can be induced by requiring students to serve, but it seems that future choices to volunteer may become less likely if the initial experience is accompanied by perceptions of external control.

5. *Theoretical and Practical Implications*

The study of volunteerism delivers potential messages, both theoretical and practical. Theoretically, the study of volunteerism is informative about the nature of helping. As exemplified by volunteerism, it informs us about forms of helping and prosocial action that are planful, sustained, and that occur in the absence of bonds of obligation. Also, from a theoretical perspective, it illustrates the benefits of conceptualizing motivation as the planful pursuit of agendas for action.

Practically, it teaches lessons about the practice of volunteerism, specifically about the ways that organizations dependent on the services of volunteers can enhance the recruitment, placement, and retention of volunteers by systematic attention to the experiences and the motivations of individual volunteers. As suggested by the functional approach, matching of recruitment appeals, volunteer tasks, and volunteer experiences to volunteers' motivations can influence the satisfaction, effectiveness, and longevity of service of volunteers.

Further, at an even broader level, studying volunteerism is also likely to yield valuable information of societal significance. It has the potential to inform about the actual and potential roles of volunteers and volunteer organizations in confronting and surmounting many of the problems that confront and challenge society.

Voting: Class

The idea of class voting appears straightforward: it refers to the tendency for voters in a particular class to vote for a particular party, political candidate, or

groupings of these, rather than an alternative option when compared with voters in another class, or classes. In other words, it describes a pattern of association between class and vote. Yet this simplicity hides considerable intricacy and ambiguity. The definition of social class in and of itself introduces much confusion—class is a much debated, even 'essentially contested,' concept. The issues raised become more complex still when class concepts are translated into measures of class position that allocate voters to classes and when attempts are made to summarize statistically the class–vote association. Explaining patterns of class voting and understanding their implications raises many more unresolved questions. All of these theoretical and methodological issues have at times been the focus of dispute. In addition, however, there has been one major substantive argument that has received more attention than all other questions and which has touched on all of them: has class lost its importance as a source of voters' political preferences?

Historically, interest in class voting arose in response in part to the failed agenda of Marxism. For classic texts in political sociology electoral politics was an expression of 'the democratic class struggle' (Anderson and Davidson 1943) that replaced, at least for the short-term, the predicted class-based revolution. This in turn led to a focus on class voting as a dispute between just two classes, the working class and the middle class, and their representatives, parties of the left and right. Early research also relied on data obtained at the level of electoral constituencies. Given the well-known problems with inferring individual vote choices from aggregate data this work had to make strong assumptions about how voters in different classes actually voted. To help overcome this limitation, modern social scientific studies of class voting have focused on its measurement through surveys of voters. From its beginnings in a few national election studies this data base has expanded through time and space to create a large body of evidence on class voting that now informs academic debate.

1. *The Two Class/Two Party Era*

The baseline for many current studies was set by Robert Alford's (1967) analysis of trends in class voting in four Anglo-American democracies (Australia, the UK, Canada, and the USA) between 1936 and 1962 using a measure of social and economic position in which occupations were aggregated to form a dichotomous manual/nonmanual class division. He also introduced the most commonly used, cited, and criticized measure of the level of class voting: the 'Alford index.' The Alford index is simply the difference between the percentage of manual workers that voted for left-wing political parties on the one hand and the percentage of nonmanual workers that voted for these parties on the other. This became standard practice in the cross-national and over-time analyses that followed, and which usually concluded that class voting is in decline. Lipset (1981), for example, presented evidence of a downward trend in the UK, Germany, and the USA between 1945 and 1980; while Inglehart (1997) points to evidence of a continuing decline from the early 1980s onwards. Indeed, whether or not class voting in modern industrial societies has declined is, for many commentators, no longer an issue. The question is *why* has it declined? A plethora of explanations have been proposed to account for this outcome (see Goldthorpe 1996, Manza et al. 1995): some assert that it has lost its importance as a determinant of life-chances and in consequence its role as a source of divergent political interests because the working class has become richer, white-collar workers have been 'proletarianized,' or because of extensive social mobility between classes. Others argue that 'postindustrial' cleavages, such as gender, race, ethnicity, public versus private sector, and various 'identity groups,' are emerging and replacing class-based conflict. Postindustrialism also impacts on class voting through the rise of post-material values as a basis of party preference, which has led to the 'new left' drawing its support from the middle classes thus weakening the class basis of left-right divisions; while rising levels of education and 'cognitive mobilization' have supposedly produced voters that are calculative and 'issue oriented' rather than driven by collective identities such as class.

Whatever their strengths and weaknesses—and there are many questions and doubts that remain unresolved in each case—all of these explanations assume that there is indeed a widespread, secular decline in class-based political action which then has to be explained. However, answers to questions about change have been strongly conditioned by choices of method and measurement. The literature on the decline of class voting that followed Alford's work has been characterized by shortcomings in both these respects.

For example, one problem with the manual/nonmanual distinction is that it obscures variations in the composition of the manual and nonmanual classes. Any changes in their composition may lead to spurious change in estimates of class voting. Thus, if skilled manual workers are more conservative than unskilled workers and the number of skilled workers increases, the difference between manual and nonmanual workers will decline even if the relative political positions of skilled, unskilled, and nonmanual workers remain the same. With this and similar indices the measurement of the class–vote association is open to confounding by changes in the shape of the class structure and in the general popularity of the parties. In other words, this type of index confuses differences in the marginal distributions of the variables with differences in the association it is supposed to measure.

The same problem applies to the apparently more sophisticated ordinary least squares regression techniques used in, among others, Franklin, Mackie and Valen's (1992) ambitious 16 nation study that represents, arguably, the culmination of this tradition.

2. *Recent Innovations*

In recent years, therefore, the rather atheoretical manual/nonmanual representation of class voting has been to a large degree superseded as researchers have taken into account more nuanced ideas about class structure. Most influential has been the class schema developed by John Goldthorpe and his colleagues (Erikson and Goldthorpe 1992). First used to study patterns of class voting over time in Britain by Heath *et al.* (1985) this instrument, unlike many other measures of class, has been empirically validated. The main classes identified by the Goldthorpe schema are the petty bourgeoisie (small employers and self-employed), the service class, or salariat (professional and managerial groups), the routine nonmanual class (typically lower grade clerical 'white-collar workers'), and the working class (foremen and technicians, skilled, semi-, and unskilled manual workers). The principal distinction underlying the distinction among the employee classes in the schema is between a service contract in which employees receive not only salaried rewards but also prospective elements—salary increments, job security and pension rights, and, most importantly, well-defined career opportunities—and a labor contract, in which employees supply discrete amounts of labor, under supervision, in return for wages which are calculated on a 'piece' or time basis. As the employment relationship of the service class in relatively advantageous in terms of employment and payment conditions, occupational security, and promotion prospects, its members have a stake in preserving the status quo. In contrast, the disadvantages of the labor contract can explain why the working class provides a basis of support for the redistributive programs of the left.

This shift to greater complexity in the measurement of class has been accompanied by a similar move away from the measurement of political choice as a dichotomy of left versus right (or left versus non-left) to a fuller representation of the voters' spectrum of choice at the ballot box. Apart from its simplicity, the main reason for the use of a dichotomy to represent voter choice seems to have been a desire to make systematic cross-national and over-time comparisons. Unfortunately, the selective nature of what is being compared undermines any true comparability. The problem is analogous to that faced in the analysis of class position. Changes in the composition of composite categories such as 'left' or 'non-left' may lead to spurious changes in estimates of class voting. The use of dichotomies to represent vote choices and social classes also precludes from observation any processes of class–party realignment. The concept of class *re*alignment in voting implies a change in the pattern of association between class and vote without any change in the overall strength of this association—i.e., without class *de*alignment (or, of course, increased alignment). But this cannot be discerned if the distinction between realignment and dealignment is prevented by restricting the numbers of parties and classes to two.

The final innovation of the 1980s and 1990s is in the statistical measurement of the class–vote association, with a move from Alford type indices to ones that are based on odds ratios, which measure the strength of the relationship between class and vote independently of the general popularity of political parties or changes in the sizes of classes. The use of logistic modeling techniques likewise capitalizes on this basic feature of the odds ratio and allows the relationship between more complex class and party systems to be summarized, thus complementing and facilitating greater sophistication in the representation of class and vote.

Research using these advances comes to rather different conclusions than those in the two-class, two-party tradition. Studies in the UK (i.e., Heath *et al.* 1995) have found little evidence of declining class voting and have concluded that 'trendless fluctuation,' or at most a 'one-off' change, best captures the pattern of association in class voting over time. The USA, by comparison has seen the growth of a new class–vote cleavage—between those who vote and those who do not—as a deficit of working class interest representation that has been associated with increased class differences in participation (Hout *et al.* 1995). Various studies reported in Evans (1999) show that although there is evidence for a linear decline in left versus non-left class voting (Nieuwbeerta and de Graaf 1999), it is not typical. For example, when examined over the long-term, levels of class voting in the UK were found to have increased during the 1940s and 1950s before falling back in the 1960s; while the 1990s have seen increased levels of class voting in new post-communist democracies as these societies have undergone the rigors of marketization. Only in certain Scandinavian countries is there robust evidence of a decline from an unusually high degree of class voting to levels similar to those in other Western democracies.

3. *New Directions*

The debate on class voting has been strong on evidence and weak on theory. Most scholars have assumed a sociological, relatively deterministic account of the transition to industrial and postindustrial politics, but there are those who have rejected these in favor of more voluntaristic models. Kitschelt (1994), for

example, argues that the electoral fortunes of European social democratic parties are largely determined by their strategic appeals, rather than by secular trends in the class structure—a line of reasoning that echoes Sartori's (1969) influential emphasis on the importance of organization, and especially parties, in the creation of class constituencies. From this perspective there is reason to believe that even in advanced industrial societies class voting might increase as well as decrease. It also implies that the adoption of class-relevant policy programs should be associated with an increase in the class basis of partisanship. Some evidence for this has been presented by Evans *et al.* (1999) who show a relationship over time between left-right polarization in parties' manifestos and the extent of class voting.

This is not to say that sociological changes have no impact, however. Changes in the relative *sizes* of classes have been thought to have implications for party strategy: most importantly, in a change to a 'catch-all' strategy by parties on the left in response to the shrinking class basis of support for those parties (Przeworski and Sprague 1986). In some political systems such moves leave open the space for left parties to attract support from marginalized working class groups; in others, such as first-past-the-post systems, we might expect that the start-up costs for electorally viable left parties would be too great. Unfortunately, many of these arguments still await rigorous tests using survey analysis. Research that tries to unravel *why* voters in different classes vote differently is in short supply, though Weakliem and Health (1994) provide evidence of the role of rational choice and inherited preferences, while Evans (1993) models the effects for future expected rewards and the likelihood of promotion conditioned by position in the life-cycle. A more explicit link between models of class voting and their dependence on advances in theories of voting behavior more generally is an area where further development might usefully occur.

Voting: Compulsory

Compulsory voting (CV) is a system of laws and/or norms, mandating that enfranchised citizens turn out to vote, and usually specifying penalties for non-compliance. The number of countries using CV in at least some of their elections is greater than commonly recognized. One recent estimate is that twenty-four countries constituting roughly 17 percent of the world's democracies employ compulsory voting to some extent (Australia 2000).

CV raises questions that strike at the heart of democratic theory. For example, is it 'democratic' to compel citizens to turn out to vote via the threat of financial or social sanction? In what sense are elections conducted under such circumstances 'free and fair'? On the other hand, what legitimacy attaches to elected representatives and their policies when large proportions of the electorate abstain? Responding to this latter question, political scientists have long considered CV an effective mechanism to increase voter turnout (e.g., Gosnell 1930). Scholarly interest in CV was piqued by Arend Lijphart's 1996 Presidential Address to the American Political Science Association, providing a detailed review of CV and a compelling case for its adoption. CV raises numerous issues for students and practioners of electoral politics, which are the focus of this article. Real-world implementations of CV are considered first, followed by an assessment of the consequences of CV for electoral politics, policy, campaigning, and the administration of elections.

1. *Implementations of CV*

Western democracies utilizing CV for at least some of their elections include Australia, Austria (in selected *Länder*), Belgium, Greece, Italy, Liechtenstein, Luxembourg, and Switzerland (just one canton). The Netherlands also had CV up until 1970. In almost all of these Western democracies CV was instituted in the early twentieth century, shortly after the expansion of voter suffrage and the political organization of labor movements in the late nineteenth and early twentieth centuries. At the same time there were some experiments with CV in American states: North Dakota (1898) and Massachusetts (1918) actually amended their constitutions to permit CV, but the respective legislatures did not implement CV in their statutes (Gosnell 1930, pp. 206–7). Abraham (1955) also reviews American flirtations with CV. CV is widespread throughout Latin America; for instance, Argentina, Brazil, Costa Rica, Ecuador, Guatemala, Honduras, Panama, Peru, Uruguay and Venezuela have CV. Cyprus, Egypt, Fiji, Turkey, Thailand, Singapore and the Phillipines also have CV.

1.1 *Inducing Compliance*

Compliance with CV is most commonly induced with a system of small to moderate fines (e.g., Australia and Belgium), sometimes in conjunction with other penalties, although a substantial number of countries do not impose fines. Other penalties include ineligibility for elected office for a prescribed period (e.g., Argentina), or ineligibility for certain types of government employment (e.g., Venezuela), or disenfranchisement (e.g., Thailand). In other countries, CV has more the status of a norm, with sanctions for non-compliance taking the form of social embarrassment, with non-voting noted on official documents (e.g., Italy). In another class of countries CV appears as a constitutional provision or in statute, but with no mention of any penalty for non-compliance (e.g., Bolivia, Chile, Liechtenstein, Egypt). Many countries also have large classes of exemptions. For instance, Australia's federal CV statute exempts non-voters with 'valid and sufficient' reasons for not turning out; Australia's courts have rigorously denied non-voters' claims of indifference between the candidates or alienation from politics as valid and sufficient reasons (AEC 1999). Age exemptions are also common: for instance, Brazil makes voting optional for citizens between the ages of 16 and 18, citizens over the age of 70, and for illiterates.

2. *Consequences of CV*

CV has a direct impact on voter turnout, evident in both aggregate and individual-level analyses. The logic of this is extremely straightforward, with the sanctions of CV offsetting the costs of going to the polls; that is, CV makes the option of not turning out costly, overcoming the fact that turning out is a low benefit activity for many citizens (Lijphart 1997, p. 9).

2.1 *Voter Turnout: Cross-national Evidence*

Even a casual inspection of compendiums of aggregate turnout statistics reveals higher turnout among countries with CV. For instance, a recent collection of data on voter turnout in 171 countries finds turnout roughly six or seven percentage points higher in the 24 countries with CV than in countries without CV (IDEA 1997, p. 32). Multivariate statistical analyses typically find CV to have larger impacts on turnout, by controlling for other institutional and political variables that affect turnout. Lijphart's (1997) review finds CV associated with a boost in turnout rates of seven to sixteen percentage points (for examples of the studies reviewed, see Powell (1981), Jackman (1987), Jackman and Miller (1995), and Franklin (1999), the latter study being distinctive for including an individual-level analysis, exploiting survey data from European Union countries). Among Latin American countries, the estimated turnout boost associated with CV is roughly eleven to seventeen percentage points (Fornos 1996).

These results are striking considering (a) large cross-national differences in institutional and political characteristics of these countries that impact turnout (e.g., Jackman's 1987 study considered competitiveness of elections, electoral disproportionality, number

of political parties, unicameralism vs. bicameralism), and (b) considerable variability in the implementation of CV among those countries that nominally have CV. In addition, of all the institutional variables found to impact voter turnout, CV has far and away the largest effect.

2.2 Voter Turnout: Evidence from Within-country Comparisons

Hirczy (1994, p. 65) makes a compelling argument that cross-national analyses provide 'no causal proof that mandatory voting actually produces high turnout,' and indeed, the causal arrow may be reversed; i.e., a country that adheres to a norm of high turnout simply 'enshrines its civic norm in law.' A research design that overcomes this threat is to compare turnout within countries, before and after the implementation or repeal of CV, or across sub-national units with and without CV. An additional strength of this research design is that, within countries, many of the factors affecting turnout remain constant, regardless of CV.

Studies of this type find CV to have large effects on aggregate turnout. Prior to the implementation of CV in 1924, turnout in elections to Australia's House of Representatives averaged 64.2 percent; in the nine elections following the introduction of CV turnout averaged 94.6 percent, an increase of 30.4 percentage points ($t = 8.7$; author's calculations, using data in Hughes and Graham (1968)). In The Netherlands, the abolition of CV in 1970 caused a drop of roughly 10 percentage points to around 84 percent (Irwin 1974, Hirczy 1994). In addition, the removal of fines for nonvoting in Venezuela in 1993 saw turnout fall by roughly 30 percentage points (Lijphart 1997, p. 9). In Austria, cross-provincial and longitudinal variation in the use of CV permits a powerful assessment of the impact of CV. Turnout in eleven federal parliamentary elections between 1953 and 1987 averaged 92.7 percent in provinces without CV; among provinces with CV turnout averaged 95.7 percent, to yield a treatment effect of 3.0 percentage points ($t = 3.4$), this smaller treatment effect reflecting a 'ceiling effect' with turnout rates bounded from above at 100 percent. A reasonable conclusion based on these studies is that CV's effects are conditional on baseline levels of electoral participation; i.e., CV is likely to have bigger impacts on turnout when other factors predispose a country to low turnout, and vice versa (Hirczy 1994). This insight can be applied in cross-national studies of voter turnout, using interaction terms or multilevel statistical models to make the effects of compulsory voting conditional on other variables.

Public opinion surveys have also been used as proxies for the 'natural experiment' of removing CV. For instance, researchers in a number of countries have asked respondents to engage in thought experiments, in which respondents report their likely behavior in a counter-factual scenario of voluntary turnout. Results from studies of this type suggest modest falls in voter turnout in Australia—to about 88 percent from the current 96 percent figure (Mackerras and McAllister 1996)—but larger falls in Belgium (Hooghe and Pelleriaux 1998), Brazil (Power and Roberts 1995), and Venezuala, as large as 30 percentage points. Jackman (1999) urges caution in interpreting these estimates, arguing that (at least in the Australian case) survey response bias produces an overestimate of voluntary voter turnout, since would-be nonvoters are less likely to respond to a survey on politics in the first place.

2.3 Political Consequences

To gauge the political consequences of CV, most scholars start by noting the near universal connection between political participation and socioeconomic status. Noting that 'low voter turnout means unequal and socioeconomically biased turnout' (Lijphart 1997, p. 2), many scholars see CV as going a long way to removing this 'bias.' Comparative studies of turnout note that the relationship between socioeconomic status and voter turnout weakens as turnout increases (e.g., Powell 1986). Thus to the extent that CV generates higher voter turnout (and the research summarized in the previous sections suggests strongly that it does), CV also removes socioeconomic differences in electoral participation. Quite simply, when almost everyone votes, there can be no socioeconomic 'biases' in turnout.

It also follows that the high turnout rates engendered by CV also have partisan and ideological implications. Since support for parties of the left is correlated with socioeconomic status (notwithstanding a lengthy debate about a decline in 'class voting'), as socioeconomic based differentials in turnout diminish, support for parties of the left increases (Pacek and Radcliff 1995, Nagel 1988, McAllister and Mughan 1986). In turn, increased support for parties of the left results in higher welfare spending and more state interventions in the macroeconomy and labor markets (Hicks and Swank 1992, Castles and McKinlay 1979). Again, to the extent that CV increases turnout, and turnout increases support for left parties and their policy agendas, then CV can be shown to have policy implications. Put simply, CV helps mobilize voters who would otherwise abstain, generating a distribution of voters' policy preferences further to the left than would otherwise result, and so party competition takes place over an interval of the ideological spectrum shifted to the left from where it would otherwise be. CV is thus causally quite remote from outcomes such as left-party success or particular policy outcomes. Indeed, this causal link could even be reversed: i.e., it is only in countries with commitments to social democratic outcomes that CV is adopted, and

in fact, this accords with the pattern of adoption of CV among Western democracies in the early twentieth century.

2.4 Other Consequences

One criticism of CV is that it compels the participation of disinterested and hence poorly informed citizens who would otherwise abstain. Lijphart's (1997, p. 10) response to this is criticism is that CV 'may serve as an incentive to become better informed'; a cross-national study by Gordon and Segura (1997) finds a small though statistically significant increase in political sophistication in countries with CV, but otherwise the evidence for CV promoting greater civic awareness is scant. Another untested argument along these lines is that CV leads to 'higher quality' political campaigns, since the parties are less concerned with mobilizing voters and more with the conversion of voters that CV guarantees will go to the polls. Lijphart (1997, p. 10) speculates that this diminishes (a) the role of money in political campaigns, and (b) incentives for candidates to use attack advertising.

Students of Australian politics have speculated whether CV leads to higher levels of party identification than might otherwise result (Mackerras and McAllister 1999), consistent with a view of voters as 'cognitive misers,' looking for heuristics to help them deal with a forced choice among parties. On the other hand, Australia's minor parties are obvious beneficiaries and keen supporters of CV, providing an alternative for voters dissatisfied with major parties, but legally compelled to turn out. Another long-standing feature of CV is a higher rate of invalid ballots (e.g., Tingsten 1937) and 'donkey ballots' (where voters simply select the first name they see on the ballot); some instances of these phenomena are protests against CV itself.

Two final points. First, CV places an onus on citizens, but the state typically reciprocates with institutional mechanisms that make it easy to comply (e.g., weekend voting, ease of registration, widespread use of postal ballots): it would be rather odd if a state made voting compulsory but did not employ these other turnout-enhancing institutional mechanisms. According to Gosnell (1930, p. 209), 'fines and penalties under a system of compulsory voting are a minor matter. The important feature of the system is that voting is regarded as a civic duty and the government does everything to impress upon voters this point of view.' Second, the more seriously a country enforces its CV provisions, the more bureaucratic resources are required to maintain registration records and ensure compliance. In Australia, these two functions—the 'carrot and stick' of CV, as it were—are administered by the Australian Electoral Commission, a large and highly professional bureaucracy responsible for all aspects of Australian federal elections. Ensuring compliance with CV is just one of many AEC functions, and the bulk of its activities are to do with other aspects of election administration (e.g., redistricting, voter registration, public financing of campaigns, ballot design, staffing polling stations, vote tallying). Thus one (perhaps unintended) consequence of an aggressive system of CV is the centralization and professionalization of election administration. In turn, this may mitigate the problems that accompany decentralized and non-professional election administration, clearly evident in the aftermath of the 2000 US presidential election.

Voting: Issue

Who should pay what in taxes? Should immigration be strictly controlled? How effectively is the economy being managed? Should women have a guaranteed right to an abortion during the first trimester of pregnancy? Each of these is commonly understood as a political issue. A political issue is defined as a policy-based controversy relevant to the mass public's evaluation of either political parties or candidates for public office. The link between citizens and their elected leaders that arises from political issues lies at the very heart of democratic governance. This article explores that link.

1. *Position and Valence Issues*

Issues can be usefully divided into two basic types: position and valence (Stokes 1963). Position issues are those on which there is meaningful disagreement among members of the mass public with regard to alternative policies. Questions of taxes, immigration, abortion, health insurance, and environmental policy are among those that usually fall within the position issue rubric, with different people having quite different preferences about government policy. Valence issues are those on which there is general agreement, usually about a goal, and the main controversy concerns which party or candidate is more likely to achieve the desired result. Virtually everyone wants a well-managed economy and safe streets; the question is who is more likely to deliver the outcome.

Assessments of parties and candidates on valence issues tend to be retrospective, that is, based on past performance (Fiorina 1981). Because such assessments are highly sensitive to the state of the times, they often have a 'tidal' character, increasing or decreasing support for a party across virtually all groups in a country. A good economy tends to help incumbents, while a bad economy or large-scale social unrest hurts. Thus, valence issues can be very important in determining election outcomes. Retrospective assessments of performance are also relatively easy to make as they require little knowledge beyond who is in office and how things are going in the country. Thus, while retrospective assessments are widely used by all types of voters in evaluating governments, the least engaged voters tend to rely most heavily on short-term retrospective judgments to guide their choice (Sniderman et al. 1991).

Position issues intrinsically require more information from the electorate. At a minimum, people need to have some preference on an issue and some sense of where the parties or candidates stand on the issue, in order for issues to affect their political judgment. While there are some very knowledgeable voters, the knowledge level of the average citizen is fairly low (Delli Carpini and Keeter 1996). This does not rule out a role for position issues in elections, but it does suggest that the role issues play will not rely on a highly informed electorate (Campbell et al. 1960).

2. *Political Parties and Social Groups*

Political parties and social groups help voters make sense of political issues. For the most part, parties form around core social and ideological cleavages in society (Lipset and Rokkan 1967). They endure across elections and tend to maintain fairly consistent orientations towards issues. Given the low attention most people pay to politics, the long-standing consistency of parties on most issues provides a critical link for allowing voters to make policy-oriented vote choices. Parties also enhance the accurate use of valence-type performance issues, as they provide the over time continuity necessary for voters to reward good performance and to punish bad performance.

Social groups can also assist citizens in casting meaningful policy votes. Labor, business, religious, linguistic, and racial/ethnic groups traditionally have

been important sources of cues for voters. Feelings toward a group and awareness of the group's position on an issue can serve to alert the voter to the issue, and can help determine the voter's own position.

3. Low-information Rationality

The low-information level of voters does not imply an unthinking or irrational electorate. In general, voters attempt to make reasonable decisions based on the information they possess (Key 1966, Popkin 1991, Lupia and McCubbins 1998). This idea is encapsulated in the phrase 'low-information rationality,' which suggests that the main element limiting the quality of the electorate's judgments is the limited amount of information voters possess. Since information is costly to acquire and no single vote is likely to be influential, the strategy of making good use of limited information is a rational strategy for voters to adopt (Downs 1957).

This in turn implies that certain types of issues will be used more readily by voters. Issues that have a straightforward moral structure (such as abortion) or those that fit into a clear symbolic framework (such as the common man vs. the wealthy) are cognitively simpler and easier to process. Hence, voters are more likely to use them in making decisions (Converse 1964).

It is also important to realize that voters themselves differ widely. More knowledgeable voters and those concerned about a particular issue are more able to process issue information (Converse 1964, Krosnick 1991, Zaller 1992). Nevertheless, the predominant characterization of the electorate is one with low information and relatively little attention to politics. And even with increasing levels of education, there has been no discernable increase in levels of political knowledge (Delli Carpini and Keeter 1996).

4. The Directional and Proximity Models of Issue Voting

How do voters connect their issue preferences to party or candidate choice? Two models offer competing explanations for how position issues operate in electoral settings. The directional model argues that successful issue campaigns develop clear strong messages to attract voters to a party (Rabinowitz and Macdonald 1989, Macdonald et al. 1991). The proximity model argues that parties must support centrist policies to be electorally successful (Downs 1957, Davis et al. 1970).

4.1 The Directional Model

According to the directional model, voters operate in a simplified issue environment in which issues have just two sides. For example, a voter might be in favor of restricting immigration or opposed to restricting immigration, or she might not care. Voters differ in terms of which side of the issue they favor and the intensity with which they favor that side. When a party takes a position on the side of the issue a voter favors, it is evaluated favorably by the voter; when a party takes a position on the opposite side, the voter evaluates it unfavorably. Voters who are more intense about an issue react more strongly than less intense voters: they like parties or candidates on their side more and display more hostile feelings toward those they oppose. Similarly, when a party takes a more intense stand on an issue, it arouses more intense feelings. It garners more favorable evaluations from voters on the same side of the issue and more unfavorable evaluations from voters on the opposite side. In mathematical terms, the product of the voter's and the party's intensity determines how strongly a voter feels about a party, either favorably or unfavorably. This effect is mediated, however, if a party goes beyond an extremity threshold.

In directional theory, parties and candidates are constrained in their intensity by the need to avoid being viewed as irresponsible or extremist. In order to draw support based on an issue, parties and candidates must lay out relatively strong stands emphasizing the policy directions they favor; at the same time they must show sufficient moderation to suggest they will be responsibly pragmatic in office. In the directional model a hypothetical voter asks, 'Are you on my side of the issues?' and 'Can I trust you to be responsible?'

4.2 The Proximity Model

The proximity model contrasts with the directional model. According to the proximity model, voters consider an ordered set of policy options on an issue. With regard to the environment, for example, the options might be a series of increasingly tougher policies regulating factory emissions. The voter is assumed to have a preference for a particular policy among the set. This is different from the more diffuse, two-sided view ('favor or oppose new environmental regulations') that characterizes directional theory. Further, in proximity theory each party is assumed to have a distinct policy position on the issue that is known to the voter. Voters evaluate parties based on the distance between the party's position and their own position. In the proximity model a hypothetical voter asks, 'How close are your positions to mine?'

The proximity and directional models are most distinct with regard to center voters. According to proximity theory voters in the center are committed to centrist policies and support parties that take centrist stands. According to directional theory voters in the center are simply neutral between the two sides and don't care which position the parties take.

4.3 Issue Strategies

4.3.1 Two-party systems. In both directional and proximity theory, the voters most critical to determining strategy in two-party contests are those in the middle of the voter distribution. In the simplest case where a single dimension characterizes the competition the critical voter is the median voter. The median is literally the voter in the middle. If, for example, there are nine voters and they are arrayed from furthest left to furthest right, the fifth voter is the median. Note that the voter in the middle of the distribution is not necessarily in the center on the issue—that depends on where the voters are located.

In an unidimensional competition, winning the median voter will guarantee victory. In the more realistic multidimensional case a single critical middle voter is unlikely to exist. Nevertheless, the principle that the voters in the middle will decide the election continues to hold, as they are the key to capturing a majority of votes.

The need to court the same constituency, however, does not imply that the two theories dictate similar strategies. In directional theory, parties must be attentive to the balance of voters on the two sides of an issue. If a clear plurality favors one side, then the middle voters will be on that side and it is advantageous for the parties to be there too. If both parties are on the plurality side, then the party that takes the stronger stand without becoming irresponsible will attract the most voters. Just as a strong magnet is more effective than a weak magnet in drawing objects to it, so a party with strong cues is more effective in garnering the support of like-minded voters.

When the electorate is divided evenly on an issue, then parties are not constrained in which side they take, because support for the two sides will tend to balance out. In directional theory it can make strategic sense for parties to diverge on evenly divided issues: there is no net gain or loss in supporting one side or the other, and by taking a distinct stand a party can develop enthusiasm from a set of potential voters.

In proximity theory parties should always adopt a position close to the middle set of voters. This follows from the fact that proximity is the key to support. If Party A is close to the middle voters and Party B is not, then the middle voters will support Party A, as will all the voters who lie on the opposite side of Party A from B, giving a majority to Party A. Thus, according to the proximity model, any party seeking to maximize votes must stay close to the middle of the voter distribution. A party that deviates from the middle on any issue is open to defeat.

4.3.2 Multiparty systems. In multiparty systems proximity theory makes no clear predictions about party strategy. Directional theory suggests that the most successful parties will take relatively strong clear stands on some issues, while avoiding an extremist label. Extremist parties can be successful in multiparty systems in that they can attract enough voters to win seats in proportional elections; however, their appeal will be limited because of their extremism.

Centrist parties are expected to be weak in directional theory, because they fail to develop strongly favorable evaluations from any voters. Some parties that are centrist on left-right are well defined on other issues, such as agricultural policy, and these parties can be successful. Parties with no strong issue stands, however, will find that while few voters dislike them, they are not the first choice of many voters.

4.3.3 Issue salience and issue ownership. Some issues are more important in elections than others. Sometimes this happens by accident and sometimes by design. In any event, if a party has an advantage on an issue compared to its competitors, then it helps the party for that issue to be more salient in the election. This is true in both two-party and multiparty systems, and under both the directional and proximity models.

Related to the idea of issue salience is the idea of issue ownership (Budge and Farlie 1983, Petrocik 1996). This concept conveys the view that parties develop reputations for being especially credible on certain issues, and thereby come to 'own' them, for example, the Labour Party in Britain on social welfare issues and the Christian People's Party in Norway on questions of public morality. Whenever the issue a party owns becomes the focus of a campaign, the party benefits. The concept of issue ownership fits well with a directional view of issue voting as parties tend to take strong stands on 'their' issues. The manipulation of issue salience, however, is important to both directional and proximity theory, and is a key element in virtually all political campaigns.

4.4 Which Theory is Correct?

The empirical evidence in most advanced industrial societies generally has supported the directional over the proximity model. Directional theory has been more able to predict how voters evaluate parties and candidates, and has more accurately predicted the type of parties (noncentrist and nonextreme) that have succeeded in most advanced industrial democracies. As yet, however, there is no consensus in the research literature on which of the two theories better represents the relationship between issues and mass support (Lewis and King 2000). In some formulations the theories are difficult to disentangle, in particular in predicting vote choice, and recent work in proximity theory has incorporated features that provide more

overlap with directional theory (Hinich and Munger 1994). Some scholars have found elements of each theory attractive, and have blended the models in an effort to provide a fuller understanding of electoral politics (Rabinowitz and Macdonald 1989, Merrill and Grofman 1999).

5. *Conclusion*

In democracies voters are presumed to influence public policy through elections. Underlying this view is the assumption that voters' issue preferences influence their vote choice. Research has shown, however, that the majority of voters, even in highly educated advanced industrial democracies, do not follow politics closely and do not have high levels of political information. The impact of issues, therefore, requires voters to use their limited information effectively. They are aided in this process by the presence of political parties that provide coherence to political systems. Further, meaningful policy-based votes appear to require considerable stimulation by political elites (either parties or candidates) to activate issues.

Two competing models, the directional model and the proximity model, have been proposed to describe the way in which voter preferences and party positions interact to determine voter choice. The alternative theories have quite different implications for effective party strategies and the nature of mass control of public policy. The question of which theory, or combination of theories, most accurately describes the role of issues in electoral systems is a matter of current controversy.

Voting: Retrospective/Prospective

In the 1950s, leading democratic theorists, under the aegis of the American Political Science Association, extolled their model of a 'responsible party system,' wherein parties vying for office would propose to the voters the policies they intended to carry out if elected. Informed by coherent ideological principles, their policy programs would be specified clearly, and significantly different from each other. The winner of the election would consequently be that party or candidate whose policy proposals the majority of voters found most attractive.

Research carried out in the ensuing decades demonstrated the unrealistic nature of this ideal. Politicians blur, equivocate, and traffic in vague generalities. When they do proffer comprehensible proposals, the centrifugal pull of the median voter induces them to

offer much the same thing (Black 1958). Voters, in turn, typically lack the information, stable preferences, and cognitive sophistication that 'issue voting,' i.e., choosing on the basis of competing policy proposals, would require (Converse 1964).

While many observers fretted that these findings bode ill for the practice of democracy, others reasoned that it was this particular model of electoral competition, and not the voters and politicians, that was deficient. They argued that, rather than consider the merits of nebulous, hypothetical policy alternatives, voters decide to either retain or reject incumbent politicians on the basis of the objective conditions that obtained during their tenure in office (Downs 1957, Key 1966, Fiorina 1981). This theory of *retrospective voting* has three major features. First, voters need to acquire little information over and above that which they assimilate in their daily lives. Second, it is the results of policies that voters evaluate, not the policies themselves. Third, elections are primarily referenda on the performance of incumbent officeholders, and so provide little guidance as to the future course of public policy. As Key (1966) put it, '(the electorate) judges retrospectively; it commands prospectively only insofar as it expresses either approval or disapproval of that which happened before.'

There is any number of indicators of well-being to which voters might respond—the crime rate, environmental quality, combat deaths, etc. Research on retrospective voting, however, has focused primarily upon economic conditions. Virtually all of it can be placed in one of two categories: Time-series analyses of aggregate economic and voting data, and analyses of responses to opinion surveys, in either cross-sectional or panel form.

1. *Time-series Analyses*

In one of the most influential studies in the history of political science, Kramer (1971) demonstrated that the better the recent performance of the American economy, the larger the share of votes won by congressional candidates of the incumbent president's party. Subsequent time-series studies of aggregate economic and voting data found that the electoral fortunes of the president himself depend importantly upon economic fluctuations (Fair 1978), as do the fates of candidates of his party running in senatorial and gubernatorial elections.

Most subsequent research followed Kramer's lead in several important ways. Incumbency is defined by the party of the president, not by whether those running for lesser office are themselves officeholders. The analyses assume voters have short time horizons—support for the incumbent party is a function of economic performance in the year or so running up to the election. Finally, the economic variable they key upon is usually per capita income change, the variable Kramer found to have the largest impact upon election outcomes.

These studies have produced overwhelming evidence as to the existence of economic retrospective voting. But it is not a uniform, ubiquitous phenomenon. In the USA, favorable economic conditions clearly benefit the incumbent president, and in on-year elections, congressional candidates of the president's party also benefit . The economy has a smaller impact upon midterm elections, however, as many voters appear to be seeking to counterbalance the ideological orientation of the incumbent president (Alesina et al. 1993, Erikson 1990). Economic retrospective voting is also stronger and more consistent in some countries than in others (Paldam 1991). According to Powell and Whitten (1993), the strength of economic retrospective voting is a function of 'clarity of responsibility' in the institutions of government. Where it is lacking, voters have difficulty in deciding whom to reward and whom to punish, thus undermining their ability to vote on the basis of economic performance. Clarity of responsibility is obscured by multiple parties in the governing coalition, minority governments, weakly cohesive parties, opposition party control of a policy-making institution (either a separately elected presidency or house of the legislature), and opposition party chairs of parliamentary committees. These features arise most frequently in proportional representation regimes.

Despite the vast amount of research that has been done on aggregate voting and economic data, there are weaknesses in this approach that make the findings less robust, less definitive, and less cumulative than one would suppose. First, although the economic measures used in these studies are perceived to be quite precise, the more historical data—particularly for years prior to World War II—are not. Kiewiet and Udell (1998) report that the electoral impact of unemployment more than doubles when a more accurate, revised series is used in place of the official Bureau of Labor Statistics series.

Second, the data series are very short, and many studies have examined even smaller subsets of the available observations (e.g., postwar mid-term elections). Researchers also omit 'unusual' election years, and make idiosyncratic choices as to the beginning and ending years of their series. Even small changes in the data series can affect results dramatically. For these same reasons, aggregate-level economic retrospective voting models, though touted as forecasting tools, are not. In such models, error bars are usually around plus or minus 5 percent, and due to sample selection effects this is surely an under-estimate. While an improvement over guesses based upon historical averages, forecasts containing that much error are neither impressive nor useful.

A reasonable response to this problem is to analyze pooled, cross-section time series of disaggregated data. Few studies have adopted this approach, but those

that have underscore the value of more data even when observations are not independent. Rosenstone's (1982) analysis of state-level data finds the electoral effects of income change to be close to the average of the effects reported in various studies using aggregate time series data, but his estimates are far more precise. Peltzman's (1990) also analyzes state-level data, but his findings are at odds with the bulk of the aggregate-level findings. Specifically, he concludes that voters base their decisions on what transpires economically during the entirety of the incumbent president's entire administration, and not just the last year or so.

Peltzman's study points to another potential deficiency in the time-series literature. Most studies posit simple retrospective voting rules on the part of the electorate, the null hypothesis being that recent trends in economic conditions have no impact upon voting decisions. A few studies have found support for alternative hypotheses that imply greater 'rationality,' either in terms of expectations formation, as in the Peltzman study, or that voters punish incumbents for deviating from a prescriptive fiscal and monetary policies (Chappell and Keech 1985). However, in an explicit comparison of the 'naïve' retrospective model vs. a 'rational' model positing that voters differentiate between systematic growth and exogenous income shocks, Alesina et al. (1993) conclude that it is the naïve model that best comports with the data.

2. *Opinion Survey Analyses*

Survey researchers have sought to account for the time-series evidence of economic retrospective voting by identifying the precise ways in which individual voters' economic evaluations influence their voting decisions. The hypothesis receiving the most initial attention was that voters 'voted their pocketbooks,' reacting primarily to trends in their own personal economic circumstances. This seemed to be a natural extension of the simple retrospective voting hypothesis that has dominated the aggregate-level time series analyses, as it posits (a) low information requirements—voters base their decisions to support or oppose incumbents on the basis of information acquired in the course of their daily lives, (b) what matters to voters are objective conditions, not campaign promises, and (c) voters are most reactive to what they have experienced recently.

What researchers found, however, was that whether or not voters were personally doing well or poorly economically had a surprisingly weak impact upon their reported voting decisions. The choice to retain or to reject the present incumbents was instead conditioned much more strongly upon their assessments of recent trends in the nation's economy (Kinder and Kiewiet 1979). Although many scholars understood these findings as showing that voters vote according to what they perceive to be the interests of the country as a whole rather than on the basis of narrow self-interest, this inference is unfounded. Voters may be motivated purely by concern for their own individual welfare, but realize that the performance of the economy overall is a superior indicator of the efficacy of the incumbent's policies. Peltzman (1990) puts it this way:

> To a crude approximation, the president's policy affects mainly aggregate income rather than its personal distribution. If voters understood this, they would respond mainly to aggregate income surprises and ignore personal deviations from the aggregate. Voters care about these personal deviations, but they are mainly irrelevant in evaluating the *policy* of their agent.

Many studies of survey data surmised that the relationships they observed between economic concerns and voting decisions were too weak to account for the aggregate-level, time-series findings. Seldom, however, did they make the calculations necessary to determine if this were actually the case. The few studies that do detect no gross inconsistencies. Indeed, after correcting for measurement error in the survey data, Markus (1988) identifies individual-level effects that would produce interelection vote swings even larger than those observed by Kramer (1971) and Fair (1978).

There are other important ways in which survey analyses of economic retrospective voting have paralleled the aggregate-level time series literature. In a study of five major Western European democracies, Lewis-Beck (1988) finds that the strength of economic retrospective voting was inversely related to the number of parties in the governing coalition. Like Powell and Whitten (1993), he reasoned that multiparty regimes obscure responsibility, making it difficult for voters to determine to whom to attribute credit or blame. Second, other survey researchers have looked beyond simple retrospective voting for evidence of other ways in which economic concerns might affect voting decisions. The most prominent of these alternatives is the prospective voting hypothesis, i.e., that voters base their decision upon how they expect the economy to perform in the near future (MacKuen et al. (1992)). But here, too, direct comparisons tend to favor the retrospective hypothesis. Specifically, Anderson and Wlezian (1997) report that much of the correlation between economic expectations and vote choice arises from respondents' attitudes concerning the incumbent president coloring their expectations about the future. Retrospective evaluations, in contrast, appear to be more resistant to cognitive consistency pressures. Many supporters of Jimmy Carter may have been confident that the economy would turn around in 1981, but few could convince themselves that 1980 had been a good year.

Finally, survey research on economic retrospective voting, as in the case of time-series analyses, has been hampered by deficiencies in the data. Here, however, the problem is the small number of survey questions

available for analysis rather than a small number of observations. The only individual-level data concerning economic evaluations and vote choice that have been gathered on an ongoing, systematic basis or those contained in the National Election Studies, which began in the early 1950s. The questions they ask are reasonably good, as survey questions go, and we are indeed extremely fortunate to have them. Nonetheless, we are left with the nagging doubt that differently posed questions might reveal more accurately the extent of economic retrospective voting.

Voting, Sociology of

Because democracies choose their governments via the ballot box, the bulk of the literature on voting behavior deals with its decisional component, focusing on who votes and for whom. This article presents a comparative assessment of research on electoral choice and electoral turnout, along with the main theories and empirical findings in the field.

1. Paradigms Explaining Voting Choice

Electoral geography was the first, and for a long time the only, clue for understanding political behavior, linking voters' choices to the social structures and the religious and political traditions of the place where they lived. Since the earliest studies of André Siegfried, Charles Gosnell, or Herbert Tingsten, this 'contextual' or 'ecological' approach, based on the analysis of aggregate electoral data, has gained in statistical sophistication, as illustrated by the school of Johnston in Britain or King in the United States. Its limitation lies in the fact that the unit of analysis considered is the group—people living in the same constituency, the same district, the same region, etc.—and that the correlations observed at the aggregate level do not necessarily hold true at the level of the individuals, as Robinson's (1950) famous article on the 'ecological fallacy' reminds us. Opinion polls provide a better tool for understanding individuals' behavior, asking them directly how and why they vote. Since World War II, survey-based research has given a new impetus to electoral sociology, especially in the United States, where the pioneer studies and the classic models explaining vote choice were developed.

The 'sociological' model originates from the local surveys conducted by Paul Lazarsfeld and his colleagues at the Bureau for Applied Social Research of the University of Columbia. Repeated interviews with a randomly selected panel of voters, first in the district of Erie County, Ohio during the 1940 Roosevelt–Wilkie presidential campaign, then in the town of

Elmira, New York, at the time of the Truman–Dewey contest reveal, to their surprise, that the campaign has but a limited effect on voters' choice. Mostly it reinforces long-standing and diffuse political preferences which reflect the norms of the groups they belong to. Constructing an index of political predisposition based on social class, religion, and rural/urban residence, the authors of *The People's Choice* can predict accurately how people vote. Those combining a rural residence, Protestant affiliation, and high social status tend to support the Republicans, while those who are working class, nonprotestant, and residing in an urban area mostly vote Democrat. The main conclusion of their book is that 'A person thinks, politically, as he is, socially. Social characteristics determine political preference' (Lazarsfeld et al. 1944). And this social anchoring accounts for the relative stability of voting choice, except among the cross-pressured or poorly integrated voters. However, in his later empirical and theoretical work such as *Voting* (Berelson et al. 1954), Lazarsfeld was to develop a more complex view of action in general and more particularly of voting behavior (his research evolution is related in Lautman and Lécuyer, 1998).

Reacting against what they see as a social determinism, Angus Campbell and his colleagues from the Survey Research Center (SRC) at the University of Michigan propose a psychological model focusing on individual decision-making. Reconstructing the chain of events that converge in what they call the 'funnel of causality,' they give special attention to the attitudes formed towards candidates, issues, and parties. On the basis of nationwide panel surveys conducted in the presidential elections from 1948 to 1956, they state in *The American Voter* (Campbell et al. 1960) that party identification is the key factor orienting vote choice. By that they mean an affective attachment to a specific party, formed early in life, generally passed over from parents to children, and reflecting the individual's social and religious background. It functions as a filter coloring their political perceptions and guiding their votes, especially for the least sophisticated: 'Like the automobile buyer who knows nothing of cars except he prefers a given make, the voter who knows simply that he is a Republican or Democrat responds directly to his stable allegiance without the mediating influence of perceptions he has formed on the objects he must choose between' (Campbell et al. 1960). Lazarsfeld portrayed voters as social conformists; the Michigan team sees them more as political believers. Yet their conclusions are very similar: the average voters are far from the democratic ideal of a rational and active citizen. Most of them are not interested in politics, display low levels of ideological awareness, and are unfamiliar with the candidates and the issues at stake. They vote according to long-standing political preferences shaped by their early socialization.

The third approach stems from Downs's seminal essay, *An Economic Theory of Democracy* (1957). It postulates, in the line of the neo-classic economic paradigm, that voters are rational and that their choice is based on a cost-benefit calculation. Voters cast their votes for the party or the candidate from which they expect the maximum 'utility' or benefits. The electoral decision between party A in office and opposition party B boils down to a simple equation, the difference between the benefits expected from the victory of party A (Ua) and the benefits expected from party B (Ub). Voters will favor party A if they see the difference between Ua and Ub as positive, party B if the difference is negative, and not bother to vote if they see no difference. Since Downs's pioneering work, elaborate econometric models have developed. Some correlate aggregate electoral results with global economic indicators such as purchasing power, inflation rates, and unemployment rates. Others use survey data to analyze individual pocket-book voting, based on the evaluation of candidates past (retrospective voting) or future performances (prospective voting). What they have in common is to shift attention from the people's demand to the supply side of politics, the specific goods offered on the electoral marketplace by competing parties and candidates.

2. *Alignment, Dealignment, or Realignment?*

These three models have been guiding electoral research agendas. In the wake of the sociological model attention was first given to the effects of social class and religion, even more so in Europe where party systems were historically built on the basis of social and religious conflicts and cleavages (see Lipset and Rokkan 1967). Rose's (1974) classic study of voting patterns in 15 democracies shows that class in Scandinavian countries and religion in the others are by far the most predictive factors explaining postwar electoral behavior, a working class position predisposing to a left-wing vote and regular church attendance to a right-wing vote. Then, in the 1960s, the Michigan paradigm became the leading model, inspiring nationwide research surveys in Europe, especially in Britain where Butler and Stokes (1969) explained long-term alignments of British voters by their party identification, itself rooted in their social background. What became known as the 'two class, two party' model does not fit as well in countries such as France with multiparty systems. There, Left/Right orientations are the substitute for party identification, equally rooted in religion and social class (Michelat and Simon 1977).

Neither model though can account for the increasing electoral change that appeared in the United States by the end of the 1960s, and in Europe at the end of the 1970's. On the basis of the SRC presidential surveys between 1956 and 1974, the authors of *The Changing American Voter* (Nie et al. 1976) revealed a decline of party ties. The proportion of 'independent' voters,

who define themselves as neither Republican nor Democrat, has risen from 23% in 1964 to 40% in 1974. Among those who still identify themselves with one side or the other the proportion who declare a 'strong' attachment or have a positive image of a party is declining, and the very link between party preference and voting is weakening. Voters seem more interested in politics, more aware of the issues at stake and more inclined to choose their candidates according to their political stands, whatever party they belong to.

Parallel studies in Europe detect similar trends of electoral volatility or instability of voting choice and partisan dealignment or gradual moving away from all parties (Crewe and Denver 1985), seen as a structural feature of the emerging postindustrial society. Social and geographical mobility is blurring the traditional class cleavages and loosening community ties. Progress in education and exposure to the media have increased the average levels of political sophistication. The rise of the permissive and individualistic set of values coined as postmaterialist by sociologist Inglehart (*The Silent Revolution*, 1977) encourage a new style of politics, more demanding and protest-prone, and promotes new post materialist issues—environmental, feminist—that cut through traditional party lines. All these trends converge to make citizens less dependent upon existing parties to make their choice. Voters are seen as 'autonomous,' 'strategic,' 'rational,' or 'reasoning' and the developing cognitive sciences are increasing studies on political reasoning mechanisms, the way voters process and organize information, the cues they rely on to make a decision, etc. (Sniderman et al. 1991). Short-term issue or candidate centered voting could well be taking the place of the former stable 'cleavage voting' with a partisan, religious, or social base (Franklin et al. 1992).

But a second research trend is taking an opposite stand, questioning the extent of this dealignment process by casting doubts on the way it is measured. The most heated controversies have developed around the supposed decline of class voting. Until now the simplest and most widely used indicator has been Alford's index, which measures the difference between the proportion of manual and nonmanual voters voting for the Left. For instance, if all the British working-class voters supported the Labour party and none among the middle classes in a given election, the value of the Alford index would be 100%, indicating perfect class voting. Measured by this index, the downward trend is undeniable. Class voting across post-World War II elections has decreased, for instance, by almost half in Britain, and more than two-thirds in Germany. But critics underline several weaknesses of such an index. Its dichotomous nature does not take into account the complexity of post-industrial occupational structure nor the complexity of party systems. It is statistically biased because it does not consider the changes in the marginal distributions of the two classes and of the two votes from one election to another. And it only measures dealignment, while various processes of electoral realignment along new cleavages such as private sector vs. public sector, self-employed vs. wage-earners, or educated vs. non- educated voters, seem to be taking place in postindustrial democracies, as shown by multiclass approaches using detailed occupational classifications and sophisticated measures such as odds-ratios or log-linear models. In Britain for instance, in the long run, Heath et al. (1991), contrary to previous findings, find no decline of class voting, just 'fluctuations without trend.' In France since the 1980s, the salaried middle classes have tended to support the Left, compensating for the drop of working-class support, attracted by the extreme right embodied by the National Front (Boy and Mayer 1997). In the United States, Hout, Brooks, and Manza dispute Clark, Lipset, and Rempel's claims about the declining political significance of social class, by showing the historical realignment in presidential post-War elections since 1968, as professionals and nonmanagerial white- collar workers moved from supporting the Republicans to voting for the Democrats (special issue of *International Sociology*, **8**(3), 1993, on class voting). Lastly, the new institutionalism approach attempts to reintegrate voters' choices in their political context, analyzing their response to changes in the electoral rules of the game, in the party structure, and in the strategies of political actors, especially concerning their uses of the media.

3. *The Puzzle of Electoral Participation*

An analysis of voting choice would not be complete without taking into account the alternative behavior: not voting. Whatever the election, a sizable proportion of eligible citizens are not registered or choose not to go to the polls. The proportion ranges between less than 5% in countries where voting is compulsory to 40% or more in Switzerland or in the United States. Whatever the country, the profile of these nonvoters, revealed by aggregate as well as survey data, is quite similar. Educated voters and members of the upper and middle classes participate more than the uneducated and the working classes, and middle-aged voters go more willingly to the polls than the very young or the very old. What has become known as the 'socioeconomic status (SES) model' (Verba and Nie 1972) postulates that well-integrated and upper-status individuals are more likely to participate because they have more resources to invest in politics—time, money, information, networks—and because they are more likely to develop the 'civic' attitudes (see Almond and Verba, *The Civic Culture: Political Attitudes and Democracy in Five Nations*, Princeton University Press, Princeton, 1963) that predispose to do so, such as interest in politics, a sense of duty, and a feeling of political efficacy. Political participation is

socially skewed. There are compensating factors, however, such as group consciousness or ethnic awareness. With the development of feminism, the difference between female and male turnout rates has disappeared, and 'black-political empowerment' in the United States since the Voting Right Acts has reduced the difference between whites and African–Americans, the latter participating even more than whites when differences in SES are taken into account (Verba and Nie 1972). On the whole, the increasing educational level of the electorate and the growth of the middle classes should gradually raise electoral participation in postindustrial societies. But paradoxically the opposite is happening. There has been a clear drop in turnout rates among American voters, from 63% of the eligible voters in the 1960 Kennedy–Nixon election to 50% in the 1988 Bush–Dukakis contest. A similar decline is developing in European democracies but the trend is recent, milder, and educational differences are far less marked (Topf 1995).

This 'participation puzzle' has revived interest in rational choice models. Because one vote has but an infinitesimal influence on the electoral outcome, the rational behavior, at first sight, would be not to bother going to the polls, and since Downs, a large body of literature has been devoted to what appeared as the 'voting paradox.' It can only be understood if one extends the notion of rationality and if one admits that voting, like most human actions, is not only guided by interest ('instrumental' rationality) but by principles, and values ('axiological' rationality) (Boudon 1997, Friedman 1996). At the beginning of the twenty-first century, along the same line, several studies try to understand the paradox of nonvoting. Some focus on the costs and benefits of voting turnout and particularly institutional factors such as registration formalities, compulsory voting, electoral rules, party competition, and all the political factors that facilitate or make meaningless the act of voting (Powell 1980). Others see nonvoting as a deliberate strategic behavior, expressing political discontent with the electoral choices available (Subileau and Toinet 1993). Studies of electoral turnout detecting nonvoters on official voting records, such as the series conducted in France by the National Institute for Statistics and Economics Studies (INSEE), are more reliable than survey data because voters are reluctant to confess what is considered as an uncivic behavior. Yet they confirm the tight imbrication of the social and political factors leading to nonvoting.

The rising number of emerging or transitional democracies and the multiplication of cross-national data bases such as the Eurobarometers, the Central and Eastern Eurobarometers, the Latino Barometer and the Russia Barometer, provide fresh opportunities to test in different political cultures the validity of the theories and concepts elaborated in Western democracies. They could also be an occasion to explore what most studies leave aside, the noninstrumental meanings the act of voting can take. Although the political outcome of elections is essential, they also have ritual, expressive, and social functions, detailed by Edelman in his classic essay about *The Symbolic Uses of Politics* (University of Illinois Press, Urbana, 1964).

Voting: Tactical

1. Tactical Voting to Affect the Allocation of Seats

The best-known example of tactical voting to affect the allocation of seats occurs in single-member districts operating under plurality rule (the plurality rule requires that the candidate with the most votes wins the seat). Imagine a race in which a right-wing candidate, R, faces a centrist C and a leftist L. One of R's supporters, upon seeing a poll that places C and L in a close fight for first, with R a distant third, may decide that voting for the second most-preferred candidate, C, is more likely to do some good (electing C rather than L) than is voting for R (which would more likely waste the vote, as far as affecting the outcome is concerned). In single-member districts, then, tactical voting tends to diminish the number of votes cast for candidates placed third or lower in the polls, concentrating them on the top two candidates.

The tendency for voters in single-member districts to avoid wasting their votes on hopeless candidates was noted as long ago as 1869 by the English electoral reformer Henry Droop. But it was Maurice Duverger, writing in the 1950s, who most clearly articulated the systemic consequences of tactical voting. In Duverger's view, tactical voting arose prominently in single-member plurality elections but hardly at all in proportional representation (PR) systems. He, thus, articulated two main propositions: one, known as Duverger's Law, asserts that single-member plurality systems promote bipartism; the other, known as Duverger's Hypothesis, asserts that multimember PR systems promote multipartism. (A third proposition dealt with runoff systems.)

Theoretical work on tactical voting since Duverger has focused on five main topics: (a) tactical voting in electoral systems other than single-member plurality; (b) the logical foundations of Duverger's Law; (c) the transition from local to global bipartism in Duverger's Law; (d) tactical voting that deconcentrates, rather than concentrates, the vote; and (e) the role of elites in fomenting tactical voting.

1.1 Tactical Voting Beyond Single-member Plurality

Reacting to Duverger's apparent belief that tactical voting was unknown under PR systems, Leys (1959) and Sartori (1968) argued that tactical voting under PR was no different in kind from that found under plurality, differing only in the degree to which it came into play—and, hence, in the degree to which it tended to reduce the number of viable parties. Sartori's notion of a continuum of systems, from strong (in which tactical voting acts forcefully to depress the number of parties) to feeble (in which tactical voting is largely absent and thus puts little downward pressure on the number of parties), is now standard in the literature.

Subsequent work has made the Leys–Sartori viewpoint more precise, both theoretically and empirically. Steven Reed, for example, has extended Duverger's Law to Japan's former electoral system (used from 1925 to 1993, with a brief postwar gap), which gave voters a single vote but used multimember districts. To illustrate Reed's extension, consider a district with three seats. Candidates expected to place fifth or lower in such districts were sometimes seen as hopeless and were thus deserted by their supporters, essentially reducing the competition to a four-candidate fight for three seats. Reed discovered similar tendencies for elections in four-seat districts to reduce to five-candidate contests, and for elections in five-seat districts to reduce to six-candidate contests. More generally, under a wide range of electoral systems, the rule is that tactical voting tends to reduce competition in an M-seat district to, at most, $M+1$ candidates or lists (Cox 1997).

Although political scientists' main reason for interest in tactical voting is its tendency to concentrate votes locally, hence to restrict party systems nationally, further research into four questions has clarified some limits of this line of reasoning. These questions are considered in the next four subsections.

1.2 Logical Foundations of Duverger's Law

First, under what conditions does tactical voting in single-member plurality systems really lead to local bipartism? Recently, various scholars (Cox 1997, Palfrey 1989, Myerson and Weber 1993) have answered this question by articulating conditions under which avoidance of wasted votes in single-member districts leads, not just to some erosion of support for third- and lower-placed candidates, but to a nearly complete erosion of such support, leaving only two candidates with non-trivial vote shares. Two key conditions identified in this work are that voters be

concerned exclusively with the outcome of the current election and that they have 'rational expectations,' meaning that their beliefs about the candidates' likely order of finish in the poll are correct. As empirical circumstances approximate these idealized conditions less closely, one expects less actual erosion of the votes of trailing candidates, and thus less pressure toward local bipartism.

1.3 Local and Global Bipartism

Second, under what conditions does tactical voting in single-member plurality systems lead to global bipartism? The answer is that, although tactical voting does lead under certain circumstances to local bipartism, it does not directly promote bipartism at the national level. Recent work (e.g., Cox 1997) has argued that how local party systems link to form national party systems depends on national-level factors, such as the nature of executive power (presidentialism vs. parliamentarism), rather than on district-specific factors such as tactical voting.

Because local and global bipartism are produced by different factors, they may or may not coincide. Sometimes they do, as in the USA: two parties in each district, two parties nationally. But it is also possible to have local bipartism coupled with national multipartism. This bifurcation between local and global party systems occurs when different parties are viable in different parts of a country, as in India.

1.4 Tactical Voting that Deconcentrates the Vote

Third, does tactical voting always act to concentrate the vote at the local level, hence to restrict the party system? The answer here is 'no.' In electoral systems using multimember districts, tactical voters will transfer excess votes from strong candidates, in addition to transferring wasted votes from weak candidates (Tsebelis 1986). This sort of tactical voting deconcentrates the vote, rather than concentrating it, and does not reduce the number of viable parties in the system. Furthermore, in electoral systems using multiple votes, voters may vote for hopeless candidates in order to avoid giving votes to viable candidates who might beat the candidate they really want to win. This sort of tactical wastage of votes again deconcentrates, rather than concentrating, the vote.

1.5 Elite Fomentation of Tactical Voting

Fourth, is it really voters who play the lead role in tactical voting? Technically, voters that care only about who wins the current election care about their vote only when it breaks a tie (or creates one), because it is only then that their vote affects the outcome. But ties between any trailing candidate and one of the front-runners are much less likely than is a tie between the top two. Thus, purely instrumental voters vote for whichever of the two front-runners they most prefer, as their votes are then most likely to do some good.

But if citizens think this way about voting, why would they vote at all? The chances of a single vote actually affecting the outcome are tiny, which suggests that the purely instrumental voter might just as well stay home and save a trip to the polls.

Scholars who argue along these lines have suggested that the key actors in generating tactical voting are parties and candidates—who have more at stake in an election and can take actions that potentially swing many votes, hence have a reasonable chance of affecting the outcome. To date, however, there is no published elaboration of how such elite-led tactical voting would differ from the grass roots tactical voting envisioned in most of the literature.

2. Tactical Voting to Affect Government Formation

The second broad category of tactical voting is that by which voters seek to secure a better allocation of ministerial portfolios. Portfolio-maximizing tactical voting has three different subcategories.

One subcategory is strategic sequencing—or voting to affect which party gets the first opportunity to form a government. This sort of tactical voting may have been important in Israeli elections prior to the reform of the rules for electing the prime minister.

A second subcategory is strategic balancing—or voting so as to prevent any single party or coalition from securing control of all bodies in a system of separated powers. This sort of tactical voting is argued to play a role in German and US elections. In the US case, the argument is that some voters vote for one party's presidential candidate but the other party's congressional candidate, intentionally seeking to deny either party control of both policy-making branches of government (Alesina and Rosenthal 1995). In the German case, a similar argument has been made to explain the opposition's consistent success in midterm state elections, which determine control of the upper house at the federal level (Lohmann et al. 1997).

A third subcategory is strategic threshold insurance—or voting to keep a prospective coalition partner's vote above a legally defined threshold to qualify for PR seats. This sort of tactical voting has clearly been important in German elections and may become so in other countries that have parties hovering around the relevant threshold values.

3. Tactical Voting as Protest

The third broad category of tactical voting is protest voting—voting against one's most-preferred party, even though it stands a good chance of winning, in

order to chasten it and modify its behavior in future. Protest voting fits the general definition of tactical voting given at the outset of the article, if one includes the result of future elections in the 'better outcome' that the voter seeks. As an example, consider a voter who prefers that party A win the seat in a single-member district but is nonetheless unhappy with some aspects of A's performance. Such a voter may try to 'send a message' by either abstaining, casting an invalid vote, voting for a third party, or (if the voter is confident that A will nonetheless win) voting for A's main opponent. The point is not to defeat A, but to reduce A's margin of victory and hopefully scare it into better behavior in future.

Voting: Turnout

Why do some people vote and others do not? Why do some countries have higher turnout rates than others? Would election outcomes change or governmental policies be different if turnout levels were higher? These are the primary questions that concern students of voter turnout.

1. Factors that Affect Turnout

With one caveat, a useful approach to explaining turnout rates of either individuals or countries entails considering the various costs and benefits of voting. The caveat is straightforward and reflects the observation that any single vote 'is lost in a sea of other votes' (Downs 1957, p. 246). Paul Meehl clearly sketches out the implication of 'this big brute fact,' namely that 'my chances of determining who becomes President [or influencing just about any election outcome] are of about the same order of magnitude as my chances of being killed driving to the polls—hardly a profitable venture … [Voting] is irrational as an instrumental action toward an egocentric end' (Meehl 1977, p. 11). To make any headway in explaining voter turnout, one must recognize that there are intrinsic or expressive benefits to be gained from voting that do not depend on the infinitesimally small probability of affecting an election outcome. Without this expanded conception, save for the small number of instances where there are penalties for nonvoting, there can be no coherent explanation for why so many people choose to cast ballots.

The significant factors that affect the costs and benefits of voting may be usefully characterized as either of the institutional or individual variety. There are three primary types of institutional variables. *Laws* that specify the registration process, the type of election districts, and the structure of the national legislature all influence turnout. *Political characteristics* like the degree of disproportionality in the translation of votes into seats and the number of political parties represent another set of institutional characteristics that affect turnout. The role of the last group of factors, which taps the connection between the *social structure* and the political process, is more uncertain.

With regard to individual characteristics, although any examination of the vast turnout literature will reveal a plethora of factors, four stand out. Although the size of the difference varies, in virtually every election context the better educated have higher turnout than those who are less educated; older people have higher turnout than the young; those who are more interested in politics have higher turnout than those whose interests lie elsewhere; and, in elections that pit parties against one another, strong partisans have higher turnout than people who weakly identify or don't identify with a party. The explanation for these patterns may be found in a careful consideration of the costs and benefits potential voters face.

2. The Costs of Voting

Focusing first on the costs that people must overcome in order to vote, previous research quite clearly demonstrates that the higher the costs, the lower the turnout. Two primary costs should be considered.

Although one can find exceptions, it is generally the case that in order to vote people must first be registered. This can entail dealing with bureaucratic requirements and be rather time consuming, especially in a country like the USA where individuals, as opposed to the government, must take the initiative to register, often well in advance of election day when the excitement that accompanies the approach of an election is usually absent. Turnout is higher in countries that impose lower registration costs on their citizens, and within a country that imposes higher costs, like the USA, turnout is lower among those who are less well equipped to bear those costs (i.e., the less educated).

All voters must bear the second significant cost of voting, deciding for whom or what to vote. Commonly referred to as information costs, people must gather or be given sufficient information to decide how they will vote. It is a cost that can be easily overlooked, because for 'people already well informed, keeping up with politics is scarcely dull, is almost effortless, and the notion that information costs something seems almost peculiar' (Converse 1975, p. 97). Yet for many, politics is barely a peripheral concern. For these less interested people, information costs are higher and their turnout is consequently lower.

Two other individual factors are helpful in mitigating information costs. The greater exposure to and experience with the political system that come with age fosters turnout by making voting decisions easier. In addition, partisans can rely on the relatively simple cues of party labels to make their choices, and consequently their turnout is also higher.

Information costs for potential voters are also reduced if they are undertaken by someone or something else. In this regard candidates and political parties are extremely useful. Voter mobilization efforts reduce information costs because they diminish the need for people to gather for themselves the necessary information in order to make their decisions. Consequently, factors that provide candidates and parties with incentives for broad-based mobilization efforts, like nationally competitive electoral districts, close elections, and lower levels of disproportionality in the translation of votes to seats, all have the effect of boosting turnout by bringing down information costs for potential voters.

3. *The Benefits of Voting*

Even in a political context where voting costs are minimized, they are never eliminated; 'voting is inherently costly' (Downs 1957, p. 265). It is therefore necessary to consider the benefits citizens derive from voting in order to explain why anyone casts a ballot at all. The 'big brute fact' that a single vote has virtually no effect on an election outcome leads to the observation that 'most of the action is, in fact, in the intrinsic values of voting *per se*' (Aldrich 1993, p. 266). This is likely to be the case even in the few countries that have mandatory voting laws, given that the penalties for nonvoting are minor and that enforcement is minimal. The higher turnout induced by these laws probably derives from the expressive benefit of fulfilling a civic obligation, rather than avoiding a sanction.

Though less strong in countries without mandatory voting, the notion that one has a duty to vote pervades most democracies. Schooling is one way this norm in inculcated, and provides another reason why the better educated have higher turnout, whether it derives from the positive feelings of having voted, or sidestepping the guilt that would accompany not performing one's civic duty. In addition, stronger partisans and those who are more interested in politics gain greater intrinsic satisfaction from voting because they are more engaged with the political system.

The association between institutional characteristics and the benefits of voting is less intuitive, but is empirically evident. Voting is more gratifying when there is a stronger connection between election results and government formation. The relationship is weaker in countries with more political parties, where post-election coalition building is far more frequent and complicated, and turnout is lower. Similarly, in countries with unicameral national legislatures, the consequences of election outcomes are more decisive for governing, and people are therefore more likely to perceive elections as meaningful and vote (Jackman 1987).

The last variable to consider is the 'linkage' between the social and political structures within a country: the degree to which social groups and political parties are aligned. In countries where substantial proportions of people with a given group (religious, racial, occupational, etc.) characteristical vote for a specific party, the benefits of voting ought to be enhanced because voting becomes an expression of group identification. Moreover, information costs are lower because people will have an easier time deciding how to cast their ballots. And where parties and groups are more closely aligned, parties have greater incentive to invest resources in mobilization efforts. At the empirical level, measuring the degree of linkage between parties and social groups has proved difficult, and reports of its turnout effects are inconsistent (Powell 1986, Jackman 1987), suggesting that the topic deserves further scrutiny.

4. *The Implications of Nonvoting*

Attention to social structure leads to the final question regarding the effects of nonvoting on election outcomes and government policy. In any country without universal electoral participation (i.e., all countries)

some groups will have higher turnout than others. Compared to their proportion of the population, some will be over-represented while others will be under-represented in the voting population. The potential political implications for the party system and election outcomes are sufficiently significant that in his presidential address to the American Political Science Association, *Unequal Participation: Democracy's Unresolved Dilemma*, Arend Lijphart (1997) advocated compulsory voting.

Two factors determine the implications of nonvoting. First, the difference between the preferences of voters and nonvoters must be considered. To the extent that what nonvoters want differs from the desires of voters, the representation of interests in the voting population will be a distortion of the interests of the larger population. If voters and nonvoters have similar preferences, then the degree of distortion will be less. The second important consideration concerns the relative size of the nonvoting population. If the number of nonvoters in an election is small compared to the number of voters, then even if nonvoters have a very different set of preferences, their small number will limit the potential for impact on the aggregate preferences of voters. However, where nonvoters are more numerous, their potential influence grows.

Several concrete examples illustrate the interplay between nonvoters' preferences, the size of the nonvoting population, and implications of nonvoting. In the USA, after the Voting Rights Act of 1965 and the widespread dismantling of legal and extralegal barriers to black suffrage in the southern states, large numbers of African-Americans entered the voting population. Their preferences were quite different from those of white voters, thereby spurring the political realignment in that region of the country. In contrast, when the USA (in 1919) and Switzerland (in 1971) extended the right to vote to women, similarly large-scale political change did not ensue. Although larger numbers of voters were added to the electorate, their preferences were not especially distinctive, and as a result the electoral consequences were minimal.

In the current political era, the potential implications of nonvoting are greatest in the USA because turnout is comparatively low and the connection between socioeconomic status and turnout is relatively strong. (In other countries, the relationship is weaker because aggregate turnout is higher.) The actual consequences, however, do not appear to be great. First, the relationship between socioeconomic status and partisan and policy preferences is modest. More importantly, when one considers the groups that comprise the nonvoting population, one finds that those groups with the most distinctive preferences (the poor and minorities) are outnumbered by others. The largest groups of nonvoters, the young and residentially mobile, are not politically distinctive, with the exception of the former's greater inclination toward political independence. Thus, 'nonvoters appear well represented by those who vote' (Highton and Wolfinger 2001, p. 10). The possibility that this conclusion applies to other countries is suggested by G. Bingham Powell's (1986) comparative analysis that finds that at the individual level within countries, age, not education, is the strongest demographic predictor of turnout.

To conclude, voter turnout is shaped by both individual and institutional factors. Explaining the connection between these factors and the decision to cast a ballot requires a consideration of the costs and benefits facing potential voters. Because the costs and benefits are not identical for all people, different groups vote at different rates. As a result, there is a possibility that the preferences of voters will not be representative of the entire population. To be sure, this sort of distortion is evident, but a number of factors suggest that in general its magnitude is not especially large.

Vulnerability and Perceived Susceptibility, Psychology of

Virtually all major theories of health behavior are based on the assumption that people estimate their vulnerability or susceptibility to a disease and evaluate the costs and benefits of precautionary behavior before taking action. Research on the accuracy of perceived risk or susceptibility is summarized, followed by a discussion of the relation between perceived susceptibility and precautionary behavior. Methodological considerations about how to measure perceived susceptibility and how to investigate its role as a behavioral determinant will be discussed. Implications for health education practice will be briefly discussed.

1. *The Role of Vulnerability in Models of Health Behavior*

Vulnerability or perceived risk is generally conceived as consisting of two components: the *likelihood* and the *severity* of negative outcomes. Most of the prevailing models of health behavior assume that decisions about risk behaviors are based on conscious decisions in which perceived risks and benefits determine behavior (see *Health Behavior: Psychosocial Theories*).

The *theory of reasoned action* (Fishbein and Ajzen 1975) and the *theory of planned behavior* (Ajzen 1991) are frequently used models of health behavior in which the probability and severity of consequences for people's health of specific behavioral practices are assumed to be a prime determinant of attitudes toward precautionary behavior. These behavioral beliefs can also include risks for health and/or well-being.

The *health belief model* (HBM) is another frequently used framework to explain preventive health behavior (Janz and Becker 1984). The model aims to describe decisions about the costs and benefits of specific actions and distinguishes several factors that are assumed to determine the adoption of protective action. Among these are the perceived vulnerability to developing a specific health problem and the perceived severity of that problem. Precautionary behavior is assumed to be most likely when perceived severity and vulnerability are high, while the perceived benefits of precautionary behavior are substantial, and the costs of behavior change are low.

Weinstein's (1988) *precaution adoption process* is also based on behavioral decision theory, and assumes a series of steps or stages preceding the adoption of preventive action to reduce the threat of negative consequences for people's health. First, people have to realize that a specific risk exists. Second, they have to realize that the risk is significant and can affect people. Third, they have to realize that they are vulnerable to the risk. After these necessary requirements, behavioral change will be a function of the perceived severity of the consequences for health and the efficacy and costs of preventive behavior.

In *protection motivation theory* (Rippetoe and Rogers 1987) perceived vulnerability is also a major factor in the motivation to avoid risk. The theory combines perceived vulnerability to the negative event with appraisals of its severity and the efficacy of the recommended (preventive) action and self-efficacy. The latter factor refers to the ability to initiate and/or sustain a specific precautionary behavior.

Thus, most models of preventive health behavior incorporate the recognition of one's own risk-status or vulnerability as an important condition for adopting behaviors that reduce these risks. The construct of vulnerability basically has the same meaning in all of the models, and it has been assessed with questions that seem more or less interchangeable. One implicit assumption of all these models is that people are able to adequately assess the risks associated with their behavior (see *Health: Self-regulation*).

2. *Accuracy of Perceived Risk/Vulnerability*

There is a substantial amount of research showing that the estimation of risk tends to be a complex process that depends on factors such as the context in which the risk is presented, the way the risk is being described, and also on personal and cultural characteristics. Risks that are more cognitively 'available' due to personal experience or media coverage tend to be overestimated. Thus, estimates of the likelihood of risks such as contracting AIDS or being involved in an air crash tend to be too high, while estimates tend to be too low for more common and/or less sensational risks such as heart disease or being involved in a car accident. The magnitude of perceived risk is also affected by how the perceived probability of a negative outcome is measured. For instance verbal methods such as a scale ranging from 1 (very unlikely) to 7 (very likely) lead to different answers than numerical methods such as a percentage scale ranging from 0 to 100 percent. Verbal measures are better predictors of individual preferences than the more difficult numerical scores. Generally, people have a reasonable idea of the relative risks of various activities and behaviors, although their estimates of the magnitude of risks tend to be biased.

Most research on biases in perceived risk focuses on cognitive factors such as availability and tends to ignore motivational factors that may influence the perception of risk. Although people seem quite aware of the relative risk of specific activities or behaviors, things can change when this knowledge is applied to their own behavior. For instance, many smokers accept the association between smoking cigarettes and disease, but do not believe themselves to be personally at risk. Motivational explanations of this perceived invulnerability tend to focus on the need to reduce feelings of fear and anxiety. Support for the role of these mechanisms is provided by research showing more biased risk estimates in situations of increased threat (see *Health Risk Appraisal and Optimistic Bias*.

In sum: Research shows that estimations of perceived risk tend to be biased, but these biases primarily concern the magnitude of risk; people seem to have a reasonable idea of the relative risk of various activities. This picture can change when dealing with risks associated with people's own behavioral practices. Under conditions of threat motivational factors could come into play and result in an underestimation of risk.

3. *Perceived Risk or Vulnerability and Behavior*

Weinstein (1984) argued that people seem able and willing to incorporate knowledge about their family history, personality, and physical or physiological attributes into their perceptions of risk or vulnerability, but seem much poorer at recognizing the relationships between their own actions and the risks they run. Considerable research effort has been directed to understand the relation between perceived risk or vulnerability and protective behavior. Harrison et al. (1992) conducted a meta-analysis of studies that examined the relation between the four major components of the HBM and various health behaviors. They reported a weighted mean effect for the relation between perceived risk or vulnerability and behavior (risk-reducing practices) in the small to medium range. Sheeran and Abraham (1996), in their review of more than 30 years of research on HBM, point at a number of limitations, and argue that more clarity is needed on the precise role of perceived vulnerability. For instance, it could well be that specific levels of perceived severity and vulnerability function as a threshold variable before perceived vulnerability has an impact on behavior. This could explain the sometimes weak relationship between perceived vulnerability and behavior.

Gerrard et al. (1996) investigated the relationship between perceived vulnerability to HIV and precautionary sexual behavior, and conclude that the often dramatic changes in sexual risk behavior of high-risk groups were only marginally related to beliefs about being at risk. Cross-sectional research suggests that people who engage in more risky behavior tend to be more aware of the increased likelihood of contracting HIV than people who tend to behave less riskily, but only modestly so (see *Sexual Risk Behaviors*).

4. *Some Methodological Considerations*

The assumption shared by many models of health behavior that preventive behavior is the result of the wish to reduce one's risks has an explicit temporal order; that is, initial perceptions of risk are expected to influence subsequent behavior. This assumption not only implies that perceived risk or vulnerability influences future behavior, but also that it is shaped by prior behavior.

A lot of research relies on correlational data. Moreover, these correlations from cross-sectional studies are often interpreted as bearing upon the perceived risk–precautionary behavior hypothesis, while they actually provided information about the accuracy of risk perceptions. This is for instance the case if people engage in risky practices, claim their risk to be low, and intend to continue their risky behavior. In such a case risk perception is clearly inaccurate (see Weinstein and Nicolich 1993).

Another issue concerns the distinction between *unconditional* and *conditional* risk estimates. Unconditional risk estimates refer to the subjective likelihood that a negative consequence will occur, based on whatever factors individuals take into account (e.g., perceptions of control, the perceived efficacy of preventive actions). Conditional risk refers to the probability of adverse consequence for health if no preventive action is taken, or their probability if a specific (preventive) action is taken. A conditional risk estimate thus requires people to indicate their risk or vulnerability given their present behavioral practices, or changes in these practices.

Although most models of health behavior refer to conditional risk estimates, most research tends to rely on unconditional risk estimates (e.g., 'How likely is it that you will get…', followed by the health risk(s) under study). The major drawback of unconditional risk estimates is that it is unclear what set of factors people take into account when answering this general question. A conditional risk estimate is more likely to be related to behavioral intentions or expectations in a consistent and interpretable manner (van der Pligt 1998).

5. *Conclusions and Future Directions of Theory and Research*

A number of biases affect the perception of risk and vulnerability. Cognitive availability has an effect on the perceived magnitude of risk, but generally people

have a fairly accurate view of their relative risk. Motivational factors, such as the tendency to deny risks and/or avoid threatening information about risks, can also affect perceived vulnerability. Unfortunately, research findings concerning the impact of perceived risk on behavior are mixed. Generally, perceived risk is a modest predictor of preventive health behavior. Some argue that the hypothesis that perceived risk is a determinant of protective behavior should be rejected or at least thoroughly re-examined. This skepticism may be premature. The absence of a consistent empirical relationship between perceived risk and precautionary behavior seems partly related to shortcomings in the design of many studies investigating this relationship, and on the way perceived risk is measured. It could well be that at a certain point the status of 'being at risk' rather than the amount of risk becomes central in people's minds. Generally, the perception of personal vulnerability to health risks seems a necessary requirement for people to consider behavioral change, but it is not sufficient actually to induce people to change risky practices.

