As recent social data show, even in the most advanced contemporary industrial societies the expansion of white-collar jobs has not yet come to an end. But there are clear signs that the rate of expansion slowed down significantly in the second half of the twentieth century. As with all social growth, the creation of white-collar jobs as a strategy to tackle problems arising from the development of economy and society as a whole is subject to the law of diminishing returns. While in the early stages of industrial capitalism white-collar employees were instrumental in the process of rationalizing production—a fact that caused widespread resentment among manual workers—in further stages they were themselves subjected to strategies of cost-cutting and rationalizing. This development began very soon after the turn of the twentieth century with the introduction of specific office machines as the typewriter, the Hollerith-machine—an early form of large-scale data-processing—and other changes in the structure and organization of office work. This process definitely has gained a new quality in recent years. In particular, the spreading of the computer, the communication revolution, and the integration of office work into controllable networks has opened new chances for quantitative control of employee activities once considered to be typical only for manual work. Whether

this tendency is outweighed by other trends towards 'lean management' and more autonomy on the job remains to be seen.

4. Status and Privilege

The Swedish–German sociologist Croner (Croner 1951) developed his 'theory of delegation,' according to which most early white-collar jobs in industry emanated through a process of division of labor and of delegation out of functions originally performed by the employer. This theory has been questioned by empirical research. Especially in modern industries many tasks performed by white-collar workers actually represent new functions without any historical precedent. It seems highly questionable that *all* early functions classified as white-collar carried with them high prestige. Especially, in the area of small-scale shop-keeping there existed extremely exploitive working conditions for clerks with low pay, no job security, long working-hours, etc. (Anderson 1976, Crossick 1977). Nevertheless, it holds true that many white-collar occupations enjoyed at least some form of privilege in comparison with manual workers, and continue to do so. Some of the differences resulted from the specific nature of their work that could not be subjected easily to quantitative methods of control. One of the traits that distinguished most—not all—white-collar jobs from blue-collar functions was a fixed income, the 'salary,' that, at least in principle, did not vary with working hours or the amount of work carried out. Because of the fact that knowledge of business transactions within the specific firm constituted the main qualification of many white-collar employees, the accumulation of such individualized knowledge gave members of the group a higher job security than manual workers, especially in the early stages of industrialization. Even in later days, the office never became the place for a general 'hire and fire' climate. As many positions of white-collar workers were integrated into large, delicately differentiated bureaucratic hierarchies, aspirations for upward mobility never vanished completely. Besides, in many countries there were, traditionally, legal privileges attached to certain white-collar occupations. These entitlements included protection against dismissal, paid vacation, continuation of wage payment in the case of illness, company pensions schemes, etc.

The idea that the class of white-collar workers as a whole would face 'proletarianization,' as put forward especially by writers in the Marxist tradition, has given way to a much more nuanced picture. At earlier stages of the development legal privileges attached to certain types of white-collar workers were generalized among larger groups. Moreover, the French sociologist Michel Crozier has argued that the consequences of rapid rationalization were often absorbed by the constant influx of female workers. Though the equation 'proletarianization-feminization' does not come out, there is some degree of truth in it. New styles of management—the movement towards 'lean management' since the 1980s, for instance—have amplified autonomy and reopened scope, at least, for certain groups among the white-collar population. On the other hand there can be no doubt that a process of narrowing and even blurring of differences between blue-collar and white-collar workers took place in the course of the twentieth century. Important groups within the white-collar population, especially clerical workers and sales personnel, have been overtaken by skilled manual workers in terms of income, job-security, even prestige. Many of the rights once attached exclusively to certain white-collar positions have, step-by-step, been granted to the workforce as a whole, making white-collar workers, at least in some countries such as Germany, important, if involuntary, harbingers of the modern social state. Though, on average, white-collar workers still appear to be privileged in relation to the manual workforce, the 'average' white-collar worker largely has become a statistical fiction due to the immense variety of positions and professions that nowadays characterize these categories.

5. Organizational Behavior

Depending on the structure of the trade union movement within the respective countries, white-collar workers tend to organize exclusively or are integrated into general unions (Behringer 1985, Bain and Pollins 1965, Bain 1972; Jenkins and Sherman 1979). In most cases union membership among white- and blue-collar workers overlaps at least to a certain degree. The main area in which both groups differ is trade union membership in general. White-collar workers are considerably less well organized than manual workers with the one exception of the public sector. Hence, their growing weight among the workforce represents one of the most important factors in the crisis of the trade union movement in developed countries in general.

6. National Differences and Pecularities

While in most industrialized countries the division between white- and blue-collar workers was never clearly marked or valid only in regard of relatively small groups, in some European countries such as Austria, Czechoslovakia, Switzerland, and Germany until the middle of the twentieth century, blue- and white-collar workers constituted distinguished entities, separated in many aspects, legal as well as organizational and ideological. Social legislation, es-

pecially pensions schemes, had been enacted before and after the First World War. They had an important impact, strengthening existing differences between white und blue-collar workers. The dividing line between the two groups structured large parts of the fabric of these societies—legislation, trade union movement, self-help organizations, political affiliations, etc. By the 1950s, the distinction between white and blue collar had begun to erode gradually, a development that was supported by the expansion of former white-collar privileges to the general workforce. Another important aspect in which German-speaking countries before the Second World War differed from other societies was the sheer size of the legally defined white-collar population which included sales personnel as well as general managers.

7. *Social Theory*

White-collar workers were introduced into the realm of modern social science at the end of the nineteenth century. The starting point was twofold: (a) the notion of a growing number of occupations, employments, and functions that shared many traits of the working-class while at the same time differing in important aspects from manual workers as well as from the higher social strata; (b) the exceptional rapid growth of these categories in the decades around the turn of the century which even outdid that of the manual workers.

The most intensive debates on white-collar workers took place in German-speaking countries from about 1890 up to the 1930s against the background of the formation of strong labor movements (largely blue-collar) and of a political system, dominated by conservative elites eager to defend the status quo and in search of numerically important allies among the general population. In the first stage of the debate, which took place before the First World War, status quo-oriented scholars identified white-collar workers as part of a new socially stable and conservative 'middle estate' and, at the same time, encouraged the state to engage in a social-protective policy (e.g., white-collar specific insurances and labor laws) while Marxist theorists predicted a general proletarianization of these groups. The 1920s saw a convergence of opinions, reinforced by the sceptical notion that the 'new middle class' in German-speaking countries seemed to figure prominently among the mass base of National Socialism. The label of a potential for right-wing extremism has stuck to the group ever since, not least through the intellectual influence of German social scientists, many of whom were forced to emigrate in the early 1930s (Fromm 1984, Speier 1986). The notion showed up again in many theories of Fascism developed in the 1950s and 1960s, generalizing what was seen to be the experience of the interwar years (Lipset 1960). In contrast, social historians who took up the debate in the 1970s tried to demonstrate the pecularities of the German and Austrian experience (e.g., Kocka 1980) while latest research has challenged the notion of a predominantly right-leaning, 'new middle class' in the 1920s altogether (Falter 1991).

The debate over the role of white-collar workers in the mass base of National socialism represented the climax and at the same time a turning point. Interest in interpretations of the white-collar group as a whole has subsided (but see Schulz 2000) in Germany as well as in other countries where it never figured prominently.

Not surprisingly, with regard to the heterogeneity of the group, social science attributed contradictory attitudes and social functions to these groups, often departing from specific traits of subgroups. One important theme over the decades has been the impact the expansion of white-collar occupations has had on the emancipation of women, whether it offered new opportunities for social mobility or whether it only helped to reproduce traditional inequalities (Suhr 1930). There has been much research on the impact of rapid technological change on office work through the decades, some with more pessimistic, others with more optimistic overtones. Studies of the service sector, for instance, stress its relative resistence to change as a result of the need to maintain a workforce even when there is no constant demand, a fact which has been labeled 'guard labor.' Other scholars have pointed to the partial regain of autonomy on the work-place as part of the automation movement in the 1970s which was said to have led to the formation of a 'new worker' (Mallet 1963). Actually, the debate referred to members of the technical staff supposedly holding key positions for potential labor disputes. Another important context was the rise of modern consumer society since the First World War in Europe and the United States. The concentration of large numbers of white-collar employees in larger cities led to the identification of them with the urban population as a whole, regarding them as pioneers of modern consumption and new forms of leisure (Coyner 1977). This notion dates back to the influential study first published in 1924, of the German social writer, Siegfried Kracauer (Kracauer 1998) and translated into many languages ever since. It has been taken up in various studies of the historic development of modern consumption and leisure, leaving out, with regard to the white-collar population, those members of the group living in smaller and middle-size cities.

Though, in the second half of the twentieth century, interest for white-collar employees in the social sciences has flared up from time to time, there seems to be no future for any revival of a wholesale white-collar worker sociology as it developed in some European countries during the interwar years. One of the most important prerequisites, the existence of a self-conscious socialist working-class, no longer exists. With

its disappearance the interest of social science, policy-makers, and the different groups that make up this strata to develop a broad definition based upon the distinction between 'us,' the 'white-collar,' and 'them,' the 'blue-collar workers,' seems to have vanished. What remains is a remarkable gap between the numerical importance of the group in question and its relative neglect by social scientists in the last decades.

Williams Syndrome

In the final decades of the twentieth century, cognitive neuroscience paid particular attention to a group of disorders known as microdeletion syndromes. These are neurodevelopmental disorders in which the missing genes on a chromosome can be identified and the resulting gene-behavior relations explored. They differ from syndromes like Down syndrome in which an entire extra chromosome is present, as in Trisomy 21. One microdeletion disorder that caused particular excitement among cognitive neuroscientists is Williams syndrome (henceforth WS). This is because WS results in an unusually uneven cognitive profile. Language and face processing are seemingly spared, whereas other higher cognitive functions (spatial cognition, number, planning, and problem solving) are seriously impaired. Initial characterizations of the syndrome at the cognitive level seemed to hold the promise of relatively straightforward gene-cognition

mappings. WS was, and continues to be, hailed as the prime example of some intact, innately specified cognitive modules in the face of general intellectual impairment (e.g., Pinker 1994, 1999). However, more recent evidence fails to support this view, favoring instead a more dynamic, neuroconstructivist approach to genetic disorders. In this entry, the cognitive processes underlying the purportedly spared domains will be examined, together with a focus on the infant starting state and the developmental trajectory leading to the phenotypic outcome.

1. *Williams Syndrome: Genetic Profile*

Williams syndrome is a rare developmental disorder and occurs in approximately 1 in 20,000 live births. It is caused by a submicroscopic deletion on chromosome 7q11.23. The deleted region contains some 20 genes, about 17 of which have been identified (Ewart et al. 1993, Frangiskakis et al. 1996, Meng et al. 1998, Tassabehji et al. 1996). Only a few of these genes are expressed in the brain and are therefore of special interest to the cognitive neuroscientist. Others affect the physical development of patients, particularly with respect to impairments to the cardio-vascular system.

Initial excitement came from the discovery that in the majority of cases of WS one copy of the elastin gene (ELN) (Ewart et al. 1993) and one copy of the Limkinase1 gene (LIMK1) (Frangiskakis et al. 1996, Tassabehji et al. 1996) were consistently deleted. ELN is important for elasticity of the heart, skin, blood vessels, and lungs. Its deletion was therefore rapidly linked to the facial dysmorphology and supra-valvular aortic stenosis (SVAS) found consistently in individuals with WS (Ewart et al. 1993). LIMK1 is expressed in the developing brain and its deletion was claimed to explain the typical pattern of spatial impairments found in the cognitive profile of such individuals (Frangiskakis et al. 1996, Mervis et al. 1999). Despite the claims about the role in WS of the ELN and LIMK1 genes in facial dysmorphology and spatial cognition respectively, direct one-to-one genotype/phenotype mappings are highly unlikely in cognitive neuroscience, as a subsequent study by Tassebehji and collaborators showed (Tassabehji et al. 1996). Three patients with SVAS were examined who had partial deletions on chromosome 7 in the same region as the clinical groups with WS. The study showed that despite the ELN and LIMK1 deletions, none of these patients had the facial dysmorphology typical of WS, nor did they display the uneven WS cognitive profile of impaired visuo-spatial cognition and enhanced linguistic capacities. They all had an even cognitive profile within the normal range. The results indicate that the ELN deletion does not alone explain the facial dysmorphology found in WS. They also suggest that the LIMK1 deletion is either irrelevant to the development of spatial cognition or that its expression interacts with a number of other genes to contribute to the spatial impairment. But it is clear that one-to-one mapping between specific genes and higher cognitive outcomes does not hold.

2. *Williams Syndrome: Phenotypic Profile*

The pioneering work of Bellugi and her collaborators initially pointed to some clear-cut dissociations in the cognitive architecture of WS. Language and face processing appeared to be surprisingly preserved in the face of both general retardation and particularly serious problems with visuo-spatial cognition, number, planning, and problem solving (Bellugi et al. 1994). Researchers in the field of WS have been fairly cautious about their claims, referring to relative strengths and weaknesses rather than absolute ones (Bellugi et al. 1999, Karmiloff-Smith 1998, Klein & Mervis 1999, Mervis 1999, Tager-Flusberg et al. 1998, Vicari et al. 1996, Volterra et al. 1996). By contrast, secondary sources cited in writings by linguists, developmental psychologists, neuropsychologists of adult brain damage, and philosophers have often used Williams syndrome to bolster claims about innate and independently functioning modules, some of which are purportedly intact and others impaired (e.g., Pinker 1994, 1999). This stems from the view that the pattern of behavioral performance found in the phenotypic outcome is a direct window on the purported innately specified, modular structure of the cognitive architecture of the brain (Baron-Cohen 1998, Leslie 1992, Temple 1997). Such reasoning treats the genetically impaired brain as if it were a normal brain with parts intact and parts impaired, ignoring the dynamic role of genetic mutation in interaction with environmental input in fostering overall brain growth. This has been particularly the case with studies of autism and Williams syndrome, in which cognitive impairments in older children and adults have been used to make claims about gene expression, in the absence of studies of the starting state in infants.

Recent studies of infants, children, and adults with WS strongly suggest that the starting state cannot be simply inferred from the phenotypic outcome (Paterson et al. 1999). Infants with WS were compared with chronological (CA) and mental-age (MA) matched infants with Down syndrome (DS), as well as MA and CA-matched typically developing controls. Despite the fact that WS adults perform significantly better than DS adults on vocabulary tasks, WS infants are as seriously impaired on vocabulary tasks as are DS infants. Moreover, despite WS adults having significantly worse problems with judging numerosities in adulthood than DS adults and control groups, WS infants perform normally, like the CA-controls, and significantly better than DS infants. In other words, the patterns obtaining in infancy turn out to be the opposite of the patterns in adulthood, pointing to the

importance of the dynamics of developmental trajectories over time, rather than a static view of the infant starting state and the phenotypic outcome.

Even in cases where the phenotypic outcome seems to display spared performance, in-depth analyses suggest that people with WS process inputs via different cognitive processes (Karmiloff-Smith 1998). In the domain of vocabulary, individuals with WS do not obey the same lexical constraints as normal controls when learning new words. In the domain of syntax, WS adults tend to display patterns typical of much younger children rather than intact performance (Klein and Mervis 1999). For example, it has been claimed that individuals with WS have intact regular past tense formation of verbs, alongside impaired associative lexical processes (Clahsen and Almazan 1998). Recent research challenges this claim in that once verbal mental age is taken into account, WS patients display no selective deficit for irregular verbs (Thomas et al. 2001). Specifically, the WS data can be placed on the normal developmental pathway found in much younger subjects. These various results are consistent with the hypothesis that the WS language system is seriously delayed because it has developed under different constraints.

WS language is not simply delayed, however. Several studies now suggest that there is an imbalance in WS at different times in development between phonology and semantics (Karmiloff-Smith 1998, Thomas et al. 2001). For example, when WS participants monitor sentences for a target word, they do not show sensitivity to certain sentential violations, suggesting that in WS semantic information may become available too slowly to be integrated with the online processing of syntax. A study of reading in WS came to similar conclusions about the weak role of semantics in learning to read new words. The WS group displayed equal levels of reading for both concrete and abstract words. By contrast, the controls found concrete, imageable words much easier to read. In general, imageability effects have been shown to be weaker in people with WS (Karmiloff-Smith 1998). A more recent study by Vicari and his colleagues demonstrated that, compared to normal controls, word learning is superior in WS if the auditory presentation of a word is accompanied by the simultaneous presentation of a photograph depicting the object (Vicari et al. 2000). This seems to be because, unlike normal controls, people with WS are defective in spontaneously forming a visual (semantic) image of auditorily presented words. Finally, when learning new spoken words and despite a vocabulary test age of 8, people with WS behave like 4–5 year olds, and do not show the pattern typical from 6 years onwards in the normal population. Like very young children, WS patients are less influenced by the semantics of the real words that the nonce terms resemble. Rather, they rely more on phonology. Taken together, a variety of studies suggest that, unlike typical development, phonological representations are at times stronger than semantic representations in their influence on the way in which WS language develops.

Although it is becoming increasingly clear that vocabulary development does not follow a normal developmental trajectory in WS and that semantics places a weaker constraint on WS language development than in typical controls, it remains possible that WS syntax is intact, as many have claimed (e.g., Pinker 1994, 1999). There are, however, a number of lines of evidence to doubt this. First, vocabulary levels are usually better than syntactic levels in WS on various standardized tasks, although both are significantly below chronological age (Karmiloff-Smith 1998). Second, even in very simple imitation tasks, participants with WS show impairment with complex syntactic constructions such as embedded relative clauses. These and various other findings in different laboratories are hardly consistent with the view that WS syntax is intact. Even in an area of relatively simple syntax—grammatical concord over sentence elements—which young, normal French-speaking children acquire easily and early, people with WS show impairment even in adulthood (Karmiloff-Smith 1998). Although the WS children learn the local gender marker (correct article) for a nonce term easily (in fact, more easily than control children), their capacity for gender agreement across sentence elements such as agreement on adjectives or pronouns is seriously impaired. Studies of Italian-speaking children have also revealed that grammatical gender is a particular problem, with WS children displaying errors never encountered in normal development (Volterra et al. 1996). Several studies (e.g., Klein and Mervis 1999) now suggest that the problems that people with WS have with semantics and syntax are often camouflaged by their good verbal memory. This again demonstrates that overt behavior is not necessarily an index of underlying cognitive competence.

A similar conclusion holds for the domain of face processing. Despite reports that WS face processing is intact (Bellugi et al. 1994, Rossen et al. 1996), in-depth studies of face processing suggest that individuals with WS use different strategies from normal controls (Karmiloff-Smith 1998). Several studies (Deruelle et al. 1999, Karmiloff-Smith 1998, Udwin & Yule 1991) have replicated earlier work, revealing normal or near normal behavioral scores on standardized tasks like the Benton Facial Recognition Test (Benton et al. 1983) and the Rivermead Behavioural Memory Test (Wilson et al. 1985). However, these studies have seriously challenged the notion that the behavioral success displayed in WS face processing capacities is subserved by normal cognitive processes. Where normal controls use predominantly configural strategies for processing upright faces and featural strategies for processing inverted faces, the WS patients tend to process the featural details of both upright and inverted faces. These different strategies have been

further explored in brain imaging studies (Mills et al. 2000). When older children and adults with WS have to match faces in an event related potential study, they display temporal processes found at no age in normal controls. They also tend to process faces bilaterally or predominantly with the left hemisphere, whereas normal controls show a right hemisphere bias for faces. All of these findings point to atypical face processing in WS, despite the normal behavioral scores.

3. Concluding Comments

Developmental cognitive neuroscience must take development seriously. The WS brain is 20% smaller than normal brains and qualitatively different in terms of brain anatomy (Bellugi et al. 1999), brain chemistry (Rae et al. 1998), and computational processing (Mills et al. 2000). This holds throughout embriogenesis and postnatal brain development and means that interaction with environmental stimuli will be subtly different. Given a very different brain, it is unsurprising that even when overt behavior seems normal, as in some aspects of WS language and face processing, these skills actually turn out to be underpinned by cognitive processes that are different from the normal case (Karmiloff-Smith 1998).

Williams syndrome is an excellent model for the neurocognitive study of genetic disorders, because of its strikingly unusual cognitive profile. The syndrome is especially important because of the way in which in-depth research highlights the need to go beyond both observable behavior and static descriptions of snapshots of developmental outcomes, to the charting of neurocognitive trajectories from infancy onwards.

Wisdom: Philosophical Aspects

Wisdom is not a central topic of contemporary philosophy. Today's philosophers seem to confirm Nietzsche's observation: 'When philosophers meet among themselves they start casting off all sorts of wonderful rubbish; above all … they hang up "the love of wisdom" like stuffy robes of office' (Nietzsche 1980a, p. 511). Common sense, on the contrary, still expects wisdom to be provided by philosophy, and the discipline's social reputation is partly based on this expectation. But as contemporary philosophy seems scarcely inclined or able to fulfill this demand, common sense draws on forms of wisdom from non-occidental cultures or from esoterics. While 'wisdom' is a term rarely used in contemporary philosophy, the literature about wisdom from the esoteric and the anthropological–cultural side is flourishing.

There is nothing wrong with sensing deficiencies in the academic field and turning to other sources instead. Yet in the second part of this article I will demonstrate that contemporary philosophy can in fact provide a great many elements of wisdom appropriate for our times. The first part is devoted to an accurate reconstruction of the main historical turns in the philosophical understanding of wisdom.

1. *Philosophy—A Concept Introduced by Plato*

As is commonly known, philosophy is related through its name to wisdom: 'philo-sophy' (in Greek: *philo-sophia*) means 'love of wisdom' or 'quest for wisdom' (in Greek: *sophia*). But this concept of *philosophia* corresponds neither to the original understanding of philosophical thinking nor to that of wisdom. The concept of *philosophia* was first created by Plato in the first half of the fourth century BC.

1.1 *The Pre-Platonic Understanding of Philosophy and Wisdom*

Philosophers before Plato neither deployed the term 'philosophy' nor described their enterprise with respect to wisdom (*sophia*). Rather, they characterized their doctrines as 'histories'. Moreover, the Greek understanding of wisdom—as paradigmatically expressed in the topical talk of the 'Seven Sages of Greece'—focused on practical, not theoretical knowledge. In everyday language, a wise person was just an expert of some kind or other (a craftsman, artist, doctor, military leader etc.); in order to be included in the catalogue of the Seven Sages his work had, in addition, to be of extraordinary political relevance. So Thales, the only ancient philosopher ever to figure among the Seven Sages, was included in this group not as a philosopher, but as an astronomer and engineer who brought military success to his community by predicting an eclipse and redirecting a river.

1.2 *Plato's Turn*

What, then, is the specific sense of Plato's introduction of the concept of *philo-sophia*—an innovation so successful that his concept is commonly taken to be *the* concept of philosophy altogether?

Three shifts are characteristic. First, the emphasis in the understanding of *sophia* as well as *philosophia* is put on theory instead of praxis. Philosophers observe the nature of things not for the sake of practical usage but for that of pure cognition. The new concept of philosophy is strictly opposed to the old practical aims of *sophia*. Second, a border line is drawn between

philosophy and wisdom: philosophers can only *strive* for wisdom—without ever actually reaching wisdom. This is why philosophy is defined as *philo*-sophy (*love* of wisdom), not as wisdom proper (*sophia*). 'Philosophy' implies an element of modesty and limitation. Thirdly, this limitation cannot be overcome—complete wisdom is reserved for the Gods only. By philosophizing we do not surpass philosophy to actual wisdom.

1.3 Strategic Implications

Plato's innovation was directed not only against the traditional and the everyday understanding of wisdom but above all against his contemporary competitors, the Sophists. In everyday language at Plato's time—where compositions with '*philo*' had long since become popular—'philosophizing' (*philosophein*) was a term without any extravagant meaning; it just meant studying, educating oneself, being inclined to reflective activity. So Plato's declaration that wisdom is impossible for humans and reserved to the Gods alone discredited not only the mythical Seven Sages but also his compatriots' devotion to philosophical activity and above all the Sophists, who at the time of Plato roved from city to city offering, for payment, lessons in rhetoric, virtue, poetry, mathematics, music or astronomy. As their name (*Sophists*) indicates, they were considered to be bearers of wisdom (*sophia*). The idea that they were in fact frauds—Plato was constantly trying to discredit the Sophists as dealers in fake knowledge, and as being the morally and intellectually dubious counterparts of the real philosopher—was the logical result of Plato's redefinition: If wisdom is altogether unattainable for humans, then the Sophists who masquerade as teachers of wisdom, must obviously be frauds.

2. Philosophy's Claim to Represent True Praxis and Wisdom

The introduction of modesty and limitations in matters of wisdom with the new concept of philosophy was an efficient strategy in distancing the Sophists, but once this was achieved the proponents of the new concept soon turned to more ambitious claims. Philosophy was successively considered capable of representing the utmost fulfillment of both practical and theoretical wisdom.

2.1 Philosophical Theory as the Highest Praxis

The move from a practical to a theoretical emphasis was meant as an empowerment of philosophy in matters of true praxis. The traditional concept of praxis, so characteristic of the original understanding of wisdom, was criticized for having in fact provided only a concept of pragmatic utility, one ignoring the very kind of praxis pertaining to the full accomplishment of human life. This higher and true sense of praxis was to be fulfilled precisely by philosophy in the new sense of theoretical activity. This tendency is obvious already in Plato, who always conceived of philosophy as the best way of human life, with respect to both the philosophizing individual and societies complying with philosophical insights. Aristotle (in his emphatic eulogy of theory in *Nicomachean Ethics* X, 7–9) declared the theoretical life to be the best and highest form of human praxis and life altogether. Significantly enough, he explained the supremacy of theoretical life by contrasting its self-sufficiency with the purposeful orientation of ordinary practical life: according to him, philosophical theory is the only activity 'loved for its own sake; for nothing arises from it apart from the contemplating, while from practical activities we gain more or less apart from the action.'