Programs aiming to increase the prevalence of protective behavior should thus not only provide risk information. It seems essential to develop interventions that also focus on how to change behavior. Future research should help to design interventions that increase risk awareness (without being too threatening), and also help to induce and maintain precautionary behavior (see *Health Education and Health Promotion*).

Vygotskij, Lev Semenovic (1896–1934)

1. Biography

Lev Semenovic Vygotskij was born on November 5, 1896 in Orsha as the second child to a secular Jewish family and spent his youth in Gomel in Byelorussia. He received private tuition and only entered school at the age of 15 to follow the last two years of a private Jewish gymnasium. Having finished school, he moved to Moscow to study law at the Moscow Imperial University and humanities at the Shanyavsky University. He finished his studies at Shanyavsky University with a Masters thesis on Shakespeare's *Hamlet* and returned to Gomel to engage in a wide variety of activities (Vygodskaya and Lifanova 1996).

His interests at the time were divided between two areas: on the one hand, since his youth he had been fascinated by literature and theater. During his university years he had pursued these interests, taking courses in literature and linguistics, attending the plays in Stanislavsky's Art Theater and Tairov's Chamber Theater, and writing theater and book reviews for literary journals. On the other hand, taking Pavel P. Blonsky's courses at Shanyavsky University on education and psychology had quickened his interest in problems of a psychological nature (Feigenberg 1996). His activities in Gomel reflected these two broad areas of interest. During these years (from 1917 to 1924), Vygotskij worked as a literary critic for local newspapers, taught different subjects (e.g., literature, philosophy, psychology) at various schools of different levels, co-founded a short-lived publishing house and an equally short-lived literary journal, and worked for the Gomel authorities as the official responsible for the cultural life of the town. In this latter capacity he contracted theater groups, held lectures on topics of general interest, and organized poetry evenings (Van der Veer and Valsiner 1991).

While in Gomel, Vygotskij became interested in the way the formal properties of a literary text evoke aesthetic experiences in the reader. This led him to deepen his interests in psychology, as did his experiences as a teacher of children and adults of highly

different abilities and penchants. He installed a psychological laboratory at one of the schools where he was teaching and conducted his first empirical psychological investigations. His account of these investigations at a congress led to an invitation by Luria (see *Luria, Aleksander Romanovich* (1902–77)) to come and work as a psychologist at Moscow University. His Ph.D. Thesis, *The Psychology of Art* (Vygotskij 1925/1971) gives a perfect overview of his early views.

Having arrived in Moscow in 1924, Vygotskij again displayed a wide variety of activities. During what was to be the last decade of his life he worked as a clinical psychologist, carried out empirical studies with children, held teaching positions at various universities, co-founded several scientific journals, headed research institutes, worked for publishing houses, and published a couple of hundred books and articles on widely diverging topics. His interests transcended narrow disciplinary boundaries. He began, for example, studying the semiotics of cinematic language with the film director Sergej Eisenstein, he developed a test to study the thinking of schizophrenics, he lectured on the problems of blind and deaf children, he initiated research into memory development, and he developed an interest in what is now called neuropsychology. In 1931, while already being a full professor of psychology, he began studying medicine. However, on June 11, 1934 Vygotskij died in Moscow of tuberculosis, a disease that had haunted him for the better part of his adult life.

The writings of Vygotskij were virtually unknown outside Russia until the publication of *Thought and Language* (Vygotskij 1962) in English stirred the international interest. Now a substantial part of his writings are available in translation. As a result, the discussion of the merits and shortcomings of Vygotskij's work has become a matter of interest to the international scientific community.

2. *Main Ideas*

Given his interest in literature and language, it comes as no surprise that Vygotskij (1962, 1994) attached great importance to language in his psychological thinking. Like other thinkers, he held that the use of language (speech, in his terminology), together with the manufacture and use of tools, is a distinguishing characteristic of humans. In his view, all truly human, higher mental processes involve the use of speech.

2.1 *From Dialogue to Self-regulation: The Sociogenetic Law*

The original function of language is communication, Vygotskij (1997a) argued. Children and adults communicate their intentions and steer or guide the behavior of the social other. This communicative process is at first very asymmetric in that the adult does most of the guiding and attributes meaning—at first often counterfactually—to the infants' utterances. Very soon, however, children become able to use words to accomplish things and, most importantly, to steer their own behavior. Self-regulation thus originates in dialogue.

A simple example is that of a child learning to cross a street. In a first stage, caregivers will tell the child to watch out carefully and children will simply follow these instructions. In the next stage, the child will say aloud to watch out and thus instruct him/herself. In the final stage, the child will merely think these instructions. Thus, a process that was originally shared between two persons, an interpsychological process, has become an individual, intrapsychological process. The child is applying to itself what was first applied by others and thereby mastered its own behavior through the use of conventional signs. With Baldwin, Janet (see *Janet, Pierre* (1859–1947)), Royce, and others, Vygotskij (1997a) claimed that all higher mental process are originally shared between persons and he coined the developmental transition from inter- to intramental processes the sociogenetic law.

This example is linked with another phenomenon that Vygotskij discussed in his writings, namely that of the intersection of thought and speech. In his view, thought and speech have different genetic roots and only merge to form verbal thought or intellectual speech at a later stage in phylogenetic and ontogenetic development. Thus, in human children both preintellectual speech (i.e., babbling) and preverbal thinking (e.g., infants expect to find an object where it was hidden previously) can be observed, while in the phylogenetic domain one sees animals solving simple problems (e.g., using an artifact to reach a goal) and displaying primitive communicative means (e.g., expressive movements). It is only in humans, however, that speech and problem solving merge to form the powerful capacity of verbal thought (see *Khler, Wolfgang (1887–1967)*). Problem solving now no longer proceeds in the graphic or visual field, Vygotskij (1997b) argued, but in a semantic field.

2.2 *Egocentric and Inner Speech*

Vygotskij's claim that speech develops in an intrapersonal situation and subsequently is used to steer the self, received additional support through his discussion of the phenomenon of egocentric speech. It was Piaget (see *Piaget, Jean* (1896–1980)) who first described the phenomenon of children who while carrying out some activity speak for themselves in a way that is often not intelligible to others. Piaget hypothesized that such speech does not take account of the viewpoint of the social other and reflects younger children's general inability to transcend their own point of view. In his view, children are at first

unable to see the world from another perspective than their own and only gradually realize, under the pressure of their peers, that theirs is a specific viewpoint.

Vygotskij criticized Piaget's interpretation of the phenomenon of egocentric speech and conducted a series of experiments to argue that children's egocentric speech is social in the sense that it addresses social others (Van der Veer and Valsiner 1991, pp. 363–9, Vygotskij 1987). He noted that egocentric speech is absent or greatly reduced when the child is alone (which suggests that it is meant for others) and that its incidence rises when the child is confronted with unexpected problems (which suggests that it has some function in the solution of problems). He also observed that egocentric speech becomes less intelligible as the child grows older. This set of results led him to posit that egocentric speech: (a) originates in normal, communicative speech and branches off at a later stage; (b) has as its function to steer the child's behavior when the need arises; and (c) becomes less and less intelligible for the outsider until it becomes proper inner speech. Egocentric speech, then, is an intermediary stage between normal, communicative speech and inner speech. Like communicative speech, it is audible, and like inner speech, it serves to guide the child's thinking.

Vygotskij went on to speculate about the properties of inner speech. He argued that its syntax must be special: it is speech that is abbreviated and tends toward predicativity, that is, omitting the subject of the utterance. He also suggested that inner speech has special semantic properties: personal sense dominates over dictionary meaning. He thus believed to have demonstrated that, in the process of becoming private, speech undergoes a series of transformations.

2.3 Word Meaning and Conceptual Development

Above it was said that children use conventional signs to regulate their own behavior. Towards the end of his life Vygotskij began emphasizing that the meanings of these signs or words change over time. Children use the same words as adults do to designate specific objects but the meaning of these words may be quite different. Thus, in the child the word 'farmer' may evoke romantic images of a person taking care of animals and growing crops, while adults may think of an entrepreneur who tries to maximize profit. Using various strategies, Vygotskij tried to prove experimentally that a mature understanding of many concepts is only reached in adolescence. In this connection, he introduced a distinction between mature, academic, or scientific concepts, on the one hand, and immature, or everyday concepts, on the other hand. Supposedly, the academic concepts express the true nature of things and are linked to other similar concepts. Together they form a coherent network covering a field of knowledge. Academic concepts are taught at school. Everyday concepts, on the other hand, often focus on irrelevant features of some subject and together form a disconnected whole. Everyday concepts are more or less independently acquired by children in informal settings.

Vygotskij's basic idea was that academic concepts and everyday concepts mutually enrich each other. The everyday concept of a farmer becomes enriched because the child learns the nonapparent fact that farmers form part of an economic market in which they try to realize certain goals. The academic concept of a farmer is enriched because the abstract notion of entrepreneurs dealing with cattle and crops is filled with concrete facts of daily farmer life and thereby gets body and flesh. Thus, academic concepts presuppose everyday concepts, build upon them, but once acquired they alter the everyday concepts in fundamental ways. The result of the interplay between everyday and academic concept is an elaborate and rich notion of the concept of farmer. Vygotskij (1935) speculated that the introduction of systems of academic concepts in school would restructure the child's whole style of thinking, that is, he assumed that the introduction of such concepts in specific subject areas would generalize to other areas. Education leads development, as he used to put it. Instruction in the school setting propels child development along lines that are each time specific for a certain culture or society.

2.4 Predicting Mental Growth: The Zone of Proximal Development

In several lectures delivered in 1933, Vygotskij transposed the sociogenetic law to the domain of cognitive prognosis. He claimed that if one were to measure what the child is able to do in cooperation with someone else (interpsychologically), one would be able to predict what the child can do independently (intrapsychologically) later on. At any given moment, both the child's dependent (e.g., with hints from an adult) and its independent performance on an IQ-test can be measured. The difference between the two IQ-scores yields an indication of the child's cognitive potential. Some children will be able to profit more from adult hints and will improve their independent score more substantially than others. These children show the richest developmental potential, Vygotskij (1935) argued. To measure what children can do independently is to measure what they can do already. To measure what children can do with the help of an adult is to measure what they will be able to do in the near future, in what Vygotskij coined their zone of proximal development. In this way, he criticized the contemporary use of IQ-tests and suggested a procedure for the assessment of cognitive potential.

3. *Relevance for Contemporary Science*

Vygotskij's ideas inspired an enormous and still growing amount of research, both in and outside the former Soviet Union.

Wertsch (1985) tried to corroborate Vygotskij's view that self-regulation develops in dialogue by investigating mother-child joint problem solving. He and others have also advanced proposals to fuse Vygotskij's ideas on dialogue and its relevance for self-regulation with those of Bakhtin.

Vygotskij's view of the nature and function of egocentric and inner speech has become a hotly debated topic and has been developed further by others (e.g., A. A. Leontiev, A. R. Luria, A. N. Sokolov). The Eastern European research is well represented in Sebeok (1968), Slobin (1966), Prucha (1983), and Wertsch (1978). Zivin (1979) gives a representative account of both the research tradition initiated by Vygotskij and Luria and its Western counterparts.

Vygotskij's concept of word meaning and his view of the dialectic interplay between academic and everyday concepts in education have also led to a whole research tradition. An excellent and critical account can be found in Wertsch (1985), while Van der Veer and Valsiner (1991) have traced how Vygotskij's research into the development of concepts was used by Western clinical psychologists to diagnose various groups of mental patients (e.g., schizophrenics and patients suffering from aphasia).

The concept of the zone of proximal development has inspired an immense number of publications. These can be divided roughly into two groups. The first group consists of publications that deal with the influence of education on development. It is analyzed, for example, how classroom discussions can promote a zone of proximal development in students, or what kind of teaching is needed to promote children's use of language for self-regulation. An overview of this kind of work can be found in Moll (1990). The second group consists of publications dealing with the assessment of learning potential. In this approach the zone of proximal development is used as an individual difference metric designed to provide information about individual students, that is, Vygotskij's original idea to measure aided and unaided performance on some IQ-test is operationalized and it is investigated whether such repeated measurements yield important prognostic information (cf. Campione et al. 1984).

All in all, it can be said that although many of Vygotskij's ideas are debatable (see especially Van der Veer and Valsiner 1991) and will have to be discarded or extended, they nevertheless have inspired a great and still growing number of researchers in the humanities. In itself this is remarkable for a man who published very little in languages other than Russian, who died more than 60 years ago and whose international fame began only 30 years after his death. The fact that Vygotskij's legacy still inspires contemporary research marks him as a true classic thinker of the humanities.

Vygotskij's Theory of Human Development and New Approaches to Education

Vygotskij's legacy is in his emphasis on social, historical, and cultural aspects of development and learning, semiotic mediation, activity, and social interaction. After about 50 'dark years' of silence, from the early 1930s (immediately after his death) to the end of the 1970s, caused in part by the repressive political circumstances in the USSR, social sciences have been experiencing Vygotskij's renaissance. Since the 1970s, Vygotskij has become a 'root theoretician' for a family of approaches in social sciences including sociolinguistics, anthropology, psychology, education, and literacy studies, among others. In fact, it is probably not an overgeneralization to say that developmental psychology and education have currently been highly influenced by Vygotskij's work. This article will describe the main tenets of Vygotskij's theory of human development, current critique of these tenets, and new approaches to education stemming from a dialog with Vygotskij's work. The article is organized around three major interrelated issues: what develops, what are the processes of development, and what are the directions of development.

1. *What Develops?*

Vygotskij argued that human development is based on the intertwining of two lines: natural, based on processes of biological maturation, and cultural, based on mastery and use of cultural means. Psychologically, these two lines are represented by lower and higher mental functions, respectively, such as memory, attention, and intelligence. For example, mechanical memorization of unrelated bits of information mainly involves lower functions of memory. Meanwhile, memorization that is based on mental structuring of information in some hierarchical classes (e.g., ax, saw, and hammer are tools) or a story connecting items to remember involves higher mental functions of memory. Vygotskij insisted that higher mental functions are formed by a reorganization of lower mental functions mediated by a cultural sign (e.g., mnemonics). Higher mental functions allow people to control their behavior: 'in the elementary form [of memory], something is remembered; in the higher form, humans remember something … the basic characteristic of human behavior in general is that humans personally influence their relations with the environment and through that environment personally change their behavior, subjugating it to their control' (Vygotskij 1978, p. 51). Thus, according to Vygotskij, what develops is higher mental functions via a mastery of cultural signs (i.e., semiotic mediation), leading to a person's development of self-regulation and self-control.

Probably the most elaborate application of Vygotskij's stress on cultural mediation as the object of development has been in the 'sign' pedagogy developed by Russian educational psychologist Davydov (1986). Davydov and his colleagues rewrote an entire elementary school curricula (e.g., math, sciences, language) representing it as a series of dialectical contradictions of mental actions mediated by cultural signs (Davydov's unit of analysis). They also changed the curriculum sequence putting the abstract concepts—higher-level cultural mediators—ahead of concrete application of them (e.g., putting study of fraction and algebra ahead of integer arithmetic). For example, according to Davydov (1986), the fraction represents the contradiction between the permanence of the object's length and the variability of its measurement, depending on the unit mediating the measurement. The mathematical formula $A/c = N$ is a model of the fraction that allows first grade students to make comparisons involving any measurement unit.

Yet a growing literature has implicitly or explicitly criticized Vygotskij for making mental functions the object of development (Rogoff 1990). These scholars have argued that culturally mediated functions are not self-contained, but instead embedded in sociocultural activities. Lave (1988), introducing the notion of 'situated cognition' demonstrates, for example, that people's computation in school-like math tasks and grocery shopping is not psychologically equal even when the problems are mathematically isomorphic. The problem solving is mediated and structured differently in these two conditions because the problems are embedded in different sociocultural activities with different goals and different social relations. In response to these and other related findings, alternative objects of development have been proposed.

Rogoff (1990) proposes a sociocultural approach in which a person's participation in sociocultural activities and communities is the object of development. Development is seen as transformation of participation in a sociocultural activity—transformation that is socially valuable. For example, when a child whose parents had previously read books to her starts asking her parents to read a book, this change indicates a

transformation of the child's participation in the reading practice. Some have argued that mediation by cultural tools and scripts pointed by Vygotskij is only a part of the developmental story and should be considered together with aspects such as social relations, division of labor, community rules and norms, and relations with other practices and communities (Engeström et al. 1999). These features of social life were often ignored in cultural research and research on child development conducted by Vygotskij and his colleagues (Vygotskij 1978).

2. *What are the Processes of Development?*

According to Vygotskij's general genetic law of cultural development, any function in the child's cultural development appears on three planes: natural, social, and psychological. Vygotskij emphasized a dynamic and emergent character of development: Each plane emerges on the periphery ('in an embryonic state') of the previous plane. First, it appears on the natural plane, when children find themselves in the environment when the function is used by other people. For example, in human society, people use gestures in their communication with each other and they often are inclined to interpret some of a child's actions as gestures. When a very young child tries unsuccessfully to grasp a remote object, the caregiver may interpret it as a command gesture to bring the object to the child.

The second plane of development is social: the child is an active participant in the function socially distributed among people. Continuing Vygotskij's example of the development of the index gesture, at some point young children notice that they can control adults by stretching their arm toward a desired object—the adults often bring the remote object to the child. Thus, on the social plane, children actively participate in the social function of controlling other people rather than finding themselves in the function fully organized by other people as it was on the natural plane. Finally, on the third plane, the function transforms from external social into internal psychological. The child's command of others transforms into the index gesture controlling the child's own attention. Now the stretched arm controls not others but the child him or herself, whose own attention is mediated by the index gesture. The developmental cycle is completed: the cultural higher mental function of the index gesture that initially exists only outside the child on the natural plane becomes the child's own on the psychological plane (Vygotskij 1983). According to Vygotskij, development involves nonlinear and systemic processes of changing relationships and organizations of mental functions.

The issue of the relationship between development and education led Vygotskij to introduce the notion of 'the zone of proximal development' (ZPD) as the gap between actual and potential development (Vygotskij 1978). Vygotskij offered two major interpretations of ZPD. The first interpretation is the ZPD as a gap between the psychological (i.e., completed) plane of development, i.e., what children can do by themselves, and the social (i.e., potential) plane, i.e., what they can do with the help of more capable others (adults or peers).

This use of ZPD defines 'teachability' of the child in a specific activity or in problem solving. If an activity or problem can be accomplished by the child with the help of more capable others, this activity or skill is considered possible to teach the child. If, however, the activity or skill cannot be accomplished by the child with the help of more capable others, it is considered not useful to teach to the child.

Unlike Piaget, who believed that instruction should follow development, Vygotskij argued that guidance can, should, and does lead development. They would differently define what is currently called 'developmentally appropriate curriculum.' Piaget insisted that learning is essentially an individual endeavor and that adults can only facilitate by providing an enriched stimulating learning environment and opportunities for children to share and discuss their egocentric thinking with each other to promote disequilibrium in the child's thinking. Adults should not interfere in the child's individual thinking because it can only lead to imposition of the adult's ideas onto the child—what Piaget called 'sociocentrism.' In contrast, Vygotskij encouraged adults to provide guidance and help and to engage students in activities that are beyond their individual levels of competence ('performance before competence,' Cazden 1992).

Currently there are attempts in education to develop 'scientific instruction' using a medical model of 'educational interventions' (Pease-Alvarez C, personal communication, 19 July 1999). The essence of these efforts is to develop educational diagnostics of students' skill deficits and prescribe an appropriate dose of standardized guidance providing no less and more help to the student than is required (Newman et al. 1989). For that purpose, some researchers have tried to develop a 'ZPD test'—a standardized assessment of a student's teachability. However, it is doubtful that a reliable ZPD test could be developed because, as Newman et al. (1989) demonstrate, the notion of ZPD is relational. A student's teachability depends not only on the student but also on the teacher (and broader communities in which the child participates). Thus, no test of the child alone would accurately determine the child's teachability—the teacher always counts.

According to this neo-Vygotskian view, the ZPD is applied not only to the student but also to the teacher. Both the teacher and the student try to manage the uncertainty that their joint activity creates. During teacher–student instructional interaction, the student learns how to do the classroom activity while the teacher learns how to guide the student. Each engages in their own zones of proximal development, which are

mutually constituted by each other—the student's learning is shaped by the teacher's guidance, while the teacher's guidance is shaped by the student's ongoing learning.

The second interpretation of the ZPD offered by Vygotskij is about the activity in which the child is involved. Vygotskij argued that at different ages, different activities become leading forces in a child's development. For young children, play is the leading activity:

> play creates a zone of proximal development of the child. In play a child always behaves beyond his average age, above his daily behavior … As in the magnifying glass, play contains all developmental tendencies in a condensed form and is itself a major source of development … Action in the imaginative sphere, in an imaginary situation, the creation of voluntary intentions, and the formation of real-life plans and volitional motives—all appear in play and make it the highest level of preschool development. (Vygotskij 1978, p. 102)

He introduced the notion of 'leading activity' as an activity that determines the child's development. El'konin and Leont'ev elaborated this notion by creating a scale of leading activities from infancy to adulthood as the base of age periodization (Griffin and Cole 1984).

Bruner and his colleagues developed the didactic notion of 'scaffolding' in their attempts to operationalize Vygotskij's ZPD in their study of dyadic interactions involving adults tutoring children (Wood et al. 1976). Scaffolding involves a series of adult strategies that assume responsibility for children's learning, such as focusing the child on the task, simplifying the task to fit the child's current mastery, maintaining the child's motivation working on the task, managing the child's level of frustration and risk involved in the problem solving, and demonstrating an idealized version of the required act (Rogoff 1990). Like Vygotskij's ZPD, the scaffolding metaphor is aimed at explaining the gaining of skills in social interaction that the child may apply later on when working alone. It focuses on how the adult fine-tunes the extent of help he or she provides the child for each successful activity outcome while viewing the child as inept, 'One sets the game, provides a scaffold to assure that the child's ineptitudes can be rescued or rectified by appropriate interaction, and then removes the scaffold part by part as the reciprocal structure can stand on its own' (Bruner 1983, p. 60).

In a critique of the concept of scaffolding, Griffin and Cole (1984) emphasize the role of the child in his or her own development, 'The metaphor [of scaffolding] becomes more problematic when we focus not on the execution of a specific task but on the changes in the child' (p. 47). This concept makes it difficult to address the issue of the child's creativity. If adult support is the universal source of a child's development, 'then there is a strong sense of theology—children's development is circumscribed by adults' achieved wisdom' (p. 47). If Vygotskij's concept of ZPD seems to be too focused on the child, then the concept of scaffolding seems to be too focused on the role of the adult in guidance. As a consequence, both concepts are limited by dyadic interaction between more and less knowledgeable partners. Besides, cross-cultural research on guidance suggests that scaffolding is not universal guidance strategy (Rogoff 1990).

Unlike scaffolding, the concept of guided participation developed by Rogoff (1990) can be applied in diverse cultural activities because it focuses on transformation of participation guided not only by more knowledgeable partners but also by sociocultural tools, culturally defined goals and problems, and social arrangements of joint activity:

> Interaction with other people assists children in their development by guiding their participation in relevant activities, helping them adapt their understanding to new situations, structuring their problem-solving attempts, and assisting them in assuming responsibility for managing problem solving. This guidance of development includes tacit and intuitive forms of communication and distal arrangements of children's learning environments; it is often not designed for the instruction of children and may not involve contact or conversation. The model is one of routine arrangements and engagements that guide children's increasingly skilled and appropriate participation in the daily activities valued in their culture (Rogoff 1990, p. 191).

Lave insists that learning is inherent to activity and an aspect of any activity. Learning occurs even despite expectations and wills of experienced members of the community—it is not a matter of whether students learn in school but a matter of what they learn. The students might actually learn what they were not expected to learn and might not learn what was expected for them to learn. Learning is not an independent activity among other activities but, like development, it is an aspect of any activity in the world.

Lave and Wenger (1991) argue that learning is situated in communities of practice. Learning is always a question about membership in the community, about participation in the community practice. A novice is not simply a person who lacks some entities called 'skills,' but rather a newcomer who needs to negotiate her or his participation in the community practice. A person engages in ongoing negotiation of membership/participation in different communities of practice. Learning, as a process of negotiation and renegotiation of participation in the community of practice, is often not prime-time community business; it is going on in the periphery of community activity. Because the community is aware of newcomers, the peripheral processes of negotiation and renegotiation of participation have a legitimate character. Newcomers are anticipated and usually organized by the community. An analysis of situated learning allows Lave and Wenger to construct a new productive concept of 'legitimate peripheral parti-

cipation' that becomes the main definition of learning and development.

Learning as a communal process is both a descriptive and guiding approach. A view of learning as communal processes embedded in communal practices has inspired many educational practitioners and researchers to explore and define new forms of guidance that can be used in schools, such as instructional conversations, reciprocal teaching, cognitive apprenticeship, community of learners, practice and problem-based learning, building a professional community, and dialogic inquiry. This family of instructional approaches and models shares at least the following important principles: Learning is a communal process, learning is embedded in activities and practices in which it occurs, learning involves development and negotiation of new communal identities, students' guided initiation of discourse and definition of problems and goals are crucial for becoming an active member of a community of practice, ownership for guidance and learning should be shared among students and between the students and the teacher, and a community is based on practice and communication. Nonschool sociocultural research on learning shares many of the same principles.

3. *What is the Direction of Development?*

According to Vygotskij, development leads toward a build-up of higher mental functions with mediated cognition increasingly playing the central role among all other psychological functions that promote self-regulation in the individual. Vygotskij's primary focus in his sociohistorical theory of development was on how human society reproduces itself. Vygotskij often saw non-Western cultures as 'historical slices' of the development of Western civilization (Luria 1976, Vygotskij et al. 1993). When the developmental directionality was considered, Vygotskij was, at least, inconsistent with his own tenet that stressed the contextual and activity specificity of intellectual functioning (Cole 1988). Prioritizing self-regulation, mastery of independent working, literacy, schooling, scientific concepts, universal rationality, decontextualization, and systematic hierarchical thinking as the pinnacle of individual's development reveal Vygotskij's ethnocentrism (Rogoff 1990, Wertsch 1985).

A diversity of goals of different communities necessitates defining development in terms of progress toward more responsible participation in specific communities of practice rather than assuming that development is a generic process independent of the goals and institutions of the communities in which an individual develops. As Tharp and Gallimore (1988, p. 31) report, 'Boys in Micronesia, where sailing a canoe is a fundamental skill, will have a ZPD for the skills of navigation, created in interaction with the sailing masters. A girl in the Navajo weaving community will have experiences in a zone not quite like any ever encountered by the daughters of Philadelphia.' At the same time, the developing individual contributes to the further development of the practices (and goals and institutions) of the community.

Griffin and Cole (1984) argue that the zone of proximal development is not just about a gap between the child's present and the adult's past but also between the child's present and the society's future. There is an increasing tendency in the social sciences to consider the developmental telos as a social construction of cultural, institutional, communal, and personal values that have both stable and dynamic components that can conflict with each other. The historical time when positive values of literacy, school, science, rationality, intelligence, and the Western civilization were unquestionable in the social sciences is gone. Stemming from Vygotskij's sociohistorical theory, new approaches to development and learning are emerging.

Wage Differentials and Structure

At a point in time in a particular economy there will be a distribution of wage rates (average total compensation per hour) across all economically active members of the population. This distribution of wages is referred to as the wage structure of the economy. The value of the wage rate of each member of the labor force will depend systematically on a set of observable characteristics of that person as well as on other characteristics that are not observed. This relation between wages and worker characteristics as well as the distribution of worker characteristics determines the wage structure of the economy. The average wage of a person with a particular characteristic relative to the wage of a person with a different characteristic (e.g., the wage of a worker in Paris relative to one in Lyon), all other observed and unobserved characteristics held constant (*ceteris paribus*), is called a wage differential. This article discusses the effects of different worker characteristics on wage structure.

1. *Earnings and Wages*

There are several different ways of defining the wage rate, and the appropriateness of any particular definition depends on the questions in which one is interested. Table 1 shows the distribution of average hourly gross (pretax) wage rates of a random sample of 4,300 full-time workers in the United States in 1995. In principle, one would like to include nonwage compensation (employer contributions for fringe benefits and social insurance programs), but such data usually must be collected from employers rather than from individuals. A worker at the 10th percentile of the distribution earned \$6.07 per hour, which means that 10 percent of workers earned less than this amount. One way to summarize the wage structure is to compare the average wage in the highest quintile (from the 80th percentile up) to the average wage in the lowest quintile (from the 20th percentile down). These estimated averages for the US in 1995 were, respectively, \$33.15 and \$5.84, a ratio of 5.7.

An alternative to the use of hourly wage rates is the use of average weekly, monthly, or annual earnings of individuals. Total earnings per year for an individual are by definition equal to the average wage times hours per year. Data on individual incomes rather than hourly wages are often more readily available in most countries. An example of this is reported in Table 2 in which the ratio of the average annual income of workers in the top quintile to that in the lowest quintile is reported for a selection of countries. The study from which this study was taken includes data for 108 different countries. The dispersion of incomes within a country generally is higher than the dispersion of wages becauseannual hours tend to be higher for

persons with higher wage rates. Notice that for the US the ratio of the highest to the lowest quintile in terms of income is 8.5 compared to 5.7 for the wage rates of full-time workers.

Table 2 shows that there is substantial variation among countries in the dispersion of incomes—as there would be if the data referred to hourly wages rather than annual incomes. A few facts are illustrated by these data. First, there tends to be substantially less dispersion in individual wages and incomes within industrialized countries than in the developing countries. Second, there is much greater dispersion of incomes in the US than in other industrialized countries. Third, the degree of wage and income dispersion in the formerly socialist countries is relatively low.

2. *The Determinants of Individual Wages*

The hourly wage rate (W) of any individual worker in a particular economy at a moment in time will, in principle, depend on a set of observable variables (such as that person's level of completed schooling) as well as on a set of factors that generally are not observed (such as the individual's innate ability, a characteristic that is difficult to measure and usually not obtained in a census-type surveys). Let X represent all the variables determining wages that are observed and U represent all the unobserved determinants. We can then specify what economists call an earnings function in which the value of W for each individual depends on X and U according to

$$W = \beta X + \gamma U + \varepsilon \qquad (1)$$

where ε is a random error term (pure 'luck') that is unrelated to the values of X and U.

β is a vector of coefficients representing the effects of each of the observable variables on wages and γ a vector of coefficients representing the effects of the unobserved variables. If, for example, we thought that there were only two observable determinants of W, years of completed schooling (S) and age (A), βX might be specified as $\beta_1 S + \beta_2 A$, and the average effect of an additional year of schooling on W would be β_1.

In practice most estimated earnings functions feature the replacement of the numerical value of W with its natural logarithm. This means that a unit increase in the value of a particular X variable causes W to increase proportionately by the coefficient on that variable. In the case of years of schooling discussed above, with the semilogarithmic form β_1 represents $(\partial W/\partial)/W$ rather than $\Delta W/\Delta S$ if W is entered in numerical form.

From the earnings function given by Eqn. (1) it is clear that the wage structure, the distribution of **W** across the working population, depends on both the joint distributions of X and U (as well as the distribution of ε) and the parameters β and γ. Wage differentials, the *ceteris paribus* difference between the average wages of individuals with one characteristic versus another, are determined by the β parameters.

The various determinants of individual wages, both potentially observable and unobserved, can be classified into five groups. These include:

(a) skill characteristics,
(b) job location,
(c) job characteristics,
(d) discrimination/nepotism, and
(e) rents.

We will discuss the variables within these groups in turn.

2.1 *Skill Characteristics*

Generally, it is presumed that in most societies more skilled workers are more productive and that they earn higher wages (see *Human Capital*). Two fairly crude but readily observable variables relating to skill of each worker are their years of schooling and potential labor market experience. Some microdata sets allow a more detailed specification of education (what subjects were studied, how many resources were allocated to each year of schooling, etc.) and experience (actual vs. potential years, amount of on-the-job-training, etc.), but this sort of detail is rare.

An important source of differences in skill and productivity differences among individuals is variations in unobserved ability and motivation. Although a few surveys have included the scores on simple IQ tests, these factors are either largely or completely ignored, that is, they are considered U rather than X variables. This illustrates a general problem associated with the estimation of earnings functions. The true model is given by Eqn. (1) above, but the researcher is only able to estimate W as a function of observed variables, that is

$$W = bX + e \qquad (2)$$

where e now represents variation in W that cannot be explained by the observed variables. We know that for most empirical earnings functions e is very important, for the fraction of the variation in W jointly explained by the observable variables is usually fairly small—between 25 and 35 percent (see Juhn et al. 1993).

There is thus a large potential for empirical estimates of the effects on W of any individual observed variable to be biased upward or downward due to the correlation of that variable with unobserved variables. In the very simple model above in which schooling and age are the only observed variables, we want to estimate the 'true' effect of S on W from the model $W = \beta_1 S + \beta_2 A + \gamma U + \varepsilon$, but we are forced because of data limitations to estimate $W = \mathrm{b}_1 S + \mathrm{b}_2 A + e$. The use of b_1 as an estimate of the true effect β_1 is in general subject to specification error which arises if S is

correlated with γU (holding A constant). It seems reasonable to suppose that persons with relatively high levels of intelligence and/or motivation (a) will tend to have higher wage rates (i.e., $\gamma U > 0$) and (b) be more likely to have relatively high schooling levels. This would suggest that b_1 would be an upward-biased estimate of β_1. Interestingly, however, the consensus of the mass of research into this question (see the review by Card 1999) is that conventional estimates of the effect of schooling on wages are probably not significantly biased in an upward direction.

Another feature of empirical earnings functions is that their coefficients may change over time. This is especially true for coefficients concerning skill variables. For example, in the US the relative hourly wage of 30-year old male workers with a bachelor's degree (16 years of schooling) to those with just a high school degree (12 years of schooling) fell from 1.18 in 1973 to 1.11 in 1979, but it then rose during the 1980s to a value 1.41 in 1989 (see Bound and Johnson 1992, Table 1). Why these changes in relative wages occurred (in the US and in other countries with relatively flexible wage determination systems such as Canada and Britain) has received a great deal of attention from economists, but the answer is still a matter of controversy.

2.2 Job Location

A second set of observable variables that are usually included in empirical earnings functions are dummy (one/zero) variables describing the location of the worker within the country. Typically the locational variables represent the size of the area in which the person lives (whether or not, for example, it is a metropolitan area with a population in excess of a million) and indicators of residence in particular areas. For example, in a hypothetical study of the determinants of wages in the Great Britain, one would include a large city dummy variable (L_{large}) and separate dummy variables for persons employed in Greater London (L_{london}), other parts of Southern England (L_{south}), and Scotland (L_{scot}). This specification would be represented as $W = b_1 L_{\text{large}} + b_2 \mathrm{L}_{\text{london}} + \mathrm{b}_3 L_{\text{south}} + b_4 L_{\text{scot}} + \cdots$ with the other observable determinants of wages (the X's in Eqn. (2)) included. The estimated coefficient b_2 in this earnings function would represent the average *ceteris paribus* wage differential between a person working in London and another working in a large city in Northern England. If, as is generally the preferred approach, W is entered as a natural logarithm, the estimated coefficient b_2 would reflect the approximate proportionate wage differential associated with employment in London.

What is the economic interpretation of coefficients on location of employment? First, because of higher land prices, it is generally more expensive to live in areas with a highly concentrated population. In order for real wages (nominal wages divided by the price level) to be equal across areas, observed wages must be appropriately higher in expensive areas. This would apply especially to very large cities within individual countries—London, Paris, New York, Tokyo, etc.

A second reason for the existence of wage differentials by job location is the preferences of workers concerning the characteristics of different areas. For example, living in a large urban area involves greater stress and poorer air quality than living in a rural area, so, holding the cost of living constant, the typical worker might have to be paid a compensating wage differential to work in the large urban area. Similarly, some regions have better weather and other amenities (like public services) than others, and one would expect that wages would be higher in the more desirable than in the less desirable areas in order for potential migrants to be indifferent between different areas. For the US, the estimated effect on wages of an area having sunshine 80 percent of the time vs. only 30 percent is, as simple economic theory would predict, a reduction of about 7 percent (Blomquist et al. 1988).

This, of course, presumes that all (or most) workers in the economy have the same preferences for the amenities of different areas. To the extent that preferences differ across the population—some people prefer rural areas (warm weather) to large cities (cold), others the opposite—predictions concerning compensating wage differentials become somewhat less clear.

A final reason for the existence of wage differentials across locations is the effect of changes in the structure of labor demand. Suppose, referring to the example above, that there was for some reason a major boom in Scotland that caused the demand for labor there to increase permanently by 50 percent. It is unlikely that there would be an immediate large migration of workers from England to Scotland, so wages in Scotland would be bid up significantly. The earnings function for Great Britain based on data collected after the demand shift would yield an estimated coefficient b_{scot} that would now be positive. How rapidly the Scottish/English relative wage would return to one (the value of b_{scot} to return to approximately zero) depends on how long it takes for a portion of the British population to relocate to Scotland.

2.3 Job Characteristics

In addition to the location of employment, an important set of determinants of wage rates is the attributes of the job held by each individual worker. We can arbitrarily define each job attribute (the set of which we will call A) as a bad—the degree to which it is physically onerous, monotonous, a threat to the worker's health and safety, has low social status, etc. It would be expected that higher values of the elements of A would require a compensating differential. Put

Table 3
Estimated relative salaries of Ph.D.'s in the US by field of doctorate and type of employer, March 1995

Field of Doctorate

State and local government	93

differently, holding all other (observed and unobserved) determinants of wages constant, the market equilibrium wage of each job would be higher for 'bad' jobs (those with high values of A) than for 'good' jobs (those with low values of A). Thus, for the specification $W = b_1A_1 + b_2A_2 + \cdots$, where the A_is are numerical representations of bad characteristics (like the injury rate of the job), we would expect to estimate positive b_is.

There are numerous examples of the operation of compensating differentials. (For an excellent introduction to the topic, see Chapter 8 of Ehrenberg and Smith 2000.) On the other hand, there are many instances in which the estimated effects of certain job attributes tend to be zero or have the 'wrong' sign (from the point of view of the theory) (see Brown 1980 for a refreshingly honest discussion of these problems).

An important set of applications of estimates of job amenities on wages is to the question of the economic value of life. If one of the As (say A_1) is the rate of accidental death associated with the occupation of the worker, then one can infer from the estimated value of $\partial W/\partial A_1$ how much individuals value—apart from the opportunity to earn and consume—place on the continuation of their lives. This information can, in principle, be used to do cost/benefit analyses of programs to reduce risks to life and health.

An example of wage differentials associated with differences in job characteristics is given in Table 3. These results illustrate some of the difficulties in the interpretation of the effect of job attributes. The sample refers to individuals working full-time in the US in 1995 who had received a Ph.D. in science or humanities. The regression equation relates the annual salary of each respondent to years since receipt of the doctorate, gender, race, and region as well as the field of receipt of the Ph.D. and the current type of employment.

The range of field effects (with economics equal to 100) is from 73 for humanities to 105 for specialists in computer science. This means that, holding gender, race, years of experience, type of employment, and region constant, the computer/humanities relative salary is 1.44. There are also substantial compensation differences across employer types. For example, Ph.D.s employed in the for-profit business sector earn, *ceteris paribus*, 29 percent more than those in tenure track academic positions.

There are various explanations of why relative compensation differentials of this magnitude exist—in this case among sets of individuals who have the same quantity of education. First, these differentials may reflect compensating differentials in the sense that some fields (economics, for example) are intrinsically boring relative to other fields (like humanities) and require higher monetary rewards in order to induce persons to study them. Some of the relative compensation levels by employer type—for example, the business/academia comparison—most likely reflect premiums that are necessary to get Ph.D.s to work in jobs that are perceived to be less rewarding in a nonfinancial sense.

A second potential explanation of differentials of this sort is that they reflect, in part, average ability differences of the individuals who are in each field or employment type. This is especially relevant for comparisons of employment type in which there is partial sorting on the basis of ability. For example, the compensation difference between academics in tenure track positions and those in both nontenure track positions and lower education (secondary schools and 2-year colleges) is very likely to reflect practices by which the 'better' Ph.D.s are granted tenure.

A third explanation of these compensation differentials is that some of them reflect temporary market factors, and there is a presumption that the high relative compensation of the computer science field in Table 3 is an example of this. This phenomenon is illustrated theoretically in Fig. 1. The demand for a particular type of labor is assumed to increase such that the demand curve shifts from D′ to D″. In the short run the supply curve, S_{SR}, is quite inelastic, reflecting the fact that the pool of persons qualified to work in this market is fixed. (In the case of computer scientists, some additional labor can be obtained from people not on the labor force or from closely related fields, but these possibilities are limited.) Thus, the short-run effect of an increase in the demand for this type of labor is to increase its relative compensation level. In the long run the supply of labor to this market

Figure 1
Adjustment of a labor market to demand shock in the short run and the long run

is very or completely elastic, for new entrants to the labor force can choose to train for this type of work. (In the case of computer specialists, young persons are induced to get Ph.D.s in that field rather than in mathematics or physics.) Over time, therefore, the relative compensation level in this market would be expected to return to its initial equilibrium value, C′, rather than stay at its temporary value, C″ in Fig. 1.

Analysis of wage differentials of various sorts can proceed along the above lines. A major example of this is the analysis of average compensation across industries. An example of this is Table 4 in which average monthly salaries across broad industrial groups are reported for six rather diverse countries. Wages in agriculture, trade, hotels and restaurants, and personal services tend to be relatively low; wages in mining, utilities, and finance tend to be relatively high. Some of these differentials reflect quality and compositional differences (that are not adjusted for in the table). But some of the differentials reflect differences in the amenities associated with work in the particular industries.

2.4 Gender and Ethnicity

A set of observable variables that are generally included in earnings functions are the demographic characteristics of the workers—his/her gender, race, or ethnicity. For example, the inclusion of a one/zero dummy variable for women as one of the *X*s in Eqns. (1) and (2) is very common. For the theoretically complete model given by Eqn. (1), which includes *all* observed and unobserved influences on wage rates, the interpretation of the (presumably negative) coefficient on women must be in terms of some sort of labor market discrimination against women. Why else would otherwise identical workers receive lower compensation? The same conclusion applies to conclusions concerning potential dummy variables on race and ethnicity for earnings functions in probably every country in the world (blacks in the US, French speakers in Quebec, Arabs in France, natives of Greenland in Copenhagen, etc.).

The problem with attributing the negative effects of gender and certain racial and ethnic distinctions entirely to labor market discrimination is that we are only able to estimate the model for which we have data, Eqn. (2) rather than the theoretically complete Eqn. (1) above. Thus, there is the possibility that the negative coefficients on gender and ethnicity reflect, wholly or in part, differences in the average value of omitted variables rather than some form of direct

Table 4
Average monthly salaries of employees by industry relative to manufacturing in 1997 for selected countries

labor market discrimination. Further, it is necessary to know exactly what is the cause of an observed wage differential if a society decides it wants to eliminate this differential (see Altonji and Blank 1999 for an extensive discussion of these issues).

2.5 Rents

Most of the above discussion proceeded as if wages are determined in markets that are similar in process to the markets for melons and equities. The fact that the commodities involved in labor markets are human beings requires that this 'model' be modified to some extent. Indeed, a set of institutions has emerged to provide modification of the outcomes that would follow from the unfettered equilibrium of the labor market. Among these institutions is trade unionism, which has, over time and across societies, taken several forms. Government policy—both directly through legislation determining wages and indirectly through its role as employer—also affects the wage structure.

At one level the existence of institutions such as trade unions creates another wage differential in which to be interested. In terms of Eqns. (1) and (2), being a union member or working in which wage rates are determined by a collective bargaining contract means that a worker could earn a higher wage than another worker who is not so situated. In this case, $W = \beta_1 U + \cdots$ is the complete wage equation, including all observed and unobserved variables, where U equals one with union representation and equals zero otherwise. We do not, of course, observe everything about the workers and his/job, so we estimate the equivalent of Eqn. (2), $W = \mathrm{b}_1 U + \cdots$

How good the estimator b_1 is of the 'true' effect of unionism β_1 depends, as in the estimation of other wage differentials, on the correlation of the omitted determinants of wages with U. In the US, the consensus estimate of the average effect of unionism on wages is about 15 percent (see Lewis 1986).

A more important effect of unionism and government policy is their influence on other wage differentials. Much of the above discussion of the structure of wages and of wage differentials reflected the implicit assumption that relative wages are, at least in the long run, free to adjust to their market-clearing levels. This assumption is all right for the analysis of labor markets in the US, Japan, and (during the past 20 years) the United Kingdom, but there are serious problems associated with its application to most other industrialized countries in which bargaining coverage is over 75 percent (vs. 18 percent in the US and 22 percent in Japan in the early 1990s). To the extent that union and/or government policy attempts to prevent increases in the dispersion of earnings, wage differentials will not behave as neatly as the elementary theory suggests. Instead, wage structures will be subject to a great deal of inertia, and they will adjust at best very slowly to shocks in demand.

That the wage structure is slow to change is not *per se* a bad thing. Indeed, I would join most economists in agreeing that stability of the distribution of income is a good thing. The problem with such policies, however, is that they often lead to heavy unemployment of those groups whose relative wages are protected.

War: Anthropological Aspects

Sun-tzu, the famous Chinese military expert, began his book *The Art of War* with the words 'Warfare is the greatest affair of state, the basis of life and death, the Way (Tao) to survival or extinction. It must be thoroughly pondered and analyzed.' These words, 2,500 years later, still hold true: war has grown more deadly, and more damaging to human existence.

In the twentieth century alone, over 250 formally declared wars took over one 100 million lives. Undeclared wars, including political repression, commu-

nal violence, and tribal genocide took millions more; for example between 50–100 million tribal people have been killed by forces and citizens of states in the twentieth century. If we expand the definition of war to include such conflicts as 'the war on drugs' and gang warfare, casualties figures rise, though accurate statistics are not available on these forms of violence.

As we enter the third millennium, one-third of the world's countries are engaged in some form of political violence. Whether these conflicts are called war or not often depends more on political rhetoric than on an accepted definition of the term. In addition, approximately two thirds of the world's security forces use human rights abuses to control their populations. The victims tend to label this violence war or dirty war, while the state tends to classify this as defense or counterinsurgency.

The world has not always been characterized by such high levels of violent warfare. Wars today are longer in duration, more deadly, and kill higher numbers of civilians than wars of preceding centuries. The reasons behind war and the ways in which it is waged change across cultures and time. The changing characteristics of war demonstrate that organized violence is not a fixed and eternal fact of biology, nor an inescapable feature of a Freudian psyche, but a human practice guided by norms of behavior and codes of conduct situated in cultural values.

1. *Defining War*

Neither the two world wars nor the several hundred local and regional wars since 1900 have brought us closer to a shared understanding of war. Most scholars accept a basic definition of war as the deployment of violence to force opponents to comply with one's will. War is organized, group-level, armed aggression rooted in hierarchies of dominance which assume winners and losers in a contest over resources, people, and power. Yet war is defined differently by the winners and the losers, by historical perspective, by soldiers and pacifists—and in each case the definitions are more politically charged than factually correct. For example, freedom fighter, terrorist, insurgent, rebel, traitor, and soldier are all terms variously applied to the same actors by different groups seeking to maximize their own political and moral justifications. Governments define war in their own interests, and militaries are loath to admit strategies that entail civilian casualties, torture, and human rights abuses. The most basic understanding of war is affected by differential and biased reporting; for example, casualty statistics for World War Two vary by millions, depending on the nationality and viewpoint of the researcher. Controlling the definitions of war are integral to the waging of war (Sluka 1992).

The ethnographic study of war and peace has added a new dimension in the understanding of political violence. This academic research has demonstrated that war is a far more complex reality than classical definitions positing a violent contest between two or more armed forces seeking a military, and thus political, victory (Warren 1993, Nordstrom and Robben 1995). Soldiers often battle unarmed civilians and not each other—evident from the ethnic cleansing of the Yugoslav forces in Bosnia and Kosovo or the two million deaths in Sudan's civil war. Paramilitaries, private militias, death squads, and roving bands of armed predatory gangs patrol warzones. Some operate at the behest of state forces while others are independent of all sovereign or rebel control. Mercenary forces are a global phenomenon today, and range from informal groups such as the Yugoslav mercenaries fighting in Central Africa to the formal Executive Outcome organization, comprised of former apartheid South African soldiers, who broker with governments as well as rebel groups. Battlezones are also home to looters, sex workers, criminals, and profiteers. Warzones are a bazaar of international arms and supplies merchants who reap billions of dollars yearly worldwide. International nongovernmental organizations are found in all warzones today, providing services ranging from conflict resolution to humanitarian and development aid. Finally, the fronts of wars are home to the inhabitants. Regardless of formal military regulations mandating the legal role of women, children, and the aged in war, all of these people fight for survival when they find themselves on the frontlines. Armed or unarmed, women defend homes and towns, children are forced to take up arms and fight, and the aged battle forced sieges. The unscrupulous sell out their neighbors for a few coins, and the altruistic set up medical clinics, schools and trade routes to provide critical resources under bombardment.

2. *The Development of War*

War is a fairly recent invention, in terms of the anthropological expanse of human existence. Humans, as a species, have lived 90 percent of their history without war. Social hierarchies and concepts of ownership appear necessary for the advent of war. The earliest form of human organization was the band: fluid egalitarian groups of nomads. The archeological record indicates that while interpersonal violence was known in bands—determined by puncture and crushing wounds from weapons—it was limited. It did not reach the level of formalized intergroup violence among contending warriors.

The first indications of organized warfare occur as ownership of animals, goods, and property create divisions within societies. With the historical development of tribal societies and protostates comes a differentiation in power, and the emergence of organized intergroup violence (Ferguson and Whitehead 1992). These societies did not have standing armies

and military institutions separate from general society; warrior status tended to be open to all able-bodied men, and, less commonly, to women. The early years of tribal war were not necessarily a dangerously lethal activity. For many tribal groups, preparations for war constituted an elaborate ritual process. The rules of engagement were often well delineated: contending factions would meet in full battle regalia and hurl challenges and possibly weapons. Casualties generally brought a halt to the aggressions. Here, it is the display and enactment of power, and not violence, that defines war. Among some communities—the archeological record suggests these were later developments—fighting was much more lethal, though the intent was seldom, if ever, genocide. The goal was to force surrender and extend control over people, property, or territory.

Formalized military institutions and standing armies develop with the rise of the 'state' as a form of political, economic, and social organization. The term state here is used in its anthropological sense—originating some 8,000 years ago, and not in the political science definition as developing in the mid 1600s. (The latter, the modern state, will be considered in the next section.) Chiefdoms are replaced by royal families or governing bodies. Social, gender, and often ethnic inequality is codified in laws of land ownership, labor rights, and inheritance. Dispute resolution becomes formalized into judicial systems, and the legitimate use of force is restricted to state leaders and institutions. Contemporary warfare—fought among contenders for power, privilege, and gain—emerges.

3. *The Changing Nature of War*

Contemporary warfare itself has changed dramatically over time and circumstance, giving lie to any notion that war is a 'natural' social phenomenon or a fixed product of overarching political organization (van Creveld 1991). The era of the modern state provides a good illustration (Holsti 1996). In Europe, the end of the Thirty Years War (from 1618 to 1648) coincided with the beginning of the modern state (marked by the Treaty of Westphalia). The Thirty Years War depopulated a large part of Central Europe. It was known for its sheer brutality: writers of the time speak of the wanton killing, torture, plunder, and destruction of anyone and anything who found themselves in the path of the aggressors. The levels of violence are attributed to the enduring impact of religious wars and the Inquisition, to the transformations wrought by urbanization and early industrialization, and to the upheavals marking the shift from kingly rule to the modern state.

Over the following two centuries the nihilism characterizing the Thirty Years War gave way to what has been called the gentlemen's war of the Enlightenment period. Formal warfare during this era often, though certainly not always, followed strict rules of conduct and engagement: soldiers fought soldiers in hand to hand combat on battlegrounds apart from human habitation. This was not a new era of war for humankind: Buddhist and Hindu scriptures 2,000 years BCE outlined similar 'gentlemen's wars' in Asia.

While military texts tend to focus on these formal military engagements between two contending armies, another form of warfare developed during this period: colonial repression of conquered peoples. In many ways these actions presaged the dirty war of contemporary times—wars that brutally targeted unarmed people in attempts to instill political acquiescence.

The colonial encounter gave rise to another distinct form of war: the guerrilla war, the mainstay of wars for independence worldwide. Guerrilla warfare was developed by nonstate actors challenging financially and technologically superior state forces. Classical guerrilla philosophy—institutionalized in the mid-twentieth century by military strategists such as Mao Zedong, Che Guevara, and Ho Chi Minh—postulates that guerrilla forces, by definition, have the support of the broad population, and it is this that gives them indefatigable strength, crucial resources, and moral political superiority. While in many cases this has proven true, it is by no means always so. Guerrilla groups such as the Khmer Rouge in Cambodia, Renamo in Mozambique, and the Contras in Nicaragua demonstrated that nonstate forces can also use repressive tactics in an effort to control populations.

4. *The Twentieth Century*

The twentieth century was characterized by sophisticated and far reaching developments in the international laws and institutions governing war and protecting peace. Despite these, this period was the bloodiest in human history. Overall, wars in the twentieth century were longer in duration, more lethal in the cost to human lives, and more destructive to societal systems than in preceding times. Simply pointing out that this era saw the advent of world war, high-tech and nuclear war, and modern paramilitary warfare does not convey the changes in the philosophy and conduct of war that occurred during this time (Keane 1996). The most dramatic example concerns the ethics of who may and may not be targeted in war. Over 80 percent of the casualties in World War One were soldiers. With the advances in modern technology and the idea that a country's citizens were now part of the war effort (given their role in producing the means of war), noncombatant casualties rise to 50 percent of all war-related deaths in World War Two. This trend escalates rapidly in the last half of the twentieth century: in the Vietnam war, more than 80 percent of all casualties were noncombatants, and at the start of the twenty-first century, civilians account for 90 percent of all war-related deaths worldwide. Not only has the line between combatant and noncombatant grown indistinct, the line between gender

and age in soldiering has too. Women die in equal numbers to men, and more children are killed in war today than soldiers. The use of child soldiers has grown in recent years: at present over three hundred thousand exist worldwide. This serious rise in civilian casualties parallels an increase in the number and sophistication of international organizations (such as the United Nations and the Organization of African States) and international legal bodies (such as the International Court of Justice and the War Crimes Tribunals) seeking to control destructive wars. Today there are 70,000 protocols protecting human rights.

5. *Theorizing War*

As the predominate means of waging war changes through time, so too do the definitions and theories of war (Simons 1999). In premodern times many, including early Christian and Buddhist societies, saw war as inescapable at times, but not as honorable; the post-war period was crafted as one of atonement. The notion of the honorable war develops in the west with the rise of the 'gentleman's war' of the modern state. Carl von Clausewitz, the famous Prussian military expert, codifies war as 'an extension of politics,' placing war directly in the rational politics of Enlightenment philosophy. Warfare, as rational, became justified—the most dangerous examples of this were seen in colonial conquests, often rationalized under the rubric of the 'evolution of civilization' by scholars.

These Enlightenment philosophies wed with the functionalist and structuralist schools in the early 1900s. Here, theoreticians investigated the 'functions' of war, and placed the causes of war in competition over scarce resources, overpopulation, and the increasing complexity of societies. At the same time, psychological and sociobiological theories were popular. These postulated aggression and self-interest as inherent to humans, and therefore as serving an evolutionary purpose. The fact that not all societies engage in war, and that the majority of the people in any society at war do not choose to fight was not addressed by these theories. Political theory within these schools was shaped by the advent of the world wars. After World War One, functionalist theories take an idealist cast that postulates the progress of civilization as one that will finally eschew war. In the wake of the vast destruction of World War Two, realist theory replaces idealism as the dominate theory in the social and political sciences. Here, war is seen as a natural effect of competition among sovereign states. In both schools the solution lies in creating strong state and international institutions to wage, and ideally to control, war.

As the period of the World Wars gave way to wars for independence, regional wars, and the Cold War, theories of war underwent another revolution. Critical to this shift is the fact that researchers around the world began to experience political violence directly, whether by intention or by accident. The reigning functionalist theories did not fit their observations (Foster and Rubinstein 1986). Clearly, the advent of nuclear war gave lie to ideals of 'victory' in war—for the first time all sides to a conflict could perish. Wars such as those fought by the USA in Vietnam and by the USSR in Afghanistan laid to rest old notions of the gentleman's war. Dirty wars such as those in Argentina, and genocides such as those conducted by the Nazis in World War Two and the Khmer Rouge in Cambodia challenged notions of the inherent functionality or rationality of war. The increases in noncombatant deaths undermined the claims of sociobiology—it became hard to argue that noncombatant deaths, widespread torture, systematic sexual violence, and the death of children were biologically or socially productive acts (Enloe 2000). Scholars also began to question Clausewitz's 'truism' that war is (predominately) an extension of politics. Certainly it is political, but the recognition of the vast sums of money made in wildcatting valuable resources in warzones and in selling war supplies worldwide made it necessary to integrate economics with politics in the war equation (Kaldor 1999). The rise of religious, ethnic, and identity factors in contemporary conflicts rendered it necessary to add social and cultural factors in with the politico-economic ones (Rupesinghe and Rubio Correa 1994). And studies of peaceful societies such as the Semai and the Quakers demonstrated that war is not inevitable, nor basic, to the human condition (Gregor 1996).

6. *The Future of War*

The dawn of the third millennium is marked by vast differences in war. While the superpowers spend trillions of dollars on high technology earth and space based weapons systems, the vast majority of today's war casualties are killed by small arms wielded by nonspecialists. The greatest dangers are the most accessible: there are estimated to be 500 million to one billion firearms in use today in the world; a lively international black-market sells every conceivable implement of war from AK47s to nuclear materials; recipes for chemical weapons can be found in basic texts; and computer specialists can wreck nationwide havoc by disrupting a country's basic infrastructural support systems. All of these facets of the war industry are set in global interactions (Castells 1998). Our theories of war must be revised to address these dynamics defining the contemporary world. Theories of war in the near future will in all likelihood address the complexities of war systems that spend billions on technological defenses (at the end of the twentieth century military spending worldwide reached 780 billion US dollars per year) while killing with inexpensive conventional weapons—and will delve into the cultural factors and economic gains as well as the political quests that underlie these realities. In the long

term, we should be prepared for the possibility that war, as we know it, may not define future conflict. While employing violence in the pursuit of dominance may continue to fuel war, violence may shift from physical killing to a different order of threat and inequality, and dominance might be reckoned along such nonmilitary factors as economics, environmental control, social viability, or a set of factors as yet unrecognized. War has not always been a part of the human condition, and perhaps future changes in sociopolitical organization and ethical systems will render war altogether obsolete. Effective research into the causes, solutions and future of war will hone combinations of theoretical inquiry with ethnography—helping to erase arbitrary distinctions between theory and data (Nordstrom 1997). The greatest advances will be in rethinking the very meanings of violence and aggression, going beyond simple biological and rudimentary social explanations to explore the complex interactions of violence and power, economics, survival, and identity both within and across local, regional, and transnational populations.

War: Causes and Patterns

War involves large-scale organized violence between states or other political units. Although the conduct of war has changed in important ways over the millennia, war itself has been a recurrent phenomenon in international politics. It is one of the primary sources of change in international systems and an important factor in the evolution of the social and political organization of societies. Theorizing about the causes of war goes back to Thucydides' *History of the Peloponnesian War* between Athens and Sparta, but scholars are far from agreement on what causes war.

1. Patterns of Warfare

The current international system represents the most recent stage in the evolution and globalization of the system that originated in Europe about five centuries ago. Warfare in this system has historically been dominated by the 'great powers,' though the frequency of wars between these leading states has steadily declined, while their severity has increased. The period since 1945 has been characterized by both the longest period of great power peace in the last half millennium and a dramatic shift in the concentration of war from Europe to other regional subsystems and from international wars to internal wars, many of which have been intractable ethnonational or religious 'identity wars.' These recent trends have led some to argue that we have reached a turning point in the history of warfare. Some argue that major war between advanced industrial states has become obsolete, while others argue that traditional wars over power or ideology will give way to a 'clash of civilizations' defined in terms of religious or cultural identity (Huntington 1996). These arguments reflect different theoretical perspectives on the causes of war.

2. Theoretical Approaches

Carl von Clausewitz (1976) wrote in his influential book *On War* that war is a 'continuation of politics by other means,' suggesting that war is an instrument of policy for advancing state interests. This implies that war ultimately involves a *political* decision by state

political leaders, so to understand war one must understand why political leaders choose war rather than other strategies to achieve their ends. Technically, we must understand the *joint* decisions by rival states, because one side can usually avoid war if it is willing to make enough concessions.

2.1 The 'Levels of Analysis' Framework

Scholars previously emphasized monocausal explanations that identified a single primary cause of war, but political scientists have moved away from such explanations. Although they prefer parsimonious explanations that explain as much as possible with as little theoretical apparatus as possible, they generally recognize that there are many possible causes of war and that there is no single factor that is either necessary or sufficient for war. One analytic framework that they have found useful for categorizing the many possible causes of war is based on patterns of causation located at different 'levels of analysis': international system, nation-state, and individual. The first focuses on threats and opportunities to states that originate in their external environment and that affect the 'national interests' of the state as a whole. The second emphasizes the internal sources of foreign policy decision making that derive from either governmental structures or processes or from societal influences outside of the government. The third emphasizes the distinctive role of key individual decision makers in the processes leading to war.

2.2 Systemic-level Theories of War

Systemic-level causes of war include the anarchic structure of the international system (defined as the absence of a legitimate authority to regulate disputes and enforce agreements), the distribution of military and economic power among the leading states in the system, patterns of military alliances and international trade, and other variables deriving from the external environment of states. The leading systemic-level approach is 'realist theory,' which begins with the assumption of the primary role of sovereign states who act rationally to advance their security, power, and wealth in an anarchic international system. Given uncertainties regarding the current and future intentions of the adversary, political leaders focus on short-term security needs, adopt worst-case thinking, engage in a struggle for power, and utilize coercive threats to advance their interests, influence the adversary, and maintain their reputations.

At a very general level, realist theory posits two distinct paths to war. In one, the direct conflict of interests between states leads at least one side to prefer war to any feasible compromise. In the second, states prefer peace to war but are driven by the structure of the situation and by uncertainty regarding the intentions of others to take actions to protect themselves through armaments, alliances, and deterrent threats. These actions are often perceived as threatening by others (the 'security dilemma') and often lead to counteractions and conflict spirals which sometimes escalate to war.

The leading realist theory is balance of power theory. Although there are several versions of balance of power theory, most posit that the primary goal of states is to avoid hegemony, to prevent any single state from achieving a position from which it can dominate over others. This leads to the instrumental goal of maintaining a balance of power through the internal mobilization of military power, external alliances against potential aggressors, or the use of force if necessary. The theory predicts that this balancing mechanism almost always works successfully to avoid hegemony, either because potential hegemons are deterred by their anticipation of a military coalition against them or because they are defeated in war after deterrence fails.

Another theory that gives primary emphasis to the systemic-level sources of war, but that is associated with a liberal perspective that downplays the conflictual consequences of anarchy, emphasizes the potential for cooperation among states, and includes some domestic factors as well, is the liberal economic theory of war. The core of the theory, which originates with Immanuel Kant's *Eternal Peace* (1795/1977), is that trade promotes peace. Trade leads to economic benefits, but the economic interdependence generated by trade leaves states vulnerable to any disruption through war, and the fear of economic disruption and the loss of the gains from trade deter political leaders from taking actions that are likely to lead to war. Realists challenge this view and argue that because trade and interdependence are usually asymmetrical they often contribute to conflict rather than deter it, either because states may be tempted to exploit their trading partner's vulnerabilities or because domestic groups vulnerable to external economic developments demand protectionist measures, which can lead to retaliatory actions, conflict spirals, and war.

2.3 National-level Theories of War

Systemic-level theories, with their emphasis on the external forces that shape state decisions for war, posit that states in similar situations behave in similar ways. The implication is that factors internal to states have little impact on foreign policy decisions. There is substantial evidence, however, that decisions for war are often influenced by internal political and economic structures, political cultures and ideologies, and domestic political processes, and over the last decade international relations theorists have been giving more attention to domestic factors.

Regime type is particularly important, based on evidence that democratic regimes behave differently in

important respects than do authoritarian regimes. Although democracies get involved in wars as frequently as do authoritarian states, frequently fight imperial wars, and once involved in war often adopt a crusading spirit and fight particularly destructive wars, it is striking that democracies rarely if ever go to war with each other. This 'interdemocratic peace' is based on standard definitions of democracy (fair, competitive elections and constitutional transfers of executive power) and war (which is often distinguished from lesser conflicts by the threshold of a minimum of 1,000 battle-related deaths).

There are several interrelated explanations for interdemocratic peace. To be valid these explanations must account not only for the near absence of war between democracies but also for the fact that democracies get involved in wars just about as much as other states do. One model emphasizes the institutional constraints on democratic leaders—checks and balances, the dispersion of power, and the need for public debate—that enable governmental or societal groups to block attempts by political leaders to take the country into war. Related to this 'institutional model' is the 'political culture model,' which suggests that the norms of peaceful conflict resolution that have evolved within democratic societies are extended to relations between democratic states, and that these norms facilitate negotiated settlements.

Authoritarian leaders face fewer institutional or cultural constraints, and they often attempt to exploit the conciliatory tendencies of democracies. This undermines democratic political leaders' expectations that their conciliatory negotiating strategies will be reciprocated, reduces the internal constraints on their use of force, and provides incentives for democratic regimes to resort to force against authoritarian regimes both to protect themselves and sometimes to facilitate democratic transitions.

The institutional model of interdemocratic peace assumes that political leaders are more inclined to war than are their peoples, but this assumption does not always hold. Jingoistic public opinion, often exacerbated by the media, can force political leaders into wars that they would prefer to avoid or preclude them from making the concessions that might prevent war. There is a strong tendency for the use of force against external adversaries to generate a temporary boost in domestic support for political leaders in the form of a 'rally round the flag' effect. Political leaders anticipate this, and are sometimes tempted to undertake risky foreign ventures in an attempt to distract attention from domestic problems or to blame other states or groups for those problems. Many contemporary ethnic wars result in part from political leaders manipulating images of ethnic rivals and mobilizing their domestic publics against those rivals in order to serve their own narrow political interests. External scapegoating can backfire, however, if it results in a military defeat.

2.4 *Individual-level Theories of War*

Whereas systemic and national-level theories emphasize the role of international and domestic forces that lead to war and suggest that individual political leaders have little impact, other theories give significant causal weight to individuals, their beliefs about the world and specific adversaries, the psychological processes through which they acquire information and make decisions, and their personalities and emotional states. Some theories emphasize cognitive limitations and affective variables that impact most people in similar ways and result in standard patterns of deviations from ideal-type models of rational decision making. Other theories emphasize the variations among political leaders in the way they define state interests, perceive threats to those interests, assess the intentions of adversaries, evaluate the merits of alternative strategies to achieve those interests, use the lessons of history to shape current policies, and respond to the pressures and uncertainties of foreign policy crises. Misperceptions of the intentions and capabilities of adversaries and third states can be a particularly important cause of war.

3. *Conclusion*

Although the levels-of-analysis framework initially led scholars to focus on the question of which level of analysis was most important in the causes of war, and thus to emphasize single-level explanations, attention has recently shifted to the question of how variables at different levels interact in the processes leading to war.

War Crimes Tribunals

From Nuremberg to The Hague and Kigali, the latter half of the twentieth century witnessed the beginnings of an international framework for the prosecution and punishment of war crimes. Yet progress in this area has been sporadic and discontinuous, often seeming to reveal as much or more about what does *not* work as about what does. Contemporary efforts to establish a permanent international criminal court usually are traced to the Universal Declaration of Human Rights adopted by the United Nations General Assembly a half-century ago. These efforts continued through a summer of 1998 meeting of more than 100 nations in Rome that led to a tentative treaty to establish a permanent international criminal court (ICC). Continuing efforts include war crime tribunal activity in relation to the wars in Rwanda and the former Yugoslavia and ongoing efforts to ratify and implement the treaty for a permanent court through the United Nations. Although there is much anecdotal and growing empirical evidence of the need for a permanent institution to deal with war crimes, there is a lack of social science analysis and a resulting knowledge base that could help to broaden the foundation of support for an international criminal court by the public. The agenda of such a court increasingly is recognized as not only involving righting wrongs of the past but also preventing war crimes in the future.

1. *The Lessons of War*

A lesson of World War I was that, left to their own devices, vanquished as well as victorious nations often will do little to punish war criminals appropriately (Marrus 1997). Following World War I, the vulnerable politicians of the fledgling Weimar Republic insisted that the prosecution and punishment of German war criminals should be handled by the German Supreme Court in Leipzig. The resulting sentences ranged from two months to four years of imprisonment and were given to only six of 12 war criminals tried from a list of more than 900 suspects supplied by the Allied forces.

The proceedings at Nuremberg following World War II were a notable improvement. The results of Nuremberg are made more notable by the fact that public opinion tended to simply favor summary execution of the captured leaders of the Axis powers. Franklin Roosevelt's Secretary of War, Henry Stimson, argued instead for a trial before an international tribunal. Roosevelt's successor as president, Harry Truman, endorsed the trial model and persuaded the Allied powers to work through the United Nations in establishing the International Military Tribunal (IMT) to prosecute and punish 'crimes against peace,' 'war crimes,' and 'crimes against humanity.'

The resulting Nuremberg Indictment was regarded as an extension of the common law of the nations involved, although this common law was far from universally recognized at the time of Nuremberg. A defense posed in response to the resulting prosecutions was that the tribunal's charges were *ex post facto*, retroactive creations. Marrus (1997, pp. 565–6) notes that the Harvard criminologist and law professor, Sheldon Glueck, responded with the common law retort that

> Surely … Hitler, Himmler, Goering, Ribbentrop, Frank, Doenitz, and the rest ... knew full well that murder is murder, whether wholesale or retail, whether committed in pursuance of a gigantic conspiracy to disregard all treaties and wage lawless wars or of a smaller conspiracy evolved by a group of domestic murderers.

Twelve war criminals included under the Nuremberg Indictment received death sentences. Three acquittals also demonstrated that such a tribunal could provide reprieve as well as punishment. The development of a jurisprudence of 'crimes against humanity' was especially noteworthy as an innovation that addressed the persecution of specific groups, in this case including the German Jews as well as other groups. And, of course, Nuremberg helped establish in the public mind the responsibility of individuals to refuse illegal orders. The tribunal's work also brought into limited question some Allied war strategies and methods, including the firebombing of German cities.

But the Nuremberg Tribunal also received justifiable criticism. The presence on the tribunal of Russian judges and the impunity of Stalin and other Russian leaders belied their wartime atrocities. Some charges of 'crimes against peace' were clumsily conceived and pursued. In spite of Eleanor Roosevelt's successful work for the adoption of the Universal Declaration of Human Rights in 1948, this effort expressly rejected a standing tribunal to deal with future war crimes. Similarly, the impetus of the

Nuremberg Tribunal was to put the Nazi war crimes into the past, and the IMT did not become the model it might have for a continuing institutional response to the problems of war crime.

2. *The Balkans and Rwanda*

There certainly was no absence of need for the prosecution and punishment of war crimes following World War II and in our more recent history. A partial contemporary list would certainly include Argentina's 'dirty war,' South Africa's apartheid, Pinochet's Chile, the acts of communist Eastern European governments, as well as more recent events in Bosnia, Kosovo, and Rwanda (Neier 1998). During the Cold War, which lasted for most of the second half of the twentieth century, human rights violations were routinely ignored by the West in the process of supporting anti-communist governments. As the Cold War ended, this tendency was extended in the ostensible interest of promoting democratization. For example, in Pinochet's Chile and Botha's South Africa, amnesties became bargaining devices to promote democratic transitions. In Latin America and in South Africa, truth commissions became compensatory vehicles of reconciliation. The liability of this approach, of course, is that political and military mass murderers have escaped prosecution and punishment.

Events in the Balkans and Rwanda evolved against this international backdrop, with the difference that feminist scholars and activists became involved in exposing the systematic use of rape as an instrument of terror and intimidation in waging war. A United Nations commission assisted by human rights groups found that in the 1990s ethnic Serb military and paramilitary groups had systematically tolerated and encouraged the raping of Bosnian Muslim women as part of the effort to drive Muslims from their communities. This form of sexual violence was recognized as a deliberate tactic used to terrorize and humiliate a civilian population not only through the immediate assaults involved, but also through the creation of forced pregnancies. Rape was also instrumental in the genocidal campaign waged by Hutu troops against Tutsi women in the war conducted in Rwanda in 1994. Both in Bosnia and Rwanda, these tactics were recognized as premeditated acts of war aimed at women.

Commission and human rights work in the Balkans and Rwanda formed the foundation for the demand that rape be recognized internationally as a war crime, in a manner analogous to assaults against noncombatants, mistreatment of prisoners, torture, and other systematic, deliberate, and premeditated forms of violence. This innovation was crucial in the formation by the United Nations Security Council of two *ad hoc* criminal tribunals for the former Yugoslavia and Rwanda in 1993 and 1994 respectively. Justice Richard Goldstone served as the first war crimes prosecutor for the Balkans and Rwanda and played an important role in successfully treating sex crimes as a form of genocide and as crimes against humanity.

Each of the *ad hoc* tribunals currently has investigators, police officers, military analysts, legal advisers, trial lawyers, and judges who are involved in developing and trying cases, from the exhumation of mass graves through the preparation of formal indictments and court proceedings, with trials, dispositions, and appeal hearings held in Arusha, Tanzania and The Hague, Netherlands. The tribunal investigators and prosecutors play unique roles through their daily contacts with victims and witnesses. This involves building the trust and cooperation that is necessary in translating victims' and witnesses' stories of atrocities into the testimony that is needed to try cases. The most severe sentence that is available to the tribunals is life imprisonment.

The tribunals have indicted about 20 persons a year since their formation. Moving from indictment to arrest and prosecution is often a formidable process, since the tribunals must rely on the police and armed forces of cooperating nations to apprehend and take indicted persons into custody. As of spring 1999, 34 persons had been arrested and charged before the Rwanda tribunal, and 26 before the tribunal for the former Yugoslavia. Assuming custody and the initiation of a prosecution, the nature of the cases and severe prospective punishments creates further incentives for the accused to delay the beginning of a trial and then pursue a lengthy defense. Justice Goldstone's successor as the chief tribunal prosecutor, Justice Louise Arbour, attempted to speed up the process by trying accused in groups, but she was rebuffed by the Court. Justice Arbour is recognized for numerous reforms and innovations that have dramatically improved and expanded the role of the *ad hoc* tribunals. The tribunal in Rwanda was mired in United Nations bureaucracy and allegations of corruption until a shakeup by Arbour that led to increased arrests and the successful prosecution of a former prime minister held responsible for a genocide that included the slaughter of more than 700,000 Rwandans in 1994. At one point, Arbour was physically prevented from entering Kosovo by Yugoslavian border guards. Undeterred, she pursued the indictment of former Bosnian Serb President Radovan Karadzic and the General Ratko Mladic. When Arbour assumed her position there existed no clear precedent for indicting a sitting head of government for war crimes, although Admiral Karl Doenitz, as the Nazi head of state following Hitler's suicide at the end of World War II, had been convicted and imprisoned for war crimes at Nuremberg. Arbour established a clear precedent when she obtained a war crimes indictment against Serbian President Slobodan Milosevic. She gained further attention when she remarked in public that

NATO leaders could conceivably stand trial for air strikes that caused civilian deaths in Yugoslavia. This signal of evenhandedness is important because figures such as Milosevic have drawn comparisons between killings in Kosovo and the execution of Vietnamese villagers by American soldiers during the war in Southeast Asia. One of Arbour's most significant achievements involved bringing war crimes prosecutions fully into the present as a 'real-time' institutional response to atrocities and genocide virtually as they happened in Kosovo.

The scale of the tasks that confront war crimes tribunals of the kinds recently established is suggested by the situation in Rwanda where more than 100,000 people, almost all Hutus, have been held in jail on charges stemming from the massacres and other crimes involved in that country's genocidal conflicts. No legal system can put all of the guilty through full and formal trial procedures, but prosecuting high-level or representative perpetrators is essential to achieving a sense of justice. There is a clear contrast between the Western-influenced emphasis on time-and-resource-consuming procedural safeguards in the tribunal context and the expedited forms of criminal and civil dispute resolution practiced in settings such as the Rwandan courts. Some combination of jurisdictions is required, with tribunal responsibility for cases with greater potential impact nationally and internationally. This kind of issue has complicated calls for a more permanent court for war crimes.

3. *An International Criminal Court*

The Balkan and Rwandan tribunals have served as prospective models for a permanent international court. In July 1998, more than 100 countries met in Rome with American participation to negotiate a treaty creating a permanent war crimes tribunal that would act independently of the United Nations and its Security Council. The result was a vote approving in principle an International Criminal Court (ICC) with powers to try cases of genocide, war crimes, crimes against humanity, and crimes of aggression. The positive votes for the treaty to establish the court came from 120 nations, with 21 nations abstaining and seven nations opposed, including the USA. Unlikely allies of the USA in this opposition included Libya, Algeria, China, Qatar, and Yemen, with Israel also not signing.

American officials involved in the negotiation of the treaty were especially concerned about the risks the ICC could pose to its own military and political purposes and personnel. These officials were quick to note that with about 200,000 military personnel permanently stationed in about 40 countries around the world, the USA has much at stake. The risk for the USA, it is argued, is increased by expectations that this nation act quickly in crisis situations, and that the world relies on the USA's being able to do so without fear of arbitrary litigation and liability. The worry is that countries such as Cuba or Libya would use the court to harass the USA in its legitimate efforts. To address this concern, the US negotiators in Rome sought guarantees that American military forces and agents would not be prosecuted by the ICC without US consent. At one point in the deliberations an American motion to obtain such guarantees was refused by a vote of 113 to 17, with 25 abstentions. The concern was that if the USA achieved such a loophole, other nations would expect similar protection. Despite the strong support from most nations for the establishment of the ICC, its future remains in doubt. The treaty requires formal ratification by at least 60 nations before it can take effect.

The provisions of the treaty provide that the ICC could proceed with a case if the accused was from a signatory nation or the crime took place within a country that had ceded jurisdiction to the international body. The court could not take jurisdiction over a case unless a national court failed to act, leading advocates to argue that its existence could constitute an important institutional incentive for countries to prosecute their own war criminals. The court would be made up of an international panel of judges, a prosecutor's office, and an administrator; it would presumably rank along with other international institutions such as the World Trade Organization, the International Monetary Fund, and the World Bank. The jurisdiction of this court is over individuals, as distinct from the International Court of Justice in The Hague, which settles disputes between countries. A key premise is that an indictment by the court of a citizen or a leader of a country would be a serious matter that would restrict the movement of those involved and in this way immediately have a significant impact, even without arrest or prosecution.

Hundreds of citizen human rights and legal groups, such as the New York-based Human Rights Watch and the International Center for Human Rights and Democratic Development in Montreal, support the creation and establishment of the ICC. The failure of the USA to strongly support the ICC is a frustration to many of these groups. Eleanor and Franklin Roosevelt were prime movers in the adoption of the Universal Declaration of Human Rights, the founding document from which many treaties of this type have followed. Yet the USA has often lagged behind other nations in the ratification of such treaties. For example, it took the USA fully 40 years to ratify the Genocide Convention. So while the USA played a major role in establishing the Rwandan and Balkan tribunals, it continues to maintain a reluctant stance with regard to the ICC.

Perhaps the strongest argument that can be made against American approval for the ICC is the control the USA might lose over the use of war crimes prosecutions as a bargaining chip in its negotiations

over the complicated conflicts it seeks to control around the world. The perplexing complexity of such negotiations was revealed with all of its frustrations in the Balkan conflict. The Clinton administration sought a settlement that would avert a war over Kosovo through its negotiation of the Dayton Accords. At first it seemed that the United Nations war crimes tribunal had assisted this process by indicting Radovan Karadzic and elevating the position of Slobodan Milosevic. However, Milosevic soon proved to be no better a partner for peace than Karadzic, and the Serbian violence was allowed to continue, resulting in his belated indictment as well. The lesson may simply be that mass killings and genocide will continue to occur until a system of deterrents comes into effect through an institution such as the ICC.

It is of special note that two of America's closest allies, Canada and Great Britain, have taken a particular interest in the Rwandan and Balkan tribunals and the ICC, often seeming to lend more durable support than the USA. The Canadian Foreign Minister, Lloyd Axworthy, built on the leadership role played by the Canadian jurist, Louise Arbour, during her term as Chief Prosecutor of the Rwandan and Balkan tribunals. Both have emphasized that armed conflicts in the world now increasingly involve struggles within rather than between nations, with parallel increases in civilian as opposed to military casualties. They argue this requires new ways of thinking about and dealing with issues of national sovereignty, so that efforts to protect the latter do not become shields used by political and military leaders to cloak such crimes as murder, torture, rape, forced deportations, and expulsions. During the Kosovo crisis in particular, and the subsequent Milosevic indictment, the British government showed a firm resolve to use international criminal law to deal with intra-national crimes against humanity.

The Canadian-born and now British-based journalist Michael Ignatieff, and the British lawyer and human rights activist Geoffrey Robertson, have been among the most effective spokespersons for a permanent international criminal court. Ignatieff's (2000) book, *Virtual War*, makes a powerful argument for just how much the politics and technology of war have changed in recent decades. Ignatieff argues that it is our failure of moral imagination to keep pace with these changes that inhibits the movement to a permanent international criminal court. Robertson's (2000) book, *Crimes Against Humanity*, paints a historically and geographically sweeping picture of a world in which violent human rights abuses more often than not go unpunished. Nonetheless, Robertson argues that the Balkan and Rwandan tribunals signal a new 'age of enforcement' that is promising and already in progress. Many share Robertson's hope that these tribunals will continue to evolve into a permanent ICC.

4. *Research Priorities*

Many important questions remain regarding war crimes tribunals. In particular, it will be important to learn how the international prosecution of war crimes is organized and to contrast this with the work of national justice systems, such as Rwanda's, which may also prosecute and punish war criminals in large numbers. Answers to the following kinds of questions would be especially useful in expanding our knowledge base: How are the presumed worst offenders and offenses selected for international prosecution? How are prosecutors and judges selected for tribunal work? What are the patterns of conviction and punishment? What is the role of international public opinion in influencing the tribunals and the prospective permanent court? What are the effects on the prosecutors and judges who become involved in this work? What are the prospects of a more permanent international criminal court and how might its work differ from the current efforts of the *ad hoc* tribunals? The importance of international war tribunal work seems obvious, and our knowledge of this work is unfortunately modest.

War, Political Violence and their Psychological Effects on Children: Cultural Concerns

1. *The Problem*

Social science research on children and war can be traced back to at least the first World War but began

in earnest during World War II. For most of this time this work has been regarded as outside the mainstream of psychological research largely because it was believed that few children were exposed to war or political violence. This is beginning to change because today civilians are increasingly becoming the victims of war. World War I recorded 10 percent civilian casualties; World War II some 50 percent, but in all subsequent wars around 80 percent of casualties have been civilians.

While it is difficult to say how many of these casualties have been children, one estimate is that during the 1980s alone some 1.5 million children may have died while an additional 4 million may have been injured. Further, even more children (perhaps as many as 15 million) may have managed to escape physically but still have had their lives thrown into turmoil as they and their families fled to other countries or became 'internally displaced' within their own countries.

2. *Mental Health*

Despite this long history the field today still focuses mainly on its initial area of concern—the possibility that exposure to political violence is a traumatizing experience for children. Certainly there is evidence that war experiences can lead to clinical illnesses involving a wide variety of variety of symptoms typically referred to as post-traumatic stress disorder (see *Anxiety Disorder in Children*).

The empirical evidence however, suggests that such suffering is not inevitable. This conclusion is based on relatively sound evidence that has been accumulated over the last half century. The only weakness in this area, it could be argued, is that researchers have tended to rely too heavily on teacher and parental estimates of child stress levels, with not enough direct measures from children themselves. A further problem is the almost complete lack of studies in which children have been seen both before and after their exposure to political violence.

The realization that children show resilience even when exposed to political violence has led investigators to search for those factors which may be helping at least some children to escape the more severe forms of stress. Early candidates in this area included personal factors such as age, sex, and personality. Surprisingly, in the context of political violence, very few studies have examined these in any systematic way, which makes it difficult to draw clear conclusions.

Additional sources of social support have attracted speculation including the extended family, the child's peers, and the wider community. Here the evidence is almost entirely anecdotal but provides many interesting ideas that warrant empirical investigation. The cognitive-phenomenological model of coping may indicate a way forward in this area. For example there is some evidence that the child's religious and political beliefs may influence the way in which political violence is appraised. On the other hand, we appear to know almost nothing about children's sources of information regarding political violence and how they evaluate these sources.

Also problematic is the long-term effect of exposure to political violence. Evidence from holocaust survivors provides the largest source of information on this subject. Here it appears that claims of universal difficulties in later life have possibly been exaggerated. In contrast, evidence from children who become refugees is mildly optimistic, at least in the medium term, with the role of the child's pre-refugee family support emerging as an important factor. Again, much of this is based on weak evidence. Unfortunately studies in this area often lack adequate (or any) control groups, while samples are open to bias because they are obtained from clinical sources.

3. *Attitudes and Values*

Either because children are modeling themselves on the adults around them or because aggressive behavior is a form of coping, the expectation has been that exposure to political violence will lead to an increase in aggressive behavior, for example when interacting with peers.

Several well-designed studies have examined this question, but evaluating the evidence is difficult because no two studies are identical. Some have involved children exposed to long-term political violence, but only one of these employed observational methods. In another study the children were observed but had only been exposed to political violence for a short time. Therefore despite the unusually high quality of the evidence, no clear conclusions can be reached. If nothing else, this illustrates the urgent need for cross-national replication of research in this area.

There has also been much speculation that children's moral attitudes and values may be altered by exposure to war, however, once again there is little empirical evidence testing this hypothesis. What evidence there is appears to come almost exclusively from one society—Northern Ireland. The suggestion is that children in Northern Ireland may have an underdeveloped sense of the complexity of moral problems. This comes from research using measures of moral reasoning. However, when moral behavior (measured using paper and pencil tests) has been examined, no effect for political violence has been found.

Whatever the explanation, permanent changes in morality are almost certainly not linked to an increase in crime among young people at this time. Juvenile crime does increase with increasing political violence but the most likely explanation for this is the absence of authority figures, such as fathers or the police, combined with extreme levels of deprivation.

4. *Social Problems*

Of course the 'normal' problems that children face during childhood do not evaporate simply because of the onset of political violence, in particular the disadvantages associated with lower socioeconomic status. Therefore, even for children in societies where there is political violence, the major hurdles of everyday life remain to be surmounted. In addition, because political violence can damage the general infrastructure of society, for example, disrupting medical services or the food supply, children may be exposed to many risks other than the obvious problems of dealing with bombs and bullets, including increased risk of accidental injury or death. These conclusions are based on good evidence. Further evidence is also now becoming available to suggest that it is likely that there is a cumulative effect with the direct negative consequences of political violence added to the effects of economic and social disadvantage.

Part of this increased risk may be due, it has been suggested, to the fact that the whole family structure comes under stress as a result of political violence. In particular this may include changes in child-rearing tactics. Further, there is speculation that these changes may carry over to influence the way in which the next generation bring up their children. Unfortunately, despite the importance of this area, the amount of hard evidence is almost negligible. Only the speculation that changes in child-rearing styles accompany exposure to political violence has really been tested and even then only in a very limited way.

In many societies schooling is an important factor in the everyday life of children. Anecdotal evidence suggests that where schools can be kept open they may act as to protect children but this needs to be confirmed empirically. On the other hand, it is clear that political violence can and often does disrupt schooling, either because children do not attend school or because schools are forced to close. The evidence for this is reliable but is confined to developed societies.

5. *Child Combatants*

Children are not always passive victims of war and/or political violence but may be involved in several different ways. By far the largest of these consists of younger children who are involved at the periphery, often in such overt political activities as rioting or demonstrating. In some societies, however, for example in South Africa and Palestine, this form of activity involved large numbers of young people and their role became central to the political struggle. Older children are more likely to be involved in clandestine activities as members of a terrorist organization. A variety of hypotheses have been entertained as to why children become involved in this form of urban guerrilla warfare. These include the thrill of danger, extension of gang related activities common at this age, or the possibility that they are modeling themselves on adult behavior. A more worrying suggestion is that the role of adult involvement is more overt—the Godfather hypothesis.

This raises the question of the relationship of these children with their families: do families approve, encourage, admire, or do they disapprove? In terms of hard evidence we know very little about these or other questions. Basically we know that children are involved but we don't know why.

Membership of paramilitary groups or guerrilla armies probably involves smaller numbers of children and young people who, as noted above, are often slightly older than their stone throwing brother and sister. In this area it may be important to recognize two types of groups, anarchic/ideologues and nationalist/separatists. Probably more children and young people join the latter.

It is clear that it is not possible to fit these young people into any particular sociodemographic or psychological categories. In particular there is little evidence to support the common claim that guerrilla organizations attract a disproportionate number of psychopathic individuals. Nor is it likely that there is a particular 'terrorist type'—even with wide criteria such as action oriented, aggressive, and sensation seeking. Instead rewards may play a role such as prestige, glamour, excitement, and even material rewards. It is not clear however if these are the reasons people join in the first place or are these factors which sustain membership?

Rather than suggesting that individuals are motivated to become political activists because of certain psychological characteristics or because of the lure of rewards, it is hypothesized that children are socialized into this role in subtle ways, particularly via the indirect impact of institutions such as the family. Also there is the possibility that schools may influence children's political ideas in certain societies, especially through the teaching of history. Of course not all history is taught in schools and in more recent times media coverage of other political struggles has also been implicated in this socialization process as paradoxically have prisons. There is also some intriguing qualitative evidence that being a victim or witnessing another become a victim may play a role in stimulating young people to become politically involved.

Finally, the UN convention notwithstanding, it must be remembered that there are still many state-run armies around the world that include children in their ranks. In addition there are many young people, mostly boys (hence the term 'boy-soldiers') who are press-ganged into serving, usually with irregular forces.

As conflicts come to an end the fear is often expressed that child member of groups trained to kill or maim will not be able to be resocialized. Anecdotal evidence suggests that this is not necessarily true. One

possible explanation, which is yet to be tested empirically, is that a key element in membership of paramilitary groups may be the development of a morality of loyalty which in turn is related to the development of a relevant situated social identity.

This is obviously a very difficult to area in which to get hard evidence. The existing evidence therefore comes from atypical group members, is largely anecdotal, and has mostly been gathered by journalists rather than social scientists. It could be argued, however, that scholars could make more use of these as primary sources. Probably the only thing we can claim to have any firm evidence on is that children and young people who join nationalist/separatist guerrilla movements are not psychopaths and come from no particular social strata of society. Other hypotheses including ideas of 'terrorist personality types' or psychodynamic explanations will always be very hard to substantiate.

6. *Children and Peace*

One of the problems, it has been suggested, in bringing peace to societies that have experienced political violence is that the next generation will have either begun to believe that there is no future, or that they will be able to think of the future only in negative terms.

Given that we know little about the way in which children develop concepts of peace and war it could be argued that it is premature to try to educate children to be peace makers (see *Peace Promotion, Psychology of*). Despite this lack of basic knowledge this process has already begun in some societies and some people apparently believe it is effective. However, there is virtually no empirical evidence to substantiate their claim. A major problem would appear to be that too much of what passes for peace education focuses on interpersonal conflict as opposed to intergroup conflict. In future, curriculum designers need to produce a more effective peace education program and also to overcome the problem that peace education *per se* is not always politically acceptable.

It could also be argued that school-based peace education is always bound to be ineffective because it targets the wrong people in the wrong setting. For example, there is speculation, if not evidence, that children's ideas about peace and war may be more influenced by what they learn from their parents than from their schools. There is definitely evidence, which is now often forgotten, that learning about such things as peace and war involves emotions primarily and that providing facts may not alter these emotions. This is obviously an area which is in need of much more research which develops what is known and makes it amenable for use in applied settings.

The alternative to peace education which is most often advocated is bringing children together from opposing groups in order to foster positive intergroup attitudes—the contact hypothesis. This has been a well-researched area for many years and now boasts an extensive literature. What this literature indicates is that for contact to be even minimally effective it has to take place under highly prescribed conditions. However, what advocates of the contact hypothesis appear to be reluctant to accept is that while there is evidence that bringing groups together promotes interpersonal contact satisfactorily, it does not necessarily promote intergroup contact.

There is also good evidence that intergroup conflict can be reduced by manipulating the process of social categorization in order to alter group boundaries. This is a strategy that both social scientists and policy makers should consider more often. The evidence also suggests it is not possible to bring social categorization to an end entirely. Rather it is better to concentrate on altering the content of stereotypes or manipulating who gets put in which social category by altering intergroup boundaries.

War, Sociology of

The sociology of war is a central topic in both political and historical sociology, since war is one of the most important policies states can pursue, and the outcomes of wars have often shaped both the formation and the dissolution of states. The literature on war is thus concerned with both its causes and its consequences.

Studies of the causes of war can be divided into three broad categories. The first type takes the system as a whole as the unit of analysis and focuses on how

characteristics of the interstate system affect the frequency of war. Debates focus on characteristics of the interstate system that are thought to increase or decrease war, such as global economic cycles, balances of power, and the increasing role of transnational organizations such as the United Nations. States are the unit of analysis in the second type, which explores the relationships among political, economic, and cultural features of particular states and their propensity to initiate wars. Social scientists disagree about the effects of political systems (democracy vs. autocracy) and economic systems (capitalist, socialist, or other) within states on war. The third type analyses war as an outcome of choices made by individual and small-group decision making. There is also no consensus on which model of individual decision making is most appropriate for the study of war. Is the decision to go to war based on a rational calculation of economic costs and benefits, or is it an irrational outcome of distortion in decision making in small groups and bureaucracies?

Theories of the consequences of war tend to focus either on its role in state formation, or on its causal impact on internal revolts and revolutions. Historical sociologists have shown that the frequency, duration, and timing of medieval and early modern warfare were the most important determinants of the size and structure of states (Tilly 1975, 1990, Ertman 1997). However, just as war can make states, it can break them too. For example, Skocpol (1979) argues that costly warfare often leads to fiscal crises and state breakdown, facilitating revolutions.

1. *Causes of War: The Interstate System*

Most studies of war that take the interstate system as the unit of analysis begin with assumptions from the 'realist' paradigm. States are seen as unitary actors, and their actions are explained in terms of structural characteristics of the system. The most important feature of the interstate system is that it is anarchic. Unlike politics within states, relations between states take place in a Hobbesian 'state of nature.' Since an anarchic system is one in which all states constantly face actual or potential threats, their main goal is security. Security can only be achieved in such a system by maintaining power. In realist theories, the distribution of power in the interstate system is the main determinant of the frequency of war.

Although all realist theories agree on the importance of power distribution in determining war, they disagree about which types of power distributions make war more likely. Balance-of-power theories (Morgenthau 1967) suggest that an equal distribution of power in the system facilitates peace and that unequal power distributions lead to war. They argue that parity deters all states from aggression and that an unequal power distribution will generally result in the strong using force against the weak. When one state begins to gain a preponderance of power in the system, a coalition of weaker states will form to maintain their security by blocking the further expansion of the powerful state. The coalitions that formed against Louis XIV, Napoleon and Hitler seem to fit this pattern.

Hegemonic stability theory (Gilpin 1981) suggests exactly the opposite, that unequal power in the system produces peace and that parity results in war. When one state has hegemony in the world system, it has both the incentive and the means to maintain order in the system. It is not necessary for the most powerful state to fight wars, since their objectives can be achieved in less costly ways, and it is not rational for other states to challenge a hegemon with overwhelming power. For example, the periods of British and US hegemony were relatively peaceful and World Wars I and II occurred during intervening periods in which power was more equally distributed. A related attempt to explain great-power war is power transition theory (Organski 1968). Power transition theory suggests that differential rates of economic growth create situations in which rising states rapidly catch up with the hegemonic state in the system, and that this change in relative power leads to war.

Debates about power transitions and hegemonic stability are of much more than theoretical interest in the contemporary world. Although the demise of the USSR has left the USA as an unchallenged military hegemon, its economic superiority is being challenged by the European Union and emerging Asian states (Japan in the short run, perhaps China in the long run). If power transition and hegemonic stability theories are correct, this shift of economic power could lead to great power wars in the near future.

Another ongoing debate about systemic causes of war concerns the effects of long cycles of economic expansion and contraction. Some scholars argue that economic contraction will increase war, since the increased scarcity of resources will lead to more conflict. Others have suggested the opposite: major wars will be more frequent during periods of economic expansion because only then will states have the resources necessary to fight. Goldstein's (1988) research suggests that economic expansion tends to increase the severity of great-power wars but that economic cycles have no effect on the frequency of war.

One significant change in the last half of the twentieth century which will require substantial revisions in realist systemic theories of war is the development and increasing power of transnational organizations (such as the United Nations), since their assumption that the interstate system is anarchical may no longer be valid. If the military power of the United Nations continues to grow, it could become more and more effective at preventing wars and suppressing them quickly when they do start. Of course, it remains to be seen whether powerful existing

states will choose to cede more power to such institutions.

Theoretical debates about the systemic causes of war have not been resolved, in part because the results of empirical research have been inconclusive. Each theory can point to specific cases that seem to fit its predictions, but each must also admit to many cases that it cannot explain. Part of the problem is that systemic theories have not incorporated causal factors at lower levels of analysis, such as internal economic and political characteristics of states. Since the effects of system-level factors on war are not direct but are always mediated by the internal political economy of states and the decisions made by individual leaders, complete theories of the causes of war must include these factors as well.

2. *Causes of War: Capitalism and Democracy*

One of the longest and most heated debates about the causes of war concerns the effects of capitalism. Beginning with Adam Smith ([1776]1976), liberal economists have argued that capitalism promotes peace. Marxists (Lenin [1917]1939), on the other hand, suggest that capitalism leads to frequent imperialist wars.

The Smithian liberal argument suggests that since capitalism has both increased the benefits of peace (by increasing productivity and trade) and the costs of war (by producing new and better instruments of destruction), it is no longer rational for states to wage war. The long period of relative peace that followed the triumph of capitalism in the nineteenth century and the two world wars that came after the rise of protectionist barriers to free trade are often cited in support of liberal economic theories (but the same facts can be explained by hegemonic stability theory as a consequence of the rise and decline of British hegemony).

In contrast, Marxists (Lenin [1917]1939) argue that economic problems inherent in advanced capitalist economies create incentives for war. First, the high productivity of industrial capitalism coupled with a limited home market due to the poverty of the working class result in a chronic problem of 'underconsumption.' Capitalists will thus seek imperial expansion to control new markets for their goods. Second, capitalists will fight imperialist wars to gain access to more raw materials and to find more profitable outlets for their capital. These pressures will lead first to wars between powerful capitalist states and weaker peripheral states, and next to wars between great powers over which of them will get to exploit the periphery.

With the increasing globalization of economics, and the transitions of more states to capitalist economies, the debates about the effects of capitalism, trade, and imperialism on war become increasingly significant. If Adam Smith is right, our future is likely to be more peaceful than our past; but if Marxist theorists are right, we may see economically based warfare on an unprecedented scale.

The form of government in a country may also determine how often it initiates wars. Kant ([1795]1949) argued that democratic states (with constitutions and separation of powers) will initiate wars less often than autocratic states. This conclusion follows from a simple analysis of who pays the costs of war and who gets the benefits. Since citizens are required to pay for war with high taxes and their lives, they will rarely support war initiation. Rulers of states, on the other hand, have much to gain from war and can pass on most of the costs to their subjects. Therefore, when decisions about war are made only by rulers (in autocracies), war will be frequent, and when citizens have more control of the decision (in democracies), peace will generally be the result.

Empirical research indicates that democratic states are less likely than nondemocratic states to initiate wars, but the relationship is not strong (Kiser et al. 1995). Perhaps one reason for the weakness of the relationship is that the assumption that citizens will oppose war initiation is not always correct. Many historical examples indicate that in at least some conditions citizens will support war even though it is not in their economic interests to do so, due to nationalism, religion, ethnicity, or other cultural factors.

Perhaps the most interesting current debate about democracy and war surrounds the proposition that democratic states never fight each other. There is clearly a strong empirical generalization to be explained, since all agree that democratic states rarely fight each other—depending on exactly how 'democracy' and 'war' are defined, some argue they never do (Weart 1998). However, scholars disagree about the causal mechanism responsible for this association. Some stress the role of political culture, arguing that the norms of toleration and mutual accommodation that prevent conflicts within democracies from escalating to violence have the same effect in limiting violent conflicts between democracies. These states consider each other part of the same 'ingroup' sharing the same values, and are thus very unlikely to fight. In contrast, others suggest that 'democratic peace' could be the result of rational self-interest. Democratic politicians may simply fear the negative impact that losing a war might have on their prospects for re-election. Further research, probably at the level of detailed case studies that can reveal precise causal mechanisms, will be necessary to resolve this debate.

3. *Causes of War: Decision Making*

Few theories of war focus on the individual level of analysis; their assumptions about individual decision making are usually implicit or undeveloped. Notable exceptions include rational choice theories (Bueno de Mesquita 1981, Bueno de Mesquita and Lalman 1992)

and arguments about organizational and small group decision making (Allison 1971).

Bueno de Mesquita begins by assuming that the decision to initiate war is made by a single dominant ruler who is a rational expected-utility maximizer. Rulers calculate the costs and benefits of initiating war, and the probability of victory, so wars will be initiated only when rulers expect a net gain from them. These assumptions generate several counterintuitive propositions. For example, common sense might suggest that states would fight their enemies and not their allies, but Bueno de Mesquita (1981) argues that war will be more common between allies than between enemies. Wars between allies are caused by actual or anticipated policy changes that threaten the existing relationship. The interventions of the USA in Latin America and of the USSR in Eastern Europe since World War II illustrate the process. Other counterintuitive propositions suggest that under some conditions a state may rationally choose to attack the stronger of two allied states instead of the weaker, and under some conditions it is rational for a state with no allies to initiate war against a stronger state with allies.

Other analyses of the decision to initiate war focus on how the social features of the decision-making process lead to deviations from rational choice. Allison (1971) argues that standard operating procedures and repertoires within states tend to limit the flexibility of decisions and make it difficult to respond adequately to novel situations. Others focus on the small groups within states (such as executives and their cabinet advisers) that actually make decisions about war. The cohesiveness of these small groups often leads to a striving for unanimity that prevents a full debate about options and produces a premature consensus. In spite of these promising studies, work on the deviations from rational choice is just beginning, and we are still far short of the general microlevel theoretical model of the decision to initiate war.

4. *Consequences of War: State Formation and Bureaucratization*

How and to what extent does war affect the formation and the structure of states? Tilly (1975, 1990) argues that 'war made states' in the early modern era. Warfare (along with the repayment of debts from past wars) cost far more than any other state policies in early modern Europe. Moreover, the timing and the nature of war shaped the structures of these developing states.

One of the most interesting ongoing debates concerns whether war facilitates or hinders bureaucratization. Weber ([1922]1978) argued that states involved in military competition with other states (e.g., Western Europe) would be more likely to bureaucratize than those that were more isolated (e.g., China, Japan). Although he does not use this terminology, he basically argues that states not facing the threat of war would be satisfied with existing administrative arrangements, whereas those competing militarily would be forced to adopt the more efficient bureaucratic form.

In contrast to this, Levi (1988) views war as a consistent impediment to bureaucratization. She argues that war raises the discount rates of rulers, causing them to pursue policies that provide immediate gains even if they are costly in the long term. Thus, rulers facing war would be unlikely to pay the high start-up costs of bureaucratization, but would instead do things like selling offices which would make bureaucracy much more difficult to implement.

Ertman (1997) suggests a related argument in which the timing of war is important. When states experienced early sustained warfare (prior to about 1450) they developed patrimonial administrations (due to lack of trained personnel and the dominance of 'cultural models' derived from feudal and Catholic institutions). These institutions were very difficult to bureaucratize due to the power of entrenched officials to block reform. Ertman argues that states that were able to avoid frequent war until later were able to develop more bureaucratic administrations.

Finally, wars that result in severe losses may facilitate bureaucratic reforms. One of the main barriers to bureaucratization is the entrenched officials in the state administration who have both the incentives and the power to block reform (Ertman 1997). These officials will not be dislodged by most wars, but their power will be broken by a severe loss at war, especially one that results in foreign occupation.

5. *Consequences of War: Revolt and Revolution*

Since the classic work of Simmel ([1908]1955, pp. 98–9) and Coser (1956, pp. 19, 95), the conventional wisdom has been that wars decrease the probability of revolts by increasing the internal cohesion of societies (the 'ingroup–outgroup' or 'conflict–cohesion' hypothesis). However, the results of empirical tests of the relationship between revolt and war have been mixed, at best.

In contrast to the 'conflict–cohesion' hypothesis, historical sociologists focusing on the early modern period (Tilly 1975, p. 74) argue that fighting wars increased the likelihood of revolts. Tilly argues that since subjects had few institutionalized mechanisms available to stop rulers from initiating wars contrary to their interests, the only option they had to try to limit war was revolt. In addition, Tilly (1975, p. 74) notes that since participating in wars weakens rulers, it increases the likelihood of a revolt.

Theda Skocpol (1979) has made the most compelling argument that war is a primary cause of major 'social revolutions.' Her argument about the origins of the French, Russian, and Chinese revolutions stresses the importance of factors that weaken the state,

making it more vulnerable to overthrow. The main factor that tends to weaken states is war, especially in the context of strong peasant communities and an alienated dominant class. This work has been the primary inspiration for the development of a 'state-centered' approach to historical sociology.

6. Conclusion

This short summary has only been able to scratch the surface of the voluminous literature on war. Future research should attempt to link the several topics discussed here, by bringing together the micro and macro causes of war, and by tying the causes more closely to the consequences of war. The increasing development of technologies of mass destruction and the rise of transnational political units will also challenge existing theoretical frameworks. Like most of sociology, the sociology of war is still in its infancy.

Warfare in History

This article divides the history of warfare into five periods: the classical era (including the wars of Greece and Rome); the Middle Ages (roughly from AD 500 to the Turkish conquest of Byzantium in 1453); the age of gunpowder (from 1453 to the American and French Revolutions beginning in 1776); the 'long nineteenth century' (from 1776 to 1918); and finally the contemporary period (covering World War II and the Cold War). Each of these periods will be defined by changes in three dimensions. First and most obviously, each period is associated with a general group of military technologies. Second, each period also involves a shift in the nature of military organization. Finally, this periodization demonstrates changes in the reasons why people have gone to war.

1. The Classical Period

1.1 Technology

The Classical period deserves consideration on its own merits and in the context of an historical debate over the influence of Greco-Roman warfare on later European patterns. In the field of technology, some historians argue that the Greeks and Romans began a pattern of using superior technology to compensate for having to fight wars against numerically superior enemies. The Persian Wars of the fifth century BC demonstrated the need for Greek city-states to combat the much larger armies of Persian kings Darius and Xerxes. Needing to slow the Persians, Spartan general Leonidas threw his much smaller force into a mountain pass near Thermopylae in 480 BC knowing that it would be destroyed to a man. Aware that his army would not return, Leonidas took with him only those men who had children to succeed them, an important consideration because the army and the citizenry were closely linked.

To avoid future Thermoplyaes, the Greeks developed both offensive and defensive technologies. Eventually, the typical Greek soldier wore nearly seventy pounds of armor and carried spears and swords that

were superior to Persian weapons. These technological solutions helped the Greeks win, but the unity that the Greek city-states showed against Persia soon devolved into internecine wars. During the most famous of these wars, the Peloponnesian War (431–04 BC), technology again proved critical. In this case, Athenian naval vessels attempted to balance the superior land power of their enemy, Sparta. Defensive technologies evolved in counterpoint as Athens, Syracuse, and other city-states built protective walls strong enough to defy even determined sieges.

The Romans also leaned heavily on technology to defeat more numerous enemies, though many Roman military technologies were not necessarily weapons systems. Building upon the Roman genius for engineering, Roman armies assisted in the construction of a system of roads (even today the Roman roads are roughly contiguous with the European highway system) that permitted the legions to move quickly from one point in the empire to another. The Romans also depended upon defensive works such as trenches and walls (Hadrian's Wall in the UK is the most famous example) to contain their enemies rather than fight them. Some historians argue that the Classical tradition bequeathed to later Western militaries the importance of looking for technological solutions to military problems.

1.2 Organization

The Greeks based their military upon the hoplite system. Hoplites (named for their shield, the hoplon) were citizens of the republic and rough social equals. Thus, Greek warfare had no concept directly analogous to the modern division of officers and enlisted men. Greek generals (such as they were) received their appointment by yearly election. Municipal assemblies also voted on when and where the city-state would go to war. As citizens, hoplites participated fully in these elections.

As nonprofessionals, the hoplites needed a fairly simple tactical system because so little time could be devoted to formal training. The result was a dense concentration called a phalanx. A hoplite's shield protected his own left side and his neighbor's right side. Thus the phalanx could only succeed when every hoplite stood his ground, lest the gap between himself and his neighbor be exploited. Once broken apart, a phalanx soon dissolved, resulting in many casualties by trampling.

The Romans trained and organized much more formally than the Greeks. Groups of about 120 men formed 'maniples,' thirty-five of which were then used to form legions of approximately 4,000 infantry and 300 cavalry (the exact sizes of maniples and legions varied significantly over time). This system foreshadowed the modern creation of platoons, companies, and brigades. The Romans used professional gladiators (named for their short, thrusting sword, the gladius) and evolved a concept of officers (usually wealthier citizens) and 'other ranks.' Increased sophistication and professional training allowed the Romans to develop a military that used various weapons, including soft iron javelins called pila. The soft iron bent on impact so that enemies could not throw them back. If victorious, however, Roman smiths could recover the pila after the battle and reshape them. The Roman system gave the legions flexibility, endurance, and striking power that few militaries could match.

The Greek and Roman systems of warfare mirrored their societies. Both preferred service by citizens, perhaps another legacy to modern nation-states. The Roman system extended citizenship to conquered people, but the effectiveness of its army noticeably declined as more non-Roman militia entered the Roman military. The citizen model was less prevalent in the armies of autocrats such as Alexander the Great. The Romans also gradually separated wealth from military service by introducing regular pay and even retirement benefits.

1.3 Purposes

Among the legacies left by the Greeks and Romans to later styles of warfare is the concept of pitched battle. The Greeks especially tended to favor violent, but short, battles intended to solve disputes in a single afternoon. The bloody nature of Greek warfare appalled many of their opponents, including the Persians, who disliked a style of warfare that left even the winners with high casualties. Despite its violence, Greek warfare did follow certain understood rules, including safe passage for heralds and ambassadors and amnesty for temples and other religious sites.

Roman warfare followed a similar pattern. Wars were generally fought with the single goal of annihilating the enemy. The Roman sack of Carthage in 146 BC is the most famous, but hardly the only example. Roman armies typically pursued retreating enemies with cavalry and often treated prisoners severely. In one case, Julius Caesar kept an opposing general on display in Rome for six years before executing him. The Roman preference for fast, deadly, decisive battles differed significantly from other cultures. The Aztecs, for example, believed that the purpose of warfare was to capture prisoners for later sacrifice.

2. The Middle Ages

2.1 Technology

The most important Medieval technology, odd though it may seem, was not a weapon, but the stirrup. The stirrup changed the traditional relationship between

cavalry and infantry. With stirrups allowing riders to grasp lances and shields firmly and with newer, more durable horseshoes allowing horses to run faster and farther, cavalry came to the forefront for most of this period. The Mongols proved to be the most successful of the horse-based military systems of the Asian steppes; by the late thirteenth century they controlled an empire that stretched from China to modern-day Ukraine. Their military relied almost exclusively on cavalry.

In Western Europe, cavalry proved to be no less important. For the aristocrats who could afford the extensive support systems that accompanied cavalry, horses meant power. The European aristocracy, as well as its Japanese counterpart, depended upon horses, armor, and swords for offensive power and increasingly larger castles for defensive power. The victory of mounted Norman knights over Anglo-Saxon infantry at the Battle of Hastings in 1066 underscored the value of cavalry. The Catholic Church even tried to ban weapons (such as the crossbow) that threatened the knight's status, though the church permitted the use of such weapons on infidels.

Technological changes also helped to end the period of dominance by the mounted knight. The Hundred Years War marks an important turning point. At the battles of Crécy (1346), Poitiers (1356), and Agincourt (1415), skilled English archers devastated French knights with the Welsh longbow, a weapon capable of rapidly delivering arrows powerful enough to penetrate armor at ranges up to 400 yards. Lacking effective missile weapons themselves, the French knights suffered terribly. At Crécy, the longbows allowed the English to defeat a French force three times its size, further underscoring the Western pattern of looking to technology to compensate for smaller numbers.

2.2 *Organization*

Military training and military service was concentrated in a relatively small group of wealthy aristocrats. In most Eurasian systems, peasants and serfs were not expected to engage in actual fighting, though they might participate in ancillary operations, particularly as archers or pikemen supporting the cavalry. The challenge to kings and other rulers, then, was to maintain the loyalty and fealty of their aristocratic vassals. In the Third Crusade (1189–92), for example, Frederick I of Germany, Philip II of France, and Richard I of England spent considerable time keeping their unruly knights and barons in check. Powerful, aristocratic military orders, relatively independent of royal authority such as the Knights Templars and the Teutonic Knights emerged from the Crusades as well.

In Japan a similar system developed, though loyalty was ordinarily based more on personal than contractual allegiances. The Japanese samurai class emerged in the twelfth century, replacing the conscript armies that had existed previously. The samurai also came to dominate Japanese politics, supplanting the traditional Japanese aristocracy. The failure of Mongol invasions of Japan in 1274 and 1281 removed any serious outside threat to the home islands, leaving the small samurai class in near-complete charge of military affairs. Civil wars and power struggles did occur, but they rarely drew Japanese peasants into the fighting.

In the Islamic world, the Abbasid Caliphate began in the ninth century to use slave soldiers called mamluks. Originally from the steppes of Asia Minor, the mamluks soon translated their military dominance into political dominance in Egypt and elsewhere in the Middle East. They were the only major Islamic force that proved capable of resisting the Mongols, defeating them in 1260 at the Battle of Ain Jalut in modern-day Israel. The mamluks, the samurai, the Mongols, and the European aristocracy, though different in many ways, shared a near-monopoly over military force in their societies, which were arranged in feudal, or at least fief-based, political systems. All of these systems were prone to succession crises and internal strife. None proved to be militarily superior to any other.

2.3 *Purposes*

Generally speaking, the motivations and purposes for warfare in this period were either religious, feudal, or both. The Islamic empires acquired tremendous territory, in part through military conquest, without significant technological advantages over their opponents. They did so by wedding religious ideology to their military forces. Under the reigns of Caliphs Umar (634–44) and Uthman (644–56), Muslim armies conquered Spain, North Africa, Persia, and the Indus River valley. Their fleets conquered Cyprus and raided Sicily and Rhodes. Qur'an readers accompanied Muslim armies, converting many men who may have joined more for plunder than for religion.

The Crusades (1095–1291) also reflect a religious basis for warfare in this period. In the eleventh century, the success of the Seljuk Turks against the Byzantines led Pope Urban II to call the First Crusade (1095–99) to defend Christianity against the incursions of Islam. The Crusades perfectly show the interplay of religion and feudal obligation. The Pope acted both as a religious leader and (more controversially) as a noble in his own right. The First Crusade (also known as the 'Peasants' Crusade') demonstrated that only knights could be relied upon to form the center of Christian armies. The peasant armies were too large to feed and too unsophisticated to stand up to the Turks. Of the 30,000 non-nobles who fought in the First Crusade, 25,000 died. Sending young nobles off to the Middle East also served a political purpose for the Pope,

removing warriors and weapons from the constant internal struggles of feudal Europe. Thus by the fifteenth century similar and roughly coequal military systems existed in Western Europe, the Islamic Empires, the Asian steppes, and Japan.

3. The Gunpowder Age

3.1 Technology

The Turkish capture of Constantinople in 1453 involved 70 heavy artillery pieces, including a 19-ton piece that fired a 1,500-pound projectile more than a mile. The appearance of these weapons was not new. Knowledge of gunpowder had moved from China to the Middle East to Europe. At the Battle of Crécy (1346) the English introduced very primitive gunpowder weapons to European warfare. Nevertheless, the dramatic Turkish success at a place Europeans considered sacred marked a watershed in military technology. Ironically, the Islamic empires subsequently proved slower to adopt gunpowder weapons than did their European adversaries. By the end of the eighteenth century, Europeans were the clear masters of gunpowder warfare on land and at sea.

Early small arms, like the arquebus, were clumsy, unreliable, and often more dangerous to the shooter than to his intended victim. Until the widespread adoption of the rifle in the nineteenth century the common command given to musketeers was 'level' rather than 'aim' since one could not expect to hit a specific target at any significant distance. Large artillery was even more dangerous to their users and so large that pieces often had to be cast at the siege site. By the sixteenth century Europeans had standardized ammunition sizes, developed training systems for musketeers, and invented more reliable firing systems for small arms. These changes made both large and small arms more mobile and effective.

Europeans developed gunpowder weapons much more quickly than any other society in this period. The simple availability of raw materials and craftsmen were important prerequisites; men who could cast church bells were in special demand as they could easily cast cannon as well. European nobles also had ample motivation to acquire new weapons for their struggles with other nobles. Finally, the European system proved more amenable to allowing private enterprises to develop and sell new weapons. The mamluks and the samurai showed a particular dislike for guns as they tended to undermine the military monopoly that kept them in power.

3.2 Organization

Guns threatened the very existence of a horse-based nobility whose expertise was in swords and lances. The age of the knight, already waning, came to an end. Non-noble musketeers replaced them. Because small arms were so inefficient when used singly, musketeers had to be arranged in lines and taught to fire and load their weapons in uson. Armies thus became much larger and more disciplined. Aristocrats who remained in military service became the backbone of an officer class that led armies mostly constituted of peasants.

Holland's Maurice of Orange (1567–1625) and Sweden's Gustavus Adolphus (1594–1632) deserve much of the credit for forming and training the new armies. They introduced regular drill and other reforms that eventually led to the classic European linear infantry formations (initially as many as 10 men deep, later two or three deep) that permitted one line to fire, then move to the back. This system maintained a near-continuous rate of fire, but required intense training (the first drill manuals appeared in 1607) and discipline in order to assure the safe and effective operation of guns. Every officer, furthermore, feared the specter of mutiny. Intense discipline, therefore, characterized most European armies; in many cases, the men feared their officers more than they feared the enemy.

Many European nations also developed powerful sail-based navies in this period. England's Henry VIII, excommunicated from the Catholic Church in 1534, sold Church lands to finance the construction of a fleet. Future monarchs continued to build upon Britain's command of the seas, introducing men-of-war in the seventeenth century that were durable enough to carry large cannon. England's *HMS Victory*, launched in 1759, was built from 2,000 oak trees, 27 miles of rope, and four acres of sails. It had 104 guns capable of firing 1,100 pounds of iron every 90 seconds. Seapower became critical to acquiring colonies, protecting merchant marines, and projecting power. Britain dominated the 'Great Age of Sail,' but Portugal, Spain, Holland, France, and others used naval vessels to increase their wealth and status.

3.3 Purposes

Three purposes dominated warfare: religion; dynastic ambition; and imperialism. The Thirty Years' War (1618–48) demonstrated the interplay of the first two. Lutheran-Catholic-Calvinist antagonisms partially explain the bloody nature of the war; Germany proportionately lost more people in the Thirty Years' War than in World War II. Religion, however, did not always determine the allegiances of the participants. Catholic France and Catholic Spain, for example, consistently fought one another for control of Italy and Flanders. Gunpowder weapons also led to a concentration of power as wealthy kings, in command of increasingly larger and more disciplined armies (not to mention artillery able to destroy castles), could compel their restless vassals to accept their rule.

The growth of monarchy meant that warfare often followed the dynastic goals of kings. Louis XIV in

France, Peter the Great in Russia, and Frederick the Great in Prussia all used gunpowder-based armies to extend their power inside their kingdoms and enforce their will outside. Often, dynastic wars spilled over into the empires Europeans were in the process of building with those same gunpowder weapons. In the Seven Years' War (1756–63), Britain seized France's Canadian and Indian colonies.

Finally, of course, Europeans translated their gunpowder weapon advantages into overseas empires. In this period, their greatest military advantage over non-Europeans was in areas accessible to their great warships. Navies allowed Europeans to enforce their will along the coastlines of Africa and Asia. On land, guns helped to make the Spanish, French, and British empires in the Americas possible. In Asia, 'gunpowder empires' such as the Ottomans and the Mughals also concentrated political power. Japan, after an initial period of experimentation with guns, effectively banned gunpowder weapons in 1587 because of the threat they posed to samurai dominance.

4. *The Long Nineteenth Century, 1776–1918*

4.1 *Technology*

This period, dominated by nationalism and industrialization, marked a tremendous advance in military technologies. Many existing technologies became much more sophisticated. Smoothbore muskets gave way in the nineteenth century to rifles, which have a groove cut in their barrels. Rifling and the conical bullet vastly increased the range and accuracy of small arms fire. After the American Civil War (1861–65) various forms of repeating rifles and machine guns emerged. Artillery also became more deadly. By 1918 the Germans had developed a gun (albeit an inaccurate one) with a range of 80 miles. Naval vessels became more deadly as well. Iron and steel replaced wood as the primary construction material and oil replaced coal as the main fuel. *HMS Dreadnought*, launched in 1906, revolutionized warfare by carrying ten 12-inch guns. *Dreadnought* set off a naval arms race that helped to cause World War I. Winston Churchill noted the importance of Dreadnought-class ships to his nation thus: 'the Admiralty asked for six, the Cabinet proposed four, and we compromised on eight.'

This period also introduced many new types of weapons systems, including (in rough chronological order), submarines, airplanes, poison gas, and tanks. By the end of this period air forces had developed all major roles for airpower in use today except midair refueling. These technologies brought war directly to civilians as never before. Many important communications technologies such as telegraphs (first used in the Crimean War, 1854–56), railroads, and radio changed the nature of military command and control. Advances in medical technology reduced the number of men who died of wounds and disease.

These technological changes affected Western and Westernized societies (including the USA and, after 1853, Japan) the most. Warfare between them, therefore, reached unprecedented levels of violence. Westernized societies also had tremendous advantages against non-westernized societies. European imperialists were thus able to use new military technologies to move inland in Africa and Asia. Most visibly, Japan, which Westernized very quickly after 1853, easily defeated China, which did not, in the Sino-Japanese War of 1894–95.

4.2 *Organization*

The most obvious change in the organization of armies and navies in this period was the increasing connection between military service and nationalism. National volunteers and conscripts replaced mercenaries, once common in Europe. Between 1776 and 1783, the American colonies used a militia with both local and national roots to defeat a British army partly dependent upon mercenaries. This contrast partially explains the fame of George Washington's crossing of the Delaware River in 1776: his national army captured 1,000 Hessian mercenaries in British service.

The American experience, though, is minor compared to the French Revolution. The logic of the Revolution and the wars that followed implied that national armies must be populated by national soldiers. The *levée en masse* of 1793 established the principle that citizens of all ages, male and female, bore some responsibility for national defense. Napoleon extended this principle and most European armies soon copied the French pattern. Nationalism inspired zeal and a willingness to endure. In 1814 Prussia created the *Landwehr* as a permanent peacetime militia and by the end of the nineteenth century most European nations had introduced national conscription. The militaries of states that were not also nations (Austria-Hungary, the Ottoman Empire) declined as a result.

The two most important military reforms of this period were Napoleon's corps system and the Prussian General Staff. A Napoleonic corps was large enough to operate independently since it contained formations of cavalry, artillery, and infantry that could act in concert. This system, however, depended on capable officers. Napoleon therefore introduced a professional officer corps open to talent in place of the aristocratic officer corps upon which Europe had come to depend. Later in the century, Prussia developed a General Staff system to plan wars. Detailed Prussian planning led to victory in the Wars of German Unification (1864 against Denmark, 1866 against Austria, and 1870–71 against France). These successes led all major Western militaries to copy the general staff idea.

4.3 Purposes

Military historians sometimes speak of a continuum between 'limited' and 'total' wars. Because warfare in this period tended to be tied to national goals and national identity, this period represented a general shift toward totality. The Wars of the French Revolution, the American Civil War, and World War I stand as cases in point. In these wars and others, huge proportions of national income were dedicated to prosecuting wars and fundamental social, political, economic, and cultural patterns were forever altered. The increased suffering (and intentional targeting) of civilians also led to totality.

Advanced technologies also made imperialism (often as an extension of nationalism) cheaper and easier for the Europeans. European militaries moved inland with steam-powered ships and railroads. Machine guns, furthermore, made military contests with natives one-sided. By 1912, the Vickers-Maxim gun could fire 250 rounds per minute. As poet Halaire Belloc noted in a turn-of-the-century (twentieth century) poem, 'Whatever happens, we have got/The Maxim Gun, and they have not.' Nevertheless, isolated cases such as the Boer Wars (1899–1902) demonstrated that modern weapons in the hands of skilled practitioners could make imperialism extremely bloody and costly. The Boers, white settlers in South Africa of Dutch ancestry, resisted the British with breech-loading guns and smokeless powder. It took the British empire more than two and a half years and almost 500,000 men to subdue less than 90,000 loosely organized Boers. The Boer Wars provided a taste of the changes to come in European military dominance after World War II.

World War I caused 20,000,000 deaths, destroyed four empires, and left in place the conditions for World War II. Only wars fought by national armies could have been so destructive. Warfare in this period combined the productive capacity of industrialization with the inspiration of nationalism. This combination, when matched with the classical legacy for pitched battle, produced a level of carnage that continues to baffle historians today.

5. The Contemporary Period, 1918–2000

5.1 Technology

Although this period has much in common with the previous period, one specific technology divides it from all that had come before. Atomic weapons have changed the very definition of warfare. Some scholars have argued that in the atomic age 'strategy,' as the term was commonly understood before 1945, has no real meaning because atomic weapons do not permit a society to apply a level of force proportionate to desired political ends. In effect, a society only has the military option of obliterating one's enemy and, in the process, taking the risk that a similar fate might befall your own society. Atomic weapons created the post-World War II superpower system that so informed not only the Cold War but dozens of regional conflicts as well. The challenge of fighting wars 'under the nuclear umbrella' led to American defeat in Vietnam, Soviet defeat in Afghanistan, and 'war by proxy' as the superpowers tried to fight each other through client states in areas as diverse as Southeast Asia, the Middle East, sub-Saharan Africa, and Latin America.

Of course, more than just atomic weapons are important to this period. World War II saw the development of effective long-range bombers and aircraft carriers, capable of bringing war directly into an enemy's homeland. Radar and sonar provided new technologies to deal with enemy air and submarine attacks. By the end of the war, jet aircraft and rockets were operational, though neither proved decisive. More sophisticated transport planes and landing craft allowed for airborne and amphibious warfare to come into maturity as well.

Since World War II, electronics and computers have revolutionized warfare yet again. Cruise missiles and other 'smart' weapons ideally provide more accurate delivery of weapons and, hopefully, fewer civilian casualties as a result. Satellites, helicopters, sophisticated avionics, and stealth technology once again have provided an upper hand to advanced societies, though the Vietnam and Afghanistan cases prove that a technological advantage is not always enough to ensure victory. Nevertheless, today Western societies still depend upon their technological advantages—much as the ancient Greeks did—to compensate for the smaller numbers of soldiers that they can place on the battlefield.

5.2 Organization

Initially, the organization of World War II armies was designed to avoid the totality of World War I. The German *blitzkrieg* system attempted to win 'lightning' victories that would not drain German manpower in the trenches. The Japanese, too, hoped to destroy the American fleet at Pearl Harbor and force the USA into a negotiated settlement. Nevertheless, totality soon emerged as the Axis powers sought to annihilate, not defeat, their enemies. More than ever before, entire societies became mobilized. Women participated directly and indirectly in numbers and ways never before envisioned. The pattern of increasing female participation has continued into the post-war period. The USA armed forces used 35,000 women in the Persian Gulf War, many of them at or very near the front lines.

The totality of World War II ruined Europe and Japan as first-rate military powers. The end of European hegemony also meant the virtual end of imperialism. Many militaries resorted to guerilla warfare to

try to defeat more technologically sophisticated enemies. Fighting underneath the 'technology threshold' has proven difficult for more advanced military systems. The Americans had great difficulty with the Vietnamese but few battlefield problems with the Iraqis in 1991 because the latter's military was much more like their own that the former's.

Since the end of the Cold War, the general trend has been to much smaller, but more sophisticated, militaries. Virtually all European states have eliminated or greatly reduced conscription. The USA abandoned conscription during the Cold War (in 1973) partially as a result of Vietnam War protest, but also to acknowledge that sophisticated weapons systems require dedicated professional volunteers to operate them.

5.3 Purposes

World War II was a contest of three ideologies: democratic capitalism, fascism, and communism. As a result, armies became politicized as never before. Young German males often left Hitler Youth organizations and entered directly into the Wehrmacht. In the Soviet Union, political commissars (including Nikita Khrushchev) served with Soviet military units and had as much decision-making authority as generals. Ideology created what John Dower called a 'war without mercy.' Though he was referring to the Pacific War between the USA and Japan, the same phrase could be applied equally to the war between Germany and the Soviet Union as well. The Holocaust and the German siege of Stalingrad, among other episodes, show the cost of the war to civilians. The former killed 6,000,000 Jews and other targets of the Nazi state. In the latter, Joseph Stalin refused to order the evacuation of the city even in its most dire moments. In the end, only nine Stalingrad children were reunited with both biological parents.

The Cold War interacted with the general decline of European hegemony to impact regional conflicts. Throughout the Third World, nationalist movements and civil wars became arenas where the superpowers armed clients but, conversely, often went to great lengths to reduce global tensions. In 1956 and 1973, for example, the superpowers brokered truces in the Arab–Israeli wars rather than risk a USA–Soviet confrontation. Regional wars like the Iran–Iraq War (1980–88) also became entangled with the Cold War; the weapons that the superpowers made available lengthened wars that had little relation to the global capitalist–communist struggle.

The end of the Cold War raises as many questions as it provides answers. The Persian Gulf War seemed to set the model for American hegemony as the lone remaining superpower. After building a coalition based around itself, the USA operated in the Gulf without the fears of Soviet response that had haunted Korea and Vietnam. The NATO air war over Kosovo, however, suggested that Russia (and perhaps China) could not be ignored. Multipolarity appears to be every bit as dangerous as bipolarity. The Western powers continue to look toward technological solutions (especially airplanes and cruise missiles) to solve military problems, suggesting that in some ways we have not come so far from the Greeks after all.

Water Pollution: Marine

This article will briefly define the term marine pollution and then go on to consider the historic growth of problems in this area and the perception of those problems. The main areas of concern in terms of marine pollution are then outlined and the international methods of regulating marine pollution problems are considered.

1. Introduction

The term pollution is used widely and rather loosely. In the context of the oceans the UN sponsored Joint Group of Experts on the Scientific Aspects of Marine Pollution (GESAMP) offered the following definitions (GESAMP 1982):

> **Contamination** is the presence of elevated concentrations of substances in water sediments and organisms.
> **Pollution** is the introduction by man, directly or indirectly, of substances or energy into the marine environment (including estuaries) resulting in deleterious effects such as harm to living resources, hazards to human health, hindrance of marine activities, including fishing, impairing quality for use of seawater and reduction of marine amenities.

These definitions are extremely valuable because they draw an important distinction between human-induced changes in the concentrations of a substance somewhere in the marine environment (contamination) and actual damage resulting from this introduction (pollution). The oceans in total are vast and have a huge capacity to dilute, and in some cases break down, a discharge if time and physical processes allow this dilution and degradation capacity to be utilized. Acknowledgment of this capacity should not imply complacency about problems arising from human impacts on the ocean, but rather help focus concern on the most important issues.

2. Historical Developments

Major public health problems in developing cities in the Middle Ages led to the construction of primitive sewers to discharge wastes to local estuaries. Such discharge of wastes improved public health but caused pollution in estuaries such as the Thames in London from the fourteenth century onwards, promoting the earliest development of sewage treatment systems. However, until the twentieth century technological development was such that only the immediate coastal environment was significantly contaminated by human activity. Despite this, the tragedy of the decimation of the great marine mammals by hunting demonstrates major and global human impacts on the marine environment from the eighteenth century onwards.

Concern over marine pollution grew from the 1950s onwards as it became clear that the ability of the marine environment to absorb discharges was not infinite and that real damage was being done by human activity. Incidents such as the mercury poisoning at Minamata in Japan, the global contamination of the oceans by radioactive debris from bomb testing and by persistent pesticides such as DDT, and the effects of the first large-scale oil spills from sinking of the new giant oil tankers changed for ever the public perception of the vulnerability of the oceans to damage from human activity.

Investigations into these incidents also began to reveal the complexity of marine contamination and pollution issues. The saga of DDT illustrates that some contaminants can very effectively become globally dispersed and furthermore can be concentrated up the food chain to cause major ecological damage far from source to nontarget organisms.

By contrast, while the effects of an oil spill are locally catastrophic in the short term, the bacteria in the marine environment have the capacity to degrade such hydrocarbon material and hence the problem is relatively localized and short term. It is also now known that the biggest sources of hydrocarbons to the marine environment are not the rare catastrophic oil spills, but rather the chronic low-level operational discharges of oil, although the impacts of the two different sorts of discharge are very different. These examples illustrate that contaminants of the marine environment can be broadly classified into several groups.

Nondegradable. Elements such as lead and cadmium cannot be degraded, although they may become stored in sediments and largely removed from biological interactions.

Slowly degraded. Some organic compounds such as DDT and PCBs are only very slowly degraded over timescales of decades or longer. Radioactive material introduced to the marine environment decays over timescales controlled by radioactive half-lives which range from seconds to millions of years. In the case of both persistent organic and radioactive contaminants, intermediate decay products can also be toxic. As with nondegradable material, these compounds may be buried in sediments and effectively taken out of the system long before they are fully degraded.

Readily degraded. The marine environment is a natural biological system containing a wealth of micro-organisms able to break down many organic compounds including substances such as sewage and oil. As noted later, however, the breakdown process itself and the products of that breakdown can cause serious environmental problems.

Since the 1950s there has been enormous growth in the scientific understanding of how the oceans function as a physical, chemical, and biological system. This has allowed a much better assessment of the local and global scale of marine contamination and pollution problems. However, it was still not until the early 1970s that the natural distributions of some important contaminants, such as cadmium, in the oceans were described. A basic understanding of the natural distribution of an element is clearly a vital prerequisite to assessing the likely contamination of the oceans from human impacts. In the case of entirely manmade substances such as DDT or artificial radionuclides, the situation is rather different since their detection in the

environment at any level implies contamination, although not necessarily pollution.

In recognition of the growing impact of human activity on the oceans, discharge controls on degradable and nondegradable materials have been introduced in many countries. These aim to minimize harmful impacts, based on the best available scientific understanding of likely effects. There is clear evidence that these controls have had beneficial effects in many areas. The resulting declines in levels of lead and some radionuclides in the oceans, for instance, have been documented. However, the pollution arising from the use of tributyl tin (TBT) as an antifouling agent in the 1980s provides a warning that our control procedures are still far from being entirely effective. Every year hundreds of new organic compounds are synthesized and used in industries around the world. The effects of the inevitable resultant discharge are rarely known with certainty and there is growing concern over their possible effects. The issue of possible estrogenic effects of chemicals discharged to the environment represents an example of a new and disturbing pollution problem that we are a long way from understanding.

3. *Current Concerns*

A series of reviews of the marine environment have discussed the changing nature of pollution threats to the oceans and also suggested a broad consensus on the nature of current threats to the oceans (McIntyre 1995, Goldberg 1995, Huber 1999). The major issues of current and likely future concern center on the effects of sewage and nutrient discharge, and the release of organic compounds including pesticides. The issue of marine litter is also still of concern, with evidence of damage to bird and marine life from the indiscriminate discharge particularly of plastic wastes from ships and the loss of drift nets. Regulations to reduce these problems exist, but policing such regulations on the high seas is almost impossible.

The global population is growing and the proportion of that population living near the sea is also growing. The waste discharges from that population will inevitably enter the marine environment, although this will hopefully be after basic treatment. Furthermore, the agricultural and industrial activity to sustain that population will inevitably result in discharges to the marine environment, even if these are minimized by the use of the best available technology. Thus it is the insidious effects of this population growth that may pose the biggest threat to the oceans.

3.1 *Sewage*

Sewage wastes contain many harmful micro-organisms. The public health effects of coming into contact with these organisms either directly, via bathing, or in foodstuffs such as shellfish, where they can become concentrated, is increasingly being recognized. Sewage wastes are rather quickly broken down by natural micro-organisms in the marine environment to release nutrients such as nitrogen and phosphorus. However, the breakdown of organic wastes such as sewage requires oxygen, or some other oxidizing agent. If the rate of breakdown of waste and associated oxygen consumption exceeds the rate at which oxygen is supplied, oxygen concentrations in the water will fall, leading, in the extreme case, to oxygen depletion and the loss of almost all animals as well as the production of noxious odors. This happened in the Thames estuary as London's population grew and overwhelmed primitive waste treatment facilities. Improvements in waste treatment since the 1950s have restored the health of the Thames. Similar stories of damage from waste discharge and subsequent recovery with improved waste treatment can be told for industrialized estuaries around the world. They illustrate that we have the technology to mitigate the effects of sewage discharges and to reverse the damage done.

3.2 *Nutrients*

Human perturbations have approximately doubled the fluxes of the nutrients nitrogen and phosphorus through the environment, while the perturbation for the nutrient silicon is much less. Thus fluxes and the relative proportions of the nutrients have changed as a result of human activity. Nitrogen and phosphorus fluxes are projected to continue to increase in the future. The resulting inputs to the oceans have already led to eutrophication problems in some areas, although on a global scale human impact has done little to increase the vast natural nutrient inventory of the deep ocean. Problems are therefore focused on the coastal environment. Eutrophication describes the process of increased nutrient load stimulating the growth of phytoplankton, the microscopic algae that form the base of the food chain. A modest stimulation of phytoplankton growth has the potential to increase the phytoplankton stock and thereby provide more food for animals further up the food chain. However, excessive nutrient inputs coupled to inadequate dilution can lead to excessive algal growth which can settle into deeper water after death and consume all the available oxygen leading to the death of animals living in deep waters. The extent of such deep-water oxygen depletion depends critically on the physical water exchange processes which promote oxygen supply to the deep waters. Thus in areas of restricted mixing, such as the Baltic or Adriatic Sea, there are serious problems, while in the much more open North Sea the problem is less significant, although all these areas receive major discharges of nutrients via rivers and the atmosphere.

Large-scale algal growth, or blooms, can also involve undesirable or toxic species and have a range

of highly undesirable effects. There is some evidence that such blooms may be increasing worldwide, although systematic studies to confirm this are not available. Indeed, on an oceanic scale, or even a regional scale, it is often difficult to quantify the level of human perturbation of the marine system, particularly since coastal and near-surface environments are characterized by great natural variability. Systematic studies of the marine environment are relatively recent, so we often do not have sufficient a time series of data to identify with confidence concentration trends for many contaminants.

3.3 Pesticides

Pesticide use has many benefits to human society, particularly in terms of increased food production. However, the release of chemicals into the environment which are designed to produce harmful biological effects is inevitably a cause for concern. The use of some pesticides such as DDT and TBT are now severely restricted, although the extent and effectiveness of such regulation varies widely from country to
country. In developing countries the use of other pesticides is continuing to increase. These will inevitably escape into the wider environment and the effect of low levels of these compounds individually or in mixtures is very poorly understood. The input of other potentially harmful organic compounds is also of continuing concern, as noted earlier.

3.4 Global Issues

In addition to these concerns over the direct contamination of the oceans, recently attention has turned to the role of the oceans within the larger global climate-regulating system. Heat and CO_2 exchange between the ocean and the atmosphere are key elements in this system. The emission of gases, such as dimethyl sulfide (DMS), from the ocean also plays a major role in climate regulation. The response of these exchange processes to climate change represents a series of poorly understood feedbacks in the global climate system. This makes predicting the effects of increasing concentrations of CO_2 and other greenhouse gases particularly difficult. Thus it is important to recognize that the oceans play a key role in the control of the whole planetary system, and hence that atmospheric pollution is linked to marine pollution.

3.5 Loss of Marine Habitats

Marine pollution is usually considered in terms of inputs of chemical wastes to the marine environment. However, there are two major issues that represent simpler and more direct threats to the marine environment. First, there is clear evidence that almost all fisheries worldwide are fully or overexploited. In the North Sea, for example, the clearest trend of environmental change is not of chemical contamination, but the vast decline in fish stocks. Globally half of the individual fish stocks are fully exploited and another 22 percent are overexploited.

The second issue is the physical degradation of coastal environments. In some cases this takes the form of total loss of habitat to reclamation. For instance, in the Humber estuary, the largest English estuary draining to the North Sea, more than 90 percent of the intertidal area has been lost to reclamation over the last 300 years. Similar losses have occurred in many other estuaries. In tropical areas half the mangrove forests have been lost to developments of some sort. These represent a massive loss of ecologically important wetlands and also loss of nutrient-processing potential. In other cases the habitat loss is not complete but involves a major reduction of ecological value. This problem is illustrated by the loss of many inshore coral reef systems to sedimentation. This occurs as changing land use patterns increase erosion and hence turbidity in the coastal waters, blocking light to the coral community and ultimately killing the corals. Eutrophication can have similar effects. Intertidal areas and coral reefs also represent important components of coastal defense against erosion and flooding. The destruction of these areas therefore represents economic as well as ecological losses.

4. Research and Regulation

Long-range transport is a feature of marine pollution issues, and hence national regulation alone is inadequate to protect the marine environment. There have been a series of initiatives focused on regional seas such as the Baltic, the North Sea, and the Mediterranean to achieve coordinated international action to manage the area. The United Nations Convention on the Law of the Sea entered into force in 1994, providing an international framework for the exploitation of the marine environment and also a requirement on states to 'use the best practical means at their disposal' to prevent and control marine pollution. While imperfect, these initiatives represent a growing realization that the oceans need to be managed at an international level to ensure their continued value for future generations.

There has also been a growing recognition that progress in managing the marine environment requires interdisciplinary scientific study involving chemists, biologists, physicists, and geologists. An important recent development has been the integration of social scientists in this work to describe the human pressures on the marine system and to consider future management options for the marine environment. An example is the recent valuation of the whole marine ecosystem at $20 billion dollars, although the meth-

odology used is controversial. Most of the value assigned to the marine environment in this analysis is associated with the cycling and storage of nitrogen and phosphorus, and hence intimately linked to nutrient and sewage pollution issues. Huber (1999) noted 'Environmental degradation impedes economic and social development and diminishes human welfare.' Thus the true cost of indiscriminate discharges to the marine environment are now beginning to be considered.

Control of marine pollution problems does not necessarily require sophisticated regulation but rather rigorous and effective planning control that assigns an appropriate value to the marine environment. It also implies controls not only of direct discharges to the marine environment, but also throughout the river catchment draining to the marine environment and of atmospheric sources upwind.

Thus several areas of real concern in terms of potential marine pollution problems can be identified, although the evidence for large-scale effects in the open ocean is modest. The oceans have a very large capacity to dilute and degrade wastes. Marine pollution problems are most evident where this capacity is not effective, such as in coastal areas with restricted circulation or for contaminants that float, such as oil or plastics. The assessment of the nature of these threats has changed somewhat over the years as we have come to understand the marine system better and also to regulate human discharges into the system. Indeed, in a recent report GESAMP noted: 'While the resolution of these issues is neither simple nor easy, in most cases the nature of the ocean's environmental problems is understood, the knowledge to solve them is available and the necessary management tools exist. What is lacking is the determination and political will to act' (Huber 1999).

Water Pollution: Terrestrial and Groundwater

1. Introduction

Water is an essential component of life. Plants and animals (including human beings) are dominantly made up of water, and rely on water to regulate temperature, carry dissolved materials inside and between cells, remove waste products, etc. Organisms cannot survive without a supply of water—human beings need to consume approximately 1.5 litres of water per day, and this water needs to be fresh (i.e., lacking in appreciable quantities of dissolved minerals) and clean. Human civilization has traditionally been

found in areas where clean water is readily available for consumption and for agriculture, but, with increasing population densities and increasing industrialization, the freshwater resources on which civilization relies are becoming increasingly strained—an estimated 1,200 million people worldwide lack a satisfactory or safe water supply (Pickering and Owen 1997). Along with overconsumption and resulting water shortages, the introduction of substances hazardous to human health into terrestrial water bodies (or pollution) is the most serious threat to the world's freshwater supplies. This article examines the scale and impacts of pollution in terrestrial, freshwater bodies such as rivers, lakes, and groundwater (underground water, specifically that below the water table). Pollution of the marine environment is examined in *Water Pollution: Marine*.

2. *Water Pollution*

Pollution can be defined as 'the introduction by man into the environment of substances or energy liable to cause hazards to human health, harm to living resources and ecological systems, damage to structures or amenity, or interference with legitimate uses of the environment' (Holdgate 1979). The major pollutants in freshwaters vary across the world, but pollution by sewage wastes is a major problem in 'underdeveloped' nations, whereas pollution from industrial effluents is, arguably, the dominant problem in overdeveloped nations (although sewage and agricultural pollution may also be serious problems). Industrial effluents may contain a variety of hazardous components, such as radioactive materials, hydrocarbons, heavy metals, and toxic organic compounds. Thermal pollution, due to discharge of cooling waters, may also have a significant effect on the biology of water bodies. A summary of the major types of water pollutants and their impacts is given in Table 1.

Many of the substances that cause pollution of water bodies are naturally present in the environment, and organisms tolerate, or even actively require, certain concentrations of these substances. It is the accumulation of these substances beyond safe levels, or the additive effects of a series of pollutants, that leads to detrimental impacts on the environment. For example, nitrates are essential to plant growth, but excess nitrate may cause eutrophication in lakes and rivers and contamination of groundwater supplies (see Sect. 3.2). In some areas, water bodies may be naturally contaminated to toxic levels. In Bangladesh and West Bengal, large volumes of groundwater used for public water supply are polluted with naturally occurring arsenic, which adversely affects the health of millions of people. Arsenic concentrations of up to 1000 $\mu g\ l^{-1}$ have been measured, well above the limits set for Bangladesh drinking water (50 $\mu g\ l^{-1}$) or the maximum concentrations recommended by the World Health Organisation (10 $\mu g\ l^{-1}$). Consumption of this water has led to widespread death and disease (Nickson et al. 1998). Conversely, many organic pollutants, such as some pesticides and industrial chemicals, are entirely artificial and so have no natural background concentration in the environment.

Following their release, pollutants undergo a variety of physical, chemical, and biological processes which act to change their concentration, and often their chemical form. Of the physical processes, mixing and dilution are particularly important. Waste discharged into a fast-flowing river will rapidly be washed downstream and diluted, whereas wastes which seep into reservoirs or groundwater may have long residence times—the water in lakes may take between 10 and 100 years to be replaced, while for groundwater the timescales may be even longer. Consequently, pollutants may build up over time, providing a long-term contamination problem. Other processes which can dramatically affect the concentration of pollutants in water bodies are adsorption and removal onto sediments, and uptake and breakdown by organisms. Sediments and soil particles, particularly those rich in organic material or clays, effectively adsorb a range of polluting substances, such as heavy metals, many organic pollutants, and some radioactive contaminants. Organisms may break down pollutants, e.g., the microbial oxidation and decomposition of sewage sludges, or may influence the transport of the pollutant, e.g., the methylation of elements such as arsenic and mercury by micro-organisms into more volatile (easily evaporated) forms. The impact of any pollutant discharged into a water body will largely depend on:

(a) the scale of the input (i.e., is the substance(s) discharged in large enough amounts to have a discernible effect on biological function?);

(b) the chemical form of the pollutant (e.g., will it undergo rapid removal onto bottom sediments, will it tend to accumulate in organisms?);

(c) the physical, chemical, and biological characteristics of the receiving water body (e.g., is the water body vigorously mixed, is it acidic or alkaline, oxygen-rich or reducing, etc.?).

As discussed above, a diverse range of pollutants may be present in freshwater systems. A detailed synthesis of the environmental behavior and impacts of each of these individual pollutants is beyond the scope of this article, and the reader is referred to the Bibliography. Instead, the potential impacts and environmental behavior of these pollutants in terrestrial water bodies is perhaps best shown by considering three case studies which illustrate the impacts of three major waste categories on terrestrial water bodies: (a) wastes from mineral extraction and processing, (b) agricultural wastes, and (c) urban and industrial hazardous wastes.

Table 1
Major types of pollutant and their impacts in terrestrial water bodies

Pollutant	Major anthropogenic sources	Environmental impacts
Oxygen-consuming wastes	Sewage effluent, agricultural run-off, some industrial effluents	Depletion of dissolved oxygen in water bodies through decomposition by aerobic bacteria, leading to death of flora and fauna. Decomposition by anaerobic bacteria produces toxic gases such as hydrogen sulfide
Nutrients	Sewage effluent, agricultural run-off	Algal blooms and subsequent death of submerged vegetation. Large quantities of rotting organic material produced causes oxygen depletion
Hydrocarbons	Drilling operations, accidental spillage, waste disposal	Various biological impacts, including death of organisms by ingestion or smothering
Other organic pollutants (e.g. organochlorines, organic solvents)	Agricultural run-off, sewage effluent, waste incineration, landfill sites, industrial effluents	Some components are carcinogenic and may bioaccumulate. Biological impacts include depression of immune system and reduced reproductive success in organisms
Acids	Acid rain, acid mine drainage	Acidification of natural waters and subsequent increase in toxic metal concentrations. Decline in species richness, death of fish
Heavy metals	Ore mining and associated industries, various technological processes	Various toxic effects depending on metal present. May bioaccumulate through the food chain
Radionuclides	Nuclear weapons testing, deliberate and accidental release from nuclear facilities	Depending on exposure, may cause cell damage, genetic defects, and cancers
Heat	Coolant waters from industry	Changes in species composition, suffocation of fish, disruption of reproductive cycle in fish and other aquatic organisms

3. *Case Studies*

3.1 Legacy of Current and Historical Mining Activity

None of the 40 main elements that are economically important to modern industrial society can be synthetically made. Instead, they must be mined, extracted, and purified, which inevitably generates waste material and frequently causes water pollution. Mining of coal and metal ores generates vast amounts of waste material that contains significant quantities of metals. These wastes are generally dumped to form spoil heaps around the mining area, or may be washed into rivers. Sulfide minerals, most commonly iron sulfide (FeS_2) or pyrite, are commonly associated with coal seams and metal ores, and exposure of these minerals to oxygen and water produces reactions of the following type:

$$2FeS_2 + 7O_2 + 2H_2O \rightarrow 2FeSO_4 + 2H_2SO_4$$
$$\text{pyrite} + \text{oxygen} + \text{water} \rightarrow \text{iron sulfate} + \text{sulfuric acid}$$

Hence, the pyrite oxidizes to form iron sulfate and sulfuric acid. This generates acid mine drainage, which lowers the pH of water bodies into which it flows, dramatically affecting ecosystem characteristics, and which may solubilize toxic heavy metals associated with the mine waste. Extraction and purification of the mined material may also cause large-scale pollution of water bodies. Use of mercury to extract gold from river sediments in the Amazon region of Brazil has caused poisoning in people living around and downstream from mining areas (e.g., Homewood 1991), while cyanide-contaminated water accidentally released from the Baia Mare goldmine in northwest Romania recently devastated freshwater ecosystems along the River Tisza in Hungary.

In countries which underwent early industrialization, such as the UK, the rapid development and subsequent decline of the mining industry means that pollution from abandoned mines is arguably a bigger threat to water quality than contemporary mining activity. In Cornwall, the former center of the UK tin mining industry, a land area of around $50\,km^2$ is covered by mine wastes derived from historical working of tin and copper deposits and large-scale extraction of kaolinite. Some of these wastes contain elevated concentrations of heavy metals and have a low pH from the oxidation of sulfide minerals, which promotes the leaching of heavy metals. The release of waste particles from the extraction and washing of mined materials has led to extensive siltation of rivers and estuaries, while groundwater percolating through disused mines has produced acid mine drainage. The most obvious example of this is the 1992 Wheal Jane incident, where 50×10^6 l of low pH, heavy-metal-enriched mine water was released into Restronguet Creek following overflow of groundwater from Wheal Jane (a recently closed mine). The biological impact of this event, however, was relatively minor, and the heavy metal input small in comparison to the existing amounts of heavy metals in the sediments derived from historical mining activity.

In the Mendip Hills, southwest England, lead concentrations in soils around some former Pb–Zn mine workings are over five percent, over 500 times higher than lead concentrations in uncontaminated soil. Much of the contaminated material is in the form of lead-rich particles, which have been mixed into the local soil and subsequently covered by vegetation. Hence, the danger of human exposure is dramatically reduced, provided the surface remains undisturbed. The neutral to alkaline pH of the soil, and the presence of the lead in a mineral form that is stable in the presence of oxygen, i.e., as a carbonate mineral rather than a sulfide mineral, means that little lead is mobilized or leached from the site. In mine waste dumps generally, toxic heavy metals may be stabilized and water contamination reduced through inhibiting leaching via the insertion of clay or geotextile liners, and maintaining pH conditions suitable for heavy metal containment (e.g., where sulfide minerals are present, constructing a low pH, low oxygen environment such as a wetland).

3.2 Groundwater and River Contamination from Intensive Agriculture

Humans have practiced agriculture for thousands of years. Shifting cultivation, rough grazing of livestock, and crop rotation systems were the dominant agricultural methods until the 1950s, when these were largely superceded by intensive agricultural techniques in Europe and North America. In intensive agriculture, traditional crop rotation is replaced by continuous cultivation of crops, which requires the addition of large amounts of nutrients to replace those lost during harvesting. This is commonly done through the application of phosphate and nitrate-containing inorganic fertilizers. Wash-off of these fertilizers into terrestrial water bodies may cause artificial eutrophication to occur, where enrichment of nutrients (particularly phosphate) causes excessive growth of surface algae. These so-called algal blooms prevent sunlight reaching deeper-dwelling aquatic species, and on death produce large quantities of organic matter which may cause oxygen depletion (see below). It is estimated that in the USA, 85 percent of large lakes near major urban areas are affected by artificial eutrophication (Jackson and Jackson 1996).

The extensive use of nitrogen fertilizers has also increased the nitrate content of surface and ground waters over the last 50 years. Nitrates are not adsorbed in soils, but are instead leached into surface water bodies and groundwater, waters which may subsequently be used for drinking water supplies. Excessive nitrate in drinking water can cause a severe blood disorder, 'blue baby syndrome' or methemoglobinemia, in babies under six months of age, and may possibly contribute to the synthesis of carcinogenic nitrosamines in the human body. In the UK, the maximum allowable nitrate concentration in drinking waters is $50\,mg\,NO_3\,l^{-1}$. In intensively farmed areas of the southern UK, such as East Anglia, however, peak winter nitrate values in rivers may exceed $100\,mg\,NO_3{?}l^{-1}$ (Alloway and Ayres 1993).

In addition to continuous crop cultivation, the development of intensive agriculture has led to increased use of factory farming methods for livestock. The organic wastes produced by large concentrations of livestock can have a serious effect on the oxygen content of water bodies. The bacterially driven breakdown of organic wastes released into natural waters consumes oxygen, e.g.

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$$

$$\text{glucose} + \text{oxygen} \rightarrow \text{carbon dioxide} + \text{water}$$

Hence, the introduction of concentrated organic wastes can deplete water bodies of oxygen, with detrimental impacts on flora and fauna. In extreme cases, where the rate of utilization of oxygen is greater than the rate at which oxygen is replenished (e.g., in canals or slow-flowing rivers), all the available oxygen may be consumed. These conditions favor anaerobic bacteria, which produce toxic hydrogen sulfide and ammonia.

3.3 The Love Canal Disaster and Landfill of Hazardous Wastes

All industrial processes produce waste. Modern lifestyles are dependent upon a vast range of chemicals and their by-products, e.g., a typical office contains

plastics, artificial floor coverings, computer components, etc. Synthesizing and producing these components inevitably produces waste, which needs to be recycled or disposed. A fraction of the waste produced may contain substances hazardous to human health, and disposal of these wastes needs to be carefully controlled. A variety of recycling and disposal options exist, ranging from uncontrolled direct dumping in water bodies such as rivers to removal and recycling of the hazardous wastes for use in other industrial processes. Where it is uneconomic or unfeasible to recycle the toxic components, incineration at high temperature is often used to break down various toxic species, although the incineration process is never 100 percent efficient, and may increase the toxicity of some waste products. For example, incomplete combustion of polychlorinated biphenyls (PCBs) in wastes can lead to the formation of toxic dioxin-containing products. An alternative and widely used disposal method is disposal at landfill sites. Landfill sites receive large quantities of domestic and commercial waste, mixed with varying quantities of hazardous wastes. Current landfill design uses a multibarrier disposal approach, where a series of barriers are put in place which are designed to slow the release of toxic components.

Dilution and dispersion, chemical reactions and biological processes (e.g., bacteria may break down some toxic organic components into less toxic forms, acid wastes may be neutralized by contact with surrounding alkaline rocks), reduce the toxic chemical species to acceptable concentrations before they come into contact with the public via surface and groundwater. The safe and long-term disposal of hazardous wastes, however, requires a thorough understanding of the physical, chemical, and biological processes occurring in and around the landfill site. In particular, groundwater movement and groundwater quality need to be monitored to assess whether toxic chemicals are being leached into water supplies. An illustration of the importance of groundwater movement in the landfill disposal of toxic wastes is provided by the disaster at New York State's Love Canal.

Love Canal was initially dug in the 1890s by William Love to connect the upper and lower Niagara River and provide hydroelectric power. The canal was subsequently abandoned until 1942, when it was purchased by the then Hooker Electrochemical Company. Over the next 10 years, the company dumped 22,000 tons of toxic chemical waste at the site, including carcinogenic lindane, chlorobenzenes, and dioxin-contaminated trichlorophenol. Population pressure from the City of Niagara Falls led to Hooker selling the site to the city school board. Prior to the sale the wastes were covered with a protective clay layer, and a school, houses, and roads were subsequently built over the landfill.

The clay cap overlying the canal, coupled with the fact that the canal was cut into the underlying clay geology, largely isolated the waste by limiting water migration (clay tends to retard water flow, and many pollutants will adsorb on to clays, see Sect. 2). The construction of a major road along the southern end of the canal in the 1960s, however, significantly altered the site hydrology. The road blocked the natural through-flow of groundwater at the site, which, until then, had been southward towards the Niagara River. Heavy rain and snow melt in the winter of 1977 caused a rise in groundwater levels, and unable to flow southwards, this groundwater filled the canal, which eventually overflowed. Contaminants migrated through surface soil layers and along sewer pipes, eventually entering the basements of houses around the site. Some buried drums of waste also broke through the overlying soil. Following national press coverage in 1978, a federal state of emergency was declared, and the worst-affected houses were evacuated, purchased by the state, and destroyed. A full review of the disaster and its aftermath is given in Hoffman (1995).

Although the Love Canal disaster is an extreme case, it does illustrate the potential long-term threat to terrestrial water quality of inadequately managed hazardous wastes. Disposing of any waste underground needs a careful consideration of water infiltration and groundwater movement—for example one of the major limitations regarding deep geological disposal of nuclear waste is the extent to which contaminants buried underground may interact with, and contaminate, groundwater.

4. *Water Pollution in the Twenty-first Century*

The twentieth century was a period of rapid technological development and population growth. The second half of the century saw the development of intensive agricultural systems, widespread nuclear power generation, and the synthesis and use of a wide variety of new organic chemicals. The wastes arising from these, and other, processes contain a wide variety of polluting substances, some of which are extremely mobile and persistent in the environment. There is now, however, a much greater knowledge of the impacts of such pollutants, and the need for controlled disposal and subsequent environmental monitoring is widely recognized. Technological developments have taken place which produce cleaner effluents and allow remediation of contaminated areas, and a much stronger legal framework exists in many countries to control polluting processes which may pose a threat to water quality. Pressure on terrestrial water resources will inevitably increase over the twenty-first century as the world's population grows, however, and it remains to be seen whether the quality of this water can be maintained.