2.2 Philosophy as Wisdom Proper

Although Plato had initially declared wisdom to be reserved for the Gods, he made the border between human philosophy and divine wisdom permeable. Ultimately philosophizing should result in a *homoiosis theo*, a 'becoming like the divine' (Plato, *Theiatetos*, 176 b 1 f). Aristotle definitely dropped the Platonic reserve. According to him, philosophy and wisdom are one—his appraisal of philosophical *theoria* in *Nicomachean Ethics* X, 7–9 is one of *sophia*. In theoretical life, he says, we realize 'the divine in our midst' and hence our 'true Self'. With Aristotle, '*philosophia*' is no longer a modest term inferior to *sophia*. Hegel's phrase that philosophy should 'lay aside the title "*love* of knowing" and be *actual* knowing' (Hegel 1977, p. 3) is Aristotelean in spirit.

3. Reaccentuating the Practical

3.1 Theory's Open Flank

But philosophy's effort to completely absorb the older practical aspects of wisdom has an open flank. In his theoretical attitude the philosopher may well possess the utmost theoretical knowledge—but this is not to possess all kinds of knowledge: genuinely practical insight, ethical knowledge and situational prudence (*phronesis*) are lacking. And, although theory may represent the highest form of praxis, it cannot as such replace all forms of praxis. Hence, specifically practical knowledge—lying outside theoretical *sophia*—requires respect and clarification in addition. This applies all the more, given that practical knowledge is (as, quite properly, Aristotle was the first to demonstrate) of an intrinsically different type from theor-

etical knowledge. So the new concept of philosophical theory, as impressive as it may be, remains in need of supplementation. Genuinely practical knowledge (which is so decisive for all our everyday orientation) requires a different approach.

3.2 *Hellenistic and Roman Philosophy*: *The Return of the Sage as a Practical Expert*

Following Greek philosophy's classical period, a return to conceiving the sage as an expert in practical matters took place in Hellenistic and Roman philosophy (with the Epicureans and Stoics). The sage once again became a figure of outstanding practical knowledge and exemplariness, knowing how to lead the best life. From now on wisdom was seen as the archetype of accomplished living. Theoretical capacities were to serve this goal.

This understanding of wisdom prevailed even in modern times. So Montaigne defined the sage as someone who appreciates that 'our great and glorious masterpiece is to live appropriately' (Montaigne 1958, p. 851). Kant too still declared that 'the teacher of wisdom through doctrine and example,' 'the practical philosopher,' 'is the real philosopher' (Kant 1992, p. 537). Even today we still expect a wise person to embody the right mode of human living.

4. *Middle Ages*

The Christian philosophy of the Middle Ages had trouble with wisdom. In the Bible the wisdom of this world had been declared to be foolishness before God (*Paul*, 1 *Cor*. 3:19; similar 1 *Cor*. 1:20 and *Romans* 1:22). This did, on the one side, have its advantages over pagan thinking, but on the other side it also called into question the very possibility of reasonable reflection and hence of Christian philosophy altogether. At the least it imposed severe limitations. Some philosophers tried to settle the conflict by developing the doctrine of 'double truth.' But distrust of purely human knowledge—be it wisdom, reason or science—prevailed. Luther was later to renew the accusation that reason is 'the devil's whore' (Luther 1964, p. 164, cf. also Luther 1967, p. 82).

5. *Philosophy in League with Science—Not with Wisdom*

In modern times, philosophy's ally has been science not wisdom. When philosophers, occasionally, do still use the term 'wisdom' what they actually have in mind is science. So Descartes uses 'wisdom' as just another name for the sum total of science (Descartes 1998, p. 65). Even Kant, though affording wisdom the highest rank, emphasizes that 'science … is the narrow gate that leads to the *doctrine of wisdom*' (Kant 1993, p. 171). Husserl was to resume this modern emphasis on science instead of wisdom by declaring 'science has spoken, from now on wisdom has the task of learning' (Husserl 1965, p. 63).

6. *Modern Philosophy's Practical Intentions*

But modern philosophy has a strong practical side too. It comes in two flavors: as technical purposiveness along the lines of science, and as moral-practical orientation taking up older elements of wisdom.

6.1 *Technical–Practical Side*

From the start modern science was addressed to technical ends. It was in this respect that Bacon and Descartes commended it. Marx then claimed that philosophy should become altogether practical—and thus realize itself by vanishing as philosophy. Even if this project has failed, the prospect of technically reshaping reality has proven widely successful.

6.2 *Moral–Practical side*

Complementary to this scientific-technical strain, to which wisdom is irrelevant, practical aspects of wisdom survive in modern philosophy's other strain, the practical one devoted to ethics and morals. It is here, if anywhere, that 'wisdom' can be a substantial term in modern times. Descartes had already conceived of ethics as 'the final stage of wisdom' (Descartes 1983, p. XXIV), and Kant, having defined wisdom as 'the idea of the practical use of reason's complete conformity to law' (Kant 1983), afforded this practical wisdom the highest rank, declaring 'the practical philosopher' to be 'the real philosopher' (Kant 1992, p. 537). In the moral-practical respect wisdom retains the highest esteem.

Enlightenment philosophers, as well as their opponents, agreed that true morality—and by consequence wisdom in its practical sense—is the most important thing for us humans. Rousseau certainly emphasized, in contrast to Kant, the simplicity of moral knowledge, but even this claim to simplicity was shared by a great many philosophers of the Enlightenment. In this they could even see the great advantage of practical over theoretical knowledge: 'It took centuries to know part of nature's laws. A single day suffices to recognize man's duties.' (Voltaire 1967, p. 342) With respect to this simplicity distinguishing practical wisdom, Wolff, D'Holbach and Voltaire proclaimed Confucius, the exemplary 'simple sage', to have been the wisest person ever.

But obviously this modern line of revalidating practical wisdom was not very fortunate. Why else would we feel disoriented and lament the absence of wisdom appropriate to our times and problems?

7. Protest Against Wisdom—Nietzsche

In the course of time modern philosophers came to protest more and more against all traditional understanding of wisdom. Nietzsche is the most prominent example.

He generally suspected the traditional ideal of wisdom to have been simply a symptom of weakness. The old philosophers' 'claim that they possessed wisdom' appears to him to have always been 'a screen behind which the philosopher saves himself because he has become weary, old, cold, hard—as a premonition that the end is near, like the prudence animals have before they die: tey go off by themselves, become still, choose solitude, hide in caves, and become *wise*' (Nietzsche 1974, p. 315). The Stoic is the paradigm case for Nietzsche. His wisdom consists in making himself insensible of the tensions of life and acquiring an armor-plated attitude. Hence Nietzsche's ruthless formula: 'The stoic type. Or: the perfect ox' (Nietzsche 1980b, p. 125).

The attitude of the 'genuine philosopher' would, in Nietzsche's opinion, be completely different: he 'lives "unphilosophically" and "unwisely," above all imprudently, and feels the burden and the duty of a hundred attempts and temptations of life—he risks himself constantly, he plays the wicked game' (Nietzsche 1989, p. 125). 'The wisest person would be the richest in contradictions, who has, at it were, organs of touch for all kinds of person: and in their midst his great moments of grandiose harmony—in us too the lofty coincidence!' (Nietzsche 1980a, p. 182).

Ultimately, however, 'wisdom' remains an improper expression in Nietzsche's view—it is too strongly impregnated by its traditional meanings. Only in a critical manner can we still refer to or draw on wisdom. The first possibility is exemplified by Nietzsche's phrase: 'There is more reason in your body, than in your best wisdom.' (Nietzsche 1966, p. 146) The second is represented by a striking claim of Nietzsche: 'My wisdom has long gathered like a cloud; it is becoming stiller and darker. Thus does every wisdom that is yet to give birth to lightning bolts … For these men of today I do not wish to be light, or to be called light. These I wish to blind. Lightening of my wisdom! put out their eyes!' (Nietzsche 1966, p. 401).

Languid wisdom or lightning wisdom, wisdom as a sedative or as dynamite—this is Nietzsche's alternative in matters of wisdom. If wisdom is referred to, one should be on one's guard as to which type of wisdom is involved.

8. Epistemological Contours

8.1 Shifting from Practical to Theoretical Philosophy

The disappointment with contemporary philosophy's neglect of wisdom is flawed by one-sidedness. One assumes elements of wisdom must be found in the field of practical philosophy, where it would indeed be hard to discover any. Conversely, however, insights of contemporary theoretical philosophy provide a great many elements giving contours to a contemporary concept of wisdom. My thesis is that the design of wisdom today is to be drawn from the epistemological development in recent decades.

8.2 Recent Insights: Theoretical Reason with the Characteristics of Practical Reason

Shifting to epistemology in matters of contemporary wisdom makes all the more sense given that in recent decades theoretical reason has been shown to be characterized by traits formerly considered typical of practical reason alone. Since Aristotle the difference between the two types of reason had been considered fundamental: theoretical reason considers permanent things, whereas practical reason deals with changeable things. Correspondingly, theoretical reason demands distance and provides perfect cognition, whereas practical reason requires involvement and allows only context-dependent cognition. In recent decades, however, theoretical reasoning has been shown to bear the same basic traits as practical reasoning: theoretical cognition too represents relative, not absolute cognition; it too is context-bound and its validity is tied to specific (axiomatic, historical, social, etc.) frameworks. In short, theoretical reasoning also exhibits the characteristics of practical reasoning. This explains why the shape of contemporary wisdom can be inferred from innovations on the theoretical side.

9. Elements of Modern Epistemology Relevant for a Contemporary Concept of Wisdom

As this view is unusual, I will set out in the following the relevant elements in some detail.

9.1 From Nietzsche to Quine: The Uncertainty of Fundaments

Nietzsche can be regarded as a forerunner of the contemporary condition in having pointed out that our theoretical cognition is of a piece with practical and pragmatic cognition: 'one may certainly admire man as a mighty genius of construction, who succeeds in piling up an infinitely complicated dome of concepts upon an unstable foundation, and, as it were, on running water. Of course, in order to be supported by such a foundation, his construction must be like one constructed of spiders' webs: delicate enough to be carried along by the waves, strong enough not to be blown apart by every wind' (Nietzsche 1979, p. 85). In the twentieth century Neurath said quite similarly, 'we are like mariners who must rebuild their ship on the

open sea, without ever being able to disassemble it in dock and reassemble it with the best components' (Neurath 1932/3, p. 206). Popper's diagnosis reads: 'just when we believed that we were standing on firm and safe ground, all things are, in reality, insecure and unstable' (Popper 1992, p. 65); 'the basis is unstable' (Popper 1969, p. 76). Quine later adopted Neurath's phrase as the motto of *Word and Object* (Quine 1960, p. VII).

9.2 *Scientific Pluralism* (*Quine*)

The inevitability of scientific pluralism is a decisive insight of contemporary epistemology that was first formulated by Quine. Even in the strong realm of science no one, singularly valid theory is to be expected, but a multitude of equally valuable alternative candidates has to be taken into account. This is a consequence of the empirical under-determination of theory shown by Quine in his seminal essay 'Two Dogmas of Empiricism' from 1951: 'Total science, mathematical and natural and human, is … under-determined by experience' (Quine 1980, p. 45). Empirical tests can only tell us that something is in need of being altered in the theory, but not exactly which element is to be changed. 'Any statement can be held true come what may. Conversely, by the same token, no statement is immune to revision' (Quine 1980, p. 43).

In *Word and Object* (Quine 1960), Quine resolutely drew the consequences of scientific pluralism: 'we have no reason to suppose that man's surface irritations even unto eternity admit of any one systematization that is scientifically better or simpler than all possible others. It seems likelier … that countless alternative theories would be tied for first place' (Quine 1960, p. 23). 'We can never do better than occupy the standpoint of some theory or other, the best we can muster at the time' (Quine 1960, p. 22).

9.3 *The Impossibility of any Meta-position* (*An Insight Common to Hermeneutics*, *Poststructuralism*, *and Analytic Philosophy*)

This also means that it is impossible to assume some meta-position which would allow us to regard the multitude of scientific theories from a superior point of view and select the 'truly right' one among them. There is no God's-eye standpoint, no view from nowhere—neither in theoretical nor in practical matters. The impossibility of such a meta-stance is a decisive insight of recent philosophy that is common to all (superficially so variant) strands: to Gadamer's hermeneutics (according to which we cannot achieve a metahistorical standpoint towards history), to Lyotard's poststructuralism ('Simplifying to the extreme, I define postmodern as incredulity toward metanarratives,' Lyotard 1984, p. xxiv), and, of course, to analytic philosophy, where this insight was first formulated not by Quine, but by Wittgenstein who declared it his 'leading principle' that there is no 'metaphilosophy' (Wittgenstein 1974, p. 116).

9.4 *Wittgenstein: Limits of Justification*

Wittgenstein has developed insights crucial to the present understanding of cognition and also relevant to every conception of contemporary wisdom altogether.

First, Wittgenstein demonstrated limits of justification with respect to the certainties of common sense. These are neither based on cognition nor could they ever be secured by cognitive justification. For these certainties are by themselves constitutive of all our activities of justification: 'All testing, all confirmation and disconfirmation of a hypothesis takes place already within a system. And this system is not a more or less arbitrary and doubtful point of departure for all our arguments: no, it belongs to the essence of what we call an argument. The system is⋯the element in which arguments have their life' (Wittgenstein 1972, p. 16).

Second, Wittgenstein showed how this structure affects all our decisions: 'Nothing we do can be defended absolutely and finally. But only by reference to something else that is not questioned' (Wittgenstein 1984, p. 16). Decisions necessarily have recourse to something which they take for granted: 'the questions that we raise and our doubts depend on the fact that some propositions are exempt from doubt, are as it were like hinges on which those turn' (Wittgenstein 1972, p. 44). 'If I want the door to turn, the hinges must stay put' (Wittgenstein 1972, p. 44).

So far this means that not only the validity of scientific theories (Quine), but also of our everyday certainties and all our argumentation cannot be conclusively secured, they possess only conditional validity. In the regress of justifications one does not reach some incontrovertible ground, but only postulates, which in principle are once again questionable. While admitting good and varied justifiability, there is no such thing as an absolute, ultimate justification.

Finally, Wittgenstein has also shown how all this applies even to the whole framework of justification and argumentation (to 'rationality'): 'We can't talk of reasons for thinking … We can describe the game of thinking, but not the reasons why we think. "Reason" only applies within a system of rules … It is nonsense to ask for reasons for the whole system of thought' (Wittgenstein 1980, p. 88). What Wittgenstein wants to draw our attention to is that the quest for reasons (for example, for reasons for the whole business of reasoning) suggests leading behind this game, but obviously it does not do so: it asks the very question that typifies this game itself and thus remains within its realm.

Hence there is no possibility of justification which absolutely vouches for itself. This is expressed in the following sentence (which, significantly enough, sounds like the dictum of a sage): 'You must bear in mind that the language-game is so to say something unpredictable. I mean: it is not based on grounds. It is not reasonable (or unreasonable). It is there—like our life' (Wittgenstein 1972, p. 73).

10. Epistemic Contemporariness and Wisdom

These epistemic advances, which characterize the present state of affairs in philosophy, surprisingly also correspond to contemporary standards of everyday consciousness. The latter is molded to a high degree by the acknowledgment that all validity is relative and by an awareness of the plurality of modes of experience, cultures, forms of life and even worlds. Owing to this correspondence, the new epistemic philosophical standards are also apt to serve as maxims for contemporary everyday orientation. They match our expectations and needs in matters of wisdom, and they do so in a manner specifically appropriate to the contemporary situation.

The present understanding of wisdom typically implies circumspection, awareness of limitation, and competence in dealing with uncertainty. The sage is someone who is attentive to neighboring and commonly neglected aspects. She is aware of the context and brings it to bear regulatively. Whereas an ignorant person confidently attributes himself a grasp of the whole, the wise person objects to such totalization. She recognizes the limited nature of all singular perspectives, is aware of differing viewpoints and attentive to the open potential for additional alternatives. She warns against misrecognizing particularities, infringements and overbearingness. She advocates justice at the level of detail and openness on the whole. So the wise person is an expert in uncertainty too. Wisdom is particularly needed in situations where justice is required with respect to diverging demands without a meta-rule being available from which one could deduce the right decision. In these cases, even though it be cognized, but only found, the wise person will have a sense for what is right. Sometimes, however, it will be important just to fend off the wrong thing while leaving open what's right. Such composure also distinguishes the wise person.

Contemporary epistemology, which emphasizes the limits of all justification and demands their respect, is thus properly tailored to the aspects of wisdom just set out. It inherently works towards a consciousness which bears traits of wisdom in high measure.

This is why a state of consciousness that has incorporated those epistemic standards and which knows how to practice them can provide orientation for our time and satisfy our demands in matters of wisdom. Whoever has made this genuinely philosophical possibility her own will be in no great need of extra-philosophical and esoteric doctrines of wisdom that have become so popular in recent years.

Wisdom, Psychology of

1. Some Historical Background to the Psychological Study of Wisdom

Since the beginnings of human culture, wisdom has been viewed as the ideal endpoint of human development (Baltes and Staudinger 2000a). Certainly, the psychological study of wisdom is still rather young compared with its philosophical treatment when considering that the very definition of philosophy is 'love or pursuit of wisdom.' Historically, wisdom was conceptualized in terms of a state of idealized being (such as Lady Wisdom), as a process of perfect knowing and judgment as in King Solomon's judgments, or as an oral or written product such as wisdom-related proverbs and the so-called wisdom literature (see also *Wisdom: Philosophical Aspects*). Important to recognize is that the identification of wisdom with individuals (such as wise persons), the predominant approach in psychology, is but one of the ways by which wisdom is instantiated. In fact, in the general historical literature on wisdom, the identification of wisdom with the mind and character of individuals is not the preferred mode of analysis. Wisdom is considered an ideal that is difficult to be fully represented in the isolated individual.

Throughout history, the interest in the topic of wisdom has waxed and waned (Baltes and Standinger in press). In general, two main lines of argument have been in the center of the historical evolution of the concept of wisdom: the distinction between philosophical and practical wisdom, and the question of whether wisdom is divine or human.

In the Western world, these two issues (philosophical vs. practical; divine vs. human) were at the center of wisdom-related discourse during the Renaissance. An initial conclusion of this debate was reached during the later phases of the Enlightenment. Recently, in conjunction with value pluralism and the need for orientation characteristic of postmodern times, interest in the concept of wisdom has been revived. Finally, archeological–cultural work dealing with the origins of religious and secular bodies of wisdom-related texts in China, India, Egypt, Old Mesopotamia and the like has revealed a cultural and historical invariance with regard to wisdom-related proverbs and tales. This relative invariance gives rise to the assumption that concepts such as wisdom with its related body of knowledge and skills have been culturally selected because of their adaptive value for humankind (see also).

Among one of the major reasons for the emergence of the psychological study of wisdom in the late 1970s, early 1980s was the search for the potential of aging or, more specifically, the search for domains or types of intellectual functioning that would not show age-related decline. Life experience and wisdom as well as professional expertise, everyday problem solving or practical intelligence were selected as topics of investigation.

2. Psychological Approaches to the Definition of Wisdom

A first approach to the definition of wisdom from a psychological perspective is its treatment in dictionaries. The major German historical dictionary, for instance, defined wisdom as 'insight and knowledge about oneself and the world … and sound judgment in the case of difficult life problems.' Similarly, the Oxford Dictionary includes in its definition of wisdom 'Good judgment and advice in difficult and uncertain matters of life.'

In a next step, psychologists further specified the content and formal properties of wisdom-related phenomena. These initial efforts for the most part were theoretical and speculative. G. Stanley Hall in 1922, for example, associated wisdom with the emergence of a meditative attitude, philosophic calmness, impartiality, and the desire to draw moral lessons that emerge in later adulthood. Furthermore, writers have emphasized that wisdom involves the search for the moderate course between extremes, a dynamic be-

tween knowledge and doubt, a sufficient detachment from the problem at hand, and a well-balanced coordination of emotion, motivation, and thought. In line with dictionary definitions, such writings refer to wisdom as knowledge about the human condition at its frontier, knowledge about the most difficult questions of the meaning and conduct of life, and knowledge about the uncertainties of life, about what cannot be known and how to deal with that limited knowledge (for an overview, see Sternberg 1990).

2.1 Implicit (Subjective) Theories about Wisdom

Most empirical research on wisdom in psychology so far, has focused on further elaboration of the definition of wisdom. Moving beyond the dictionary definitions of wisdom, research explored the nature of everyday beliefs, folk conceptions, or implicit (subjective) theories of wisdom. The pursuit of answers to questions such as 'what is wisdom?', 'how is wisdom different from other forms of intelligence?', 'which situations require wisdom?', 'what is a wise act?', and 'what are the characteristics of wise people?' have been at the center of psychological wisdom research during the 1980s (for a review, see Sowarka 1989, Sternberg 1990).

These studies in principle build on research initiated by Clayton (e.g., Clayton and Birren 1980). In her work three dimensions were typical of wise people: (a) affective characteristics such as empathy and compassion, (b) reflective processes such as intuition and introspection, and (c) cognitive capacities such as experience and intelligence. The focus of a study conducted in 1985 by Sternberg was the location of wisdom in the semantic space marked by other constructs such as creativity and intelligence. Wisdom was found to be described by six dimensions: reasoning ability; sagacity; learning from ideas and environment; judgment; expeditious use of information; and perspicacity. The greatest overlap was found between intelligence and wisdom. The sagacity dimension, however, was specific to wisdom. In later theoretical work, Sternberg defined wisdom as balancing intrapersonal, interpersonal, and extrapersonal interests to achieve a common good through a balance between adaptation to, shaping of, and selection of environments (Sternberg 1998).

Another major study on subjective theories of wisdom was conducted by Holliday and Chandler (1986). A factor analysis of the attributes judged to be 'most prototypical' of a wise person and wise behavior revealed two factors. One dimension was labeled 'exceptional understanding of ordinary experience,' i.e., combining qualities of the mind with practical virtues of leading a good life. The second factor was labeled 'judgment and communication skills,' i.e., qualities like comprehending, weighing consequences, and giving good advice.

Another study in the tradition of implicit-theory research involved asking subjects to nominate wise people and subsequently characterize nominees (Sowarka 1989). Two findings were of special importance. First, it seemed that the characterization of wisdom and wise persons was a task readily performed by elderly research participants. Second, subjects emphasized the notion that the persons they had nominated as wise displayed 'excellent character.'

Finally, there is initial evidence on the implicit theories about wise acts (Oser et al. 1999). Wise acts seem to be characterized by the following seven features: (a) paradoxical, unexpected; (b) morally integer; (c) selfless; (d) overcoming internal and external dictates; (e) striving towards equilibrium; (f) implying a risk; (g) striving towards improving the human condition.

From this research on implicit theories of wisdom and wise persons, it is evident that people in Western samples hold fairly clearcut images of the nature of wisdom. Four findings are especially noteworthy. First, in the minds of people, wisdom seems to be closely related to wise persons and their acts as 'carriers' of wisdom. Second, wise people are expected to combine features of mind and character, and to balance multiple interests and choices. Third, wisdom carries a very strong interpersonal and social aspect with regard to both its application (advice) and the consensual recognition of its occurrence. Fourth, wisdom exhibits overlap with other related concepts such as intelligence, but in aspects like sagacity, prudence, and the integration of cognition, emotion, and motivation, it also carries unique variance.

2.2 Explicit Theories and Assessment of Wisdom

A more recent line of empirical psychological inquiry on wisdom addresses the question of how to measure behavioral expressions of wisdom. Within this tradition, three lines of work can be identified (Staudinger and Baltes 1994): (a) assessment of wisdom as a personality characteristic, (b) assessment of wisdom in the Piagetian tradition of postformal thought, and (c) assessment of wisdom as an individual's problem solving performance with regard to difficult problems involving the interpretation, conduct, and management of life.

Within personality theories, wisdom is usually conceptualized as an advanced if not the final stage of personality development. Wisdom, in this context is comparable to 'optimal maturity.' A wise person is characterized, for instance, as integrating rather than ignoring or repressing self-related information, by having coordinated opposites, and by having transcended personal agendas and turned to collective or universal issues. Ryff and Whitbourne, for example, have undertaken the effort to develop self-report questionnaires based on the Eriksonian notions of personality development, especially integrity or wis-

dom. Recently, wisdom, in the sense of self-development and maturity, was operationalized using various scales of the California Q-sort and was found to predict life satisfaction in old age (Ardelt 1997).

Central to Neopiagetian theories of adult thought is the transcendence of the universal truth criterion that characterizes formal logic. This transcendence is common to conceptions such as dialectical, complementary, and relativistic thinking. Such tolerance of multiple truths, that is, of ambiguity, has also been mentioned as a crucial feature of wisdom. Empirical studies in this tradition by Labouvie-Vief (1994) or Kramer et al. (1992), found that, at least up to middle adulthood, performances on such measures of adult thought evince performance increases.

Besides these measures of wisdom as a personality characteristic, or as a feature of mature thought, there is also work that attempts to assess wisdom-related performance in tasks dealing with the interpretation, conduct, and management of life. This approach taken by the Berlin wisdom paradigm is based on lifespan theory, the developmental study of the aging mind and aging personality, research on expert systems, and cultural–historical definitions of wisdom (Dittmann-Kohli and Baltes 1990, Baltes and Smith 1990). By integrating these perspectives, wisdom is defined as 'an expert knowledge system in the fundamental pragmatics of life permitting exceptional insight, judgment, and advice involving complex and uncertain matters of the human condition.'