Water Resources

Water resources encompass the freshwaters of the world. The geographic distribution and flow of freshwaters affect supplies of water available for human use, and associated problems of surplus, scarcity, and pollution. Psychological and behavioral research has focused on the perception of water problems and decision-making models, while phenomenological research has explored the deeper meanings of water use. Social scientific research on water has evolved from description of regional water problems, to economic and institutional analysis of alternatives and, more recently, to political and cultural dimensions of water problems. Although flawed, Karl Wittfogel's research on social aspects of water development stimulated work of theoretical and practical value, which argues for continuing attention to comparative international research on water resources.

1. Freshwaters of the World

In the social sciences 'water resources' generally refer to the freshwaters of the world. Freshwater includes precipitation that falls over the continents as rain or snow, infiltrates into soils and groundwater aquifers, runs off into stream networks that drain the continents, evaporates from lakes and transpires from vegetation, and ultimately flows back into the deltas and estuaries along the continental margins. As coastal and marine resources involve different types of use, they are treated separately (see *Water Pollution: Marine*). Advances in global environmental science may lead to greater integration fresh and saline water research.

Freshwaters constitute only 2.5 percent of the world's water resources, the bulk of which (96.5 percent) are in the oceans. The largest proportion of freshwaters are frozen in ice caps and glaciers (68.7 percent), followed by groundwater (30.1 percent), lakes (0.26 percent), the atmosphere (0.04 percent), marshes (0.03 percent), rivers (0.006 percent), and biological water (0.003 percent) (Shiklomanov 1993). Biological waters are small in volume but have great social significance because they include the water in human bodies.

In addition to their physiological and ecological importance, freshwaters have been central to fundamental social debates about property, power, public interest, and the role of the state. Those debates, in turn, have influenced the course of environmental science, technology, and law; and those fields have deepened understanding of the distribution and flows of water from one location, physical state, and quality to another.

2. Water Distribution and Flows

The static percentages of freshwater mentioned above must be qualified in four important ways to understand their social significance. First, freshwaters cycle dynamically in space and time. For example, biological waters are replaced (through ingestion, perspiration, and excretion) on timescales of hours to days, while groundwater is only replaced (through discharge and recharge) on timescales of tens of thousands of years. These temporal cycles have profound implications for human water supply and pollution control.

Although biological water needs do not vary much within species, they do vary across geographic regions. The distribution of freshwater varies by latitude and by climatic processes within latitudinal zones, which range from arid to humid and which vary on seasonal, annual, and longer timescales.

These variations have implications for human water use that are analyzed through water budget analysis. A water budget compares the amount of water supplied by precipitation with the amount of water consumed by evaporation and transpiration from vegetation and crops—the largest use of water worldwide. The difference between precipitation and evapotranspiration defines the magnitude and duration of surplus and scarcity, which societies address by acquiring supplemental water, draining excess waters, or moving to more favorable habitats.

Freshwaters also vary in physical characteristics, chemical composition, and aquatic life. These charac-

teristics reflect the broad climatic and physiographic contexts that shape the landscape of stream networks, groundwater aquifers, and wetlands. Variations in freshwater distribution, characteristics, and landscapes condition human water experience, which is the primary concern of this article (Gleick 1998). People who live in snow covered alpine watersheds have different water supplies, quality, and problems from those living in temperate or tropical watersheds fed by rain. People living in downstream environments face different water opportunities and problems from those upstream. It is well known that downstream groups face water quantity and quality problems generated by upstream groups; but it is appreciated less widely that downstream groups often have the political and economic power to regulate and constrain upstream development. Many engineering projects of the twentieth century failed to meet their intended goals or gain public support, in large part due to inadequate understanding of such basic social and behavioral aspects of water. Increasingly it is recognized that social research represents an important frontier for water resources management (Baumann and Haimes 1988).

3. *Psychological and Behavioral Aspects of Water*

In addition to supporting life, water has distinctive psychological characteristics. At a physiological level, 'thirst' is experienced differently from 'hunger' and other needs. Psychological disorders (e.g., water phobias) include fears of immersion, swimming, and drowning. At a social level, perception of water-related risks and adjustments, have received attention in behavioral research on flood and drought hazards, beginning in the 1960s. Flood and drought hazards research evolved from an early emphasis on description of disaster losses and recovery strategies to research that seeks to explain decisions to locate in floodplains (White 1945).

Droughts develop more slowly than floods and involve different processes of perception, behavior, and adjustment (Saarinen 1966). Water-related disease hazards range from disease vectors in aquatic habitats to inadequate water supply for washing, and vectors that breed in wet areas (White et al. 1972). Reexamination of pioneering studies of hazards designed to assess the effects of increased knowledge have noted limited progress in reducing economic losses. Efforts to develop general decision-making models to address water problems developed a key analytical construct, known as the 'range of choice,' which attributed failings to undue narrowing of the alternatives considered (Wescoat 1992).

Criticism of behavioral research on water has focused on structural constraints, especially in developing countries. These criticisms led to research on social vulnerability to water problems. Another, smaller, line of phenomenological inquiry has questioned assumptions about human experience of water (Bachelard 1983, Cosgrove and Petts 1990).

4. *Cultural Representations of Water*

Social research on the representations of water (e.g., in texts, arts, and popular culture) is scattered across many fields. In the sphere of belief systems, it includes creation stories such as the *Enuma Elish* that begin with a watery chaos from which fundamental divisions emerge. Comparative studies of flood stories (Dundes 1988), water deities and rituals, and paradise gardens 'underneath which rivers flow' (*Qur'an*, passim) have continuing significance for many cultures.

In the modern era, numerous travel accounts proceed from source to sea on major rivers of the world. While tourists generally travel downstream, 'imperial' explorers often labored against the current, searching out navigable trade routes and resources (e.g., Rennell on the Ganges; and Lewis and Clark on the Missouri River). Some literary works, such as Henry David Thoreau's *Walden*, influenced contemporary and subsequent views of water. There has been less research on water in the visual arts, music and film. One exception is the use of photography in environmental perception research related water resources management and planning (Litton et al. 1974).

5. *Water as a Natural Resource*

Questions about managing water as a natural resource, and about whether 'water is different' from other resources, have been central concerns of social scientists. They are pursued in close association with engineering, natural sciences, and law.

Water management has been dominated by engineering sciences, which have addressed social ideas and problems implicitly if not explicitly from antiquity to the present. Debates on the origin of rivers were resolved with the development of watershed science in seventeenth century France, which made it possible to estimate water supplies. The expansion of irrigation agriculture advanced with the development of water budget analysis. Water pollution control evolved with advances in instruments to measure organic and inorganic contaminants.

This is not to say that traditional water management is unsophisticated, impractical, or ineffective. Humoral theories that originated in Greek and Islamic sciences are still practiced effectively in rural South Asia. Hindu temple tanks and modern irrigation works operate parallel, though not always in coordination, with one another (Lansing 1991). The contrast between traditional and modern breaks down at many points. Some traditional irrigation societies devised highly sophisticated water diversion and mea-

surement systems that required elaborate forms of social organization (e.g., *qanats* in Persia). Many modern water systems, by contrast, are supply-driven with little measurement or management of water. Irrigation efficiences in some areas of the western US are only 50 percent, compared with rates of 90 percent in Israel and Jordan.

The most acute water problems seem to occur in low-income areas subject to civil unrest, state corruption, vague water laws, and/or highly skewed land tenure regimes. These conditions have arisen in irrigation systems and peri-urban areas of developing countries. In those situations, the laws, policies, and regulations that do exist rarely are implemented.

Laws define aspects of water that society regards as a resource. From antiquity to the present, legal systems have defined certain aspects of water as natural rights, others as social rights, and still others as *res nullius*. Legal struggles reflect changing social values and water demands.

Social research on water laws has focused on four major themes: (a) access rights; (b) water rights transfers; (c) institutional fragmentation; and (d) transboundary conflicts. Research on access rights asks who (including animals) has rights to use water and what are the social and environmental consequences of different access regimes. Research on water transfers has focused on the impacts of property rights transfers from one type or location of water use to another (Saliba and Bush 1987). Research on institutions has highlighted fragmentation, gaps, and redundancies among water organizations; and it has more recently begun to focus on power relations among organizations and their social and environmental consequences (Emel and Roberts 1995). Transboundary conflicts encompass water pollution and floods, as well as water scarcity. During the 1990s, a large body of research focused on transboundary water problems in the Middle East (e.g., Biswas et al. 1997, Committee on Sustainable Water Supplies for the Middle East 1999).

It is not clear what influence social research has had on water laws to date. The slow pace of legal reform has led social scientists to concentrate on public policies where legal issues may be at stake but decisions will likely be made by water managers and users. One of the oldest policy debates revolves around questions of whether 'water is different' from other resources. Most social scientists grant that water has unique physical qualities and uses but some, principally economists, have argued that water is no different from other resources. By this argument, water is a means to ends that have social values that may be, indeed must be, compared with other values, if society and individuals are to make rational decisions to improve human welfare and environmental quality.

These arguments have stimulated detailed empirical research on the economics of water use. One set of researchers has quantified the price elasticity of demand for residential water use while others have focused on agricultural water values (Baumann et al. 1998). These sectoral studies were drawn together in models for optimization and multiobjective management of complex river basins in the 1960s. These models sought to calculate trade-offs among competing water uses for agriculture, flood protection, recreation, municipal, and industrial sectors.

The principal internal debate in these efforts pitted optimization models, based on neoclassical economic principles, against simulation models based on behavioral models of decision-making. After sobering recognition of the limited use of these models, and further technological advances, research in the 1990s began to develop decision support systems (DSS). That work built upon research in human–computer interactions, river basin operations, and adaptive environmental assessment and management.

More recently, environmental economists have sought to estimate 'nonuse' values of waters that remain in natural watercourses, the value of 'ecosystem services,' and the trade-offs among competing environmental objectives. As in other applications, these water resources efforts rely largely on contingent valuation and other indirect methods.

As is evident in the examples above, water resources research has been more concerned with pragmatic inquiry (in the philosophical and colloquial senses of the term) than in leading debates in the social sciences (Wescoat 1992). It strives to define the social dimensions of pressing water problems and evaluate the consequences of alternative courses of action. Early research focused on river channel problems (e.g., flooding, navigation, and pollution). This emphasis on channels, rather than basins or watersheds, reflected legal and technical constraints on the role of the state in natural resources management. A concurrent line of research sought to describe river basin problems and resources. Basin surveys became increasingly important in the early twentieth century in Europe and the US. The Tennessee Valley Authority (TVA), authorized in 1933, sought to address problems of severe economic poverty, land degradation, and bureaucratic fragmentation. It included regional resource surveys, the design of planned communities, and economic development programs. Although the TVA experiment was not replicated in the US, it had growing significance in postwar development programs in many countries (e.g., the Damodar, Gal Oya, Indus, and Mekong river basins).

Policy reforms in the 1930s were influenced by social research on water financing, pricing, and decision-making. The TVA framework was broadened to the scale of national water planning in the 1960s. These efforts culminated in the US with the 'Principles and Standards for Planning Water and Related Land Resources,' which established four evaluation criteria: national economic development, regional economic development, environmental impacts, and other social

effects (e.g., community impacts). Economic research focused on the first account, while other social scientists focused on the other three accounts.

One line of opposition to these economic and multiobjective approaches argued that water is different from other resources and that it has unique importance in supporting life. These views were advanced both by water developers arguing for irrigation projects and their environmentalist and antidam opponents. Indigenous values often conflict with all of these arguments and approaches, though oppositions between indigenous and modern values are sometimes presumed rather than studied closely. Although arguments for the inherent natural or cultural value of water have sometimes been self-serving, they effected a major shift from water development to environmental management in the late-twentieth century. In some cases, they have disputed the possibility of commensurating different water uses and values (Espeland 1998). Policy stalemate is sometimes taken to be evidence of incommensurable values. Analysis of institutional problems, including conflict and stalement, was a major research advance in the 1970s and 1980s. In earlier decades, water organizations increased in scale and scope to address increasingly complex water problems, but they often weakened local institutions. In response, some research focused on local irrigation organizations (Ostrom 1992), while others assessed bureaucratic behavior and reform (Coward 1980). As engineering projects failed to meet their planning objectives and had unanticipated social impacts, increasing attention was directed to 'institutional strengthening,' 'capacity-building,' and 'participatory development' (Uphoff 1992). After two decades of research and experimentation, the importance of institutional factors is well established, though the efficacy of institutional alternatives remains a high research priority.

Beyond these economic and institutional approaches, social scientists have examined an array of specific social impacts in ways that have redefined water resources management. Social research on large reservoirs has focused on displacement and resettlement of people whose homes and lands are flooded by reservoirs, examining issues of equity, state performance, and antidam movements that have stopped international aid for projects in India, Turkey, and China.

Recognition that women, especially in poor rural societies, spend disproportionate amounts of time and energy carrying water and managing domestic water and sanitation, led to social research on water and gender. Development assistance, by contrast, often addressed men in those societies. Feminist research has shed light on women's understanding of water resources (e.g., Feldhaus 1995), and gender was one of four top priorities identified by the UN Commission for Environment and Development in 1992 for improving water management. Movements have organized around environmental problems in aquatic and riparian habitats, including species extinction, wetlands preservation, groundwater contamination, and river restoration. During the 1990s, a large number of watershed movements arose in the US to address issues ranging from nonpoint source pollution to riparian habitat protection and landscape identity. Social scientists have sought to understand how these movements articulate environmental values (intrinsic, instrumental and inherent) with political strategies, organizational dynamics, and environmental consequences.

A growing line of research focuses on political aspects of water management that behaviorist approaches failed to explain. These political issues include acute water problems faced by the poor, corruption and violence in water administration, inequitable access to water, vulnerability to flood hazards, and devolution of state authority to nongovernmental organizations. Brown and Ingram (1987) have attempted to explain problems faced by low-income ethnic minorities by contrasting 'community' and 'commodity' values in water. A broader, but fundamentally flawed, political framework was put forward by Wittfogel (1981).

6. *Water and Power: Wittfogel's Theory of Hydraulic Civilizations*

Wittfogel argued that irrigation agriculture had a formative role in the development of complex bureaucratic social organization, initially in the large arid floodplain environments of Asia which constituted a distinctively 'Oriental mode of production' that has, throughout history, threatened democratic societies. This contorted web of arguments was refuted soundly on empirical and theoretical grounds. Archaeological research on early irrigation systems showed that large-scale irrigation agriculture often followed complex state formation and had no consistent relationships with 'despotism' as Wittfogel defined it.

Notwithstanding these flaws, Wittfogel's work had two lasting implications for social research on water resources. First, it provoked three waves of research that included leading social scientists. The first wave included archaeologists and social historians who challenged the historical argument (e.g., Butzer 1976). The next wave of students focused on structures of power in modern irrigation systems. A third generation of students became involved in the applied institutional experiments described earlier (Coward 1980). The theoretical contributions of each group was sharpened by their response to, and continuation of, debates provoked by Wittfogel.

Wittfogel's second legacy was to draw together structural aspects of water management that were previously neglected or treated separately. His frame-

work encompassed environmental conditions, technologies, economic patterns, property regimes, state organization, social class, and modes of social power. Discerning the relationships among these structures of water management remains a major challenge for water researchers.

7. Conclusion

Of the natural resources, water seems especially prone to social experimentation. Its fluid characteristics make it less subject to private control than land, and thus more open to collective control. It is more subject to social control than diffuse resources like the atmosphere, which eludes most (purposeful) human management efforts. Water resources thus lie at a vital intersection between public and private control. The historical interactions between public and private water management, and social research on them have yielded insights of broader significance for the social and behavioral sciences.

One important observation on the twentieth century's water research concerns the changing significance of social research in different parts of the world. In the late-nineteenth century, US and Australian water specialists traveled around the world for models and lessons of water development in Asia, the Middle East, and Europe. The subsequent dominance of US and European researchers was based on advances in the theory and practice of integrated river basin development. But the most creative social research on water management in the late-twentieth century occurred in developing areas that were open to institutional experiments in irrigation, domestic water supply, and sanitation (Lansing 1991, Uphoff 1992). The most creative transboundary water research focused on Middle Eastern water problems. US and European research remained innovative in the fields of floodplain management, urban water management, and water resources effects of global climate change.

These observations point toward a number of opportunities for future inquiry, including: (a) collaborative research on transnational water problems; (b) research on social scales of water control from the local to global; (c) critical assessment of trends from public water management toward private and market-based water management; and (d) research on experiments in 'science-based policy' and 'adaptive management' of complex water ecosystems (National Research Council 1999).

Waterfront Planning

Waterfront planning considers the future of the shoreline rivers, lakes or oceans, especially the redevelopment of abandoned port lands in urban areas.

1. *Evolution of the Port–City Interface*

Waterfront redevelopment became a major planning activity in almost every port city in the 1970s and 1980s. Transport geographers such as Hoyle (1988) suggest that redevelopment is only the latest stage in the evaluation of the port–city interface (Table 1). The primitive cityport of the nineteenth century (Stage I) used medieval technology to unload sailing ships: nets, pulleys, and carts. Many ports were rebuilt in the late nineteenth century (Stage II) to accommodate steamships with warehouses, linear quays, and rail terminals. The Port of London Authority (1908) was an early public agency which consolidated privately-owned docks and built modern facilities. Its example was followed by other cities so that much of the urban waterfront in the mid-twentieth century was publicly owned, devoted to port industrial uses and not accessible to the general public.

The modern industrial cityport (Stage III) emerged quite quickly in the 1960s and 1970s due to powerful technological changes. Passenger terminals disappeared as jet aircraft replaced ocean liners. Fleets of small fishing boats were replaced by factory vessels. General freight switched to container ships. Huge bulk carriers and supertankers needed ocean terminals. Port-related industries in multistorey facilities departed for suburban sites with expressway access, or to other countries.

New port facilities required less labor, and more land. Container ports were approximately 40 times faster than conventional cargo facilities, using a fraction of the labor (Chilcote 1988), but needed 10 times the land for staging fast rail or highway access. Competition from new ex-urban port facilities was fierce (Stage IV). In a few years, Port Elizabeth, NJ replaced Manhattan, Oakland replaced San Francisco, Tilbury replaced London, and Boston and Philadelphia lost much of their cargo trade. By 1980, almost every maritime city had underutilized port lands available for redevelopment (Stage V) on the

Table 1
Stages in the evolution of the city–port interface

Stage	Symbol ○ city ● port	Period	Characteristics
(I) Primitive cityport		Ancient–medieval to 19th century	Close spatial and functional association between city and port
(II) Expanding cityport		19th–early 20th century	Rapid commercial and industrial growth forces port to develop beyond city confines, with linear quays and break–bulk industries
(III) Modern industrial cityport		mid-20th century	Industrial growth (especially oil refining) and introduction of containers and ro-ro facilities require separation and increased space
(IV) Retreat from tthe waterfront		1960–1980s	Changes in maritime technology induce growth of separate maritime industrial development areas
(V) Redevelopment of the waterfront		1970–1990s	Large-scale modern port consumes large areas of land- and water-space; urban renewal of original core

Source: Hoyle et al. (1988)

front doorstep of its central business district (CBD). The largest ports had enormous derelict areas; London had over 5000 acres available in 1980, in docks that had been the busiest in the world only 20 years before. Whole communities of dock workers became unemployed.

2. Opportunities and Problems for Waterfront Planning

The good news was that the abandoned port lands were in large, publicly-owned blocks close to the CBD of many cities. Most waterfront sites did not need expropriation of private property or displacement of residents, common problems in previous urban renewal projects. The waterfront became available during a period when many cities were looking for lands to expand the financial and service industries in their CBD (see *Urban Planning: Central City Revitalization*). Best of all, waterfront sites have a strong sense of place, with long views, milder microclimates and opportunities for long, uninterrupted walks that one rarely finds elsewhere in most cities.

Waterfront planners faced enormous difficulties in redeveloping these sites. The port authorities and railways withheld their lands and interjurisdictional conflicts impeded planning. Conflicting demands for economic development, parks, and jobs increased political difficulties. The sites were often polluted and encumbered with industrial structures like grain elevators, which have heritage value but are difficult to reuse. Port lands had inadequate local utilities and were often cut off from the CBD by expressways and railway lines, requiring large early infrastructure investments.

3. Waterfront Planning Practice

While most nineteenth century cities considered their waterfronts as industrial districts to be exploited for maximum economic development, some shoreline was improved for public uses. The 1909 *Plan of Chicago* was a leader in this approach, reserving the entire shoreline of Lake Michigan for public parks. Gracious waterfront parks and promenades were sometimes added during infrastructure projects, using fill to extend the land adjacent to the downtown. New York's Battery Park, London's Victoria and Albert Embankments, and the Seine esplanade in Paris were welcome improvements. Waterfront projects by F. L. Olmsted, especially the Charles/Muddy River improvements in Boston, would prove influential as a result of their natural systems approach.

New planning techniques evolved for 1970s waterfront redevelopment projects. Most projects were implemented by a redevelopment authority, although the level of government which controlled the agency depended upon who was willing to make the early infrastructure grants. Good implementation practice required these agencies to manage three areas: politics, finance, and urban design.

3.1 Politics

Excellent long-term political management is required for waterfront redevelopment except in rare cases such as the Barcelona Olympics or Lisbon World's Fair, where deadlines and national pride pushed the projects forward in record time. Most urban waterfronts take decades to rebuild because the sites are large and complex. It often took five to ten years to build the development coalition needed to have a plan approved. Good relations with local governments was an advantage, since they often controlled infrastructure needed for redevelopment. Unilateral action by a senior government often led to long-term delays.

Good political management included:

(a) good relations and no surprises for sponsoring governments,

(b) board of directors well connected to all levels of governments,

(c) strong links to local government at staff and board levels,

(d) good relations with local residents, and

(e) linking private development with public benefits, especially waterfront parks.

3.2 Finance

Waterfront redevelopment requires start-up capital investment for land assembly, site clearance, environmental remediation and infrastructure. These costs make the projects unattractive to the private sector, since it takes years before political consensus is reached and land is ready for building. Substantial government start-up grants were required for most waterfront projects in the 1970s, while many governments were reducing funds for urban redevelopment. Many agencies therefore pursued investment by developers using some form of public–private partnership. The agency could assemble and clear land, negotiate planning approvals and install infrastructure. Private developers were solicited to complete the project. Private investment started late, built slowly, and cycled with the local property market. Flagship projects, such as the World Financial Center (New York) or Canary Wharf (London) often did not arrive until an agency had demonstrated credibility with site improvements, small developments and changing the waterfront image. Big projects also waited for a positive point in the real estate cycle, or risked bankruptcy like Canary Wharf.

Good financial planning practice included:

(a) access to long-term funding for infrastructure,

(b) streamlined developer selection process,

(c) incorporating recessions into financial plans, and

(d) some infrastructure and social housing projects waiting for recessions.

New York's Battery Park City Authority set a good example in the use of bonds to finance capital investment.

3.3 Urban Design

The most important element of waterfront urban design is to provide continuous, public access to the water's edge. A high-quality pedestrian promenade along the shoreline is appreciated by the public and adds value to adjacent property. Political controversies erupted in London and Boston when developers seized ownership of the water's edge, while the Toronto agency was dismantled after delays in delivering waterfront parks.

Urban design for waterfront redevelopment should facilitate over, several decades, implementation of:

(a) small development increments,
(b) tight phasing plans,
(c) simple infrastructure that can be phased,
(d) adapt existing infrastructure and buildings,
(e) continuous public access to the water's edge,
(f) view corridors down streets to the water.

Comprehensive schemes designed by one architect were discredited by early urban renewal projects. The 1979 plan for Battery Park City in New York was influential for its approach and urban design guidelines. The plan's extension of the Manhattan street grid allowed flexibility, easy phasing, small increments and simple infrastructure. The agency's commitment to creating quality public space before development made it a leader in urban waterfront design.

The waterfront redevelopment agencies learned from each other as they developed a new planning model. Baltimore, Boston, and Toronto were influential in the 1970s; the first two for festival marketplaces developed by the Rouse Corporation, and the latter for public programming facilities in recycled industrial buildings. These ideas were quickly copied around the world. A waterfront formula emerged: a festival marketplace, an aquarium, office buildings, condominium apartments for young urban professionals and perhaps a hotel. Like most formulae for planning, it did not replicate well in other countries and cultures, leading to poststructuralist criticism of global corporations overwhelming the local population while providing few benefits for the displaced industrial workers (Harvey 1989).

The best waterfront planning pays close attention to a local sense of place and waterfront-related uses (Breen and Rigby 1994, 1996). While an authentic place is hard to define, plans which renovate buildings, keep waterfront uses (fishing fleets and marinas), and provide walkways and parks seem to be the most successful. Vancouver's Granville Island demonstrated adaptive reuse of modern industrial buildings, while London's Hays Galleria and Venice's Arsenal renovated historic warehouses. At a regional scale, the best waterfront planning uses ecosystem principles to preserve shoreline environmental integrity, while providing public access and trails.

Completing redevelopment of big sites like the London Dockland may take 20 years. Meanwhile, a new generation of waterfront sites is emerging. Large waterfront railway yards, such as San Francisco's Mission Bay, New York's Riverside South and Vancouver's False Creek may offer a different planning challenge. Since these lands are typically owned and developed by large private companies, planning initiative is falling more to the private sector than did the 1980s public–private partnerships. While these new developers may require less public subsidy, it remains to be seen whether public benefits such as affordable housing and open space can be secured from this new generation of waterfront redevelopment.

Watson, John Broadus (1878–1958)

J. B. Watson the founder of the behaviorist school of psychology was born on January 9, 1878 in Travelers Rest, a poverty stricken village in South Carolina. His

father deserted the family when he was 12. His mother, a deeply religious woman, sold what little they had and moved to Greenville, a larger town, in the hope of providing better education for the children. In 1894, through the help of their church, John was admitted to the Baptist Furman College, from which he graduated with an M.A. degree in 1900. He was then admitted to the University of Chicago where 3 years later he became the youngest person to receive a Chicago Ph.D. He remained there until 1908 as Instructor and assistant to James Angell, the eminent philosopher. In 1904 he married Mary Ickes who was the youngest sister of Harold Ickes, the influential Secretary of the Interior in Roosevelt's 'new deal' cabinet. Harold disapproved of the marriage, and may have played a part in the problems Watson was to face later. In 1908 he moved to Johns Hopkins University as Assistant Professor and Chair of Psychology. Almost all of Watson's seminal work was produced in the relatively short span of the ensuing 12 years. In 1920 his academic career came to a premature end when he developed a love affair with a young student, Rosalie Rayner. Anticipating that the affair may lead to unwanted publicity for the university, Watson decided to inform the president of the university. At the interview the president demanded his immediate resignation which Watson instantly wrote. The anticipated scandal broke in newspapers some three months later, when his wife Mary filed for divorce. As soon as the divorce proceedings were complete, on December 31, 1920, Watson and Rosalie were married. Watson was penniless, having left everything he owned to Mary and Rosalie had been disowned by her parents, who disapproved of the marriage. For a time they stayed with friends in New York. Eventually, Watson was offered a position in the advertising agency, J. Walter Thompson Company. In accord with the company policy that all employees must have personal experience of selling, Watson was sent to New Orleans to sell fishermen's boots door-to-door. Upon returning to headquarters his ideas and proposals were so successful that within two years he had risen to the position of Vice President. Having reached the top of his profession, fallen, and risen to the top of another profession, Watson was to suffer yet another tragedy. In 1935 Rosalie died of pneumonia. She was 37. He was never to recover from this loss. He died a disappointed, depressed man on September 25, 1958 at, ironically, the Johns Hopkins Hospital in Baltimore.

In harmony with the spirit of his times Watson believed in the supremacy of science, and its power for resolving our social and personal problems. Psychology, he thought, must become a 'natural science.' His seminal paper, *Psychology as the behaviorist views it*, sometimes referred to as 'the behaviorist manifesto,' was published in 1913. Its essential arguments were that to be a natural science psychology must adhere to the principles that are basic to all sciences, including the principle that what is studied must be public, i.e. observable and replicable by more than one person. Therefore, the subject matter of psychology should be behavior and nothing else. These views came under severe attack from the psychological establishment for two main reasons: first, they implied that the work of the past several decades, based on the method of introspection, had to be discarded or at best, disregarded; and second, they conflicted with the established view that psychology studies the mind, the psyche, feelings, thinking, and the like. If psychology only studied behavior, what was to be made of such concepts? Watson's answer was that these concepts had no place in science. Thus, the controversy over behaviorism arose not as much from the proposal that the science of psychology should study behavior, as it did from Watson's insistence that it should study nothing else.

Watson wrote many scholarly articles, monographs, books, and popular articles developing his view of the behaviorist science of psychology. He believed the function of psychology is to 'predict and control' behavior which, when fully achieved, would result in the good society. He wrote 'behaviorism ought to be a science that prepares men and women for understanding the principles of their own behavior ... I wish I could picture for you what a rich and wonderful individual we should make of every healthy child if only we could let it shape itself properly and then provide for it a universe in which it could exercise that organization (1925). With reference to the introspectionists' efforts to obtain verbal reports of phenomena that occur 'inside' a person, he asserted that such events are no different from events outside the body and they are, just as behavior, fully amenable to objective, scientific investigation. Language is a form of behavior and, therefore, subject to behaviorist study. Personality is the result of 'what we start with and what we have lived through (1919). Since, as far as it was known at the time, what we start with could not be changed, personality could only be developed or changed by appropriately arranging the environment. Watson's statement 'Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select—doctor, lawyer, artist, merchant-chief, and yes, even beggarman and thief, regardless of his penchants, tendencies, abilities, vocations, and race of his ancestors' is quoted in almost every textbook. However, the very next sentence is 'I know I am going beyond my facts and I admit it, but so have the advocates of the contrary and they have been doing it for many thousands of years (1925). The apparently deliberate omission of this sentence by his critics unfairly suggests an extreme claim that Watson did not make.

After his departure from academic life Watson continued to lecture, supervise research, and write on

psychology. Between 1922 and the death of Rosalie he conducted a course on behaviorism at New School for Social Research, corresponded with Bertrand Russell, Yerkes, Titchener and others, many of whom contributed to his course as guest lecturers. His book *Behaviorism* (1925) was originally written as lectures for this course. His research with 'Little Albert' where he and Rosalie conditioned the fear response in the boy to furry objects is often cited, but his research with a large number of other infants is less known. In later studies he supervised the elimination of the fear response in doctoral research by Mary Cover Jones. His views on child rearing were extreme, arguing that the development of emotional ties with infants should be avoided and that parents should not hug and kiss their children. He advised parents to follow this, in a popular book written with Rosalie Watson (1928). Some years later he changed his position on this and expressed regret that he had advocated it.

The roots of behaviorism go back much earlier than Watson. Lloyd Morgan's book, *Introduction to Comparative Psychology* (1894) sets the beginning of 'animal psychology' which necessarily required research into behavior. The assumption that the principles discovered through research into animal behavior will also hold for humans began to gain strength. Further, Pavlov's discoveries of conditioning, Darwin's theory of evolution indicating a continuity across species, and Thorndike's theory of learning based on research into animal behavior contributed to a *Zeitgeist* for the emergence of behaviorism. Watson's doctoral research which was entitled *The psychic development of the white rat correlated with the growth of its nervous system* (published as *Animal Education*) emerged in this context. His major contributions were to articulate the prevailing ideas, explicitly to formulate behaviorism, and to elaborate the ideas and principles that follow from it.

Watson regarded himself primarily a researcher and often referred to himself as 'a laboratory man.' He was interested in broad range of phenomena and in finding new ways of investigating them. It is little known that he was a pioneer of what later came to be established as Ethology. Beginning in 1906 he spent two summers on the Dry Tortugas islands, off Florida Keys, studying the behavior and homing patterns of noddy and sooty terns. Between 1907 and 1915 he published eight papers on the homing behavior and spectral sensitivity of birds. He was also a pioneer of what is now known as behavioral pharmacology. In his last year at Johns Hopkins he had begun to investigate the behavioral effect of ingested alcohol, with the collaboration of Edward Thorndike at Columbia University. The project was abandoned when he resigned. In his second profession in advertising he continued to develop innovative ideas, and pioneered the technique of associating an attractive image with the product even if they are not related intrinsically. The first of these, showing pictures of attractive women in an advertisement for Pond's face creams was very successful, and the technique became established, lasting to the present.

In his relatively short span of years in academia Watson became one of the most influential individuals in psychology. He was president of the American Psychological Association in 1915, editor of *The Psychological Review, The Journal of Animal Behavior,* and *The Journal of Experimental Psychology* that he founded. His influence on psychology has been broadly profound and enduring, but seldom recognized. Throughout his career Watson maintained the practice of not replying to his critics. Nevertheless, the controversy over behaviorism continued unabated, and in time detracted from recognition of Watson's scientific researches. This, combined with his departure from academia in mid-career, produced the unfortunate result that all of his ideas about the science of psychology, personality, language, and his researches into conditioning were taken and developed by his contemporaries and by later psychologists, notably by B. F. Skinner, without due acknowledgment. Nevertheless, the signs of Watson's influence in the shaping of contemporary experimental psychology remain evident.

Wayfinding and Navigation Behavior

Navigation is the purposeful movement through an environment, such as walking through a neighborhood or driving through a town. The task of navigating is achieved through the combination of locomotion and wayfinding. Locomotion refers to the physical movement through space, perceiving objects and where they are in the environment, and moving toward a visible place or object while avoiding various obstacles. Examples of locomotion include walking through a large shopping mall from store to store, or driving a car through a city center. Wayfinding involves the thought processes and thinking that enables movement to distant locations—locations that cannot be

seen from the current position in the environment. Wayfinding activities include choosing routes for travel, planning trips, and making estimations of distance, estimations of travel time, and orientation estimates to distant, unseen locations.

Social scientists are interested in navigation and wayfinding from various perspectives. Psychologists study navigation and wayfinding as a cognitive representation, exploring the various ways people may mentally represent the world around them (Tversky 2000). Landscape architects explore navigation and wayfinding to gain insight into the design of environments such as buildings, neighborhoods, and towns that are aesthetically pleasing and easy to navigate (Lynch 1960). Economists study navigation and wayfinding to understand people's shopping patterns and behaviors, and from this determine locations for distribution of goods and services that optimize profits (Fotheringham and Curtis 1992). Developmental psychologists test children's navigation and wayfinding abilities to understand which skills are acquired at what age, and from this develop curriculum materials (Hart and Moore 1973). Anthropologists study navigation and wayfinding behavior in previous and present cultures to explain hunting and foraging behavior as well as settlement patterns. Geographers' interest in navigation and wayfinding behavior interleaves with many other social scientists, studying all of the examples listed above. In addition, geographers explore methods for visualizing this spatial information in the form of paper and digital maps, written and spoken directions, onboard vehicle navigation aids, and virtual reality spaces (MacEachren 1995).

This article distinguishes between different wayfinding tasks, describes the strategies most frequently used to wayfind, and describes various systems of reference used to maintain orientation while wayfinding.

1. *Wayfinding Tasks*

Allen (1999) identified three categories of wayfinding tasks that he termed the commute, the explore, and the quest. The first, and most common type, is the commute. A commute involves traveling between two known places along a familiar route. This form of wayfinding is routine, where success in arriving at a destination is measured in terms of travel time (shortest time) and the amount of effort to negotiate the route (the fewest stops and turns). Little attention is required to accomplish this wayfinding task, which is most often associated with a person's travel from home to work, home to school, or home to a store. This wayfinding behavior is studied, for example, to monitor and control automobile traffic, and plan for new or upgraded roads.

The second wayfinding task is the explore. An explore involves travel through an unfamiliar area with the intent of learning about the unknown environment. The start and destination of an explore are often known places, typically the same place, but routes traveled while on an explore are new. Explores are not routine, and require strategic planning of places to visit and routes to travel to avoid becoming lost. This wayfinding task would be typical of tourists visiting a city for the first time, and would be considered in the design of tour maps and tourist information to assist the visitor.

The third wayfinding task is the quest. The quest, like an explore, begins at a familiar place, but ends at an unfamiliar destination. In this case, the destination is known to exist, but has not previously been visited. Information about the spatial relationship between the beginning and ending points of a quest are provided in the form of directions, typically maps or verbal directions. Cartographers have placed a great deal of effort in the design of navigation aids for quests, from simple verbal directions, to the standard paper road map, to the design of sophisticated vehicle navigation aids for automobiles.

2. *Wayfinding Strategies*

Though there are only three classes of wayfinding tasks, there are various strategies used to carry out these tasks. These strategies include piloting, following marked trails, habitual locomotion, dead reckoning, path integration, and lastly the use of internal representations. These strategies, though presented here as separate individual strategies, can be used together to carry out a wayfinding task. In addition, a particular strategy can be used to carry out more than one wayfinding task.

Piloting relies on the use of landmarks for orientation. The immediate goal in piloting is to traverse from the present landmark to the next landmark. The present landmark serves as a basis for orientation by providing a link back to the familiar environment, and information on where to go next. The spatio-temporal sequence of landmarks provides information on wayfinding progress, indicating how much of the trip has been completed and how much remains. Piloting is a strategy typically used in explores by tourists, or a person recently locating to a new city.

Following marked trails entails wayfinding that relies on a system of trail markers to highlight a route. Marked trails can include a road network with road signs and mile markers, multiple walking paths through a wooded area, or color-coded lines along the floor of a corridor in an office complex. Marked trails are becoming critical in the design of large build environments, such as hospitals, to aid people in finding a particular unit, such as X-ray or pediatric cardiology, while under stressful situations (Carpman and Grant 1997).

Habitual locomotion, on the other hand, is a strategy that develops after repeated navigation

through an environment, resulting in what has been referred to as route knowledge. Generally, habitual locomotion develops from piloting strategies, and after repeated exposure, the sequence of landmarks and the actions to be taken at each landmark are remembered. With increasing exposure to a route, habitual locomotion results in the development of commutes.

Path integration strategies, unlike habitual locomotion or piloting, are not based on the current landmark, or on the sequence of landmarks, but instead are based on orientation to the starting point of a route. Path integration enables travel directly back to the starting point along a novel route, after having traveled a complex route directed away from that point. This strategy necessitates constant knowledge of the direction or orientation back to the starting point. This wayfinding strategy is difficult, and is not common for humans in everyday wayfinding tasks, but instead is a common behavior in nonhuman species, such as honey bees and rats, studied extensively by behavioral psychologists (Gould 1986, Tolman 1948). It is also a strategy used in the sport of orienteering, where participants use a map and compass to navigate an unknown wilderness course.

Dead reckoning is a wayfinding strategy that entails first determining the direction to a destination, and then systematically searching until the destination is reached. Methods for orientation for dead reckoning generally include reliance on solar and lunar information, auditory information, and vestibular and proprioceptive information. Some cultures studied by anthropologists are able to use wind and water currents for orientation. Reliance on dead reckoning requires that the navigator perform periodic updates on position, making small corrections in distance and direction estimates while moving through the environment.

Wayfinding based on use of an internal representation requires reliance on a 'cognitive map' in which relative positions of landmarks, routes between landmarks, and the orientation and distances between landmarks are represented mentally. This spatial knowledge is referred to as survey or configurational knowledge. This is the most complex and sophisticated wayfinding strategy. Geographers and psychologists have long studied internal representations and the implication these representations have on navigation and wayfinding behavior; (for overviews see Downs and Stea 1973, Golledge 1999, Kitchin and Freundschuh 2000, Moore and Golledge 1976).

3. *Systems of Reference*

People rely on systems of reference, or reference frames, to stay oriented during navigation and wayfinding. Without reference frames, one would be lost. A reference frame can be as simple as knowing the starting point of an exploration and the direction of travel, or tying pieces of cloth to trees in the woods to mark a traversed path. In contrast, reference frames can be as complex as measurement of latitude and longitude positions, or the use of other abstract coordinate systems such as the Universal Transverse Mercator Grid. An effective reference system has a known origin (starting point) and a system for representing position, and direction (e.g., left/right, north/south, bearing of 90°).

There are three types of reference frames: egocentric, allocentric, and geocentric. An egocentric frame of reference is one in which the body is used as the point of reference. In this case, wayfinding decisions are based on the body's current location while moving through the environment. When a decision point is reached—a point in the environment where a choice is made to go straight, to turn left or right, or to turn around—the resulting choice is based on one's current location rather than on some other object or place.

When orientation is based on objects or places, such as objects in a room, or a plaza in a city, orientation is based on an allocentric reference frame. These objects and places that are used for orientation are called landmarks. A landmark is an object or place that stands out from its surroundings, holding a special significance for the navigator. Examples of landmarks include a chair, a street intersection, a unique building, a road, a region, or a mountain. Not only do landmarks serve as organizing features for the navigator, they can also have certain actions associated with them. For example, a street intersection may prompt a driver to turn left to go home, or turn right to go to a store. Reliance on an allocentric reference frame enables the navigator to travel novel routes, to take a different route back to the starting point.

A geocentric reference frame relies on abstract reference systems for orientation. These systems are called abstract because they do not exist in the environment. They are products of human invention, superimposed on the environment and used to specify location with a coordinate. Unlike egocentric and allocentric reference frames, geocentric reference frames must be learned through education and training. Examples of geocentric reference frames commonly used for orientation include the Geographical Grid (latitude and longitude) and the Universal Transverse Mercator system. Like other reference systems, the basis for location in a geocentric reference system is an origin. For the Geographical Grid, the origin is the intersection of the equator (0° latitude) and the line of longitude that bisects the Royal Observatory in Greenwich, UK (0° longitude). All measurements for latitude and longitude with the USA (and other Western countries) are made in reference to that origin (for a full discussion of reference systems, see Muehrcke and Muehrcke 1992). The basis for measurement using the Geographical Grid is the

calculation of angles, directions, distances, and the curvature of the earth. Technology has simplified the measurement of latitude and longitude with the development of global positioning systems (GPS). GPS can measure location on the earth's surface quickly, and with reasonable accuracy. The low cost of GPS systems has enabled a proliferation of these measurement devices, enabling almost anyone to find their location on the earth.

Wealth Distribution

Wealth represents a stock of accumulated assets; income represents a flow of current output. Families not only receive income over the course of a year but also save part of their income in the form of housing, savings accounts, stocks, bonds, and the like. Such accumulated savings are referred to as wealth. The first part of this article explains why wealth, like income, has an important bearing on the well-being of families and individuals. The second part develops the concept of household wealth; the third discusses some of the problems inherent in its measurement; the fourth shows how the structure of household wealth has changed over time; and the fifth presents time trends in the inequality of wealth. Data drawn from the USA will be utilized to illustrate parts of the discussion in the text.

1. Wealth and Well-being

Why are we interested in household wealth? Most studies use income as a measure of family well-being. Though certain forms of income are derived from wealth, such as interest from savings accounts and bonds, dividends from stock shares, and rent from real estate, income and wealth are by no means identical. Many kinds of income, such as wages and salaries and transfer payments, are not derived from household wealth, and many forms of wealth, such as owner-occupied housing, produce no corresponding income flow.

Moreover, family wealth by itself is also a source of well-being, independent of the direct financial income it provides. There are four reasons for this. First, some assets, particularly owner-occupied housing, provide services directly to their owner. This is also true for consumer durables, such as automobiles. Such assets can substitute for money income in satisfying economic needs. Families with the same money income but differing amounts of housing and consumer durables will have different levels of welfare.

Second, wealth is a source of consumption, independent of the direct money income it provides. With the possible exception of consumer durables, assets can be converted directly into cash and thus provide for immediate consumption needs. This is also true for the equity in owner-occupied housing, because second mortgages and home equity loans are another source of credit.

Third, the availability of financial assets can provide liquidity to a family in times of economic stress (such as occasioned by unemployment, sickness, or family break-up). In this sense, wealth is a source of economic security for the family over and above the income that it directly provides.

Fourth, large fortunes can be a source of economic and social power that is not directly captured in annual income. Large accumulations of financial and business assets can confer special privileges to their holders. Such large fortunes are often transmitted to succeeding generations, thus creating family 'dynasties.' They can also enable individuals to influence the political process through large donations to candidates

running for public office. Thus, wealth holdings provide another dimension to household welfare over and above income flows.

2. What is Household Wealth?

The conventional definition of household wealth includes assets and liabilities that have a current market value and that are directly or indirectly marketable. A typical list of assets includes owner-occupied housing and other real estate; cash, checking and savings accounts; bonds and other financial instruments; corporate stock; equity in unincorporated businesses; and trust fund equity. This measure will be referred to as 'marketable household wealth' (or simply 'household wealth'), since it represents those assets over which the family or individual has control. This notion corresponds to wealth as a store of value and is used in conjunction with a standard national accounting framework.

Table 1 presents the balance sheet for the US household sector in 1989. The wealth accounts are first divided into two major categories: assets and liabilities. Assets consist of items owned by households which have a positive value to them, while liabilities are debts, which by definition have a negative value. The difference between total assets and total liabilities

Table 1
Balance sheet of total household wealth in the USA, 1989 (billions of dollars)

Panel A: Marketable net worth	Value of component	Percent of total assets
I. Total assets	20,268	100
A. Tangible assets	8,960	44
1. Owner-occupied housing	6,118	30
2. Other real estate and undeveloped land	2,842	14
B. Financial assets	4,817	24
1. Checking accounts, cash, and currency	497	2
2. Time deposits, money market funds, CDs, IRAs, Keogh plans, and other retirement accounts	3,280	16
3. Bonds and financial securities	690	3
4. Life insurance cash surrender value	351	2
C. Equities	5,490	27
1. Stocks and mutual funds	1,394	7
2. Unincorporated business equity	3,478	17
3. Trust equity	618	3
D. Miscellaneous assets[a]	1,001	5
II. Liabilities	3,040	15
A. Mortgage debt	2,470	12
B. Other debt	571	3
III. Net worth	17,228	85
Memo:		
A. Home equity[b]	4,367	22
B. Pension fund reserves	2,857	14
C. Consumer durables	1,934	10
Panel B: Other concepts of household wealth	**Value of component**	**Ratio to net worth**
Marketable wealth	17,228	1.00
Marketable wealth plus consumer durables	19,162	1.11
Marketable wealth minus home equity	12,861	0.75
Augmented wealth	28,670	1.66
A. Pension wealth	3,540	0.21
B. Social security wealth	7,902	0.46

a Gold and other precious metals, royalties, jewelry, antiques, furs, loans to friends and relatives, future contracts, and miscellaneous assets. b Gross value of owner-occupied housing less outstanding mortgage debt.

is called net worth or, simply, wealth. In 1989, total household assets amounted to 20.3 trillion dollars, total liabilities were 3.0 trillion, and household net worth was 17.2 trillion.

Assets are divided into three main groups. The first, tangible assets, include stocks of real goods that are both 'reproducible,' such as houses, and 'nonreproducible,' such as land. In 1989, total tangible assets owned by households were worth 9.0 trillion dollars, which amounted to 44 percent of total household assets. The major tangible asset owned by households is owner-occupied housing (that is, houses that are lived in by their owner). This accounted for 30 percent of total household assets. The second component consists of land, apartment buildings, other rental property, and other real estate held by households. This group made up 14 percent of all assets.

The second major group is referred to as financial assets. These are assets which function as money or are readily convertible to money. They include cash, demand deposits (checking accounts), and time and savings deposits, which function directly as a means of exchange. They also include bonds, notes, and financial securities issued mainly by corporations and the government. Such securities are 'promissory notes,' by which the borrower agrees to pay back the lender a certain amount of money (the principal plus interest) at a certain date. The fourth component in this group is the 'cash surrender value' of life insurance funds. Certain life insurance plans (called 'full life insurance') allow individuals to contribute to a savings fund, and the amount the individual can withdraw from this savings fund is referred to as its cash surrender value.

In 1989, financial assets constituted 24 percent of household assets. Demand deposits and currency together amounted to only 2 percent of total assets, while time and savings deposits together with CDs, money market funds and pension accounts constituted 16 percent. Bonds and other securities amounted to 3 percent, while the cash surrender value of insurance plans was only 2 percent.

The third major group consists of equities or ownership rights. A corporate stock certificate issued by a company represents ownership of a certain percentage of the company's assets. Unincorporated business equity refers to small businesses (such as a farm or a store) owned directly by individuals, in contrast to corporations which are owned through stock shares. A person's equity in an unincorporated business is the value of the business. The third item, trust fund equity, refers to bank deposits, securities, corporate stock, and other financial instruments, which are held in a special legal arrangement called a trust fund. In a typical trust, the actual assets are managed by a specially named administrator (often a bank), and the income earned from the assets in the trust are remitted to individual beneficiaries. Trust funds held for individuals are counted as part of household wealth.

As a group, equities comprised 27 percent of total household assets in 1989. Corporate stock shares made up 7 percent of total household assets, unincorporated business equity 17 percent, and trust fund equity 3 percent.

On the liability side, the major form of household debt is home mortgages. A mortgage is a loan, issued normally by a bank and usually for a period from 15 to 30 years, that is used to finance the purchase of real property, particularly houses to live in. In 1989, mortgage debt comprised 81 percent of total household debt. The remaining 19 percent consisted of other household debt, including automobile and other consumer loans and credit card debt. Together, total household debt amounted to 15 percent of the value of total household assets.

Three other entries are shown in the bottom of Table 1. The first of these is home equity, defined as the gross value of owner-occupied housing less outstanding mortgage debt. This represents the amount of money a family could net from the sale of the house (after paying off its outstanding mortgage balance). Home mortgages amounted to 29 percent of the value of owner-occupied housing. As a result, home equity made up a smaller proportion of total assets than the gross value of owner-occupied housing—22 vs. 30 percent.

The second entry is the reserves (assets) of pension funds. These funds are accumulated mainly by corporations in order to pay pension benefits for their workers when they retire. In 1989, they amounted to 14 percent of total household assets. Technically speaking, these reserves are not part of marketable household wealth, since households have no control over the assets in these funds and cannot directly draw on these funds. However, these reserves are held for the benefit of individuals and therefore have some of the characteristics of a trust fund. The third category, called consumer durables, includes automobiles, washing machines and other appliances, furniture, and other long-lasting household equipment. Cars are the major component of household durables, and altogether durables amounted to 10 percent of total assets.

A theme that regularly emerges in the literature on household wealth is that there is no unique concept or definition of wealth that is satisfactory for all purposes. One alternative definition is the sum of marketable wealth and consumer durables. This concept is useful because consumer durables provide consumption services directly to the household, though they are not easily marketed and the resale value of these items typically far understates the value of their consumption services to the household. As shown in Panel B, the sum of marketable wealth and consumer durables amounted to 19.2 trillion dollars in 1989, which was 11 percent greater than marketable wealth.

A second is defined as marketable net worth minus net equity in owner-occupied housing. This definition

represents a more 'liquid' concept than marketable wealth, since one's home is difficult to convert into cash in the short term. It thus reflects the resources that may be directly available for consumption or various forms of investments in the short term. This concept totaled 12.9 trillion dollars in 1989, 75 percent of marketable wealth.

One of the major developments since the end of World War II has been the enormous growth in both public and private pension systems. Even though such pension funds are not under the direct control of individuals, they are a source of future income to families and thus may be perceived as a form of family wealth. Moreover, as Martin Feldstein (1974) has argued, insofar as families accumulate 'traditional' wealth to provide for future consumption needs, the growth of such pension funds may have offset private savings and hence traditional wealth accumulation.

A wider definition of household wealth will thus add some valuation of pension rights, from both public and private sources, to marketable wealth. Such a measure provides a better gauge of potential future consumption. Augmented household wealth is defined as the sum of household marketable wealth, social security wealth, and pension wealth. Social security wealth is defined as the present discounted value of the stream of future social security benefits, and pension wealth is defined as the present discounted value of future pension benefits (see Wolff 1992, for a discussion of measurement issues). As is apparent from the definitions, these two forms of wealth are not fungible or marketable, since individuals cannot convert these assets into cash.

What is the rationale for including these two forms of wealth? The main motivation is that, from the standpoint of an individual, a future guaranteed flow of income is in many ways like owning a financial asset. Indeed, there are marketable assets called 'annuities' which have precisely the characteristic of providing a steady stream of income after a certain time (or age) is reached. The anticipated social security (or pension) benefits that an individual will receive after retirement is comparable to such an annuity. From the individual's point of view, then, a guaranteed stream of future pension or social security benefits may be as much a form of wealth as money put into a savings account that will be drawn on after retirement.

According to my estimates, total pension wealth in 1989 was 3.5 trillion dollars and total social security wealth was 7.9 trillion dollars (see Panel B). Together, they amounted to 66 percent of marketable net worth. Social security wealth by itself was thus larger than any other component of household wealth, including owner-occupied housing and total bank accounts.

3. *Problems in Measuring Household Wealth*

There have been four principal sources of data for developing household wealth estimates: (a) estate tax data; (b) household survey data; (c) wealth tax data; and (d) income capitalization techniques. Each has its characteristic advantages and disadvantages.

3.1 *Estate Tax Data*

Estate tax data was the first major source of data used for wealth analysis. When someone dies, that person's assets are said to comprise his or her estate, and estate tax records are actual tax returns filed for probate. Such data have a great degree of reliability, since they are subject to scrutiny and audit by the state. Their main limitation in the USA, at least, is that the threshold for filing is relatively high, so that only a small proportion of estates (typically 1 percent or so) are required to file returns. In the UK the threshold is considerably lower, so that the majority of estates file tax returns. This is also true for some states in the USA, as well as Washington, DC, which have their own estate tax requirements.

Another difficulty with this data source is that the sample consists of decedents. Since most researchers are interested in distribution of wealth among the living population, a technique based on 'mortality multipliers' is used to infer the distribution of wealth among the actual population. If mortality rates were the same for each group, then the wealth of decedents would constitute a representative sample of the living population, and researchers could use the estate data directly. However, mortality rates are much greater for older people than younger people, so that different 'weights' must be given to the estates filed by decedents of different ages. Mortality rates are also higher for men than for women (that is, women, on average, live longer than men), and also higher for black individuals than whites. As a result, estates are assigned a weight based on the inverse of the group's mortality rate, and these are then used to generate the size distribution of wealth in the living population.

Estimates of wealth inequality based on this technique are, as might be expected, quite sensitive to the precision of the mortality multipliers. The estimates can have a very large standard error, particularly for the young, since there are very few of them in the sample. This means that the results are very sensitive to who happens to die in a given year and may therefore not be very reliable for young adults. There are two other problems associated with this technique. First, insofar as mortality rates are inversely correlated with wealth (that is, the rich tend to live longer), the resulting multipliers can be biased (see Shorrocks 1975). Most studies do try to correct for this problem by using mortality rates for the wealthy that are lower than for the population as a whole, due to the longer expected life span of the wealthy.

Second, the distribution of wealth estimated by this technique is for individuals rather than for families. Changing ownership patterns within families (for example, joint ownership of the family's house) can

affect estimated wealth concentration. For example, marital customs and relations have changed over the century. Married women now inherit more wealth and have higher wealth levels than they did in 1900 or 1930. This reduces individual concentration even if household wealth inequality does not change. For example, between 1929 and 1953, Robert Lampman (1962) reported that the percentage of married women among top-wealthholders increased from 9 to 18 percent.

As a result, since most researchers are interested in the distribution of family wealth rather than individual wealth, additional imputations must be performed to infer family wealth from estimates of individual wealth holdings. These typically involve making assumptions about marriage patterns—in particular, the correlation between the wealth holdings of spouses (whether, for example, rich husbands tend to be married to rich wives or poor wives).

Another problem with this data source is under-reporting and nonfiling for tax avoidance. Though the returns are subject to audit, the value of cash on hand, jewelry, housewares, and business assets are difficult to ascertain. Their value is typically understated in order to reduce the tax liability of the estate. Moreover, *inter vivos* transfers (that is, transfers of wealth between living individuals), particularly in anticipation of death, can bias estimates of household wealth among the living. If older people pass on wealth to their children just before they die, then their estates would tend to under-represent the wealth of comparably aged individuals still living.

Estate tax data have been used by Atkinson and Harrison (1978) for the UK, and Lampman (1962), Smith (1984), and Wolff (1996a) for the USA. The long-term time-series on wealth concentration for the UK and the USA are based on estate tax data.

3.2 Household Survey Data

Household surveys are questionnaires that are given to a sample of households in a population. Their primary advantage is to provide considerable discretion to the interviewer about the information requested of respondents. Their major drawbacks are that information provided by the respondent is often inaccurate (response error), and, in many cases, the information requested is not provided at all (nonresponse problems). Another problem is that, because household wealth is extremely skewed, the very rich (the so-called 'upper tail' of the distribution) are often considerably under-represented in random samples. An alternative is to use stratified samples, based typically on income tax returns, which oversample the rich. However, studies indicate that response error and nonresponse rates are considerably higher among the wealthy than among the middle-class. Moreover, there are problems in 'weighting' the sample in order to reflect the actual population distribution. Household surveys have been used extensively in many countries (see Wolff 1996b for a survey).

3.3 Income Capitalization Techniques

The third source of wealth data is based on the 'income capitalization' technique, which is usually applied to a sample of income tax returns. The earliest use of this technique on US data was a 1939 study by Stewart. In this procedure, certain income flows, such as dividends, rents, and interest, are converted into corresponding asset values based on the average asset yield. For example, dividends are capitalized into corporate stock holdings by dividing dividends reported in an income tax return by the average ratio of dividends to corporate stock in the economy as a whole. This technique when applied to a large sample of tax returns can provide an estimate of the size distribution of wealth.

This source also suffers from a number of problems. First, only assets with a corresponding income flow are covered in this procedure. Thus, owner-occupied housing, consumer durables, and idle land cannot be directly captured. Also, in the USA, state and local bonds cannot be estimated, because this source of interest income is exempt from federal income taxes. Second, the estimation procedure rests heavily on the assumption that asset yields are uncorrelated with asset levels (that is, for example, that large stock holders will receive the same average return on their stock holdings as small stock holders). Any nonzero correlation between asset holdings and yields can produce biased estimates. Third, the observational unit is the tax return. Various assumptions must be made in order to construct family wealth estimates from tax unit wealth.

3.4 Wealth Tax Data

A fourth source is wealth tax return data, which are available in a number of European countries such as Germany, Sweden, and Switzerland. These countries assess taxes not only on current income but also on the stock of household wealth. Though there is typically a threshold for paying wealth taxes, population coverage can be considerably greater than that of estate tax returns. However, the measurement problems are similar to those of estate tax data. The filer has a great incentive to understate the value of his or her assets, or even not to report them at all, for tax avoidance. Moreover, the assets subject to tax do not cover the full range of household assets (for example, consumer durables, pensions, and life insurance policies are often excluded). In addition, the observational unit is

the tax return unit, which does not directly correspond to the family unit. Wealth tax data have been used extensively by Spant (1987) for an analysis of wealth trends in Sweden.

4. *Changes in the Composition of Household Wealth*

There have been some significant changes in the composition of marketable wealth in the USA over the last two decades. One of the most salient trends is the rising indebtedness of American families, with the debt–equity ratio leaping from 15.1 to 18.9 percent between 1983 and 1997. The principal source of these increases is not rising consumer debt, like credit card balances. In fact, nonmortgage debt as a fraction of total assets fell from 6.8 to 5.2 percent over the period from 1983 to 1997.

Rather, the primary source is rising mortgage debt, including home equity loans and second mortgages, which climbed from 6 to 11 percent of total assets. Indeed, mortgage debt as a share of the value of homeowner's property increased from 21 to 36 percent. Whereas the total market value of homes remained almost constant as a share of total assets over this period, net home equity—the value of the house minus any outstanding mortgages—plummeted from 24 to 19 percent of total assets.

A second notable change is that pension accounts rose from 1.5 to 9.2 percent of total assets between 1983 and 1997. However, this increase almost exactly offset the decline in liquid assets, from 17.5 to 9.8 percent. As a result, the explosion in the use of various pension type accounts, like IRAs, 401(k) plans, and other thrift plans, rather than increasing overall family savings, appears, instead, to have allowed households to substitute tax-free pension accounts for taxable savings deposits.

A third important change is the sharp rise in the share of corporate equities in total assets, from 9.0 to 14.5 percent, reflecting the bull market in corporate stocks. However, this result does not reflect the full extent of the growth in corporate stock holdings, because stocks are also indirectly held in mutual funds, pensions accounts, and trust funds. If we include these, then corporate stocks, both directly and indirectly owned by households, almost doubled, from 11.3 to 20.6 percent of total assets.

5. *The Recent Rise in Household Wealth Inequality*

The final part of the analysis both highlights the sharp increase in wealth inequality in the USA since the early 1980s and illustrates the sensitivity of wealth inequality estimates to different definitions of household wealth.

Table 2
Composition of marketable household wealth in the USA, 1983 and 1997 (percent of gross assets)

	1983	1997
Principal residence (gross value)	30.1	29.3
Other real estate (gross value)	14.9	10.6
Business equity	18.8	17.3
Liquid assets[a]	17.5	9.8
Pension accounts[b]	1.5	9.2
Financial securities	4.2	3.1
Corporate stock and mutual funds	9.0	14.5
Net equity in personal trusts	2.6	3.6
Other assets[c]	1.3	2.6
Total	100.0	100.0
Debt on principal residence	6.3	10.7
All other debt[d]	6.8	5.2
Total debt	13.1	15.9
Memo		
Debt/equity ratio	15.1	18.9
Net home equity/total assets	23.8	18.6
Principal residence debt/house value	20.9	36.4
Stocks directly or indirectly owned/ total assets[e]	11.3	20.6

Sources: 1983 and 1995 Survey of Consumer Finances (tape) and the Federal Reserve Board Flow of Funds.
a Checking accounts, savings accounts, time deposits, money market funds, certificates of deposits, and the cash surrender value of life insurance. b IRAs, Keogh plans, 401(k) plans, the accumulated value of defined contribution pension plans, and other retirement accounts. c Gold and other precious metals, royalties, jewelry, antiques, furs, loans to friends and relatives, future contracts, and miscellaneous assets. d Mortgage debt on all real property except principal residence; and credit card, installment, and other consumer debt. e Includes direct ownership of stock shares and indirect ownership through mutual funds, trusts, and IRAs, Keogh plans, 401(k) plans, and other retirement accounts.

The calculations shown in Table 3 indicate an extreme concentration of wealth in 1995. The top 1 percent of families (as ranked by marketable wealth) owned almost 39 percent of total household wealth. The figures also show that wealth inequality, after rising steeply between 1983 and 1989, increased at a slower pace from 1989 to 1995. The share of wealth held by the top 1 percent rose by 3.6 percentage points from 1983 to 1989. Between 1989 and 1995, the share of the top percentile grew by a more moderate 1.1 percentage points. Projections to 1997, on the basis of asset price movements between 1995 and 1997, suggest that wealth concentration may have risen sharply again over these two years, largely from the surge in stock prices (and the fact that stock shares are highly concentrated in the hands of the rich). The share of the top 1 percent appears to have grown by another 1.6 percentage point.

The inclusion of automobiles in household wealth (the only consumer durable available in the wealth survey data) lessens the estimated share of the richest

Table 3
The percentage share of total household wealth owned by the richest 1 percent of households in the United States, 1983–1997

Year	Marketable net worth	Net worth plus autos	Net worth minus net home equity	Augmented wealth
1983	33.8	32.6	42.9	19.0
1989	37.4	36.1	46.9	20.3
1992	37.2	35.9	45.6	NA
1995	38.5	36.4	47.2	NA
1997	40.1	NA	48.6	NA

Sources: 1983, 1989, 1992, and 1995 Surveys of Consumer Finances, and Wolff (1992). Projections to 1997 are based on the change in asset prices between 1995 and 1997. Note that automobiles are the only consumer durable included in the survey data.

1 percent by about 1 percentage point in 1983 and by 2 percentage points in 1995. This reflects both the fact that automobiles are more widely distributed in the population than other assets and that the importance of vehicles in the portfolio of poorer and middle-income families has risen over time. However, the data also show similar time trends—a sharp rise in wealth inequality between 1983 and 1989 followed by a modest increase from 1989 to 1995.

Household wealth excluding home equity is even more concentrated than marketable wealth, with the richest 1 percent (as ranked by this concept of wealth) owning 47 percent of the total. The trend in inequality is similar, with the share of the top 1 percent gaining 4.0 percentage points between 1983 and 1989 and another 0.3 percentage points in the ensuing six years. Projections to 1997 suggest another rise in the share of the richest percentile, by 1.4 percentage points.

Table 3 also shows the trend in the share of augmented household wealth owned by the top 1 percent of wealthholders as ranked by augmented wealth from 1983 to 1989. The addition of pension and social security wealth has had a significant effect on measured wealth inequality because pension and social security wealth, particularly the latter, have grown much faster over time than marketable wealth and because social security wealth is more evenly distributed in the population than marketable assets. The gap in the share of the top 1 percent between marketable wealth and augmented wealth was almost 15 percentage points in 1983 (34 vs. 19 percent). However, wealth concentration based on augmented wealth still shows an increase between 1983 and 1989 (more current estimates are not available).

Future research might most appropriately be focused on understanding the factors behind changing wealth inequality both in the USA and other advanced nations (household wealth data are not currently available for less developed countries). How have relative wealth holdings changed among age groups, among income classes, across racial and ethnic lines within a country, between families with children and those without children, and across gender lines? How have wealth holdings changed among countries of the world? What are the respective roles of household savings and intergenerational wealth transfers in explaining wealth differences among individuals and between groups? What are the reasons for rising indebtedness among American families, and how does this compare to other countries? These are some of the salient research issues that occupy current researchers in the field.

E. N. Wolff

Weber, Max (1864–1920)

Max Weber was born Karl Emil Maximilian Weber in Erfurt, Thuringia on April 21, 1864. His father, Max Weber (1836–97) was a lawyer from a family of wealthy industrialists and merchants with international connections, whose core business was a linen factory in Oerlinghausen, in Westphalia. His uncle transformed this factory, which had been a traditional family concern, into a model modern business. 'The Protestant Ethic and the Spirit of Capitalism' contains thinly concealed elements of this history. Weber's father was a younger son in this family. His father pursued a legal and political career, serving in the German Reichstag 1872–84. Politicians and intellectuals, particularly historians, frequented the Weber household in Berlin. His mother, Hélène (née Fallenstein) was highly educated, religious, and active in poor relief.

Weber entered the University in 1882, studying law, as well as economics, ancient history, philosophy, and theology, and entered into the student life of the time, joining a fraternity. He served the first year of officer training in the army at Strasbourg, where relatives of his mother's were prominent at the University. He returned to Berlin in 1884, and concentrated on law and legal history. Here he became a hard working scholar with a sedate lifestyle, simultaneously pursuing his legal education and taking exams, completing military service, and continuing his academic studies. Levin Goldschmidt and August Meitzen instructed him in *Staatswissenschaft* and he became a doctoral student under Goldschmidt, also briefly clerking at the Royal District Court of Charlottenburg, and performing military service in Posen.

His dissertation, 'Development of the principle of joint liability and the separate fund in the public trading company from the household and trade communities in the Italian cities' (1889), based on hundreds of Italian and Spanish sources, was well-received. He joined the *Verein für Sozialpolitik* (Association for Social Policy) out of a concern with the 'Polonization' of the Eastern regions of Germany, and became involved politically in the *Evangelisch-sozialer Kongress*. He continued his academic work, receiving his Habilitation under Meitzen for 'Roman agrarian history and its importance for state and civil law' in 1891. During this period, the *Verein für Sozialpolitik* employed him for a study of 'The conditions of the agricultural workers in East Elbian regions of Germany.' The study, a huge empirical survey designed as the basis of policy recommendations, marked a new direction in his career. The recommendations were controversial, but made his reputation as an agricultural economist, and enabled him to secure a Professorial appointment in *Nationalökonomie* at Freiburg in 1894. From there he was appointed to a similar position at Heidelberg.

A mental breakdown after the death of his father ultimately led him to relinquish his teaching duties, but eventually he returned to an active role as an editor and producing scholar. His major 'methodological' essays (posthumously published as his *Gesammelte Aufsätze zur Wissenschaftslehre* in 1922) included part one of 'Roscher and Knies' published in 1903, 'Objectivity in Social Science and Social Policy' in 1904, part two of 'Roscher and Knies' and 'Critical Studies in the Logic of the Cultural Sciences' in 1905 and 1906, and, in 1907, 'Critique of Stammler.' With the 1904–5 publication of 'The Protestant Ethic and the Spirit of Capitalism,' his work began to take several new directions. During this period Weber traveled to the US, where he spent several months, appearing as an Agricultural Economist at the 1904 St. Louis World's fair, and visiting American relatives. His experiences were the basis for some of his subsequent writings. He became fascinated by the revolution of 1905 in Russia, learning the language in three months in order to follow the unfolding events, and wrote extensively on them, from a point of view that emphasized matters of social structure. Over the next few years he completed his work on ancient agrarian economic life, agreed to take over the editing of a work which evolved into the text now known as *Economy and Society*, which Weber was never to complete. He became engaged publically in questions of university policy, and also pursued inquiries into industrial psychology in the family textile works, an expression both of his interest in the rationalization of work and his recognition of the role of such psychophysical factors as fatigue in work processes.

Weber also played an active, though characteristically combative role, in two academic organizations, the Social Policy Association and the German Sociological Society. He was one of the founders of the German Sociological Society in 1909, but left soon after because of his views on the separation between

scholarship and advocacy. These views, which later became famous, if not well understood, under the label 'value-free science,' were developed and elaborated in a complex and long-running dispute within the Social Policy Association. This dispute began largely as a political dispute over matters of policy but it escalated quickly and was transformed by Weber and his brother Alfred into an accusation that their opponents in this dispute had confused considerations of value with objective policy considerations, a point that was particularly crucial for Weber, who rejected the bland statism of his monarchical socialist older colleagues. Weber articulated an elaborate rationale for his position that followed from his notion of the nonrationality of ultimate value choice. He also argued that maintaining this separation was part of the duty of university professors.

Weber's role in what was to become *Economy and Society* expanded and he became author rather than editor, a task which together with the series of studies that comprised 'The Economic Ethics of the World Religions,' occupied him until his death. Neither project achieved final form. During World War I Weber, a reserve officer, worked as a hospital administrator, until a reorganization made his services unnecessary. When the outcome of the war became clear, he wrote a series of articles in the *Frankfurter Zeitung* on the future constitution. During this period he gave two speeches with parallel titles to the Munich Free Students Association, 'Science as a Vocation,' apparently in late 1917, and 'Politics as a Vocation' in early 1919, after which both were published. The speeches were an aggressive and telling challenge to the cultural and political optimism of the time, and in the Weimar era remained relevant, especially to the long-running discussion of the 'Crisis of the Sciences.' After the war Weber served as a member of a group invited to participate in *Reichsamt des Innern* (Office of the Interior) meetings which produced the general outlines of the constitution of what became the Weimar Republic (Mommsen 1984), became a professor of economics at Vienna in 1918 and Munich in 1919, and unsuccessfully pursued a career in politics. His untimely death, June 14, 1920 in Munich, came when his influence among intellectuals was at its peak.

1. *Weber's Early Work*

Weber's habilitation dissertation, although he later dismissed it as a 'one of the sins of his youth' (quoted in Tenbruck 1987), together with an essay on 'The Social Basis of the Decline of Ancient Civilization' (1896) marked him out as an original scholar. The dissertation used his knowledge of medieval land tenure law to illuminate the Roman agrarian situation. It depended on the plausible but unprovable assumption that two of the different methods of mapping used by the Roman Colonial land surveyors corresponded to different types of land tenure: untaxed, roughly measured lease rights from public land, and precisely measured, private taxed lots. He argued that the size of the private lots suggested that they were too small for subsistence, and that the smallholders on this land had from the first depended on access to public land to survive, but that this access was eventually cut off by the rich, who could pay for leases and work the land with slave labor. He reasoned that the poor but free peasants were forced, by the inadequacy of their holdings, to assume labor obligations to landlords as rent, and later to be legally bound to the soil. When new slaves were no longer available, barracked slaves, who had enabled production for the market, had to be raised in status, freed sufficiently to encourage them to reproduce, making them essentially into serfs. Increasingly, money transactions were replaced by transactions in kind, the coastal commerce on which the slave produced surpluses depended vanished, and the cities diminished in power and in fiscal, and consequently political, importance for the state. The new rural economic order was manorialism *de facto*, so this was in effect an account of the origins of the medieval agrarian order.

2. *The 1903–1907 Methodological Essays*

Contemporary disputes in ancient history, notably the 'Bücher–Meyer controversy,' over a stage-theory of the development of the *oikos*, were formative for Weber. His most important methodological article, 'Objectivity in Social Science and Social Policy,' was published in 1904, on the occasion of the transfer of control of the *Archiv für Sozialwissenschaft und Sozialpolitik* to a team of editors of which he was the leading member. Weber argued that to construct a historical explanation, or even an object of explanation, requires conceptualization, that he examined in terms of the concept of ideal-types, which he distinguished from mere classifications that simply sorted objects into categories. Ideal-types typically diverged from reality, or were applied to empirical cases from which they diverged, as in the case of ancient capitalism, but served the purposes of the historian by virtue of the fact that they allowed the historian to ask questions that are meaningful in the present. Thus, while ideal-types were indispensable to the historical disciplines, these disciplines were also prone to a particular kind of error. The mistake in each case is that something that is properly regarded as an idealization of a phenomenon is treated as a real force or a teleological process. In Weber's hands, this was a powerful means of methodological criticism. Not only did it serve to indicate how the developmental models of his near predecessors and contemporaries, including Marx, used the idealization to constitute the phenomenon it explained, it called into question the project of final conceptualizations of history or social life, as well as

the cognitive status of such conceptual constructs as 'the state.'

The line between the parts of historical understanding that are relative and those that are nonrelative and factual is difficult to draw. In 'The Logic of the Cultural Sciences,' he spoke of the 'real causal processes' which our concepts give an intelligible form to. In 'Objectivity' he argued that 'genetic ideal-types,' are themselves relative to a culture-bound historical interest: the calculation of probabilities is fully objective, but the selection and conceptualization of the conditions cannot be. These are inherent limitations of a social science that must operate with concepts whose meaningfulness derives from sources outside of the science itself: sciences which speak 'the language of life' a language which is itself necessarily bound to a historical moment and its values (Weber 1949).

This argument takes on a special significance in connection with his account of values themselves. Weber argued that scholarship could at best enable judgments about the adequacy of means for ends, the consistency of ends, the separation between and the difference between factual and valuative considerations, but could not constitute the basis of either value judgments or the endorsements of policies, at least to the extent that the valuative purposes of the policy could not be given scholarly justification. Ultimate value choices, worldviews, religions, and national cultures were alike in that they were ultimately matters of commitment, not reason, and consequently questions of 'superiority' were misplaced.

3. *The Protestant Ethic Essay*

These basic methodological ideas, and especially the idea of ideal-types, figure in Weber's 1904–5 essay, *The Protestant Ethic and the Spirit of Capitalism*. The core problem of the essay was to account for the disruption and replacement of traditional economic life, and he argued that it was in part the indirect effect of Protestantism. Reformation theology, and particularly Calvinism, altered the problem of salvation. The doctrine held that the Elect, those predestined for salvation, are called to worldly tasks and an ascetic lifestyle: worldly monasticism. But, Weber reasoned, the doctrine of predestination was psychologically intolerable, and produced deep anxiety, which had to be allayed by pastoral assurances that faithful work in a calling was a sign of election, creating a novel and powerful psychological sanction for conduct. The theological premise thus had the indirect effect of producing a personality that, in the appropriate setting, becomes the austere, abstemious, rationalizing capitalist.

There are many controversial features of this account, some of which result from the fact that the doctrinal element of the ideal-type that Weber constructed only imperfectly corresponded to the theological doctrine of much of Protestantism in Europe. Nevertheless, the account is deeply compelling, in part because the depictions of the believer accord so well with a character type that unquestionably did leave a profound mark on western culture. Weber closed the essay with some prophetic remarks about the course of western culture, and an important analysis of the cultural situation created by the secularization of the 'ethic.' He observed that the rosy blush of its 'laughing heir,' the Enlightenment, has faded, and that the inexorable demands of the modern, rationally organized economy, enforce the organization of work into 'callings' but strip them of their religious meaning. He commented that even the accumulation of wealth takes on the character of sport, and the people in the machine of capitalism became divided beings, 'Specialists without spirit, sensualists without heart (1958a).

In his late lectures on economic history, Weber restated the thesis with some different emphases, notably with respect to the rational organization of free labor, which Weber came to see as especially crucial, and indeed to be the distinguishing feature of modern capitalism in contrast to booty capitalism, trade, and political capitalism, all of which were found in the ancient world. The crucial moment was when 'the production of goods was emancipated from all the bonds of inherited intelligence, and came under the dominance of freely roving intelligence' (1961), the moment in which the craftsman was replaced by the worker, and the owner of the firm supplied tools, exacted discipline, and assumed the risks. This change was, Weber thought, a precondition for the mechanization of work with the goal of saving labor costs, and in this sense rationalizing labor. And together with this was the rationalization of the use of capital generally, through rational accounting methods, rational price setting for the purpose of profit, and backed by calculable law. The worldwide expansion, and continued success, of these practices did not rest on the foundation of religious belief. Weber also provided an overview of other factors in the development of capitalism, such as calculable law, and other contingencies, like the availability of coal in Europe, without which, he argued, 'the revolution in the means of work … might have stopped and modern capitalism in its characteristic form never would have appeared' (1961).

4. *Economy and Society and the Economic Ethics of the World Religions*

In the last decade of Weber's life he produced a major methodological text; 'The Categories of an Interpretative Sociology,' a major systematic work, the incomplete *Economy and Society*, and the bulk of his mature substantive work, 'Economic Ethics of the World Religions.' The essays that make up this work are overtly concerned with the question of why a

rational capitalism based on calculability originated exclusively in the West. But their larger theme is the general problem of the cultural specificity of the West, that is to say the peculiarity, in world terms, of Western political, economic, and legal institutions. But the uniqueness of the West requires an unusual explanation.

The general development of religious ideas corresponds to the development of particular social strata, with peasants having a strong affinity for magic, aristocratic classes for a kind of self-justifying, charismatic self-conception. These affinities tend to be relatively stable and do not work to transform the social structures in which they arise. The problem of explanation, consequently, is to identify the point of openness in which a very specific kind of innovation, namely those that have transformative effects on individuals or groups, might arise. The general promise of religion is health, wealth, and happiness. And the basic affinities to strata express these needs in forms specific to the strata.

The exceptional cases are the salvation religions, which offer rebirth or redemption, and more generally religions that are doctrinally open to rationalization, and that produce potentially transformative innovations through rationalization. Religious rationalization, however, while producing new coherence or consistency in religious doctrines, characteristically serves to produce discrepancies with other 'spheres' from which religious life is differentiating under the same pressure of circumstance. A general problem which all salvation religions must face up to is the problem of the relationship between destiny and merit, the problem of theodicy, which these religions develop in extraordinarily elaborate ways—ways which on the one hand 'rationalize' the discrepancies by making the fact of evil or bad luck intelligibly consistent with the religious ideology, but also in ways that are consequential for practice. The Chinese solution, for example, was to reconcile the two by recourse to popular magical practice, which in turn had negative consequences: a 'deep repugnance to undertaking any change in the established conduct of life because supernatural evils are feared' (1961). Ancient Judaism, in contrast, devised solutions that excluded and repudiated magic, and this carried over into Christianity and consequently into the western worldview in a way that favored the eventual development of science and technology.

Weber pointed to many similar indirect effects of general institutional conditions, conditions that do not directly determine possibilities, but nevertheless greatly reduce the probability of developments in a particular direction. Rationalization, for example, means the attainment of greater consistency and completeness, but the two take various different forms for intellectuals and practical persons, such as merchants, and the direction that rationalization takes in a given situation or in the face of given problems is governed by many circumstantial contingencies. Weber saw the various forms and processes of rationalization as interacting with one another, that is to say saw rationalization in one sphere as creating difficulties which require rationalization to relate to spheres, and thus producing a kind of dynamic ongoing process of mutually reinforcing rationalization. Occasionally Weber appears to slip into the error of regarding the rationalization process as itself a historical force, but these rare cases ordinarily can be interpreted in causal, and typically 'interest' terms, as when for example the rationalization of modern law on the continent is interpreted as driven by the status interests of law professors.

5. *Economy and Society*

Economy and Society consists of a typology of forms of social action, especially institutional action, together with extensive historical commentary on the types. Weber said that the claim to be made on behalf of the typology was its usefulness; and the elaboration of the typology is an extended demonstration of the uses to which the types could be put in analyzing actual historical forms, particularly of institutional structure, and characterizing their historical course of development as the product of the basic properties of the type, always with the caveat that these were idealizations rather than 'real' types with a teleological character.

The most famous of these typologies involves beliefs legitimating authority and the forms that were characteristically produced by these beliefs. The categories were charismatic, traditional, and rational–legal. These were ideal types, which almost never, if ever, appeared in reality in a pure form. Traditional authority was based on unwritten rules believed to have been handed down from time immemorial; rational legal authority rested on the belief in the validity of written rules produced according to written procedures, and charismatic authority was the authority of the extraordinary person. Weber had in mind of course such figures as Napoleon and Jesus Christ, but he found many more modest examples in Indian gurus and medieval battle leaders, and in each of these cases obedience rested not on either written or unwritten rules but on the direct influence of the exceptional individual himself. Weber was careful to point out such things as the attenuated charismatic element in the modern monarchy and the jury.

Charismatic authority, Weber observed, is inherently unstable, though its temporary effects, and thus historical consequences, may be great. Gradually the critical charismatic leader must support his followers materially and this marks the beginning of the transformation of charisma into the everyday. Charismatic regimes also face problems of succession, and the 'routinization' of charisma through ritual in order

to pass on charisma to successors soon becomes transformed into something akin to traditional authority, or alternatively into a bureaucratic system.

The value of the ideal type is not so much that it serves to predict as that it enables one to ask relevant questions or identify relevant causal processes. But this process is itself governed by our cognitive purposes rather than something inherent in the historical world itself. Much of Weber's discussion of the historical case material is indeed about the logical unfolding of implications of basic ideas such as charisma or rational legal authority. However, there is no sense in which this unfolding is causally inevitable. It is rather that concepts like charisma are useful in making processes intelligible precisely because the elaboration of the idea corresponds to the kind of developments that historical agents actually bring about in the course of their actions employing their own ideas, beliefs, and so forth.

6. *Weber as a Political Thinker*

Weber was self-consciously part of the post-Bismarck generation, and an ardent nationalist who was deeply concerned about the problem of succession of leaders. Bismarck's career had shown how forceful and successful leadership produced popular acquiescence and even enthusiasm, but with the effect of making Parliament weak and irrelevant, and undermining party loyalty. Weber saw this form of popular leadership, exemplified for him by both the unelected Bismarck and the elected Gladstone, as a key to the nature of modern politics: modern regimes were mass democracies in fact, regardless of the forms of constitutions, because they required mass legitimacy and support to be effective. The selection of leaders, and beyond this the administrative machinery of parties, were constrained by the demands of effective electoral politics. He was concerned on the one hand that interest-faction parties, especially parties that inevitably were bureaucratically organized, would be effective electorally, but that this would assure the predominance of party hacks rather than figures who could act boldly as leaders. He resnded by suggesting a presidential office in which the president required support in the form of a plebiscite rather than party support, and thus stood above and outside of party structures. Although this analysis supported a liberal and democratic republican form of government, Weber nowhere based his argument for this form of state on traditional liberal constitutional concerns, such as the preservation of rights or the expression of the will of the people, notions he regarded as mythological, but instead based it on the problems of selecting great leaders in the face of the modern need for popular support for the tasks of nation-building.

Many interpreters have noted that the Nietzschean language of greatness that Weber employed, as well as the specific concerns about freedom he expressed, are rooted in a morality of the value of 'personality' that is potentially in conflict with constitutional liberalism, and especially to its egalitarian elements. When he observed that in rational work organizations 'each man becomes a little cog in the machine and, aware of this, his one preoccupation is whether he becomes a bigger one,' and when he asked if 'a portion of mankind (can be kept) free of this parceling out of the soul' (quoted in Mayer 1956) his concern was with a form of freedom accessible only to the few. Yet Weber's argument proceeds on more than one level. On the one hand he presented the state as a tool whose distinctive and necessary means is violence, and traced the origins of the historical conditions that constrain the possible present forms of state. But he made the point that the state is a means not necessary merely to the achievement of his own values, but to the achievement of virtually all this-worldly values: only someone like a Tolstoyan Saint has no need of the state. For the rest, there are no alternatives.

7. *Weber's Reception*

Weber was not employed as a professor during his most productive years, and exerted relatively little influence through the training of students. His primary personal influence was through a salon that he and his wife held in Heidelberg which attracted many of the best minds, and particularly the best young minds, of the university, across various disciplines. This group included Georg Lukács, Emil Lask, and Karl Jaspers. Jaspers portrayed him as an existentialist hero: 'an idealized modern man who resolutely exposes himself to intellectual risks and lives through intellectual tensions passionately without accepting final resolutions' (Schluchter 1996).

The Nazi period cut off serious discussion of Weber, who was described in the intellectual circles that supported the regime with the derogatory term 'liberal,' a characterization that shaped the revival of his thinking in the postwar period. Weber's 'liberal' admirers, such as Jaspers, promoted the idea that Germany would have been saved from Nazism had Weber been accepted as political leader, and as a consequence, after the Second World War, Weber was reinterpreted as a precursor of the new federal republic and its form of liberal democracy. This distortion was attacked relentlessly by Mommsen in his dissertation (1984) which noted Weber's attitude toward the normative premises of conventional liberal constitutionalism and suggested that his devotion to the idea of great leadership placed his thoughts uncomfortably close to the fascist *Führerprinzip* leadership principle of Nazi political thought. This suggestion produced a controversy that broke out in a visible way in the 1964 commemoration of the centennial of his birth, when the thesis was radicalized by Marcuse and Habermas.

Mommsen later stressed that he did not believe that Weber's own intentions had been antidemocratic in the Nazi manner, but that nevertheless 'it crossed the boundaries of the traditional understanding of democracy and was amenable to reinterpretation in an antidemocratic sense' (1984).

Weber's thought appears early in the US, but not as a founding figure of sociology, since he had no 'system' of the sort that other German and American thinkers had, and was only intermittently identified as a sociologist. Economists first translated his work: Frank Knight his *General Economic History*, based on student lecture notes and some added material from earlier work, Talcott Parsons his 'Protestant Ethic,' the argument of which was popularized in Britain by R. H. Tawney. After the Second World War, the American social sciences, and especially sociology, were exported, in part as an alternative to Marxism, and Weber's ideas, understood primarily in American terms, became influential, in the UK and in Germany itself. The characteristic emphasis was on value-free science and the rejection of ideological thinking, and on specific sociological concepts, such as charisma and bureaucratization, and on Weber's rejection of the Marxist claim of primacy of material over spiritual or institutional explanation. Weberian approaches typically were seen as emphasizing the practical demands of bureaucracy, or the autonomous role of interests other than economic interests, such as ideal interests. The notion of the Protestant ethic fit with analysis of modernization and development of the sort that were part of the American response to third world and anticolonial movements, and were generalized and applied to such countries as Japan.

Weber came to be regarded as a distinguished forebear of antipositivist sociology by virtue of his use of the terms 'meaning' and 'understanding' to differentiate his own approach to sociology. The refinement and appropriation of Weber's idea of an interpretative sociology by phenomenologists such as Alfred Schütz became one source of a phenomenological approach to sociology. Weberian ideas were also conveyed through the writings of such figures as Karl Mannheim and Norbert Elias, but in forms increasingly distant from Weber's own thought. This set the stage for a series of rediscoveries within sociology of 'the original' Weber so that the 1980s and 1990s saw within sociology, and especially in the work of such writers as Wolfgang Schluchter, and more generally in connection with the *Max Weber Gesamtausgabe* project, a much more disciplined return to Weber's original concerns, and a vindication of the importance of such basic problems to Weber as the problem of Western uniqueness.

Although in his final post and through much of his teaching career Weber was an economist and economic historian, his influence on economic history has been limited. But within political science and sociology, by the end of the twentieth century, a great many of the fragments of Weber's thought had become part of the standard conceptual tool kit. It is doubtless a result of Weber's gift as a clarifier of concepts that these tools have shown such as an astonishing staying power. In many cases, such as the concept of charisma and Protestant ethic, the concepts passed into common usage.

Weberian Social Thought, History of

1. *From Weber to Weberianism*

In portraits of individual thinkers, the adjective 'Weberian' is as widely used as 'Marxian,' 'Durkheimian' or 'Freudian.' The expression 'Weberian Social Thought,' however, is an awkward one if taken to imply the existence of a unified, coherent body of work, a determinate set of beliefs, or a group of committed followers. Weber's admirers can be as jealous of his work as Marx's are of the work of Marx. Despite Weber's clearly enormous influence on twentieth century social and political analysis, there has never been a Weberian school of sociology comparable to that which grew up around Durkheim's work. There has also never been a Weberian school of political science, or a Weberian movement to match the power and intensity of Marxism or psychoanalysis. The reasons for this are as follows: the immense range of Weber's interests; the fragmented character of his work as a whole and the difficulty of reducing it to a small number of basic formulae; Weber's own disdain towards intellectual hero worship; and the intellectual and political circumstances in which his work was made available after his death in 1920. His statement that science was tied to the course of progress, and his expressed hope that his own work would one day be made obsolete, merely add irony to an already complex and fragmented legacy.

Weber's social thought does not contain a specific 'theory of' the family, state, education, history, and so on, although these have been the objects of subsequent efforts at reconstruction. It is rather a set of sensibilities, political commitments, and principles of analysis. These constitute the elements from which the various branches of 'Weberian social thought' are made up.

Politically Weber was both a liberal and a nationalist. His nationalism was the product of its time and has had little impact on his subsequent admirers, save as an embarrassing inconvenience. What Ralf Dahrendorf (1967) called his 'strange liberalism' expressed itself not in an explicit theory of human rights or justice—towards which abstractions he was skeptical—but in the search for those institutional arrangements which would ensure 'individual freedom of movement' and a politically educated citizenry in a rationalized, bureaucratized world, whose problems socialism threatened to exacerbate. Weber's political commentaries combine a concern with parliamentary or party machinations, an analysis of the major social

and economic groups of a society (considered in terms both of group interests and of group status), and the geopolitical situation of modern nation states. In these commentaries the value of freedom and the question of the qualities of human beings which a culture breeds are more important than the need to defend particular institutional arrangements on principle.

The focus of Weber's substantive sociology is the economic and social history of Europe, the major world religions, and large scale civilization complexes. The principal tool for this is the ideal type, the one-sided exaggeration of empirical reality from the point of view of a phenomenon's 'cultural significance.' Weber's ideal typical descriptions of social processes are notable for sure-footed shifts between levels of abstraction—achieved by the use of ideal types of varying degrees of generality—and for the deployment of the same type in a variety of historical settings without loss of nuance or specificity. His sociology knows neither rigid classifications of phenomena, nor social or historical laws, nor decisive individual events. He rejects holistic theories of society, anti-individualist or teleological philosophies of history, and cultural/political utopianism. The task of the social scientist is both to respect science's limits and to fulfill its vocation by promoting culturally significant historical knowledge and clarity concerning current conditions of political action, while offering no prescriptions for action. The Weberian social scientist is thus not a public intellectual in the sense that he is a nation or a people's or a class's conscience, but rather one who possesses specialist knowledge and makes that knowledge available to government and to an educated public when circumstance permits. In Raymond Aron's terms (1988), the Weberian social thinker is 'isolated and available.'

Weber's comparative study of civilizations and world religions convinced him that the secularization and rationalization of social relations in the West had not relieved individuals of the burden of previous religious struggles or conflicts, but had rather turned them inward. The centrality of 'struggle' in his work refers not merely to tragic and ineliminable conflicts between social and political interest groups or world views, but also to individually experienced conflicts between the demands placed upon modern human beings by a disenchanted world and their inward spiritual needs.

As Weber was influenced by, and integrated the thought of numerous predecessors—notably Machiavelli, Kant, Marx and Nietzsche—so the list of his successors is long and varied. Karl Mannheim, Carl Schmitt, Hans Morgenthau, Raymond Aron, Alfred Schutz, Ralf Dahrendorf or Barrington Moore may all be considered practitioners of 'Weberian social thought' in one form or another, though in each case key elements of Weber's work are neglected or rejected. Many others, notably German neo-Marxists have accepted the broad terms of Weber's diagnosis of the modern world—particularly his 'disenchantment' thesis—without endorsing either his response or the tools with which he constructs it. Significantly, Catholic social thought has found nothing congenial either in Weber's philosophy of social science or in his political writings, which decisively reject both holistic forms of social analysis and organicist social ethics.

2. *Weberian Social Thought in Germany*

The history of Weberian social thought is paradoxical and discontinuous, particularly in Germany and the USA. Following Weber's death in 1920, the hasty attempts by Marianne Weber to make both his work and life more broadly available in Germany met with mixed results. While Weber's work—in particular the lecture 'Science as a Vocation' of 1919—continued to be widely discussed, and many considered him to be the greatest of all German sociologists. However, in the intellectual climate of the Weimar Republic, Weber's research program, which refused to attribute agency to social wholes, and which endorsed the comparative analysis of social structures and cultural systems, met with broad indifference. The attractions of dialectical, utopian or messianic grand narratives, exemplified by Weber's one time protégés Georg Lukacs and Ernst Bloch, or by Oswald Spengler, and of holistic sociological analysis, proved greater to the generation which matured after World War I. With the advent of national socialism in 1933, Weberian social thought met with open hostility in universities which were oriented to holistic, Volkish doctrine and practice, and in which analysis and the drawing of categorical distinctions was considered typical of 'the Jewish intellect.' In the quarter century following its publication in 1922 *Wirtschaft und Gesellschaft*, considered by many to be Weber's *magnum opus*, had sold no more than 2000 copies.

After 1945 the advent of a Federal Republic oriented officially to a US image of democratic values, and the denazification of German universities, further weakened the link between German sociology and its classical roots. The formal and substantive influence of the American occupying forces culminated in an intellectual climate combining two basic needs for an empirical and methodologically sensitive social inquiry; and for what Helmut Schelsky (1959) called 'a neutral background ideology with a non-antagonistic character.' Neither these, nor the widespread postwar belief that social science ought to be a direct participant in the planned reconstruction of European society, were conducive to a revival of Weberian social thought. Wolfgang Mommsen's study ([1959] 1984) then strengthened an association between Weber and an outdated, bellicose nationalism. A measure of redress came in Heidelberg in 1964 with the conference to mark the centenary of Weber's birth, though notably all the keynote speakers were at the time

working outside Germany. In the 1960s and 1970s, while Weber's diagnosis of modernity—particularly the accounts of rationalization and disenchantment—remained an indispensable resource for second and third generation critical theorists, German social thought of the period was predominantly neo-conservative. This was exemplified by the neo-Aristotelianism in political philosophy and Gehlen's theory of institutions in sociology, neo-Marxist and neo-Freudian. The 'left Nietzscheanism' of the late 1960s did little to alter the predominant image of 'Weberian social thought' as a mode of cultural and political analysis within universities. In the year 2001 Weberian social thought in Germany is less a distinct style of thinking which rivals Marxism, rational choice theory or structuralism, than a set of analytical/conceptual tools or resources, a starting point, deployed by different scholars in a wide variety of settings. For the rest, Weber's work continues to be the object of hermeneutic puzzlement. Notable here are efforts to reconstruct the meaning of his work as a whole (Tenbruck 1980, Hennis 1988) and to systematize it into a coherent developmental history of the West (Schluchter 1981), both of them expressions of uncertainty as to what 'Weberian social thought' is. Hennis' interpretation, which plays down the developmental aspects in favor of Weber's 'vision of man,' claims that at the center of Weberian social analysis lies the study of the way in which individuals in different social locations conduct their lives. Though regarded as somewhat idiosyncratic in his native Germany, this has proved popular in Anglo-Saxon scholarship and has led to claims that Weber's work has affinities with contemporary diagnoses of post-modernity and even with some branches of cultural studies.

3. *Weberian Social Thought in Britain and America*

Paradoxically, Weberian social thought has flourished as readily in the English-speaking world as it has in Germany. Responsibility for this is frequently attributed to Talcott Parsons. Parsons contributed the first English-language monograph devoted to Weber's work as a whole, volume 2 of *The Structure of Social Action* (Parsons 1937) and also published a translation of *The Protestant Ethic and the Spirit of Capitalism* in 1930, and part of *Wirtschaft und Gesellschaft* in 1948. But this would be to ignore the role of numerous German *émigré* scholars in the USA in the 1930s and 1940s, such as Alexander von Schelting and Albert Salomon, and the presence of Karl Mannheim in the UK after 1933. The most accessible general collection of Weber's writings, *From Max Weber* (1946), was translated and edited by the *émigré* Hans Gerth with C. Wright Mills, and was followed in 1949 by Edward Shils' translations of three pieces on the philosophy of social science and culture, *The Methodology of the Social Sciences* (Weber 1949).

Nevertheless, more than one scholar loyal to European traditions of social thought has observed that in the course of the twentieth century the ideas of German thinkers in particular—one thinks here of Heidegger, Nietzsche and Freud—have been trivialized as they have been transferred to North America, and that that those of Weber are no exception. Hence the claim that the Weberian social thought which flourishes in the Anglo-American world might be interpreted as a bloodless version of the original which inspired it. This is certainly the view of Wilhelm Hennis (1988), who has laid responsibility for this at the door of Talcott Parsons. Parsons' functionalist account of institutions, scientist account of the nature of action, and evolutionary conception of history represent, so it is alleged, a misuse of Weberian ideas. In particular, it blinds us to the tragic sensibility that animates both Weber's conception of Western history and politics and his relationship to his own scientific activity. The Americanized Weber is, it is claimed, a Weber to whom the grand historical dramas and passions that unfold on the pages of Marx and Nietzsche meant little.

Yet against this charge, it may be recalled that Weber himself was an admirer of both the political and cultural achievements of three Protestant cultures outside Germany, the Netherlands, the UK and the USA. Weberian social thought in North America, which has ignored the tragic element in Weber, may be seen with caution as a partial reciprocation, an acknowledgment of how Weber's own thought might have appeared in North American conditions, freed of the specifically European burdens which Weber took it upon himself to bear. A central Weberian motif is after all, the need of the social scientist to face up to 'the demands of the day,' whatever they may be.

In addition, in should be noted that more than one Weberian baton has passed through the hands of Anglo-Saxon scholarship. As well as Salomon, Schelting and Gerth, versions of Weberian social thought have been promoted by Hans Morgenthau, Gunther Roth and Reinhard Bendix in the USA, and by John Rex and other conflict theorists in the UK. Morgenthau's realist theory of international relations, in which priority in political analysis is given to the power political interests of large nation states and the conduct of statesmen, bears the imprint of Weberian thought throughout. Secondly, Weber's historical sociology of domination, mediated by Bendix and Roth, has exerted a major influence on the analysis of the pattern and dynamic of development in Western and non-Western societies alike. The work which has grown up around Barrington Moore, Theda Skocpol, Bendix, and, arguably, Perry Anderson, owes a good deal more to Weber's own sociology of domination than to Parsons' version of it. These writers, however, unlike Weber, have generally organized their material

according to a theme, pattern or formula—dictatorship or democracy, Kings or people, the Absolutist State, the priority of external over internal pressures in revolutionary situations. And these historical sociologists have only fleetingly employed the distinctively Weberian rhetorical device—to be found even in his most antiquarian studies—of making implicit reference to current political circumstance. In the UK, the version of sociology which came to be known as conflict theory, and associated in particular with the work of John Rex and Ralf Dahrendorf, may be taken as a conscious effort to deploy Weberian categories in the analysis of industrial labor and race relations. A characteristically Weberian feature of such work was that it combined empirical inquiry, theoretical and methodological self-consciousness, and a sense of the social and political urgency of the problem addressed.

4. *Weberian Social Thought in France*

Weberian social thought has never taken root in France, as is made clear by the late appearance of French translations of Weber's work: *Science as a Vocation* and *Politics as a Vocation* in 1959, *The Protestant Ethic and the Spirit of Capitalism* in 1964, *The City* in 1982, *The Sociology of Law* in 1986. *Economy and Society*, while translated into Spanish in 1944 and Italian in 1961, has yet to appear in full in a French edition. This is partly explained by the entrenchment of national intellectual traditions in the first half of the twentieth century, exemplified by the oft-noted mutual indifference of Weber and Durkheim. Within sociology, the Durkheimian School remained important in the 1920s, and the reception of Weber's work was sporadic. Maurice Halbwachs reviewed Weber's *Protestant Ethic thesis* in 1925, and Raymond Aron's *German Sociology* of 1935 devoted a chapter to Weber. But the former remained a committed Durkheimian while Aron's text did no more than make a French audience aware of Weber's existence. The other potential conduit for Weberianism in France in the 1920s, Georges Gurwitch, knew German social and political thought primarily via the legal philosopher Emil Lask, and following World War II became openly hostile to what was seen as Weber's interpretative arbitrariness, nominalism, and lack of dialectical acumen.

Paradoxically, the role of the USA in postwar France, and doubts about the scientific status of sociology and attendant search for new voices appeared to make possible a revival of the fortunes of Weberian thought, with many younger French sociologists spending time in America and encountering both Weber and survey research. Yet the prestige of Durkheimian sociology gave way not to Weberianism but to Hegelian/Marxian and later Heideggerian and Nietzschean philosophy, an exclusion reinforced by the notorious intensity and intimacy of a French intellectual life dominated by Paris. With the exception of Raymond Aron and Julien Freund, no major French intellectual of the postwar period could be described as a Weberian social thinker, and even Aron, who maintained a constant dialogue with Weber and whose public role was the Weberian one of political educator oriented to 'the demands of the day,' offered the French public only a restricted version of Weberian social thought. Oriented primarily to the relationship between ethics and politics in the lives of political actors, it largely avoided the sociological analysis of the dynamic of material interest that found its way even into Weber's most journalistic political commentaries. And where Weber's political commentaries emphasized the tragedy of individual choice, Aron sought to reconcile conflicting values. It may be argued that in the 1950s this Weberian social thought for statesmen found its way into the thinking of many who passed through Aron's hands at the *Institut des Sciences Politiques* and *Ecole Nationale d'Administration*.

In the 1960s a more social, less overtly political form of Weberianism developed around the work of figures such as Alain Touraine and Jean Marie Vincent, who deployed Weberian categories in the study of industry and organization, and of new forms of social conflict. This work also allowed for a Weberian critique of the bureaucratizing tendencies within the French State. Since 1980, with an increasing awareness of the importance in Weber's work of the themes of life conduct and style of life, the work of figures such as Pierre Bourdieu and Michel Foucault has been held to display affinities with that of Weber. However, while Bourdieu's theories of 'cultural capital' have some affinities with Weber's account of status and prestige, his work as a whole owes as much to Marx and Durkheim. Michel Foucault's work on power, discipline, and the conduct of life bears thematic comparison with Weber but his archaeological and genealogical historical method, and libertarian conception of politics, differ from Weber's in basic respects.

5. *Weberian Social Thought in Other Countries*

Outside the European mainstream 'Weberian social thought' has been enormously influential without gaining a distinct foothold or producing significant modification or extension. In Italy, those elements of Weber's work which are of importance have been grafted on to an already established tradition of realist social and political analysis which overlaps with Weber's approach at numerous points. In the Soviet Union before World War II and in state socialist countries after it, Weberian social thought did not flourish. In the 1920s, while Russian historians such as Neusychin discussed Weber's account of feudalism and of the origins of capitalism with some sym-

pathy—albeit through aligning Weber with Marx—the ethical and political dimension of Weber's thinking—exemplified by *Science as a Vocation*—remained a closed book. This state of affairs, in which Weber's work was either shown to have affinities with Marxism or rejected for its combination of neo-Kantianism and undialectical positivism, prevailed throughout the Soviet bloc, and to a considerable extent in the West too, until the mid-1970s, until renewed interest among Western scholars in Weber's work as a whole began to have an effect in state socialist countries. In countries such as Poland—which before 1945 had a strong indigenous tradition of non-Marxist social thought—Weber's work has exerted a growing influence since the 1970s, firstly on discussions of ethics and politics, and since 1989 on discussions of the ethical and religious significance of economic conduct in rapidly transforming societies. One of the more remarkable episodes in the history of Weberian social thought concerns Japan. The opening of Japan following the Meiji restoration led to numerous intellectual exchanges with an imperial Germany that was rapidly developing while retaining many elements of a feudal/traditional ethos. Weber's co-editor Emil Lederer spent two years in Tokyo in 1923–1925, as did Karl Löwith in 1936–1941. The effect of these, was that the Protestant ethic thesis was discussed as early as 1910 in Japan, and Japanese translations appeared of the *General Economic History* (1927), of *Science as a Vocation*, *The Meaning of Ethical Neutrality* (both 1937), and *Politics as Vocation* (1939) before they appeared in English.

6. *Weberian Social Thought After 1989*

The history of Weberian social thought since the end of World War II has been largely one of the way in his work has been mediated and refashioned to suit changing political, economic, and intellectual circumstance. The fruits of those efforts have been ambiguous, the elements of Weber's own thought being developed in different directions and not always to Weberian purposes. Parsonian functionalism and Schutzian phenomenology are notorious cases in point, along with the fragmented appearance of Weber's work in anthologies, and the concentration of empirically informed Weberian social thought in the areas of industry and organization. Yet following the collapse of communism in 1989, with the geo-political tensions in Europe which gave rise to nationalist wars and the unification of Germany, and the rapid development of capitalism and the trappings of democracy in China and East Asia, there may be grounds for arguing that the history of Weberian social thought has come full circle. Also, that the current problems and dilemmas facing Europeans and non-Europeans alike are more directly Weberian than they have been at any time since his death.

Questions asked via Weberian categories during the cold war—are Western societies evolving towards a rationalized and disenchanted 'modernity'? What are the appropriate terms in which to understand the nature of human action? Has ideology come to an end? What are the main dimensions of power and authority within industrial enterprises and bureaucratic organizations?—may begin to yield to ones which recall the atmosphere of political and social urgency which animates Weber's own texts, is a united Germany with its capital in Berlin a threat to its Eastern neighbors, or for that matter its Western ones? What social consequences follow a state of affairs in which the European community confronts its poorer neighbors as a land of seasonal opportunity and as a fortress? Is there a difference between Protestant and Catholic social thought on European integration? What effects do new forms of commerce and enterprise have on relationships between urban and rural areas in societies with large peasant populations? What of the relationships between majority and minority populations? Do the institutional arrangements in the new democracies foster or hinder the political education of their citizens? What are the consequences of the rapid transition to a market economy for family structures, welfare provision and, above all, for the manner in which individuals are able to conduct their lives? What is the relationship between religion, ethics, and economic or political conduct? Can these questions be posed in the same way in Europe and the rest of the world, or is it still necessary to take into account the different religious and civilizational parameters through which they are addressed?

It would be un-Weberian to predict the future of Weberian social thought, but one might surmise that until 2020 the search for the core elements of Weber's own world view will wane as its protagonists reach the end of their careers. At the same time, the questions which Weber asked of his own time, questions which twentieth century social and political science have been either able to avoid or reluctant to address, may cast a well-defined shadow over the social and political world of the first half of the twenty-first century.

Weight Regulation: Psychological Aspects

The scientific challenge of weight regulation is to understand the processes which lead some people to maintain a normal, stable weight, and others to become unhealthily fat or dangerously thin.

Body size usually is characterized in terms of body mass index (BMI) (computed as the ratio of weight measured in kilograms to the square of height measured in meters). A BMI below 18.5 is defined as underweight, from 18.5 to 24.9 as normal weight, from 25 to 29.9 as overweight, and over 30 as obese. The predominant weight disorder in the industrialized world is obesity and now almost one in five adults are obese, and twice as many are overweight (Seidell and Rissanen 1998). Anorexia nervosa and bulimia nervosa fall at the other extreme of weight disorders, and while they don't match the prevalence of obesity, together they represent the most common psychiatric diagnoses for young women today (Hoek 1995).

1. Weight and Weight Control

Weight control problems appear to be very different at the two extremes. Most obese people are aware of their weight problem and try to regulate their food intake, but often they find it impossible to exert enough control, or to maintain control over a long enough period, to achieve a normal body weight. In contrast, patients with eating disorders appear to exert excessive control over their body weight, successfully defying biological and social pressures to eat. In between the two extremes lies the normal-weight population. At one time it was assumed that these would be the 'normal' eaters, that is, not worried about weight and regulating their energy balance without any deliberate effort. However, this view is looking increasingly questionable. In Britain, for example, the proportion of the population who are obese has doubled since the mid-1980s, and concerns about weight control are widespread, even among the normal-weight, suggesting that weight regulation is neither effortless nor effective. The normal-weight population probably includes a minority who maintain a normal weight without deliberate effort, a larger group (most often men) whose weight slowly increases over time, but who make little attempt to regulate it, and the largest group (in which women predominate) who are chronically attempting to control their food intake in order to regulate their weight closer to the contemporary ideals for body shape.

Research into psychological aspects of weight regulation is predominantly in three areas: (a) the psychological processes leading to the development of eating disorders, (b) the psychological processes leading to obesity, and (c) the causes and consequences of dietary restraint.

2. Weight Regulation in Eating Disorders

Psychological research on eating disorders has a long history dating back to observations in the eighteenth century that extreme loss of weight could have a psychogenic origin. More recently, the formal psychiatric diagnosis of anorexia nervosa was established, with key features being extreme weight loss, a morbid fear of fatness and deliberate restriction of food intake to achieve a low body weight. Bulimia nervosa was

characterized later as a distinct but related disorder, sharing a morbid fear of fatness, but with an eating pattern consisted of binge eating followed by self-induced vomiting or purging to achieve weight control (Garfinkel 1995). Much of the psychological research on eating disorders has been concerned with the origin of fear of fatness, and although there are a number of aetiological theories (see Brownell and Fairburn 1995), the most widely accepted view is that eating disorders emerge in response to the cultural pressures for a slim physique in vulnerable individuals. Recent evidence suggesting that there is a genetic element to eating disorders is consistent with the idea that there is an inherited predisposition which depends upon events in the environment to emerge as a disorder (Bulik et al. 2000).

2.1 Weight Control in Anorexia Nervosa

From the perspective of weight regulation, the most interesting question is how anorexic patients successfully maintain a low body weight, when everyone else finds it so difficult. There has been surprisingly little progress in understanding this process. Implicit in the etiological accounts is the idea that eating disordered patients are exceptionally highly motivated. Weight gain is so much feared that any degree of suffering is acceptable to avoid it. Cognitive factors may play a part, with clinical evidence indicating that anorexic patients use an elaborate array of cognitive strategies to render the idea of food and eating undesirable. A third factor is personality; anorexic patients tend to be both perfectionist and persevering, either of which might facilitate weight control. However, none of these factors appears to capture the secret of the extraordinary, albeit pathological, weight control capacities of patients with anorexia nervosa.

2.2 Weight Control in Bulimia Nervosa

The phenomenology of bulimia nervosa illustrates a different weight control strategy, involving giving in to the desire to eat during binge episodes, but avoiding the consequences of eating (weight gain) by inducing vomiting (Garfinkel 1995). Many bulimic patients start inducing vomiting as a temporary means of gaining control over their weight, but in practice both the sense of loss of control and the size of the binges, often increase. One explanation for this is that appetite is modified by the postingestional calorific consequences of feeding, and if these are attenuated by vomiting then appetite increases to compensate. Inducing vomiting after eating is certainly an effective strategy for weight control, but in terms of adverse psychological and physical effects, the costs usually exceed the benefits.

3. Weight Regulation in Obesity

The problem of obesity needs to be investigated on several levels in order to understand (a) why it has become so much more common over recent decades, (b) why some people are so much fatter than others, and (c) how obesity treatments could be made more effective.

3.1 The Increasing Prevalence of Obesity

Most accounts of the shifts in obesity prevalence over time draw not on changes in social or psychological conditions, but on the combination of an environment which favors a positive energy balance and an appetite control system which evolved when the food supply was limited. There is now an abundant, highly palatable, food supply in industrialized countries. At the same time, transportation systems and mechanisation have reduced the energy demands of everyday life. If human beings evolved to store energy supplies, then it is not surprising that so many people are now overweight (Hill and Peters 1998).

3.2 Emotional Theories of Obesity

Psychologists' first incursions into understanding the causes of obesity at an individual level focused on underlying psychopathology, with suggestions that eating served unconscious needs. These ideas came largely from clinical observations by psychodynamically-orientated therapists. Empirical studies have shown that levels of psychopathology are no higher in the obese than the normal-weight population, and although there is evidence that severely obese adults have raised levels of depression and anxiety, this appears to be a response to the multiple handicaps and stigmatization associated with obesity (Sobal 1991). Unfortunately, popular discourse continues to equate obesity with psychological problems, leading to greater problems of stigmatisation.

3.3 Psychobiological Theories of Obesity

This perspective was followed by psychophysiological models which combined investigations of the psychophysiology of obesity and food intake with assessments of eating behaviour. Obesity was hypothesized to be caused by low responsiveness to internal cues for satiety combined with high responsiveness to external food cues. Laboratory studies showed differences in responsiveness to food between obese and normal-weight adults, and the theory was reinforced by parallel observations on animal models of obesity (Schachter 1968). At around the same time, the idea of

a 'set-point' for weight was put forward, suggesting that each individual had a particular level of fat stores which was defended by up-regulating appetite if they were depleted, and down-regulating it if they were filled. At the time, the 'fact' that most people had a fairly stable body weight over their lifetime was adduced as support for the set-point theory. Obese people were hypothesized to have a higher than normal set-point, and would show abnormalities of appetite when they lost weight to below their own set point weight. However, subsequent research suggested that it was not obesity *per se* nor even weight loss which was linked with abnormal appetite, but deliberate weight control (Herman 1978). Obese people who were not bothering with weight control appeared to respond normally to food and satiety cues, while normal-weight dieters showed a pattern of responses which resembled the dieting obese. These observations led to tremendous interest in research on the effects of dietary restraint (see below) but a period of relative stagnation in research into the psychological process in obesity.

3.4 Psychological Treatment for Obesity

Psychological treatments for obesity developed primarily from a behavioral analysis of the problem. Obese people were hypothesized to have abnormal eating habits, which tended to promote a positive energy balance. The earlier formulations of the so-called 'obese eating style' incorporated rapid eating (preventing the normal processes of satiation emerging during the course of the meal), chaotic eating (eating in a wide range of different places), as well as the idea of externally-cued eating. None of these ideas survived rigorous examination, but in the meantime, they had proved to be useful as the basis for behavioral treatment. Treatment incorporated stimulus control (ensuring that exposure to cues for eating were controlled), slow eating, and limiting the number of places in which eating occurred, along with the standard behavioral procedures of self-monitoring, goal-setting, and self-reinforcement. The first results were very positive (Wing 1998). In time, cognitive elements were added to the programs, including modifying self-defeating cognitions and dealing with the lapse-relapse sequence. Cognitive behavior therapy (CBT) is now regarded as the gold standard for obesity treatment, and CBT training has been identified as a necessity for other health professionals. However, it remains true that many patients drop out of treatment, few lose substantial amounts of weight, and many regain the weight that they have lost, so there is still a great deal of scope for improvement.

Current thinking on obesity treatment has recovered from a period of despondency about treatment efficacy by acknowledging that weight losses are likely to be relatively small, and taking account of the fact that even small weight losses can have significant benefits for health (Allison and Pi-Sunyer 1995). There is a recognition that obesity is a chronic disorder requiring continuing care. There is a renewed interest in the psychological aspects of obesity, particularly the problems of body image and social stigmatisation, and some suggestion that treatments which offer a broader-based approach produce better overall outcomes on health and wellbeing. Most importantly, the difficulties which almost all obese people experience in losing weight has led to greater interest in prevention, in the hope that interventions could be initiated before overweight is established and health and well-being are compromised.

4. Weight Regulation and Dietary Restraint

While health risks associated with overweight emerge only at a BMI of over 25, many women aspire to a much slimmer figure as promoted across all forms of media (Brownell 1991). In search of the slim ideal, many women, and even pre-adolescent girls, try to restrict what they eat in order to control their size. The concept of dietary restraint was put forward in 1975, to describe an eating pattern which consisted of attempted control over eating, interspersed with regular failures of control (Herman 1978). Several psychometric measures have been developed, starting with the original Restraint Scale, but subsequently distinguishing the concepts of attempted control (now often called restrained eating) and failures of control (called counter-regulation or disinhibition). A raft of experimental studies showed that restrained eaters were less responsive to satiety, more responsive to palatability, and more likely to show over-eating in response to negative affect. Binge eating was also conceptualized in relation to restraint, following the realisation that most binge eaters were also chronic dieters (Wardle and Beinart 1981). These observations turned existing ideas on their head in suggesting that attempts to regulate food intake might be the cause of, and not simply a response to, problems of eating control.

4.1 Restraint and Inhibition

The association between restraint and regulatory problems is now well-established, but there is still uncertainty about the mechanism, and especially about why restrained eaters should ever actually eat *more* than unrestrained eaters. The cognitive model of restraint proposes that after a high calorie preload (in the laboratory) or a dieting transgression (in everyday life), the dieter 'reasons' that they might as well take advantage of the situation and leave dieting until tomorrow. The psychobiological model suggests that after a long history of imposed cognitive control, in which normal biological controls have been overridden and food intake patterns are chaotic and

irregular, sensitivity to satiety or hunger signals becomes blunted and learned patterns of hunger and satiety are disrupted. The emotional model suggests that the dieter copes with negative emotional states with dissociation, and as part of this, loses contact with their restrictive intentions. There is some evidence for each of these processes, but as yet there have been no definitive studies that distinguish between them.

4.2 Implications for Treatment

When the paradoxical effects of dietary restraint were invoked to explain binge eating in bulimia, this led to cognitive-behavioral treatments focusing not only on helping bulimic patients to take a more positive view of their body, but also to relinquish rigid dietary restraint. Likewise in obese binge eaters, loss of control over eating has been interpreted as a consequence of strict dieting. This view was supported by the weight history of many obese patients, among whom any period of losing weight on a diet seemed to be followed inexorably by regain to higher than initial weight, as well as by the poor outcome of most obesity treatment programs, where long-term follow-up showed that many patients ended up fatter than when they had started. Caution was counseled in offering conventional dietary treatment to obese binge eaters, and some psychologists promoted so-called 'un-dieting' treatments, where obese patients could be helped to stop their long-established habits of trying (and failing) to restrict what they ate (Goodrick et al. 1998).

4.3 Deliberate Weight Control

Recently, there have been signs of a renaissance of interest in deliberate weight control in the face of the epidemic scale of the obesity problem. Evidence is emerging that dieting is not inexorably associated with problems of control (Howard and Porzelius 1999). Among the obese, binge-eaters have not been found consistently to be more restrained than nonbinge-eaters, and contrary to expectations, obese binge-eaters fare no worse than nonbinge-eaters in conventional dietary treatments. In the normal-weight population, individuals who are either dieting or at least 'watching their weight' appear to consume healthier diets than nondieters, and probably gain less weight over time. There has also been a realization that most research on dietary restraint in the normal population was based on comparisons between restrained and nonrestrained eaters, but since restrained eaters probably become restrained because they were susceptible to weight gain, the causal processes may be more complex than was thought.

On present evidence it seems likely that restraint can increase the risk of loss of control, but there may be riskier and less risky forms. Flexible restraint has been associated with better weight control than rigid restraint. Eating regimens with regular meal patterns and a balanced nutrient intake are probably better than short-term drastic restriction. Negative body image is very often the motive for attempts at weight loss, but may in itself increase the difficulty of controlling weight, so interventions which improve body image could facilitate weight control. Higher levels of physical exercise consistently are associated with better weight control, both in the normal population and in maintaining weight loss after treatment, and deserve a higher profile in psychological treatments.

5. The Future

In recent years one of the most influential developments has been the observation that individual differences in weight are under substantial genetic control. Identical twins are highly similar in weight at all stages of life, and consistently more similar than fraternal twins. The results of twin studies are supported by adoption studies which have shown that the BMI of adoptive children is correlated strongly with the BMI of their biological parents and barely at all with the adoptive parents' BMI. These findings have important implications for psychological research into weight control, pointing to the need to investigate eating behavior in 'at risk' populations (Faith et al. 1997). If shared family environment plays much less of a part in determining weight than has been believed, then this raises the question of what aspects of the individual environment promote weight regulation and control.

In the past, psychological research on weight regulation has tended to run a parallel course to research on biological processes, but the best progress is likely to come from integrative approaches in which the control of appetite and weight is seen as the product of a network of interactions among the elements from different domains. There have been tremendous advances in understanding the biological basis of obesity, and a growing interest in new pharmacological treatments, all of which offer great opportunities for psychological research as we seek to understand how biology and behavior are integrated to achieve weight regulation.

Welfare

Welfare is the result of an expanding production of care, financial benefits, or other services for ensuring the material and cultural conditions for the reproduction of humans as biological beings, as economic producers and members of a work force, and as social beings and citizens (the conditions of integration in society and of social cohesion). These functions for satisfying a set of needs are performed through various informal or institutionalized arrangements (ranging from family support to public assistance and social insurance funds) and by various types of actors (families, employers, nonprofit organizations, public administrations, etc.).

By identifying the present-day producers of welfare, the first part of this article will show that what we now commonly call the welfare state represents a combination of the factors of production of welfare, wherein the state plays a major but not exclusive role. The second part will describe the combinations corresponding to different types of welfare states. Finally, recent trends in welfare and reforms thereof in response to the 'crisis of the welfare state' will be examined.

1. *The Producers of Welfare*

There are three major producers of welfare: civil society, the market, and the state. Depending on its history, level of economic development, and political and social structures, each country has worked out its 'mode' of welfare production, characterized by a particular combination of these three pillars in what has been called the 'welfare triangle.'

1.1 *Society*

Forms of solidarity based on belonging to a neighborhood, community, or family represented the first means of social protection and care for individuals, before state institutions replaced face-to-face solidarity with public welfare systems. The family and nonprofit organizations, in particular, are major producers of welfare in civil society.

1.1.1 The Family. The family used to be the major supplier of welfare to individuals. But even in welfare states, it remains an influential producer of welfare, supplying as it does much of the food, housing, education, and care to children and the elderly. These unremunerated activities performed by families—and mainly by women—have always represented a basic guarantee for the individual against the contingencies of life. When old-age pension funds did not exist and the person had neither an inheritance nor an estate, the best guarantee for old age was to have many children who could later satisfy the basic needs of their aging parents, when the latter would no longer be fit to work. Family care, a fundamental sort of welfare in preindustrial societies, was also one of the preconditions for the development of wage labor: 'Participation in wage labor presupposes a support-system of unwaged labor outside the labor market' (Taylor-Gooby 1991, p. 100).

Even though the modern welfare state has assumed many of the family's traditional roles (especially in providing income support, education, and care to the young and old), the family still produces welfare.

During the 1980s and 1990s, the spread of joblessness and the aging of the population have increased its role. For one thing, unemployed young people live longer with their parents. For another, governments have, given the increasing number of dependent older persons, encouraged families to increase their help and care for aging parents—the intention being to curb the growth in public expenditures devoted to caring for the elderly. In families with four generations, two of them in retirement, young retirees quite often have to handle the needs of both their unemployed adult children and their dependent elderly parents. However, the family's role as a producer of welfare varies from one type of welfare state to another. Since welfare in southern Europe, for example, tends to be organized along the lines of providing monetary benefits, families there have to make up for the lack of adequate services.

1.1.2 Nonprofit organizations. Nonprofit organizations are important producers of welfare, even in developed welfare states. The friendly or mutual aid societies of the past were the harbingers of the public social security systems of our times. At present, nonprofit organizations cooperate closely with the state in order to produce welfare. In many continental European countries, the state provides financing, and nonprofit organizations deliver services. In Germany for instance, most of the assistance provided to families and the elderly comes through federations of nonprofit organizations. The same holds for France. Nor should we set the nonprofit sector at odds with the marketplace. Many for- and non-profit hybrids have come into being. In France for example, certain home services for the elderly are provided through associations, which take the elderly's place as an employer of home helpers and bill them the costs.

1.2 The Market

In the welfare vacuum in the early nineteenth century, security and well-being depended on one's estate, on one's status as property-owner. The person who owns 'a capital or an estate thus has insurance whereas those who own nothing depend on others in case of need' (Hatzfeld 1989, p. 27). At the turn of the twentieth century, a new type of security arose, based on social law (mainly labor law) instead of property rights. It served as the foundation for social insurance and social security systems.

On the periphery of these national welfare systems, the market continues, through private insurance funds and for-profit social services, satisfying part of the population's welfare needs. Several national welfare systems allow for public as well as private, for-profit activities. Such is the case for health in France and Germany, and for education in the United Kingdom.

Since the 1980s, 'neoliberal' supporters of free enterprise have advocated fully or partly privatizing social insurance and, in particular, retirement funds (World Bank 1994). However, privatization risks splitting the population in two: those who have the means of contracting out to a private insurance policy and those who will depend on public assistance for minimal support.

Companies, too, produce welfare for their employees. To provide employees with (supplementary) health or pension benefits, they usually turn to the marketplace and private insurance funds. When such benefits are provided under collective agreements, representatives of labor and employer organizations run the programs. This happens in the countries described as 'neocorporatist' (Germany, France and The Netherlands). In some countries, such as the United States or Japan, company programs provide basic access to welfare. The phrase 'corporate welfare' has been used to describe the Japanese system.

1.3 The State

Before the late nineteenth century, the state primarily intervened in society in order to maintain law and order rather than to provide social security for all. It played the role of a police on the periphery of the 'self-regulating' marketplace (Polanyi 1944). Public assistance was, in the main, repressive.

Modern welfare states have arisen out of the massive industrialization and urbanization trends, and their consequences for the emerging working class. Working class poverty motivated increasing state interventions in social policy. As wage-earning developed, more and more people had a single source of income: the sale of their labor in the marketplace. Whenever their strength failed, when illness, joblessness or old age felled them, their lives plunged into insecurity. In this context, security could no longer depend on owning property or on individual responsibility. It would be linked to the labor law and the status of wage-earner. As sociohistorical studies have established, the welfare state was built up on a new linkage, characteristic of 'wage-earning society,' between the dependent status as wage-earner and an extensive system of protection against risks (Castel 1995). Wage-earning employment and social security formed a system. The state would regulate it and vouchsafe the wage-earners' new 'social rights.' Through its legislative and regulatory interventions, the state gradually made insurance for covering the risks of health and old age compulsory for employers and their employees; and it organized social protection.

As Ewald (1986) has shown, the technique of insurance led to a new conception of responsibility and risk, which has served as the foundation for the development of the welfare state. This conception broke with the liberal doctrine of individual responsi-

bility and fault; and insurance offered a way out of the blind alley of paternalistic company-run welfare policies. It has thus become possible to avoid the quest to find a fault and the party causing it. The insurance technique replaces this quest with the question of how to collectively share the costs of risks. It has served as the basis for another conception of security in industry, and introduced a new rationality and a different paradigm of risk and security. On this basis, welfare states would develop after World War II. The welfare state represented a social pact between wage-earners and employers, a pact backed by the state and, to a large degree, organized by it in various ways from country to country.

Modern welfare states guarantee a comprehensive set of social rights to all citizens. These rights have thus become a major part of citizenship. This universality differentiates contemporary welfare from the social laws of earlier times, which mainly targeted the poor or the working class. According to Briggs (1961), the welfare state modifies the interplay between forces in the marketplace in three main ways. First of all, it guarantees a minimum income to individuals and families. Second, it reduces insecurity by enabling individuals and families to cope with the risks related to illness, old age, unemployment, and disability. Third, it guarantees all citizens, regardless of class or social status, access to certain standard of social services and facilities. As a consequence, the idea of the welfare state centers around this reference to the necessity of counterbalancing the market economy's negative effects. For this reason, 'decommodification' was one of the principal indicators used by Esping-Andersen (1990) to draw up a classification of 'welfare regimes' that is now solidly established in the literature.

2. *Three Types of Welfare Regimes*

Initially, comparative research on welfare resorted to a single model of the welfare state, under which one quantity was used to measure the contribution to welfare, namely public expenditures on it. Countries were thus classified on a scale based on these expenditures. This sort of approach to understanding the welfare state led to the 'industrialization' or 'convergence' thesis (Wilensky 1975), which maintained that the major determinant underlying the development of the welfare state is economic growth, with its bureaucratic and demographic implications. Accordingly, the degree of welfare in a country was causally linked to the level of economic development there. This implied that all developed countries would gradually converge toward similar social security programs. This single-minded 'developmentalist' view of progress proved unable to account for the diversity and specific characteristics of welfare programs in different countries, and even less able to explain the timing of the introduction of such programs. Reducing all forms of public interventions to the single quantity of expenditures on welfare does not enable us to understand the specific ways that, from country to country, the state itself has been built up through close interactions with civil society (Rosanvallon 1990). As it turned out, the same level of expenditures might correspond to considerable differences in welfare states, in both their objectives and forms of organization. For these reasons, it was necessary to identify and analyze different types of institutional models of the welfare state.

The typology of welfare states worked out by Esping-Andersen (1990) has replaced the foregoing approach. This scholar identified 'three worlds of welfare capitalism'—social democratic, conservative-corporativist, and liberal or residual—a typology based on three criteria:

(a) the level which the system has reached in 'decommodifying' needs, i.e., the degree to which individuals or families can maintain a socially acceptable standard of living, independent of their participation in the market;

(b) the system's impact on social stratification;

(c) the relationship between state, market, and family.

The social democratic welfare state, typical of Scandinavia, is the most 'universalist' of the three systems. It offers not just a high level of protection against risks, but also a good supply of services. This type of system ranks highest on the scale of decommodification, since its extensive 'social rights' grant individuals the most freedom from dependency on the market. Under this model, taxes serve to cover the costs of social services and benefits. The main aim is an equal redistribution of wealth. Hence, this type of system has a unifying effect on social stratification.

The conservative-corporativist welfare state is based on the wage-earning relationship. Benefits and services are granted as a function of one's occupational category. The aim is not to redistribute wealth but to partly replace wage-earners' income so as to maintain their status when they are at risk. This sort of system is financed not through taxes but through payroll contributions. Despite its generous benefits, it ranks lower on the scale of decommodification than the social democratic welfare state. Eligibility for benefits depends on access to the labor market and maintenance in the wage-earning status. When employment difficulties crop up, whole groups of young people, women, etc., lose their eligibility and fall back into the safety net of public assistance. Usually found in continental Europe outside Scandinavia, this type of system sometimes goes under the name of 'continental welfare state.'

The liberal or residual welfare system assigns the most weight to the market economy and the least to the state. As a consequence, it ranks lowest on the decommodification scale. The state intervenes only as

a last resort, and it serves mostly means-tested benefits tied to the person's income. Very limited welfare is provided with the intention of favoring the person's return to the labor market. In terms of social stratification, this system causes intense inequality between those who can take out private insurance and those who have to live on fixed, restricted allocations, and who are often stigmatized for receiving them. The United States of America is frequently mentioned as resembling, in many ways, this type of system.

As we can see, each of these welfare systems corresponds to a particular combination of welfare producers. Each combination of the three pillars—civil society, the market, and the state—in the welfare triangle represents a specific system of social protection. This combination cannot be reduced to state interventionism; instead, it assigns the state a degree of influence that varies along with that of the other two pillars of the welfare state.

3. *The Challenge: Reforming Welfare States*

Since the late 1970s, fierce criticism has increasingly been voiced about the crisis of contemporary welfare states. So far, however, reforms have met with strong institutional inertia. Most systems of social protection still have much the same structure as when they were set up four or five decades ago. The crisis of the welfare state was, at first, diagnosed in terms of the fact that all demands for welfare have gradually converged on the state, which, thus overburdened, has proven ineffective or even inefficient.

Several proposals of various sorts have been made for reforming the welfare state in line with this diagnosis. One sort seeks to reduce radically the state's role; the actions of Thatcher in Great Britain and of Reagan in the United States have been interpreted in terms of this 'retrenchment' (Pierson 1994), as the state withdraws from welfare to the profit of the market. The supporters of another sort of reform have argued for 're-embedding' solidarity in society (Rosanvallon 2000), so as to readjust the state's role by reinforcing the pillar of society in the welfare triangle, whence the idea of a 'welfare mix.' Rein and Rainwater (1986) have argued that the welfare state is too narrow a framework to cope with details about the economic well-being of individuals in a society. Accordingly, reforms must reckon with all the producers of welfare, and with how they form new combinations in the welfare triangle.

From a similar perspective, current thought about coping with the crisis of European welfare states has taken as a starting point the specific institutional arrangements in each country (Bonoli and Palier 2000). 'Each of Europe's welfare regimes confronts a different set of adjustment problems depending on their particular characteristics and thus differs in their paths to reform' (Ferrera et al. 2000, p. 431). For instance, the conservative-corporativist type of welfare system tends to be caught up in the vicious circle of 'welfare without work' (Esping-Andersen 1996). This syndrome incapacitates the system from dealing with the challenge of an aging population and its consequences for old-age pension funds. Such welfare states have usually implemented generous schemes for allowing wage-earners to withdraw from the labor market well before the age of retirement. They have thus favored the emergence of an 'early exit culture' that makes it impossible for pension reform to work. For this type of system, improving the ratio of the actively working to the retired population entails shifting from passive income support to active job policies for targeting aging wage-earners so as to maintain their employability and keep them in the work force (Guillemard 2001).

In conclusion, as this example shows, although European welfare states face the same challenges (in particular, demographic aging), they have to adopt reforms as a function of their particular problems. Imaginative solutions have to be tailored to the specific situation. They will come out of a complex process that cannot be reduced to a single procedure.

Welfare: Philosophical Aspects

'Welfare' is not an easy term to define with precision, even restricting attention to human beings. In the abstract, it refers broadly to the happiness, well-being, or good of an individual, society, political association, and so on. More concretely, it also refers to particular ingredients and sources of happiness or good. Life itself is an essential element of any human being's welfare, for example, and the means of basic subsistence, including food and shelter to some minimal extent, can be viewed as vital sources of human welfare whose provision should be guaranteed by government, as in the term 'welfare state.' The sources and ingredients of human happiness are so various, however, that 'welfare' in the philosophical sense must not be limited to basic needs or the means of satisfying them. In this article, four different interpretations of welfare are discussed critically. 'Welfarist' moral philosophies are also contrasted with 'nonwelfarist' moral philosophies. The first step is to dispel some confusion surrounding the term 'utility' and its relationship to welfare.

1. *Welfare and Utility*

Modern economists, decision theorists, and game theorists typically distinguish between welfare and utility. Utility in their terminology refers to the value of a mathematical function—strictly speaking, any function in a family of informationally-equivalent functions—that *represents* the preferences of a person or of society such that, for any pair of alternatives in the feasible set of outcomes, a larger value is assigned to the preferred alternative. The relevant family of informationally-equivalent utility functions is determined by the given assumptions of measurability and interpersonal comparability of utility. In this regard, measurability must not be confused with comparability across persons. A measurability assumption (such as ordinal measure, cardinal measure, or ratio-scale measure) specifies a particular degree of precision with which any person's preference ranking can be represented by utility numbers—the more precise, the smaller the family of informationally-equivalent utility functions. Such an assumption is logically independent of any comparability hypothesis, according to which the utility representations of different persons' preferences are mutually dependent. Given comparability, the utility function which can be used to represent a person's preferences depends on the utility function selected from the family available to represent another person's preferences. In the absence of comparability, however, there is no constraint of this sort on which members of the relevant families can be used to represent the different persons' preferences.

To illustrate, suppose that utility numbers are ordinal and noncomparable. Given the ordinal measure, a person's utility function is unique only up to positive monotonic transformations. Such transformations preserve the order of relative priority of the utility numbers assigned to the alternatives. Given noncomparability, it is permissible to transform any person's utility function without altering the utilities of other people. Thus, a person's ordinal noncomparable utility ranking generally provides no more information than that contained in his own preference *ordering*—a complete, reflexive, and transitive relation—over the alternatives.

If utility numbers are assumed to be cardinal and noncomparable, however, then a person's utility function is unique up to positive linear (strictly speaking, affine) transformations: the cardinal noncomparable family of informationally-equivalent functions is more restricted than its ordinal counterpart, which admits positive nonlinear transformations. A cardinal noncomparable utility ranking represents preference information that is richer than his preference ordering, namely, the relative *intensity* with which he prefers one option to another. If his revealed attitudes toward risk are independently assumed to measure how much subjective importance he assigns to his different options, for instance, the Von Neumann–Morgenstern method of cardinalization is appropriate and expected utility functions are valid cardinal noncomparable representations of his preference intensities (see, e.g., Binmore 1994, pp. 259–78, 304–15).

To take a final illustration, if utility numbers are interpersonally comparable, then one person's utility function cannot be subjected to any transformation unless every other person's utility function is similarly transformed. A cardinal comparable utility ranking provides information not only about the person's preference intensities, for example, but also about how intense his preferences are in comparison to those of other people. To construct such a utility ranking, however, there must be a method of making interpersonal comparisons apart from a method of cardinalization (Sen 1979). For instance, a person might extend sympathy to the other members of his society by adopting their personal preference intensities while imagining himself in their respective positions at any

pair of alternatives. He must also be able to render the different persons' intensities dimensionally compatible in order to compare them. By reducing them to a common unit, he could form a suitable extended preference reporting that when he places himself in their respective positions, he believes that one person i's preference for x over y is of greater intensity than another person j's preference for y over x, for any two persons and any pair of alternatives. His personal preferences, a subrelation of his extended ones, might continue to be decisive for his actions. But if he can extend sympathy to others in this way, his preferences can be represented by a cardinal comparable utility function. At the same time, different people may disagree with respect to interpersonal comparisons, and thus form conflicting extended preferences. *A fortiori*, different people may have conflicting personal preferences and conflicting cardinal comparable utility functions.

In general, a utility function encapsulates information about measurability and interpersonal comparability of the underlying preferences. As a device for representing this preference information (including orderings, intensities, and interpersonal comparisons), utility in this technical sense is quite distinct from any substantive idea of welfare. Indeed, utility in this sense can conflict with welfare if the preferences being represented are not valid welfare judgments: larger utility values can be assigned to alternatives which, though preferred by the agent, are worse in terms of his welfare or better than alternatives he rejects. Some have argued that the term utility should thus be confined to the technical meaning so as to avoid needless confusion resulting from the identification of utility with 'good' (e.g., Broome 1991a, 1991b). Perhaps so. But there are reasons to proceed with caution in this. First, utility continues to be associated with welfare—'being useful or beneficial'—in our everyday language. Even within economics, this everyday association still surfaces occasionally. More confusion may be caused by trying to banish it than by living with it.

Second, the identification of utility with welfare has a long history within both economics and philosophy (Sen 1987, 1991). Bentham, J. S. Mill, and other classical utilitarian philosophers held that utility means happiness or enjoyment in the sense of pleasure and absence of pain, for example, and that actions ought to be evaluated in terms of their consequences for general happiness or social welfare, maximization of which is the sole ultimate standard of good (see *Consequentialism Including Utilitarianism*). For these thinkers, any action or other thing is 'useful' or 'has utility' if and only if it has a tendency to promote pleasure net of pain. They deny (what is commonly asserted) that something may give much pleasure yet be useless, or that something may be useful even though it tends to promote more pain than pleasure. Earlier thinkers such as Hume and Helvetius also may have held this hedonistic idea of utility if not the distinctive utilitarian doctrine that general utility maximization is the *sole* ultimate test of good conduct.

As Mill (1965, pp. 45–6) elaborated the hedonistic idea, three kinds of utilities can be produced by human actions, namely: 'utilities fixed and embodied in outward objects' (such pleasures are created by 'investing external material things with properties which render these serviceable to human beings'); 'utilities fixed and embodied in human beings' (again, such enjoyments are made possible by 'conferring on human beings qualities which render them serviceable to themselves and others'); and, finally, 'utilities not fixed or embodied in any object, but consisting of a mere service rendered; a pleasure given, an inconvenience or a pain averted, during a longer or shorter time, but without leaving a permanent acquisition in the improved qualities of any person or thing; the labor being employed in producing an utility directly, not (as in the two former cases) in fitting some other thing to afford an utility.' Useful material objects and educated human beings are *means* to pleasure, of course. After repeated experience of their consequences, however, these more or less permanent sources of pleasure can become inseparably associated with the idea of happiness itself, and thus be seen as concrete ingredients of the good (Mill 1969, pp. 234–9).

Perhaps because utilitarians were so influential in the development of classical economics, the hedonistic interpretation of utility was also widely accepted by economists prior to the 'ordinalist revolution' of the 1930s and 1940s. Classical economists were preoccupied with the production and distribution of material wealth, however, and so tended to focus their attention on the kind of utilities embodied in material objects susceptible to accumulation. As used by Mill (1965, pp. 48–54), for example, the term 'productive labor' is confined to those types of actions that produce utilities embodied in material objects. Actions are classed as 'unproductive labor' (however useful to society) to the extent that they produce the other two kinds of utilities. Moreover, 'productive consumption' (i.e., investment) includes consumption by productive laborers of things which are necessary to maintain and increase their own health, strength, capacities of work, or population. But it does not include any consumption by unproductive laborers (those who do not produce material wealth) or consumption of luxuries by the productive themselves (however pleasing these forms of consumption are to the community). In short, although they did not deny that other kinds of utilities existed, economists in the classical tradition (from Smith and Ricardo to Marshall and Pigou) tended to identify utility with material welfare and to be especially concerned about the needs of those members of the community who produced the kind of utilities embodied in material wealth.

In the post-Second World War period, utilitarian ethics have declined in influence and hedonistic conceptions of utility have largely been abandoned by economists and philosophers. Whereas philosophers (including utilitarians) have typically gone on to identify utility with some nonhedonistic idea of welfare, however, economists have generally adopted the technical idea of utility in its purely ordinalist form—utility is merely a convenient mathematical tool for representing interpersonally noncomparable preference orderings (see *Rational Choice Explanation: Philosophical Aspects*). It is not obvious that philosophers should follow economists in viewing utility as a merely technical term, distinct from welfare. (For a controversial argument that this shift in the meaning of utility within economics—the product of the 'ordinalist revolution'—does not imply 'progress' because it has involved 'losses in understanding human welfare,' in particular, 'material welfare,' including any person's objective interpersonally comparable material needs; see Cooter and Rappoport 1984.) But perhaps they should, without necessarily accepting the narrow restriction to pure ordinalism. Even so, it would be incorrect to conclude that because technical utility values are distinct from, and can conflict with, substantive welfare values, there is some inescapable contradiction between utility in the technical sense and welfare. This leads to a third reason for caution in insisting on a divorce between utility and welfare, to wit, the technical idea of utility may remain a formal aspect of any adequate conception of welfare if judgments about welfare are a species of preferences that can be represented by utility functions. In that case, technical utility, as a formal component of the idea of good, could be seen as a vestige of earlier utility concepts that identified utility with welfare.

Whether or not judgments about welfare can be represented by utility functions, the question remains: what are such judgments about?

2. *Conceptions of Welfare*

At least four different conceptions of welfare continue to be debated in the literature.

2.1 *Welfare as Pleasure*

Although currently out of favor, hedonistic conceptions have not vanished entirely. Hedonism is typically dismissed as crude and naive, however, both as a psychology and as a theory of welfare. Expectation of pleasure is not the sole motivational force in human nature, it is said, and human good involves myriad things other than pleasure. No rational and moral person would be happy, for example, if his life consisted solely of a stream of supreme pleasures guaranteed by artificial means.

Perhaps such arguments are decisive against some versions of hedonism. But, as already discussed, the classical hedonism of Mill, Bain, and others does not deny that many things are means to pleasure which can also become valued as ends-in-themselves, in which case they are seen as concrete ingredients of happiness. Classical hedonism is not a purely subjective doctrine. It insists that some kinds of pleasures are embodied in material objects and human qualities, and can only be experienced by people who possess those objects and qualities, which must first be produced. Particularly intense intellectual and moral pleasures can only be experienced by agents who possess the relevant intellectual and moral capacities, for example, and those capacities must be developed in part by the agents themselves.

2.2 *Welfare as Preferences*

Perhaps currently most influential, preference-based approaches typically conceive personal welfare in terms of personal preferences and social welfare in terms of social or ethical preferences that are constructed in some way from the set of personal preferences. Nevertheless, there is an ambiguity in the key notion of 'preference-satisfaction': it may mean the fulfillment of preference by a suitable shift in the way the world is; or it may mean the satiation of preference by a suitable shift in the subject's conception of the way the world is. Proponents of preference-based approaches typically insist on the latter 'satiation' interpretation because of their implicit subjectivism. Fulfillment without satiation (e.g., posthumous fulfillment of preferences) does not count. From this subjectivist perspective, hedonism can be viewed as a special case, in which a claim is made that expectation of pleasure is the sole *ultimate* motivation of preference. But defenders of preference-based conceptions usually reject that claim as implausible.

Two versions of the preference-based approach should be distinguished. One defines 'preferences' as actual or hypothetical 'choice behavior,' which is in principle observable under certain conditions (see, e.g., Harsanyi 1992, Binmore 1994, 1998). A person's preference for x over y is 'revealed' by his choice of x when y is available, independently of his desires or other motivations for the choice. In contrast, the other version defines preferences as 'desires' rather than 'choices' (see, e.g., Hare 1981, Griffin 1986). A preference for x over y implies greater desire-satisfaction (though not necessarily pleasure) at x than at y. Nevertheless, the agent could—and perhaps should—still make a counterpreferential choice of y over x in this case. Of course, the notion of 'counterpreferential choice' makes no sense under the choice-based approach. But that approach is silent about the motivations people have for making the choices it views as comprising personal or social

welfare. It needs to be supplemented by a theory of motivation, not only to explain why people do make those choices but also to justify why those choices ought to be seen as conducive to welfare. For its part, the desire-based approach does not lack a theory of motivation. But its theory may well be inadequate. It is arguable that people are not always motivated to choose the options that they expect will bring them the greatest desire-satisfaction, nor should they be. Perhaps they should be motivated to sacrifice their greatest desires because of strategic considerations, for example, or moral commitments (Sen 1977).

However preferences are interpreted, the main appeal of preference-based conceptions seems to reside in their implicit subjectivism: the welfare of any individual or society is judged from the subjective viewpoint of that particular individual or society. The contents of welfare judgments may vary significantly across different persons or social groups (see *Diversity and Disagreement*). Nevertheless, the appeal of any purely subjective interpretation of welfare is quite limited. People may be deluded, for example, or ill-informed, or resigned to their customary positions as slaves or 'untouchables' in highly inegalitarian societies (see *Adaptive Preferences: Philosophical Aspects*; *Irrationality: Philosophical Aspects*). Their personal preferences may thus be poor indicators of personal welfare. Moreover, people may be unable to imagine themselves in others' shoes, or they may clash over interpersonal comparisons, or display undue bias against others' interests. As a result, they may fail to construct ethical preferences that can serve as social welfare judgments.

Defenders of preference conceptions typically respond to these difficulties by suitably laundering preferences. Conditions are specified that a person's choices or desires must satisfy before they can be accepted as conducive to his own welfare or that of his society. Thus, for example, Harsanyi (1992) suggests that a person's choices are conducive to his own welfare only if they are informed and conform to the expected utility axioms, whereas his choices are conducive to social welfare only if, in addition, they are ethical. Ethical choices must conform to the equiprobability model of moral choice. The person must forget his own position (defined broadly to include family history and genetic makeup) and imagine himself occupying the position of any person in society with equal probability. He must also extend sympathy to each person j by making the same 'self-oriented' choices j would make while in j's shoes. He can then infer interpersonal comparisons of cardinal utility which—on the independent assumption that all persons share a fundamentally similar human nature (including attitudes toward risk used to measure the relative importance of different choices), which is revealed to anybody who fights against his biases by adopting the 'impersonal' perspective of the equiprobability model—are identical to those inferred by anybody else who goes through this procedure. Finally, he must aggregate impartially over the cardinal comparable utilities he experiences at each person's position to construct social welfare judgments, which turn out to be (average) utilitarian in form. (For difficulties surrounding the interpretation of Harsanyi's theorems as derivations of utilitarianism, see, e.g., Sen 1986, pp. 1122–4.)

Even if such hypothetical preferences have appeal as conceptions of welfare, the subjectivism which is usually thought to be the main strength of preference-based approaches is lost unless agents actually affirm the hypothetical preferences under the relevant conditions. To preserve an element of subjectivism, individuals and societies must willingly adopt those preferences before they can be said to be conducive to the welfare of those particular individuals or societies. If actual adoption of the preferences is a necessary condition of good, however, attention is redirected to theories of evolution and education which explain how people can be motivated to develop the intellectual and moral capacities required to make the relevant choices or form the relevant desires (see *Evolution, Natural and Social: Philosophical Aspects*). It is not clear whether a credible theory of this sort can be supplied to anchor the desire-based variants. But whether or not human capacities can be developed such that human beings invariably obtain the greatest desire-satisfaction from making the choices that comprise personal or social welfare, defenders of choice-based versions of the preference conception require a credible theory of motivation.

2.3 Welfare as Resources

In resource-based conceptions, personal welfare is defined in terms of an objective list of resources broadly defined, whereas social welfare consists implicitly of the effective production and fair distribution of the relevant resources (see *Justice: Philosophical Aspects*). Rawls (1971, 1993) can be read as offering such a conception, for example. He refers to 'primary goods' as 'things which every rational man is presumed to want' and 'things citizens need as free and equal persons,' and provides a (perhaps incomplete) list that includes 'basic rights and liberties,' 'freedom of movement and free choice of occupation against a background of diverse opportunities,' 'powers and prerogatives of offices and positions of responsibility in the political and economic institutions of the basic structure,' 'income and wealth,' and 'the social bases of self-respect' (1971, pp. 60–5, 1993, pp. 178–90). Dworkin (1981, 1990) spells out another approach of this sort.

There is little doubt that human welfare depends on the possession of such valuable things as those listed by Rawls or Dworkin. Data on the extent to which a person possesses these items may provide helpful

indicators of different aspects of his good, even if the indicators cannot be combined into a single index of personal welfare. Similarly, data on the social distributions of these things may provide indicators of different dimensions of social welfare, with the same caveat.

Nevertheless, resource-based conceptions face at least two difficulties. First, it seems that the relevant resources are conducive to welfare only because they are objects of suitably laundered preferences. As Rawls suggests, for example, primary goods are things which every person would prefer to have if he were rational and reasonable. Furthermore, since a person's holdings of one resource (say, political responsibilities) can interfere with his holdings of another (say, wealth), it seems that his preferences must settle which balance of resources is proper for his welfare. Similarly, it seems that social or moral preferences are needed to settle which of many competing social distributions of resources are permissible if not essential to social welfare. If this is right, resources may well be essential ingredients of welfare but they properly figure as objects of preferences.

The second difficulty is that resource-based conceptions do not take account of interpersonal variation in human capacities to convert resources into the achievement of ends (Sen 1990). This problem leads to another way of conceiving welfare.

2.4 Welfare as Capabilities

Sen (1985a, 1985b, 1990) argues that human well-being should be conceived in terms of 'capabilities'—or 'positive freedoms' (see *Freedom: Political*)—to achieve valuable human 'functionings' given by some objective list. He points out that different people may have unequal capabilities to convert resources into achievements. Physically handicapped people may need more income than the able-bodied need to achieve a given level of mobility, for example. People who are genetically vulnerable to particular diseases may need more medicines than the less vulnerable need to achieve a given standard of health. Women may need more food than men need to achieve a given standard of nutrition. Racial minorities may need more educational and job opportunities than white males need to achieve a given level of career success if racist attitudes are prevalent. The elderly may need more wealth than the young need to achieve a given standard of living. These are essentially empirical questions.

Such examples suggest that capability-based conceptions can remedy a serious deficiency in resource-based approaches to welfare. But, as with resources, it seems arguable that certain capabilities are properly viewed as essential components of welfare because they are objects of suitably laundered preferences. Some capabilities are in effect things that every rational or moral person is presumed to want or choose. To the extent that anybody lacks these benchmark freedoms, reasonable people may agree that some form of special compensation ought to be provided so that the person can function 'normally,' for example, income subsidies, extraordinary medical assistance, affirmative action in hiring decisions, and so on. Furthermore, beyond the benchmark capabilities which everyone is presumed to need, it seems that a person's preferences must determine which balance of extra capabilities is proper for his welfare since capabilities to achieve some functionings can presumably interfere with capabilities to achieve others. Again, since one person's capabilities might interfere with another's, social or moral preferences are needed to settle which of many competing social distributions of capabilities (including benchmark capabilities) is permissible if not essential to social welfare.

If this is right, it seems that some version of the preference-based conception of welfare may have appeal as a way to combine insights from the various approaches discussed. The upshot is that preferences must be suitably laundered not only to satisfy certain formal conditions of rationality and morality but also certain substantive conditions. In particular, preferences can be welfare judgments only if they give due weight to certain valuable resources, making due allowance for interpersonal variation in capabilities. Moreover, a credible theory of motivation is required to explain how individuals can come to hold the relevant preferences, even if hedonism is rejected.

If some version of the preference approach has such potentially broad appeal, *welfarist* moral philosophies might adequately capture the phenomenon of human welfare. This will be the case if the relevant preferences can invariably be represented by technical utility functions, and if utility information is all that matters for the construction of social or ethical preferences.

3. Welfarist Philosophies

Welfarist philosophies are distinguished by their exclusive reliance on utility information. Perhaps the most well known examples of such philosophies are the standard versions of utilitarianism. But there are many different forms of welfarist philosophies. They can be clarified by means of the concept of a *social welfare functional* (SWFL) (Sen 1986, pp. 1111–28). For a given set of alternatives, any SWFL maps a given set of personal utility functions (one for each person in society) into a social or ethical preference which can itself be represented by a technical utility function. Since each person's utility function is an element of some family of informationally-identical utility functions as determined by the given assumptions of measurability and comparability, however, the SWFL is required to satisfy an invariance re-

quirement: it must generate the same social or ethical preferences if any given set of personal utility functions is subjected to transformations permitted by the measurability and comparability assumptions.

Welfarism is a condition of strong neutrality imposed on the form of a SWFL. It requires that if each person's utility values with respect to one pair of options x and y are equal to his utility values with respect to another pair w and z—subject to transformations permitted by the given measurability and comparability assumptions, then the SWFL must generate the same social or ethical preference over the one pair as over the other. The only information that matters for a welfarist SWFL is utility information. Nonutility information has no influence.

Arrow's (1963) well-known 'impossibility theorem' shows that any welfarist SWFL must generally be dictatorial if personal utility functions are ordinal and noncomparable. But a dictatorial procedure cannot generate social or ethical preferences that give positive weight to each person's utilities: the dictator sympathizes with nobody but himself in determining social preferences. (For variations and extensions of Arrow's theorem, including its extension to the case of cardinal noncomparable utilities, see Sen 1986, pp. 1073–106, 1114–15.) It follows that welfarism can have appeal as a philosophy of human welfare only if utility information is sufficiently rich to support the interpersonal comparisons required to construct ethical preferences. As Harsanyi's equiprobability model of moral choice illustrates, one person can be assumed to replicate the operation of a welfarist SWFL over a set of comparable personal utility functions, without that person becoming an Arrovian dictator.

Although various forms of welfarist philosophies making use of comparable utilities have been investigated in the literature, doubts remain that any adequate philosophy of human welfare can be put into a welfarist form.

4. Beyond Welfarism

Even if some version of the preference-based conception turns out to have broad appeal, a nonwelfarist philosophy—one that relies to some extent on nonutility information—may be required to capture that conception of human welfare. Myriad forms of nonwelfarist philosophies are conceivable. Such a philosophy may take the form of a SWFL that does not satisfy the relevant strong neutrality condition. The SWFL might make use of nonutility information about the alternatives—some alternatives might belong to an individual's 'protected sphere' of choice, for example, or some might involve 'primary goods'—to generate ethical preferences that can be represented by utility functions. Or it might rely on nonutility information to distinguish between different kinds of utility functions representing different kinds of preferences, some of which are held to be inherently more valuable than others (Riley 1988, 2001). The relevance of any particular nonutility information is determined by the conception of welfare under consideration. In the latter case, for example, the information that different kinds of utility functions ought to be identified and arranged in a lexical hierarchy is supplied by the idea of welfare itself, which is taken to have this sort of multidimensional structure.

Nonwelfarist philosophies may also eschew the form of an SWFL. Harsanyi's (1992) version of rule utilitarianism takes the form of a two-stage game, for example, in which a cooperative game is played at the first stage to select an optimal moral code and a noncooperative game is played at the second stage where players are restricted to strategies permitted by the optimal code. This game structure gives a special status to whatever outcome is assumed to prevail in the absence of agreement at the first stage. Also, the rules of any selected code will govern right and wrong actions independently of any strong neutrality condition. Alternatively, a nonwelfarist philosophy might take a value pluralistic form (see *Value Pluralism*), in which welfare is only one of plural irreducible values in ethical evaluations. Sen (1985a, 1985b) proposes a dualistic structure in which the value of 'well-being' cannot be reduced to that of 'agency,' for instance. By implication, incompleteness or even inconsistency might arise in all-things-considered ethical preferences if well-being comes into conflict with agency.

Welfare Programs, Economics of

All more developed nations have created some set of means-tested public assistance or welfare programs, designed to protect vulnerable groups from economic destitution. Among the groups that are often targeted by such programs are elderly, poor children, disabled persons, and low-income families, especially single-mother families. In many cases, these programs are designed to provide an income supplement to those who cannot work or earn income. Other public assistance programs may be designed to support low-wage workers and help make it economically viable for them to continue in employment. As we shall see, there is often a conflict between the goal of subsidizing income versus encouraging work, which often spills over into controversy about the design and operation of welfare programs. In part because of this controversy, welfare programs have been the focus of ongoing public and political discussion in many nations. This has provided an incentive for extensive research among social scientists about the effects of such programs.

1. Traditional Welfare-program Design

The design of a traditional cash-benefit program can be seen in Fig. 1, which shows the budget constraint under a typical cash-benefit program. This welfare program pays a benefit (G), often called the guarantee level, to those at the lowest levels of income. In Fig. 1 we show G paid to those who work zero hours, and assume that those who do not work have little other income. Of course, some families might have other income that would make them ineligible for welfare benefits, even if they were not working. As hours of work increase and earnings rise (at a given wage, w), the welfare benefit declines at a rate t, the benefit reduction rate or benefit tax rate, until at some income level (Y^* in Fig. 1, at H^* hours of work) benefits disappear entirely. This is point A in Fig. 1 and is often referred to as the break-even point.

Several aspects of the design of this welfare program are important. Note first that the maximum benefit payment occurs at the lowest hours of work. On the one hand, this assures that the poorest families receive the most aid. On the other hand, this creates disincentives to work, by increasing the income available to nonworkers from 0 to G. Note second that the rate at which income increases for families below the break-even point is lower than the rate at which earnings rise. For every hour worked between 0 and H^*, earnings increase by the hourly wage (w), but income increases only by $w(1 - t)$. This is because public benefits are reduced at a rate t for every hour worked. This is equivalent to a reduction in the hourly wage; for every hour worked, these families earn only $w(1 - t)$ rather than w. Standard analysis of income and substitution effects suggests that wage changes have theoretically ambiguous effects on work incentives, but the empirical literature indicates that wages are positively correlated with labor supply among low-wage workers. This means that a lower wage will lower labor supply.

The enactment of a welfare program similar to that

Figure 1
Budget constraint under a traditional cash-benefit program

described in Fig. 1 is expected to reduce labor supply, by increasing the number of persons who choose the zero hours point, as well as by reducing hours of work among those who would have worked somewhere between 0 and H^* hours in the absence of a welfare program. In addition, because of the 'kink' in the budget constraint at point A, some people whose hours would be greater than H^* in the absence of the welfare program will find it preferable to drop to a point below H^*.

One way to view the trade-offs inherent in this type of welfare program is to realize that this program essentially contains two policy parameters—the maximum level of benefits, G, and the benefit reduction rate, t. But there are often at least three goals for these programs: to provide adequate income support to those who are not expected to work, to provide work incentives for those who can work, and to keep government spending at a reasonable level. If there is an increase in the benefit level G, this improves income support, but reduces work incentives and increases government spending. If the benefit reduction rate t is lowered, this moves the break-even point up the income distribution, to higher levels of income and higher hours of work. The result is an increase in work incentives for those at zero or low hours of work, but this will also induce more welfare participation among those near the new (higher) break-even point. It will also increase government expenditures, by expanding eligibility to more families.