The body of knowledge and skills associated with wisdom as an expertise in the fundamental pragmatics of life, entails insights into the quintessential aspects of the human condition, including its biological finitude and cultural conditioning. Wisdom involves a fine tuned coordination of cognition, motivation, and emotion. More specifically, wisdom-related knowledge and skills can be characterized by a family of five criteria: (a) rich factual knowledge about life, (b) rich procedural knowledge about life, (c) lifespan contextualism, (d) value relativism, and (e) awareness and management of uncertainty (see Baltes et al. 1992 for an extensive definition).

To elicit and measure wisdom-related knowledge and skills, in this approach participants are presented with difficult life dilemmas such as the following: 'Imagine, someone receives a phone call from a good friend who says that she/he can't go on anymore and has decided to commit suicide. What would the person be thinking about, how would the person deal with this situation?' Participants are then asked to 'think aloud' about such dilemmas. The five wisdom-related criteria are used to evaluate these protocols. The obtained scores are reliable and provide an approximation of the quantity and quality of wisdom-related knowledge, and judgment of a given person (see Staudinger and Baltes 1994). When using this wisdom paradigm to study people who were nominated as wise according to nominators' subjective beliefs about wisdom, it was found that wisdom nominees also received higher wisdom scores than comparable control samples of various ages and professional backgrounds.

Part of the Berlin paradigm also is a general framework outlining the conditions for the development of wisdom as it is instantiated in persons (Baltes et al. 1992). The model presents a set of factors and processes which need to 'cooperate' for wisdom to develop. First, there are general individual characteristics related to adaptive human functioning such as intelligence and personality. Second, the model presumes that the development of wisdom is advanced by certain expertise-specific factors, such as a strong motivation to find out about life, practice with difficult life situations, and being guided by a mentor. Third, the model implies the operation of macro-level facilitative experiential contexts. For instance, certain professions and historical periods are more facilitative than others. Further, given the experiences certain social–cognitive processes (life planning, life management, and life review) are assumed to be critical for the development of wisdom-related knowledge and judgment.

The empirical work based on this ontogenetic model and the measurement paradigm, produced outcomes consistent with expectations. Contrary to work on the fluid mechanics of cognitive aging, older adults performed as well as young adults (for a review see Staudinger 1999a). It seems that wisdom-related knowledge and judgment emerges between the ages of 14 and 25 years. Furthermore, when age was combined with wisdom-related experiential contexts, such as professional specialization specifically involving training and experience in matters of life (e.g., clinical psychology), even higher levels of performance were observed. In line with the historical wisdom literature, that portrays wisdom as the ideal combination of mind and virtue, it was found that wisdom-related performance was best predicted by measures located at the interface of cognition and personality, such as a judicious cognitive style, creativity, and moral reasoning. Neither intelligence nor personality independently of each other made a significant contribution to wisdom-related knowledge and judgment. The predictive pattern is of an almost complementary nature when wisdom-related performance in adolescence is considered.

2.3 Is there Wisdom-related Potential?

Researchers of wisdom are usually quite aware that it is a courageous undertaking to try to study wisdom empirically; a complex and content-rich phenomenon which, as many scholars have claimed, defies attempts at scientific identification. However, research on explicit theories of wisdom has shown that it is possible to measure wisdom in terms of a personality characteristics (standardized or open-ended), a characteristic of

adult thought, as well as performance (judgment, advice) on difficult life tasks.

Given the fact, that wisdom-related performance had been successfully operationalized, the question arose of whether it was possible to modify this performance or more specifically to increase wisdom-related knowledge and judgment. It should also be noted that, not surprisingly, the overall level of wisdom identified was below or around the theoretical mean of the scale. Thus, leaving a lot of room for improvement. So far, to our knowledge three studies have been conducted to test these ideas. One was carried out within the framework of Neopiagetian notions of wisdom. It was demonstrated that the level of reflective judgment in adolescence could be raised by presenting examples of higher-level responses (Kitchener et al. 1993).

Within the Berlin wisdom paradigm two different approaches have been successful in activating wisdom-related potential. The first study took into account the fact that wisdom may be too complex a knowledge system to be traceable in an isolated individual. Rather, it may be the case that higher performance levels are found if two minds can interact before responding to the wisdom dilemma. And indeed, when two individuals usually interacting about life problems in everyday life (real dialog) had a chance to do so before they individually reflected and responded to wisdom tasks, the performance level was increased by one standard deviation (Staudinger and Baltes 1996). In line with notions of symbolic interactionism, performance increase was also identified when participants thought about what other people might say while thinking about the problem (virtual dialogue). The second study focused on one of the five wisdom-related criteria, value relativism, and adopted a very successful memory training technique, the method of loci, for use in the realm of wisdom-related performance (Baltes and Staudinger 2000a). Participants were trained to think about life problems located at different regions of the world. At post-test, participants trained in the knowledge activating strategy outperformed the control group by more than half a standard deviation.

3. *Conclusion and Future Directions*

The concept of wisdom represents a fruitful topic for psychological research: (a) the study of wisdom emphasizes the search for continued optimization and the further evolution of the human condition, and (b) in a prototypical fashion, it allows for the study of collaboration between cognitive, emotional, and motivational processes. We expect that future research on wisdom will be expanded in at least three ways: (a) the further identification of social and personality factors and life processes relevant for the ontogeny of wisdom, (b) the exploration of wisdom as a meta-heuristic aimed at orchestrating mind and virtue towards human excellence (Baltes and Staudinger 2000a), and (c) the contribution of wisdom research to building a psychological art of life (Staudinger 1999b).

Witchcraft

The scientific study of witchcraft has been concentrated in two research fields clearly separated in time and space: historians' studies of the enigmatic outburst of witches' trials in early modern Europe, and anthropological studies of the role of witchcraft in notably African and Melanesian societies during colonial and postcolonial periods. In her introduction to a conference volume commemorating the 30-year anniversary of Evans-Pritchard's classical study *Witchcraft, Oracles and Magic among the Azande* (southern Sudan), Douglas (1970 p. xiii) noted with some apparent surprise the deep chasm between these two fields of study: 'The anthropologists of the 1950s developed insights into the functioning of witch beliefs which seemed about as relevant to the European experience as if they came from another planet. Dangerous in Europe, the same beliefs in Melanesia or Africa appeared to be tame, even domesticated; they served useful functions and were not expected to run amuck.' In retrospect, one might wish the second half of this quotation to be still true. The growing obsession over the last decades in many parts of Africa and Melanesia with new forms of witchcraft seems to reflect, on the contrary, widespread popular worries that it has 'run amuck.' Yet Douglas's trenchant observation did highlight striking differences between the trajectories of witchcraft studies by historians and anthropologists and, therefore, offers a challenging starting point for any effort to come to a more general survey of the topic.

The differences between the two fields are, indeed, so great that some authors even objected to the use of the same term. Crick (1979), for instance, warned that the term witchcraft was so saturated with implications stemming from European history that anthropologists working on other areas had better avoid the term altogether. One problem with such a puristic stance is that this English term (or the corresponding French, Spanish, and Portuguese terms) have been adopted widely by people throughout the Southern hemisphere. A more substantial objection might be that despite huge variations the representations concerned revolve around basic conceptions that are surprisingly similar. In many parts of the world notions that are now commonly translated as witchcraft refer not only to hidden human aggression, but also to more specific representations about people being able to double themselves, leaving their bodies at night and flying off to nocturnal meetings with their accomplices.

Especially anthropologists, confronted by a bewildering proliferation of imaginaries in this field, have tried to clarify things by formulating strict definitions and distinctions. The best-known is Evans-Pritchard's proposition—on the basis of the distinctions the Zande, the subjects of his first book, supposedly made—to distinguish witchcraft and sorcery: the first referring to an inborn quality, the second to the use of acquired means. But even for neighbouring areas in Africa this distinction proved difficult to maintain in view of the fluidity and dynamics of witchcraft discourses. More recently, some authors (see Geschiere 1997) suggested that this search for clear-cut definitions and classifications risked to make anthropologists blind to the surprising dynamics of these representations and their chameleonic qualities which are crucial to understand how they can adapt themselves so easily to modern changes. In this treacherous field of study, researchers may have to resign themselves to working with fuzzy notions that may exhibit a common core but at the same time engender highly variable and constantly changing elaborations. The differences between the historians' and the anthropologists' versions of witchcraft are illustrative of the widely varying implications these notions can acquire.

The historians' view paid more attention to the dynamics of these representations. After all, a central question to them was why persecutions of witches—quite rare throughout what was sometimes called the 'dark' Middle Ages—acquired epidemic forms in several parts of Western and Central Europe, precisely at the dawn of modern times (sixteenth and seventeenth century). Historians like Robert Mandrou or Norman Cohn explained this as the effect of a longer process of the diabolization of local witchcraft beliefs. Popular worries about perpetrators of evil within the local community (*maleficium*) increasingly became linked to ecclesiastically inspired visions of a Satan's cult. In the confessions of people accused of witchcraft—increasingly obtained under torture by the henchmen of ecclesiastical and secular courts—the Devil emerged as the leading figure at their nocturnal meetings. Some historians related the quite sudden proliferation of witch-hunts after 1500, therefore, to the disciplinary action of the State and the Church that

ever more affected the local communities. Muchembled (1993), for instance, sees a clear distinction in the archives between two discourses: the one of the witnesses who accuse their neighbours of destroying corps, cattle, and even human lives, and the one of the judges who force the accused to relate all this to their dealings with Satan. Thus, Muchembled construes a direct link between the witch trials and the rise of the absolutist State combined with the religious struggles inspired by Reformation and Counter Reformation; he sees these trials as an emanation of the 'forced acculturation' of popular culture by a 'triumphant centralization.' However, in the beginning of the 1970s other historians, mainly working on England, had already advanced another explanation, emphasizing rather the increased willingness of notably rural people to accuse their fellow villagers. Thomas (1971), for instance, related this to the deepening inequalities within rural communities. Richer villagers increasingly resisted older obligations to share with their poorer fellowmen, translating feelings of guilt about this into witchcraft accusations. In this view, State and Church were rather drawn into these affairs by pressures from below.

Thus, there seemed to be a more or less clear contrast between a continental pattern—that for some time also affected Scotland due to dynastic links with Denmark—in which State and Church authorities played a key role with their obsession with the Devil; and a quite different one, prevailing in England, in which locals pressurized the authorities to do something about the *maleficium* of the witches in their midst. More recently, however, this contrast was nuanced by several authors (Briggs 1996, Barry et al. 1996), who emphasized that on the continent as well, tensions and accusations within the local communities played a key role, while direct involvement of State or Church authorities in the persecution of witches was the exception—certainly in the most absolutist States (France, Spain)—rather than the rule. Moreover, they signaled that in England as well, Satan came to play an increasing role in the witches' confession, be it belatedly and less prominently. Yet it is clear, despite such different emphases, that in the historians' interpretations witchcraft could not remain a local issue but had to be studied in interaction with broader power structures, notably the State and the Church. After all, the historians' very sources—mainly court archives—were produced by the latter. An attempt by Ginzburg (1990) to relate the imaginary of the witches' sabbath to a set of folk beliefs—going back to Neolithic times as some sort of substratum throughout Eurasia—received a lukewarm reception and clearly fell outside the historians' main paradigm.

Anthropologists, in contrast, for a long time continued to address witchcraft as a local issue, trying to resolve its riddles by in-depth studies of local relationships and conceptions. Yet their approaches were also subject to quite surprising turns. Evans-Pritchard's Azande study, often quoted as a classic in the field, hardly proved to be a trendsetter. Its focus was on issues of cognition—on why the Azande combined very commensensical explanations with interpretations in terms of occult aggression. But it inspired a series of micropolitical studies in which witchcraft was analyzed—in line with the functionalist ideas that dominated the discipline at the time—in relation to social order and integration. In a series of in-depth monographs of local societies in what at the time was called British Central Africa, anthropologists of the 'Manchester school' studied witchcraft accusations as a form of social control. Typical for this approach was Max Marwick's characterization of witchcraft as 'a social strain gauge': as a measure of sociopolitical tensions, but also as a way to restore social order. It was this interpretation that produced the in retrospect somewhat amazing view of witchcraft as 'tame' and 'domesticated' (see quote from Douglas above).

It is questionable whether this view applied even during the colonial period under the *pax britannica* (c.q. *gallica*). But it is clear that it hardly prepared anthropologists to confront the quite spectacular dynamics of representations of the occult after Independence. It is difficult to decide whether accusations and rumors, let alone actions, in terms of witchcraft increased after Independence (just as the old debate among anthropologists on whether witchcraft 'increased' or 'decreased' after the colonial conquest had no conclusive ending). But it is quite clear that it came out into the open, in many parts of postcolonial Africa. Witchcraft became a hotly debated issue, not only in the street rumors of *Radio Trottoir*, but also in newspapers, on TV, etc. It was striking, moreover, that rumors and references to the occult forces proliferated especially in the more modern sectors of society: in relation to modern forms of entrepreneurship, national politics, sport, and the new institutions for healthcare and education. The view, to many still self-evident, of witchcraft as a 'traditional' relict that will automatically disappear with modernization—'witchcraft will disappear with electric light' as a Dutch missionary in Cameroon claimed in 1971—became difficult to maintain in view of the popular tendency to address precisely such modern developments in terms of these occult discourses. Neither did the anthropological image of witchcraft as a local phenomenon prove to be of much use for understanding the spectacular increase in scale of these rumors that acquired national or even transnational dimensions. No wonder that after the 1960s anthropologists tended to abandon the topic to theologians and journalists. An approach in terms of social order proved to be of little help in analyzing the new transformations of these local beliefs.

In many parts of Africa, for instance, there was increasing popular concern about new forms of witchcraft that were explicitly related to the *nouveaux*

riches who were supposed to accumulate wealth by exploiting the labor of their witchcraft victims. Often people made a contrast between older forms of witchcraft in which the victims were 'eaten' and the new one of 'selling people,' that is, turning them into some sort of zombies and selling them to work on 'invisible plantations.' The fear of such new threats triggered a frantic search for new forms of protection, for instance, urgent appeals to the State authorities to intervene. The pressing character of the witchcraft issue was further highlighted by the lethal witch-hunts that marked the end of Apartheid in the northeastern part of South Africa—young men, encouraged by *nganga* (witch-doctors) and claiming to act as local representatives of the ANC, executing dozens of 'witches' (Niehaus 1993). The half-hearted implications of State authorities in such witch-hunts in many parts of the continent made it all the more urgent to gain deeper insight into the modern dynamics of witchcraft discourses.

No wonder that since the early 1990s there has been a new wave of witchcraft studies in Africa and Melanesia, notably by anthropologists concentrating on the relation with popular views of 'modernity' —that is, the dreams of the modern, in all its varieties, that effect ever wider strata of the population (cf. Comaroff and Comaroff 1993, Geschiere 1997). This linking of witchcraft and modernity, according to some even a new paradigm, implied attention to particular aspects that could explain the continuing resilience of these local beliefs—notably their circular character, their moral ambiguity, and their striking capacity to relate local realities of the family and the home to global processes of change.

The circularity of witchcraft discourses is expressed most vividly in the paradox that the main protection against witchcraft often is to be sought in the very same field. In many parts of Africa, for instance, the *nganga* (healer) is supposed to be able to offer protection and healing only because of his (or her) overdeveloped witchcraft. In some societies there is a consistent effort to conceptually or even institutionally separate the *nganga*'s (or the chief's) occult power from the evil forces of the witches. Then witchcraft seems to be, indeed, unequivocally evil. But in practice, such distinctions between positive and negative forms of occult power are often highly precarious and controversial. In many African societies, for instance, *nganga* remain highly ambivalent figures—healers but at the same time suspect because of their dealings with extremely dangerous forces. The *nganga* is, therefore, also a striking example of the moral ambiguity of these forces. Basically these forces are certainly evil, but—as in the *nganga*'s case—they can be canalized and used in a constructive way. In this more positive sense, witchcraft—it is in such a context that this English translation of African notions becomes, indeed, problematic—can even be seen as a precondition for accumulating wealth and power. This applies especially to the new modes of enrichment that seem to bring out ever more starkly the ambivalence of witchcraft conceptions: the rumors, mentioned above, about the new witchcraft of wealth that turns its victims into zombie-laborers express horror about such treacherous attacks, but also fascination with the new riches this acquired. It is these ambiguities that give witchcraft discourses their elasticity and their surprising capacity to relate the global to the local. In most parts of Africa and Melanesia these discourses still are rooted strongly in the local setting, notably in the intimacy of kinship: witches are supposed to have a special hold over their kin or in any case to work through an ally 'within.' Yet, the same discourses are invoked to cope with the unsettling modern developments: the vagaries of the world-market, the dazzling riches of the happy few and the recurrent mishap of the many in their pursuit of the new forms of wealth. In such contexts, witchcraft rumors can attain truly global dimensions referring, for instance, to the circulation of zombies on a world scale or to the appropriation of extremely potent 'medicine' from Europe or India.

Such anxieties about hidden aspects of modern developments are certainly not special to Africa or Melanesia (cf. the seminal studies by Taussig 1987 and Kapferer 1997 on, respectively, Amazonia and Sri Lanka). The new anthropological interest in the paradoxical link between witchcraft and modernity inspires even an alternative reading of developments in what are thought to be typically 'modern' societies. Already in the 1970s, the anthropologist Favret-Saada (1977) highlighted the surprising resilience of witchcraft practices in the French countryside in a truly innovative analysis of how words are charged with power, but also of how the researcher herself became unavoidably involved. In a more direct relation to modern forms of politics and communication, Geschiere (in Meyer and Pels in press) drew attention to intriguing parallels between witch-doctors and 'spin-doctors' in respectively African and American politics—both manipulating esoteric expertise and 'public secrets' that shroud the exercise of power. In her detailed analysis of rumors on Satanism and child abuse in present-day England, La Fontaine (1998) demonstrated the relevance of anthropological witchcraft studies on Africa and Melanesia in such a modern context. The broader interest of new directions in the study of witchcraft, often still seen as the archetype of the traditional, is precisely that they help to debunk simplistic opposition between modern and traditional, science and magic, transparent and opaque, or even more simply between the West and the rest. Comparative studies, like the one mentioned in this paragraph, show that even in the West modernity retains its own forms of enchantment and opacity.

Wittgenstein, Ludwig (1889–1951)

1. Life

Ludwig Josef Johann Wittgenstein was born in Vienna on April 26, 1889 as the youngest of eight children of Karl and Leopoldine (née Kalmus) Wittgenstein. His father was a protestant, his mother a catholic, and the children were brought up in catholic faith. Wittgenstein was of partly 'Jewish' descent (three-quarters according to Nuremberg laws), and he accepted this classification to the point of self-attributing character traits that counted as Jewish in the Habsburg monarchy of the turn of the century. (Weininger's *Geschlecht und Charakter* impressed him deeply.) The family had become one of the wealthiest of the Habsburg Empire in the iron and steel business, and young Ludwig got his early schooling from private teachers until his father decided to send him to the *Realschule* (technical gymnasium) at Linz in 1903, no doubt hoping him to become an engineer, where he passed his '*Matura*' in 1906.

The Wittgenstein home in Vienna was very *fin de siècle*. On the positive side, the house was open to artists and composers, the family exercising generous Maecenatism; Ludwig read intensively in his youth, and there is documented influence from Goethe, Schopenhauer, Heinrich Hertz, Karl Kraus, Wolfgang Köhler, and others. On the negative side, the children were attended more by staff than by their parents, and the sons had definitely self-destructive tendencies. At least two of Ludwig's brothers, possibly a third one, committed suicide, a tendency which Ludwig had to combat himself for most of his life. Looking back at his childhood, he considered it to have been unhappy.

Having graduated from the Linz *Realschule*, Ludwig went to the Technische Hochschule Charlottenburg (now Technische Universität Berlin) where he studied mechanical engineering and was awarded his 'Diplom' in 1908. He went to Manchester in the same year to do research in aeronautics; however, he began to develop a growing interest in pure mathematics and read Bertrand Russell's *Principles of Mathematics* of 1903 and Gottlob Frege's *Grundgesetze der Arithmetik* of 1893. Fascinated by these books' enterprise of deriving mathematics from logic, he visited Frege in Jena in 1911 who encouraged him to study with Russell in Cambridge. He was a student in Cambridge from 1911 to 1914, but although attending some classes in philosophy (notably with George Edward Moore), his work had more or less the character of an extended dialogue with Russell on questions of logic and the foundations of mathematics.

During his Cambridge time, Wittgenstein experienced the first of a number of deep emotional friendships with young men. Although he was homosexual, the relation with David Pinsent probably remained platonic until it was ended by the latter's death in World War I. One love relationship, with Francis Skinner in Cambridge in the 1930s, is known to have been fulfilled sexually, but Wittgenstein broke it off, just as if unfit for happiness in human bonds, and in addition, deeply ashamed of his disposition.

He volunteered for the Austrian army in 1914 and served, with distinction, throughout the war; extant diaries testify to ongoing work that was to lead up to his only philosophical book published during lifetime, the *Logisch-Philosophische Abhandlung*, which was actually finished in summer 1918 and first appeared, very poorly edited, in Ostwald's *Annalen der Naturphilosophie* for 1921. The book became famous only after an English translation, under the title *Tractatus Logico-Philosophicus*, had been published in 1922 when Wittgenstein, after having trained as an el-

ementary school teacher, was teaching children in villages in Niederösterreich—evidently in order to live a morally meritorious life. However, he had to resign in 1926 because of punishing a schoolboy too severely, and he would probably have given way to despair had not his sister, Margarete Stonborough, asked him to build her new Vienna house together with his friend, the architect Paul Engelmann. (The building now houses the Bulgarian embassy.)

Philosophical contact with Cambridge had never been cut off completely. Back in Vienna, Wittgenstein had some philosophical conversations with members of the 'Vienna Circle,' notably Moritz Schlick and Friedrich Waismann. Thus, although a lecture by L. E. J. Brouwer is said to have given the last push, it was not completely out of the blue that Wittgenstein returned to Cambridge in 1928. Having given away his inherited fortune to his brothers and sisters after the war, he had to apply for a fellowship (submitting the now famous *Tractatus* as a doctoral dissertation). This was his way of earning his living until his death, except for holding a chair in Cambridge from 1939 to 1947 and living on savings now and then. He held regular classes in Trinity College, laconically entitled 'Philosophy' or 'Philosophy for Mathematicians.' A difficult person and not popular with most of his colleagues, his teaching success with a small number of students was enormous and accounted for his burgeoning philosophical ideas to be spread far ahead of the posthumous publication of his constantly rewritten notebooks and typescripts.

Except during wartime, Wittgenstein regularly went to Vienna in summer and for Christmas to see his family. Also, he several times went to Skjolden on the Sognefjord in Norway where he had had a little solitary house built before World War I. In 1939, with the assistance of John Maynard Keynes, he succeeded in applying for British citizenship which allowed him to travel in '*Großdeutschland*' even as an Austrian 'Jew' and to arrange for two of his sisters to be declared 'Aryan' in exchange for transferring large valuta parts of the family money to the German Reichsbank. During World War II, he served different jobs outside the university that he considered more important than doing philosophy.

Wittgenstein's second book, the *Philosophical Investigations*, was more or less finished in 1946—finished in the sense of Wittgenstein himself considering it as printable. But a general mood of dissatisfaction with philosophical results seems to have got an increasing grip on him. Even though he continued writing and discussing philosophical questions, he was suspicious of finished answers. Asking the proper questions was, in his view, the important thing—an attitude which he had developed in the 1930s and which he expressed more and more sharply. In this mood, Wittgenstein did not press for publication. Living outside Cambridge for much of his remaining time, he alternately sought company and solitude until cancer of the prostate, diagnosed late in 1949, had worsened so much that traveling became impossible. He died in Cambridge on April 29, 1951.

2. *Philosophical Work*

Wittgenstein's early (*Tractatus*) philosophy can be regarded usefully as an attempt at answering two questions: Why are logical truths true? How can we recognize that they are? He did this by inventing a theory of meaning which, in turn, was based on an ontological theory of the most general features of reality. Starting from the observation that logical truths, as he had come to know them from the work of Gottlob Frege and Bertrand Russell, are always syntactically complex, Wittgenstein first stipulated that there is but one way of constructing complex sentences from components, viz., by combining the components in a complex which is a 'truth function' of the components (if every single component is either true or false, this is sufficient for the complex sentence to be definitely true or definitely false). The components may be complex themselves; but according to a second stipulation, the combinatory process originally starts from components that are elementary sentences, i.e., sentences which are not truth-functional complexes of anything else. If a complex sentence has been constructed from n elementary sentences, there are 2^n different combinations of each of them being either true or false; this is the postulate of mutual independence of the elementary sentences which is characteristic of 'Logical Atomism.' If the complex sentence comes out as true in every such combination, then it is logically true (e.g., 'If it is neither raining nor snowing, then it is not raining' is true, no matter whether or not it is raining and whether or not it is snowing). This is manifest for anybody who understands the complex sentence; thus logical truth 'shows itself,' and both questions above are answered if every elementary sentence is either true or false. Here a third stipulation comes in: Every elementary sentence is a 'picture' of an elementary 'state of affairs' which either exists, in which case the elementary sentence is true, or does not exist, in which case the corresponding elementary sentence is false. Existing elementary states of affairs make up the 'world' as it is. By a picture, Wittgenstein means an isomorphic correlation of the simple signs (which he called 'names') whose concatenations form the elementary sentences and of simple 'objects' which make up the elementary states of affairs. Given a set of elementary states of affairs and a set of elementary sentences, normally there will exist several possibilities to correlate simple signs and simple objects while preserving isomorphy; the actual correlation, according to a further stipulation, is chosen by the speaker who correlates sentences with states of affairs by thinking a state of affairs as a sentence's sense. Since 'names' occur in many different sentences, this think-

ing of the senses of whole sentences reduces the alternative correlations and thus determines certain objects as the meanings of given names which can form other sentences; so the understanding of new sentences can be explained.

So far, Wittgenstein's stipulations add up to a referential and speaker-oriented theory of the meaning of sentences that explains logical truth. However, he added restrictions two of the most provocative of which are the following: First, the states of affairs that make up the world and are necessary for language to be meaningful are all natural ones; there are no moral or aesthetic states of affairs. Evaluative pronouncements are, therefore, nonsensical. Second, the fact that a state of affairs is correlated with a sentence as the latter's sense, or the fact that a speaker correlates sentences with states of affairs (and in consequence, names with objects) by this or that 'projection rule' is not itself a state of affairs, which means that any description of this correlation is nonsensical too. Wittgenstein accepted this consequence by declaring all *Tractatus* sentences nonsensical, even if helpful, in the book's last propositions. On which Frank P. Ramsey is said to have commented 'What you cannot say you cannot say, and you cannot whistle it either' (an allusion to Wittgenstein's popular gift of whistling entire pieces of classical music). A third restriction often goes unnoticed, viz. that the *Tractatus* theory of meaning is restricted to declarative sentences, excluding questions, imperatives, optatives, and interjections. Wittgenstein hoped these might be incorporated into his framework by proper analysis, without, however, attempting to do so; the same holds for his failure to even look for real examples of elementary sentences.

In a period of hard work from 1929 until about 1936 which it has become customary to call 'intermediate,' Wittgenstein renounced Logical Atomism, i.e., the supposition that elementary sentences are mutually independent; all candidates (e.g., simple color statements) proved to exhibit meaning relations with other ones of the same kin (what is green is not red). So the idea of systematic dependency being co-responsible for meaning emerged. This fell in line with the new idea of devising a nonrepresentational (nonsymbolic) conception of meaning: pieces in chess have a meaning (a role), without representing anything, simply in virtue of their place in the rules of the game. If linguistic elements played a role in a system of rules for their use in social interaction, this might well suffice for their meaningfulness. However, the appeal to rules implied a problem of its own. If rules are identified by means of their linguistic expressions, there must be meaningful expressions for there to be meaning (an obvious interpretation regress), and if rules have to be agreed upon there must be rules to confer validity on the agreement procedures (an obvious ruling regress known from constitutional and international law). Sticking to the idea of meaning to be found in systems of rules, Wittgenstein invented one of his most famous tools, the 'language-game,' which he elaborated in the posthumous masterpiece of his 'late philosophy,' the *Philosophical Investigations*. A language game may be understood as a set of regularities in behavior, involving several people, where the use of certain elements (to be identified as linguistic on further inspection) on the one hand depends on what has been done and what the other circumstances are, and on the other hand is relevant for further things to be done subsequently, either by the 'speaker,' 'audience,' or by third parties. These regularities in behavior have to be rich enough to differentiate, e.g., statements from commands; thus 'The window is open,' if playing the role of a command, will evoke responses different from when it is used as an answer to a question.

Commands do not qualify as such simply by being followed by someone else's doing something. They occur only where the speaker has the required kind of authority, and the addressee, rather than actually doing something, has to do it. (This is why utterances with given meanings are possible only in a social setting that provides for the characteristic rights and duties—languages are embedded in 'forms of life.') Both facts can, in the event, be analyzed as certain rules being followed by the people concerned, and it is here that Wittgenstein's solution to the double-regress problem about rules sets in. Rather than asking how to identify or how to establish rules, he asked how behavior looks like if it is rule-following behavior. If behavior is rule-following, the rule it follows can be extracted from it in the following way. There is a description of the behavior that makes use of the rule although the people who follow the rule do not make any use of the rule themselves. With Wittgenstein, a behavior *B* follows the rule *R* if *B* conforms to *R*, if it is learnable and if it goes without saying, i.e., is mutually expected among the people concerned. This is not new to present-day sociology, of course, but it served Wittgenstein to cut off both regresses sketched above. Nobody among the people who follow the rule need be able to identify it, and it need not be enacted, or agreed upon.

Anchoring linguistic meaning in practices that are complex in such a way that they can truly be described as rule-following has the consequence that there is no linguistic meaning outside a community. Whether or not an utterance is a command depends on others to expect a certain person now to do something. Unless they expect the person to do so, the speaker has not uttered a command. Meaning an utterance in a certain way is not something a speakers achieve by exhausting their very own mental resources and capacities (it is not due to their capacity of 'intending' in a traditional sense). Saying something meaningful, as well as meaning something, depend on others to be prepared to understand the speaker in a given way. This implies one of Wittgenstein's most famous theses, viz. that there cannot be a language private to one speaker, i.e.,

a language whose signs have their meanings no matter whether or not others understand them or react to them. However, Wittgenstein argued his critique independently, thus providing indirect evidence for his social account. The only rule available to a 'private meaner' would stipulate something like: '*S* means *x* if and only if I remember *S* to have meant *x* in the past'; since what is to be explained, viz. '*S* means *x*,' occurs in the explanation, the only available rule turns out to be void.

Whereas this famous 'private language argument' has attracted much philosophical debate, a side effect has proved to be more fruitful. Wittgenstein used the language of sensations as his example and so proved, by implication, that it is not possible to report on one's own sensations by way of privileged inner observation. (For in an unproblematic situation of observation, using the right words is a test of the observer's linguistic competence; if others cannot interfere, reports on one's own sensations would have private meanings in the sense defined above.) The idea that there is privileged knowledge of one's own sensations (and other 'conscious' psychological states like moods, emotions, impressions, and the like) originates in the fact that speakers have a special authority in expressing them, and Wittgenstein took two ingenious steps. First, he pointed out that the speaker's privilege is just one case among others of utterances (often prefaced by 'I know' as in 'I myself know best what is good for me') which are privileged according to our social rules rather than epistemically. Second, he interpreted them, rather than as reports, as being meaningful in the same way as nonverbal expressive behavior is, viz. in virtue of playing a recognizable role in a behavioral pattern. Thus, 'Ouch' or 'I am in pain' are meaningful insofar as they occupy the place of crying in the series injury/crying/winning attention (a series that exhibits nicely the structure, which is characteristic of commands, of authority/imperative/expected behavior, or the structure of precondition/utterance/expected reaction that characterizes meaningful utterances in general).

By parity of reasoning, the symmetry of verbal and nonverbal expressive behavior implies a last important result. Just as verbal utterances owe their meanings to others' reactions, so nonverbal behavior expresses what it does in virtue of others' socially established response. Now if one cannot make head or tail of the notion of an inexpressible psychological state (as Wittgenstein argued at length), a person's psychological state is what he or she could express at the moment, and then what that person is feeling, thinking, wishing, etc. is co-defined by how others would react should he or she exhibit expressive behavior. Wittgenstein is, thus, the first philosopher to have touched the topic of what has come to be called 'Social Anti-individualism.' In an unduly neglected paper, Fleming (1978) has likened Wittgenstein's view of the interpretation of expressive behavior to the interpretation of pictures. Pictures owe their content to a civilization's way of seeing them. Their content is manifest because it is defined by established interpretation. Just so, established responses to other persons' behavior are operative in determining their psychological situation. This is what distances Wittgenstein from Logical Behaviorism. Rather than being inferred from behavior, psychological facts are directly observable; and rather than just being ascertained by observation, they are dependent on external interpretation.

Although Wittgenstein developed his 'middle' and later philosophy in opposition to and correction of his *Tractatus* ideas, there is considerable continuity both as regards content and methodology. In point of content, Wittgenstein is sure to be the first philosopher in history who developed his philosophical ideas from thoughts about how it is that the elements of language have meaning. In this respect, our linguistic competence plays a role, with Wittgenstein, not unlike that of our epistemic abilities in Kant's far-reaching deductions outside epistemology. As regards methodology, Wittgenstein insisted, both in the *Tractatus* and in later writings including the *Philosophical Investigations*, that good philosophy has a peculiar task, i.e., that of clarifying obscurities that have been and are constantly being produced, either when scientists misunderstand what they are doing or when scientific or everyday questions and experiences are misunderstood and linguistically distorted by bad philosophy. This continuity has often been stressed, but for at least two reasons it should not be over-estimated. First, the task of clarifying was all that was left over for philosophy in the *Tractatus* since its theory of meaning reserved all meaningful statements for the natural sciences. Second, the assignment was a piece of explicit methodology which Wittgenstein did not obey in practice. In contrast, Wittgenstein's later conception of meaning admits to philosophy every useful language-game (e.g., that of describing language-games), the assignment of the task of clarifying being motivated by his experience of how much linguistic distortion his own early philosophy had suffered from; and clarification meant method rather than methodology—there is sure to exist no other corpus of philosophical writing so densely packed with repeated demonstrations of how translating philosophical questions and theses into everyday language provides clarity. As an original contribution to our picture of what philosophy can achieve, Wittgenstein developed this clarificatory way of handling philosophical thinking into intellectual therapy. The real aim is achieved when the philosopher, by way of rectifying his distorted use of language, has come to see that there has never been any philosophical problem except for the riddles he got entangled with by falling prey to the temptation of highbrow speaking. Wittgenstein went so far as to say that after such therapy, there was no place in philosophy for controversial theses or

theories. Whereas many take these declarations at face value, others have argued that in view of the substantial and controversial achievements of his later philosophy, the declarations should be either interpreted in a restrictive way or taken as overstating an otherwise valuable methodological warning.

3. *Impact*

Wittgenstein's influence on the intellectual life of the twentieth century has not been uniform or coherent; early and late philosophy, written work and teaching contact, work and personality have appealed to different interests. The general public has been and still is mostly interested in his disconsolate life; following the arbitrary turns of fashion, he has been canonized in a way that would, to his utter disgust, have nowadays turned him into an unwilling victim of talk shows. Furthermore, Wittgenstein's prose style has been all the rage since the *Tractatus* was published, and whereas every Tom, Dick, and Harry arranged their texts in decimal notation before 1953, quoting aphorisms from the *Philosophical Investigations* became imperative for feuilletonists in Anglo-Saxonia from that date, and in the German speech area after 1960 when Suhrkamp had timidly published a joint edition of both of Wittgenstein's masterpieces (together with a '*Beiheft*' in order to secure respectability for an unknown Austrian–British philosopher by documenting the interest of poets like Ingeborg Bachmann).

As regards more serious questions, research has been affected differently by the *Tractatus* and by subsequent work, and by the latter differently depending on whether people were confronted with Wittgenstein's teaching in Cambridge or with his writing. The *Tractatus* gained a great popularity soon after the publication of the bilingual edition in 1922, and it exerted considerable influence on some of the members of the 'Vienna Circle' who had gathered around Moritz Schlick and were striving for a really scientific philosophy. The most enduring effect was to be the 'verification theory of meaning' which, as stated in the *Tractatus*, identified any proposition's meaning with the set of distributions of 'true' and 'false' to its elementary sentences which make the proposition true; elaborated by the circle's most influential member, Rudolf Carnap, it made its way into logic, philosophical semantics (the present-day truth-condition semantics), and is even influential in linguistic semantics. Karl Raimund Popper's disclaimers notwithstanding, the *Tractatus* theory that only those sentences have sense which risk to wreck on experience is a clear forerunner of his falsifiability theory of cognitive significance, influential in sociology and psychology since the 1940s.

In his philosophizing since 1929, Wittgenstein influenced some bright Cambridge students who learnt, from his live example, that being sober, honest, and clear was more important than, and at least as attractive as, producing high-faluting and sloppy nonsense. Following the advice to rephrase any philosophical sentence in everyday idiom, they began to form a veritable movement, Ordinary Language Philosophy, which had its high tide in the 1950s and early 1960s. The most famous and most important representative was Gilbert Ryle, Oxford based but on friendly terms with Wittgenstein, whose seminal *Concept of Mind* of 1949 inaugurated Logical Behaviorism, to be superseded by Functionalism; so it is a safe guess that without Wittgenstein, present-day research on the mind-body problem would look entirely different. Further effects resulted from the publication of the *Philosophical Investigations*, jointly in German and English, in 1953; the impact in philosophy was heavy, but surprisingly small in linguistics (the reason being, perhaps, that John L. Austin's speech act theory won the day). At present, the most interesting developments, in the behavioral sciences outside philosophy, seem to be going on in Cognitive Science and in Ethnomethodology. In Cognitve Science, Hubert Dreyfus and others have argued forcefully that intelligent achievements cannot be accounted for by supposing that subjects are following explicit rules but have to follow them implicitly in Wittgenstein's sense. This has been condensed into the prediction that the architecture of the brain's working is to be regarded as connectionist rather than computational. In Ethnomethodology, Peter Winch and others have suggested that without a Wittgensteinian conception of forms of life, an adequate understanding of alien societies cannot be attained.

On the whole, however, Wittgenstein's influence, on the behavioral sciences, has remained marginal outside philosophy. In particular, social anti-individualism is still awaiting proper conversion into research strategies, just as is an adequate use of Wittgenstein's conception of language games in linguistic pragmatics.

Women and Psychiatry

To understand the role of women in psychiatry, a context is necessary. This will be provided by tracing the history of women in medical roles.

1. *The History of Women in Health Care*

Throughout history women have been healers and caretakers, playing multiple roles, as pharmacists, nurses, midwives, abortionists, counselors, physicians, and 'wise women,' as well as witches.

From 4000 BCE there were women who studied, taught, and practiced medicine, including Moses' wife Zipporah. The first known woman physician, Merit Ptah, practiced in 2500 BCE. The Chinese record, in 1000 BCE, women engaged in typical physician-like activities.

The Roman, Soranas, believed women were divinely appointed to care for women and children. His criteria for practitioners included literacy, anatomic understanding, a sense of patient responsibility, and ethical concerns, particularly regarding confidentiality. However, Roman women physicians were rarely permitted to perform in the same capacities and positions as men.

Women founded and staffed early hospitals in 260–220 BCE; the deaconesses of the early Christian church developed the first public health systems (Shryock 1959). Middle Eastern hospitals were founded in the sixth and seventh centuries CE. By the eighth century Arab medicine began to flourish. Since Muslim men were forbidden from having contact with women who were not family members, women cared for women. In Islamic Spain, women received medical educations and were surgeons before the twelfth century.

European medical education formally began in Salerno, Italy, in the ninth century. By the tenth and eleventh centuries, women apparently studied there (Corner 1937). When medical degrees were first awarded in 1180, they went only to men. Women received a special diploma until the fifteenth century. A woman physician, Trotula, was an important eleventh century academic and teacher in Salerno. She wrote major texts on obstetrics and gynecology and headed a department of women's diseases. Her contributions were significant because, at that time, women provided all obstetrical care and many had no training. However, many of her accomplishments, and those of other women, were attributed to their husbands and sons.

An early twelfth century abbess, Hildegarde of Bingen, was a healer, philosopher, composer, and scientific scholar who provided scientific data on nervous system regulation and an understanding of normal and abnormal psychology.

Initially, women were ambivalently received when they expanded their traditional midwifery roles, and they were prevented from obtaining medical training. However, in England, the need for physicians during the Black Death of 1349 opened the way for women to study medicine.

In 1423 Constanza Calenda became the first woman formally to obtain a medical degree. She lectured in medicine at the University of Naples. Although, in the fourteenth and fifteenth centuries women practiced medicine in Italy, France, England, and Germany, their practice was usually limited to bleeding, administration of herbs and medicines, and reducing fractures, in addition to midwifery. In some parts of Europe, women also practiced as physicans, surgeons, orthopedists, and ophthalmologists. It was generally believed that women were better able to treat women's diseases. Many served kings, royal families, and even the military.

Despite this success, by the end of the fifteenth century the movement to exclude women from practicing gained momentum; they were specifically limited to functioning as midwives. This coincided with the misogyny of Johann Sprenger and Heinrich Kraemer, in the *Malleus Maleficarum* of 1486, which laid out much of the philosophy of the inquisition. Witch-hunting focused on the 'spiritual and mental' inferiority of women. Even when active witch-hunts subsided, their effects remained and women were eliminated from many medical roles.

In the seventeenth century, when examinations and licensing procedures were required for physicians, women were rarely allowed to sit for required examinations.

2. *Women in Eighteenth and Nineteenth Century American and European Medicine*

In colonial America, the healing role of women was critical to survival, since medical care of families was the responsibility of the women. There were no medical schools and relatively few trained physicians. Training was obtained by going abroad or apprenticing.

In 1765 Dr. John Morgan founded the first 'regular' American medical school. By excluding women, it began a tradition of barring them from formal medical training in the USA. Still, many women set up 'irregular' practices without diplomas, having apprenticed in homeopathic or eclectic traditions. Toward the latter part of the nineteenth century, US women began to study in European medical schools.

In 1847, Elizabeth Blackwell became the first woman accepted to a 'regular' US medical school. When she received her MD from the Geneva Medical School, the New York State Medical Association censured the school. In 1850 Harriet K. Hunt, an 'irregular' practitioner in Boston, applied for admission to Harvard Medical School. She was admitted, but denied her seat when the all-male class threatened to leave if women were admitted. It was not until 1946 that Harvard Medical School finally admitted women.

By mid-nineteenth century, three all-female medical colleges were founded in the USA: the Women's Medical College of Pennsylvania, one in Boston (now Boston University), and another in Cincinnati. Several US universities, including Syracuse, Michigan, Iowa, and California accepted women (Luchetti 1998).

During the Civil War, Dr. Mary Edwards Walker was awarded the Medal of Honor, the most prestigious military award, for her performance as a surgeon. She was, however, subjected to enormous criticism of her qualifications. The medal was rescinded in 1917 after a change in guidelines limited it to men in combat. It was reinstated in 1977 (Luchetti 1998).

In 1878 the National Eclectic Medical Association became the first medical society in the USA to accept women for membership, but the American Medical Association (AMA) continued to be closed to women.

Negative attitudes about women physicians were supported by a 'new science' rationalizing the inferior status of women on biological grounds. An 1873 book stated, 'higher education for women produces monstrous brains and puny bodies.' It quoted an 1848 obstetrics textbook stating that women have 'a head almost too small for the intellect but just big enough for love.'

The road continued to be difficult even for those women who managed to obtain training. Ann Preston, founder of the Women's Medical College of Pennsylvania, described the entry of women onto the wards of the Pennsylvania Hospital, 'We entered in a body, amidst jeerings, groaning, whistlings, and stamping of feet by the men students … On leaving the hospital, we were actually stoned by those so-called gentlemen' (in Alsop 1950, pp. 354–5).

Denied hospital appointments, US women began to open their own hospitals and clinics. In 1857 Elizabeth Blackwell, her sister Emily, and Marie Zakrzewska established the New York Infirmary for women and children. In 1862 Marie Zakrzewska founded a similar hospital in Boston. They also founded the Women's Medical College of the New York Infirmary in 1868. They believed that women received an inferior education and they sought to correct this problem by establishing rigorous entrance exams and longer clinical training than other medical schools.

There were many important successes for women at the end of the ninteenth century. Dr. Mary Putman became a member of the New York Academy of Medicine in 1880. In 1875 Emmeline Cleveland, Dean of the Pennsylvania Women's Medical College, be-

came the first woman physician in the USA to perform major surgery.

The role of women in medicine, however, continued to be hotly debated. In 1881 Rachel Bodley, Dean of the Women's Medical College of Pennsylvania, surveyed the 244 living women graduates of the school and found that, despite persistent belief that training for women was wasteful, the overwhelming majority were in active practice, and those who had married reported that their profession had no adverse effect on their marriages, nor had marriage interfered with their work. Many early women physicians were from medical families and they joined family members in practice. By 1876, 0.8 percent of US physicians were women. By 1890, 35 US medical schools admitted women, and in 1900 6 percent of physicians were women (Luchetti 1998).

During this period, women physicians graduated from some European universities in Italy, Switzerland, and the UK. There was a woman chair in obstetrics in Italy.

In 1866 Elizabeth Garrett-Anderson opened a dispensary for women and children in London during a cholera epidemic. People were grateful for medical attention, even from women. In 1874 Sophia Jex-Blake, Elizabeth Garrett-Anderson and others opened the London School of Medicine for Women. The medical hierarchy threatened to blackball any male who taught there, and no teaching hospital would allow women to practice. For several years women could not get the needed training for registration in medicine.

In 1877 the Royal Free Hospital in London allowed women access to its facilities. Dublin accepted women in the early 1880s and the Scottish schools followed in 1895. The Royal College finally opened its exams to women in 1910.

In Canada the situation was no different. Dr. James Barry (1797–1865), Inspector General of the British Army Medical Department and subsequently Inspector General of Hospitals for Canada, was discovered to be a woman after her death. She was the first woman doctor to practice medicine in Canada.

3. *Women in Twentieth Century Medicine*

Despite many changes, negative attitudes about women in medicine persisted. In 1905, the President of the Oregon State Medical Society stated:

> hard study killed sexual desire in women, took away their beauty, brought on hysteria, neuroasthenia, dyspepsia, astigmatism and dysmenorrhea … Educated women could not bear children with ease because study arrested the development of the pelvis at the same time it increased the size of the child's brain and therefore its head. This causes extensive suffering in childbirth. (in Bullough and Voght 1973)

In 1900, women comprised 10 percent of the students at 18 medical schools, 50 percent at Boston University, and 40 percent at Tufts University. Johns Hopkins opened its medical school in 1893 with the financial help of women, who exacted the condition that women be admitted on the same terms as men, based on qualifications. By 1917, Dr. Florence Sabin became the first woman full professor at that institution (Luchetti 1998).

Abraham Flexner, in his Carnegie Commission Report on the status of US medical education (1910), stated: 'Medical education is now, in the United States and Canada, open to women upon practically the same terms as men. If all institutions do not receive women, so many do, that no woman desiring an education in medicine is under any disability in finding a school to which she may gain admittance.' Further, he stated, 'Now that women are freely admitted to the medical profession, it is clear that they show a decreasing inclination to enter it.'

Flexner's Report established medicine as an academic discipline in the USA, with high standards for training and practice. This resulted in the closing of many medical schools, often those that admitted women. Thus, the number of female physicians in the USA leveled off at between 4 and 7 percent until the 1970s, a lower percent than in the vast majority of other countries.

Other countries did not experience this abrupt drop and continued to report higher percentages of female physicians. In 1965, for example, 7 percent of US physicians were women, in the Soviet Union 65 percent, in Poland 30 percent, in the Philippines 25 percent, in the German Federal Republic 20 percent, in Italy 19 percent, in the UK and Denmark 16 percent, and Japan 9 percent (Lopate 1968).

Medicine has been viewed as a male profession in the USA more than in most other countries. Some hypothesize that this occurred because medicine has had higher prestige and income than many other professions. It is also likely that science requirements were not considered appropriate for US women who were thought to be suited to caretaking, but not instrumental activities. The practice of medicine represents a melding of roles, the caretaking functions of physicians fit the 'traditional' views of women's roles, but the technological and instrumental aspects do not. Although cultures conceptualize these issues differently, in Cuba where gender stereotypes are disparaged, traditional roles for women in health care persist and 30–40 percent of physicians are women, while virtually all nurses and midwives are women.

The choices of specialty has remained constant since women were admitted to medical schools in the USA. Women have characteristically entered pediatrics, internal medicine, psychiatry, family practice, and, more recently, obstetrics and gynecology, anesthesiology, dermatology, radiology, pathology, and many medical subspecialties. The surgical fields remain sparsely populated by women.

Regardless of the specialty, academic and administrative appointments as well as other decision-making positions are almost exclusively held by men; women tend to be involved in direct patient care (90 percent of female physicians in the USA). In the 1970s, the fact that women assumed this role was used as an argument for increasing their numbers in medical school. They could be counted on to meet the health care needs of the population.

In countries where women have made significant progress in the health fields, changes have occurred most often in times of war, physician shortages, or major cultural reorganization. In Russia, midwives proved effective doctors in the Russo-Turkish War of 1870, thus beginning the influx of women into medical schools. After the 1917 revolution, the prestige of medicine declined in Russia, and women were admitted to medical school in great numbers. By 1940 62 percent of Soviet physicians were women. As elsewhere, Russian women held a disproportionately small number of senior positions (Nadelson and Notman 1995).

The large numbers of women in medicine in the former USSR, in low prestige positions, reduced the differentiation between doctors and paramedical workers. The *feldscher* (semiprofessional health worker or physician's assistant) was a female role, and apparently remains so in Russia and the other former Soviet republics.

The rise of female health professionals in China occurred along with the reorganization of the medical care system and the society. About half of Chinese physicians are women. In 1950, 50,000 midwives were reeducated as local health workers or 'barefoot doctors' (usually women peasants who receive basic medical training and provide medical care to meet the needs of fellow workers).

The increase in numbers of women physicians in the early 1970s in the USA coincided with the civil rights and women's movements. At the beginning of the twenty-first century almost 50 percent of graduating medical students and over 20 percent of all physicians are women. There continue, however, to be disparities in the leadership roles of women in medicine. A 2000 report (Nonnemaker 2000) indicated that although women graduating from medical schools were more likely to enter academic careers, their numbers at higher academic levels were significantly lower than expected and their rates of advancement were slower than men's.

4. *Women in Psychiatry*

There are historical references to the care of the mentally ill from early classical times. Mental illness was generally framed in terms of religion and there were sanctuaries performing religious rites to treat people. As pagan faiths lost favor, there was a deterioration in the quality of treatment afforded the mentally ill, because mental illness was increasingly seen as caused by supernatural powers, evil spirits, or demons (Zilboorg 1941). It took many centuries before there was institutional care comparable to ancient times (Zilboorg 1941).