A wide variety of empirical studies have attempted to estimate the impact of benefit levels and benefit reduction rates on labor supply. In fact, in the 1970s, the US government funded a series of randomized experiments known as the negative income tax experiments, which compared the impact of different levels of G and t (Robins 1985, Munnell 1987). (A cash-assistance program as outlined in Fig. 1 that is run through the tax system is known as a negative income tax; in this case one receives a payment if income is below a certain level, and pays taxes if income is above a certain level.) Other researchers have used variation in benefit levels and effective tax rates across states in the USA to look at the impact of these parameters. Moffitt (1992) summarizes this literature. His conclusions are that the primary cash support program in the USA for low-income families (Aid to Families with Dependent Children or AFDC) created nontrivial work disincentives. (AFDC was replaced with a block grant known as Temporary Assistance to Needy Families or TANF in 1996.) A midpoint estimate of the impact of AFDC is that it reduced work by about 5.4 hours per week, a 30 percent reduction in work effort.

There are circumstances under which these tradeoffs between income support and work incentives may be less problematic. For instance, for a population from whom little or no work is possible or expected, it may be easy to set a high G (allowing greater income support), along with a high t (creating a break-even point at a low level of hours). The limited work incentives in this design are unimportant if there is no desire to encourage work among the eligible population. An alternative way to avoid these problems is to institute a mandatory work program for welfare participants who are judged to be able to work. For example, a wide variety of states in the USA have experimented with what are typically called 'workfare' programs, which mandate that work-eligible recipients must work a certain number of hours in publicly created jobs in order to maintain eligibility for their benefits. These and other work-incentive programs are discussed below.

Researchers have also noted that these tradeoffs between work and cash support may be less problematic in a situation where there is 'stigma' associated with being on welfare. Moffitt (1983) has modeled this situation, showing that if persons believe there is a cost to being on welfare (such as the stigma of being looked down on by one's neighbors), this will make persons less likely to use it, and will shift welfare participation only to the neediest cases. If stigma is greater among those who are more able-bodied and work-ready, and less among needier and less work-able persons, this will reduce the work disincentives of the program, while protecting its income-support aspects. Of course, if stigma is also high among needy persons who are not able to work, this could make the program less effective as a social safety net. It may be difficult to target efforts to increase participation among the neediest without also reducing stigma and increasing participation among the less needy as well.

Stigma is only one reason why participation rates (often called take-up rates) among those eligible for a program are often far below 100 percent. There may be costs associated with participating, related to the regular reporting and certification process. There may also be a lack of information about the program among eligibles. It is not unusual to find that close to half of those eligible for a particular public-assistance program do not participate in it (Blank and Ruggles 1996).

While much of the research literature has focused on the labor supply effects of traditional welfare programs, other concerns have also been raised about such programs. For instance, welfare programs which provide support for mothers with children may increase the incidence of divorce or out-of-wedlock childbearing. The literature on these effects is much more controversial, and also more limited in terms of empirical sophistication. In general, there is little evidence of strong benefit effects on family fertility or female headship, but there are also methodological problems with much of the literature on this topic. (Moffitt 1992 also discusses these issues. A more recent review occurs in Robins and Fronstin 1996.) Disagreement over the impact of the negative income tax experiments on divorce and separation has also

resulted in more recent estimates suggesting the impacts were relatively small (Cain and Wissocker 1990).

2. *In-kind Benefits*

So far, the discussion has presumed that welfare programs pay out cash benefits, which are theoretically indistinguishable from other sources of income. Many welfare programs provide in-kind benefits, however, which are available only for particular types of consumption. For instance, in the USA, the food-stamp program provides special coupons which recipients can use in lieu of cash at the grocery store. Similarly, housing assistance programs typically subsidize rent, or child-care assistance programs subsidize child-care costs. (For a description of the research relating to food stamps, see Ohls and Beebout 1993; for a similar survey of the literature on housing subsidies in the USA, see Newman and Schnare 1992.)

In most cases, the same issues that arise in traditional cash-benefit programs also arise in in-kind programs. These in-kind programs provide subsidies, which are then reduced in some manner as incomes rise. This raises the same questions about income support, work incentives, and incentives for family formation.

In-kind benefits are a more constrained form of a subsidy than cash benefits, however. Figure 2 shows the income constraint that emerges in the presence of a food subsidy. On the X-axis is food consumption and on the Y-axis is all other consumption. The food-stamp program shifts the income constraint from F_1–C_1 to F_2–C_2'. Note that the line segment C_2'–C_2 is *not* part of the new budget constraint. The additional resources expand food purchases only, and cannot be used to expand other forms of consumption.

If these in-kind subsidies are relatively modest, they should cause little distortionary behavior. Individuals who were choosing point A on the income constraint F_1–C_1, now move to point A' on the income constraint F_2–C_2', somewhere within the northeastern quadrant to the right and top of point A. Note that at A', a family consumes both more food and more other goods, that is, they substitute some of their earlier (cash) spending away from food to other goods. If, however, the food subsidy is relatively large or the family spends little cash on food, there is some possibility that the family would prefer to be on the C_2'–C_2 segment of the budget constraint, rather than on the F_2–C_2' segment. In this case, the in-kind program constrains expenditures and forces families to choose the consumption point C_2', where they consume more food than they would if they had received a cash benefit rather than an in-kind benefit. Indeed, research in the USA, which compares food stamps to a program that provides an equivalent subsidy in cash, concludes that families who receive cash reduced their food expenditures by between 20 cents to 25 cents per dollar of food-stamp benefits, suggesting that the in-kind form of the benefit forced families to purchase a higher quantity of food than they would with an equivalent amount of cash (Fraker et al. 1995). In contrast, for elderly or disabled food-stamp recipients, there was little difference in their consumption when given food stamps vs. an equivalent amount of cash.

Figure 2
Income constraint with in-kind benefits

Economists have traditionally believed that in-kind programs are inefficient, since a cash transfer of an equivalent amount could make a family at least as well off, and might make them better off if they want to allocate more of their spending to another category of consumption. Those who support in-kind benefits tend to make two arguments in response. First, there is often more widespread support for in-kind programs than for cash programs. That is, the median taxpayer might be more willing to provide food stamps than general cash assistance. This raises the question of whose preferences are being maximized in poor support programs. While lower-income people might prefer less constrained subsidies, taxpayers might prefer to provide constrained assistance, in order to limit the extent to which public dollars are used to subsidize behavior that taxpayers believe is inappropriate. If welfare programs are meant to be responsive to taxpayer concerns, in-kind programs might be a reasonable way of providing support. Second, many have noted that in-kind programs often come attached to their own 'lobby.' For instance, food stamps are heavily supported by agricultural interests, while public health insurance is heavily supported by the health industry. This may provide a level of political support and protection for these more targeted in-kind programs—support that general cash-assistance programs often lack. In the midst of regular waves of budget-cutting fervor at both the state and national levels, public assistance programs are often vulnerable.

Figure 3
Notched budget constraint under a traditional cash-benefit program with added in-kind benefits

A series of targeted, smaller, in-kind programs may be more politically viable and enduring in the long run than a single, large cash-assistance program (such as a negative income tax).

In-kind programs often raise another problem as well. Many of them are designed to phase out more abruptly than cash programs (although cash programs may be designed to phase out quickly as well). For instance, housing-subsidy programs often pay substantial benefits up to a particular income level and then cease, rather than slowly lowering benefits to a continuous break-even point. This creates a 'notch' in the budget constraint.

Figure 3 graphs a budget constraint in which a traditional cash-benefit program is supplemented by an in-kind benefit program for some specific good (this could be a program providing supplemental assistance to pay for food, housing, child care, or any other specified good.) In Fig. 3, the in-kind program provides a benefit of G_2–G_1, which is available to all families with incomes below Y_2 and who work less than H_2 hours at the specified wage w. Once income ses above Y_2, the in-kind benefit ceases. In this case, the cut-off point for in-kind benefits (D) is above the break-even point for receipt of cash benefits (C). The result is a very oddly shaped budget line, G_2–A–B–D–E, with a notch at B–D when the in-kind benefits cease. Standard economic analysis suggests that a number of families will choose point B and resist increasing their hours above H_2, since that means the end of their in-kind subsidy. This causes a 'welfare trap,' in which increases in work can actually produce a decline in income. Depending on the size of the notch, such a trap might be a real problem for policy makers who want to increase people's employment and economic self-sufficiency.

Public-assistance systems with multiple-benefit programs layered on top of each other typically have some notches or welfare traps imbedded in them. In addition, high marginal tax rates can result when multiple programs have phase-out ranges in the same distribution of earnings, each acting as a separate tax on earnings. Blinder and Rosen (1985) discuss the pros and cons of 'notched' budget constraints. Under some circumstances, it may be preferable to create a notch rather than to reduce benefits more continuously, particularly if a slow benefit reduction would greatly increase potential eligibility for the program and a fast benefit reduction would create high marginal tax rates over a range of income.

3. *Programs that Subsidize Work*

Increased concern with the work disincentives imbedded in traditional welfare programs has led to a series of changes in the structure of public assistance programs in the USA, and similar changes are occurring in other countries. This concern is driven by a variety of factors. Increasing labor-force participation among women at all skill levels has made government support for mothers who stay at home less politically popular. In the USA growing public-assistance caseloads and a growing concern with the problems faced by low-income single-mother families have led to increasing concern about finding ways to help these families permanently to escape poverty and avoid welfare 'dependency.' (Blank 1997a discusses many of these issues.) In Europe, sustained high unemployment rates have also increased caseloads and increased public spending on welfare-related programs. The result has been a growing emphasis on work-oriented welfare reform. This has taken several forms.

3.1 *Welfare-to-work Employment and Training Programs*

In the 1990s, major efforts were made to meld job-search and employment programs with traditional welfare programs. In some states, this took the form of mandatory welfare, or work for your benefits, as noted above. Other states in the 1980s began to experiment with serious job search and job placement programs aimed at welfare recipients. The result of these efforts has been a revolution in the way that public assistance offices operate and what services they deliver. In addition, a variety of very well-designed evaluations of these efforts reinforced the belief that such policies could increase work and earnings, and decrease public-assistance spending. (The interaction between these experimental results and political decision making is reviewed in a set of articles in the 1991 *Journal of Policy Analysis and Management* **10**.)

These evaluations indicated that even rather minimal efforts at job-search assistance seem to produce employment and earnings gains among women on welfare (Gueron and Pauly 1991). The returns from

Figure 4
Budget constraint under a wage-subsidy program

these programs are usually greater than the costs to the government budget, making them cost-effective policies. The resulting earnings increases are not huge—at most around $1,000 per year—but they represent a large percentage increase in earnings among women, many of whom had little earned income to start with.

Since 1996, US states have had almost full discretion to design their own cash public-assistance programs. The result is a wide variety of experiments, many of which meld work and welfare together even more closely. For instance, many states have lowered their benefit reduction rates, increasing work incentives for those on welfare. Many states have also expanded their emergency-assistance programs (now often called 'diversion activities'), which help welfare applicants deal with immediate problems, such as an ill family member or a housing eviction, without entering them permanently on the welfare rolls. All states are mandating that a growing share of their caseload participate in job-search and job-placement programs. Many states have also instituted serious sanctions, cutting benefits among families who do not respond to the mandate to enter a job-search program. (For a discussion of these changes, see Blank 1997b, Gais and Nathan 1998, or Gallagher et al. 1998.)

This movement to a more work-oriented welfare system has reduced caseloads and increased labor-force participation by single mothers. It has also raised a host of new policy-related questions, such as whether former welfare recipients will be able to maintain their jobs during an economic downturn, and whether women who initially enter very low-wage positions will be able to increase their earnings over time, becoming more economically stable and self-sufficient.

3.2 Wage Subsidies to Support Work

In the face of increasing demands that welfare recipients move into work as quickly as possible, the question has emerged, 'How do we design a safety net that supports work?' If one believes that work—even in unstable jobs and at low wages—is preferable to welfare, then providing the public support that enables steady workers to support their families becomes increasingly important.

A major innovation in the USA, which has been very important in increasing the returns to work and raising labor-force participation among adults in low-income families, is a wage-subsidy program called the Earned Income Tax Credit (EITC). The structure of the EITC is very different from traditional welfare programs. It provides a subsidy to low-wage workers in low-income families, based on family income but conditioned on work.

Figure 4 graphs the budget constraint produced by the EITC. In contrast to traditional welfare programs (where a nonworker receives the maximum level of benefits), a nonworker gets zero benefits from the EITC. As work hours increase, the EITC subsidizes the wage at a rate t_1. Hence, the effective wage rate faced by the worker rises from w to $w(1+t_1)$. When earned income reaches Y_1 (at H_1 hours of work), the subsidy reaches its maximum level ($Y_1'-Y_1$). It stays at this level while earned income increases from Y_1 to Y_2, providing a flat subsidy to the worker. As earned income rises past Y_2, the subsidy is phased out at a rate t_2, which lowers the wage rate to $w(1-t_2)$. The subsidy ends entirely at the break-even point when income reaches Y_3.

Note several things about the design of the EITC. First, its maximum subsidy levels occurs at incomes between Y_1 and Y_2 (hours between H_1 and H_2). In order to reach the maximum subsidy, a person must work some (substantial) amount of time. Second, the work incentives imbedded in the EITC vary across different segments of the EITC budget constraint. For nonworkers or very low-hour workers the impact is positive, as the EITC raises wage rates. For workers with earnings greater than Y_1, the impact is likely to be more negative, particularly in the benefit reduction range when the effective wage rate is reduced.

These theoretical observations are consistent with the empirical research to date, which suggests that the EITC has had a strong positive effect on work effort among single mothers, who tend to be nonworkers or low-hour workers (Eissa and Leibman 1996), but has had a small negative effect on the work effort of wives, whose family income is more likely to be higher, putting them in the benefit reduction range (Eissa and Hoynes 1998). These labor-supply effects may be somewhat tempered by the complex design of the EITC. It is possible that few low-income workers fully understand its structure or can easily calculate how the EITC affects their own incentives.

It is also worth noting that the EITC and the minimum wage reinforce each other in useful ways. The minimum wage provides an income base to workers, which means that the EITC subsidy need not

be as large. This is important, because the larger the maximum subsidy the more difficult it is to do the benefit reduction. At a high subsidy level, if a relatively low benefit reduction rate (t_2) is chosen, the break-even point for the EITC would occur far up into the earnings and income distribution, substantially increasing the number of persons who receive the subsidy and making it less targeted to low-income workers. On the other hand, if a high benefit reduction rate is chosen quickly to reduce the subsidy, then the work disincentives in that part of the budget constraint are greater. The minimum wage assures that low-income workers can reach a target level of earnings without the problem of how to 'claw back' a very large EITC subsidy. Similarly, the EITC reinforces the higher take-home pay provided by the minimum wage, and allows the level of the minimum wage to remain lower, while still increasing income among low-income workers. This presumably reduces the potential disemployment effects of the minimum wage.

The importance of recent increases in the USA in the EITC and the minimum wage together can be easily calculated. The earnings of a single mother with two children, working full-time at the minimum wage and receiving the EITC, would have risen from $9,856 in 1989 to $14,056 in 1998 (in 1998 dollars), a 40 percent increase due entirely to these policy changes. This is a substantial addition to earnings for low-income families. It is not surprising that these changes appear to be causally related to the increase in labor-force participation among single mothers (Meyer and Rosenbaum 1998).

3.3 *Additional Work-support Programs*

While job-search assistance programs and wage-subsidy programs are often discussed as a primary way to encourage work, most countries also operate a variety of other programs that help or hinder the movement of less skilled persons into employment.

Particularly for many single mothers, the cost of childcare can substantially increase the expense of working (or, alternatively, reduce the take-home pay generated by employment). Public subsidies to offset child-care expenses among working low-income mothers can increase work incentives. If childcare is viewed as an hourly expense (call it c), the returns to work are $(w - c)$. If a subsidy (s) is provided, then returns to work rise to $(w - c(1 - s))$. This is the same as an increase in the effective wage and should increase work effort. There is clear research evidence that childcare assistance can increase labor supply among low-income mothers (Anderson and Levine 1999).

The availability of health care is also an issue for working low-income families in the USA. Families that receive public assistance have historically been eligible for Medicaid, the publicly provided health-insurance plan. Leaving public assistance has usually meant losing Medicaid. Since few low-wage jobs offer health insurance, this often means going without insurance, and may lead a number of families to stay on welfare in order to continue receiving Medicaid. The evidence on the magnitude of this effect is mixed (Winkler 1991, Moffitt and Wolfe 1992), but recent welfare reforms have mandated that states offer ongoing Medicaid coverage to persons leaving welfare for at least some period of time. This is one area, however, where the USA lags behind many European nations. Their nationalized health-insurance systems make health-insurance coverage a nonissue in the choice between work and welfare.

Other types of programs may also be important in supporting income and work under particular circumstances. The regular collection of child support from noncustodial parents is one way to guarantee additional income among single mothers whose earnings may be low. Subsidized public transportation systems, with routes that run through low-income neighborhoods, may lessen travel costs and travel time for potential workers. Strong enforcement of anti-discrimination laws may also improve the availability of jobs for certain populations. In short, a wide variety of policies can be important in assisting low-income families into employment.

4. *Conclusions*

Given the multiple goals associated with welfare programs, it is not surprising that there has been constant controversy about the appropriate design of such programs. It is clear that there are a number of alternative policy choices which may be attractive for different groups among the poor population.

For groups that not expected to work and for whom income support is the primary consideration, such as the infirm and elderly, traditional welfare programs may be highly effective and desirable. Indeed, the Supplemental Security Income program in the USA, designed to provide income support to elderly and disabled individuals, is designed as a traditional welfare program, and continues to receive widespread public support.

For groups that expected to work, a wide variety of programs can encourage work. Many of the changes in US welfare programs over the 1990s were designed to provide better work incentives and a stronger set of supports to working low-income families (as opposed to cash assistance to nonworkers). The expanded EITC wage subsidy appears to have been particularly effective in increasing labor-force participation among low-wage single mothers with young children. And the shift toward mandated participation by welfare recipients in job-search and job-preparation programs has added to these labor-force participation increases.

In the USA, as in many other nations, welfare programs are multilayered. Both the state and federal governments often have some program responsibility. These programs include a mix of cash and in-kind

support programs. They include a mix of more and less work-oriented programs aimed at different groups in the population. Some are run at the local level, while others are run through the national tax system. The effect is a quite confusing array of programs, which can produce overlapping incentive effects on individuals who are eligible for multiple programs. But such a mix of programs is also a response to the multiple goals and the desire to differentiate between different groups among the poor. And many of these programs have their own community of political advocates who support them and lobby for maintaining and/or expanding them. This may produce a network of programs that in sum provide much greater overall support to lower-income families than would be achieved by a more streamlined and unified welfare system.

Welfare State

A welfare state is a state that is committed to providing basic economic security for its citizens by protecting them from market risks associated with old age, unemployment, and sickness. Protection is provided by a range of social policies, including health care, unemployment benefits, and old-age pensions. Changing norms about the need for protection and the appearance of new risks mean that the policies included under the welfare state rubric have shifted over time. While health care, unemployment, accident, and sickness benefits have formed the core programs, other policies such as social services, child-care policies, and family allowances are included in the study of the welfare state. Although early analysts of welfare states emphasized the importance of education, subsequent work has largely excluded education.

The term 'welfare state' first emerged in the UK during World War II as part of an effort to boost wartime morale and to contrast the British state with the Nazi warfare state (see Flora and Heidenheimer 1987). The welfare state symbolized the solidarity of the British people, which would be sustained after the war by a new set of social policies available to all British citizens. The Beveridge Report of 1944 supplied the blueprint for the British welfare state, with its vision of a state that would guarantee freedom from want to all its citizens. British sociologist T.H. Marshall ([1949] 1964) provided an influential early

analysis that linked welfare state development to the emergence of full democracy. He traced history as the progressive development of rights: civil rights in the eighteenth century, political rights in the nineteenth century, and social rights in the twentieth century. For Marshall (1964), the social rights embodied in the welfare state were the means by which the equal status of citizenship could sharply limit, although not override, the inequalities created by the market.

Subsequent efforts to identify the origins of the welfare state took issue with this formulation. The seeds of contemporary welfare states were traced back to Bismark's compulsory social insurance laws of the 1880s. The motivation for creating welfare state programs in Germany had little to do with democracy and much to do with social control. The rhetoric of citizenship, solidarity, and equality was notably missing in nineteenth century Germany, casting doubt on Marshall's (1964) neat progression of rights outside of the UK. The diverse motivations that characterized the origins of welfare states were reflected in the variety of mechanisms that financed and delivered social benefits. The Bismarkian model of social insurance provided benefits to workers on the basis of dedicated taxes—called contributions—paid into state-mandated schemes. Benefits were linked to contributions and thus tended to be status-preserving rather than equalizing. The Beveridge model relied on general taxation and provided flat-rate benefits to all citizens. By setting a high minimum level of benefits, the aim was to reduce inequality.

One enduring stream of welfare state research has sought to develop typologies to classify cross-national variation in the scope and design of welfare state programs. Richard Titmuss's (1958) classification of welfare states into residual, institutional, and industrial-achievement models was an early influential categorization. Building on Titmuss (1958), sociologist Gøsta Esping-Andersen (1990) developed the welfare state typology most widely used in contemporary welfare state research. The typology identifies three welfare state regime types—liberal, conservative-corporatist, and social democratic—that differ by the role they assign to the state, market, and family for ensuring well-being. Each model is further distinguished by the quality of social rights it creates and by the system of social stratification it produces.

The *liberal* welfare state presumes minimal interference of the state with the market. Welfare benefits are designed to limit their impact on the market. Accordingly, benefits for working-age adults tend to be minimal and are often subjected to a means test in which recipients must show they have no other source of support. Social rights are weak and states do little to alter market-created stratification. Private social benefits provided by firms are common and serve to deepen stratification. Countries that exemplify this model include the USA, Canada, and Australia. The *conservative* model provides generous social rights but seeks to preserve market-based status differentials. Benefits are commonly provided through social insurance in which the size of benefits is linked to previous contributions. Reflecting the influential role that the Catholic Church played in these countries, conservative welfare states rely heavily on the traditional family to promote well-being. This aim is reflected in the minimal provision of social services. Examples of conservative welfare state regimes include Germany, Austria, France, and Italy. The *social democratic* model, found in Scandinavia, is based on principles of universalism in which generous benefits are provided to all citizens. These welfare states seek to promote equality by ensuring strong social rights. Unlike the conservative welfare states, social democratic welfare states provide extensive social services designed to relieve the family—and women in particular—of its traditional responsibilities. Likewise, social democratic welfare states intervene extensively in markets in order to promote social protection.

In reality, most countries incorporate features of more than one model. For example, the USA provides social insurance for the elderly with a system that has egalitarian features and is based on contributions. Moreover, the UK, the original welfare state, fits poorly within the typology. Some analysts have proposed a 'fourth world of welfare' characteristic of Australia and New Zealand. Although these states provided minimal formal social benefits, they have sought to ensure social rights and equality through a system of wage-setting labor courts and high tariffs. Students of Southern Europe have emphasized the distinctiveness of welfare provision in such countries as Italy, Spain, and Greece. These welfare states have been called 'familial,' reflecting the prominent role assigned to families in providing social welfare. Despite the many qualifications and amendments to Esping-Andersen's (1990) typology, it continues to provide an important reference point in the welfare state literature.

Considerable research has sought to account for the development of welfare states and for the variation among them. The earliest work links welfare state development to the level of economic growth. Based on a mutivariate quantitative analysis of 64 countries, Wilensky (1975) showed that the initial emergence of welfare state provision was a function of economic growth. Among the richest countries, however, he demonstrates that the correlation between wealth and welfare state provision breaks down and instead a variety of political factors account for differences. A second line of research focuses on these political factors in the richest countries. Most influential has been the 'power resources' argument, which views working-class power as the key determinant of welfare state development. Because social policies empower workers vis à vis employers, power resources analysis sees the welfare state as part of the 'democratic class struggle' (Korpi 1983). The power resources school

relies on cross-national quantitative data and regression analysis. Historically oriented researchers have criticized the power resources school for overlooking the importance of other social forces, among them business and the middle classes. A third major line of analysis, the historical institutional approach, relies on qualitative comparative case analysis to account for differences in welfare state development (Immergut 1992). This work highlights the role of political institutions in shaping welfare state origins and development (Weir et al. 1988). In the 1990s, these three lines of explanation were joined by a fourth school of feminist analysis (Orloff 1993). Feminist studies of welfare states highlight the role of ideology about gender roles and families as a central factor in determining the type of welfare state. Feminist analyses have broadened the scope of inquiry to social services relevant to the family and policies related to women's rights, often neglected in welfare state studies.

Since the 1980s, welfare states have faced new pressures due to economic shifts and changes in families and gender roles. Persistently high rates of unemployment in Europe, low wages in the USA, growing numbers of female-headed households, and increasing female labor force participation have altered the social and economic assumptions on which welfare states were built. Moreover, as social programs, especially pensions, have matured, they have become very costly. Demographic changes, notably aging populations and smaller workforces, exacerbate these pressures. These conditions have prompted new questions about welfare states. One line of inquiry examines whether welfare states face serious retrenchment as a consequence of these shifts and whether the politics of welfare state retrenchment differ significantly from the politics of creating welfare states (Pierson 1994). Analysts agree that the broad popularity of most welfare state programs makes them difficult to dismantle. There is much less agreement about whether the modifications that have been made in welfare states are significant and whether new social and economic conditions have altered the ability of welfare states to promote equality and social solidarity.

A second new line of inquiry asks whether the increased pressures on welfare states—economic globalization, in particular—are causing them to converge or whether long-standing national differences in type and amount of social provision will endure (Scharpf and Schmidt 2000). This work examines the institutional foundations of welfare states with special attention to the relationship between welfare states and economic arrangements. One key question animating this work is whether social policies are a hindrance to economic growth or whether social policy can contribute to economic competitiveness in an open economy. Questions about welfare state convergence also appear in an emerging literature about the impact of the European Union on national systems of social provision.

In addition to the research about how and why welfare states are changing, a third line of argument makes policy and normative arguments about how welfare states should be restructured. In the 1990s, the Organisation for Economic Cooperation and Development issued a series of influential studies arguing for more 'active' welfare states, which emphasize policies that help beneficiaries work instead of providing passive compensation. These arguments reflect new assessments of risk, security, and welfare states. The earliest generation of welfare state theorists argued for universal programs available to all citizens (Titmuss 1958). Such programs, they believed, would build social solidarity and would be politically strong due to their broad base of beneficiaries. Since the 1980s, there has been growing disagreement about how welfare states should be organized and about what values they should promote. Some analysts defend the classic political logic of the welfare state and argue for an updated universalism that addresses the needs of working families and emphasizes education (Skocpol 2000). Others emphasize the benefits of risk and the need to target social benefits more efficiently. Likewise, arguments about the proper role of the state vs. civil society and about the proper balance of rights vs. responsibility have animated academic as well as policy debates.

Most welfare state research has focused on the developed world because it is only these countries that have recognized and enacted a range of social rights broadly applicable to all citizens. As the developing world has changed, with some regions such as East Asia growing richer and others, such as Africa, growing poorer, there has been increasing interest in studying systems of social protection in these regions. The focus on social protection broadens the field of inquiry beyond traditional welfare state studies to examine how a wide range of market, government, and social arrangements affect well-being.

Welfare State, Geography of

The term 'welfare state' describes the state institutions and policies that are devoted to the delivery of human and social services, poverty amelioration, and enhancement of human well-being. In general, the welfare state is intended to ensure that the basic needs of the population are met with regard to food, housing, education, income, and health. The provision of social welfare serves two interrelated purposes. The first is to provide a social safety net through which citizens of a country should not drop. This role reflects a belief in the social rights of the citizenry and the responsibility of the society to each of its members. The second purpose of the welfare state is to provide a labor force with the skills, human capital, and basic well-being necessary to make it economically productive. The bundle of services provided through the welfare state, the means of provision, and the outcomes or effects of provision are not fixed. Rather, the welfare state is temporally and geographically variable. This variability reflects the interaction between changing ideas about human well-being, how best to attain it, and the specific conditions, practices, and resources that are available for meeting well-being in different places. This variability forces us to consider the geography of the welfare state and, specifically, two critical questions: (a) what are the processes by which unevenness in welfare provision is created? And (b) at what scale are welfare services provided?

These issues are considered under the following headings. Section 1 provides a basic characterization of the forms and functions of the welfare state. Section 2 considers reasons for this variation, including differences in the ability to provide social and human services, differences in the ways that states conceptualize their social role with regard to the well-being of the people who live within their territories, and the role of international organizations. The final section anticipates future changes in the welfare state in both developed and developing countries.

1. Forms and Functions of the Welfare State

The term 'the welfare state' is really a misnomer, as welfare states may take a variety of forms, and these forms have important implications for the citizens, communities, and economies of countries. Among the many typologies developed to characterize the forms of welfare states, those of Gøsta Esping-Andersen (1990) and Diane Sainsbury (1996) describe the framework of welfare provision within a country.

1.1 Typologies of the Welfare State

Esping-Anderson focuses on the ways in which ideas and beliefs regarding welfare and the state's role in meeting economic needs have shaped the form of welfare provision. He identifies three basic 'welfare state regimes':

Liberal welfare states respond to market and labor force imperatives. Many benefits, such as health insurance and pensions, are linked with employment. Means testing is used to determine eligibility for state services, and relatively modest cash and voucher benefits are provided for those deemed eligible.

Conservative/corporatist welfare states rely on state provision of services, rather than on market or private provision. These states often manifest normative ideals of a nuclear family characterized by a male breadwinner and a woman who tends to the family.

Social democratic welfare states promote a vision of the state as the guarantor of social rights. These states promote equality of benefits at high levels as a way of minimizing the effects of social class and income. Welfare benefits are used to equalize the ability of all citizens, regardless of income, to participate in the political community.

This study was based on 18 countries characterized by advanced market economies in the 1980s. As such, it reflects a tendency in the literature to conceptualize welfare states as being limited to industrialized democracies, rather than to consider the welfare apparatus in all countries. It is unclear, then, whether this typology will hold for countries at different stages

of development or undergoing transition to market economies. This typology also assumes countries develop their welfare apparatus in response to national political cultures, ideologies, and internal political pressures. The experience of countries beyond the 18 studied is clearly at odds with that assumption, as the development of their welfare policies and institutions is shaped by external influences from international aid and lending organizations and by a globalized economy dominated by transnational corporations. As such, the typology developed by Esping-Anderson may not fully describe the geography of the welfare state.

Sainsbury's study is significant in helping to understand the differential impacts of the welfare state on citizens and in understanding the ways in which gender ideologies shape the structure of social provision. As noted by Esping-Andersen, some welfare state regimes are based on normative ideals of family and gender roles. Sainsbury's framework clarifies the bases of entitlement to welfare provision under different regimes, drawing on her characterization of gender ideologies within countries. From this starting point, she traces the effects of welfare regimes on gender relations and the gendered division of labor in the family and society. As with Esping-Andersen, Sainsbury's research is based on developed, Western countries. Sonia Alvarez (1998) extends this approach in her analysis of gender policies in Latin American countries. Both studies demonstrate that the effects of gender equality reforms in welfare policy vary widely from country to country based on the ways that gender ideologies are embedded in their political economies, creating a differentiated geography of welfare provision and well-being.

1.2 Decisions about Welfare Provision

The welfare state can be conceptualized as a framework that guides three types of decisions with respect to welfare provision: decisions about services to be provided, institutional arrangements for provision, and the scale of provision and decision-making.

Decisions about the services to be provided and the conditions under which they are provided are the basis of Esping-Andersen's typology. The differences between these regime types center on three questions: (a) whether welfare is primarily a matter of private provision through employment or is a universal right; (b) what constitutes 'basic needs'; and (c) the extent to which welfare services are used to redistribute income and equalize the material bases of quality of life for all citizens. To these questions, geographers add a fourth: at what scales will decisions about welfare be made and services provided?

Liberal welfare regimes, such as that in the United States, place employment at the center of needs provision. Minimum wage provisions are intended to ensure workers' ability to pay for housing, food, clothing, and transportation. Pensions and health care are typically provided through a mix of employer and employee contributions. Eligibility for other services is often linked to employment, job training, or the search for employment. For example, the Personal Responsibility and Work Opportunity Reconciliation Act (PRWOR) is the 1996 legislation that restructured welfare provision in the United States. PRWOR links public assistance to participation in programs to make recipients more employable. Education is central to this model, and is notable for being the sole welfare service for which universal access is guaranteed; indeed, many liberal welfare regimes do not characterize education as a welfare service. While some degree of redistribution of wealth may occur through welfare provision in liberal regimes, the redistribution is minimal. Welfare services are only intended to meet basic needs and provide recipients the opportunity to enter the labor force. The slogan 'welfare as a hand up, not a hand out' is characteristic of this approach. By contrast, conservative and social democratic regimes rely more directly on state provision of services, and so are characterized by a large social sector for health, housing, pensions, and income support, regardless of employment status. As noted previously, what differentiates these two regime types is that conservative regimes such as the United Kingdom, Germany, and France place more emphasis on the nuclear family and on gender ideologies that reinforce women's labor force position in contingent and low wage jobs. In addition, the conservative emphasis in welfare provision is on guaranteeing basic needs, although a considerably broader spectrum of services is typically considered 'basic' as compared with liberal regimes. Social democratic regimes, such as those in Norway and Sweden, tend to have a larger redistributive goal than the other two regimes. As such, they strive toward universal provision at very high levels and across a much wider variety of services.

The institutional arrangements for welfare provision are implied in Esping-Andersen's typology, but these arrangements require additional attention. They are the subjects of growing political debate across most welfare regimes, and they reflect fundamental beliefs as to the appropriate relationships between the state, market, and civil society. In practice, institutions within all three of these spheres play a role in welfare provision, with the state playing an important regulatory or coordinating role. Liberal regimes conceive of the state as the provider of last resort for most welfare services, with the previously noted exception of services that prepare and maintain a productive labor force. Welfare, to a considerable degree, is the responsibility of individuals and firms, and becomes an issue for state intervention only when one or the other of these does not meet their responsibilities. In that situation, the state has regulatory powers that may be used to create rules and incentives for firms

and individuals to conform to expectations with regard to employment and welfare, and to impose penalties for noncompliance. The primary state role is one of developing workforce capacity, creating incentives for individuals to work, and maintaining a regulatory environment that guides decisions made by firms about benefits and work conditions for employees. In addition, states attempt to develop a voluntary sector through which many social services are provided; these efforts involve tax deductions for charitable contributions and the provision of funds to some nonprofit, nongovernmental organizations that are involved in direct service provision. These organizations are an important part of what Jennifer Wolch (1990) terms 'the shadow state.' While not institutionally part of the state apparatus, their existence and activities are regulated by the state and they perform vital services for the state.

Since the 1980s, many conservative and social democratic regimes have moved closer to the liberal form of welfare provision. Many developing countries, whose welfare apparatuses are not as well developed as those in industrialized countries, have also moved to this model due to structural adjustment and austerity programs imposed by international lending and aid organizations. At the same time, many new jobs in countries around the world do not provide the support for welfare provision that was assumed with liberal welfare regimes. These changes have shifted the boundaries between state, market, and civil society in ways that place the responsibility for maintaining welfare on civil society. However, these changes represent only a *shift* in the role of the state, not a *declining* role, as these changes are enabled and regulated through state action (Staeheli, et al. 1997).

The scales at which decisions about welfare provision are made constitute the final element that shapes the geography of the welfare state. Much of the discussion about the welfare state has focused on the national scale, even though service provision is often local. Late twentieth-century trends in welfare provision, though, highlight the limitations of such a focus. Many industrialized nations have begun to devolve much welfare decision-making to local and regional scales. Developing countries, as well, face pressures for devolution. For example, the United Nations Development Program argues in its Poverty Report that moving decision-making to local levels is an important element in creating governance structures that are more responsive to the needs of the populace, are more accountable, and will be more effective in poverty reduction (UNDP 2000). At the same time, increased globalization of the economy shifts economic decisions to scales above the nation-state. Finally, supranational and international institutions also shift the locus of decision-making. The European Union, for example, is attempting to harmonize social welfare provision and labor regulations, and international human rights conferences call for the development of standards of well-being and social provision. The combined effect is a reconfiguration of the scales at which decisions are made and welfare ensured. These trends highlight the importance of understanding the geography of the welfare state as multiscalar, in which decision-making with regard to various aspects of welfare provision is shifted between scales. While some aspects of decision-making and welfare provision may be devolved, other aspects may move outside the gambit of the nation-state to supranational and international scales.

2. *Sources of Variation in Welfare Provision*

The structure of the welfare state within any region or country is the result of the interplay of many pressures and contextual factors. Some of these pressures may be specific to a particular place or country; these pressures might include gender and family ideologies. Other pressures might come from higher scales, such as the development of an international human rights regime that promotes a different ideology of gender and family. The interaction between processes, conditions, and practices that operate at local, national, and global scales gives rise to geographic variation in the welfare state and human well-being. While the sources of variation are many, three are of particular importance: the resources upon which states can draw, differences in ideology and political culture that shape the ways states conceptualize their roles, and pressures from international organizations.

The resources available to countries are clearly related to their overall level of wealth; at the same time, the need for social spending is also related to wealth. As a result, rich countries may have relatively small expenditures for welfare as a proportion of GDP, while still meeting basic needs. Thus, the Republic of Korea has a relatively small public budget and a low level of expenditure for social needs. As a relatively wealthy country, however, the overall level of well-being is high. By contrast, Pakistan and Indonesia have relatively large public budgets as a proportion of GDP. The proportion of the public budget, however, that is directed to social needs is very low, with predictable implications for overall well-being (UNDP 2000).

The above statements make clear that well-being and the success of welfare projects are affected by the pre-existing levels of well-being, by expenditure levels, and by the priorities established by national governments. The interaction between state action and contextual conditions in different localities gives rise to the uneven geography of welfare and well-being. Here the importance of the typologies developed by Esping-Andersen, Sainsbury, and others becomes clear, as those typologies reflect priorities and beliefs as to social rights. Social democratic and conservative regimes posit welfare as a social right of citizenship;

liberal regimes do not to the same degree. Also at work are differences in the ways that regimes conceptualize the responsibilities of citizenship. Conservative regimes assign families a high level of responsibility for individual and community well-being once basic needs are met, whereas social democratic regimes do not. The balance between rights and responsibilities for welfare, then, reflects ideologies related to the idea of dependence and the roles of families and communities (Fraser and Gordon 1994). Some countries take well-being to be a social responsibility, and do not link citizenship to dependence. Others take well-being to be an individual responsibility and link citizenship with independence. The question facing developing countries and countries undergoing economic and politic transitions is which path they will follow. Here the role of international organizations becomes clear.

International organizations can influence, and in some cases determine, the path that countries will follow as they develop their welfare apparatus. The role of the World Bank and International Monetary Fund in structural adjustment policies is well known. These organizations have made emphasis on productive activities a condition of development assistance. This has led to a redirection of public expenditure away from basic needs provision to public expenditures that support job growth (Corbridge 1993). While education may be a priority in this regard, health care, housing, and basic human needs may not. There is a widespread belief that responsibility for social reproduction has been shifted to families, and most particularly, to women (Lustig 1995).

Other international organizations propose poverty reduction strategies that rely on local communities, rather than national government support for social safety nets. The UNDP (2000), for example, argues:

> The foundation of poverty reduction is self-organization at the community level. Such self-organization is the best antidote to powerlessness, a central source of poverty.... What the poor need, therefore, is not resources for safety nets but resources to build their own organizational capacity.

To the extent that such statements actually guide the development of welfare state apparatuses in poor countries, they would result in a high priority placed on local communities, rather than state or business support, as a basis for poverty reduction. This would represent a fourth model, not anticipated by Esping-Andersen. It is a model, however, that is based on a gender ideology in which women play critical, and often uncompensated, roles in social provision. This new model is also characterized by heightened variability in both institutional structures at the local level and welfare outcomes, as diverse structures interact with diverse local conditions. The result is a model of welfare provision with a complex geography, and in which well-being is clearly related to the jurisdictions within which people live and work.

3. *Anticipating the Future Welfare State*

There is a widespread belief that the commitment of states to social welfare provision is declining in countries around the world. The 1999/2000 World Development Report, however, does not show a consistent trend toward decreased public expenditure as a percentage of GDP, nor does it show a consistent trend toward retrenchment of public expenditures on social services. Indeed, of 47 countries reporting expenditures in both 1980 and 1997, 36 had either maintained or increased spending on social services (World Bank 1999, Table 14).

It is clear, however, that the pattern of expenditures is changing, even if the total level is not. The United Nations and World Bank have called for new approaches to social welfare and poverty amelioration. They urge a reorientation of welfare policy to integrate poverty amelioration with other goals of economic development, sustaining environments, better governance, and building community assets. The attempts to build social institutions and orient welfare policy to enhancing the capacity of communities to provide for their members are consistent with the language of welfare reform in developed countries. Increasingly, the social capital within communities is being looked to as a resource in welfare provision. Under these conditions, the welfare state may take on a larger coordinating role, providing institutional frameworks, with a smaller role in direct service provision.

The outcome of this emerging form of the welfare state is not clear. It seems reasonable to expect, however, that heightened variability and unevenness will characterize both the geography of institutional practices and the geography of outcomes. It may be that this unevenness will reflect the resources, capacities, and intentions of communities and localities in ways that make the welfare state more responsive and effective. However, as Cope (1997) suggests, it may also create new forms of uneven development, with rich areas getting richer and poor areas getting poorer.

Welfare State, History of

1. The Origin and Use of the Term Welfare State

The term was coined in England in the 1940s. It is to be found in *Citizen and Churchman* (1941) by William Temple, Archbishop of York, where it is contrasted with the Power State or Warfare State. After the publication of the Beveridge Report in 1942, the term soon came to be applied to the hopes for postwar reconstruction and by 1948 was used regularly for the postwar reforms. The meaning of 'welfare' had not suffered the deterioration that had afflicted the word 'charity.' Although Beveridge himself disliked the term for what he called its 'Santa Claus' connotations and preferred the older term 'social service state,' 'welfare state' normally carried a favorable meaning.

Welfare had a different set of connotations in American English. 'Public Welfare,' as understood in the USA then and since, excluded the elements of social insurance, with its claims to benefit as of right, which were so prominent in the British construction of the term (Lindeman 1937). 'Welfare state,' once imported from Britain, thus carried a stronger association of paternalism (Skocpol and Ikenberry 1983).

In that respect Germany was closer to the USA. In the early years of the Federal Republic, when many English terms were naturalized into German, it seemed natural to render 'welfare state' with the similar word *Wohlfahrtsstaat*. Such similarities can be misleading. *Wohlfahrt* was associated with charitable gifts, and *Wohlfahrtsstaat* had acquired a pejorative connotation during the crisis of the Weimar Republic, as when in 1932 Chancellor von Papen accused politicians of the early years of the Weimar Republic of attempting to turn the state into a *Wohlfahrtsstaat*, and thereby weakening the moral strength of the nation. The Federal Republic wished to return to the Weimar tradition in social policy without falling foul of the associations of the term *Wohlfahrtsstaat*. One possible course was to use the term in its positive English sense and to resort to *Versorgungsstaat* to convey the pejorative meaning. The alternative was to revive a nineteenth-century term, *Sozialstaat* (Ritter 1989). The issue has never been settled decisively, although *Sozialstaat* is the more usual.

If the term dates from the 1940s, its definition also owes much to the changes of that period. According to Asa Briggs, 'A welfare state is a state in which organized power is deliberately used (through politics and administration) in an effort to modify the play of market forces in at least three directions—first by guaranteeing individuals and families a minimum of income irrespective of the market value of their work or their property; second, by narrowing the extent of insecurity by enabling individuals and families to meet certain "contingencies" …; and third, by ensuring that all citizens without distinction of status or class are offered … a certain agreed range of social services' (Briggs 1961). These are usually taken to relate at least to medical treatment, housing provision, and education. Briggs added a reference to the best standards available, but it has since been generally accepted that such an aspiration is unrealistic.

2. The 'Origins of the Welfare State'

Such an emphasis on the 1940s leaves the historian with the task of relating these innovations to what had gone before, i.e., to consider the 'origins of the welfare state.' Three national examples briefly indicate how differently the origins of the welfare state have been constructed.

2.1 British Historiography

Since 1961 this has operated in terms of the transformation of old institutions by new principles, forged at moments of political crisis (Fraser 1973). The first of these institutions was the Poor Law, which established the responsibility of each local parish for the relief of the poor (1603) and was reformed in 1834 on more explicitly deterrent lines in response to population growth and agricultural change. The subsequent history has been presented in terms of new social problems caused by industrialization, the Victorian

origins of collectivism in public health and factory regulation, the crisis of the Poor Law at the end of the nineteenth century, and the consequent Edwardian legislation (1905–14). This put an end to the possibility of a gradual extension of Poor Law services on a nondeterrent basis and provided for needy and deserving groups in other ways. It introduced free school-meals, a school medical service, tax-financed old age pensions for the poor, and national health and unemployment insurance, supported by a national network of labor exchanges. Alongside these measures 'New Liberalism' articulated a theoretical justification for state intervention in society and economy. The scope of this legislation was limited in respect of population covered and of benefits provided, but it has been regarded as having laid 'the foundations of the British welfare state.'

The interwar years saw housing provision added to the prewar measures, but social policy responded slowly and piecemeal to economic and social problems. It adapted rapidly once World War II had created new problems and a new spirit of citizenship. The postwar legislation, roughly but far from exactly based on the proposals of the Beveridge Report (1942), universalized national insurance, extended its benefits to cover a greater range of contingencies ('from the cradle to the grave'), and established a mainly tax-financed national health service. This was accompanied by tax-financed child allowances, the extension of housing provision, and free secondary education. Fundamental was a government commitment to a policy of full employment, based to some extent on a belief in the efficacy of Keynesian demand management that was, however, far from unequivocal. The transformation of old social services by new principles of universalism had been presented in the Beveridge report as a characteristic British revolution. Historians followed a similar line, which fitted into the then dominant 'Whiggish' historiography with its emphasis on the continuity of British history and the adaptability of its political leaders. In the influential view of the sociologist T. H. Marshall the welfare state had achieved the extension of citizen rights from civil rights via political rights in the past to a new body of social rights (Marshall 1950). The blueprint of the welfare state as established in the 1940s was for a long time presented as a major British contribution to postwar social reconstruction in the wider world.

2.2 German Historiography

This has located the origins not merely of its own welfare state but of the welfare state as such in the establishment of compulsory insurance for workers by the German Empire under Bismarck in the 1880s. It has both emphasized the pioneering role of Germany and the continuity of its insurance institutions despite drastic political change. This emphasis on the role of Bismarck, notorious for his hostility to the claims of the working-class movement, as the originator of the welfare state has presented historians with the problem of reconciling these two aspects of his policy. Until recently it was suggested that wooing the workers with the benefits of social policy was an intrinsic aspect of Bismarck's attempt to suppress social democracy. This view had the merit of presenting the welfare state as the achievement of the democratic forces while recognizing that the policies usually were not what these had been demanding. The publication of documents on Bismarck's social policy has cast doubt on this view of his aims and there is a need for re-interpretation (Tennstedt and Winter 1993, 1995).

The transition from the establishment of institutions with limited scope to the conscious acceptance of the people's welfare as an essential object of the state is located by German historiography in the Weimar Republic. It found expression in the text of the constitution but also across a range of its institutions, several of which had developed from war-time innovations. Collective bargaining backed by compulsory arbitration, subsidized housing, the preservation of prewar social insurance for both blue and white collar workers, and unemployment insurance as part of labor market policy, all suggest that the Weimar Republic was a welfare state in deed as in word. In German history the breakthrough to the welfare state was therefore achieved not after World War II but after World War I. However, the Weimar welfare state was unable to live up to its expectations (Abelshauser 1987). The political acceptance of its new role was insufficiently broadly based. As the earlier quotation from von Papen suggests, repudiation of the Weimar Republic in the years of economic crisis was connected closely with its social policy.

Although marginalized and only just saved from drastic changes in 1942, the social insurance system survived the Nazis. In the immediate postwar years of economic ruin, forced migration, and impoverishment it faced perhaps its greatest test. All accumulated funds had been lost. In the Russian zone of occupation it was reconstructed radically along lines originally proposed by the left-wing critics of Weimar policy. It was no more sacrosanct in the West. The French quickly followed the Russian example. Drastic British proposals followed, based partly on Social Democratic ideas from the Weimar years, partly on Beveridgean lines. They involved retrenchment and thereby aroused opposition well beyond the threatened vested interests. Opposition rallied around the defense of the Bismarckian inheritance in social insurance, which was presented as one of Germany's proud contributions at a time when the nation badly needed a boost to national self-esteem. With the onset of the Cold War the proposals were dropped as the Western occupation powers gave priority to working with German public opinion. It was left to the Federal Republic to deal with the problems of funding social

security; under CDU leadership the traditional structures were almost completely reinstated. Significant reform was delayed until 1957. In that year the introduction of the 'dynamic' pension, linked to average wage levels, represented an imaginative response to the problems of the Federal Republic: not just the problem of inflation but that of the low pension levels which contrasted sharply with the rising standard of living enjoyed by the working population. At a time when the legitimacy of the Federal Republic was fragile, this pension reform contributed significantly to the acceptance of the regime. In 1958–61 proposals to remodel the sickness insurance system and contain its spiralling costs were defeated. The Bismarckian prototype had acquired a secure political profile.

Thus, in the German Federal Republic the 1940s were a period of defence and restoration. The emphasis on the significance of the Bismarckian reforms for the long-term development of the German welfare state and the tendency to identify it narrowly with contributory social insurance were forged in the political conflicts of those years. This emphasis was reinforced in the early 1980s by the centenary celebrations of the Bismarckian reforms. Much of the German historiography of the welfare state was created in the 1980s (Ritter 1983, 1986, 1989).

These examples indicate that the history of the welfare state has been perceived differently in different countries, in terms of periodization and of emphasis. This reflects not only its actual development in different states but certainly also the political purposes which historiography has served.

2.3 The Swedish Model

These points must be made more briefly for the influential Swedish model of the welfare state. There, it was developments in the 1930s that had the significant long-term effects that they singularly failed to have in Britain or Germany. The expansion of the earlier limited social security provisions took a significantly different form. Unlike Germany, where insurance contributions and benefits differed according to levels of income, Swedish benefits were paid, as in Britain, at a flat rate for all. But they differed from both the German and the British provisions in that retirement pensions and sickness insurance were financed from general taxation. They were set at a level that provided pensioners with an adequate income, something that the British pensions, tied to contributions that even the lowest-paid could afford, entirely failed to do. Significant differences between the policies of these three welfare states also extended to industrial relations and taxation.

The Swedish welfare state has been presented as the achievement of class mobilization and labor solidarity. Standard accounts have stressed the long period of Socialist-dominated government and cooperation between government and labor organizations in the shaping of labor market policies (Baldwin 1990).

3. A General History of 'The Welfare State'

If it exists at all, the history of the welfare state, as distinct from the history of individual welfare states, must be sought on a higher level of generalization. A welfare state is a state of a certain kind, distinguished from earlier kinds by the addition of a new set of objectives and institutions. Its history must be sought within the wider context of the history of the state. It presupposes the unification of law across the state territory, the establishment of bureaucracies, and the elimination or control of intermediate forms of authority. It is, however, also characterized by new systems of domination, consisting of distributing elites, service bureaucracies, and social clienteles. The process by which these objectives were both established and extended to include the whole nation has been driven by the advent of representative democracy, but it also drew on older concerns to maximize the human resources of the state. In addition, these new state objectives have been connected intimately with the development of modern industrial capitalism.

The state became a welfare state because it dealt increasingly with the social consequences of the particular way in which modern industrial capitalism was established. These consequences, often described as externalities, resulted from the narrow definition of the legal obligations of capitalist entrepreneurs, which contrasted greatly with the obligations imposed on entrepreneurs in the older corporatist economy. This emancipation of the entrepreneur was a deliberate act of state policy, undertaken in the interest of increasing 'the wealth of nations' and thus the power of states over against other states. It undoubtedly had that effect. Enterprise took new and unforeseen forms once it was freed from old regulations. To limit obligations towards workers to the short-term purchase of their labor power, towards the community to the payment of local taxes, and to resort to competition without responsibility for those driven out of the market, all this encouraged innovation and facilitated capital accumulation. But it created problems that resulted from economic decisions while being external to the economic process.

3.1 Combinations and/or Transfer Payments

These problems could be dealt with in at least two ways. (a) By combination, intended to limit free competition over wages, or to pool the economic resources of individuals, or both (trade unions and mutual aid societies). To what extent that was possible depended on the attitude of the state and on the

capacity of individuals for organization. (b) By state action in whatever territorial units—national, provincial, or local—it exercised its power. That meant taxation and a limited redistribution of the resources originally distributed by the market. The administrative capacity that made it possible to introduce graduated taxes and differential tax allowances as instruments of redistribution is an important aspect of this history.

The legalization of combinations to increase wages in turn made it increasingly possible for individuals to satisfy their needs through the market, thereby creating opportunities for new kinds of enterprise. The legalization of mutual aid associations created structures of redistribution, which could operate as alternatives to the bureaucratic structures of the state. In countries in which the development of bureaucracy had not advanced far, or where it was viewed with mistrust, subsidies from taxes became a way of making mutual associations more effective. Such subsidies were not unconditional but subjected the association to a greater or lesser degree of control. An extreme example of such control was the compulsory establishment of combinations on the order of the state, such as the German sickness funds and trade associations to administer accident insurance. The higher the level in the administrative hierarchy on which the state operated to redistribute resources, the greater the degree of uniformity it could impose.

3.2 Goods and Services

So far the focus has been mainly on the redistributive role of the welfare state. The problem of externalities has also been addressed by the public provision of goods and services, which the market supplied only in ways deemed politically unacceptable. Such goods and services, considered necessary for the common good as politically defined, have included the infrastructure of public health, the provision of healthy and environmentally approved housing, of medical treatment, and of schools, but this list is far from exhaustive. Here, too, subsidies could take the place of full state provision, e.g., in respect of houses, food, or schools.

3.3 Regulation

Since externalities had been allowed to arise because the state had regulated the conditions of production in minimal ways, it also began to introduce new regulations. Under such regulations the market was permitted to supply goods and services only on conditions acceptable to the state. Instead of providing housing, the state regulated the conditions of tenancies. Instead of running its own schools, it regulated and inspected those provided by other bodies. And, as in Thatcherite Britain, it regulated the sanitary infrastructure while relying on the market to provide it. Such regulation could be accompanied by subsidies. However, such regulation suffers from the same considerations that applied to the general conditions of production in the first place. By regulating the actions of the market, the state is liable to hinder innovation and to make the market an inefficient mechanism for economic growth.

Finally, the state has been able to regulate the economy itself in such a way as to minimize externalities. Examples are the state regulation of wages and the regulation of the economy so as to reduce cyclical fluctuations. At all stages of this process, the question has to be faced whether the object is being achieved at the cost of economic innovation and efficiency. For that reason there are limits to what regulation can achieve.

A radical alternative has been for the state to take over the running of the total economy. That rules out a welfare state, defined as a state that modifies the play of market forces, and it creates a state so different that it is better not to describe it as a welfare state. That is not to deny, however, that 'communist' states provide social services and organize transfer payments in the interest of social security. This article does not deal with the history of states with a command economy, confining itself to the history of what is sometimes called the liberal welfare state.

Even there the importance of the welfare elements of the state can vary according to the extent to which entrepreneurs did in practice externalize their costs. Where company welfare was built into the entrepreneurial ethic, as in Japan, state expenditure on social security has been restricted compared with other advanced industrial countries.

4. The History of Welfare States Since 1945

Despite this attempt and others (Flora and Heidenheimer 1982) to construct explanatory models of the welfare state as a general phenomenon of European and subsequently extra-European history, the established tradition of nation–state history has led historians to study developments both before and after 1945 in terms of individual states. They have given prominence to the political circumstances under which social policy was constructed and emphasized the importance of national traditions.

Some few generalizations across countries are feasible. Thus, the experience of the 1930s had demonstrated that institutions of social security were seriously vulnerable to periods of mass unemployment. Such periods greatly increased the demands for transfer payments, while also reducing the income from which these were made. This was particularly true of contributory insurance, but it also applied to finance from general taxation. This lesson had been learned, and in the 1940s macro-economic policy

became a policy component of every state, whether it had passed through the experience of a war economy or, like Sweden, had not. In some countries this period saw major reforms and extensions in social security, as in Britain, France, and Sweden. In others, major reforms had to wait until the 1960s and early 1970s after the restructuring of the economy had yielded its rewards, as in The Netherlands and Italy.

Even where significant legislative innovation occurred in the immediate postwar years, subsequent expansion of the economy provided the setting for a period of further change in the 1960s and 1970s. Indeed, the most convincing historical generalizations that can be made about the welfare states since 1945 refer to the effect of major changes in the international economy. A long period of economic recovery in Europe led by the 1960s to a remarkable growth in national income. This in turn both raised expectations and facilitated the introduction of more generous provisions. Levels of benefits were raised, flat-rate pensions complemented by graduated ones that mirrored differences in original earnings and appealed to the better off, while those disadvantaged by or excluded from earnings-based insurance systems received compensatory entitlements.

By contrast, the setback to economic expansion in the mid-1970s, triggered by the oil-price crisis, caused a fall in employment, except where special measures for job creation had been implemented (as in Sweden). This, in turn, led to rises in social security payments and falls in the revenue available for the purpose. Steady increases in the gross national product, which had spurred ambitious changes in entitlements in the previous decade and a half, could no longer be assumed. Nor had recent rapid growth in social expenditure been due only to deliberate changes in entitlement. It had also been caused by such demographic, cultural, and technological changes as an increase in the proportion of the elderly, a rise in single-parent families, and the growing cost of medical treatment. To the fiscal crisis that occurred in every country sooner or later, even in Sweden, was added a crisis of belief in the assumptions on which welfare states had been based. Yet these assumptions had been deeply implanted in the citizens, and many vested interests created. Measured by the radical debate that broke out, the actual changes in welfare states were not great, even in Great Britain, where the call for the rolling back of the state had been loudest.

5. *Historiography of Welfare States*

There are several ways in which the original traditions of welfare state history have been modified.

5.1 *A Gender-conscious Historiography*

Just as the feminist movement has since the 1960s exerted a political influence on the agenda of policy making itself, so it has also changed historical perceptions. Feminist historians have highlighted the way in which social policies were shaped by assumptions about the gender divisions of labor, power, and social responsibility. They have shown how little the basic assumption that each adult woman was dependent on a male earner was borne out in reality. Contributory insurance, with entitlements dependent on the performance of waged labor over most of the adult life span, had been at the center of welfare state history. It looked very different through the eyes of feminist historians, but these have not merely confined themselves to criticism. By drawing attention to policies in support of motherhood, they have reconstructed the outlines of welfare state history (Pedersen 1993, Koven and Michel 1993). By making historians more aware of the implications of gender, this emphasis has yet unrealized potentials. Male roles, once so taken for granted as to be largely invisible to historians, have in turn become objects of historical study.

5.2 *Welfare State History 'from Below'*

The history of social policy traditionally has been written through the eyes of 'policy-makers' and administrators, and occasionally of political philosophers, trade union officials, and radical politicians, authority figures all. Welfare state history has been particularly resistant to the search for history as experienced by those without power and influence. Yet the construction of social policy and its administration is that of a relationship, in which the recipients of 'benefits' are at least half the story. Like all forms of history from below, attempts to recreate their experience has been hindered by their inarticulacy, at least in forms that have survived as records. But once historians search, they are able to find evidence, not merely for recent times but at least in England going back well into the past (Lees 1998, Vincent 1991).

5.3 *Studying the 'Mixed Economy of Welfare'*

One result of paying more attention to the lives of the poor has been to downgrade the importance of state provisions and to draw attention to the mixture of resources that made up the economy of the poor. Since public authorities frequently did not intend to provide those in need with a full subsistence—and, when they did, were not good at judging the amount required—this should be unsurprising. It has made this history less state-centered (Katz and Sachsse 1996, Thane 2000). This trend has been reinforced by a change of social policy in several countries in the 1980s, Britain and the USA in particular. The replacement of direct state provision of services by contractual relationships with charities and profit-making providers has given prominence to the concept of the 'mixed economy of welfare.'

Third, at a time when the clients of the welfare state are drawn from all citizens, contemporary studies of social policies have come to pay attention to the mixture of resources at the disposal of citizens, particularly of the elderly, whether these were from public, occupational, or commercial sources. Since that mixture differs in different countries, comparative studies have moved from an exclusive preoccupation with state provision towards a concept of welfare regimes more broadly defined (Esping-Andersen 1990). The influence of comparative studies by social scientists on historiography is the final issue to be considered.

5.4 Comparative Studies

The historical study of welfare states was for a long time overparticularized. Attempts to identify categories suited for generalizations were left to social scientists specializing in the quantitative analysis of policy outcomes. This has been a dynamic field of study since the 1970s, but it developed in a particularly ahistorical form. One reason was its dependence on information provided by such international agencies as the United Nations and the Organization for Economic Co-operation and Development. Little of this went further back than the 1960s, so that the historical perspective was limited. Second, the questions asked and the explanatory power of the answers provided were constrained by the availability of such quantitative evidence, which was at first largely limited to figures of expenditure. The narrowness of these comparative studies was only slowly overcome as new evidence became available, e.g., the Luxembourg Income Study in the 1980s, which provided internationally comparable income-distribution data at microlevel, and as researchers began to approach national governments and other agencies directly to construct their own database. Third, the choice of appropriate categories for comparison across different national contexts is notoriously difficult and not always successful.

Evidence of this kind was, in any case, unable to provide explanations that advanced beyond the discovery of correlations. Intentions were ignored, because unsuited to standardization, and important dimensions of history were thereby ruled out of court. The most important result of these correlations was to group welfare state regimes into three main types: liberal, corporatist, and social democratic. It is more obvious that these describe ideal types than that they describe clearly differentiated clusters of indicators. Australians have demurred at the inclusion of their country in the same category as the USA; Germans have felt unhappy at being grouped with Italy and France; and the case of Britain is recognized widely as a hybrid. It is certainly not possible to write anything like a common history of the several welfare states grouped into any one of these types, with the possible exception of the four social democratic ones, who all happen to be Scandinavian.

Yet, by their very limitations, comparative empirical studies have helped to identify so-called anomalies and to encourage the intensive historical investigations of individual cases (Castles 1989, which includes Japan and Israel). The gulf between the social scientific and the historical study of welfare states has narrowed, as indicated by sharply focused comparative histories of pensions and of public health or by a five-volume history of individual welfare states addressing similar questions and written on a common editorial plan (Baldwin 1990, 1999, Flora 1986/2000).

Well-being and Burnout in the Workplace, Psychology of

Job-related well-being is a specific aspect of subjective well-being and comprises as positive features phenomena such as job satisfaction, job attachment, involvement, and job morale; impaired job-related well-being includes experiences such as job tension, depression, burnout, and alienation from work (Warr 1990). The well-being concept refers both to minimal and temporary changes in employee mood and affect and to long-term disturbances of mental health (e.g., chronic anxiety or psychosomatic complaints). Research has paid more attention to long-term job-related well-being than to more momentary fluctuations in mood and affect. It is typical for work-related research to examine mental health and well-being in normally working samples who are not psychiatric patients.

1. *Conceptualizations of Well-being and Burnout*

Generally, it is assumed that well-being is not a unidimensional concept (Diener et al. 1999). This holds also for job-related well-being. However, authors disagree about the exact number and content of the separate dimensions of job-related well-being. Based on the conceptualization of arousal and pleasure as two independent dimensions, Warr (1987) proposed a model of job-related well-being comprising three dimensions: the first dimension runs from displeasure to pleasure, the second from anxiety to comfort, and the third from depression to enthusiasm. Additionally, feelings of competence and aspiration also can be regarded as facets of job-related well-being (Warr 1990).

Burnout is a specific and severe form of disturbed job-related well-being, originally mainly observed in human service professionals. The burnout syndrome comprises as key dimensions emotional exhaustion, depersonalization (i.e., negative and cynical attitudes towards one's clients or patients), and reduced personal accomplishment (Maslach and Jackson 1981). Researchers have observed that burnout does not develop only in human service professions, but also that it can occur in practically all kinds of jobs.

2. *Theoretical Models on Job-related Well-being and Burnout*

In the late twentieth century, researchers put much emphasis in the development of theoretical models on the relationship between work situation factors and job-related well-being (Kahn and Byosiere 1992). Among the most prominent models are the job characteristics model (Hackman and Oldham 1976), the job demand–job control model (Karasek and Theorell 1990), and the vitamin model (Warr 1987).

In their job characteristics model, Hackman and Oldham (1976) specified five core job characteristics which they assumed to be crucial for high internal work motivation and employee satisfaction: skill variety, task identity, task significance, autonomy, and feedback from the job. These job characteristics are expected to impact critical psychological states (i.e., experienced meaningfulness of the work, experienced responsibilities for work outcomes, and knowledge of the results of work activities), which in turn impact on the motivation and satisfaction as outcome variables. Furthermore, Hackman and Oldham proposed that moderators such as growth need strength, contextual satisfaction, knowledge, skills, and abilities have an effect on the relationship between core job characteristics and critical psychological states and also on the relationship between critical psychological states and outcome variables.

Similarly to the job characteristics model, the job demand–job control model (Karasek and Theorell 1990) received much attention within work and organizational psychology. In the original version, the job demand–job control model describes two dimensions relevant for job-related well-being: job demands and job control. In this model, job demands refer to high workload and time pressure; job control includes decision authority and intellectual discretion. It is assumed that the combination of high job demands and low job control resulting in high-strain jobs has severe negative effects on employee well-being. The model assumes that a combination of high job demands and high job control results in active jobs which have more beneficial effects for employee well-being. More recently, other work situation factors, such as social support and informational control, have been incorporated into the job demands–job control

model (Karasek and Theorell 1990, Terry and Jimmieson 1999). These extended models state that the effects of high-strain jobs will be most negative under conditions of low social support. High informational control, however, is predicted to attenuate the negative impact of high-strain jobs.

In his vitamin model, Warr (1987) proposed that job-related well-being is affected by job characteristics in a way similar to the effects of vitamins on physical health. Basically, the vitamin model suggests that some job characteristics have a linear effect whereas others have a nonlinear effect on well-being. Among the job characteristics assumed to be linearly related to well-being are physical security, a valued social position, and availability of money. Job characteristics assumed to show a curvilinear relationship with well-being include opportunity for personal control, opportunity for skill use, externally generated goals (i.e., demands), variety, environmental clarity, and opportunity for interpersonal contact. More specifically, the vitamin model assumes that well-being increases as these latter job characteristics increase; however, at a very high level, these job characteristics will cause a decrement in well-being.

Specific models have been developed which aim at explaining the emergence and development of burnout (Schaufeli and Buunk 1996). These models refer to individual, interpersonal, and organizational processes. For example, with respect to individual processes, burnout has been explained as resulting from a pattern of wrong and unrealistic expectations, as progressive disillusionment, as a failure in keeping up an idealized self-image, as a narcissistic disorder, as a disturbed action process, and as loss of coping resources. At the interpersonal level, the specific emotionally demanding relationship between caregiver and clients in addition to unsatisfactory social comparison and unbalanced social exchange processes are regarded as being the main causes of an individual developing burnout symptoms. With respect to organizational processes, individual burnout has been described as an effect of an unhealthy organization.

3. *Empirical Studies About Predictors of Job-related Well-being and Burnout*

Stressful working conditions were found to be negatively related to employee well-being, in both cross-sectional and longitudinal studies (Kahn and Byosiere 1992, Zapf et al. 1996) (see *Stress in Organizations, Psychology of*). Such stressful working conditions include physical stressors (e.g., noise), role stressors (e.g., role ambiguity, role conflict), work overload or time pressure, and more specific stressors such as monotonous work and attentional demands. Similarly, two out of the three burnout factors, i.e. emotional exhaustion and depersonalization, were found to be substantially correlated with job stressors such as lack of role clarity, role conflict, role stress, stressful events, workload, and work pressure (Lee and Ashforth 1996).

Moreover, other aspects in the work situation such as specified in the job characteristics model are positively related to employee well-being, particularly job satisfaction (Fried and Ferris 1987). Among these job characteristics, job control plays an important role. Job control is not only directly related to employee well-being but also acts as a buffer in the stress process. This buffer effect implies that in work situations with high-control stressful working conditions have a less negative impact on employee well-being than in work situations with low control. However, unlike depressive symptoms or anxiety, burnout seems to be unrelated to job control (Lee and Ashforth 1996).

Other work-related variables which play an important role in employee well-being are social support and group process characteristics, particularly a positive team climate and high cohesiveness within the team (Lee and Ashforth 1996, Sonnentag 1996). Persons who receive a high level of high social support from their supervisors and co-workers and also persons who experience a good team climate and a high cohesiveness within their teams enjoy a better well-being than persons who lack social support and who suffer from an unfavorable group process.

Additionally to these general findings about stressful working conditions, control at work and social support, research revealed that there is substantial individual variation in the relationship between work situation variables and individual well-being. Particularly an internal locus of control seems to protect one's well-being, also in relatively unfavorable work situations (Kahn and Byosiere 1992).

Moreover, job-related well-being is not only affected by a person's work situation or an interaction between work situation variables and individual characteristics such as locus of control. A number of studies have shown that personality dispositions such as negative affectivity are directly related to job-related well-being (Warr 1996). Also life satisfaction was found to have an effect on job-related well-being.

Taken together, job-related well-being and burnout have multiple causes, which lie partially in the person's work situation and partially in his or her personality. It seems that particularly the combination and interplay of various factors are responsible for a person's job-related well-being

4. *Empirical Studies About the Consequences of Job-related Well-being and Burnout*

Low job-related well-being and burnout are not only unpleasant experiences. They may threaten the individual's functioning within the work organization. Empirical research shows positive correlations be-

tween job-related well-being and job performance (Warr 1996). However, these correlations are relatively small in size and do not necessarily imply that well-being affects performance. It might be that performance has an effect on job-related well-being or that both well-being and performance are influenced by other factors such a leadership behavior. Moreover, studies revealed that impaired job-related well-being and burnout show small to moderate correlations with absenteeism and turnover intentions, two phenomena associated with high organizational costs (Lee and Ashforth 1996, Warr 1996).

5. *Intervention Programs*

Different kinds of interventions aim at the protection and improvement of job-related well-being. Most interventions are oriented towards the individual, i.e., to the way an individual perceives or deals with unfavorable working situations. Other individual oriented interventions are designed to directly influence the individual's psychological and physical well-being, for example, by progressive muscle relaxation, biofeedback, cognitive-behavioral interventions or meditation techniques (Kahn and Byosiere 1992, Murphy 1996). Empirical evaluations of these programs show that a combination of physical relaxation exercises and cognitive-behavioral interventions work best, particularly with respect to general aspects of well-being and the emotional exhaustion component of burnout (Murphy 1996, Schaufeli and Buunk 1996).

Another approach to improve job-related well-being consists of workplace interventions. During such workplace interventions, jobs are redesigned, e.g., by increasing employee control at work, by reducing specific job stressors or by introducing self-managed work groups. Empirical studies show substantial beneficial effects of such workplace interventions on job-related well-being (Kahn and Byosiere 1992). Since workplace interventions tackle the source of disturbances of well-being, they are to be preferred to individual-oriented intervention programs.

Well-being and Health: Proactive Coping

1. *Proactive Coping as a Blend of Coping and Self-regulation*

Proactive coping refers to a set of processes through which people anticipate or detect potential stressors and act in advance to prevent them or to mute their impact (Aspinwall and Taylor 1997). As such, proactive coping is a blend of two extensively studied processes, *coping* and *self-regulation*. Coping consists of activities undertaken to master, reduce, or tolerate environmental or intrapsychic demands perceived as representing threat, harm, or loss (Lazarus and Folkman 1984). Self-regulation is the process through which people control, direct, and correct their own actions as they move toward or away from various goals (Carver and Scheier 1998). Proactive coping combines these two processes by examining people's emotions, thoughts, and behaviors as they anticipate

and address potential sources of adversity that might interfere with the pursuit of their goals (see Aspinwall 2001, Aspinwall and Taylor 1997).

1.1 Contrast to Other Approaches to the Study of Stress and Coping

The typical approach to the study of stress and coping examines how people try to solve existing problems and to manage the psychological distress they bring. The proactive coping approach, in contrast, focuses on people's efforts to identify potential sources of stress and take steps ahead of time either to prevent them or to mute their impact. For example, whereas a study of stress and coping might ask how students would manage if they had three final exams on the same day, a study of proactive coping might ask what students in such a position did ahead of time to alter their situation (for example, by asking one of their professors for an extension or by dropping one of the classes to avoid such a situation).

In the domains of aging and work, the proactive coping concept has been used to examine situations in which people, rather than being passively shaped by their environments, respond to actual or potential environmental changes by gathering information about new environments and selecting and modifying environments to meet their needs. For example, studies of proactivity in aging take as their starting point people's efforts to learn about their residential options, to select a particular retirement community in the first place (for example, by selecting one with opportunities for health-enhancing recreational activities), and to develop social resources once they arrive (Kahana and Kahana 1996). Similarly, studies of workplace entry suggest that new employees engage in several strategies to learn about their new environments and to develop social resources and that these strategies are often related to subsequent job performance and satisfaction (Ashford and Black 1996).

As these examples illustrate, proactive coping efforts may be applied to short-term, discrete situations or to developmental challenges and losses that are anticipated by the individual. In both cases, activities critical to understanding people's outcomes in educational, residential, and work settings occurred prior to or early in the course of some event or transition and served to change their experience of the situation. This signal property of proactive coping—the possibility of changing or altering one's outcomes in potentially stressful situations—is one of the principal distinctions between proactive coping and anticipatory coping. *Anticipatory coping* refers to efforts to brace oneself for the expected consequences of a known, imminent stressor. In proactive coping, the outcome of a situation may be unknown, and there is also room for one's actions to affect one's outcomes. Thus, proactive coping may involve a wide range of processes involved in trying to understand and alter various future possibilities (see Aspinwall 1997, Gollwitzer and Bargh 1996).

2. The Proactive Coping Model

The proactive coping model (Aspinwall and Taylor 1997) examines the personal, social, and situational factors that may influence the nature and quality of efforts to detect and respond to potential stressors. As shown in Fig. 1, proactive coping is thought to have five inter-related stages: (a) resource accumulation, (b) recognition of potential stressors, (c) initial appraisals of potential stressors, (d) preliminary coping efforts, and (e) the elicitation and use of feedback about the success of one's efforts.

Proactive coping starts with the accumulation of specific resources and skills that facilitate the detection of potential problems based on either warning signs from the environment or internal processes of reflection. Once a potential problem has been detected, it must then be appraised. At this stage, the predominant questions are, What is it? and What is it likely to become? Correspondingly, one must mentally simulate a variety of possible directions the situation and one's efforts to address it might take. Additionally, as illustrated by the star burst at right, the need to regulate negative emotional arousal evoked by detecting a potential stressor may compromise one's efforts to appraise it. Appraisal of a situation as potentially problematic may promote greater sustained attention to it, whereas efforts to reduce the threatening implications of the information may reduce attention to it, potentially compromising the accuracy of the appraisal. In the next stage of the model, initial appraisals of potential stressors give rise to preliminary coping efforts. These efforts, in turn, may be more or less successful in eliciting information about the nature of the problem and the appropriateness of one's preliminary efforts to address it. This information may, in turn, qualify one's appraisals and lead to the modification of coping efforts.

2.1 Using the Model to Understand the Relation of Individual Differences to Stress-related Outcomes

The model and its feedback loops provide a framework for understanding how individual differences, such as optimism and neuroticism, may be related to proactive efforts to anticipate and manage potential stressors and thus to long-term physical and mental health outcomes. For example, dispositional optimism, the expectation of more good than bad outcomes in the future, has been shown to predict increased attention to potential threats to health, as well as more elaborated appraisals of such threats (see Aspinwall 2001

Figure 1
Aspinwall and Taylor's (1997) five-stage model of proactive coping (source: Aspinwall and Taylor 1997; reproduced by permission of American Psychological Association from *Psychological Bulletin* **121**: 417–36)

for review). In dozens of studies, optimism has also been linked to more active and less avoidant ways of managing problems. To the extent that active coping is more likely than avoidant coping to elicit information about their problems, optimists' subsequent coping efforts should be better informed and thus more likely to succeed. Through such processes, the successful proactive management of problems could account in part for optimists' success in a wide range of life domains.

In contrast, other individual differences may reliably impede the acquisition and use of information about potential problems and ways to manage them proactively. Some individual differences, such as neuroticism, anxiety, and repression, are linked to heightened attention to negative information, but also to difficulties in processing such information. Further, these traits typically predict more avoidant forms of coping, strategies that are less likely to elicit information about potential stressors. Over time, then, such ways of handling problems and information about them may lead to coping efforts that do not correspond well to the nature of the problem. Thus, the feedback loops in the model provide a way of thinking about the relation of individual differences to the accuracy of people's initial appraisals of problems, and for thinking about the ways that preliminary coping efforts may be differentially successful in eliciting useful information about problems.

2.2 *Other Influences on Proactivity*

Many other personal, social, and situational factors are likely to influence proactive coping (Aspinwall and Taylor 1997). For example, busy, demanding, unpredictable environments may make potential stressors more difficult to detect early in their course, leading to further resource depletion as problems may grow larger before they are detected. Further, such environments may interfere with the development of coping skills and social resources (Taylor et al. 1997). At the individual level, differences in the value placed on future, as opposed to current, outcomes may also play a role in important forms of proactivity, such as preventive health behavior and conservation efforts (Strathman et al. 1994).

3. Applications to Health

Successful proactive coping may promote physical and mental health in many ways. First, addressing a problem earlier in its course requires fewer resources and may be more likely to be successful. The proactive coping model may be useful in understanding preventive behavior and early responses to physical symptoms, including emotional and other barriers to early detection. Second, successful proactive efforts to manage both large and small problems should serve to reduce an individual's total exposure to stress and thus be linked to better physical and mental health. Even if problems cannot be prevented altogether, proactive efforts to address potential problems are unlikely to be wasted, as they may contribute to one's knowledge base for use in future efforts. Third, in studies to date, a central aspect of proactivity seems to be the development of social resources, which themselves have robust links to good health outcomes.

4. Future Directions

Continuing research on proactivity in major life transitions, as well as in everyday behavior, should foster an increased understanding of the social cognitive and developmental underpinnings of coping. To date, the coping literature has been characterized by excessive reliance on retrospective self-reports of coping over long intervals and by coping measurements that sum together many different kinds of activities undertaken to solve problems, regulate emotions, and shift priorities in the face of adversity. Careful delineation of the component activities of proactivity, such as regulation of attention, planning, mental simulation, and the elicitation and use of feedback about the success of one's coping efforts, how such components develop (Friedman and Scholnick 1997) and influence lifespan development (Freund and Baltes 1998), and how they are affected by personal, social, and environmental factors will add greatly to the understanding of successful proactivity and, ultimately, inform interventions to foster proactivity in health, educational, and work settings (Schwarzer 2000).

Additionally, increased attention to the role of social factors in successful proactivity may prove fruitful. In the aging and workplace examples, people entering new environments acted quickly to cultivate social resources. Social resources may play a key role in proactive coping, as people use the opinions and outcomes of others to make predictions about what the future might hold for themselves (Aspinwall 1997) and actively enlist others' assistance in appraising and managing potential stressors. Further, understanding how people prevent losses of social resources by altering their behavior to counteract expected discrimination (Miller and Myers 1998) or by responding to incipient problems in close relationships may prove to be important in understanding mental and physical health outcomes over time.

Finally, the study of proactivity may be expanded to include thoughts and actions in the service of not only preventing adverse outcomes, but also creating future opportunities (Schwarzer 2000). Future efforts to understand both kinds of proactivity may increase our understanding of people's capacity to shape their environments and outcomes through their capacities for future-oriented thinking and action.

Well-being (Subjective), Psychology of

When people evaluate the quality of their lives, we label this 'subjective well-being.' Their appraisals might come in the form of life satisfaction judgements, as pleasant emotional reactions to life events, or as feelings of fulfillment. Thus, subjective well-being (SWB) includes both cognitive judgements and affective reactions in which people evaluate their lives and circumstances. It can vary from abject depression and complete dissatisfaction at the low end, to elation and consummate satisfaction at the high end. In addition to reactions to one's life taken as a whole, subjective well-being includes evaluations of specific components of one's life such as work, marriage, health, recreation, and religion. SWB includes global assessments of a person's life from childhood to the present, and also more specific evaluations that are focused on a narrower time frame such as the past month. In sum, SWB includes all the components about how people think of and evaluate their lives. SWB includes everyday concepts such as happiness, morale, zest for life, and peace of mind.