The first 'morotrophium' or house for 'lunatics' is recorded in the Byzantine world in the fourth century CE. These institutions began to spread to other areas of the world, generally privately funded. Pilgrimages were made to shrines believed to eject evil spirits. One of the early morotrophiums (house for lunatics) was St. Dymphna, a home for mental healing run by women in 1200 CE.

Over the next several centuries asylums were established in many parts of Europe and the Middle East, often with the support of women. In the sixteenth century, the Sisters of Charity took in the mentally ill when hospitals refused to admit them (Tomes 1994). By the seventeenth century some French institutions began to train nurses to care for these patients. In general, however, care was punitive and often inhumane.

A seventeenth-century Swiss woman physician, Barabara von Roll pioneered in the treatment of mental illness and opened the field of 'psychosomatic medicine' by documenting the connection between physical and mental health. (Brooke 1997).

By the eighteenth century mental illness received greater attention in Europe and the USA. Although the focus was primarily on nosology and categorization, some therapeutic approaches included bloodletting, purgatives, dousing in ice water, and placement of the patient in a spinning chair until the patient lost consciousness. Benjamin Rush, the founder of US psychiatry, was an advocate of the latter method since he believed that congested blood in the brain caused mental illness, and the movement would relieve it (Alexander and Selesnick 1966).

During the nineteenth century, wives of US physicians entertained asylum patients in their homes, to 'calm a fevered mind' (Tomes 1994). They were often responsible for the 'moral' atmosphere of the institutions and advocated respect and attention to promote recovery. Dorothea Dix pioneered efforts to care for the mentally ill and reform inhumane practices.

In the late nineteenth century, about 200 women physicians staffed US asylums (Lunbeck 1994). In 1880, Alice Bennett became the first woman chief of a women's division, Norristown State Hospital. Bennett's unpopular and outspoken opposition to mechanical restraint and neglect of the chronically insane eventually caused her to lose her position.

By the twentieth century increasing numbers of women worked with the mentally ill. The development of psychoanalysis in Europe attracted many women who were important in the development of the field. In 1923, the American Psychoanalytic Association admitted two women, Lucille Dooley and Marion Kenworthy. Karen Horney challenged psychoanalytic

theory, and a school of psychoanalysis evolved around her work.

Over the next few decades, many notable women psychoanalysts emigrated from Europe to the USA. Prior to World War II, 30 percent of European and 20 percent of US psychoanalysts were women (Chodorow 1986). They contributed substantially to the growth and influence of psychoanalysis in the USA. Among the early women leaders were Clara Thompson, Hilda Bruch, Helene Deutsch, Phyllis Greenacre, Judith Kestenberg, Marianne Kris, Margaret Mahler, Edith Jacobson, Stella Chess, Frieda Fromm-Reichmann, and many others who pioneered as researchers and clinicians.

Grete Bibring became the first woman to head a department of psychiatry and become a full professor at Harvard Medical School. She was at Beth Israel Hospital in Boston. Viola Bernard was the first woman APA vice-president; she also led other psychiatric organizations and made pioneering contributions to social psychiatry.

Psychosomatics evolved in the 1930s with the significant contributions of women, such as Therese Benedek and Helen Flanders Dunbar. Marion Kenworthy was notable in exerting an influence on the military, successfully facilitating an increase in the number of mental health units on army bases (Deutsch 1959). In addition, she was a founding member and president of the Group for the Advancement of Psychiatry and became the first woman president of the American Psychoanalytic Association in 1958.

After World War II, women leaders emerged in organizations and academia, including Evelyn Ivey, Eveoleen Rexford, Helen Beiser, Jeanne Spurlock, Mildred Mitchell-Bateman, and June Jackson-Christmas. It is notable that the latter three were African-American.

Much of the leadership in the development of child psychiatry came from women, including those mentioned above. Melanie Klein developed internationally accepted theory concerning early life psychodynamic processes. Anna Freud contributed significantly to the understanding of ego development.

The 1970s marked another increase in numbers of women in psychiatry, coinciding with the women's movement in the USA. Still, women had few leadership roles although 20 percent of psychiatrists were women. In the 1980s and 1990s, women's leadership increased. Carol Nadelson was elected the first woman APA president in 1985, followed by Elissa Benedek and Mary Jane England. Carolyn Robinowitz became senior American Psychiatric Association Deputy Medical Director, and the first woman psychiatrist medical school dean. The APA has had several women officers, including its first women assembly speaker, Donna Norris. Other psychiatric organizations have had a few women leaders but have not developed female leadership in proportion to the increasing numbers of trained women psychiatrists.

Neuroscientist Nancy Andreasen was the first woman editor of the American Journal of Psychiatry. Judith Rappaport became the head of child psychiatry at the National Institutes of Mental Health. In Canada, Judith Gold was the first women president of the Canadian Psychiatric Association. In Australia, Beverly Raphael, the first woman psychiatry chair, became the first woman president of the Royal Australia New Zealand College of Psychiatry. Sarah Romans became the first woman psychiatry chair in New Zealand. Felice Lieh Mak, chair of psychiatry in Hong Kong, was the first woman elected president of the World Psychiatric Association, and Astrid Heiberg became the first woman professor of psychiatry in Norway. Women psychiatrists continue to expand their leadership roles in many countries of the world, and to become significant researchers in evolving areas of psychiatry. However, women's roles in organizational and academic leadership continue to be small.

5. *Female Leadership in Medicine and Psychiatry: The Twenty-first Century*

Although the number of women trainees in psychiatry in the USA approaches 50 percent, and there are substantial numbers of women in junior faculty positions in psychiatry, as in all areas of medicine, there are many fewer women at senior ranks than would be projected by the size of entering cohorts.

Women continue to make slower progress in academic psychiatry as in the rest of academic medicine. They often lack research training and rarely have the mentorship that will enable them to advance their careers. They are, less often than their male colleagues, offered research opportunities during training or at entry level academic positions, and they tend to be assigned clinical, teaching, and administrative tasks that are time-consuming and do not allow them to develop the necessary skills to enable them to progress academically. The pressures are greater for women interested in academic careers since they are in their peak childbearing years when they must also commit themselves to their career development.

Women in academic psychiatry, as in other fields of medicine, are less likely to have peer-reviewed grants or publications than men. Senior women in psychiatry in the USA are relatively productive in terms of research and publications, but they constitute only 5 percent of professors and 2 percent of department chairs in psychiatry. Controlling for relevant variables, women psychiatrists also earn less than men (Leibenluft 1999). This is not substantially different in other countries and in other medical fields.

It is interesting to note that the citation rate for women's articles has been reported to be higher than it is for men (Sonnert and Holton 1996). One report also found that both men and women full-time faculty were equally career motivated and that marital and family

status were not correlated with publication numbers. Being a parent, however, caused greater problems in academic productivity for women than for men (Carr et al. 1998). Women also had less institutional support. Compared to men with children, women with children had fewer publications. Lack of on-site and backup childcare, and other family leave policies presented significant problems for women faculty with children. Women with children had greater dependent responsibilities but similar professional time allocated responsibilities. There were no significant differences between the sexes for faculty without children (Carr et al. 1998).

Women experience a longer time to promotion than men. The difference in research productivity and publications, however, does not account for the large gender difference in promotion to senior ranks (Tesch et al. 1995, Tesch and Nattinger 1997).

Although childbearing and rearing remain key reasons for womens slower progress in their careers, there are other obstacles. Women's commitment, qualifications, and capabilities are questioned and doubted more than men's. Discrimination and the subtle harassment and demeaning of women continues to exist. Women are often related to in transferential roles. They are perceived and treated by many men as mothers, daughters, sisters, etc., making it difficult to also be a colleague and peer (Moss-Kanter 1977, Milwid 1982). This is also observed in group situations where women's opinions have been observed to spark negative and resistant responses, and their credibility in positions of leadership is often questioned (Nadelson 1987, Reich 1989).

A 1965 report in the *Harvard Business Review* suggested that these views are deeply entrenched. They reported that half of the men surveyed were not comfortable working for a woman; one fifth felt that women were temperamentally unfit to be leaders, and half of both men and women did not feel that women could succeed. Twenty years later the majority of men no longer felt that women were temperamentally unfit for management but the women continued to feel pessimistic about acceptance in the corporate world (Bowman et al. 1965, Sutton and Moore 1985).

Interestingly, an AAMC report (Bentsen 1998) stated that medical school deans, when questioned about the qualities necessary for their success, weighed interpersonal skills higher than any others, including academic and clinical experience, in their list of important qualities necessary for medical school leadership. They also highly ranked personality traits, managerial experience and taking pride in the accomplishments of others. Many of these traits are those characteristically attributed to women.

Men and women also have different perceptions of the need for female leadership. A survey at a medical school searching for a dean revealed that 99.9 percent of the women students and faculty and only 50 percent of the men thought that more women leaders were needed in medicine (Scadron et al. 1982). More current data on women in medical leadership implies that this attitude has not substantially changed. The usual reasons given for the lack of female leadership are that the numbers of women available are not sufficient, and/or that they are not motivated because of family responsibilities. The evidence suggests, however, that men and women in similar cohorts have different career trajectories, and that women are not promoted at the same rate as men, despite comparable qualifications (Tesch et al. 1995).

Clinical psychiatry has a rich history of female contributions and leadership. If the field is to continue to evolve and expand its knowledge base, women must play a vital role in research. That 50 percent of US trainees are women suggests that the talents and potential contributions of this substantial group will be lost if only 50 percent, rather than all of them, are seen as potential future researchers.

Women's Health

1. Introduction

Women's health is a broad term referring to physical and mental health problems that are of exclusive concern for women, and which are more common in women or which differ in presentation, severity, or consequences in women compared to men. Women's health is often defined in terms of reproductive health and safety for younger women and in terms of diseases that appear in the female reproductive organs. However, the most prevalent diseases in women are cardiovascular diseases. The universally lower social and economic status experienced by women, compared to that of men, also contributes to poor health and lack of access to care among women. As part of this lower status, violence against women has become a worldwide public health concern.

1.1 Demographic Imperatives

Substantial changes in women's health and life expectancy have occurred over the past 100 years. At the beginning of the twentieth century, in much of the Western industrialized world, life expectancy at birth for women was less than 50 years. Life expectancy at birth for women in most industrialized countries is now well into the late 70s and the early mid-80s, on average about seven to eight years longer than men. By age 65 and over, this gender gap narrows, and by age 85, life expectancy for women is very close to men's. Life expectancy is increasing in all countries. The worldwide birth rate is slowing down, which means that the proportion of older women will increase substantially as well as numbers.

Since most chronic diseases and disabilities occur in older women, in many respects women's health is concerned with older women. However, in developing countries, infectious diseases and maternal mortality remain high relative to those of industrialized countries. Since most of the world's women live in developing countries such as Asia, Africa, and Latin America, the impact of morbidity and mortality from these causes is significant from a global perspective. Cultural practices, views about health, and women's economic and social roles also greatly influence their physical and psycholsocial health. Since women live longer than men in most parts of the world, an array of poorly understood cultural, social, and behavioral consequences follow upon those changes. The increasing interconnectedness of the world by telecommunications and faster travel means that women's traditional roles may be rapidly influenced and changed dramatically by the alternatives presented to women through these channels. It is well documented that education for women can improve their health, increase women's reproductive autonomy, and increase women's life expectancy. The Global Burden of Disease report (Murray and Lopez 1998) has projected a decline in death from maternal mortality and an increase in noncommunicable diseases in women from 28.1 million death (1990) to 49.7 million in 2020. These changes are primarily due to reductions in early death in infancy, childhood, or in young adulthood from infectious diseases and improved prenatal care.

2. Socioeconomic Factors and Women's Health

2.1 Women's Socioeconomic Status

Worldwide, women's incomes are lower, and they are less educated than men, limiting their ability to meet

personal and family economic and social demands (UN 1995). In most of the world, women have primary responsibility for childcare and for maintaining the household (Haw 1995). Most women work either as employees or in subsistence agriculture as providers of food and shelter. In 1994, approximately 45 percent of the world's women aged 15–64 were economically active (International Labor Organization 1994) outside the home. The percentage of households headed only by women in Western Europe increased from 24 percent in 1980 to 31 percent in some areas of the world, it now exceeds 50 percent. In Africa, 60 percent of rural women live below the poverty line (Haw 1995). Total social and economic demands on women are therefore often higher than for men, and their ability to cope with these demands is often constrained by their socially defined roles, creating psychological as well as social conflicts. For example, women's family roles as primary parent may be in conflict with the need to earn a living. Some industrialized countries in Scandinavia and Europe offer flexible work policies, maternal and family leave, but this is far from being the rule.

2.2 Women's Health and Low Socioeconomic Status (SES)

SES is inextricably linked with poor health across the life span in both men and women. The effects of SES on women's health compared to men's health have not been well studied. Health effects of SES in women are likely to be confounded by marital status and by spousal income. Women who are not married are often of lower SES and women who are single heads of households are almost universally of lower SES than women who are married. Thus, it is difficult to separate the effects on health of women's social class from the effects of their spouse's social class. Most infectious and chronic diseases are more prevalent in women of lower socioeconomic status than in women of higher SES. In the United States in 1997 among women aged 65 and over, 12 percent of white women, 27 percent of African American women, and 26 percent of Hispanic women were living below the Federal poverty line (US DHHS 1999).

3. Medical Care

Medical care is a factor in women's health in several ways: (a) access to care is more limited for many women because of their lower economic status, (b) treatment of disease in women may be characterized by less aggressive follow up or by differential lack of recognition of the disease in women compared to men, (c) knowledge about the efficacy of treatments in women is limited by the past lack of clinical trails including women. Federal policies now require inclusion of women in medical research in many developed countries. Women in developed countries use more medical care services than men and are the major decision makers for healthcare utilization for their families. In developing countries, medical care is a more limited resource and so may be preferentially available to men. Reproductive health policies in many developed and developing countries restrict the rights of women to use contraceptives or to seek abortion for unwanted pregnancies. Prenatal care is limited as well, leading to higher maternal mortality rates in women of lower SES and in less affluent countries. Education of women in developing countries has been shown to reduce the birthrate and increase the use of contraceptive measures (World Health Report 2000).

4. Cultural and Ethnic Factors in Women's Health

Being a member of an ethnic group that is not the dominant culture in a country is often associated with a higher risk of disease and death. This happens at least in part because of the lower SES and ethnic discrimination often associated with immigration or minority status. In some instances, cultural or ethnic factors may be protective if traditional culture provides extensive social support and networks or includes better health or dietary practices than the dominant culture. In many cultures, women are denied education, employment, and basic human rights, and immigration may offer the opportunity to improve their circumstances. However, women from more traditional societies may be more dependent on their male partners, and immigration may result in greater isolation and substantial stress related to cultural dissonance of their expected role and the role of women in the dominant society (Carballo et al. 1996).

4.1 Culture and Healthcare

Immigrant and minority women usually face economic, legal, linguistic, and cultural barriers in obtaining healthcare. The higher vulnerability of immigrant and minority women to sexual abuse and violence increases their risk for sexually transmitted diseases (STDs) and posttraumatic stress disorders; issues which are rarely addressed in the healthcare settings in which these women find themselves. Even if a healthcare provider is sensitive to these issues, women may be reluctant to reveal what has happened due to fear and cultural taboos.

4.2 Ethnicity

The social environment encountered by women of color may account for a substantial part of ethnic differences in health. For example, Cooper et al. 1999) have described the higher rates of hypertension in African Americans compared to whites as arising

from their interaction with the social environment. Cross-national comparisons of Jamaicans and African Americans have shown that life expectancy amongst Jamaicans is six years longer than African Americans (74 compared to 70). African American women are at higher risk of cardiovascular diseases and hypertensive diseases. Obesity in African American women is consistently over 50 percent. The prevalence of most genetic factors is relatively low and none have been identified that contribute significantly to ethnic differences in health.

5. *Psychosocial Factors*

Some social and psychological factors significantly contribute to women's health status either directly as risk factors for disease, or indirectly by creating vulnerability to disease. Higher levels of social support have often been linked to better health outcomes in both men and women. Social support may modify the effects of other variables upon the risk of coronary heart disease. This may occur because social support may directly reduce reactivity to acute stressors, or by modifying behavioral risk factors. Social support may be an important factor in buffering the effects of stressors on cardiovascular diseases and blood pressure. Women may respond differently to social support than men, or may access different kinds of social support.

Social isolation has been linked to a higher risk of all-cause and cardiovascular mortality rates in both men and women (Kaplan and Salonen 1988). Social isolation may be more common in older women, although this issue has not been studied globally. Certainly, poorer survival among men leads to a disproportionate number of older women living alone. In the United States in 1990, 35.3 percent of all women aged 60+ were living alone (Casper and Barnett 2000). In countries where the sex difference in survival is greater, social isolation may be greater for women in old age. Social isolation in women is also linked to poorer SES.

5.1 *Psychological Factors*

Gender differences in the influence of traits such as hostility and anxiety on health have not been examined extensively. Matthews and Owens (1998) found that anger suppression and hostile attitudes were associated with higher levels of carotid atherosclerosis in middle-aged women. Knox et al. (1998) reported that coronary heart disease was more prevalent in women with higher levels of hostility. This association was modified by the presence of social support.

5.2 *Health Behaviors and Practices in Women*

Health behaviors such as preventive mammography screening or vaccinations and lifestyle factors such as smoking or obesity or exercise are important determinants of health in women. According to a 1998 survey of health behaviors, about 25 percent of US women aged 55+ are physically inactive and this number increases with age. Obesity is around 50 percent for African American women. Smoking prevalence has declined, but about 15 percent of women in the 55+ age group still smoke. Behavior or lifestyle factors also are associated with compliance with treatment for existing disease. For example, a study of adherence to cholesterol guidelines among women with heart disease revealed that older women, African American women, and married women were less likely to use lipid-lowering medications. Women who exercised, did not smoke, and drank moderate amounts of alcohol were more likely to use lipid-lowering medications. In the United States in 1997, the median percent of women who reported they had had a mammogram in the past year was 73.7 percent (range: 56.5–83.6 percent) 85 percent had a cervical smear and 66.4 percent had both a clinical breast exam and a mammogram. Screening behavior may increase with age as perceived risk increases. Women aged 55+ tend to seek both breast and cervical screening more often than younger women do. Acculturation and ethnicity also can affect health behaviors: Latin-American women who are less acculturated tend to smoke and drink less, exercise less, but are more often obese. Similar patterns are seen for African American women.

5.3 *Violence Against Women*

Violence against women, including rape and domestic assault, has also become a worldwide concern and a public health issue. Violence is related to the lower social and economic status of women compared to men. The World Health Organization (1996) has reported that the prevalence of physical abuse against women ranges from 20 percent to 50 percent based on 40 studies covering 24 countries on four continents. Rape and other forms of violence co-occur frequently. As well as having immediate and lasting physical health effects, such occurrences can affect women's psychological well-being; including self-esteem, poorer perceived health, obsessive disorders, eating problems, difficult interpersonal relationships and depression (Russo and Denious 1997).

6. *Menopause*

Although menopause has been more of a concern in developed countries, as maternal mortality declines and life expectancy increases in the developing world, the rate of growth in numbers of postmenopausal women is projected to increase. At this time, approximately 25 million women worldwide pass through menopause every year. By the year 2030, there will be 1.2 billion menopausal and postmenopausal women,

with an added 47 million new entrants each year (Hill 1996). By the decade 2020–2030, there may be nearly 5 million women reaching age 50 in sub-Saharan Africa, over 7 million in India and over 10 million in China. In the future, the vast majority of postmenopausal women will not be European in ethnicity. However, competing risks from the AIDS epidemic in Africa may well attenuate the numbers of women reaching middle age. As women age, their overall mortality rates and cardiovascular or cancer mortality rates tend to converge with men's rates, but do not generally exceed them. This convergence is often attributed to declining estrogen levels in women. The menopause is also accompanied by a number of other changes in both physical and mental health in women and by changes in social and cultural roles played by women.

Much of the menopause research had included only women of European background who are urban and affluent and relatively healthy (Kaufert 1996). In a number of cultures, menopause frees women from the threat of pregnancy and may even increase their status. Symptoms of menopause may vary by culture as well. The most consistently reported symptoms are hot flushes, ranging from nearly 60 percent in an affluent European sample to seven percent in Karachi. Reports of these symptoms are substantially lower in Japanese women (Lock 1998) compared to US or Canadian women. As well, symptoms associated with menopause by Japanese women are very different and may be more related to aging in general than to menopause *per se*. Menopause is often portrayed as a catalytic or even catastrophic event for women's health. For example, the increase in cardiovascular disease seen in women after menopause is primarily attributed to decrease in estrogen levels. However, other diseases such as breast or colorectal cancer, and dementia, also increase more rapidly after menopause. This fact is not consistent with the view that menopause is the major reason for decline in the health status of women. If she lives long enough, every women undergoes menopause, but most women do not become ill or dysfunctional after menopause. The great variations in cultural and socioeconomic factors influencing health status among women also suggest that the effects of biological menopause on health are no doubt contributory, but do no solely determine an older women's health status. Symptoms of the menopause vary across cultures, again suggesting social and cultural influences on the experience and importance of menopause in health.

7. *Disability and Aging*

Women in areas of the world other than the US and Europe more frequently suffer from lifelong nutritional deprivation, chronic and repeated exposures to infectious diseases, and poorer access to healthcare. Their reproductive experience is also very different, involving multiple births, possibly longer periods of breast feeding, and greater exposures to sexually-transmitted diseases. Older women in the non-European world more often face widowhood, divorce, abandonment, and poverty, and may carry the burden of caring for the elderly and grandchildren. Women spend a greater proportion of their older years with limitations in physical activity than do men with activities of daily living (ADLS) and instrumental activities of daily living (IADLS). The need for caregivers providing assistance with ADLS or IADLS also increases in women with age at a greater rate than it does for men. The percentage increase with age of women with unmet assistance needs is greater than for men, reflecting their greater longevity but also their higher levels of disability (US DHHS 1999). Such factors have a substantial social and economic impact upon the families of these older women.

8. *Conclusions*

The global response to the growing imperative of women's health in developed countries has included national policies which provide for increased research funding, establishment of wider availability of clinical care programs targeting women, and increased allocation in the private sector to treatments targeting women's diseases. Many countries and the World Health Organization have established a number of centers targeting women's health. Although women around the world often live longer and are healthier at younger ages than men, this longevity is often accompanied by greater levels of disability and health problems related to women's lower SES and restrictive traditional roles. In the most economically deprived areas of the world, women's lower status places them at higher risk of death, female infanticide, genital mutilation, socially sanctioned murder or suicide (of unwanted wives, for example), unwanted pregnancies, and sexually transmitted diseases such as AIDS. Globally, womens' health issues range from the subtle problems of menopause to the most glaring issues of outright violence and economic and social injustice.

Women's Religiosity

In Western societies, women are more religious than men on every measure of religiosity. Why this should be has attracted the sporadic attention of clergy, sociologists and psychologists, but it has never been a major interest of either sociologists of religion or feminists. The sociology of religion has only belatedly included gender on its agenda (Woodhead 2000). Feminists have been more concerned with why there are so few women in the priesthood than with why there are so many in the pews. They have also been concerned with documenting the historical antiwomen stance of Christianity, the pre-Christian spirituality of women, and the spirituality of hitherto ignored but highly gifted individuals, rather than documenting the ordinary religiosity of millions of churchgoing women. Feminist theories that religion is bad for women need to come to terms with, but in fact often ignore, women's opting for formal religion in greater numbers than men. This article reviews the possible explanations for women's greater religiosity, focusing particularly on mainline churchgoing in the west in the twentieth century. More detailed reviews may be found in Beit-Hallahmi and Argyle (1996, Chap. 8), Francis (1997), and Walter and Davie (1998).

1. Data

Whether it is a matter of churchgoing, private prayer, or the content of religious belief, women appear more religious than men, and have been for at least 200 years (Douglas 1978). Within Western Christianity, mainline churches demonstrate the greatest fall-off in attendance by men; independent, Pentecostal and Orthodox churches have been able to resist the trend. The extent to which secularization is caused by men reducing religious observance more than women varies by country (Woodhead 2000).

The dimension of religious life where the difference between women and men is biggest is private devotion—prayer and Bible reading. This raises the question whether men engage in religious practices when they are publicly acceptable or even required, but tend not to bother with private devotions when there is no social pressure. It is possible that secularization, defined as the decline in the social importance of religion, tends at the same time to lead to religion's feminization. Islam and Judaism, in which religion is still part of public life, involve men more than women in public worship.

Independent of degree of belief, *what* men and women believe differs. Women, if they are asked to describe the God in whom they believe, concentrate rather more on a God of love, comfort, and forgiveness, while men tend to refer to a God of power, planning, and control. How can such differences be explained?

1.1 Material and Social Deprivation

Neo-Marxist deprivation/compensation theories see religion as a way in which oppressed people cope with their misery and suffering. If, as feminists argue, women are more oppressed than men, we would expect more women than men to turn to religion. There certainly are examples of this, especially in the early periods of industrialization both historically in the West and in currently industrializing societies. In advanced industrial societies, however, there is less evidence for this theory of female religiosity, churchgoing being related to parenthood and employment status rather than to measurable indices of gendered deprivation.

1.2 Lack of Status

Women's systematic exclusion from better paid jobs, from political office, and from other parts of the public world has reduced their social status. Christianity's proclamation that God loves every individual equally may be more immediately attractive to those who are not accorded respect in society. Once inside the church, however, women may find themselves even more deprived of status and power vis-à-vis male members. Yet women remain in greater numbers than men. Ozorak (1996) found that many women valued their churches for the social and emotional support which existed irrespective of their exclusion from formal power; for those more concerned with connection and relationship than with hierarchy and power, the female fellowship of the church empowered them even though the office-holding men monopolized the glory.

Conservative churches and synagogues that emphasize traditional gender roles within the family appeal to many women: they provide status for the wife and mother, and provide hope that conversion may turn their menfolk into responsible husbands and fathers. This is no mean attraction for a woman struggling to rear a family in the slums of a newly industrializing city, whether she be a Methodist in Manchester in 1800 or a Pentecostal in Sao Paolo in 2000.

1.3 Guilt

A number of psychological studies show that women experience more guilt feelings than men. If one of the main purposes of Christianity is to assuage guilt, then we would expect it to attract those who feel a need for forgiveness. Some churches actively foster guilt feelings, which they then offer to resolve. Churches have often portrayed women as more guilty, more profane, than men. Insofar as Christianity induces guilt, we may say that religion not only compensates for a societally created deprivation of status and self-respect, but actually fosters the very deprivation that it then compensates for. This is perhaps the nearest to a feminist theory of why women should be attracted to a religion that oppresses them. Though there is plenty of historical evidence of this kind of process, some recent studies have not found that contemporary churchgoers have high levels of guilt.

1.4 Birth and Child-rearing

Christian faith is supposed to provide comfort against anxiety and existential terror; psychological studies point out that women generally have higher levels of fear than men. This could be related to their more direct involvement in the inherently scary businesses of birth and death and their day-to-day responsibility for child rearing. Men have comparable familiarity with sickness and death only on active service during wartime—a time when they too are more likely to turn to religion. What motherhood does for women, perhaps only war can do for men?

There have been very few studies into the spirituality of childbirth, so it is too early to say whether experiencing the 'miracle' of birth accounts in part for female religiosity. Much more research has been done into religiosity in relation to childrearing. The general pattern is that having children to look after raises men to the religious level of women; it is possible that the vulnerability and dependency of young children raises religious issues that men can normally avoid. It is therefore parenthood, not motherhood, that raises questions of existential anxiety and a desire to involve children in religion.

1.5 Workforce Participation

A major thread in theories of secularization is that the more people are immersed in the institutions of modernity, notably by working for bureaucratic and/or capitalist organizations, the more secular they are likely to become. Women who stay at home are therefore protected from the secularizing influence of the modern marketplace. This hypothesis (classically formulated by Luckmann) has led to a number of empirical surveys aiming to determine whether, and if so why, women who go out to work are less religious than those who stay at home.

The findings of these studies vary by country. Taking a paid job in, for example, Australia where there is a secular ethos in the workplace is likely to have a more secularizing effect than taking a job in the American bible belt. Since both data and hypotheses remain inconclusive, a constructive avenue of research might be to look at the *type* of paid work done by women. Women's paid work is far more likely than men's to be of a caring nature, involving skill in interpersonal relations and 'emotional labor.' If what protects women (and some men) from the secularity of modernity is not family life but interpersonal care, then those employees engaged in caring work should be compared with those engaged in other kinds of work. If research were to confirm that women paid to care are more religious than those paid to do other things we would still be left with a puzzle: are they more religious because the caring nature of the work protects them from secularity, or do they enter caring work because they were more religious to start with?

1.6 An Ethic of Connection

Gilligan (1982) considers that women operate according to a flexible ethic of compassion and connection rather than abstract justice. Woodhead (2000) has used this insight to critique the 'privatization thesis,' namely that in an alienating, plural modern world, people retreat to the private sphere where they find identity, meaning, and … religion. She suggests that this thesis makes sense from a male perspective,

but women are less involved in the alienating public sphere. For them, religion has less to do with providing meaning and more to do with articulating the social relationships that are so important to their lives. Traditional churches do this by encouraging the family, but they can also encourage other kinds of relationships. A religion whose founder emphasized love and compassion is more likely to appeal to Gilligan's women. Indeed, male clergy have often struggled to make Jesus appeal to macho men. Their concern finds an echo in Thompson's (1991) finding that what is correlated with Christian religiosity is not census-bureau gender but a 'feminine' worldview, that is, one that is affectionate, sympathetic, sensitive to the needs of others, eager to soothe another's feelings, tender, and loving toward children.

1.7 Death

The extent to which religion is a way of helping humans deal with death has been extensively debated. What is clear is that women encounter death disproportionately as carers, and also as mourners. In the times of high infant mortality, women may have been more affected than their husbands by the deaths of their children, though men were more likely than women to lose a spouse—as nineteenth century gravestones bear ample witness. Today, with women living longer than men and marrying younger than them, wives are very likely to outlive their husbands. Spousal bereavement is now a much more common experience for women than for men. Whether or not this helps to explain women's greater religiosity, it seems very likely to lie at the root of the most common form of afterlife belief in the modern West, namely a belief in reunion with loved family members. Women who place a high value on personal relationships are unlikely to give them up when death intervenes, and this may possibly account for women being more likely than men to experience the presence of one who is dead.

Insofar as St Paul is correct that life after death is central to Christianity, and insofar as women have a greater interest in there being life after death, we may postulate that some women's religiosity may be rooted in their experience of death and bereavement. On the other hand, it may be the other way around—that more women than men believe in life after death simply because of their general religiosity.

Women's Suffrage

The campaign for women's suffrage has been the most visible feature of that broader historical movement for ending women's subordination to men that we now call feminism. Demands for women's vote and full citizenship have arisen as part and parcel of efforts to democratize political participation, during the transition from absolutist monarchies to democratic republics. These efforts first began in western Europe and North America where citizenship, including the right to vote, was accorded first to adult men, initially as propertied heads of households and increasingly, from the mid-nineteenth century onward, as male individuals. Advocates of women's suffrage demand that the franchise be accorded without distinction of sex, in parallel with other campaigns that argued for ending exclusions based on property qualifications (i.e., class) or race. They argued that women constitute half the human race and must not be excluded from political decision-making.

1. Women's Suffrage and Democratization

In some European societies, critiques of women's subordination—by women and men alike—antedated by several centuries the demands for women's suffrage that erupted with the advent of the French revolution in 1789. From that time forth, however,voting quickly became a symbol of full citizenship and personal independence—for women as well as for men. Women's suffrage advocates saw the vote not as a goal in itself but rather as the key to all other reforms, a means for women to acquire the political power necessary to improve or transform their disadvantaged situation in the short run (primarily through improved educational and economic opportunities), and, in the

long run, of dismantling the laws, structures, attitudes, practices, and knowledge that undergirded male dominance. Women's suffrage advocates argued that women's participation in community decision-making could be effective at various levels: in school boards, in workers' or business councils, in local, regional, or provincial affairs. But the most desirable and seriously contested form of voting in the newly emerging representative governments was at the national, federal, or parliamentary level. It was there that questions about the national budget and taxation, and about war, peace, and social and economic policy were being decided. It was also there—where power, authority, and control over collective resources were most concentrated—that the strongest resistance to woman suffrage would be found. The problem suffrage advocates faced in these new male-dominated regimes was to convince already established and exclusively male bodies to acknowledge women's capabilities and equality and to admit them to full citizenship, not as a privilege but as a right. In virtually all countries women suffrage advocates included some sympathetic men. In some countries, however, antisuffrage forces mobilized substantial numbers of supporters of both sexes on the grounds that women should not be permitted in, or were unsuited for, public affairs. In their view, public business was exclusively men's business, and women, as legal dependents, should consider their interests represented by husbands, fathers, or guardians.

Despite very substantial resistance, the twentieth century ultimately witnessed the mass enfranchisement of women throughout the world, along with proclamations of (and sometimes even the granting of) their equal legal, educational, and economic rights. The United Nations Convention on the Political Rights of Women (1952) firmly underscored women's equal right to vote. Only in authoritarian societies where political representation and community decision-making have not been permitted has the demand for woman suffrage been muted. At the beginning of the twenty-first century, only a few sovereign states in the Middle East, such as Saudi Arabia (where no one votes) and Kuwait, have unconditionally refused to enfranchise women. What political power the vote actually provides to women or men in different countries, however, varies greatly, depending on the size and strength of political parties, the modes of election, and many other factors.

2. *History of Women's Suffrage*

The first explicit arguments for women's participation in political decision-making were expressed at the outset of the French Revolution, initially by the Marquis de Condorcet in 1787 and 1790, and in a number of anonymous pamphlets that turned these arguments into demands to be admitted to exercise the *droit de cité*, denouncing masculine aristocracy and challenging men's right to make the rules for women. As revolutionary French assemblies proceeded to declare the Rights of Man, to draft constitutions and reshape old laws for a new society, individual women such as Olympe de Gouges and men such as Pierre Guyomar insisted on women's full inclusion in the decision-making process. After four years of resisting eloquent arguments for women's inclusion, revolutionary political leaders shut women out of political life on the grounds that women and government should not be mixed, an argument that had centuries-old roots. These demands were widely repeated in the 1830s and again, in early 1848, when leaders of the revolutionary Second Republic decreed universal (manhood) suffrage, and a group of Parisian women immediately organized to protest their exclusion. Deliberate choices of words from 'male' to the more subtle '*en âge viril*' signaled the exclusion of women from political affairs, and campaigns ensued to change the wording of electoral laws, as from 'male' to 'person' or to stipulate 'and women' following 'men,' or to add the term 'of both sexes' to qualify the masculine 'Français.' Despite these early beginnings, however, French women only acquired the vote in 1944; the French campaign for woman suffrage began earlier than elsewhere and lasted far longer. Resistance to women in positions of authority was deeply embedded in France. There the 'Rights of Man' were constantly qualified on grounds of 'public utility' when it came to women's rights.

In the English-speaking world, governing elites began to re-examine their electoral laws in the late eighteenth- and early nineteenth centuries. Demands for women's suffrage were strongly expressed during the 1820s. The Reform Act of 1832 in England added the word 'male' to qualify electors, even as it broadened the franchise greatly, and in the next few decades a number of other European countries moved to do the same. The campaign for a Second Reform Act in the late 1860s mobilized women to seek inclusion. John Stuart Mill brought their demands to change 'male' to 'person' to the floor of Parliament during his brief tenure as representative of Westminster; although parliamentary suffrage was not forthcoming, qualified women did obtain a local vote in 1869. The campaigns in England would continue into the twentieth century, when they rose to a new peak, thanks to the combined efforts of the National Union of Woman Suffrage Societies (NUWSS) and the more militant activities of the Women's Social and Political Union (WSPU). The spectacular and extensive campaigns of the WSPU from 1906 through 1913, featuring mass parades, public demonstrations, occasional incidents of violence against state property, and the imprisonment and force-feeding of suffrage militants by British authorities gained world media attention and set a benchmark by which all other campaigns were subsequently judged. The cause of woman suffrage

became a decisive political issue for both England and Ireland, and Irish suffrage advocates did not soon forgive their parliamentary deputies, who in 1912 sacrificed the cause of British women's suffrage in order to obtain Irish home-rule. Ironically, Irish women did receive the vote along with English women who met certain property or educational qualifications in 1918; 'universal' suffrage including all women did not become a reality in the United Kingdom until 1928.

In the United States, democracy without women began to emerge in the 1820s, as various states slowly lifted property qualifications on white male voters. The demand for the vote was a key feature of the 'Declaration of Sentiments' issued by the first women's rights convention, held in Seneca Falls, New York, in 1848. Because US electoral laws were made at the state level, not at the federal level, suffrage advocates faced the challenge of organizing suffrage campaigns on a state-by-state basis, following their exclusion from the federal amendment that enfranchised black men after the Civil War. The territory of Wyoming enfranchised women in 1869, and Utah territory in 1870, but these proved exceptions until new western states granted votes to women in the 1890s. Resistance to woman suffrage remained strong in the eastern, central, and southern states. In the United States, racial and immigration issues complicated the problem still further and from the passage of the Fourteenth Amendment to the Civil Rights Movement of the 1960s, even black men's vote in southern states was often qualified by literacy requirements, poll taxes, or threats of physical violence. Finally, in the early twentieth century, suffrage leaders decided to attempt the federal amendment approach again; following a huge prosuffrage campaign, reminiscent of the British suffrage movement, Congress passed the nineteenth amendment, which was successfully ratified by a majority of states and became law in 1920. Democracy, even without women, was not an unproblematic development, even in the US; indeed, few nation-states had wholeheartedly embraced the principle of full democratic participation in government by the end of the nineteenth century, even for all men.

The first nation-states to enact full woman suffrage were New Zealand (1893) and two Australian states (1894, 1899). Originally British colonies, these South Pacific outposts of the British Empire—like the western states of the USA—proved more favorable to women's citizenship than the older, more settled, and more authoritarian societies of Europe and Asia.

In some twentieth-century continental European countries, where the demographic balance had tilted and adult women began to outnumber men significantly, the prospect of convincing men in power to enfranchise women became even more complicated. This complication was compounded by concern among ruling elites over Marxist-socialist enthusiasm for enfranchising all women along with all men, irrespective of social class (endorsed by the Second International in the 1890s); the Socialist Women's International endorsed unrestricted suffrage for women in 1907. It was further compounded by longstanding concerns among otherwise liberal, even progressive men that women would vote as the priests dictated, to the detriment of progressive (often anticlerical) secularizing regimes (especially after the Roman Catholic Church muted its earlier opposition to woman suffrage following World War I). Meanwhile, Finnish women obtained the vote alongside their menfolk in 1906, when Finland obtained a degree of independence from the Russian Empire; by 1913 Norwegian women were also fully enfranchised, followed by Danish women in 1915. Suffrage campaign strategies would differ markedly, depending on whether men had already been enfranchised in a particular setting, and to what degree.

3. *The International Woman Suffrage Alliance*

The International Woman Suffrage Alliance (IWSA), founded in 1902, brought national organizations of European and North American women together to support each other's campaigns in a more politically astute, systematic fashion. By 1913, the IWSA had affiliated societies from most European countries (including Bulgaria, Hungary, Romania, Russia, and Serbia), and from the far-flung corners of the British Commonwealth—Australia, Canada, and South Africa. The 1920s would see a remarkable extension of IWSA's network, to include delegations from Latin America, Egypt, China, and other non-Western countries. But the organization's leadership became increasingly torn between the need to focus on suffrage in countries where women did not yet have the vote, and the need to advance progressive women's agenda for change in the countries where they could already vote. Issues of married women's nationality, combating state-regulated prostitution and the traffic in women and children, and fostering peace were the focus of considerable activity by IWSA's board and member organizations. Controversy over protective legislation for women workers vs. absolute equality in the workplace led to schism in the organization in 1926, and to a reorientation of focus.

4. *Women's Suffrage from the 1920s to the 1950s*

In some countries, women sometimes gained the vote with far less of a struggle than in France, England, or the United States. After World War I, for instance, new governments accorded woman suffrage as part of universal suffrage in a number of European countries, defeated during the war, that had acquired new, progressive regimes—Weimar Germany, the Austrian Republic, Hungary, etc. The Russian Revolution in

1917 brought women the vote, but the subsequent rule of the Communist Party ensured that they would have no choice in whom to vote for. Western and Central European political parties began to develop an interest in women voters, at the same time attempting to keep them at arm's length from party decision-making positions or candidacy for office. The various socialist parties elected the most women to office, but even then their leadership was reluctant to allow women representatives much leeway in deviating from the party line, which continued to insist on noncooperation with 'bourgeois' feminists. Catholic political parties were equally reticent when it came to incorporating women into party leadership. In a time when adult women very often outnumbered men, all parties were understandably interested in whether or not women might vote as a bloc. Several initiatives to form women's political parties and coalitions (e.g., England, Sweden, Austria) did not succeed, and overall it seems to be the case that during the early years, women's voting patterns resembled those of men, and often they were somewhat more conservative. This did not deter fascist governments from striking out against elections in general, and in particular, against the ostensible threat of women's active participation in political life.

In Latin American countries, where voting, even for men, was often restricted by birth, property, literacy, marital status, or racial qualifications, suffrage became a priority for women in some countries and not in others. Woman suffrage became an important issue in Cuba, Uruguay, and Brazil, and in Mexico during the late 1920s and early 1930s, but seemed less urgent in other Latin American states, where social justice issues were paramount concerns for political women. Miller (1991, p. 96) observes that 'effective universal suffrage, male and female, did not exist anywhere until after World War II.' But Lavrin (1995) emphasizes the breadth and importance of woman suffrage campaigns in Argentina, Uruguay, and Chile, accompanied by the emergence of women's parties.

Only after 1945 did women's suffrage find a place in the political cultures of most Asian countries. Indonesia and Japan enfranchised women in 1945, while Chinese women gained the vote in 1947. India enfranchised women in 1949, following independence (though limited suffrage for some women had existed since 1919). Successful decolonization campaigns have led to women's enfranchisement in many other countries. (A comprehensive chronology of women's suffrage can be found in Daley and Nolan 1994).

5. *Scholarship on the Women's Suffrage Movement*

Scholarship on the history of the women's suffrage movement has expanded substantially since the 1960s, thanks in part to the development of social history and the inclusion of women's movements in the study of political movements and collective action and also to the dramatic growth of women's studies as an academic field. Contextualization of the various national and local suffrage movements has been an important objective of recent studies, along with comparative studies of the international women's movement (Rupp 1997). Scholars have also published comprehensive biographical studies of some of the internationally prominent suffrage movement leaders, including Elizabeth Cady Stanton, Harriot Stanton Blatch, Carrie Chapman Catt, Millicent Garrett Fawcett, Hubertine Auclert, and Aletta Jacobs, and have pressed for the recognition of women's suffrage leaders in national and international biographical dictionaries. Others have begun to examine the cultural history (theatre, literature, arts, campaign propaganda, public manifestations, even trials) of the most expansive woman suffrage campaigns. The literature on the British and American suffrage movements is voluminous; only the most recent works will be listed below (bibliographies in these works will lead readers to the earlier and classic works; see also the bibliographies in Offen 2000 and Daley and Nolan 1994). Documentary films have brought the British and American suffrage campaigns to the attention of English-speaking television audiences (MacKenzie 1988, Ward et al. 1999), and commemorative museum exhibits organized in London and various American states have attracted sizeable audiences. In other countries the movement for women's suffrage has also begun to generate a growing historical literature, in a variety of languages, even as political scientists debate the results that woman suffrage has had in various political contexts. Comparative analyses of women's suffrage movements are still in their early stages (see Bolt 1993 and Bader-Zaar 1994), and a global assessment of the long-term significance and consequences of women's suffrage remains to be undertaken.

Word Classes and Parts of Speech

There is a long tradition of classifying words, for the purpose of grammatical description, into the ten word classes (or parts of speech) noun, verb, adjective, adverb, pronoun, preposition, conjunction, numeral, article, interjection. While each of these terms is useful, and they are indispensable for practical purposes, their status in a fully explicit description of a language or in general grammatical theory remains disputed. Although most of the traditional word class distinctions can be made in most languages, the cross-linguistic applicability of these notions is often problematic. Here I focus primarily on the major word classes noun, verb, and adjective, and on ways of dealing with the cross-linguistic variability in their patterning.

1. *The Classification of Words*

Words can be classified by various criteria, such as phonological properties (e.g., monosyllabic vs. polysyllabic words), social factors (e.g., general vs. technical vocabulary), and language history (e.g., loanwords vs. native words). All of these are classes of words, but as a technical term, word class refers to the ten traditional categories below (plus perhaps a few others), most of which go back to the Greek and Roman grammarians. In addition to the terms, a few examples are given of each word class.

Noun	*book*, *storm*, *arrival*
Verb	*push*, *sit*, *know*
Adjective	*good*, *blue*, *Polish*
Adverb	*quickly*, *very*, *fortunately*
Pronoun	*you*, *this*, *nobody*
Preposition/adposition	*on*, *for*, *because of*
Conjunction	*and*, *if*, *while*
Numeral	*one*, *twice*, *third*
Article	*the*, *a*
Interjection	*ouch*, *tsk*

(In this article, the more general term 'adposition' will be used rather than preposition, because many languages have postpositions rather than prepositions, and word order is irrelevant in this context.)

The special status of the classification above derives from the fact that these are the most important classes of words for the purpose of grammatical description, equally relevant for morphology, syntax, and lexical semantics. This makes the classification more interesting, but also more complex and more problematic than other classifications of words. Besides the term word class, the older term part of speech (Latin *pars orationis*) is still often used, although it is now quite opaque (originally it referred to sentence constituents). The term word class was introduced in the first half of the twentieth century by structuralist linguistics. Another roughly equivalent term, common especially in Chomskyan linguistics is 'syntactic category' (although technically this refers not only to lexical categories such as nouns and verbs, but also to phrasal categories such as noun phrases and verb phrases).

The main two problems with the maximal word-class above are (a) that some of the classes intersect (e.g., the English word 'there' is both a pronoun and an adverb), and (b) that the different classes do not have equal weight; while most languages have hundreds of verbs and thousands of nouns, there are far fewer pronouns and conjunctions, and often only a handful of adpositions and articles. The solution that is often adopted explicitly for the second problem is to make a further subdivision into major word classes (nouns, verbs, adjectives, adverbs) and minor word classes (all others). (Alternative terms for major and minor classes are content words/function words and, especially in Chomskyan linguistics, lexical categories/functional categories.) This distinction is discussed further in Sect. 2. The solution to the first problem that is implicit in much contemporary work is that pronouns and numerals are not regarded as word classes on a par with nouns, verbs, prepositions, and so on. Instead, they are regarded as semantically highly specific subclasses of the other classes. For instance, there are nominal pronouns (e.g., *he, who*), adjectival pronouns (e.g., *this, which, such*) and adverbial pronouns (e.g., *here, thus*). Similarly, there are adjectival numerals (*five, fifth*), adverbial numerals (*twice*), and nominal numerals (*a fifth, a five*). Some languages also have verbal pronouns and verbal numerals. Accordingly, this article will not deal with pronouns (see *Pronouns*) and numerals (see *Numeral Systems*).

2. *Content Words and Function Words*

In all languages, words (and entire word classes) can be divided into the two broad classes of content words and function words. Nouns, verbs, adjectives, and adverbs are content words, and adpositions, conjunctions, and articles, as well as auxiliaries and words classified as 'particles' are function words. While there is sometimes disagreement over the assignment of words and even entire word classes to these two broad categories, their usefulness and importance is not in doubt. Content word classes are generally open (i.e., they accept new members in principle) and large (comprising hundreds or thousands of words), and content words tend to have a specific, concrete meaning. They tend to be fairly long (often disyllabic or longer), and their text frequency is fairly low. By contrast, function word classes are generally closed and small, and function words tend to have abstract, general meaning (or no meaning at all, but only a grammatical function in specific constructions). They tend to be quite short (rarely longer than a syllable), and their text frequency is high. This is summarized in Table 1.

The reason why auxiliaries are not included in the traditional list of word classes is probably merely that they are not prominent in Greek and Latin grammar, but in many languages these 'function verbs' are very important (English examples are *be, have, can, must, will, should*). The class 'particle' is really only a waste-basket category: function words that do not fit into any of the other classes are usually called particles (e.g., 'focus particles,' such as *only* and *also*, 'question particles,' such as Polish *czy* in *Czy mówisz po polsku*? 'Do you speak Polish?,' or 'discourse particles' such as German *ja* in *Das ist ja schön!* 'That's nice! (expressing surprise).'

The precise delimitation of function words and content words is often difficult. For instance, while the conjunctions *if, when, as,* and *because* are unequivocally function words, this is less clear for words like *suppose, provided that, granted that, assuming that*. And while the adpositions *in, on, of, at* are clearly function words, this is less clear for *concerning, considering, in view of*. In the case of adpositions, linguists sometimes say that there are two subclasses, 'function adpositions' and 'content adpositions,' analogous to the distinction between content verbs and function verbs (= auxiliaries). Another widespread view is that word-class boundaries are not always sharp, and that there can be intermediate cases between full verbs and auxiliaries, between nouns and adpositions, and between nouns/verbs and conjunctions. Quite generally, function words arise from content words by the diachronic process of grammaticalization (see *Grammaticalization*), and since grammaticalization is generally regarded as a gradual diachronic process, it is expected that the resulting function words form a gradient from full content words to clear function words. When grammaticalization proceeds further, function words may become clitics and finally affixes, and again we often find intermediate cases which cannot easily be classified as words or word-parts.

3. Defining Nouns, Verbs, and Adjectives

In the following, the emphasis will be on the content word classes nouns, verbs, and adjectives (for adverbs, a problematic class, see Section 5.3 below). The properties of the function words are more appropriately discussed in other contexts (e.g., auxiliaries in the context of tense and aspect, conjunctions in the context of subordinate clauses, and so on).

Before asking how nouns, verbs, and adjectives are defined, it must be made clear whether a definition of these word classes in a particular language (e.g., English or Japanese) is intended, or whether we want a definition of these classes for language in general. The widely known and much-maligned definitions of nouns as denoting 'things, persons, and places,' of verbs as denoting 'actions and processes,' and adjectives as denoting 'properties' is, of course, hopelessly simplistic from the point of view of a particular language. In most languages, it is easy to find nouns that do not denote persons, things, or places (e.g., *word, power, war*), and verbs that do not denote actions or processes (e.g., *know, lack, exist*), and many languages also have adjectives that do not denote properties (e.g., *urban, celestial, vehicular*). However, if the goal is to define nouns, verbs, and adjectives in general terms that are not restricted to a particular language, these simplistic notional definitions do not fare so badly.