1. *SWB and Quality of Life*

A pivotal early finding in the field was Bradburn's (1969) discovery that pleasant emotions and unpleasant emotions form separable entities, and different factors influence each. In other words happy emotions and unhappy ones are not polar opposites: people's experience of one does not tell us much about how much of the other they feel. The importance of this finding is that even if we understand totally what causes depression, anxiety, and unhappiness, we may have little knowledge of what causes positive feelings of joy, affection, and contentment. Thus, we must understand the positive end of well-being to gain a full understanding of quality of life. The balance between pleasant and unpleasant emotions in a person's life is termed 'hedonic balance.'

In the 1970s another major component was added to SWB: life satisfaction. It was discovered that although satisfaction with life was related to hedonic balance, it formed a separate factor. Therefore it is now commonplace for SWB researchers to measure life satisfaction, pleasant affect, unpleasant affect, and satisfaction with specific life domains.

The classic Greek philosophers inquired as to what constitutes the 'good life,' and Asian thinkers such as Confucius explored similar questions. Many valued characteristics such as virtue, wisdom, and pleasure have been proposed as essential components of the quality of life. In the field of subjective well-being, researchers examine how people themselves evaluate their lives, using whatever standards and characteristics they choose. In this approach the factors that determine whether people will view their life as good are studied, and researchers do not impose their own set of values in judging that life. Thus, SWB is a democratic approach to quality of life in that it grants recognition to people's own evaluations of their lives.

As the wealthier nations achieved economic prosperity during the twentieth century, people became increasingly concerned with quality of life that goes beyond material prosperity. Social indicators measuring factors such as education, health, and equality arose in order to yield a measure of well-being that transcended economic security. At the same time, after World War II an interest in subjective well-being variables led survey researchers to measure quality of life from people's internal frame of reference. Pollsters asked people how satisfied and happy they were. In early survey research there was an emphasis on the effects of demographic variables on SWB. For example, Campbell, Converse, and Rodgers (1976) examined samples of Americans, and determined how much demographic factors such as age, sex, income, education, and ethnic group correlated with reports of SWB. To their surprise—and this finding has been replicated numerous times—demographic variables accounted only for a modest portion of SWB. If demographic variables such as income do not account for much of the variation in SWB, what does?

2. *Temperament*

People's personalities have an important influence on whether they are happy or unhappy (see Diener and Lucas, chap. 11 in Kahneman et al. 1999). Studies of monozygotic vs. dizygotic twins who were reared together or apart from birth demonstrate that SWB has a substantial heritable component. Because they share all their genes in common, identical twins reared apart are more similar in their levels of SWB than are fraternal twins who are raised together. Although heritability tends to be strong, the influence of shared early home environment appears to be weak. Other types of studies tend to support the importance of personality to SWB. For example, there is a substantial consistency across situations in people's satisfaction, as well as considerable stability of SWB in adulthood. Furthermore, personality traits such as extraversion

and neuroticism show substantial correlations with levels of pleasant and unpleasant affect, respectively (Headey and Wearing, 1989).

3. *Adaptation*

When good and bad events happen to people, it is not surprising that they react with happiness or unhappiness. Over time, however, they usually adapt, returning toward their earlier level of SWB (see Diener et al. 1999 for a review). Often people may adapt to very good or very bad events in a relatively short time. Adaptation combined with the effects of personality led Headey and Wearing (1989) to propose the 'dynamic equilibrium' model in which personality determines the long-term baseline level of SWB, but in which events can temporarily move people above or below their baseline. However, it must be noted that people do not completely adapt to all life circumstances; some environmental factors can move people's baseline up or down. For example, people who are born with multiple disabilities are less happy as adults, even though they have had many years to adapt to their conditions. Similarly, people in very poor nations are also less happy than those in wealthy nations. Thus, happiness seems to arise from a combination of the effects of personality with long-term conditions that have a pervasive effect on people's lives. Recently, the idea has emerged that SWB also depends on cognitive habits related to how people perceive and interpret events.

4. *Goals*

People have various values and goals that they believe are important. When they make progress toward their goals, they tend to be happier, and when they fail to move toward their goals, they are less happy. One way that people can adapt to bad conditions is to change their goals. For example, if a woman is failing at her goal to become president, she might focus on doing her job particularly well, and on the accomplishments within that position, and therefore the disappointment due to the failure would be likely to diminish. On the other hand, happy people tend to adopt goals for which they possess adequate resources to be successful. Thus, it is found that resources such as money, physical attractiveness, or social skills are most related to SWB when they are relevant to achieving the person's goals (see Diener et al. 1999).

Ryff and Singer (1998) propose that purpose and meaning in life are essential to mental health. Several researchers have concluded, however, that the content of a person's goals can influence SWB. Brunstein et al. (1998) found that goal strivings must be congruent with a person's motives to produce SWB, and Kasser and Ryan (1996) proposed that goals must be intrinsic rather than imposed to enhance SWB. Emmons (1986) found that success at goal strivings is related to positive affect, whereas conflict between one's goals is related to negative affect. Thus, the relation between goal striving and SWB is more complex than originally believed.

5. *Cultural Differences in SWB*

Certain variables predict life satisfaction in some cultures, but not in others (Diener and Suh 2000). For example, self-esteem is a strong correlate of satisfaction in highly westernized, individualistic cultures, but not in collectivistic societies where the group is more important in defining who one is. Similarly, consistency and acting in congruence with the self are stronger predictors of SWB in individualistic than in collectivistic cultures. Also, individualists on average heavily use their own emotional feelings to judge their life satisfaction, whereas collectivists are more likely to weight normative prescriptions for happiness, and the views of others. For collectivists, SWB must include the belief that significant others evaluate one's life well. The explanation for these differences between nations is that various cultures emphasize different values and goals, and therefore tend to make certain information chronically salient so that it is used when people judge their lives.

Not only are there cultural differences in the correlates of SWB, but average SWB levels differ across nations as well. For instance, high levels of SWB are currently reported in northern European nations, whereas much lower levels are reported in eastern European countries. Several factors seem to account for the differences between nations in SWB: wealth versus poverty, political stability versus instability and social disruption, and culture. In terms of culture, some societies seem to emphasize a positive approach to life, and the desirability of happiness. In these 'positivity cultures' there are higher levels of satisfaction than are predicted based on wealth or objective factors alone.

6. *Changing Focus*

In the early days of research on SWB, the focus was on large surveys, and the determination of what demographic factors are most correlated with 'happiness.' Recently attention has shifted to the influence of temperament, in combination with environmental circumstances. However, another new direction is to examine the processes that determine feelings of well-being. For example, the goals people select may be as important to satisfaction as are objective life circumstances. Similarly, people may focus on the desirable elements in their lives or the problems, and this can influence their SWB. People's memory structures for good versus bad events, their interpretation of events, and the information they use when judging

their life circumstances have recently become important topics of study.

7. *Methodological Issues*

Because the area of subjective well-being has roots in survey research, broad, representative samples of many nations are available, and this has been a major strength of the field. Questions arise, however, in considering the validity of the measures of SWB. Virtually all measurement of variables in this area have been based on global self-reports: on one occasion people report on numbered scales how happy or satisfied they are. Fortunately, research has shown that there is a degree of validity to these survey instruments. The SWB scales correlate with nonself-report measures such as smiling, the reports of family and friends, interviewer ratings, daily reports of mood, and whether individuals can quickly recall more good events than bad events from their lives. Nonetheless, certain obvious biases can enter into self-report measures of SWB. For example, people cannot recall with accuracy their moods over a long period of time. For this reason, researchers in the field have begun to supplement the global self-report measures with experience sampling measures of SWB, in which people are asked at random moments about their moods and level of satisfaction. The most desirable way to measure SWB is with a battery of assessment devices, including experience sampling, informant reports, and memory measures because these measurement methods complement each other in terms of protecting against specific measurement artifacts, and also because together they yield a multimodal assessment of various manifestations of well-being: experience (global self-reports and experience sampling), behavior (reports of informants and nonverbal behavior), and memory (the recall of good and bad events).

One of the challenges in studying SWB is to determine what causes it and what is caused by it. Because it is difficult to do experimental work with random assignment to conditions in this field, most work is correlational and cross-sectional. This leaves open the question of whether many variables are causes or consequences of SWB. For example, if people feel in control of their lives and report that their marriage is strong, are these causes of happiness, results of being happy, or caused by some third variable such as temperament? Diener (1984) referred to this issue as the question of 'top-down' vs. 'bottom-up' influences on SWB.

One method used to gain some insight into causal networks influencing SWB is longitudinal panel designs in which people are measured repeatedly over time. From such data we can conclude, for example, that marriage on average causes SWB rather than simply the alternative explanations that happy people marry more often, and stay married more. Similarly, there is longitudinal evidence suggesting that income leads to somewhat higher SWB rather than it being the case that happy people earn more money. In a few areas there are experimental or quasiexperimental studies. For instance, lottery winners seem to be somewhat happier than controls, suggesting that money may have a causal influence on SWB. In addition, negative income tax experiments (in which randomly selected welfare recipients are given greater monetary benefits) suggest that increased income can also heighten stress. Thus, there is beginning to be some examination of causality in this field, but most conclusions remain based on self-report measurement at a single point in time, and thus do not speak to issues of causality.

8. *Future Research*

Because SWB is a relatively new field, and scientists have only recently begun research in this area, there are many unanswered questions. One issue is, given the influence of temperament, the degree to which happiness can be learned. For instance, can people learn cognitive styles of perceiving and interpreting the world that will heighten their joy and contentment? A related question is: what is the optimal level of SWB? People cannot and should not be happy every moment; the unpleasant emotions serve useful functions. But what degree of pleasant vs unpleasant emotions is optimal for healthy functioning? Similarly, what level of life satisfaction will allow people to remain motivated and perform well, and yet view their lives in positive terms?

The possibility of attaining happiness through modern drugs brings the above question into focus. On the one hand, people could conceivably make themselves very happy on an ongoing basis with drugs that will be created in the foreseeable future, pharmacopeias without the side-effects of current drugs. Would this method of achieving happiness undercut motivation and interfere with our other values? For example, might people become too happy, and might they then ignore good social relationships and personal responsibilities?

The scientific study of SWB is in its infancy, and therefore researchable questions abound in virtually every area. We now have developed, however, the basic methodological tools to analyze empirically how people feel about their lives, and why.

West Africa: Sociocultural Aspects

This article offers an overview of social worlds, values, and material and nonmaterial cultures of the region south of the Sahara from Mauritania to Cameroon. Attention is paid, in particular, to modes of social solidarity and the cultural dynamics of community formation in West African settings.

1. *The People*

West Africa is mainly peopled by Black Africans. Some groups of Berber and Arab descent inhabit the Saharan extremes. A small Lebanese diaspora, distributed mainly along the coast, occupies a role in commerce not unlike the Indian traders of eastern and southern Africa. Malaria deterred European settlement.

2. *Linguistic Diversity*

A striking aspect of West Africa is its linguistic diversity (Dalby 1977). Nigeria, a country of c. 100–120 million people, covering only about a seventh of the region, is estimated to have between 250 and 400 languages. (The huge expanse of eastern and southern Africa, by contrast, is dominated by closely related Bantu languages.) Language diversity in West Africa mainly reflects *in situ* development of long-settled farming communities, rather than long-distance migration. European languages, especially English and French, became established as public languages during the colonial period.

3. *The Agrarian Base*

West Africa divides into three broad environmental and cultural zones—an agro-pastoral desert edge dotted by ancient towns involved in trans-Saharan trade, a coastal rain forest zone shaped by external (sea-borne) commerce (including the Atlantic Slave Trade), and an intermediate zone of drier forest margins and wetter savannas, with a history of endogenous agrarian development dating back several thousand years.

The intermediate zone is the heartland of West African civilization and culture. It is here that local crops, notably white yam (*Dioscorea rotundata*), African rice (*Oryza glaberrima*), and a range of millets ('hungry rice,' pearl millet, and one race of sorghum), were first domesticated. The intermediate zone also provided the oil palm (*Elaeis guineensis*)—the source of oil used in cooking, a mild alcoholic beverage (palm wine), raw material for soap and medication, and ribs, trunks and leaves from which bags, hammocks, roofs, building frames, and bridges are made.

In the eastern part of West Africa, along the forest–savanna transition and in the river valleys of the savanna, yam-oil palm farming systems prevail. Away from the riverine environments sorghum and pennisetum millet tend to replace yam as staples. The pattern repeats in the western half of West Africa, but with African rice taking the place of white yam (though today African rice is partly replaced by Asian rice, perhaps first introduced by the Portuguese in the era of the slave trade but spread widely only in the last century).

The early rise of a relatively intensive heartland agriculture went hand in hand with other socio-technical changes, as evidenced by ancient iron working and terracotta art work, suggesting permanent

settlement and complex division of labor in the intermediate zone at an early date.

The sacred importance and symbolic significance accorded intermediate-zone crops, even where they have been squeezed out of farming by commercially more productive introductions, is a notable aspect of West African material culture. Wild palms supply a rich red oil that remains an essential ingredient in many rituals, ceremonies, and remedies, greatly favored over the more common plantation substitute. The tasteless white rices of the coastal wetlands are considered no substitute for the nutritionally superior red rices of the interior. From Ghana to eastern Nigeria, yam survives as a preferred staple despite cheaper root crop substitutes. In the *Arrow of God*, Nigerian novelist Chinua Achebe appropriately made the disruption of a new yam festival in eastern Nigeria a striking metaphor for the far-reaching disruption of West African social and cultural values caused by colonial conquest (Achebe 1964).

4. *Lineage Society: 'Wealth in People'*

West African agriculture depends on the hoe. The soils of the wetter savannas and adjacent forests are not suited to plough cultivation. Due to fly-borne disease, pastoralism is well developed only along the desert margins. Elsewhere it is not easy to accumulate wealth in livestock. Successful hoe agriculture depends on abundance of human labor. A central social value in the West African heartland is 'wealth in people.' This has many manifestations. The importance of a chief, for example, is expressed in terms of wives, children, and domestic dependents, rather than through holdings of land and livestock.

But in hoe agriculture, timing and coordination of labor are as important as numbers of workers, especially in strongly seasonal savanna cultivation systems. Interhousehold labor cooperation, and the social values, crop types, and farming practices conducive to such cooperation figure strongly in West African agrarian social systems. In the old days the young people of an entire community might pool their labor for farm operations. Today it is more likely that they will form cooperative gangs to tackle back-breaking and time-constrained jobs on a rotational basis. Where agriculture is commercialized labor gangs ply for hire.

Labor cooperation is a practical manifestation of an egalitarianism among the young typical of West African heartland social organization. This egalitarianism is frequently fostered through initiation into so-called 'secret' societies, widespread and still powerful in parts of the region. Such societies typically tend to support social values among the young, strikingly in contrast with hierarchical values prevailing in the world of the elders. From Guinea to Cameroon the senior grades within secret societies form a ladder along which elders compete to advance.

French Marxist anthropologists in the 1960s and 1970s wrote about this typical opposition between youthful egalitarians and ranked elders, as 'lineage' society, or a 'lineage mode of production,' clearly differentiated from feudal relations found in medieval Europe and elsewhere (Seddon 1978). It was conceived that elderly elites, drawing on the language of kinship and descent for legitimation, reproduced themselves at the expense of the labor of cadets. According to some authors this amounted to a kind of class conflict. The explanation was controversial. An alternative explanation is that typical agrarian societies in the West African heartland are the complex outcome of a number of competing principles of social solidarity, none of which, by itself, can sustain a satisfactory community life over the longer term.

5. *Agrarian Social Solidarity*

As suggested, two principles of social solidarity often encountered in West African heartland social formations are egalitarianism and hierarchy. They offer quite distinct approaches to the problems of keeping social groups together (Douglas 1993). Neither, alone, can sustain a community except in the short term. Compromise is an essential prerequisite for survival.

In a land-abundant setting, hierarchs may be able to do little to prevent youthful egalitarians from forging their own breakaway communities. But breakaway youthful egalitarians quickly run into problems of leadership. Youth labor gangs often have their own 'government,' and spend large amounts of time in dispute settlement, to the detriment of the work in hand. Charismatic leadership sometimes helps the egalitarians to go-it-alone for a time, but as with sectarians everywhere, splits lie around the corner. The more settled authority of the elders offers clear advantages. The typical West African agrarian compromise seems to have allowed for the emergence of spheres of partial autonomy for women and youth within a more complex social totality presided over by elders (and ancestors). Achieving such coordination and compromise without recourse to strong centralized political institutions was often the work of the 'secret societies' (for both men and women) found particularly in the Upper Guinean section of the Atlantic Coast in the western half of West Africa, and more widely in the region. In communities welded by initiation and secrecy, a social contract renewed or reinforced typically manifests itself from time to time in dramaturgical terms (often as masquerade display). The arts of masking are among the greatest manifestations of West African material culture and societal values.

The test of any mode of social solidarity is the extent to which it permits humans to flourish. A central fact about many decentralized ('stateless') societies of the

West African heartland is that they often sustained denser populations than adjacent territories with a history of strong (and often strongly oppressive) central institutions (Middleton and Tait 1958).

6. *Society and Culture at the Margins: Coast and Desert Edge*

International trade rather than agriculture was a mainstay of life at the coast and on the desert edge. It is in these regions that we first see most clearly the emergence of a trade-related West African urbanism, with its own distinctive institutions and cultural values. Along the desert edge, long-distance trade was associated with the early spread of Islam, and with Islam came literacy, science, and an enhancement of bureaucratic capacity. A process of modernization and reform took shape among desert-edge trade-related towns and polities in the late eighteenth century, and by the mid-nineteenth century larger regional formations, such as the Sokoto Caliphate (Last 1969), covered a large part of what is today northern Nigeria. Two interior languages—Hausa and Maninka (Dioula)—developed some importance as media of regional communication, along with written Arabic for letter writing and record keeping.

At the coast, trade was stimulated by European contacts from the fifteenth century. Christianity gained several footholds, and small ports and polities oriented to the Atlantic trade developed, at times ruled by mercantile elites of Afro-European descent. Coastal trade pidgins, drawing first on Portuguese and later on English, developed into a distinctive family of mutually comprehensible English-oriented pidgins and creoles, today perhaps as widely spoken in coastal urban centers from The Gambia to Cameroon as Hausa or Dioula, the trade languages of the savanna, are spoken in interior West Africa. The English-oriented pidgins and creoles have considerable importance in coastal West Africa as means of communication among the nonelite, and in popular music and entertainment (Todd 1984).

Globalization is no new phenomenon in desert-edge or coastal West African communities. From an early date children of trading elites might be sent to Cairo or Liverpool for their schooling. Nelson's victory against Napoleon's fleet at the Battle of the Nile in 1803 was known in Kumasi within weeks; that the news made sense at all implies a sophisticated world map in the West African interior. The typewriter was in use among Christian converts in the interior of Yoruba-speaking country (now western Nigeria) within decades of its invention. The colonial telegraph, and now the modern satellite phone, are among means through which globally dispersed West African families have maintained and developed their wide networks of social contacts in the modern period.

Conversion to the 'world religions,' Islam and Christianity, tells us about growing global awareness even at early dates. Coastal linguistic creolization was part of a larger process of cultural creolization that helps explain the international outlook and mobility of many West Africans today (Hannerz 1987). Diaspora communities of West Africans, often involved in trade, are found in most world cities today, and not just in the capitals of the former colonial powers. It is not uncommon to find street children or unemployed youth in Dakar, Douala, Freetown, or Lagos with a better grasp of politics and world issues than well-educated teenagers in Britain, America, or France.

7. *The Impact of External Trade on Social Values*

Arguments and compromises over social values took different forms under the impact of long-distance trade from those already described for heartland agrarianism. We need to distinguish internal and legitimate trade from the slave trade. Vigorous internal trade, exchanging forest and savanna products (notably cattle, kola nuts, and salt) was a stimulus to social and cultural innovation in a number of communities located on major north–south internal trade routes.

Typical adaptations to long-distance trading (Cohen 1969) included the development of culturally distinct diasporas (Hausa cattle dealers in western Nigeria, or Fula kola dealers in Sierra Leone for example). At times agrarian elites maintained some control of diaspora trading groups through intermarriage. At other times diaspora communities have been confined to special settlements (Zongo, Sabon Gari) at the edge of villages or towns.

In other cases, women or youth have been free to exploit the potential of semi-autonomous social spheres to build up commercial activities. Igbo young men from eastern Nigeria have long adapted the gang-like structures of the labor company to itinerant trading (in for example second-hand clothing, cloth or motor spares). Agrarian labor cooperatives often double, or develop, as rotational savings and credit associations for the purposes of commerce.

Women traders are prominent throughout the West African costal and forest zone, but especially so in Ghana and southern Nigeria. Large-scale female traders, sometimes with little or no formal education, are to be encountered traveling the world, often in groups, perhaps as likely collecting car spares in Taiwan as exporting a consignment of red palm oil to London. West African women's involvement in commerce typically began with local and regional foodstuffs trade neglected by the colonial commercial houses. The extensive yam trade from the Middle Belt interior to burgeoning colonial coastal cities of Ghana and Nigeria would be an example. In patrilineal

communities women are life-long brokers between kin groups. Taken in conjunction with the gender solidarity fostered by initiation, this helps set up an extra household social space in which women's commerce has tended to flourish.

But we need to be careful not to impute modern ideas about individualism and enterprise to the development of West African trading relationships with the wider world. Frequently overseas or trans-desert trade was the monopoly of rulers who kept a tight rein on contacts and commercial information. Those controlling the trade-based polities of coast and desert-edge were more likely to be monopolists and autocrats than agents of an enterprise culture. In the nineteenth century the spread of firearms allowed trade-oriented rulers extensive use of socially unaccountable force. A not dissimilar militaristic adventurism has reasserted itself in some parts of West Africa (notably in Liberia and Sierra Leone) as the twentieth century ends, prompted by an international political vacuum and a surfeit of cheap weapons from the ending of the Cold War.

The mode of social solidarity that tends to predominate under war-lord autocracy is not individualism but fatalism, a fact illustrated in the 1997 elections in Liberia, where a war-weary population voted for the strongest of the faction leaders from a destructive seven-year civil war, reasoning the most powerful autocrat was the best guarantee of a kind of peace. Fatalism is little appreciated as a basis for social solidarity, but may be preferable to the mayhem of a bush civil war. Here we have an insight into why social life on the West African frontier so often seems to have been characterized by quietism, and a subsistence-oriented conservatism, rather than by the expansive individualism associated with the making of the American frontier (Kopytoff 1987). The attitude is 'we make no demands other than to be left to get on with our lives.' The old heartland agrarian social mix continues to have a certain basic appeal where the alternative is the postmodern violence of late twentieth century conflict in Liberia and Sierra Leone.

8. *Social Consequences of the Slave Trade and Colonial Rule*

Perhaps between 10 and 15 million West Africans were sold into Atlantic slavery from the sixteenth to nineteenth centuries, and 8–10 million into trans-Saharan slavery. In addition to the adverse demographic impact, in a region dependent on labor-intensive hoe agriculture, the conversion of human beings into commodities dealt an enormous blow to the trust essential to the functioning of many social institutions (Inikori 1982). It is hard to overestimate the continuing consequences of the slave trade for the evolution of social values in West Africa. Fatalism, fear of entrepreneurial individualism, distrust of chiefs, and undue respect for autocrats in return for basic security are among the symptoms of the damage. Distrusts inherited from the era of the slave trade remain a factor in the nihilism of much of the current youth-led violence blighting the region. How ordinary West Africans continue to come to terms with the harsh social legacy of the slave trade is also very apparent in popular religion, in ideas about chiefs as shape-shifting witches, or through divination and possession as ways of addressing old betrayals and coming to terms with disastrous breakdowns in family or community solidarity (Shaw 1997).

Colonial protection in West Africa arose from initiatives to eliminate the slave trade, beginning with the assumption in 1807, by the British Crown, of administrative responsibility for Sierra Leone, an eighteenth century West Coast settlement for freed slaves founded by British Christian philanthropists. Ending the slave trade became the pretext for a series of moves by industrializing European powers to control resource extraction and guarantee markets for their own manufacturers. By the end of the nineteenth century West Africa had been carved up by the Germans, French, and British (Crowder 1968).

Colonial rule at the beginning of the twentieth century was militaristic, often formally racist, and based on a protectionist principle of imperial preference. Although colonial regimes built railways and some roads, and Christian missions under colonial protection introduced school education and Western medicine, colonial autocracy did nothing to repair the adverse social legacy of the slave trade.

9. *Postcolonial Social Trends*

Postcolonial leaders in the region have continued the path of colonial autocracy, paying more attention to external opportunities than local accountability. Aid donors and Western governments hope to see a flowering of individualism and rational choice to support a flourishing modern market society, but without taking full account of the extent to which the slave trade and colonialism prevented the development in West Africa of the informal checks and balances between state, market, and civil society upon which modern market society depends. West African people still retain the option of retreating towards heartland survivalism. But even this option is no longer as open to all comers as once it was.

The population is ever more youthful; more than 50 percent of all West Africans are under the age of 18. The colonial migratory labor options that once took teeming Sahelian youth to the coastal plantations and cities have begun to fail in modern times (Cooper 1996). Under recession conditions, migrants no longer gain enough wealth to return to intermediate zone homes to assume the status of rural elders. Not all have villages to which to return. Some are the landless

descendants of former domestic slaves. Others have begun to succumb to HIV/AIDS. Many are now permanently hustling the city streets, locked into a vicious circle of poverty, petty crime, and drugs. Despairing of the future, some of these younger elements have been willing recruits (from the streets of Monrovia, Abidjan, and other coastal cities) to militia groups fighting the 1990s wars for diamonds and timber in rural Liberia and Sierra Leone. Embittered by their lack of social recognition they hit out at everything in their path, including those who seek refuge in the old agrarian compromise. This is the new 'masterless class,' in awe only of its own charismatic and demagogic leaders. Human rights mean little, and atrocity multiplies.

There is a widening recognition that West African youth is in crisis, but as yet less recognition that the crisis is not only one of crime, drugs, and weapons but also one of basic social values (Richards 1996). Youthful egalitarianism has slipped free of the restraints of a wider and more complex set of social compromises. Enclaved within bush war zones by the ferocity of their own violence, and by civilian fear and hatred, but still able to accumulate forest and mineral resources readily saleable overseas, the masterless egalitarians have a capacity for prolonged survival. The fission that normally ends egalitarian adventures may not come into play if armed enclave groups, lacking other exit options, find themselves locked in place by the unremitting hostility of the wider society. Perhaps the violence can be tamed only by a search for new compromises between the distinct, and currently disengaged, modes of social solidarity of youth and elders, men and women.

But some would say that youthful egalitarianism is not the only challenge to established social compromise in contemporary West Africa. The disengaged individualism of newly enriched and internationally footloose commercial elites also poses urgent problems. Yet despite current difficulties, the vibrancy and inventiveness of West African society and culture continues to impress. Social renewal in West Africa must reach beyond old solutions, and turn away from ineffectual inducements to value change—the casually proffered carrot-and-stick of the international community. Perhaps some of the urgently required thinking about complex social values, and new forms of social solidarity, will emerge from debate, fostered by some West African and African-American scholars and activists, about moral accountability for the evils of the slave trade.

Western European Studies: Culture

The ontological and epistemological status of culture has received much attention in recent social science literature (Sewell 1999). This article assumes a parsimonious position on these debates. Culture as a concept has a cognitive and material dimension. As a form of cognition, culture is the realm of shared meanings that permits mutually informed social interaction within bounded spaces. This anthropological view of culture points to culture as a medium of social life and measure it in the 'thick description' of shared social practices (Geertz 1973). Culture as material object refers to expressive forms such as art, music, literature, architecture—more recently, state institutions and legal codes. Material culture is analytically distinct from but not unrelated to the anthropological concept of culture. This entry traces the development of both senses of culture in post-war European Studies. While individual nation states have diverse intellectual traditions that articulate themselves differently in cultural studies, this entry will focus on commonalties rather than differences.

1. Culture in the Shadows: West European Studies to the 1980s

Until the mid-1980s, culture as either an analytic frame or causal variable was conspicuously absent from the social science research on Europe. Apart from Elias' studies of court society and the civilizing process that linked modern notions of manners to the

formation of the nation state (Elias 1994) and Kantorowicz's study of the king's 'two bodies' (1957) (both of whom were 'rediscovered' in the 1980s), culture, for the most part, remained in the shadows of social science analysis. The work of British cultural historian Raymond Williams (1958) that followed in a tradition of 1930s European Marxist cultural analysis was a rare exception to the general trend. Williams' cultural and historical sociology was the precursor to what became known as British Cultural Studies in the 1970s (for example, Hoggart 1961).

Two dimensions of culture's transparency accounted for its absence in European Studies. First, intellectuals did not question Eurocentrism—the idea that Europe was the seat of civility and apex of modern civilization. Weber's 'Introduction' to *The Protestant Ethic and the Spirit of Capitalism* (1958) suggests the embeddedness of Eurocentrism. The hegemonic position of the European cultural heritage in the West rendered it moot as an analytic category among sociologists and political scientists. European culture with a capital 'C' was elite culture and left to the purview of art historians and literary critics.

Second, culture was absent, but traditions were not. There was an implicit assumption in social science that traditions, however under specified, played a role in European political life. The collective *mentalité* of European society—and social science—viewed culture and tradition as intrinsic to each other. Analysts rarely parsed this linkage and produced anthropological accounts that demonstrated that peasants and modern political practices were antithetical to each other. Banfield's (1967) study of a southern Italian village that ascribed its political backwardness to deeply rooted traditions is a classic in this genre. Customs and superstitions that had plagued them for hundreds of years trapped Banfield's Italian peasants in a premodern and unchanging landscape of political practices. Wylie's *Village in the Vaucluse*, (1974) a kinder study in a similar vein portrayed French peasants whiling away their time at boules and drinking at local cafés while high politics was conducted in a distant Parisian capital.

The assumptions that undergrid Eurocentrism and traditionalism rendered culture so transparent as to make it invisible. Moreover, these assumptions were fundamentally conservative. In the late 1970s and early 1980s, social history engaged the attention of first historians and later sociologists—usually influenced by Marxism (see the introductory summary in Bonnell and Hunt 1999). At first, the politically engaged scholars who emerged in the 1970s viewed culture as suspect—a position that changed as the decade progressed. In the new historical anthropology of Europe, peasants were subversive (Ginzberg 1980); religious events were riotous (Davis 1975); oppressed apprentices murdered cats to get control of their work situation (Darnton 1985); and communist comrades could also be Christian (Kertzer 1980).

The combination of cultural conservativism and Socialist politics were not the only entities that contributed to the lack of attention to culture as an analytic frame. Social scientists working in the positivist mode favored in the 1950s and 1960s considered culture as too imprecise a concept to operationalize. As a variable, culture appeared to lack explanatory power. Where culture was taken into account we have the classic studies of Almond and Verba (1989), who measured political culture in sharply defined variables all pointing to the fact that the more Protestant a group was, the more democratic they were likely to be (for summaries, see Berezin 1994, 1997b).

2. *Analysis Follows History: The 'Cultural Turn' in European Studies*

No matter what ideological position one espouses or analytic method one favors, content always defines culture, whereas trajectory defines history. By 1990, social history became the 'new cultural history' (Hunt 1989). Europe was in many instances the site of the emerging 'cultural turn' (Bonnell and Hunt 1999). Specific historical changes in the last quarter of the twentieth century contributed to the new salience of culture in analyses of European society.

Political scientists and historians frequently refer to the period between roughly 1950 and 1970 as the period of the 'post-war settlement.' That period was characterized on the political front by the consensus supported by the US of the containment of communism and on the economic front by the corporatist bargain that kept labor and business in accord. The European welfare state contained class conflict while valorizing class politics. European parties represented genuine ideological differences. A spirit of prosperity prevailed.

This bargained equilibrium with its cultural and ideological concomitants began to break down in the 1970s. The student revolts of the late 1960s and the period of terrorism, 'iron years' as the Italians labeled them, pointed to an emerging 'end of ideology' politics (Lumley 1990). By the 1980s, social science followed history. New Social Movements (NSMs) emerged that prioritized values over interests (i.e., peace, environment) and identity politics (i.e., gender, ethnicity) superceded class politics as traditional European parties began to fractionate (Cohen 1985).

The fall of the Berlin Wall and the collapse of communism in 1989 coupled with the commitment to European union signaled the end of the 'old' Europe. In academia, Eurocentrism gave way to multiculturalism (Joppke and Lukes 1999), nationalism to postnationalism. Postmodernity replaced modernity and the Enlightenment, the cornerstone of Eurocentricism, came into question (Wagner 1994). Inglehardt (1977) following in the research style of Almond and

Verba, documented 'postmaterialist' values. Social scientists turned to culture in an attempt to make sense of a society and politics that traditional modes of analysis could neither explain nor comprehend.

Transformation was not merely cultural and conceptual. Political and economic shifts fueled the retreat to identity and post-materialism. The 1970s and economic recession in Europe was the death knell of class collaboration. In the wake of European recessions, socialist technocratic parties emerged as well as out and out conservative parties such as Margaret Thatcher's neoliberalism. Traditional left and right parties began to lose their constituencies. Kertzer's (1996) analysis of the re-reorganization of the Italian Communist Party underscores the schizophrenia of changing European values. Formerly the strongest Communist Party in Western Europe, the party needed an infusion of new ideas in the early 1990s. But it could not decide upon its new name or the design of its flag. The Italian Communist Party finally agreed to change its name to the Democratic Party of the Left. Its flag incorporated 'postmaterialist' values by superimposing an environmentally correct tree over its traditional hammer and sickle—thus wedding green to red, new to old.

3. *Analytic Transformation*

Social and political change brought culture out of the shadows and into the full light of social scientific analysis. Identifiable analytic shifts occurred between 1980 and 2000. Among the multiple possibilities for categorizing these trends, this entry identifies four as salient: first, the move from class to identity; second, the move from connoisseurship to material culture; third, the new focus on culture and institutions; and lastly, an emerging interest in democracy, civil society and political culture. These shifts, presented here as discrete categories of analysis, in practice often shade into each other.

3.1 *Class to Identity*

Class was the initial venue that wed culture to political mobilization and social closure. Influenced by the early, more culturalist and consciousness-based writing of Karl Marx, scholars tried to understand why and how working class culture became a vehicle of class based political action. The seminal study in this vein was E. P. Thompson's *The Making of the English Working Class* (1963). Influenced by this work, other social historians began to focus on class cultures. Stedman-Jones (1983) focused on British languages of class; Sewell (1980) examined how a corporate idiom shaped the political culture of French artisans; and Calhoun (1982) argued that established traditions forged solidaristic social ties within local communities that generated class cohesion among eighteenth-century British workers. Hebdige (1979) showed how British youth culture was a form of class identity and social rebellion.

Bourdieu (1984) redirected the focus of class studies from Karl Marx to Max Weber by incorporating the idea of status. His insight that capital could be cultural and social as well as purely economic launched a genre of studies on social boundary making. Bourdieu (1977) argued that habitus shaped the perceptions of a group to include and exclude based on cultural and social cues. Lamont (1992) built on this work by studying middle class, and later working class, men in the United States and in France to test empirically how boundaries and the conception of 'one of us' were formed.

Sexuality, gender, race and nationality have become the basis of identity studies on Europe. Foucault's (1990) three-volume work on the history of sexuality that questioned the entire concept paved the way for studies of the body (Laqueur 1990). Hunt's (1992) monograph on the 'family romance' of the French Revolution linked Freudian analysis of sexuality to issues of gender and politics. Borneman's (1992) study of kinship in the former East and West Berlin linked issues of gender and national identity. Soysal's (1994) discussion of post-nationalism argued that citizenship, a category of nationality, is a malleable identity category that transcends the materiality of space.

With the exception of British media studies, the European ideology of connoisseurship relegated studies of art, music, film, architecture, and literature to the relevant humanities disciplines. Since the mid-1980s, social scientists have reinvented art as material culture and produced a broad range of studies. For example, Griswold (1986) studied Renaissance revivals on the British stage. Biernacki (1995) studied the cultural significance of divergent factory regimes among woolen workers in Britain and Germany. Politics and cultural production is an emerging area of interest. Mukerji (1997) wrote on the relation between formal gardens and French state building.

Consumption as an economic process that intersects with cultural production has informed a whole genre of studies of Americanization and globalization in European studies. DeGrazia (1989) studied how American film culture defined and penetrated European films in the 1920s and 1930s. French gastronomy (Ferguson 1998) and furniture design (Auslander 1996) were intimately connected to issues of class autonomy and national identity and citizenship. Consumption is now global and studies document the invasion of foreign capital and cultural products on European soil. McDonalds and the culture of fast food are a frequent target. A recent special edition of *Le Monde Diplomatique* entitled 'L'Amerique dans les Tetes' ('America in the Head') provides an example of the concern with the Americanization/globalization of European culture.

3.2 Institutional Studies of Culture

Institutional studies of culture that focus upon how the state mobilizes cultural and political institutions, such as schools, the military, language consolidation, nationality codes, as well as symbolic entities such as art, music, and architecture to create identities has arguably the longest trajectory in European cultural studies. Weber's (1976) *Peasants Into Frenchman* is an early work in this genre that provides a history of how the French state mobilized local cultural institutions to create a state centered French national culture. Mosse (1991) looked at the phenomenon of what he termed the 'nationalization of the masses' to document how territories that had become nation states became bounded cultural political spaces in the early twentieth century. In 1983, Hobsbawm's and Ranger's influential anthology *Inventing Traditions* emphasized the fact that all national cultures were the products of carefully designed state rituals and symbolic practices—beginning with the British monarchy.

The intersection of state institutions and cultural practices dominated European political cultural studies from the mid-1980s to the present (Steinmetz 1999). In the wake of Ozouf's (1988) influential book on rituals and the French Revolution, Hunt (1984) explored the link between the 'poetics of power' and the 'sociology of politics' to describe the 'unexpected invention of [French] revolutionary politics' (p. 3). Scholars followed Hunt's lead—turning to, for example, Nazi Germany (Fritzsche 1998) and fascist Italy (Berezin 1997a). Scholars who focus on membership issues in nation states demonstrated how states institutionalized political culture in diverse approaches to citizenship law (Brubaker 1992). In a series of articles, Laitin (1989) and Laitin and Sole (1994) argued that language consolidation in European nation states was analogous to a tipping game where it was rational to learn a national language if one wished to participate in consolidated national language markets.

3.3 Democracy, Civil Society and Political Culture

The studies of democracy and culture, a relatively new preoccupation, divide into two groups: first, scholars influenced by Jurgen Habermas' theories of the public sphere and those influenced by the theory of social capital. Habermas' *The Structural Transformation of the Public Sphere* (1989) posited that the origins of democratic civil society lay in the exchange of information and ideas in public space from eighteenth-century coffee houses to modern newspapers. Multiple groups of citizens could meet and discuss and arrive at democratic consensus.

This new version of political culture was heavily dependent on the valorization of public discourse and was particularly appealing to social scientists contemplating the reconstruction of civil society in the former Eastern Europe. In an influential article that rethought T. H. Marshall's (1964) conception of citizenship, Somers (1993) argues that citizenship rights rather than attributes of individuals are deeply embedded in a set of institutional practices that are highly dependent upon the permeability of local public spheres. In contrast to much of the theoretical literature that Habermas' notion of the public sphere has generated, Zaret (2000) provides the first extended empirical study that examines the modes of communication available to a public in early modern England.

Putnam's *Making Democracy Work* (1992) building on Alexis de Tocqueville's theory of democratic association introduced social capital to studies of political culture. Putnam studied the success of the Italian regional governments in Italy over a 20-year period. He attributed the more efficient governments found in the north, in contrast to the south, to a political culture of association that produced a high level of trust and cooperation among participants in governments. He terms this talent for government 'social capital'—meaning that a citizenry that participated in multiple networks of associations developed an elevated capacity for acting democratically. To date, Putnam's work has generated volumes of research on American democracy, but little empirical work on Europe itself. This will likely change as the results of trans-European collaborative studies on social capital become available.

4. New Turns

The analytic trends that I have outlined are in progress and will continue to occupy researchers for years to come. They raise questions for which the answers are decidedly not in yet. But what is new on the horizon? In addition to the areas I have outlined, four additional themes are just beginning to occupy scholars. First, European identity will begin to supersede national identities as a focus of research. In part, this will emerge as a response to the European Commission's push to create not only a European market but also a European space (Kastoryano 1998). Some of these attempts, as the search for a common European history that does not focus on war, will be strained. But the temporal effects of transborder life will no doubt contribute to the formation of a European consciousness. The second area of interest will no doubt be the new technologies of communication, particularly the internet. At the time of writing, all political parties in Europe have websites. The ramifications and efficacy of a virtual public sphere is a whole terrain that has not been explored and will no doubt take off as the internet had done. A third emerging area is the field of Europe/America comparisons. This is relatively novel, as in the past America was viewed as 'exceptional.' As Europe becomes more consumer oriented, and as it continues to deal with the in-

corporation of immigrant groups, America becomes a more likely comparative venue than it has been in the past.

The last area is the paradoxically growing importance of 'memory' studies (Nora 1996–8). The European absorption with its past, particularly the period of Nazism, genocide, fascism and collaboration, has taken on a surprising urgency as the continent struggles to shape a vision *of* and program *for* its future. The tendency began in 1985 in Germany with the public controversy known as the historians' conflict (*Historikerstreit*) (Baldwin 1990). The concern with memory has continued as scholars attempt to come to terms with Vichy France (Rousso 1991) and Nazi Germany (Maier 1988). An offshoot of the obsession with the past has been the emergence of a field of 'compensation' studies that examines whether nation states can come to terms with the horrors of state sponsored genocide in monetary terms.

In short, to write about Europe in the year 2001, is to write about a continent in the midst of vast political, social, and technological transformation. Underneath this truism, lies the observation that cultural studies thrive in times of upheaval and uncertainty. The last 20 years of European studies suggest that political and social problems that standard notions of modernity and rationality cannot explain forces culture to the forefront of everyone's research agenda. There are no signs that this trend is likely to reverse itself at any time in the near future.

Western European Studies: Environment

The study of social and political aspects of the natural environment in Western Europe has been a major growth area since the early 1970s. All social science, disciplines, in particular history, geography, economics, psychology, sociology, and political science, have seen the development of major environmental research fields, although the relative importance of each discipline has varied between countries and over time. Cross-national variances are generally the result of specific disciplinary traditions; variations over time are mainly the outcome of changes in the importance of particular environmental discourses.

There are important differences in the conception of 'the environment' between different social science disciplines. While the interaction between human society and the natural environment is the most common element, many approaches, in particular within geography and environmental psychology, also include the entire physical (e.g., the built environment) and social environment.

The terms used to delineate this field of activity have also reflected major social and political changes. The label 'environmental' to define an area of policy or politics first came into use in the 1960s in the USA and subsequently also became popular in Western Europe. Radical critiques of environmentalism led to increased references to 'ecology,' 'ecological,' and less frequently, 'ecologism.' Since the success of the German Green Party on an anti-nuclear, ecological platform in the early 1980s, the term 'green' has come to be used in a wide variety of settings, in the 1990s referring to virtually any activity that had previously been labeled 'environmental.'

The great variety and scope of social science work in this field escapes easy compartmentalization and makes it difficult to do justice to all approaches involved. There are four broad areas of research that are crucial to the agenda of environmental sociology and political science, but that can also be used to discuss the contribution of other disciplines: environmental philosophy and political theory, environmental attitudes and behavior, social movements and green parties, and environmental policy.

1. *Environmental Philosophy and Political Theory*

Political theorists took a relatively long time to take up the challenge of modern environmental politics. Up to the late 1970s, 'ecological thought' had barely been recognized as a subdiscipline of political thought and philosophy. Ecological 'thinkers' mainly came from outside academia, or at least from outside the realm of political theory and philosophy. However, this period of relative neglect was followed by a major expansion in the 1990s when ecological political thought became a major area of academic activity in Western Europe, particularly in the UK and The Netherlands. The aim was to establish a theoretical basis for ecologism as a separate political theory with a distinct identity rather than as an extension of established traditions such as liberalism, anarchism, or socialism. One of the major inspirations was the work on deep ecology and ecocentrism that had emanated from North America and Australia. Among its important European antecedents were the writings of the Norwegian philosopher Arne Naess (Dobson 2000).

The main challengers of ecocentric political theory in Western Europe are various approaches broadly associated with a libertarian vision of socialism; anarchism, and more recently, liberalism also play a role. Following on from the politics of the student movement, a revival of interest in Marxist thinking in the 1970s also extended to ecological questions. The ideas of the Frankfurt School, anarchist approaches as well as more traditional Marxist views dominated continental theoretical debates in the 1970s and 1980s. Continental theoretical discourses gave more prominence to sociological theories rather than environmental ethics. The work of Ulrich Beck and his theory of the *Risk Society* (Beck 1986) was particularly influential. However, the resonance of Niklas Luhmann's (1986) equally sweeping, if rather more pessimistic, attempt to employ systems theory to devise a theory of ecological communication was mainly limited to the German-speaking academic world.

Apart from the formulation of a green theory informing current political practice, the history of ecological thought is a major research area. West European historians, philosophers, economists, and sociologists have devoted considerable attention to the study of environmental aspects of the work of philosophers, scientists, economists, social theorists, and other writers preceding the arrival of 'modern' ecological thinking (Pepper 1984, Wall 1994). In particular, from the perspective of the 'sociology of science,' the history of ecology as a scientific discipline has been of great interest, involving also the role of scientific 'ecologists' in the definition of research and political agendas. The link between 'ecology' and other political ideologies has been another major focus of debate. Among the most contentious topics is the analysis of the history and current development of ecological thought in the context of authoritarian political traditions, including the ideology of the German Nazis (Bramwell 1989, Ferry 1992).

However, rather underdeveloped is the political sociology of environmental ideology and knowledge, analyzing, for example, why particular theories or knowledge claims have greater resonance than others in certain countries and specific historical periods. Among the few studies addressing these issues is Jamison et al.'s (1990) analysis of the changing 'knowledge interests' of environmental groups.

2. *Environmental Attitudes and Behavior*

Environmental attitude research started as a serious academic activity in the 1970s. The first wave of studies was mainly policy oriented, intended to measure the degree of environmental concern and support for environmental policies that had started to be formulated and implemented in most European countries in the late 1960s and early 1970s. Sociologists were at first mainly interested in the socio-demographic background and political orientation of 'environmentalists.' Most of the political analysis of environmental concern in the late 1970s and 1980s was inspired by Ronald Inglehart's theory of 'postmaterialist value change.' This analysis interpreted the rise of environmental concern as part of a far broader 'silent revolution' that was producing a new political agenda dominated by 'left-libertarian' issues (Lowe and Rüdig 1986).

The 1980s and early 1990s saw a major expansion of environmental attitude research. With the rise of global environmental issues and green consumerism, research priorities focused on the multidimensional nature of public attitudes, the role of 'environmental knowledge,' the conditions for behavioral change to save the environment, and the acceptance of specific environmental policies. In particular, the perceived gap between expressed environmental concern and the reluctance of the public to engage more deeply in environmental behavior or to accept stronger environmental policy measures, such as higher energy prices, became a key topic. In theoretical terms, the role of post-materialism as a guiding concern waned, and other approaches, in particular rational choice theory, became more important. More attention also began to be paid to public discourses and personal narratives of environmental questions, with focus groups and qualitative studies becoming a more popular research tool (Diekmann and Jaeger 1996, Macnaghten and Urry 1998).

Research about environmental attitudes and behavior has also played a major role in other social science disciplines. Within environmental psychology, a wholly separate research tradition on environmental attitudes was established, grounded in a more holistic approach to human interaction with the socio-physical environment, with particularly interesting contributions to the analysis of the perception of different environmental problems and the barriers of environmental consumer behavior (Pol 1993).

A key research focus for sociologists, psychologists, and other social science disciplines has been the concept of risk. 'Risk perception' and 'public attitudes to technology' became major research topics in the wake of environmental protest against nuclear power and other 'big' technologies, particularly in Germany. Following on from the analysis of public perception of risk was the development of 'risk communication' strategies, aimed at increasing public acceptance of specific technologies (Renn and Zwick 1997).

Also in the economic sciences, the analysis of environmental attitudes and behavior has played an important role, in particular in cost–benefit analysis based on the allocation of monetary values to environmental goods. This is done with surveys asking hypothetical questions about the public's willingness to pay for particular goods, as well as the analysis of existing behavior to elicit 'revealed preferences' about

trade-offs between environmental and other goods. Such contingent valuation methods became particularly influential in UK policy discourses in the 1990s, but they also attracted strong criticism on ethical and methodological grounds (Foster 1997).

Social science research on environmental attitudes and behavior has attracted other controversies. Research on risk perception and risk communication has been attacked for its instrumentalization to manipulate public opinion to increase the public acceptance of particular technologies. The rise of relativist, 'social constructionist' approaches in the environmental social sciences has offered contradictory opportunities to use research results to influence political debate. For example, a 'cultural theory' of environmentalism which sees environmental concern as a response to cultural change rather than to 'real' environmental problems could be seen as undermining the legitimacy of environmental groups. Other approaches, particularly from the sociology of science, have targeted the claims of science in legitimating public policy, seeking to establish the credibility of lay persons facing environmental threats to make relevant knowledge claims (Lash et al. 1996, Redclift and Benton 1994).

3. *Social Movements and Green Parties*

Environmental concern and green consumer behavior do not directly engage the individual in the political process. This is different where people support particular pressure groups and parties, or join in protest activity, to campaign for specific environmental policies or for a general green worldview. The analysis of environmental politics thus includes environmental political behavior at the individual level, but it also focuses on the behavior of groups and parties.

The politicization of the environment in Western Europe was chiefly the role of a new generation of protest movements that started to emerge in force in the 1970s. This new phenomenon attracted the academic attention of a fairly wide range of social scientists. At first, descriptive case studies of specific incidents of protest or environmental conflict were the main approach. But by the late 1970s and early 1980s, the notion of 'new social movements' had emerged as the dominant paradigm. The 1980s and 1990s saw a very substantial development of this field. The cross-national comparison of environmental social movements became a major focus; the reception of key elements of US social movement theory, in particular the 'Resource Mobilization' approach, led to more sophisticated research designs and theoretically informed empirical studies.

Methodologically, the study of protest events became a very influential approach, particularly for cross-national comparisons. Another key feature of empirical research was the study of individual movement participants and group members, their social backgrounds and motivations. Studies of environmental groups as organizations, based on national and cross-national surveys of such groups, focused *inter alia* on network formation and interrelationships with other political actors (Dalton and Kuechler 1990, Della Porta and Diani 1999, Rootes 1999, Rucht 1991).

One of the most significant aspects of the politicization of the environment is the rise of ecological and green parties. After party formation in the 1970s and 1980s, such parties entered parliament in most West European countries during the 1980s and 1990s (the main exceptions being Norway, Denmark, and Spain); by the late 1990s, green parties had entered national government in Italy, Finland, France, Germany, and Belgium.

Green parties have attracted substantial research efforts, both in the form of major national case studies and cross-national comparisons. Much of the cross-national analysis has focused on the influence of aggregate factors such as electoral systems and economic conditions on the green parties' development. There is also a wealth of empirical national and cross-national studies on green ideology, the internal structure of green parties, their members and activists, and green voting (Delwit and De Waele 1999, Kitschelt 1989, Richardson and Rootes 1995).

4. *Environmental Policy*

The social sciences continue to play a fairly marginal role in the general academic literature on environmental policy, with approaches from the natural sciences and technical disciplines dominating the field. Within the social sciences, most of the publications addressing questions of environmental policy come from geography, economics, and the legal professions, while sociology and political science play a more minor role.

In Western Europe, environmental policy started to become an important research topic in the early 1970s. The policy optimism of the early years was often disappointed, and one important research theme was the question of the implementation deficit that prevented policies being as successful as intended. Also popular were cross-national comparisons between 'leaders' and 'laggards' in environmental policy innovation, often involving the USA and one or more European countries, or, somewhat later, the UK and Germany.

The 1970s and 1980s also saw increasing environmental policy activism within the European Union (EU), and the study of policy development and implementation of EU policy became a major growth area. With the rise of global environmental issues and the creation of international environmental regimes in the 1980s and 1990s, the international level became an important focus of policy research, with international

relations approaches playing a more influential role in the literature.

The 1980s and 1990s brought a major shift in the debate about policy instruments, away from traditional 'command-and-control' regulation to new economic instruments. Policy discourses became increasingly dominated by economic ideas. With the 1992 Earth Summit, the idea of 'sustainable development' was placed firmly on the policy agenda, and many European countries played a lead role in furthering this debate at local, national, and EU levels (Rüdig 1999).

Environmental policy research in Western Europe is well established but there remain many key challenges to be addressed. One of the them is the lack of interdisciplinary work, with public policy specialists, international relations experts, sociologists of science, and many other social science disciplines researching in parallel without taking much notice of each other. Some of the shortcomings of research are related directly to this failure to break down disciplinary boundaries. One such area that has received comparatively little attention is issue-making and agenda-building processes. The application of discourse analysis to public policy research is likely to play an important role in future research (Fischer and Hajer 1999), as are studies of social movements. The role of science and the media could make an important contribution toward improving the understanding of the formation of environmental policy agendas.

With the increasing role of European and international environmental policy processes, the interlinkages between the international, EU, and national policy processes is a major research challenge. In the past, the study of international relations, EU politics, and national public policies has been addressed by separate academic communities; in the environmental field, major attempts have been made to combine international and national processes—for example, in research on the effectiveness of international environmental regimes. In Western Europe, in particular, environmental policy is a 'multilevel' process, and the study of the interlinkages between EU and national as well as subnational policy processes has become a major research area (Weale et al. 2000).

Finally, the question of the impact of environmental policy has to be addressed. In Western Europe, there is a large body of empirical material on differences in policy approaches in different European countries (Hanf and Jansen 1998, Jänicke and Weidner 1997). Comparative environmental policy impact studies in Western Europe suggest that economically successful nations also had successful environmental policies. The only institutional element associated with environmental policy success is a general feature of economic policy making—neo-corporatism. There is, however, no firm evidence so far on the relative effectiveness of particular environmental institutions and policy instruments (Rüdig 1999).

5. *Conclusions*

Social science research on environmental issues is thus well established in Western Europe. In terms of the wider political discourse, environmental economics and other 'policy' oriented approaches have had the most impact. Within a purely academic ambit, green political theory has been the most outstanding success story. Environmental sociology and political science have established very strong research traditions, but have tended to struggle to be recognized as 'relevant' knowledge producers by environmental activists and policy makers alike. In an area defined increasingly by highly technical, 'scientific' policy discourses, the social sciences face a stark choice between either leaving the field to other disciplines, or successfully challenging the legitimacy of rival knowledge producers, thus establishing the reflection about the social and political premises of environmental thought and action as a key element in the protection of environmental public interests.

Western European Studies: Gender and History

Gender and history have combined in the last three decades to produce new understandings of how events, social structures, and fundamental elements of culture operate in Western Europe. Historical analysis has come to recognize gender as relational systems of power in which both men and women operate and to which both contribute as agents and members of larger cultural constructs. The principle developments in gender and history emerged as social history concerns focused on women gave way to post-structuralist and postmodern critiques of historical practice. The linguistic or cultural turn has shaped the premises and practices of gender and history so as to reveal how gender saturates categories of culture once presumptively believed to be scientifically neutral.

Rooted initially in the women's movements in America and Western Europe as they emerged out of the new social movements of the 1960s, gender history began as women's history. Most early explorations of women's historical experience operated within a social history paradigm, seeking out neglected materials to recuperate lives long deemed irrelevant to traditional modes of historical research. While some advocated pursuing women's history in isolation as a political choice highlighting the patriarchal qualities of apparently objective history, others argued for recuperating the causes and frameworks of female erasure in the context of larger historical narratives (see Bock 1989 for a consideration of both positions). The notion that women were best analyzed in the wider cultural context came to predominate, in part because of epistemological concerns within history as a discipline.

1. *Fundaments of Gendered Discourse*

As social relations are carried out in language and culture, gender and history have been informed by post-structuralist understandings of language and postmodern analyses of culture. While these overlap significantly, particularly in seeing culture as symbolic and expressed in language, the emphases are distinct. Theorists and historians who have studied language argue that attention must be paid to the historical specificity of linguistic constructions and to the general gender inflections language encodes. The questioning of a tacit acceptance that language is 'neutral' revealed how all communication is endowed with the power of social custom and historical practice. The 'cultural turn' similarly challenges the neutrality of older explanatory models, positing that all inquiry must admit that culture constructs meaning. Culture is the primary object of inquiry in this formulation, rather than language.

1.1 *Taking the 'Cultural Turn'*

The 'new cultural history' emerged from dissatisfaction with the limitations of social history and engagement with post-structuralist critiques. Historical analysis revealed huge variations in social categories over time and place. Instead of a coherent understanding of the social in the past, the picture just became more and more complex. Post-structuralists like Jacques Derrida and Michel Foucault challenged the tenets of scientific truth and objective reality posited by structuralism. Historians accordingly turned to culture as an explanatory device. While 'culture' is a slippery term, new cultural history in-

cluded concerns about the methodologies of historical practice, an epistemological skepticism with respect to narrative truth claims, and an interest in culture as a symbolic or semiotic system (Bonnell and Hunt 1999). The cultural turn opened up new ways to examine problems and issues related to gender as an artifact of culture and a determinant of symbolic configurations.

1.2 Gender, Language, and Historical Analysis

Post-structuralist analysis contributed to an awareness of language as constructed by context, while post-structuralist feminism articulated how gender difference is formulated in language rather than in the referent, and materiality is produced by linguistic formations. Seemingly 'natural' things (like bodies) are actually complex constructions. Gender is created by interactions of individuals, institutions, and social norms. The repetitive quality of perceived sexual difference is produced by discreet, contingent experiences. These experiences are inscribed in language and shape notions of sexual difference. For instance, the term 'biology,' in describing sexual difference, is taken to be neutral, scientific fact. But 'biology' has a history which belies its apparent neutrality. It was an early nineteenth-century term to describe sexual differences in early 'nature vs. nurture' debates concerning human development. 'Biology' in some circles was utilized to normalize gender bias: women's differences were in need of explanation. The persistent association of men with culture and women with biology points to the power embedded in language (Bock 1989).

Analysis of the discursive constructs of gender in historical terms has been formulated in the context of postmodern theories of language and subject formation. Luce Irigaray (1985) has attempted to rewrite sexual difference without the binary of masculine–feminine, arguing for a 'labial politics' which privileges female embodiment as a way of revaluing the binary and hierarchical notions of gender. Moi (1985) has expressed concern that Irigaray's position is essentialist and ahistorical, but Irigaray's poetic rendering of the problem has inspired interrogations of the relational positioning of masculine and feminine values in history.

Anglo-American theorists have generally been more materialist, but efforts have been made to utilize French linguistic deconstruction in historical analysis. Joan Scott (1988) argues that gender as formulated in language can be analyzed by drawing on deconstruction to dismantle hierarchical binaries of language in historical settings. Social relationships based on notions of sexual difference include within them power dynamics, the experience of which can be traced over time. Expressions of gender and power occur in cultural symbols, in the conceptualization of institutions, in kinship systems, and in subjective identity. Gender becomes a way to understand how society has been organized around the power differentials embedded in notions of difference.

The focus on discursive formations to some has risked the effacement of agency and the dispersal of explanatory models of historical change. Prompted by such fears, many historians have self-consciously paid attention to issues of agency. Concerns remain that the role of gender in producing larger historical change is not apparent, and efforts continue to articulate causal relationships between expressions of gender in culture or language and events or persons.

2. Gender and Identity Formation

That gender historically has been a component of identity seems difficult to dispute. In the twentieth century, identity has been located largely in psychosexual development, while other components of identity (work, family, religious affiliation) are seen as cultural overlays. Whether through differentiating the subject through knowledge of genital difference (Sigmund Freud) or through language in the mirror stage (Jacques Lacan), gender difference is considered foundational to notions of identity.

2.1 Histories of Sexualities

In the psychosexual models of identity, biological sex and gender constitute identity even though historians have noted that sexuality has not always been regarded as foundational. Much historical work has been devoted to understanding the meanings attached to sexuality and sexual behaviors in the past as key areas in which gender operates. The resulting explorations have at once brought into question the psychosexual account of the meaning of sexuality and introduced new paradigms in which sexuality is seen as experienced in relation to society and power.

The history of sexuality reflects the problem of how to treat the sex/gender system historically. The separation of sex from gender allows for a more precise rendering of the effects of embedded assumptions. 'Sex' as anatomical difference between male and female bodies is theoretically distinct from 'gender' as the social processes of becoming male or female. The history of sexuality has focused on gender in this sense because mapping sex and gender separately has proved ontologically unsatisfying. Unlike other domains in which gender was first recuperative and then theorized, the history of sexuality was framed initially in discursive terms and then the particulars of past sexual experience were recovered.

Michel Foucault's *The History of Sexuality* (1978) situated the history of sexuality in an analytics of power. Outlining a model of power as operating in elliptical, subversive, and counter-intuitive ways, Foucault moved away from narrative forms which did

little to suggest how or why attitudes toward sexuality changed over time. Examining the cultural and social forces which constrained and policed expressions of sexuality, Foucault found that a proliferation of discourse brought the body and its functions under the pervasive view of larger structures of authority, namely the church and the state. Foucault challenged the standard paradigm that Victorian prudery replaced a more frank and free sexual climate which lasted until the seventeenth century. Instead, Early Modern Europeans lived amidst a whole host of structures which directed sexuality, while the Victorians talked about sex and talked about not talking about it all the time. They moved sex into the home behind closed doors and shrouded it in secrecy, but Victorians who tried to shield children from sexual knowledge and restrict sexuality to heterosexual monogamous relationships had the effect of proliferating discourse about sex. The proliferation of discourses brought the body and its functions—ironically, given the purported interest in making sex more private—under the more pervasive view of larger structures of power and authority, namely the church and the state. Foucault's understanding of sexuality as having a history and that this history was integrally intertwined with institutionalized power structures opened up historical analysis to the implications of sexuality with respect to both gender and sex.

The absence of actual agents and questions about the particulars of Foucault's revised narrative encouraged explorations of the relationship between gender and sex. Much work has been devoted to recuperating the human and historical specificity of the discursive environment Foucault described by locating behavior previously ignored or undetected. Explorations of sexual rituals such as courtship and marriage have revealed how social constructions of sexuality operated in the past (Evans 1993). Topical issues include deviance, the implications of sexually transmitted disease, and sexual coercion and violence. Historical specificity has made it clear that the emphasis on modern notions of identity as a product of sexuality are quite recent. The recuperation of a multiplicity of sexualities which are not linked necessarily to underlying identity formations has provided ammunition for opponents of tradition-based sexual policies. The claims of universal 'right' and 'wrong' lose their explanatory power in the face of historical variation.

2.2 Gendered Embodiment

The history of sexuality has been linked to new conceptualizations of the body. Western thought for much of modernity has downplayed the importance of the materiality of corporeal existence. The thinking subject was typically represented as pure intellect, as if the mind operated without a body. Gender and history have called into question the disembodied thinking subject and the corporeal body as a stable, material object.

Since Descartes' distinction between intelligence and thought (*res cogitans*) and corporeal existence (*res extensa*), the mind–body split he posited allowed for a notion of the body as a machine which obeyed laws of 'nature.' That 'nature' resolutely defined certain types of bodies (white, male) as normative while all others were lesser, inferior, or uninteresting remained largely unquestioned. Historians demonstrated that scientific disciplines including medicine, anatomy, and anthropology produced a hierarchized model of sexual and racial difference based on the normative white male body. The menstruating, lactating, reproducing female body was the epitome of difference and inferiority. Historically, pressure to police, control, and contain the persistent physicality of the female body was chronic.

Coming out of feminist concerns about social difference as inscribed on female bodies, the historians of the body have moved on to question the assumption that the body is always and everywhere constitutive of the self in the same ways. Feminist scholarship in the 1970s frequently engaged with the question of 'essentialism' as opposed to social construction. The central debate was whether men and women had 'essential' biological differences or were different because of socially constructed ideas and norms (Riley 1988). The body was a particularly fierce battleground, since so much of female oppression seemed tied to bodily functions. While some argued that female corporeality defined in terms of reproduction caused women's oppression, others were less pessimistic. Cultural feminists and activists in the women's health movement embraced the female body as the source of specifically feminine ethical sensibilities. The distinctive qualities claimed for the female body signaled the limitations of the debate as few initially questioned the epistemological grounding of biological difference.

Because of the existence of biological difference between male and female bodies, essentialism was hard to put to rest. How could one theorize the body at all without reference to essential differences? One direction was to explore understandings of the body over time. Historians of the body found that the meanings attached to the seemingly stable facticity of the body were not really stable at all. Even the idea that there are two sexes was relatively new. From ancient Greece until the late seventeenth century, the dominant model was that there was only one sex—male—and that women were simply the inversion of it (Laqueur 1990). While some have questioned whether the single sex model was entirely dominant, much scientific thought organized its understanding of the body and its functions on the one sex model. The cultural addenda to the one sex model were astonishing in their range and importance, particularly for notions of sexuality. For instance, cultural wisdom

held that women needed penetrative sex to keep all their organs in the proper place and in working order.

Another mode of inquiry began to question the very existence of corporeal embodiment. The materiality of the body can be seen as a function of text and physicality. This is not to say that bodies do not exist. Rather, the body is always mediated by context, the social constructions, and the notions of difference (of age, race, gender, mobility, and so forth) in which it exists. If embodiment is no more or less real than the contexts which create it, the question remains whether the conditions of constraint in which female bodies seem to operate can be dismantled (Grosz 1994).

2.3 Instability and Masculinity

In many domains of knowledge, male bodies remain the unspoken norm, but efforts to historicize not just the male body but the ideas which are attached to it as appropriately 'masculine' have suggested how difficult the normative position is to maintain in practice. Gender male is a product of men either succeeding or failing to embody appropriate behaviors. Since many of these behaviors are negatively defined as being 'not feminine,' masculinity is often difficult to assert and maintain effectively, and masculinity as a result is often highly compensatory. A brief examination of how concerns over masculinity have shaped larger ideological and historical configurations suggests how compensatory strategies of masculinity have had significant effects on Western European society.

The study of masculinity was initially resisted by some feminist scholars who came out of women's studies. Many feared that masculinity was just another way of studying men—that historians who emphasized masculinity were in a sense highjacking one of the central purposes of women's studies, which was to restore women to the history written largely by men and privileging, usually uncritically, the male subject. But, as Natalie Zemon Davis (1976) noted, consideration of women in isolation from men was rather like imagining a class society consisting only of peasants. Ignoring men is no better intellectually or logically than ignoring women. The two operate in conjunction with each other to create historically specific definitional frames for both masculinity and femininity. Studying one alone necessarily distorts the picture.

It turns out that masculinity is often marked by the deliberate absence of women, suggesting that gender still constructs masculinity even without gender female physically present. John Tosh (1994) has argued that masculinity is always, in Western society at least, a matter of public demonstration at home, at work, and in all-male associations. The three elements are mutually dependent and reinforcing, but also highly unstable. Being able to establish and provide for his family was a crucial marker of male adulthood. The male head of household was expected to maintain order and discipline in his family, and the failure to do so marked his masculine status as fundamentally suspect (Davidoff and Hall 1987). As the model of marriage became less authoritarian and the idea of separate spheres gained acceptance, masculinity at home was often asserted by husbands with even greater vigor. Although the notion of separate spheres has been challenged, the persistence of gender differentiation was perceived as an important element in masculine self-definition.

As Tosh (1994) has pointed out, work was even more complex to negotiate than family. Work for nineteenth-century British middle-class men had to support the family, but it also had to be dignified and the man's commitment to it complete. If work was supposed to be a vocation for middle-class men, for working-class men, the mechanization of work represented a serious threat to his sense of self. Without work defined as 'meaningful' to confirm their masculinity, male workers often insisted on more sharply distinctive notions of appropriate male and female behavior. When women were workers, they were emphatically assigned to different tasks that were defined as inferior in terms of the skill levels required. Masculinity in the workplace thus depended on the inferiority of women, expressed either as female incapacity or as lesser status (Rose 1988).

Tosh's third element, male associations, includes a range of institutions, from boy scouts to colleges to men's dining clubs. The homosociality of these and myriad other all-male settings provided practical supports for masculine privilege in terms of contacts and access to other men of power in the case of many adult organizations. More significantly, collective homosociality produced the notion that masculinity was located solely in the company of men. The persistence of women's discomfort in the face of such expressions of masculinity remained and is still a powerful element shaping gender configurations.

Because masculinity is defined against femininity, the relationality of the terms makes them unstable. Historians, for instance, have found that masculinity was at times associated with homosexuality as an appropriate masculine behavior. In Renaissance Florence, homosexual behavior was widespread despite being heavily penalized. The configuration of the older man as the active penetrator and the younger man as the passive penetrated partner were conceptualized to support notions of gender hierarchy which posited men as active and women as passive. Denunciations of men for assuming the incorrect role were frequently accompanied by language which subsumed the transgressor into negative female roles (Rocke 1996). Homosexual behavior could support masculinity if it conformed to gender norms, but was increasingly figured as a threat to appropriate masculine behavior in the nineteenth century. The emergence of the New Woman and the increasingly visible homosexual subculture which deliberately played with the signifiers of

masculinity made for the assertion of masculinity as patriarchal and resolutely heterosexual (Showalter 1990).

Masculinity, gender historians have revealed, is dependent on a range of variables which are themselves culturally constructed. Because masculinity is not always easy to inhabit and because the stakes for men in losing the privileges which generally accompany masculinity are very high, it is as much a source of anxiety as of power. The recent visibility of mass movements that emphasize masculinity and support it with emotional language and highly orchestrated collective bonding experiences suggests that the anxiety is still very much present.

2.4 Gender Roles as Performance

Recent efforts to explore the history of identity formation have incorporated post-structuralist theories to tease out how the self was defined in gendered terms and how the gendered self related to others and to entities such as the state. Continental post-structuralist feminism has largely followed Jacques Lacan's psychoanalytic theory, developing the analysis of discourse in a mode which remains highly attenuated from material concerns. Lacanian psychoanalysis feminists, led by Julia Kristeva (1980), have re-interpreted the mirror stage of development to emphasize the abjection of the female subject. If the unspoken male subject in Lacan's formulation comes to his identity through engagement with the mirror image of the self, for the female subject, this experience is violent and alienating.

Judith Butler's articulation of gender as performance captures a number of elements of post-structuralist theory which have then been utilized to examine identity formation in the past. Butler (1990) argues that gender is best understood as a performance in which the subject is constituted in relation to the regulatory practices of society. The norms of these practices are themselves culturally constructed around heterosexuality defined by masculine and feminine binaries. Gender is actually wholly performative around those binaries such that it exists only in constituting a particular identity. While some historians expressed concern with the postmodern tendency to deconstruct without offering positive constructions, notions of identity as performative have helped recuperate historically specific moments of identity formation. Understanding gender as a signifying practice helps reveal how it is integral to other expressions of identity in specific historical settings.

3. Politics of Several Varieties

Going back to the ancient Greeks in the Western European tradition, politics has been a highly gendered pursuit. Politics was one of the main arenas in which men achieved honor and glory in the ancient world, and despite the overlay of Christian asceticism, politics has remained that, despite the attempt to present political participation as a gender neutral act on behalf of the public good. Throughout much of history, men of appropriate class standing defined themselves in terms of their eligibility for public political life. Even though politics is no longer formally restricted to male participants in Western Europe, old exclusivities die hard.

3.1 High Politics and Political Theory

The replacement of monarchical systems of governance with more or less democratic ones in Western Europe was long assumed to be a gender neutral change for the better. The rights-bearing political subject was, however, always male until the twentieth century, a fact noted but generally unquestioned by historians. Recent analysis has revealed that gender difference has been foundational to conceptions of politics throughout the Western tradition (Pateman 1988). Ancient theorists, particularly Aristotle, described political participation as reliant on the qualities of mind and body of men. Female inferiority was based on mental and physical weakness which required the restriction of women as much as possible to the home. That this restriction was in place largely to protect paternity and inheritance dropped out of the theoretical descriptions of society. Both Aristotle's teleological analysis of politics and the persistence of anxiety about paternity and female sexuality enabled the political arrangements to remain almost entirely male in expression.

The gendered logic beneath the political was obscured by the elaboration of misogynous overlays concerning women, beginning especially in the late Middle Ages with the emergence of the *querelle des femmes*. Except in France, where women were explicitly barred from monarchical inheritance, the occasional female monarchs only underscored the rule that men did politics and women did not. This was true in the Italian and Dutch republics as much as in monarchical states, and remained generally unquestioned until the French Revolution.

The positing of universal citizenship based on inherent rights presented a philosophical and practical challenge to all-male political arrangements. Even when other notions of hierarchy and difference were falling, however, gender remained. Joan Landes (1988) has argued that political participation as articulated in the French Revolution was foundationally masculinist rather than contingently or accidentally so. Not simply a matter of women being overlooked, revolutionaries made an active effort to differentiate the ability to be public and political based on sexual difference. The assumption remained that sexual difference rendered women incapable of proper political activity. The

increased language about domesticity and women being properly 'private' in the nineteenth century was a result of the reassertion of politics as properly gendered male. Ironically, the ancient justification for female exclusion from public affairs—concerns about her chastity and female sexual voraciousness—was completely overwhelmed by the assumption of female sexual passivity. White middle-class women were increasingly seen as asexual, although this was constructed against assumptions that women of other races and classes were sexually voracious and threatening (Hammonds 1999).

As this recounting of gender and politics has suggested, participation in high politics has long been organized and informed by notions of exclusion which are consistently centered on women as problematic. The persistence of the gendering of politics in the twentieth century can be seen in the long fight that was necessary to secure female suffrage in most Western European states and in the paucity of women elected to high office and in positions of leadership in political parties. The awareness that this persistence is not 'natural' but constructed has prompted some elected officials and feminists to challenge the overwhelmingly male character of high politics, but the association of women with domesticity remains strong.

4. *The Politics of the Personal*

The gendering of high politics, of course, is dependent on the gendering of domains regarded as outside of politics. The personal or the private are just as much elements of the political as matters of electoral politics and state policy. This was an important lesson of the women's movement, but the implications of it remain controversial in many areas. The fractures in social policy often go in many directions, as a number of areas related to sexuality and sexual expression suggest. The relationship of work to family is just one of the most prominent places in which public politics have become highly contested over what used to be considered private issues.

4.1 *Social Policies for Work and Family*

Work and family have long been seen as quintessentially opposites: work is public while family is private. But work and family are no longer seen as naturally occurring or organized in light of the historical analysis of gender. The language of 'natural' gender roles remains strong with respect to work and family, but the linking of the terms as historically inseparable has been combined with the imbrication of family and work issues in the welfare state. Even in the domain of social policy, understandings of gender as historically specific and constituted in cultural terms can inform policy development.

Gender history has focused on the cultural determination of work and family in Western Europe. Examinations of tax records and census documents reveal that the gendering of work does not follow the expectation that men will do heavy work while women do the less physically demanding jobs. In fact, work has long been assigned to men and women along culturally determined lines which were a function of the household as the unit of production for much of Western European history. Efforts to understand the historical relationship between work and family led to the emergence of two important paradigms. First, historians of women posited that women enjoyed a relatively positive working experience—with greater opportunity and higher wages—before industrial capitalism. Some even referred to early modern women's work as a 'golden age' in Western Europe. Second, historians argued whether continuity in the face of patriarchy or change in conjunction with larger historical trends best defined the history of women's work (Sharpe 1995). The controversy has produced efforts to historicize the workings of patriarchy so that the components of continuity are understood for their flexibility. This has enhanced present-day understandings of the persistence of gendered workplaces, occupational structures, and wage scales. At the same time, concerns about seeing the history of women's work as always the same produced a critique that emphasizes the interactive nature of gender in the workplace. Men's and women's roles shift in relation to each other and to larger economic changes such as the rise of industrial capitalism.

The gendering of occupations outside the home seems to follow shifts in competition between men and women for jobs. The chronology and geography of these shifts remains under exploration, as does the direction of change. Do changes in the family enable changes in workplace gender configurations or does the gendering of work force changes in the family (Berg 1993)? The question remains an open one, but is relevant to Western European controversies over the welfare state and gender patterns in employment. The present trends toward the separation of sex from marriage, increased divorce rates compared to earlier historical periods, child-rearing increasingly handled outside the family, and adjustments in the gendering of labor, signal significant transformation in work and family organization. The male breadwinner model persists, but along with it is increased pressure on men to participate in the emotional life of the family. If men are to be more involved in the family, the recognition of women's unemployment suggests that women are no longer automatically considered to be wives and mothers with paid employment as a secondary identity.

The points of articulation between policy and cultural expressions are the subject of recent analysis. Diane Sainsbury (1999) has argued that different and competing models of the welfare state are actually

both the result of gender and familial ideologies. The deficiencies in much welfare state analysis are a result of the failure to recognize gender as a crucial organizing framework in policy. Language and culture once again are the loci in which gender and history provide the bases for analysis.

5. Implications and Conclusions

Because gender is operative in all times and places in which human beings interact, gender and history provide the means and methodologies to understand the developing global community. Postmodern analytical techniques when applied to problems of gender in history in Western Europe have produced understandings of identity, politics, and sexuality in terms of their interrelations. Historical practices have just begun to articulate how specific experiences in different times and places relate to each other. Given that human communities are always male and female, and thus always marked by negotiations over expressions of masculinity and femininity, over the meanings of the body, and over the valuation of work and family, gender and history encompass issues global in scale in which to situate local understandings and problems.

Western European Studies: Geography

1. The Changing Discipline of Human Geography

This section presents a brief history of geographical thought in order to situate the approaches that human geographers have developed in studying Western Europe (for a fuller history, see Johnston 1991). During the nineteenth century, geography in Western Europe sought to describe and explain the spatial distributions of the natural world and of people and their activities. However, association between strong strands of environmental determinism that sought to explain human characteristics in terms of natural environmental conditions, exemplified by the work of Ellen Semple, and the politically discredited doctrine

of *Lebensraum* in Nazi Germany, produced a shift from explanatory concerns to regional description. While there were variations between national 'schools,' with the French under the influence of Paul Vidal de la Blache most powerfully exemplifying the regional descriptive approach, there was also a degree of commonality of approach to geographical scholarship across Western Europe.

Then, in the 1960s, influenced by earlier developments in North America summarized as the 'quantitative' and 'conceptual' revolutions, human geography in Western Europe began to be redefined. The emphasis switched to spatial science and explanation of generalized spatial patterns, drawing on ideas from neoclassical economics, and from qualitative regional description to quantitative—especially statistical—analysis of spatial patterns. Initially 'revolution' was concentrated in a few Departments in the UK and Sweden. From there, it diffused to other parts of Western Europe. These changes were contested, however. Much Western European geography retained a strong interest in the uniqueness of places, a focus that later re-emerged, albeit in a modified way. It soon became clear that spatial science had major limitations. Initially, behavioral geographers in Western Europe, as in North America, responded to these by seeking more realistic assumptions about the knowledge and motives that underlay peoples' spatial behaviors (Pred 1967). This did little to remedy the explanatory weaknesses, however. Consequently, human geographers sought stronger explanations grounded in more powerful abstractions of the processes that generated spatial patterns. As a result, Marxian and neoMarxian political economy soon became the focal point of 'critical' geography within Western Europe (Carney et al. 1980) and more generally (Harvey 1982). However, there were again strong counter-pressures, with humanistic geography (Ley and Samuels 1978) emphasizing human agency, meaning, intentionality, and individual life-worlds, rather than the unfolding structural logic of capital in explaining spatial variations in human activity.

Around the late 1970s, however, some important changes emerged in the social sciences, with implications for theory and practice in human geography and the ways in which Europe was studied. As a result, human geography in Western Europe became a pluralist discipline, encompassing many epistemological positions and substantive focuses, with strong links to cognate social sciences. Most importantly, there was an elaboration of seminal ideas about the centrality of space to social and economic life and growing recognition of the significance of spatiality in many of the social sciences. This generated a constructive dialogue within Western Europe across national and disciplinary boundaries. It involved social scientists seeking to infuse their theories with spatial sensitivity, and geographers (such as Massey 1984) exploring relations between social process and spatial form. 'The difference space makes' to the constitution of societies, and the ways in which economic, social, and political processes operate within the structural limits that define capitalist economies, became cross-disciplinary research frontiers.