In the first part of the twentieth century, the structuralist movement emphasized the need for rigorous language-particular definitions of grammatical notions, and notionally based definitions of word classes were rejected because they patently did not work for individual languages or were hard to apply rigorously. Instead, preference was given to morphological and syntactic criteria, e.g., 'if an English word has a plural in *–s*, it is a noun,' or 'if a word occurs in the context *the … book*, it is an adjective.' But of course this practice was not new, because words like *power* and *war* have always been treated as nouns on morphological and syntactic grounds. Some older grammarians, neglecting syntax, defined nouns, verbs, and adjectives exclusively in morphological terms, and as a result nouns and adjectives were often lumped together in a single class in languages like Latin and Greek, where they do not differ morphologically. But the predominant practice in Western grammar has been to give priority to the syntactic criterion. For instance, adjectives in German have a characteristic pattern of inflection that makes them quite unlike nouns, and this morphological pattern could be used to define the class (e.g., *roter/rote/rotes* 'red (masculine/feminine/neuter)'). However, a few property words are indeclinable and are always invariant (e.g., *rosa*, as in *die rosa Tapete* 'the pink wallpaper'). These words would not be adjectives according to a strictly morphological definition, but in fact everybody regards words like *rosa* as adjectives, because they can occur in the same syntactic environments as other adjectives.

Thus, there is universal agreement among linguists that language-particular word classes need to be defined on morphosyntactic grounds for each individual language. However, two problems remain. (a) The generality problem: how should word classes be defined for language in general? Morphological patterns and syntactic constructions vary widely across languages, so they cannot be used for cross-linguistically applicable definitions. (b) The subclass problem: which of the classes identified by language-particular criteria count as word classes, and which only count as subclasses? For instance, English has some property words that can occur in the context *is more … than*, e.g., *beautiful, difficult, interesting*. Another group of semantically similar words (e.g., *pretty, tough, nice*) does not occur in this context. Nobody takes this as evidence that English has two different word classes where other languages have just a single class (adjectives), but it is not clear why it does not count as sufficient evidence.

The solution to the generality problem that is usually adopted (often implicitly, but cf. Schachter 1985 and Wierzbicka 2000) is that one defines word classes on a language-particular basis, and then the word class that includes most words for things and persons is called 'noun,' the word class that includes most words for actions and processes is called 'verb,' and the word class that includes most words for properties is called 'adjective.' However, the subclass problem has not been solved or even addressed satisfactorily, and the use of word-class notions in a general or cross-linguistic sense remains problematic.

4. *Characterizing Nouns, Verbs, and Adjectives*

Despite the theoretical problems in defining word classes in general, in practice it is often not difficult to agree on the use of these terms in a particular language. This is because nouns, verbs, and adjectives show great similarities in their behavior across languages. Their most common characteristics are briefly summarized in this section.

4.1 *Nouns*

In many languages, nouns have affixes indicating number (singular, plural, dual, see *Grammatical Number*), case (e.g., nominative, accusative, ergative, dative), possessor person/number ('my,' 'your,' 'his,' etc.), and definiteness. Some examples follow.

(a) Number. Khanty (Western Siberia) *xot* 'house,' *xot-yyn* 'two houses' (dual), *xot-yt* 'houses' (plural).

(b) Case. Classical Arabic *al-kitaab-u* 'the book' (nominative), *al-kitaab-i* 'the book's' (genitive), *al-kitaab-a* 'the book (accusative).'

(c) Possessor person/number. Somali *xoolah-ayga* 'my herd,' *xoolah-aaga* 'your herd,' *xoleh-eeda* 'her herd,' *xooli-hiisa* 'his herd,' etc.

Syntactically, nouns can always be combined with demonstratives (e.g., *that house*) and often with definiteness markers (*the house*), and they can occur in the syntactic function of argument (subject, object, etc.) without additional coding. Thus, in a simple two-argument clause we can have the *child*$_N$ *caused the accident*$_N$, but not **smoke*$_V$ *causes ill*$_A$. (Here and in the following, the subscripts *N*, *V* and *A* indicate nouns, verbs and adjectives.) Verbs like *smoke* and adjectives like *ill* need additional function-indicating coding to occur in argument function (*smok-**ing** causes ill-**ness***). Because reference is primarily achieved with nouns, it is nouns that can serve as antecedents for pronouns (compare *Albania's destruction of itself* vs. **the Albanian destruction of itself* (impossible)). Finally, nouns are often divided into a number of gender classes which are manifested in grammatical agreement (see *Grammatical Gender*).

4.2 *Verbs*

In many languages, verbs have affixes indicating tense (present, past, future), aspect (imperfective, perfective, progressive), mood (indicative, imperative, optative, subjunctive, etc.), polarity (affirmative, negative), valence-changing operations (passive causative, see *Valency and Argument Structure in Syntax*), and the person/number of subject and object(s) (see *Grammatical Agreement*). Semantic notions that are more rarely expressed morphologically are spatial orientation and instrument. Some examples follow.

(a) Tense. Panyjima (Australia) *wiya-lku* 'sees,' *wiya-larta* 'will see,' *wiya-rna* 'saw.'

(b) Subject person/number. Hungarian *lát-ok* 'I see,' *lát-sz* 'you see,' *lát* 's/he sees.'

(c) Valence-changing. Turkish *unut-* 'forget,' *unut-ul-* 'be forgotten' (passive), *unut-tur-* 'make forget' (causative).

(d) Spatial orientation. Russian *vy-letat*' 'fly out,' *v- letat*' 'fly in,' *pere-letat*' 'fly over ,' *vz-letat*' 'fly up.'

Syntactically, verbs generally take between one and three nominal arguments, e.g., *fall* (1: patient), *dance* (1: agent), *kill* (2: agent, patient), *see* (2: experiencer, stimulus), *give* (3: agent, patient, recipient). Nouns and adjectives may also take arguments, but they are not nearly as rich as verbs, and nouns that correspond to verbs often cannot take arguments in the most direct way (compare *Plato defined beauty* vs. **Plato definition beauty* (impossible); additional coding is required: *Plato's definition of beauty*. Verbs always occur as predicates without additional coding, whereas nouns and adjectives often need additional function-indicating coding when they occur as predicates, namely a copular verb (cf. *Halim works*$_V$ vs. **Halim a worker*$_N$ (impossible), **Halim hard-working*$_A$ (impossible); here the copula *is* is required).

4.3 *Adjectives*

In a fair number of languages, adjectives have affixes indicating comparison (comparative degree, superlative degree, equative degree), and in a few languages, adjectives are inflected for agreement with the noun they modify. Some examples follow.

(a) Comparison. Latin *audax* 'brave,' *audac-ior* 'braver' (comparative), *audac-issimus* 'bravest' (superlative).

(b) Comparison. Tagalog (Philippines) *mahal* expensive;' *sing-mahal* 'as expensive as.'

(c) Agreement. Hindi *acchaa* 'good' (masculine singular), *acchee* (masculine plural), *acchii* (feminine singular/plural).

In many languages, adjectives show no inflectional properties of their own. Syntactically, a peculiarity of adjectives is that they can typically occur in comparative constructions (whether they show affixes marking comparison or not), and they can be combined with degree modifiers of various kinds that do not co-occur with verbs and nouns (e.g., *very hot*$_A$, *too difficult*$_A$, cf. **work*$_V$ *very*, **too mistake*$_N$ (impossible)). Adjectives generally occur as nominal modifiers without additional coding (cf. *a bald*$_A$ *man*), whereas nouns and verbs mostly need additional function-indicating coding when they occur as modifiers (**a beard*$_N$ *man*/*a man with a beard*, **a shave*$_N$ *man*/*a man who shaves*).

5. *Difficulties of Classification*

The general properties of nouns, verbs, and adjectives that were sketched in Sect. 5 are sufficient to establish these classes without much doubt in a great many languages. However, again and again linguists report on languages where such a threefold subdivision does not seem appropriate. Particularly problematic are adjectives (Sect. 5.1) but languages lacking a noun–verb distinction are also claimed to exist (Sect. 5.2), and Sect. 5.3 discusses adverbs, which present difficulties in all languages.

5.1 *The Universality of Adjectives*

In contrast to nouns and verbs, adjectives are sometimes like function words in that they form a rather small, closed class. For instance, Tamil (southern India) and Hausa (northern Nigeria) have only about a dozen adjectives. Interestingly, in such languages the concepts that are denoted by adjectives in the small class coincide to a large extent (Dixon 1977): dimension ('large,' 'small,' 'long,' 'short,' etc.), age ('new,' 'young,' 'old,' etc.), value ('good,' 'bad'), color ('black,' 'white,' 'red,' etc.). Other concepts for which English has adjectives (e.g., human propensity concepts such as 'happy,' 'clever,' 'proud,' 'jealous,' and physical property concepts such as 'soft,' 'heavy,' 'hot') are then expressed by verbs or by nouns. For instance, in Tamil, 'heavy man' is *ganam-uḷḷa manuṣan*, literally 'weight-having man,' and in Hausa, 'intelligent person' is *mutum mai hankali*, literally 'person having intelligence.'

But even more strikingly, many languages appear to lack adjectives entirely, expressing all property concepts by words that look like verbs or like nouns. For instance, in Korean, property concepts inflect for tense and mood like verbs in predication structures, and they require a relative suffix (see *Relative Clauses*) when they modify a noun, again like verbs (cf. (b) (i), (ii)) below.

(a) Predication

(i) Event

salam-i *mek-ess-ta*
person-NOMINATIVE eat-PAST-DECLARATIVE
'the person ate'

(ii) Property

san-i *noph-ess-ta*
hill-NOMINATIVE high-PAST-DECLARATIVE
'the hill was high'

(b) Modification

(i) Event

mek-un *salam*
eat-RELATIVE person
'a person who ate'

(ii) Property

noph-un *san*
high-RELATIVE hill
'a high hill'

While languages where all property words can be classified as verbs are very common, languages where all property concepts are nouns are less widely attested. A language for which such a claim has been made is Ecuadorian Quechua: in this language, property concept words can occur in argument position and take the same inflection as nouns (cf. (a)(i), (ii) below), and nouns can occur as modifiers without additional coding, like property words (cf. (b) (i), (ii) below).

(a) argument position

(i) Thing

wambra-ta-mi
child-ACCUSATIVE-FOCUS
wajta-rka
hit-PAST.3RD.SINGULAR
'he hit the child'

(ii) Property

jatun-ta-mi

big-ACCUSATIVE-FOCUS

wajta-rka

hit-PAST.3RD.SINGULAR

'he hit the big one'

(b) modification

(i) Thing

rumi wasi

stonehouse

'stone house'

(ii) Property

jatun wambra

big child

'big child'

Thus, it is often said that while nouns and verbs are virtually universal, adjectives are often lacking in languages. However, it is generally possible to find features that differentiate a property subclass within the larger class to which property words are assigned. For instance, Korean property verbs do not take the present-tense suffix *-nun*, and Ecuadorian Quechua thing words do not combine with the manner adverb suffix *-ta* (e.g., *sumaj-ta* 'beautifully,' but not **duktur-ta* 'in a doctor's manner'). Here the subclass problem arises: on what grounds do we say that Korean has two classes of verbs (non-property verbs vs. property verbs), rather than two word classes (verbs and adjectives)? Since this question is difficult to answer, some linguists have claimed that most languages have adjectives after all, but that adjectives have a strong tendency to be either verb-like or noun-like (e.g., Wetzer 1996).

5.2 *The Universality of the Noun–Verb Distinction*

For a few languages, it has been claimed that there is no (or only a very slight) distinction between nouns and verbs, for instance for several North American languages of the Wakashan, Salishan, and Iroquoian families, as well as for a number of Polynesian languages. For instance, in Samoan (a Polynesian language), full words referring to events and things show intriguingly similar behavior. Both thing (or person) words and event words seem to occur in the same predication structures (a) and in argument positions (b) below.

(a) Predication

(i) Thing

sa fōma'i le fafine

PAST doctor the woman

'the woman was a doctor'

(ii) Event

sa alu le fafine

PAST go the woman

'the woman went'

(a) Argument

(i) Thing

e lelei le fōma'i

GENERIC good the doctor

'the doctor is good'

(ii) Event

e lelei le alu o le vasi

GENERIC good the go of the bus

i Apia

to Apia

'it's good that the bus goes to Apia'

Clearly, the similarity of thing-words and event-words in such languages is quite striking and differs dramatically from what is found in the better-known European languages. But thing-words and event-words do not behave exactly alike in Samoan; the pattern above is asymmetrical in that *fōma'i* means 'be a doctor' and 'person who is a doctor,' but *alu* does not mean both 'go' and 'person who goes,' but rather 'the fact of going.' Upon closer examination, it has usually turned out that major word classes which can be called nouns and verbs can be distinguished even in the problematic languages.

5.3 *The Problem of Adverbs*

Adverbs are the most problematic major word class because they are extremely heterogeneous in all languages, and unlike for nouns, verbs, and adjectives, no semantic prototype can be identified easily for them (cf. Ramat and Ricca 1994). The most that can be said in general about adverbs is that they serve to modify non-nominal constituents (verbs or verb phrases, adjectives, other adverbs, sentences). Perhaps the

concept of adverb should not be taken too seriously, because there are very few properties that adverbs of different kinds share. Five broad subclasses of adverbs are often distinguished: setting adverbs (locative: *here, there, below, abroad*; temporal: *now, then, yesterday, always*), manner adverbs (*quickly, carefully, beautifully*), degree adverbs (*very, too, extremely*), linking adverbs (*therefore, however, consequently*), and sentence adverbs (*perhaps, fortunately, frankly*) (see Quirk et al. 1985 for the most comprehensive semantic classification of adverbs).

Setting adverbs, degree adverbs, and linking adverbs are relatively small, closed classes, and they often share properties with function words. Sentence adverbs are rare in most languages, and their great elaboration is probably a peculiarity of the written languages of Europe (Ramat and Ricca 1998). The only sizable subclass of adverbs that has equivalents in many languages is the class of manner adverbs. Many languages have a productive way of forming manner adverbs from adjectives (e.g., English *warm/warmly*, French *lent* 'slow,' *lentement* 'slowly'). But this also makes manner adverbs problematic as a major word class, because one could argue that adjective-derived manner adverbs are just adjectives which occur with a special inflectional marker to indicate that they are not used in their canonical noun-modifying function. This point of view is non-traditional, but it seems quite reasonable, and it is strengthened by the fact that in quite a few languages, adjectives can be used as manner adverbs without any special marking.

One of the main features that unifies the various subclasses of adverbs in languages like English and French is that four of the five classes contain adjective-derived words ending in *-ly/-ment* (only setting adverbs are almost never of this type). This is certainly no accident, but it should also be noted that this is probably a feature typical of European languages that is hardly found elsewhere.

6. *Theoretical Approaches*

While the identification and definition of word classes was regarded as an important task of descriptive and theoretical linguistics by classical structuralists (e.g., Bloomfield 1933), Chomskyan generative grammar simply assumed (contrary to fact) that the word classes of English (in particular the major or 'lexical' categories noun, verb, adjective, and adposition) can be carried over to other languages. Without much argument, it has generally been held that they belong to the presumably innate substantive universals of language, and not much was said about them (other than that they can be decomposed into the two binary features [±N] and [±V]: [+N, −V] = noun, [−N, +V] = verb, [+N, +V] = adjective, [−N, −N] = adposition) (see *Linguistics: Theory of Principles and Parameters*).

Toward the end of the twentieth century, linguists (especially functionalists) became interested in word classes again. Wierzbicka (1986) proposed a more sophisticated semantic characterization of the difference between nouns and adjectives (nouns categorize referents as belonging to a kind, adjectives describe them by naming a property), and Langacker (1987) proposed semantic definitions of noun ('a region in some domain') and verb ('a sequentially scanned process') in his framework of Cognitive Grammar. Hopper and Thompson (1984) proposed that the grammatical properties of word classes emerge from their discourse functions: 'discourse-manipulable participants' are coded as nouns, and 'reported events' are coded as verbs.

There is also a lot of interest in the cross-linguistic regularities of word classes, cf. Dixon (1977), Bhat (1994) and Wetzer (1996) for adjectives, Walter (1981) and Sasse (1993a) for the noun–verb distinction, Hengeveld (1992b) and Stassen (1997) for non-verbal predication. Hengeveld (1992a) proposed that major word classes can either be lacking in a language (then it is called rigid) or a language may not differentiate between two word classes (then it is called flexible). Thus, 'languages without adjectives' (cf. Sect. 6) are either flexible in that they combine nouns and adjectives in one class (N/Adj), or rigid in that they lack adjectives completely. Hengeveld claims that besides the English type, where all four classes (V−N−Adj−Adv) are differentiated and exist, there are only three types of rigid languages (V−N−Adj, e.g., Wambon; V−N, e.g., Hausa; and V, e.g., Tuscarora), and three types of flexible languages (V−N−Adj/Adv, e.g., German; V−N/Adj/Adv, e.g., Quechua; V/N/Adj/Adv, e.g., Samoan).

The most comprehensive theory of word classes and their properties is presented in Croft (1991). Croft notes that in all the cross-linguistic diversity, one can find universals in the form of markedness patterns; universally, object words are unmarked when functioning as referring arguments, property words are unmarked when functioning as nominal modifiers, and action words are unmarked when functioning as predicates. While it is not possible to define cross-linguistically applicable notions of noun, adjective, and verb on the basis of semantic and/or formal criteria alone, it is possible, according to Croft, to define nouns, adjectives, and verbs as cross-linguistic prototypes on the basis of the universal markedness patterns.

For a sample of recent work on word classes in a cross-linguistic perspective, see Vogel and Comrie (2000), and the bibliography in Plank (1997). Other overviews are Sasse (1993b), Schachter (1985), and further collections of articles are Tersis-Surugue (1984) and Alpatov (1990).

Word, Linguistics of

In thinking about words, the first question is how to divide an utterance up into them. The simple answer is that words are demarcated by spaces, just as they are on this page. But this simple answer depends on the existence of writing. In speech, we do not normally leave a space or pause between words. Most languages throughout history have not been written down. Surely we do not want to say that only written languages have words, and, even with written languages, spacing does not provide an entirely satisfying answer. For example, English compounds can be spelled in three ways: open, closed, or hyphenated, and some items can be spelled in any of these three ways without being affected in any detectable way: *birdhouse*, *bird-house*, *bird house*. We do not want to say that the first spelling is one word, the last spelling two words, and the middle one neither one word nor two, which we would have to do if we accepted spaces as criterial. The better conclusion is that spelling conventions are not a completely reliable clue to whether something is a word or not.

Some linguists avoid the problem by claiming that the whole notion 'word' is theoretically invalid, just an artifact of spelling. In their favor is the fact, which people are always surprised to learn, that not all languages have a word for 'word.' The classical languages, biblical Hebrew, classical Greek, and classical Latin, for example, all have terms that are systematically ambiguous among 'speech,' 'word,' and 'utterance' but none has terms that distinguish clearly among these notions and certainly none has a special term that means just 'word.' Even in the opening verse of the Gospel of John, 'In the beginning was the Word,' it is still not clear just what is the meaning of the Greek word *λόγος* [*logos*] that we conventionally translate as 'word.' Many scholars believe that the best translation is 'thought' or 'reason.'

The classical languages are not alone. The anthropologist Bronislaw Malinowski declared that the distinction between word and utterance was not an obvious one to most peoples, that 'isolated words are in fact only linguistic figments, the products of an advanced linguistic analysis' (Malinowski 1935, p. 11), suggesting that there was no reason for most languages to distinguish between words and utterances. Nonetheless, most modern linguists believe that all languages do have words, whether their speakers are aware of the units or not. The question then becomes how to figure out what a word is and how to identify words in a way that is valid for all languages, written or spoken, and, since language is first and foremost spoken, our answer must not depend on writing.

The earliest explicit discussion that we have of the notion 'word' and of words in the speech stream is in the work of Aristotle. Aristotle made a distinction between an utterance or sentence, for which he used the term *λόγος* [*logos*] (confusingly, the term that we

usually think of as meaning 'word'), and a word, which he called: *μέρος λόγου* [meros logou], literally 'piece of an utterance.' Aristotle's term is still with us, since it was translated literally into the Latin term *pars orationis*, from which in turn we derive the English term 'part of speech' by a similar literal translation. He defined this new entity as a component of a sentence, having a meaning of its own and not further divisible into meaningful units (*De interpretatione* 2–3). In other words, Aristotle saw the speech stream as being divided up into atomic pieces, each being what we now call a word. The problem of defining words and identifying them was thus one and the same for him. Aristotle, incidentally, identified only two types of words, or parts of speech, which correspond roughly to our own nouns and verbs.

It is difficult for us to appreciate the importance of Aristotle's realization that the speech stream could be divided into pieces, because we are aware of words. We have been taught to think of language in terms of words and if we think about speech, it is not as a stream, but as words lined up one after the other, like pearls separated by knots on a string. But in a culture without writing or in a culture such as that of ancient Greece, in which writing played an extremely small part in the life of even the most educated people, this conception is not at all obvious. After all, the philosophical school of Aristotle was called peripatetic because his method of teaching consisted of discussion, conducted while walking about in the Lyceum of Athens. This intellectual style was purely oral, not written, and for both Plato and Aristotle, language was spoken, not written. Indeed, Aristotle's teacher Plato had a deep distrust of writing, which he called inhuman. This role of spoken language in classical Greece must be underscored because spoken language, unlike modern written English, is not a string of pearls. We do not speak in single words with spaces between, and so the discovery that speech could be broken down into smaller component words was indeed remarkable.

Was it an accident that Aristotle made his discovery about words in one of the first societies with writing? Many people would say that written language, even an alphabet, is a prerequisite for linguistic awareness: we cannot begin to analyze the stream of language until we see it recorded in writing. This claim faces a number of obstacles, most prominently the fact that the most advanced system of linguistic analysis known prior to the advent of modern linguistics in the nineteenth century was that of the Sanskrit grammarians, the best known of whom was Panini. Panini flourished around 500 BCE. His grammar was embedded within an oral tradition of grammatical analysis of the Sanskrit sacred texts that must have begun long before him. Strikingly, we have no evidence at all of writing in Sanskrit until at least several hundred years after Panini, leading to the conclusion that the Paninian tradition of linguistic analysis, which recognized not only words, but also the internal parts of words, and used the notion of 'zero' long before the Hindu mathematicians who introduced it to the rest of the world, existed before the advent of writing in India.

So writing is not a prerequisite to recognizing that the stream of language can be broken down into words. Even so, having language written down as an object must have assisted in the recognition of the words. The evidence from early writing is tantalizing, but mixed. On the one hand, the earliest writing systems, notably Sumerian cuneiform and Egyptian hieroglyphics, had no consistent means of dividing the text into words. Similarly, ancient Semitic and Greek texts were usually written continuously, with no spaces between words, and the practice extended into medieval times for Latin. Even among modern languages, Chinese, to this day, is always written without any spaces between words. On the other hand, later cuneiform scripts did mark the boundaries of words and the Etruscans, whose alphabet was based on the Greek alphabet, marked these from quite early on by means of a centered dot, a practice continued by the Romans: when one looks at the inscriptions on such monuments of Imperial Rome as Trajan's column, inscribed in the same Roman forms that we use most commonly today on our word processors and which are consequently so strikingly readable, one sees these same dots separating the words. In the Semitic scripts that descend from the first alphabet there are special forms of certain letters that appear only at the ends of words. The Greek letter sigma has two forms, one of which is used only at the ends of words. Even when there were no spaces between words, these languages could not be written without knowing where a word ended. Finally, the Aramaic scripts (notably Syriac, in which many important documents of the early Christian church were written, and which is still important for Christian scholars today) were the first to develop a cursive form, where all the letters of a word are joined together into a single unit, again impossible without knowing where a word begins and ends.

So there is evidence from early in the history of writing that, although a writing system can record language without breaking it down into words, it is equally possible to represent the breaks between words. What permits people to do this reliably? How do we know where one word ends and the next one begins in spoken language?

For some languages, the answer lies in sound, specifically word stress or word accent. In the simplest case, every word in the language is stressed on the same syllable, so that one can quite easily recognize the words directly from the stresses. Hungarian and Czech, for example, have inexorable word-initial stress, while Persian has word-final stress and Polish has stress on the second-to-last syllable. In all of these cases, even if a person does not speak the language, he or she can usually tell directly from the stress where the

word breaks are. Even a computer, properly programmed, would be able to break up the speech stream of these languages into words without knowing what any of these words mean.

Of course, not all languages are quite so simple. In English and Russian, for example, although every word has a main stress, so one can determine the number of words in an utterance from the number of main stresses, the stress patterns of these words are not easily predictable; some words are stressed on the first syllable (e.g., '*sym*pathize'), while others are stressed on the last (e.g., 'kanga*roo*') and others on the second-to-last ('re*mem*ber') or even the third-to-last ('a*no*maly'). A fluent speaker just knows for every word where the stress lies and speakers seldom make mistakes. No one says 'sympath*ize*,' or 'kang*a*roo,' or 'ano*ma*ly.' So an English speaker has no trouble telling where the word breaks are, but the task is quite overwhelming for a learner or for a simple computer program. In the most problematic type of languages for a stress-based method of word division, as with French or many of the languages of India, there is no word stress, so that phonology cannot be used to detect word division in a simple way.

But French still has words, so there must be some nonphonological way to isolate words. One clever test that linguists use for word divisions involves interruption. Take a sentence like *Theformerleaderremainedinsidethe WhiteHouse*, which is here written without spaces in order to emphasize the difficult nature of the task. Where can this sentence be interrupted? We may understand this question in two ways. One involves pauses: where is it possible to pause naturally? The other involves insertion: where can we insert elements in the string without affecting its structure. Curiously, the two give us slightly different answers. The natural-pause criterion identifies words as follows: *The former leader remained inside the White House*. Insertion gives us the following breaks (with inserted elements in parentheses): *The* (*recalcitrant*) *former* (*American*) *leader* (*stubbornly*) *remained* (*ensconced*) *inside* (*precisely*) *the* (*stately*) *White House*. The resulting sentence may not be elegant, but it is English. We do not normally pause after the definite article 'the' in English, because the article is what linguists call a clitic, an element that cannot be pronounced as a word all by itself, though other criteria such as insertion may identify it as a word. We cannot either pause or insert an element between the two elements of 'White House' because, despite the space in the standard orthography, 'White House' is a single compound word. We may then use the twin criteria of possible natural pause and insertion in order to identify the breaks between words in a spoken utterance. These criteria, though seemingly simple, depend on the *possibility* of pause and insertion. A learner thus has to compare numerous utterances before being able to break an utterance up reliably into words.