There was growing recognition that relationships between social processes and spatial forms are reciprocal, contingent, and indeterminate. This led to exploration of the ways in which such relationships actually do evolve and the spatiotemporally variable forms that they take, directing attention to the institutions through which societies and their geographies are constituted and reproduced. The prime focus of concern became middle-level theories and concepts as human geography underwent an 'institutional turn.' Linked to this, poststructural approaches resulted in greater sensitivity to the limitations of, and absences from, metanarratives. This was associated with a broader 'cultural turn' in human geography and the social sciences, and heightened awareness of cultural variation in the ways in which capitalist societies are constituted and of the variable meanings that people, places, and events can assume because of this (Hudson 2001).

Paralleling developments of the 1980s in terms of sociospatial relationships, in the 1990s the social sciences in Western Europe increasingly acknowledged the significance of connections between the social and natural worlds in understanding societies and their geographies. As such, another 'traditional' geographical concern was given a new twist and became central to broader social science debates. One consequence of this was growing interest in Actor–Network theories, which seek to bridge the divide between social and natural worlds and explore how human subjects and nonhuman objects become contingently linked in networks in particular time/space contexts (Thrift 1996).

These growing concerns with relationships between society, space, and nature coalesced in debates about processes of globalization, links between 'the global and the local' and their impacts on and in Europe (Amin and Thrift 1994). This led to recognition that changes at 'global' and 'local' levels are reciprocal and complex rather than simply one-way and one-directional. While processes of globalization influence 'local' change in Europe, those processes are affected by 'local' place-specific effects in Europe (from the formation of the European Union to local social movements protesting about environmental pollution or cultural destruction). Some see 'globalization' as homogenizing, eliminating differences between places under the relentless pressures of capital accumulation and technological advances in transport, information technology, and telecommunications as the world of places dissolves into a world of flows (Castells 1996). In contrast, human geographers in Europe have conceptualized it as a complex interplay of processes that both link and help define varying spatial scales in

a complex mosaic. Globalization is seen as the latest phase of combined and uneven development, enhancing the distinctiveness of places and their importance in the contemporary world.

2. Changing Emphases in the Geographical Study of Western Europe

2.1 The Changing Geopolitical Map of Europe and the Meaning of 'Western Europe'

The dramatic changes in the geopolitical map of Europe in the postwar period have attracted the attention of geographers (such as Williams 1998). These changes include:

(a) the division of Europe between East and West following the partition of Berlin and the lowering of the imaginary but highly influential 'iron curtain' in 1948;

(b) the creation of the European Coal and Steel Community in 1951 and then the European Economic Community (EEC) in 1957 by the Benelux countries, France, Germany, and Italy;

(c) the formation of the European Free Trade Area (EFTA) in 1961 by nations that either did not want or were not allowed to join the EEC (Austria, Denmark, Finland, Ireland, Norway, Switzerland, the UK);

(d) the subsequent revision of the boundary between the EEC and EFTA, and the admission of nonEFTA states to the EEC; and

(e) the collapse of state socialism in the east in 1989, the destruction of the Berlin Wall, and a new phase of expansion of the European Union (EU), as it had become in the process of deepening economic integration, in the 1990s.

By 1995 the EU had expanded to 15 member states. Currently, there are several other applicant nations in Central, Eastern, and Southern Europe (Cyprus, the Czech Republic, Estonia, Hungary, Poland, Slovenia, and Turkey). Other nations (Bulgaria, Latvia, Lithuania, Malta, Romania) may become applicants for accession in the foreseeable future (Hudson 2000).

Three cleavage planes have been decisive in this ongoing partitioning of geopolitical space, in creating boundaries between different groupings of nation-states and in the allocation of nations to groups. First, there was a deep division for four decades between nations embracing capitalism and those embracing state socialism. Second, within the former group, there was a split between those committed to parliamentary democracy and those (temporarily) characterized by dictatorship (Greece, Portugal, and Spain). Third, there is continuing competition between models of national capitalisms and varying relationships between national economies and (welfare) states (Hudson and Williams 1999). There has also been competition between national states and interests and supranational interests represented in the emergent EU. The evolving postwar geopolitical map of Europe has thus been the product of highly contested processes.

2.2 New Multiscalar Geographies of Governance and Regulation: Restructuring the National State

The changing architecture of governance and regulation within Europe has been a related focal point of study. In postwar Western Europe, there were strong pressures to check the spread of communism, prevent future wars between its major states, and create a more effective political voice in the international arena. This led to the construction of supranational European institutions, beginning a process of redefining the architecture of governance and regulation in Europe.

Within the EU, there has been an upward drift of power, a 'hollowing out' as part of processes of national state restructuring (Jessop 1997). The increased regulatory competencies of the EU have been interpreted in one of three ways. First, for some, shifting state regulation 'up' a spatial scale signifies evidence of an emergent superstate. Second, it is argued that political changes in the 1980s and 1990s produced a complex hybrid form of decision-making processes in the EU, combining intergovernmentalism and cooperative federalism. Third, others view the EU as one element within a more complex multilevel and multidimensional system of governance. Whatever the interpretation, however, the EU is seen as weakened by a deep democratic deficit (Painter 1999).

While the EU can be seen as the most elaborated example of an emergent multilevel system of governance and regulation, there are strong continuities with the past, especially in the continuing significance of national states. Some new forms of economic and financial globalization ('stateless monies,' for example) do take matters beyond the effective control of many national states. However, the view that the significance of the national state is being eroded via 'hollowing out' has been challenged on various grounds. In many respects, national states in the EU retain considerable powers (Anderson 1995), and these states are perhaps the paradigmatic case for 'hollowing out' theorists.

3. Europeanization, Globalization and the Impacts of these Processes within Europe

The development of the EU as a homogenized economic space, together with the extension of capitalism into Central and Eastern Europe, created new spaces in which companies can reorganize their activities. This has become another focus of geographic research in and on Europe (Hudson 1999a). The

prospect of the Single European Market generated a surge in intraEU foreign direct investment and enhanced cross-border acquisitions within the EU. These often led to rationalization, plant closure, and job loss. Investment by Western European companies in CEE also increased somewhat, although heavily spatially concentrated at national and subnational scales, further widening spatial inequalities.

Europe-wide strategies have frequently been part of broader corporate globalization strategies. Creating bigger European companies via acquisition or merger has often been necessary to enable the enhanced spatial scale of corporate organization. There has also been an increase in strategic alliances between these bigger companies, especially in manufacturing industries characterized by high entry costs, continuing importance of economies of scale and scope, rapidly changing technologies, and substantial operating risks (Dicken and Oberg 1996). Processes of acquisition, merger, and strategic alliance have also reshaped parts of the service sector, ranging from banking and financial services to retailing, in response to competitive pressures and possibilities created by technological changes and deregulation (Hudson 1999a).

In the 1990s, transnationals based in the USA, Canada, and south east Asia increasingly entered strategic alliances with European companies. There was also a surge in acquisition activity by nonEU transnationals in Europe, along with increased direct inward investment in anticipation of completion of the Single Market. Inward Foreign Direct Investment (FDI) to the EU has been concentrated in banks and financial services and in existing major metropolitan centers. Simultaneously, technological advances in computing and telecommunications, deregulation of previously nationally protected markets in services, and resultant pressures on companies to cut costs to remain competitive, led to decentralization of back-office functions to peripheral locations. There was some further inward investment in manufacturing, but with a rather different geography. Investment in activities such as European headquarters offices and research and development (R&D) has been in major cities in economically strong core regions, but has been limited in extent. Most has been in routine production activities in consumer good sectors such as automobiles, electronics, and 'white goods.' It has involved both acquisition of existing companies and factories and inward investment in new 'greenfield' manufacturing plants, the latter typically in peripheral locations in both Eastern and Western Europe (Hudson 1999a).

3.1 The Rise of the Regional Economy and the Rediscovery of the Urban Economy in Europe

Some researchers in Western Europe have increasingly identified the region as the crucial territorial and institutional framework for economic success, linked in part to debates about national state 'hollowing out' and regional devolution. There have been two strands to this work. First, stimulated by Bagnasco's (1977) seminal study, there has been great interest in industrial districts, regionally concentrated mono-industrial production systems, producing a range of labor-intensive consumer goods (such as clothing, shoes, or ceramics). They are organized via relatively egalitarian horizontal networks of small firms, built around trust and linked into complex social divisions of labor. These districts are also characterized by cooperative capital–labor relations, and by supportive institutional structures in the local state and civil society. The net result is flexible production systems, able to respond swiftly to changing tastes and consumer demands. Since the 1970s, there have been a number of studies of similar industrial districts in various parts of Europe (for example, see Maskell et al. 1998) while some scholars have conceptualized key 'command and control' nodes within global cities, such as the City of London, as a particular form of industrial district (Amin and Thrift 1994).

The second strand focuses upon a different type of territorially clustered network structure, with close links between companies and the institutions of state and civil society, but based upon hierarchical and asymmetrical power relations between the constituent firms. These are production systems driven by major firms, with others linked to them in tiered supply chains, with Baden-Württemberg perhaps the 'classic' European example (Herrigel 1996). A more recent variant of this regional economic structure is linked with inward investment, especially from Japan and south east Asia, as assembly plants attract component suppliers to locate nearby. This has led to contested claims about a 'new' type of higher quality of investment in 'embedded' branch plants, more integrated into the surrounding regional economy than traditional 'global outpost' branch plants and so with greater regional developmental potential. Such new factories are also seen by some as bringing new, enriching, and more satisfying multiskilled jobs but by others as offering intensified, multitasked jobs that further disempower workers (Hudson 1999a).

Emphasis on the importance of regional cultures and institutions in an associational economy underpinning regional economic success has led researchers to highlight the significance of concepts such as regionally specific social capital, trust, untraded interdependencies, tacit knowledge, learning, and appropriate institutional structures. Important studies in this regard include Amin and Thrift (1994) and Storper (1995), although others are more skeptical about this 'regional cultural and institutional turn' (Gertler 1997, Hudson 1999b). Nonetheless, such ideas have also been increasingly influential in urban studies as geographers have developed new perspectives on cities (for example, see Amin and Thrift 2001).

4. Structural Economic Change, Service Sector Growth, and Feminization of Labor Markets

Service sector growth as part of a changing social division of labor has been the most significant structural change in the European economy and led to claims about the emergence of postindustrial and postFordist economies. There have also been important changes within the service sector. Initially, service sector expansion was closely linked with growing state involvement over much of Europe. More recently, the dominant pattern has been shrinkage of the public sector and expansion of private sector services. The most significant feature of the latter has been growth of private sector business and financial services, often linked to financial product innovations and deregulation of financial markets (Tickell 1999).

The increasing importance of the service sector has also been associated with three important changes in European labor markets. First, further 'feminization' of the labor market has led to some growth of well-paid, full-time secure professional employment for women but more generally growth has been in less desirable jobs. Second, women form a disproportionately large part of the 'flexible workforce,' produced by the growth of new forms of employment contract and part-time and casual work (Perrons 1998). Third, service sector growth, especially in business and financial services, has led to renewed focus on urban environments as key nodes of economic dynamism (for example, see Keil and Ronnenberger 2000). This has led to increasing interest in the characteristics of urban environments seen as conducive to high order service sector growth and the attraction of dynamic new services and cultural industries within an emergent 'knowledge economy.' Echoing earlier work on successful regions, this again emphasizes the significance of 'soft' infrastructure and informal social relationships as well as the necessary 'hard infrastructure' of transport, telecommunications, and informatics networks (for example, see Amin and Thrift 2001).

5. New Geographies of Identities

European identity and the criteria used to denote 'Europeans' have emerged as a focus of interest. EU member states have clearly become *de facto* multiethnic and multicultural societies, raising questions about cultural and ethnic variation and issues of (multiple) identities at national, regional, and local scales within the EU and about the character and location of the boundaries of the EU (Amin 2001). Boundary definition is closely tied to processes of 'othering' and the criteria by which 'Europeanness' is to be judged. As the EU expands, particularly eastwards into areas that border on or are part of Asia as commonly understood, these issues become more pressing.

One conception of a singular European identity would see it constructed through a process analogous to that involved in creating national identities. However, the project is now to transcend those identities. Previously the 'imagined community' was national; in the new imagination it is to be European (or perhaps more accurately EU). For many people, there is now undoubtedly greater awareness of other cultures and lifestyles elsewhere in Europe. Such shared activity and communication spaces do not necessarily translate into a shared European consciousness, however. The EU's cultural and educational policy initiatives have sought to encourage the formation of a common consciousness and shared identity beyond existing local and national affinities. This view of European identity and 'Europeanness' sits comfortably with the preferences of many members of political élites within Europe. However, it lacks a firm grounding in popular consciousness (Smith 1995).

There are pressures from national states and their citizens to resist further erosion of national identity and sovereignty. The Danish rejection of the Euro and the electoral success of extreme right-wing political parties in countries such Austria, Belgium, and France, for example, suggests the resurgence of more insidious and xenophobic nationalisms and racisms (White 1999). Furthermore, there are strong pressures from 'suppressed nations' seeking their own national states, so that territory corresponds with identity, as events in the Caucasus and the Balkans in the 1990s made painfully clear. At the same time, however, localist and regionalist movements challenge national states and seek greater autonomy from the center, asserting their particular cultural and territorial identities over the national. Often this builds upon past histories of national states suppressing subnational variation and culture in the process of building national identities (see, for example, Fernández Rodríguez 1985). Such tendencies are expressed widely over Western Europe (Anderson 1995). These regionalist and substate nationalist tendencies often emerged in a complex relationship to processes of globalization, Europeanization, and the emergence of the EU. Often they were seen as a way of resisting global forces via forging alliances between the regional and supranational EU levels, bypassing the national state. Thus complex geographies of hybrid identities were forged, with allegiance to territories at different scales, which became a focus of interest for human geographers and social scientists (Amin 2001).

6. Geographies of Social Inequality

One consequence of processes of political and economic restructuring is that Europe has become a more sharply divided place, characterized by deepened sociospatial divisions. Processes of economic restructuring have etched the contours of inequality

more deeply into the European landscape, at several spatial scales: between countries, between cities, and between regions within countries; and within cities and regions (Bennett et al. 2000). There are growing divisions between the long-term unemployed—structurally excluded from the labor market—and the employed, but also within the employed workforce (in terms of wages and terms, conditions, and security of employment). There has been growing recognition of gender divisions (Perrons 1998) while issues of ethnic and racial divisions have often been exacerbated by EU expansion and by immigration and fears of 'the other,' especially those of different skin color (White 1999). There has also been a growing recognition that spatial divisions intertwine in complex ways with those of class, ethnicity, and gender (Hadjimichalis and Sadler 1995).

7. *Social Exclusion, Inclusion and 'Third Sector' Local Economic Initiatives*

Growing unemployment, poverty, and inequality in the EU have led to growing concern—academic and political—with new ways of creating work and delivering services to disadvantaged communities. The focus of this attention has been on the social economy and 'third sector' economic initiatives, typically constructed at local level and designed to tackle social exclusion. While social exclusion encompasses a variety of dimensions beyond lack of waged employment, in practice attention has increasingly been focused upon tackling problems of unemployment, especially long-term and amongst the young, as these have become stubbornly persistent in Western Europe. The emphasis is upon creating new forms of socially useful work as an alternative to both private sector and state employment that will provide meaningful jobs for the unemployed and/or provide services that are no longer provided by state or markets to deprived communities (Lipietz 1995). There are concerns, however, that this may simply provide cut-price alternatives to public sector welfare services while reproducing inequalities from mainstream economy and society within the 'third sector' (Amin et al. 1999).

7.1 *Sustainable Societies and Places*

Sustainability in various guises—of natural environments, economies and societies, cities and regions—has become a further research focus within Western Europe, not least because it has become a pressing practical and political issue. Initially the emphasis was upon investigating ways of enhancing natural environmental sustainability but it was increasingly recognized that this must be situated in the context of transition to methods of production and transportation and lifestyles and consumption patterns with a lighter ecological footprint. This encompassed both technological innovation to generate materially more efficient methods of production and movement and institutional and regulatory changes to increase the efficiency of resource use and reduce waste. Environmental and social justice were increasingly seen to be intimately linked. Such issues are likely to become more important on geographical and social science research agendas in Western Europe in the twenty-first century, at a variety of spatial scales from the global to the regional and urban (Hudson 2001).

8. *Conclusion*

There were significant changes in the practice of human geography in Western Europe in the second half of the twentieth century, in how geographers studied Europe and in what they studied as Europe itself changed. Furthermore, growing interest in the social sciences with relationships between society, space, and nature—geography's established mainstream concerns—led to exciting developments across national and disciplinary boundaries in the study of Europe. These in turn had wider ramifications within geography and parts of the social sciences within and beyond Europe.

Western Europe Studies: Health

The health domain has served as a focal point for investigating the emergence and extension of state capacities for social governance in Western Europe. Such studies have considered, on the one hand, the desire and ability of nation–states to govern the health sector, and, on the other, the amenability of the health sector to governance. Governance, in this case, refers to efforts by governments to intervene in the private provision of medical services. Not only have governments throughout Western Europe underwritten the costs of medical care, they have introduced standards and mechanisms for the control of the quality, availability, and cost of medical services. Consequently, governance of the health sector has entailed government regulation of medical practitioners, and hence, political conflict between doctors and the state (see *Health Care Systems: Comparative*; *Health Policy*; *National Health Care and Insurance Systems*).

1. Health Politics

1.1 Interest-group Politics

Political scientists have regarded the health area as a test case for the theory of political pluralism. Pluralist theory focuses on interest groups as the key actors in the political process (see *Interest Groups*; *Interest Groups, History of*; *Pluralism*). Citizens, the theory assumes, form interest-groups when confronted with problems, and use these groups to lobby for the resolution of these problems. As a result, both the array of organized groups and the pattern of governmental activity should, in theory, reflect these popular demands. Studies of the role of medical associations in health politics have called this model into question, however. Medical associations appear to have had a strong influence on health policy decisions. To the

extent that medical associations are able to veto any proposal to which they are opposed—by threatening to go on strike or by questioning the medical soundness of government programs—one can speak of 'undue' or excessive political influence, or even of professional dominance. Although successful interest-group influence is part and parcel of the pluralist paradigm, such one-sided influence would constitute a fundamental challenge to the pluralist ideal of politics as a compromise amongst competing interests.

1.2 History of Health Insurance: the Nineteenth Century

Research on Western European health politics has investigated the conflicts surrounding public health insurance programs. Beginning in the late eighteenth and early nineteenth centuries, many European governments introduced laws for registering and subsidizing voluntary mutual aid societies or sickness funds (Friendly Societies, *Hilfskassen*, *Mutuelles*, *Società di Mutuo Soccorso*), which provided their members with cash benefits and medical treatment. National mutual aid society legislation was enacted in Britain in 1793, Spain in 1839, Belgium in 1849, France in 1834, Italy in 1886, Sweden in 1891, Denmark in 1892, Switzerland in 1911. Early laws—those passed before 1850—were most concerned with monitoring the activities of these popular associations. After 1850, government legislation often included funding for the mutual aid societies. In the late nineteenth and early twentieth centuries, lawmakers made the subsidies conditional on improvements in insurance coverage and medical benefits, requiring, for example, that funds accept all applicants and that they provide access to medical treatment, rather than only the more common cash benefits, which were to cover income-loss during illness.

After Germany introduced compulsory public health insurance (*gesetzliche Krankenversicherung*) for industrial workers in 1883, many other European nations followed. Austria introduced compulsory health insurance in 1888, Luxembourg in 1901, Norway in 1909, Britain in 1911, the Netherlands in 1913 (for cash benefits only) and in 1943 (for medical benefits), France in 1930, Greece in 1937, Spain in 1942, Italy in 1944, Belgium in 1944, Portugal in 1946, Sweden in 1946, Finland in 1964, Denmark in 1971. Early compulsory health insurance laws often built upon the basic structures provided by the voluntary mutual funds, leaving health insurance administration to the preexisting funds, but making membership for certain population groups compulsory.

The politics of mutual aid society and compulsory health insurance legislation are diverse. Many different types of political parties, spanning the political spectrum, introduced legislation intended to expand health insurance coverage. In France and Germany, conservatives proposed mutual aid society legislation against the opposition of liberals, whereas in Sweden and Switzerland, for example, the situation was just the reverse. German socialists opposed conservative Chancellor Bismarck's compulsory health insurance, but, as they found they were able to use the sickness funds as an organizational resource, they later came to champion the insurance system. Indeed, it is precisely such alliances between political parties or social movements and the sickness funds that explain some of the partisan variation regarding statutory (that is, required by law) health insurance. Whereas in Germany, the territorial sickness funds (*allgemeine Ortskrankenkassen*) became a social democratic and union stronghold, in Belgium, the sickness funds were closely allied to the liberal, Catholic, and the socialist political parties. In the Netherlands, many sickness funds were started by doctors; in Sweden, they were tied to the Temperance (anti-alcohol) and Free Church (opposed to the State Church) movements, which, in turn, tended to be supporters of the liberal party, as were many Swiss sickness funds.

Some of the most important political conflicts surrounding nineteenth century and early twentieth century legislation concerned the issue of whether insurance coverage should be voluntary or compulsory, whether employers or workers or both should pay contributions and in what amounts, what proportion of the population—often defined in terms of occupational groups—should be covered, and how to achieve portability of insurance benefits. These issues tended to be of more direct concern to labor unions, employers, and the mutual aid societies than to doctors, and can thus perhaps be better viewed as 'class' issues than 'professional' issues. Not surprisingly, studies of this early period—which include contributions from history, sociology, and politics—have tended to be concerned with the causes and consequences of the rise of social insurance, and of the welfare state, more broadly. A key question has been whether the rise of working-class organizations and parties, as well as differences in working-class political mobilization—the degree to which members of the working-class actually voted for workers' parties or joined trade unions, whether these organizations were divided by religious cleavages, and whether parties and trade unions cooperated—can explain the emergence of different programs of social protection in different European nations. A second line of questioning has been whether fear of class unrest is the sole motivation for government initiatives in this period, or whether states had other considerations related to their need for political legitimacy, particularly as parliamentary democracy came to be established in some nations but not in others (see *Class: Social*; *Christian Parties: European*; *Employers' Associations*; *Labor Unions*; *Social Movements: Resource Mobilization Theory*; *Social Democracy*; *Labor Movements, History of*; *Social Question: Impact on Social Thought*; *Social*

Security; *Social Welfare Policy: Comparisons*; *Socialism*; *Voluntary Associations, Sociology of*; *Welfare*; *Welfare State*; *Welfare State, History of*).

1.3 The Interwar Period: Doctors vs. Sickness Funds

As the growth of both voluntary and compulsory health insurance expanded the market for medical care in the first third of the twentieth century, conflicts arose between doctors and both mutual aid societies and government insurance authorities. Whether public or private, the insurance carriers (those responsible for administering health insurance) sought to reduce the costs of medical treatment by restricting the fees that doctors could charge to insurance patients. These insurance conflicts coincided with doctors' achievement of professional status, and encouraged the efforts underway to organize members of the profession into effective lobby associations (see below). Now health, politics had indeed become very much characterized by professional politics, and scholars studying twentieth-century health legislation have focused largely on the opinions, strategies, and success of organized medical professions in shaping government health programs to their liking.

For medical organizations, the key issue was to avoid becoming economically dependent on health insurance practice, and, especially, to maintain the status of doctors as independent practitioners in face of efforts to turn doctors into employees of the sickness funds. In Germany, the sickness funds relied on individual contracts with doctors and direct third-party payment (i.e., the sickness funds paid the doctors directly) to keep fees low; only doctors that agreed to the conditions of the funds were admitted to insurance practice. This type of system is also known as a 'closed panel' or, in contemporary language, as a 'preferred provider' health insurance system. When the German system was to be extended to larger sectors of the population through the *Reichversicherungsordnung* (Imperial Insurance Code) of 1911, the two main doctors' associations, the *Leipziger Verband* and the *Deutsche Ärzteverein*, led a successful strike that culminated in the *Berliner Abkommen* (Berliner Accord) of 1913. This agreement established a bipartite board of representatives of both the medical profession and the sickness funds to govern entry to sickness fund practice, thereby ending the funds' unilateral control of access to the insurance market.

In Germany, doctors fought within an established insurance system for ever better conditions of practice. Other medical associations looked to the German example, and fought for these measures from the start. In France and Switzerland, for example, a series of quite similar issues occupied health insurance debates from the beginning of the century through the 1960s. Doctors preferred a fee-for-service payment method (which allowed doctors to charge patients a separate fee for each service performed); they opposed third-party payment (*tiers payant*) and wished to receive payment directly from patients, leaving the patients to submit their bills to the sickness funds for reimbursement (*tiers garant*); medical associations were willing to negotiate collective fee schedules (lists of maximum fees, called *Gebührenordnungen* or Conventions) with insurance authorities, but they were opposed to individual contracts and asserted the individual discretion of physicians to charge more in difficult cases, or for all cases, if the physician was particularly well-known. Realizing that these conflicts were inherent in insurance practice, medical associations fought also against the extension of compulsory health insurance systems to entire populations, preferring instead that government or government-subsidized insurance remain voluntary, or at least compulsory only for those with low incomes. Insurance carriers, on the other hand, did not wish to be responsible for undefined and uncontrolled costs, and lobbied for government regulation of medical fees, and the extension of compulsory coverage.

1.4 The Postwar Period: National Health Systems

After the Second World War, most Western European governments massively expanded their health insurance coverage, many insuring entire populations as a right of citizenship. Not only health insurance, but the health system as a whole was the subject of reform efforts. In 1946, a Labour government introduced the British National Health Service (NHS) to provide healthcare to all citizens through publicly-owned hospitals and publicly-paid doctors. In order to overcome opposition from the British Medical Association—which largely represented the interests of the general practitioners—plans for salaried practice for outpatient care was dropped; instead general practitioners would be under contract to the NHS, and paid on a capitation basis (a yearly flat-fee per patient enrolled with a particular doctor, regardless of how much or how little treatment is received), as they had been by the Approved Insurance Societies (Friendly Societies approved to carry national health insurance), since the National Insurance Act of 1911. Similar ideas of universal provision of healthcare through salaried hospital doctors and national health hospital plans were discussed in other nations as well, such as France (in 1944) and Sweden (in 1948), but failed due to medical opposition.

In a second wave of reform in the 1960s and 1970s, however, many European governments introduced controls on doctors' fees, salaried service for hospital physicians, and national plans for health systems. In France, the decrees of May 12, 1960, promulgated by de Gaulle, established a system of departmental conventions (lists of maximum fees) for the control of

doctors' fees, which was replaced by a national convention in 1971. The Debré reform of 1958 established new mechanisms for hospital planning, created full-time salaried posts for hospital physicians, called for phasing out the private practice privileges of hospital chiefs of staff, and reformed medical education. In Sweden, a Social Democratic government banned private medical practice from public hospitals in 1969, and, in conjunction with the reform, hospital physicians agreed to be paid on a salary basis. In Italy, an agreement between the Italian Communist Party and the Christian Democrats established the Italian National Health Service (*Servizio Sanitario Nazionale*) in 1978. In 1986, the Spanish socialist government converted the national health insurance to a national health service, as well.

Even in nations where no formal changes in type of health system were made, efforts were made to introduce more effective measures of cost-containment, as well as hospital financing and planning. The German Cost-Containment Law of 1977 (*Krankenversicherungs-Kostendämpfungsgesetz*) provided for tripartite discussion of healthcare costs amongst representatives of government, sickness funds, and the medical profession, and for limits on the collective reimbursement made from the sickness funds to health insurance doctors. Subsequent reform efforts (most importantly in 1981, 1992, and 1997) have focused on further improvements in cost-containment and in extending these mechanisms to the hospital sector. In the Netherlands, too, legislation governing healthcare prices and hospital planning was introduced in 1982 that built upon a preexisting framework of negotiations between sickness funds and healthcare providers.

Since the 1990s, one can observe a shift in emphasis from direct government regulation of health prices and planning to experimentation with 'market' reforms. In the Netherlands, reforms have aimed to increase competition amongst insurance carriers. In the United Kingdom and Sweden, efforts have been made to introduce 'internal markets' and to increase 'public competition,' by creating mechanisms for the purchase of health services by local healthcare authorities and general practitioners (in the UK), and units of local government (in Sweden), (see *Health Care Markets: Theory and Practice*; *Health Economics*; *Public Management, New*).

2. Health Governance

2.1 Corporatism

The power of the medical profession is a central theme not only in studies of government efforts to introduce and to reform public health programs, but also in research on the effectiveness of different health policies. Here, the theory of corporatism has proved to be a useful organizing principle for comparing government health care strategies and their effects (see *Corporatism*). Proponents of a corporatist approach examine the ways in which medical doctors are organized in different countries. In Germany, for example, all doctors treating public insurance patients are required to belong to Associations of Sickness Fund Doctors, which in turn are represented by a peak association (*Kassenärztliche Bundesvereinigung*). They are thus not only highly organized, but organized into a single association. This legacy of the early days of German health insurance has allowed the government to leave many aspects of health policy—such as cost-containment measures—to arenas of collective negotiation between representatives of the sickness funds and the medical profession. Consequently, some policy analysts view negotiation—or governance through association—as an attractive alternative both to direct government intervention ('State') or purely economic mechanisms ('Market').

Scholars investigating the impact of government intervention in the medical area have also raised the question of the meaning of health reforms for the freedom and power of the medical profession. Is the right to a private practice an integral part of medical freedom—as many doctors' associations have argued—or is the defense of the private market an outmoded vestige? Although many different aspects of the resources and privileges of doctors have been subsumed under the general term 'power,' investigations of the health area indicate that there may be several dimensions of medical power—not all of which vary together.

2.2 Theories of the Professions

Theories of the professions—an offshoot of sociological research on stratification—try to explain why some occupations are more privileged than others. Debate has concerned both the indicators of 'privilege' and its causes. The 'functionalist' approach views the essence of professionalism in the demonstration of the efficacy of a particular body of knowledge which generates public legitimacy for the autonomy of judgment of its practitioners. The 'historicist' approach, by contrast, argues that the emergence of a domain of knowledge and the association of that domain with an occupation grouping is an arbitrary and political process which can only be understood historically. The health field has proved a fertile ground for this debate, because of the apparent unparalleled success of doctors in this 'professionalization project.' Western European studies have advanced the historicist argument, in particular, as research has detailed the great variation in the boundaries of professional knowledge, the organization of medicine, and the character of medical privilege across Europe (see *Func-*

tionalism in Sociology; *Historicism*; *Medical Sociology*; *Medical Profession, The*; *Parsons, Talcott (1902–79)*; *Professionalization/Professions in History*; *Professions, Sociology of*; *Health Policy Social Stratification*; *Social Inequality in History (Stratification and Classes)*).

Theories of the professions emphasize the process by which the medical profession became unified into a single, recognizable profession, and how members of this profession were able to upgrade their collective status, achieving recognition from both governments and the public for their claims to expertise. Debate continues, however, about the extent to which health expertise translates into success in the political arena. If one compares the success of medical professions in defending their right to set their own fees, and to an unregulated private practice—their 'economic autonomy,' so to speak—variation in Western Europe does not appear to be accounted for by variation in professional monopoly. In Switzerland, for example, government regulation of medical licensing, and even against medical quackery, has been relatively weak, yet the Swiss Medical Association has been highly successful in blocking the introduction of compulsory national health insurance and controls on doctors' fees. An alternative explanation for such variation may lie in the properties of political institutions and their effects on political decision-making (see *Institutionalism*). Professional associations—in particularly those representing medical specialists—appear to be more universally successful in other areas of decision-making, however, such as individual decisions about treatment (clinical autonomy), or political debates about more purely 'medical' matters (such as funding of medical research or issues of medical malpractice). Whether an issue becomes defined as 'medical,' 'economic,' or 'social,' however, is very much a matter of politics, and hence at the core of professional strategies.

2.3 States and Social Control

Following the lead of Norbert Elias and Michel Foucault—as well as, of course, the classical sociologists Durkheim and Weber—scholars have tried to reconstruct the meaning of health intervention for the relationship between state and society (see *Durkheim, Emile (1858–1917)*; *Elias, Norbert (1897–1990)*; *Foucault, Michel (1926–84)*; *Weber, Max (1864–1920)*). The idea is to understand both why states become involved in regulating the health of citizens, and how beliefs associated with concepts like health, disease, and contagion are formed. The direction of analysis is not only from state to society, but examines how social practices involving health and hygiene—for example, the set of manners that demarcate the boundaries of appropriate public behavior—establish culturally-specific concepts (also called 'collective representations') of state and society. In this way, the 'politics of the body' are thought to be construct images of the body politic, and hence to influence citizens' attitudes and behaviors vis-à-vis social collectivities and political authorities. Consequently, work in this vein has interpreted health beliefs and health practices as part of a system of social and political domination. This type of 'constructivist' or 'postmodern' approach has often been adopted by proponents of a 'gender' approach. Here, ideas about the body, and the relationship of doctors to patients of both sexes are thought to play a role in establishing definitions of gender differences (see *Control: Social*; *Conventions and Norms: Philosophical Aspects*; *Deconstruction: Cultural Concerns*; *Gender and Feminist Studies*; *Gender and Feminist Studies in History*; *Gender and Health Care*; *Gender History*; *Body, History of*; *Norms*; *Postmodernism in Sociology*; *Postmodernism: Methodology*; *Social Constructivism*).

2.4 State Sovereignty

Finally, studies of healthcare governance have been part of a more general debate about the rise and future of the nation–state. Healthcare has been used as an example by which one can observe the origins and development of the institutions and mechanisms of governance peculiar to Western Europe. The complexities of governing the healthcare sector have provided empirical substance to a more general debate about whether classical state sovereignty is on the wane. The growth of the welfare state—precisely through the expansion of programs like national health insurance and national health services—has involved governments increasingly in negotiations with social actors—medical professions, labor unions, employers, and the like—thereby, in the eyes of some scholars, eroding states' hard-won 'internal sovereignty' (the independence achieved by absolutist rulers from medieval corporations, estates, cities, or other subnational political actors). The international integration of national economies, and, especially, the regional integration of the Western European economies is, analogously, thought by some to threaten states' 'external sovereignty' (the autonomy wrested by modern European nation–states from supranational authorities, such as the Catholic Church) (see *Absolutism, History of*; *Luhmann, Niklas (1927–98)*; *Nations and Nation-states in History*; *Rokkan, Stein (1921–79)*; *State Formation*; *State, History of*; *State and Society*; *State, Sociology of the*).

Whereas the problems of 'domestic' health politics and health governance have been investigated quite thoroughly, far less research has focused on the emerging problems of international or, especially, European health governance. It will be a challenge of future research to refine the concepts and issues that have emerged from national contexts (albeit in comp-

arative perspective)—such as the medical profession, professional autonomy, corporatism, national healthcare systems—in light of international cooperation and integration. Further, while a focus on Western Europe has promoted interdisciplinary research—with political scientists and historians, for example, using sociological theories of the professions as a departure for their own research—an equally pressing challenge will be to look beyond the borders of Western Europe for alternative approaches to the definition and study of 'health.' Lastly, as the study of health, like many policy areas, becomes increasingly influenced by an economics perspective—with market mechanisms favored by policy-makers and economic models of decision-making by social scientists—the remaining social and behavioral sciences will need to articulate compelling arguments for their continued contribution to the study of health.

Western European Studies: Religion

1. Church and State

The study of Western Europe has been until modern times the study of Christendom, and the evolution of fundamental western institutions such as the state and civil society cannot be adequately understood without an analysis of the Church and its institutions. Historical studies of European institutions have been necessarily preoccupied with the development of relationships between the state and the church. During the Roman Empire, the Christian community had been a cult whose millenarian doctrine sharply separated the religious community from the secular world. Eschatological expectations about the Second Coming meant that Christian leaders had little interest in shaping this world. The conversion of Constantine, the foundation of Constantinople as a Christian city and the acceptance of Christianity as the official religion of the empire brought about the end of Christian chiliasm. In the late fourth and fifth centuries, the papacy emerged as a governmental institution that exercised this-worldly rulership.

The collapse of the Roman Empire and the advance of barbarian kingdoms in the fifth and sixth centuries created the foundations of feudalism. As Christianity came to adjust to the existence of the secular institutions of this world, such as kingship, it was forced to reconsider the relationship between the church and the state. Medieval Christian theology provided basic models of power, legitimacy, corporation, and immunity that have been, and remain an influence in western political institutions. Throughout the medieval period, Christian theologians struggled to reconcile two problematic principles: the state was an institution of violence, but it was necessary for social order, and the Church, whose foundation was a divine act, depended upon the state to secure its soteriological purpose. What was common to medieval belief and what came to shape the growth of constitutional theory was the assumption that power should exist within a normative framework (Canning 1996).

The medieval Church inherited the impulse of primitive Christianity to disengage from political life,

but this impulse could not be comprehensively applied since the Church was ultimately dependent on state institutions (Wolin 1961). The Protestant Reformation created a new vision of independent, self-governing communities in which the sanctified individual would be liberated from the tyranny of secular powers and the corruption of ecclesiastical institutions. It was a vision of the transformation of power to godly rule that inspired the American Revolution. Lutheranism embraced a nostalgic vision of the purity of the primitive Church with which to challenge Catholic institutions, but it came to recognise that the congregations of the 'visible Church' would need discipline in order to prepare for the 'invisible Church.' The sins of this world were the pretext for a theory of the state as a moral authority, but Luther went further to recognise that the state was necessary to release Christian souls from the tyranny of the Church in the world. The fundamental instability of this relationship between the sovereignty of the state and the divine mission of the Church produced an endless cycle of reformation and counter reformation that structured political life in Europe for centuries.

Sociologists have studied the pastoral counsel of Reformation Protestantism as an important cultural foundation for the growth of capitalism (Weber 1930). Although the 'Protestant Ethic thesis' is controversial, there is evidence that Protestant divines contributed both to the ethos of entrepreneurial capitalism and the social conditions that promoted the rise of democracy. Catholicism has therefore been seen as a conservative tradition whose opposition to Protestant rationalism gave rise to the Counter Reformation and to Baroque culture and institutions. The stark interiors of northern Protestantism were clearly demarcated from the exuberant and luxurious interiors of southern Catholic Europe.

The authority of the Church universal was further compromised by the growth of nationalism and the nation-state. The Peace of Westphalia (1648) produced a political system of nation states and forced the churches to operate within national boundaries. The French Revolution created the modern notion of national citizenship and a secular republican tradition that profoundly challenged European Catholicism. Modernization has been necessarily associated with secularism and the growth of scientific criticism of revelation as the foundation of Christian belief. Radicals like Marx and Engels regarded socialism as a necessary condition for the effective criticism of religion as part of the ideology of a dominant class. In addition, the growth of secularism had paradoxical consequences for European Judaism by offering Jews the possibility of assimilation, when the French National Assembly granted civil rights to Jews in 1791. Marx had argued that 'the Jewish Question' could not be solved merely by the political emancipation of Jewry but only by a social transformation of society. The spectre of assimilation broke the Jewish community into reform and counter-reform traditions, but European anti-Semitism continued to exclude Jews from public life and laid the foundations for the Holocaust. Mass emigration of Jews to the USA has profoundly changed the religious demography of Europe.

The dramatic decline of institutional religion in the twentieth century gave rise to the secularization thesis in the 1960s (Wilson 1966). The contrast between the USA where religion appeared to flourish and the secularity of most European societies was a topic of considerable interest. In America, the consequence of post-war migration was to convert religious identity into a sign of American membership (Herberg 1955), whereas in Europe religious affiliation was more persistently associated with class membership (Thompson 1963). Contemporary research on religious institutions in Europe has been less triumphal in its assessment of secularization in recognising the continuing importance of religion for what sociologists have called 'collective representations' (Durkheim 1954).

Whereas post-war studies of religion were preoccupied with the study of church–state relations, the Protestant–Catholic divide, and the survival of religion under communism, contemporary research has been interested in the impact of globalization, the growth of non-Christian religions and the rise of new religious movements. While the Christian churches have institutionally declined, religious cultures continue to flourish in European society.

2. *Secularization Thesis*

It has been a basic assumption of the sociology of religion that the Christian churches in Europe have, from the nineteenth century, been subject to a profound and ineluctable process of secularization. While there is clear evidence of secularization in the sense that membership of, and participation in, Christian churches have declined, religious identity continues to play a generic role in national identity and consciousness. In *The Social Teaching of the Christian Churches*, Troeltsch (1931) argued that the oscillation between church and sect that had shaped much of European history had come to an end with the final erosion of the universal church. Religious life would become a matter of private belief and practice. The growth of an urban industrial society had undermined the social, cultural, and intellectual conditions that made religious attachment and belief possible (MacIntyre 1969). While sects continue to flourish, there is incontrovertible evidence of the institutional decline of mainstream Christianity (Wilson 1976). Within this general pattern of decline, there are however discernible differences between the predominantly Catholic and Protestant regions and states

(Martin 1978). Catholicism has remained a dominant cultural force in Italy, France, Spain, Portugal, and Poland. In France an estimated ninety percent of the population is Roman Catholic and two percent is Protestant. In Ireland, 92 percent are Catholic and 80 percent attend church weekly.

Catholicism, prior to political liberalization in the late twentieth century, was central to the expression of nationalism in continental Europe and remained a major counter force to communism. Recognition of the importance of Catholicism for moral leadership of the working class produced a notion of 'hegemony' in the study of European politics (Gramsci 1971). The social and cultural influence of Catholicism has been closely associated with its control over education. In Ireland, for example, while the state provides over 85 percent of funding, Catholic boards of managers generally control schools. The dominance of the Catholic Church on the European right guaranteed that regional, party, and class divisions were often drawn along religious lines.

After the Second World War, Catholicism also played an important cultural and political role in relation to atheist communism. The Polish Solidarity movement decisively demonstrated the capacity of Catholicism to survive communism and to act as a conduit of social protest and change, because it is embedded in national identity. Irish national identity and republicanism have also been thoroughly merged within a Catholic tradition. Despite the Catholic Emancipation Act (1829), the Protestant–Catholic divide in Northern Ireland has remained an obstinate fact of political life. Owing to the political alienation of the population to the pre-1922 British state, the majority equate being Catholic with being Irish. With the end of the Cold War and the fall of communism, Catholicism may play a diminished role in the articulation of nationalism and national identity. In Spain, General Franco rose to power in 1936 following his attack on the socialist government. Franco's regime was decidedly Catholic and supported traditional values against godless atheism, but the collapse of the Franco regime following his death in 1975 has resulted in the diminution of the public authority of the Catholic Church. Economic prosperity and growing multiculturalism in Eire has also brought about the beginning of a partial divorce between state and church.

In Protestant societies, the relationship with the state has been more remote, and hence the political influence of the churches has been obscured. While the Catholic Church has largely resisted Protestant infiltration in France and Italy, the Protestant countries have been religiously more diverse and the churches have enjoyed a privileged rather than a monopolistic position. In the Lutheran traditions of Scandinavia, the churches have been incorporated into the state, where religious functionaries became a component of the state bureaucracy. In Norway, Article 2 of the constitution proclaims both the existence of religious freedom and recognises the Evangelical Lutheran religion as the official religion of the state. In practice, the separation of church and state is recognised, despite the fact that the cabinet has the right to appoint bishops. In the UK, the Church of England functioned as a national church with the monarch as head, but religious tolerance and pluralism have been accepted principles of Lockean liberalism. In the UK there has been no real equivalent to Bismarck's *Kulturkampf* to secure cultural homogeneity. The political transition from a confessional state to religious pluralism has been typical of English political gradualism in which discriminatory laws against Catholics and Jews were pragmatically abandoned rather than explicitly rejected by an assertion of religious equality. While the devolution of powers to regional parliaments in Scotland and Wales has weakened the political significance of the Church of England, Anglicanism will no doubt remain an important ingredient of Englishness. The UK has been a society of 'tolerant discrimination' rather than a fully-fledged melting pot in the American tradition (Boyle and Sheen 1997).

Prior to the unification of Germany in 1990, religion played an important part in defining the cultural differences between East and West Germany. In the united Germany, the constitutional right of return to Germany by ethnic Germans (*Aussiedler*) has insured cultural homogeneity and implicitly reinforced the role of religion as an essential element of being German. Around eight percent of the population are foreigners who are not permitted citizenship, and their children may have difficulty in obtaining naturalisation. The Weimar Republic rejected a state church, but Hitler destroyed the liberal constitution in 1933 and established National Socialism on the basis of one people, one state, and one leader. In the 1949 constitution, the separation of church and state was recognised, but religious education in state schools was a constitutional obligation. In contemporary Germany, approximately 45 percent of the population are members of the Evangelical Church and around 37 percent are Catholic. Because Christian traditions play an important part in national identity, there is some tension between Catholics and Protestants (for example over Christian symbols in state schools).

3. *Migration and Multiculturalism*

The history of religion in western Europe has been dominated by two issues, namely church–state relations and secondly the cultural divisions between Protestantism and Catholicism. This historic pattern has been shaken by two inter-related processes, namely the secularization of society and the globalization of the European economy. Post-war European economic prosperity has combined with a greying population to

produce a multicultural society that satisfies its labor market needs by migrant labor. The working-age population of Europe is declining rapidly and by 2030 it is estimated that the ratio of working taxpayers to nonworking pensioners in Germany and Italy will drop to 1:1. Young migrants, whose fertility rate is typically higher than the host population, are filling the gap between workers and non-workers. This structural dependency on foreign labor has drawn in significant numbers of non-Christian migrants, whose presence is permanently changing the cultural map of Europe. In many European countries, the foreign migrant community is 10 percent of the host population. The most significant group, both in numbers and influence, is Muslim. There are 10 to 13 million Muslims in Europe, and in Germany the foreigners will make up 30 percent of the population by 2030, most of whom will find employment in cities such as Munich and Frankfurt.

Global aging and labor shortages in the developed world will insure that immigration and religion remain on the political agenda of European societies. Migrants from Pakistan to the UK, from Turkey to Germany, from the Middle East and North Africa to France, and from Indonesia to the Netherlands have produced a diasporic politics that has raised fears about the impact of Islamic fundamentalism on democratic institutions in Europe. In Germany, Turks and Kurds entered the labor market in the 1960s and 1970s, and these 'guest workers' are now a consistent more or less permanent second generation, amounting to approximately two million people. While many of these migrants are secular, Islamic organisations play an important part in their social and political organisation. In France, there is a strong nationalist feeling that North African Muslims (*maghrebins*) cannot assimilate to French republican culture. The *hijab* case (*l'affaire des foulards*) in 1989 caused a divisive public debate about the desire of Muslim girls to wear the *hijab* in state schools. The French intellectual Left regard secular schools as important for personal liberation from religious ideology, while the Right interpret the hijab as an attack on French national custom. In English culture, there has been an established tradition of distrust towards Islam that can be illustrated for example by hostility to translations of the Qur'an in the sixteenth century (Matar 1998). In recent legislation, there has been some accommodation to the beliefs and practices of other religions, such as the acceptance of customs relating to the wearing turbans by Sikhs, animal slaughter, and solemnization of marriages. However, the 'Rushdie Affair' involving the publication of *The Satanic Verses* in 1989 by the novelist Salman Rushdie and the *fetwa* placed on him polarized British public opinion, and reinforced the public perception of Muslims as fanatics whose culture is fundamentally incompatible with parliamentary democracy and liberal values. The Rushdie Affair confirmed the view of many intellectuals that European culture is fundamentally racist and that its world-view is deeply Orientalist in which the Muslim has become 'the Other' (Said 1978). In France, a poll by *Le Monde* in 1989 revealed that about 70 percent of the French population associate Islam with fanaticism. Attempts by Muslim intellectuals living in Europe to counteract these negative stereotypes have had little impact on the general population (Ahmed 1992). The difficulties of finding a peaceful solution to the Middle East crisis and the apparent failure of the Oslo agreement as illustrated by the Palestinian Intifada will continue to fuel hostility towards Islam (Turner 1994).

4. *Conclusion: Religion and Civic Culture*

Latin Christianity had created a common religious and political culture in medieval Europe. The Reformation and the division of Europe broke this dominant culture into competing states with distinctive national religious traditions. The growth of nationalism in Europe had very diverse consequences for the churches, but religious symbols, often combined with epic literature and folk culture, have been indispensable for the creation of nations as 'imagined communities' (Anderson 1983). This vitality of religious symbols in nation formation has been constructed on the basis of conservative hostility to both secularism and communism. The dominant transformations of religion in the twentieth century have been brought about by the secularization of Europe and the decline of communism as a significant atheist alternative to theological belief systems. In the twenty-first century, the religious map of Europe is changing once more as globalization has created cultural hybridisation. The new component of this ideological cartography is Islam, but there are other changes that have come to the attention of social scientists, namely the emergence of new religious movements and alternative expressions of religious consciousness involving syncretism (Hamilton 1995). Europe governments have frequently attempted to curb the development of such sects by legislative means. There is considerable public anxiety about New Age groups, Scientology and Jehovah's Witnesses. In 1995 the British home secretary refused entry to the Rev Sun Myung Moon who had planned to enter the UK to hold services for the Unification Church. In Germany, the federal government has identified 25 sects that are seen to be a threat to 'democratic values.' These religious problems of a multicultural society are now a generic aspect of European politics, and are indicative that the traditional Protestant–Catholic–Jewish divisions of European politics have been further complicated by global hybridity (Robertson 1992). Changes in the nature of the study of religion as a European institution are thus reflections of the growth of global religious cultures.

Western European Studies: Society

Scholars of Europe have long been driven by an infrequently stated question: what confluence of social factors accounts for the fact that this small subcontinent came effectively to dominate the world by the end of the nineteenth century? This question predates the advent of 'Western European studies,' but Western European studies have nevertheless had to come to terms with it.

Weber's assertion that Western Europe's position in the world was the product of a unique and unrepeatable set of economic, cultural, and political factors that together produced a novel form of advanced industrial society forms a frame for the present examination of how Western European studies have approached 'society.' The strengths as well as the fault lines of the field are still shaped by Weber's claim, even as the society Weber took as his model has changed almost beyond recognition. Some contemporary scholars go so far as to question whether the very foundations of European dominance—industrial capitalism and the nation–state—can any longer meaningfully be said to exist in a Europe characterized by post-industrialism and supra-national integration. Others insist that both the nation–state and the set of complex social relations that developed along with the rise of industrial capitalism, however modified by late twentieth century transformations, continue to form the basis for a distinctive Western European society.

1. Models of Western European Social Development

Beginning in the mid 1960s, Western Europe's extraordinary world historical success was taken up with renewed vigor among social scientists. This new wave of socio-historical scholarship set itself against earlier modernization literature (see *Modernization, Sociological Theories of*) and its frequently unhistorical assumptions regarding the portability to the developing world of the modern Western nation–state form. It returned to Marx's and Weber's insistence that attention to historical specificity and nuance be drawn into the service of effective theory building.

1.1 Determinants of European Dominance

A catalog of determinative societal features, the unique combination of which is found in Western Europe, includes:

(a) the formation of highly centralized, authoritative, and bureaucratic national states;

(b) the homogenization and integration into nations of disparate regional subcultures that, crucially, were already less stratified than outside Western Europe;

(c) the development of citizenship;

(d) the rise of capitalist industrialization and the attendant destruction of traditional ways of life; and

(e) conflict between aristocratic, commercial/bourgeois, urban working, and rural peasant classes.

1.2 State Building

That the formation of strong states preceded—historically and logically—the construction of coher-

ent nations has become widely accepted. Powerful, centralized states evolved out of the feudal system of 'parcellized sovereignty,' as Weber characterized it. For Anderson (1974), these absolutist regimes of Western Europe represent a 'paradox' of social and political development central to the idea of Western modernity: absolutism protected aristocratic privilege and property, yet also provided the opportunity for rising urban commercial classes to promote their interests. Tilly (1975) elaborates the characteristics of absolutist 'stateness' as the formal autonomy of government, differentiation from nongovernmental organizations (such as the church), centralization, and internal coordination, and agrees that the benefits of strong states were not the monopoly of the states themselves: rights and privileges also accrued incrementally to subject classes. These social and political rights—the unplanned offspring of absolutism—were protected by the increasingly bureaucratic apparatus of states, forced by the logic of their own development to recognize procedural norms. Tilly also highlights how extraction of taxes from the bourgeoisie helped build state structures.

With extraction comes repression. One of Moore's (1966) many contributions is to insist that violence, both on behalf of and against ruling classes, be given its due place in understanding Western state-building processes. Where absolutism eventually led to distinctively Western liberal democratic outcomes, violence was a key part of the process. In England, enclosures eliminated a traditional peasant way of life, and the Civil War beheaded a king. The French Revolution made war on the landed elites. (This model does not hold for all contemporary democracies in Western Europe. As Tucholsky 1973 said in 1930, 'Due to inclement weather the German revolution was held in music.') The winner—ultimately throughout Western Europe—was the bourgeoisie, whose interests no longer had to vie with traditional elites for state protection.

1.3 Nation Building

Strong states only developed into nation–states where social and cultural integration occurred within their boundaries. This process of nation building has been the subject of an enormous and diverse literature (see *Ethnonationalism, Cultural Concerns*). Why did it happen in Western Europe?

Some commentators ask whether this is even the right question, suggesting that a previous generation of scholarship depicting nation building as part of a vast process of modernization exaggerates the depth and extent of national integration. Grillo (1980) argues that there are few, if any, states in Western Europe where integration is complete, and finds the 'European repertoire' from which the concept of nation is constructed to be arbitrary. Rogers (1991) shows that even in France, the archetypical case of a homogeneous, integrated nation, enormous local and regional socio-cultural differences persisted late in the twentieth century.

New research, however, continues to demonstrate that Western European societies are indeed more fully integrated than most others. In a comparative study of demographic integration, Cotts Watkins (1991) looks at how the process of national integration in the nineteenth century was accelerated by the expansion to the national level of previously local networks and institutions, such as transportation, communications, education, and labor organizations. Diverse patterns of fertility began to converge, and in turn spurred the processes of state building and market integration.

Again, why in Western Europe? Anderson (1983) offers an explanation linked to the development and dissemination of national print languages that in their adoption superseded both Latin and spoken vernaculars. These languages, combined with the distributive technologies of capitalism, allowed for dramatically increased communications among nascent bourgeois classes. These classes formed the basis for assimilative 'imagined communities,' or nations: constructed, perhaps even artificial, yet nations nonetheless.

Elias (1939), largely unread and unrecognized until the 1970s, takes a very different approach to the question of European particularity in constructing homogeneous nations. Elias places his startlingly detailed empirical account of the development of manners within a broader theoretical discussion of civilizing and state-building processes that subjected entire classes to new codes of 'civilized' social conduct. By his account, bourgeois civil society could develop within the confines of the absolutist state only because it adopted certain recognizable social features of court society.

1.4 Social Dimensions of Citizenship

The realm of civil society in which citizenship developed is contained within the classical nation-state form. The rights and obligations of citizenship are enjoyed by members of the 'nation,' subject to the structuring influence of the 'state.'

Habermas (1962) makes a distinctly social case for the development of citizenship within a uniquely Western European public sphere. He notes that 'public' was long synonymous with 'the state,' but that the structure of absolutist societies in England and France allowed for a parity of educated persons—bourgeois as well as aristocratic—to engage one another as social equals outside the confines of state structured (court) relations. These social innovations had direct political consequences, but Habermas argues that the public sphere could only emerge

through the impetus of a new form of society that allowed citizenship fully to develop.

The very social bases of citizenship, according to Pateman (1988), rest upon civil society's gendered foundations, firmly embedded in the theoretical premises of the social contract itself. This has far-reaching consequences for the conduct of social life, including derogating the importance of the familial. The establishment of the originary social contract on gendered grounds exposes supposedly 'universal' categories—liberty and equality, for example—as inherently particularistic and misogynist.

Gauthier's (1977) critique of the social contract is even more damning. For Western European societies, the social contract is far more than a theory; according to Gauthier contractarianism is an ideology, a deep structure that orders every aspect of social life. This ideology justifies rights, duties, and institutions, both between persons and between persons and society. The central institution justified by the contract is the market, acquisitive participation in which is the hallmark of Western European humanity. For Gauthier, the central problem with the social contract as ideology is that it is designed both by and for bourgeois men. Not only women, but workers as well have been denied full access to its institutions, and can therefore be regarded as less than wholly human.

2. *Consolidation and Inclusion*

If the socio-historical processes leading to the construction of Western European nation–states were unique, equally so was the nature of the consolidation of those states after two world wars. Western European studies have lavished attention on the nominally inclusive quality of this period. The explosion of industrial capitalist development was more regulated in Western Europe than elsewhere in the First World. Economic prosperity allowed for the institutionalization of social services that would have been considered utopian by nineteenth century social democrats. 'Abstract,' 'exploited' labor, previously subject to the destructive market forces that Marx and Weber agreed typified capitalist society, might now become 'social' labor, secure in a network of meliorating and compensatory social, economic, and political compromises.

The term 'bounded capitalism' is frequently used in Western European studies to denote a distinguishing set of institutional attributes, including unemployment insurance, healthcare systems, social security, industrial policy and relations, macroeconomic policy, national financial institutions, and social bargaining. As Gourevitch (1986) argues, despite important differences among Western European countries in the extent to which they adopted these institutions, bounded capitalism became the norm rather than the exception in the postwar period.

2.1 *The Welfare State*

The postwar Western European social compact built around bounded capitalism, in contrast to the purely abstract universal inclusiveness of social contract theory and the socially exclusive attributes of contractarianism discussed above, promised fully to integrate once excluded classes. Indeed, one of the welfare state's initial successes was to mitigate the demographically disruptive effects of postwar industrialization by absorbing displaced rural populations. In addition, welfare policy helped redistribute social risks from the community and the family to the state.

Modernization theory holds that welfare filled a 'functional' vacuum created by the encroachment of the market into household and community based economies. The functionalist argument continues to find adherents. Kaelble (1987), for example, argues that the generous welfare states of Northern Europe developed out of necessity where older people could not rely on the family for support. Given the extended family structure of Southern Europe, in contrast, less state support was necessary. Modifying functionalism, Korpi (1983) finds that generous social policy developed in Sweden because groups who needed it were able to mobilize themselves in its support. The comparative strength and 'resource power' of national working-class movements, in this analysis, are decisive in determining diverse welfare outcomes. Marxist critiques, in turn, suggest that the origins of mid-twentieth century social policy lay in the conservative cooptation of trade union demands by Bismarck and other late nineteenth century *Realpolitikers*, thereby further legitimating class domination. These origins at the confluence of private capital, wage labor, and state policy, says Offe (1984), are reproduced in persistent structural contradictions between the incompatible needs of capitalist accumulation, social security, and state regulation.

Another approach to the political economy of welfare states situates social policy regimes within an analysis of class coalitions and other institutional factors. Esping-Andersen (1990) delineates three principle types:

(a) 'social democratic' (Scandinavia), which achieved a high degree of 'decommodification' (i.e., protection of citizens from the insecurity of the market) and extensive cross-class support;

(b) 'conservative' (continental Europe), where somewhat lower levels of decommodification were nevertheless fairly comprehensive, and supported by a broad social consensus; and

(c) 'liberal' (Anglo-Saxon countries), where individualist social traditions prevented political agreement on generous benefits.

Rhodes and Mény (1998) add that continental policies were strongly influenced by church and social reformers. An important contribution of such approaches is to suggest that, during the heyday of

welfare capitalism, the social contract was effectively rewritten in some parts of Western Europe, and only modified in others.

2.2 Interest Representation

The literature on interest representation that dominated scholarly discourse from the 1950s to the 1970s, based on an Anglo-Saxon pluralist model, took interests, their representation, and the mediating role they played in the social structure as given. The pluralist model, derived from liberal individualist principles, assumed that all interests were theoretically equal, and equally capable of being represented within the social system. More recent studies, based on European evidence, have tended to problematize interest formation and representation.

An important result has been the corporatist model of interest representation (Schmitter 1979). Corporatism describes forms of associational behavior in which organizations are less competitive than in pluralism, and where certain types of interests—especially labor and capital—are status prioritized within the system of interest representation. The corporatist model is most useful in describing the inclusive, mid-century phase of Western European development. Its applicability to late twentieth century social structures is significantly more controversial (see below, Sect. 3).

For Touraine et al. (1984) the conflict between the workers' movement and the interests of capital lies at the very roots of European modernity. If market capitalism is characterized in part by its socially disintegrative force, then the outcome of the labor/capital conflict will alter—for better or worse—the structure of social solidarities and stratifications. Until the economic crisis of the 1970s, Western European labor and capital got along better than in any other part of the world. To the extent that this was achieved largely outside the bounds of a formal plebiscitary process, some argue that the outcome came at the expense of full democracy. As Berger (1981) puts it, interest groups in Western Europe perform crucial functions that were once the exclusive province of political parties and governments, which suggests a fundamentally new and expanded role for 'society' as against markets and politics. If this was once so, the economically and politically driven process of European integration has since altered the structure of interest representation.

2.3 New Social Movements

Another way to look at the putative rise of society is as a fusion of the political and nonpolitical spheres. The so-called New Social Movements (NSMs) that began in Western Europe with student unrest in the 1960s moved a wide array of 'social' issues into the 'political' realm, and mobilized new classes and generations of social-political actors.

NSMs are considered by most commentators to be new above all in comparison with the classical social movements, especially labor. These older movements were defined by their relation to the power structure (disadvantaged), their goals (class benefit), and their methods (institutional pressure) (Tarrow 1989, Tilly 1978). NSMs, in contrast, often work outside formal channels of political pressure, are driven by profuse mobilizing agendas not necessarily linked to the direct advantage of the social actors themselves, and are frequently made up of the economically and socially privileged.

NSMs are seen as reformist and parochial, without the socially transformative potential that labor represented. Offe (1987) sees the movements emerging out of growing affluence and the interests of social actors 'peripheral' to the labor market whose mobilization is enabled by the generosity of the welfare state. Tarrow (1989) suggests that the fused social/political structures of the 1970s and 1980s created opportunities for the expression of new grievances. Habermas (1981) sees NSMs as a defensive reaction to the encroachment into private life of threatening capitalist and bureaucratic structures. Kreisi et al. (1995) argue that 15 years' worth of NSM activity corresponds directly to altering party alignments in different countries, that is, the movements arose due to political opportunity structures. Inglehart (1990) sees these opportunity structures as opening because of intergenerational change and 'postmaterialism.'

3. Decline of the Nation-state?

The coherence and authority of European nation-states, and the way in which social life is ordered within them, have been subjected to powerful tests since the 1970s. Restructured economies, the decline of the labor movement, European integration, immigration, welfare and demographic crises, increased social inequality, and a host of other challenges have assaulted the stability of the boom years and eroded the social compact that characterized postwar bounded capitalism.

Some scholars ask whether the structural integrity of the nation–state, and the modified social contract premised upon it, can survive such supranational pressures. Wieviorka (1992) suggests that three basic components of Western European social life—industrial society, an egalitarian state, and national identity—have become distorted to such an extent that dangerous obverse tendencies are gaining ground: 'postindustrialism' has produced social selfishness and declining solidarities; state institutions find it difficult to act on egalitarian principles due to fiscal pressures; and nationalism has become increasingly linked with xenophobia. Others, most notably Milward (1992),

argue that Western European responses to recent challenges, at both the national and supranational levels, have actually strengthened the nation–state's social legitimacy and authority.

While the denationalization of economic production and the decline of Fordist industrial structures may or may not have produced a 'postindustrial' society in Western Europe, it is widely agreed that exogenous change in the form of European integration and globalization have reduced the abilities of national governments to effect socially bargained, market-correcting economic policies and to counteract increasing social inequality. The extent to which these changes have undermined the bases for corporatism is the subject of a lively debate (Scharpf 2000).

3.1 Crisis of the Welfare State

Welfare states throughout Western Europe have cut their benefits, and face fiscal and demographic crises of varying degrees. Aging populations create a shift from system contributors to recipients, deindustrialization and 'Eurosclerosis' have produced high unemployment, and the labor market has been transformed by the growing proportion of nonstandard work and the mass entrance of women into the workforce.

Central to recent literature on the welfare crisis are issues of gender and family. Feminist scholars have criticized the political economy approach to welfare state studies because in concentrating its attention on the state and market, it ignores the family and the structural ramifications of women's unpaid domestic work, and in focusing on 'equity' without considering gender, it falsely universalizes equality. At an even more fundamental level, Orloff (1993) asks whether welfare state scholarship is correct to assume that welfare states actually promote overall social well-being and security, since its premises are putatively sexist.

Because of two trends, even 'mainstream' Europeanist welfare state scholars must now acknowledge the issue of women's role in the labor market and the family. First, many women entering the workforce take part-time or fixed term employment, and are penalized because benefits are geared toward men working full time (Rhodes and Mény 1998). Nonstandard work is also becoming more common among men. Second, fertility rates have plummeted since the 1960s. Rates are lowest in countries with low levels of female employment and stingy welfare benefits (e.g., Italy and Spain). From a rationalistic economic point of view, argues Becker (1981), families decide to have fewer children as it becomes more expensive to raise them. By extension, in Scandinavia, where the welfare state is supportive of women's work and child rearing (through day-care facilities, healthcare, etc.), fertility rates have not dropped as dramatically through the late 1990s.

3.2 Immigration and Exclusion

As populations age and fertility declines, immigration becomes increasingly crucial to Western European societies. Since at least the 1960s, 'guest workers,' at the invitation of governments, have filled holes in the job market and replaced falling birth rates. Their role has been complex: needed for their labor, but resented for their 'otherness,' guest workers and other immigrants have challenged norms of inclusion. In spite of Western Europe's liberal, pluralist, universalistic premises, cultural differences have at times been racialized as part of an exclusionary ideology and derided as impediments to civic incorporation.

Migration patterns, especially in Western Europe, were established in the 1960s by two flows: guest workers, most of whom came from southern and eastern Europe (including Turkey) at the implicit or explicit invitation of states, and immigrants from former colonies. With the significant exception of southern Europe, which changed in the 1980s from a region of emigration to one of immigration, these patterns still largely hold through the end of the century (Miles and Thränhardt 1995).

Rates of naturalization among European countries vary considerably. Brubaker (1992) attributes France and Germany's sharply different rates to fundamentally different conceptions of sovereignty and assimilation. The French, Brubaker says, understand the nation as the creation of the state, while for the Germans the nation is the basis of the state. Soysal (1994), in contrast, argues that postnational international norms have led to 'deterritorialized' notions of rights. She challenges the assumption that citizenship is imperative to membership, since many social rights are enjoyed by noncitizens.

The rights of immigrants, regardless of how they are acquired or conferred, are often shown to be in conflict with actual social treatment. Racist conceptions of otherness tied to immigration, according to Taguieff (1988), are 'differentialist' in their invocation of fundamental cultural distinctions between 'natives' and 'foreigners'; this contrasts with an older 'inegalitarian' notion of biological differences. Indeed, racism has accompanied immigration throughout the region, even while some commentators (e.g., Wieviorka 1992) see important national variations. Others see Western European-wide patterns of racism and exclusion emerging. Balibar and Wallerstein (1988) argue that the most effective defense against this trend is a solid conception of universal civic equality, which should replace more problematic notions of national identity and belonging.

3.3 Social Policy

The extraordinary process of European integration that began modestly in the early postwar years and

accelerated toward the sweeping treaties of the 1990s was primarily economic and secondarily political in motivation, structure, and outcome. Yet, an accompanying social aspect of European unification has begun to receive scholarly attention, namely, the nature of social policy within the authoritative structure of the European Union (EU).

Europeanists ask whether the elevation of economic and political authority to the EU level will find a correlate in social policy. Leibfried and Pierson (1995) argue that a 'social Europe' already exists, and is actively engaged in policies of redistribution, thanks in part to the efforts of trans- and cross-national pressure groups percipient enough to recognize that in certain issue areas power resides in Brussels, not national capitals. Ireland (1995) notes that on immigration issues, EU administrators have taken an activist stance to protect foreign workers and their families, stepping in where national governments have failed to uphold human rights. But Streeck (1995) cautions, first, that EU intervention in a few areas does not reflect an ideologically driven reformist agenda. Second, the EU is beholden to market interests, and will withdraw any move toward social intervention if it threatens market dominance. Streeck's view implies that corporatism at the national level has been defeated by European integration (for a counter argument see Scharpf 2000); indeed, he claims that labor was present in the integration process only insofar as it represented a European-wide market for labor.

3.4 Collective European Identity

Does a transnational European social constituency exist that might eventually force the EU to take more aggressive steps to alleviate market produced inequities and nationalistic exclusionary practices? More abstractly, is the idea of vesting citizenship and collective identity in 'Europe' far fetched? Given the horrific record of twentieth century European nationalisms in protecting human rights and maintaining peace, might superseding the nation-state not be an evolutionary advance?

Scholars occupied less with policy analysis than with theoretical questions of identity and membership have recently addressed these questions. Habermas (1996) argues that the nation–state is mortally ill, and has been in decline since it began to repudiate and exclude everyone regarded as foreign. The process of moving from national to supranational regimes and governance should be viewed as part of the unfinished historical process of modern nation building. The initial steps of nation building in Europe, when the nation replaced disintegrating traditional ties of early modern society, Habermas asserts, is precisely analogous to the present situation in which national sources of solidarity and the moral bases of society are eroding. But what is to replace problematically national sources of identity and belonging? Habermas suggests that pan-European attachment to a shared political culture in the form of an enlarged and fully inclusive public sphere may develop, and that it is the only alternative to increased particularism in multicultural states.

National identities historically evolved through simultaneous inclusion and exclusion, such that every 'us' was defined against an opposing 'them.' Delanty (1995) questions how a collective European identity might develop without asserting an exclusionary 'Fortress Europe,' geographically defined by the shifting borders of the EU. The contemporary idea of Europeanism is not morally neutral, suggests Delanty, but rather constructed through technocratic and media-driven agendas that can neither replace national nor constitute collective identity. Smith (1997) articulates a view widely held among Western Europeanists: firmly entrenched national identities will continue to trump supranational European identity because the affective bonds that support nationalism do not exist for Europe as a whole.

Whether and how such pan-European bonds might develop will occupy scholars in coming decades. The social bases of European nation–states did not grow organically; they were constructed along with the nation-states themselves. The interplay between national form and social content has been based in part on national, regional, and global power factors. These dynamics are fluid, as the process of European integration demonstrates. If economic and political integration can find an inclusive social correlative, exclusionary nationalisms may indeed be mitigated.

K. W. Moore

Whig

Originally a term of abuse, 'Whig' is a term used to describe a diverse, yet identifiable, party or grouping which was historically important in Great Britain from the late seventeenth century to the mid-nineteenth century. Although now extinct, its ideas and sympathies left important legacies to nineteenth century political life and culture. It is also used to refer to a party, also now extinct, which flourished in the United States in the second quarter of the nineteenth century. Although the Whigs in both countries shared a set of attitudes and dispositions rather than any coherent political doctrines or ideology, the term 'Whig' may still be used in contemporary political discourse.

1. *The British Whigs*

The Whigs were the dominant force in parliamentary politics in the eighteenth century and they remained important in the first part of the nineteenth century. Founded in opposition to Charles II, they embraced the principles of the 'Glorious' English revolution of

1688 and were supportive of the Hanoverian succession of 1714. The Whigs rejected royal absolutism and by extension any claims by the monarch to exercise personal authority. The Whigs' central ideas emphasised the virtues of limited government, the importance of a balanced or mixed constitution based on parliamentary power and representation based on property not individual rights. Whig thought was especially influenced by the writings of John Locke (1632–1704) and the classical republicanism of James Harrington (1611–77). Whig ideology thus stood in contrast to Tory views about the prerogative rights of the Crown on the one hand and radical populism and democratic individualism on the other. Under Sir Robert Walpole (1676–1745) the Whigs' loyalty to these ideas introduced a new and relatively coherent party character into parliamentary politics, although the ties which bound the Whig Party were likely to be personal and familial rather than doctrinal. Given that formal party organization was not a feature of parliamentary politics until the mid-nineteenth century, social ties were especially important in binding the Whigs together. Whigs were largely, but not exclusively, drawn from the aristocratic and landed interest which to some extent explained their conviction that there was a natural link between a strong property-owning class and the protection of liberty.

The Whig Party, although a recognizable entity in British politics, was never wholly united. In addition to personal rivalries and generational differences, there were severe splits over the American revolution of 1776 and the French revolution in the eighteenth century and parliamentary reform in the nineteenth century. The French revolution saw the Whigs split into two antagonistic groups in 1794: those who opposed the violence inherent in the revolution and who supported war with France and those who looked more favorably on the revolution and could see no cause for war with France. The criticism of the French revolution was led by Edmund Burke (1729–97) who in his *Reflections on the Revolution in France* (1790) and his *Appeal from the New to the Old Whigs* (1791) provided a defence of gradual constitutional change which influenced later conservative thought. The pro-French party was associated with Charles James Fox (1749–1806).

The new political agenda created by industrialization and democratization in the nineteenth century further weakened the Whigs. As the expansion of the franchise created new pressures to organize outside parliament as well as within it, the Whigs found their ideas and their politics eclipsed by radicals and liberal reformers who stressed the rights of individuals and looked to the state to effect social, economic, and political reform. With the formation of the Liberal Party in the 1850s, the distinctive character of the Whigs was eroded. In the party realignments over the Irish issue in 1885–6 the Whigs finally lost their identity and the word largely went out of political currency.

2. *The American Whigs*

The theorists of the American revolution shared much of the intellectual heritage of the English Whigs in their emphasis on constitutionalism, balanced government and liberty, and their admiration for classical republicanism. American whiggery also parallelled the aristocratic and landed character of English whiggism in its appeal especially to the plantation owners of the south. And whiggism had a strongly Protestant appeal in the United States as in England.

A separate and distinctive Whig Party did not however arise in the United States until 1834 when a loose coalition of opponents of President Andrew Jackson (1767–1845) and his policies emerged around the leadership of Henry Clay. The name 'Whig' was deliberately taken to signal the new party's opposition to Jackson's assertive view of presidential power (which evoked memories of monarchical rule) and support for national development in contrast to Jackson's agrarian populism.

The coalition which formed the Whig Party included the National Republican Party, supporters of Henry Clay's American System, the anti-Masonic party, and anti-Jackson Democrats. Although the Whigs could not agree on a presidential candidate in 1836, in 1840 they united around William Henry Harrison who defeated Martin van Buren. When Harrison died after only a month in office, John Tyler, a strong supporter of states rights, succeeded as President. Tyler became increasingly distanced from the Whig Party's more nationalistic senior figures Clay and Daniel Webster. The Whig Party won the presidency again in 1848 with Zachary Taylor. The Whigs were the majority party in the Senate between 1841 and 1844 and controlled the House of Representatives between 1841–2 and 1847–8.

Millard Fillmore, Taylor's vice-president who succeeded to the presidency on Taylor's death in 1850, was the last Whig president. Regional and policy divisions, especially over free soil and slavery, weakened the Whigs in the 1850s and the Party ran its last presidential candidate, Winfield Scott, who lost against Franklin Pierce in 1852. Factions of the old Whig Party were subsequently absorbed into the Democratic Party and the Republican Party which in 1860 nominated a former Whig, Abraham Lincoln, as its presidential candidate.

3. *Contemporary Usage*

Although rarely used in contemporary political debate the term 'whig' is occasionally used to refer to liberals who are suspicious of democratic populism and abstract political theories, believing instead that political liberty is best promoted by the preservation of property and reforms rooted in the specific institutions of a society. It is also still used to refer to a school of historical writing which sees historical development as

a benign, purposive, and progressive process. Although this so-called 'whig view of history' is most commonly associated with nineteenth century writers such as Thomas Babington Macaulay (1800–1859), it may be used more broadly to refer to any evolutionary historical theory.

White-collar Workers, History of

1. Preliminary Remarks

Although now in many developed industrial societies white-collar workers represent, at least in numerical terms, the single most important group within the general workforce, their delimitation and their specific social profile in relation to blue-collar workers and public servants remains ambiguous and controversial (Kocka 1980, 1981, Lockwood 1989). With hardly any other social stratum was and is the complex interrelation between the actual appearance of a group, its self-definition and its treatment as an object of investigation so clear as with the white-collar employees.

The sociological interest in these groups has a long tradition which dates back into the late nineteenth century. It arose mainly for two reasons: (a) the exceptional rapid growth of the various groups, labeled as 'white-collar workers,' *Angestellte*, *employŭs*, *impiegati*, *empregados*, etc. and (2) the fact that these groups, with regard to some objective features of their working conditions, aspects of their legal status, as well as their consciousness and their behavior, differed markedly from other social groups already established. Interest was nowhere so strong as in the German-speaking countries, where, as a field of the emerging social sciences, a special *Angestelltensoziologie* developed. This pecularity was mainly due to the existence of a radical labor movement and of a strong bureaucratic tradition. The institution of the privileged 'civil servant' served as a role model for many white-collar workers and attributed much to the relative depth of the distinction in relation to the blue-collar workers in the respective countries. However, comparative historical research shows that the terms 'white-collar workers,' *Angestellte*, *employŭs*, *impiegati*, and *empregados* are in no way interchangeable. The delimitation and, particularly, its social 'meaning' vary strongly historically and from country to country. Though much of the special social profile of the various groups labeled as 'white-collar' has faded away, there still remain some important differences, especially in relation to blue-collar workers.

2. Definition by Functional Criteria

In many countries in everyday language as well as in scientific usage the term white-collar worker refers to a group of dependent workers which, compared to manual or blue-collar workers, is occupied not directly in the process of manufacturing. Rather it is situated in functional as well as in spatial terms *before* the process of manufacture, *beside* it and *behind* it. One encounters white-collar workers in all economic sectors, even agriculture, at least, as it is organized commercially and as a large-scale business. However, the actual domain of the employees is the service

Table 1
White-collar workers in the US, GB, and Germany 1882–1950 (in percent of the total labor force)

	USA	GB	Germany
1882			6.1
1900	12		8.5 [1895]

Note: These numbers include white-collar employees in private businesses as well as in the public sector

Table 2
Percentage of women in white-collar occupations in Germany, 1882–1982

Year	All sectors	Office and public service	Sales personnel	Engineers and technical personnel
1882	11.7		19.0	
1895	14.7	4.5	30.0	
1907	19.7	16.8	42.0	
1925	29.7	34.5		4.4
1933	34.6	36.0	77.9	
1939	39.8	47.0	79.1	6.0
1950 (FRG)	38.6	40.0	78.3	8.6
1970	49.2	50.3	81.5	12.0
1982	52.4	64.6	80.5	11.1

sector; that is, trade, banking, insurances, where they always made up the predominant part of the workforce. In addition, large groups of employees are to be found in industry and the public sector. Since the end of the nineteenth and above all in the course of the twentieth century employees have increased their share in all sectors considerably in all developed societies compared to that of manual workers and public servants (see Table 1).

With respect to their productive functions white-collar workers differ from manual workers in that they—varying with the economic sector in which they are employed—perform directing, overseeing, constructive, analyzing, administrative, commercial, and information-processing tasks. These criteria may lead, in many cases, to a clear distinction between manual workers and white-collar employees in private enterprises. They are hardly suitable for a clear distinction between officials or civil servants (*Beamte*) and employees (*Angestellte*) in the public sector. The functions of these two categories normally overlap. But the upper ranks of the hierarchy are staffed by employees with the status of civil servant (Humphreys 1958). *Beamte* and *Angestellte* differ by legal status rather than by types of functions.

3. *Origin and Growth*

The origins of some white-collar professions may be traced back to the premodern period. Among them figure, for instance, the commercial employees which at that time still had a good chance to reach the status of a self-employed salesman later in life. Nevertheless as a mass stratum one has called white-collar employees rightly the 'latest child of industrial capitalism.' Two main developments contributed to the rapid growth of the group: (a) the shifting balance between the 'first' (agriculture) and the 'second sector' (industry) in favor of the 'third,' the service sector (Fourastiй 1963)—a development that took place first in Great Britain while other industrial nations followed suit in the course of the nineteenth and twentieth century; (b) the rise of 'Organized Capitalism' (Hilferding 1981) since the end of the nineteenth century, a phase characterized by the growing importance of organization, planning, information-gathering, bureaucratic control, and the creation of structures within and outside industry to serve these ends. The relative growth of the share of the employees within the public sector, however, is determined not only by changes in the function of the modern state but also to a large extent by the political will either to expand or to restrict the spread of particular privileges attached to the status of civil servant (*Beamte*). Such privileges are, for example, the protection against dismissal and pension schemes, etc.