Where to pause or insert may seem obvious (though again our familiarity with written language may give us false confidence), but there are places in our sentence where, although linguistic analysis tells us there are breaks between elements, these breaks are below the word level, and where, though a machine might be tempted, both pause and insertion are impossible for speakers of the language. For example, 'leader,' 'remained,' and 'inside' can easily be divided into 'lead-er,' 'remain-ed,' and 'in-side,' yet no English speaker would insert an element or pause at these divisions. Here we are dealing with the meaningful parts of words, which linguists call morphemes, the divisions between which are not easily recognized by speakers.

Aristotle identified two types of words, nouns and verbs. School grammars permit more: adjectives, adverbs, pronouns, prepositions, and conjunctions. Linguists call these different types lexical categories and distinguish between open and closed categories. Open categories are those to which new members may be added easily, either by word formation or by borrowing from other languages. In English, the open categories are noun, verb, and adjective. We add new nouns at a tremendous rate, verbs and adjectives more slowly. The other categories are closed: for example, no new pronoun has been added to English since 'them' was borrowed from Old Norse over a millennium ago.

The lexical categories differ from language to language. The class of adjectives is much smaller in many languages and in some, like the Dravidian languages spoken widely in South India, it has only a dozen or so members. Even the class of verbs may be very small in some languages (e.g., Bengali). English also has more prepositions than most languages; some Austronesian languages of Indonesia have only one. Languages may even lack certain lexical categories. English is unusual in having a category of adverbs separate from adjectives and many linguists believe that the distinction between the two is not even valid for English. It has also been claimed that some languages do not distinguish nouns from verbs.

How to define the categories is another question. The traditional definitions are based on meaning: a noun denotes a person, place, or thing; a verb denotes an action or state; an adjective denotes an attribute. But these definitions are problematic. Nouns like 'love' or 'confusion' denote states, not things, as do adjectives like 'solid' and 'angry,' while relational nouns or verbs like 'mother,' 'son,' and 'include' fall under none of the standard meaning-based definitions. Modern linguists prefer instead to define the categories grammatically, in terms of how they function in a sentence. A noun is thus the head or main word of a subject or object phrase, an adjective/adverb a modifier, and a verb the main word of a predicate phrase.

Over the last century, the major research preoccupation of linguists concerned with words has been with

analyzing their internal structure or morphology. Almost all languages have internally complex words, though a few, notably Vietnamese, have very simple word structure, limited largely to compounds, words formed by combining words, like English 'shoelace' or 'boxcar.' In most languages, the majority of complex words are formed with suffixes like the '-er' and '-ed' in 'leader' and 'remained' above. Somewhat less frequent across language are prefixes like 'un-' in 'undo,' 'unpack,' and 'unroll.' In English and many other languages, prefixes and suffixes may combine, resulting in words like 're-institut-ion-al-iz-ation' or the infamous 'anti-dis-establish-ment-ari-an-ism.' Less common means of forming complex words may involve internal sound changes like 'mouse/mice' or 'goose/geese' or even changes in stress like that between the verb 're*ject*' and the noun '*re*ject.' Another mechanism is to repeat part of a word: in ancient Greek, the past tense of a verb is produced by repeated the first consonant; the stem '*graph*' (meaning 'write') becomes '*gegraph*' in the past tense, and similarly for other verbs.

Linguists distinguish two grammatical functions of complex words, inflection and derivation. The word inflection descends from the Latin verb meaning 'bend.' The idea is that a word bends or adjusts its shape to fit its context in a sentence. In English, the vast majority of verbs inflect, or adjust their shape, for person and tense by suffixation in a simple fashion: the past tense/past participle form of most verbs is formed by adding the suffix '-ed' as in 'remain-ed,' the third person singular present adds '-s' ('remains') and the present participle adds '-ing' ('remaining'). Elsewhere, the verb is morphologically simple ('remain'). We may say that the four verb forms ('remained,' 'remains,' 'remaining,' and the uninflected 'remain') constitute a set, with the grammar deciding the context in which each member of the set will appear. We call this set of forms a lexeme and we use the uninflected form (here 'remain') to name the set. For most English nouns, there are two inflected forms in the set of each lexeme, the singular and the plural.

English inflection is very simple, but other languages are much more complex. In many of the Indo-European relatives of English, nouns and adjectives inflect differently depending on their function in a sentence, the way English pronouns do ('I, me, my, mine'). A Russian noun or adjective will usually have ten inflectional forms. Verbs can be much more complex. Some languages have noun classes or genders, a dozen or more in the Bantu languages that dominate Africa, and in these languages many verbs have a distinct inflectional form for every gender. Verbs also often inflect for tense and for the person and number of the subject, with the result that verb inflection may become baroque, with over two hundred forms for every verb in ancient Greek, a thousand or more in Navajo, and a theoretically infinite number for each verb in Turkish. Experimental studies have shown that the inflected forms of a single lexeme are very closely tied to one another in the mind.

The other mechanism for forming complex words is derivation, which results in new lexemes, rather than contextually limited forms of the same lexeme. Thus, 'bakes,' 'baked,' and 'baking' are all inflected forms of a single verb lexeme, 'bake,' but 'baker' and 'bakery' are different words, nouns, distinct lexemes from 'bake,' though formed by the same general method (suffixation) as the inflected forms. And each of these nouns in turn may be inflected: 'bakers, bakeries.' Two different lexemes like *bake* and *baker* will normally not be as tightly connected in a person's mind as are the forms of a single lexeme.

This brings us to the general question of how words are stored in the human mind, how we retrieve them when we speak or write, and how we recognize them when we understand language. This is the frontier of linguistic research on words and it involves cooperation among linguists, psychologists, and neuroscientists. The results of this line of research are very exciting, though not well enough established to allow for firm conclusions. What we can say is that the question of what is a word will continue to be fundamental, even as the methods of research on language become more and more sophisticated.

Word Meaning: Psychological Aspects

Word meaning can be studied from multiple perspectives including linguistic, philosophical, and psychological. This article focuses on the issues of meaning of most interest to psychologists: how to characterize the knowledge that constitutes people's mental representation of meanings, and how to describe the use of this knowledge in interpreting words that are heard or read.

1. Approaches to Word Meaning

When people think casually about the topic of *word meaning*, they typically think of dictionaries. They view dictionary entries as constituting a statement of a word's meaning. They also think of the dictionary as the ultimate authority on the correct meaning: in any dispute, they defer to the dictionary definition as determining what is right. In doing so, they adopt implicit assumptions that word meanings belong to a language, as opposed to its users, and that there are experts who alone are qualified to report the true meaning of each word.

Elements of this sort of view appear in some linguistic and philosophical approaches to word meaning. For instance, language is sometimes treated as an abstract system to be analyzed, without reference to the users of the system. And Putnam's (1975, Chap. 12) influential philosophical approach to meaning appeals to a 'division of linguistic labor,' suggesting that correct use of some common words can be determined only by experts who have special knowledge of the entities in question.

However, modern *lexicographers*—those who write dictionaries—do not hold such a view themselves. Their job in providing dictionary definitions is not to report the 'true' meaning of a word that is divorced from what ordinary speakers of the language use the word to mean. The meanings associated with words change over time, as their use by speakers of the language shifts. For instance, 'nice' currently has a highly positive connotation but in earlier times referred to someone who was ignorant or foolish; 'hussy' meant a housewife, and 'mistress' was simply a feminized form of 'mister' (Hock and Joseph 1996, Chap. 7). Just a generation ago, 'mouse' referred only to a small rodent; now it is used more often to refer to a computer peripheral. The goal of lexicographers must therefore be to capture something about how a community of speakers uses a word at a particular time in the history of the language (see, e.g., Laird 1978).

Psychologists interested in word meaning take a perspective more similar to that of lexicographers than to either the layperson's intuitive view or the view reflected in the kinds of linguistic and philosophical approaches mentioned. Psychologists view meanings as changeable, as belonging to individual language users, and as shared across communities of language users. But psychologists, unlike lexicographers, are particularly interested in mental representation and in the cognitive processes that draw on mental representation. Their primary goals in the study of meaning are to characterize the knowledge that constitutes word meanings and to describe how this knowledge is used in interpreting words heard or read.

2. Meaning as Concepts

A standard way of describing what constitutes a word meaning, for a psychologist, is to say that meanings consist of *concepts*. Concepts are coherent nonlinguistic knowledge about some entity or set of entities (e.g., a person could have a concept of his or her brother Max and also a concept of what brothers are in general). A strict one-to-one correspondence does not exist between the words known by a person and his or her concepts, since a person can have a concept without having a word to label it. (Children in the early stages of language learning presumably are often in this situation.) Also, a person occasionally may know a word but have little or no meaning associated with that word. In most cases, though, the words stored in a person's memory will have meanings associated with them, and the argument is that the stored meaning for each word consists of a concept. Thus, for any given person, the meaning of 'brother' consists of his or her concept of what a brother is, the meaning of 'run' consists of his or her concept of what running is, and so on. For many common words, the associated concept is assumed to be similar for most people, and so the meaning is shared.

The idea that word meanings are concepts, though, does not delve very far into the question of the nature of meaning. If meanings are concepts, and psychologists want to understand the nature of meanings, they need to know in more detail what concepts consist of. Psychologists have devoted much effort to the study of concepts, both for their own sake and in order to understand word meaning (e.g., see *Natural Concepts, Psychology of*).

An early answer to the question of what concepts are like was suggested by linguists pursuing their own interests in word meaning. The proposal from linguistics was that the meaning of a word is a set of *defining features*; that is, features true of all things appropriately called by that name and together separating

those things from all things called by other names. For instance, defining features for the word 'bachelor' might be 'adult,' 'male,' and 'unmarried.' This proposal was closely related to analyses by anthropologists suggesting that kin terms such as 'mother' and 'grandmother' could be analyzed in terms of elements of meaning such as such as sex (male vs. female) and generation (one removed vs. two removed). Psychologists initially adopted the defining features view as a view of the nature of concepts, not of word meaning. Under the perspective that word meanings consist of concepts, though, the circle back to the original linguistic theorizing is closed, with the difference that psychologists considered defining features to constitute the mental representation of the meaning, not a meaning detached from individual minds.

By the mid 1970s, psychologists were finding this analysis of concepts and meanings problematic because for many words, it was impossible to determine defining features. Rosch and Mervis (1975) suggested that concepts consist, instead, of sets of features having varying strengths of association to the category. For instance, most fruits are juicy but a few are not; many fruits are sweet, but some are not; some have a single pit while others have many seeds. The most common features, like *sweet* and *juicy* for fruit, are true of prototypical examples but are not defining features. If word meanings are represented by concepts, then according to this analysis, they are represented by concepts that include *prototypes* and probabilistically associated features, but not defining features.

Refinements and modifications to this view of concepts have been made. Most notable is the idea that concepts are not simply unstructured collections of features; instead, they are held together by a 'conceptual glue' that provides information about the relation of features to one another and to the entities in question (e.g., Murphy and Medin 1985). For instance, a person's concept of birds might include the information that they all have wings, that most fly, and that some nest in trees, but these are not unrelated pieces of information. Instead, the concept includes the knowledge that having wings has a particular causal relation to flying and being able to fly has a particular causal relation to being able to nest in trees. If concepts include such information, then word meanings, likewise, do.

3. *Multiple Meanings: Polysemy*

Research on concepts has thus by now provided a fairly detailed (though still evolving) view of what concepts consist of. In that sense, word meanings are also understood in some detail. However, saying that meanings are concepts leaves some important issues unresolved. These issues revolve around the fact that many words have more than one meaning. In a small number of such cases, a word has two unrelated meanings, such as 'ear' meaning either a sense organ or a part of a corn plant. In these cases, it is often historical accident that the two meanings are expressed through the same word. During the earlier history of the language, two more distinctly different words may have been used, but they evolved into the same form as changes to the sound or spelling patterns of the language took place. Of greater interest for theories of meaning are cases of *polysemy*, where a single word has two or more meanings that are related in some way. For instance, the word 'run' means something somewhat different, but not entirely so, in each of the following phrases: 'run a race,' 'run errands,' 'run for election,' 'run a company,' 'the machine is running,' 'the water is running,' 'the movie runs three hours.' In other cases of polysemy, a word may be used in more radically different (yet still clearly related) ways. For instance, the word 'newspaper' most typically refers to a physical object consisting of printed pages of newsprint, but in sentences like 'The newspaper is being sold' or 'The newspaper says Jones is leading in the polls,' the same word is being used to refer to the corporate entity that produces the physical object, or to the writers whose writing appears in the physical object. Sometimes a word is even used as a part of speech it has not been used as before, as 'siren' is in 'The police sirened the car to a stop' (Clark and Clark 1979). The challenge for a psychological view of meaning is to explain how mental representations accommodate the different senses a word may have, and how the intended sense is understood.

One approach to addressing this challenge is to say that people have a single meaning stored in their memory for a given word, and variations on that meaning are created by the context it occurs in. A person would take into account his or her stored concept for the word along with other information in the sentence and discourse context to determine the meaning. In some cases, there may be regularities in what kinds of meanings can be constructed that allow people to quickly arrive at the relevant meaning. For instance, there may be a general rule that says that names of objects can be used to stand for people associated with those objects, making figuring out the meaning of cases like 'The newspapers says Jones is leading in the polls' straightforward (Nunberg 1979). In other cases, there may be no standard rule, but other aspects of the context, including knowledge of the background and goals of the person who said or wrote the sentence, are sufficient for the reader or hearer to figure out the right meaning.

This view assumes that the word's meaning itself changes in the contexts. An alternative way of framing what happens is to say that *interpretation* of the word is modified by the context, but the word meaning itself stays the same. For instance, the meaning of 'newspaper' is always about a physical object made of

newsprint, but a person can draw on that meaning, along with any standard rules and various clues from the sentence and discourse context, to figure out that the speaker is using the word 'newspaper' to refer to something somewhat different. This alternative framing is more consistent with the idea that meaning consists of concepts, because it distinguishes between meaning as stored knowledge and the use of that stored knowledge to construct an interpretation on an occasion of use.

Whichever framing is used, it is unlikely that all variations in interpretation/meaning are constructed anew in interpreting a word in a particular context. One reason for thinking so is that it has been impossible to determine 'core' meanings from which all other meanings can be derived. For instance, there is no set of features associated with the central meaning of 'run' that seem to be true of all the senses of 'run.' In some cases, senses of a word seem to develop in *chains* (Lakoff 1987, Case Study 2), where one sense derives from another, and another from that one, until there are senses having little or nothing in common with the typical sense. For instance, the concept associated with 'box' in its most central sense is something like a rectangular container made of cardboard for storing solid objects. However, there have come to be cardboard juice boxes (for drinking, not storing, and for liquids, not solids). From those developed plastic (not cardboard) reuseable juice boxes, and from them, plastic juice boxes in the shape of various animals (not rectangular). A plastic bear-shaped juice box has none of the properties associated with typical boxes, yet people willingly call it 'juice box.' Thus it seems likely that people learn and store senses for 'box' that are distinct from and in addition to their stored knowledge about ordinary cardboard boxes. Another reason for thinking that at least some of the variations are stored in memory is that some are encountered repeatedly (as in the case of 'juice box'), so it would be inefficient to have to derive them anew each time.

If, as this last point suggests, a number of different senses are stored in memory, one might wonder what part of the stored knowledge should be identified as the concept that constitutes the word's meaning. One way to resolve the problem may be simply to say that each word has multiple concepts associated with it, with the concepts in some cases differing only subtly from one another. Just as a person's concept of a sparrow vs. of a finch may be distinct but only slightly different, so may be his or her concepts associated with a polysemous word like 'run.'

4. *Meaning Across Languages*

So far, all the examples discussed have been of English words and their associated concepts. Speakers of English generally have the intuition that the distinctions they make between chairs and sofas, bottles and jars, and so on are so obvious that the same distinctions must be observed by speakers of other languages: the words would differ but the concepts associated with them would be the same. However, the situation is not that simple. Words that are traditionally translated as equivalent by dictionaries are not always fully equivalent on closer examination. For instance, Spanish speakers apply the word '*botella*' to a much narrower range of objects than English speakers apply the word 'bottle' to. On the other hand, English speakers apply the word 'on' to a more restricted range of spatial relations than Spanish speakers apply the word '*en*' to. Apparently, the concepts associated with the words are not identical. Such differences can be found across many languages and for words labeling many different kinds of entities.

This observation raises at least two important questions, one theoretical and one practical. The theoretical one concerns the relation between language and thought. A controversial proposal in psychology and linguistics has been that the language a person speaks influences the way he or she perceives the world (see Lucy 1992). If the meaning of 'bottle' and '*botella*' are not the same, or the meaning of 'on' and '*en*' are not, do people in some way perceive the objects or spatial relations differently depending on their language? For instance, if five objects are all called 'bottle' in English, but require two different names in Spanish, does the Spanish speaker see them as more different than the English speaker does? The available evidence suggests not (Malt et al. 1999). However, the *cross-linguistic differences* may influence other aspects of thought, such as how early a child learns a word or what features he or she first focuses on (e.g., Bowerman 1996).

The practical issue concerns *second language learning*. Second language instruction has typically taught vocabulary as paired associate learning: students learn that 'chair' is '*silla*' in Spanish, 'bottle' is '*botella*,' and so on. If the words are not truly equivalent in their meaning, then learners' use of the words may not be like native speakers'. For instance, learners may use the word '*botella*' for the same set of objects that they would use 'bottle' for in English and not realize that their use is inappropriate. It may take second language learners extensive experience with the language to fine tune their meanings and their word use to match native speakers, if they ever do.

Word Order

As is well known, words in clauses and phrases are not strung together in a random fashion but are ordered in a communicatively significant way. Thus, for example, *John hit Mary* does not mean the same thing as *Mary hit John*. Moreover, the word orderings that are communicatively significant are not cross-linguistically uniform. Thus, whereas in English neither of the events described in the above two italicized clauses could be expressed with the verb in initial position, i.e., as *Hit Mary John*, this is precisely the order of words that would be used in Samoan or Berber. The nature of the word order patterns found within and across languages and the factors underlying their occurrence and distribution has been a topic of intensive study from a number of different perspectives. This article provides an overview of functional—typological research on word order concentrating on three issues, namely, the classification of languages in terms of their basic word order, the determination of the degree of language-internal word order variation, and the attempts to formulate a unifying principle of order capable of accounting for both cross-linguistic and language internal word order patterns.

1. Basic Word Order Typology

1.1 The Clause

Ever since Greenberg (1963) it has been the custom to classify the clausal word order of a language in terms of the location of the verb and its arguments relative to each other in transitive clauses (as opposed to intransitive or ditransitive ones) into one of the following six types: SOV, SVO, VSO, VOS, OVS, OSV, where S stands for subject, O for object, and V for verb. The transitive clauses which have served as the basis for word order classification are active, positive, declarative clauses with two nominal (not pronominal) participants, a definite human agent, and a definite nonhuman patient such as *The man killed the snake*, or *The girl extinguished the fire*. Greenberg took the order obtaining in such clauses to be the basic order of a language. For languages exhibiting more than one arrangement of the S, O, and V in the relevant type of clauses, the basic order was identified as the statistically dominant order.

Nowadays it is generally recognized that not all languages fall into one of the six word-order types. First of all, there are languages which simply lack transitive clauses with two overt NP participants, such as Puget Salish. Second, in many other languages, though clauses with two overt nominal participants do exist, they are quite rare, as both of the arguments must, or tend to, be expressed by pronominal affixes on the verb or by clitics elsewhere in the clause. For example, in her analysis of narrative texts in the South American language, Yagua, Payne (1990) found only 45 transitive clauses with two overt nominal participants, which constitutes less than 10 percent of the transitive clauses (463) and only 3 percent of all the clauses (1516) in the texts considered. In such languages, it may not always be possible to discern a clearly dominant order among the verb and its nominal arguments. Dryer (1997) suggests that the basic order should be at least twice as frequent as the order or orders with which it contrasts. In terms of such a criterion, none of the transitive orders in Yagua qualify as basic, as the frequencies noted by Payne were: VSO (19), SVO (15), and OVS (11). The third type of languages which may fall outside the six-way typology are languages in which, while transitive clauses with two overt nominal participants are quite frequent, no single order may unequivocally be dominant, as the ordering of constituents may be determined not by their grammatical relations but rather by their pragmatic status and discourse role.

In view of the above, several modifications of Greenberg's typology are currently in use. One involves using double classifications such as VSO/VOS or SVO/VSO. Another involves augmenting the six-way typology by a seventh type, namely, no basic order. A third modification consists in reanalyzing the six orders in terms of a three-way opposition of verb position into verb-initial, verb-medial, and verb-final. The most radical modification is that suggested by Dryer (1997), who argues for replacing the six-way typology by two separate two-way typologies of SV vs. VS and OV vs. VO, which together define four types: VS & VO, SV & VO, SV & OV, and VS & OV. While

this typology also concerns the order of nominals in transitive clauses, it differs from all of the above in being based on the presence of only one nominal participant, as opposed to two. Accordingly, it is more widely applicable and easier to apply than the six-way typology.

Despite the problems posed in classifying some languages in terms of their basic transitive order, the cross-linguistic investigations conducted since the 1960s identify the same basic word order preferences consistently; the most common basic order is SOV (+/−45 percent), followed closely by SVO (+/−35 percent), and then VSO (+/−10 percent). The three object-before-subject orders are all highly uncommon as basic orders, with VOS occurring slightly more frequently than OVS, and OSV being extremely rare.

Turning to the basic order in other than transitive clauses, with few exceptions (e.g., Salinan, Woods Cree, Makushi), the basic order of the sole argument of the intransitive verb is the same as that of the S argument of a transitive clause. Consequently, the classification of a language's transitive order also covers that of intransitive clauses. This also holds to a large extent for ditransitive clauses, i.e., clauses featuring, in addition to an agent and patient, a recipient (e.g., *Mother gave the baby a toy*.) Again with relatively few exceptions (e.g., Nadeb, Trumai, Yoruba) recipients tend to be placed on the same side of the verb as the O in transitive clauses, and typically occur contiguous to the patient. According to Primus (1997), in the basic order recipients are never separated from the patient by the agentive argument.

1.2 The Phrase

Order within phrases is characterized typically in terms of a two-way typology originating in the dependency tradition and the work of the nineteenth-century German typologists. This two-way typology is based on the division of the constituents of phrases into head/modifier pairs such as: verb/object, verb/adverbial, auxiliary/main verb, adposition/noun phrase, noun/adjective, noun/genitive, noun/relative clause, etc. (where the first member of the pair is the head and the second the modifier). As reflected in Vennemann's (1972) natural serialization principle and its analogs, languages are assumed to show a preference for serializing constituents with reference to either the head > modifier or the modifier > head schema. Those that exhibit basic transitive VO order are expected to display head > modifier order, and those that have basic OV order, modifier > head patterns. Languages that conform to these expectations are termed consistent. Consistency, however, is viewed currently not as the cross-linguistic norm, but rather as an ideal to which languages approximate to various degrees. And indeed very few languages are absolutely consistent in ordering all their modifiers either to the left or the right of the head. Thus, for example, of the 142 languages in Greenberg's Appendix II, only 68 (48 percent) exhibit consistent ordering in relation to just four head/modifier pairs, i.e., the verb and object, adposition and noun phrase, noun and genitive, and noun and adjective. Needless to say, the number of consistent languages drops once further head/modifier pairs are considered.

Several refinements to the expectation of consistent ordering have been suggested. One of these is the principle of cross-category harmony (PCCH) formulated by Hawkins (1983). The PCCH states that languages display a preference to generalize the order obtaining in one head/modifier category to that of other categories. Departures from this preference in one head/modifier category are in turn likely to induce comparable departures in other head/modifier pairs. Thus, for example, Hawkins notes that the continuum in verb position, verb-initial, verb-medial, and verb-final is reflected in the position of the noun in relation to its modifiers, VSO languages being more consistently noun-initial than SVO ones, and non-rigid SOV languages (SOV languages which allow for the placing of some modifiers to the right of the verb) less consistently noun-final than rigid SOV ones.

Another refinement to the preference for consistent ordering has been introduced by Dryer (1992) who argues that this preference actually involves not head modifier pairs but rather lexical and phrasal categories. Dryer suggests that languages tend to be either right-branching, in which phrasal categories follow non-phrasal categories, or left-branching, in which phrasal categories precede non-phrasal categories. This is argued to hold irrespective of which is considered to be the head and which the modifier. For non-branching categories, no word-order predictions are made. Thus, according to Dryer's branching direction theory, whereas, for example, a genitive phrase (e.g., of John) and relative clause (whom I met) should occur on the same side of the noun, a demonstrative phrase need not, as it is not a branching category; nor need an adjective pattern as the genitive phrase or relative clause, since it is not a fully recursive phrasal category. While Dryer's word order predictions receive strong cross-linguistic support, their correctness is heavily dependent on specific theories of constituent structure which are not uncontroversial.

The notion of consistent ordering in its various guises relates to the order of head/modifier pairs and says nothing about the ordering of modifiers relative to each other. This latter aspect of phrasal order is still under investigation. One subset of modifiers whose order has received detailed attention is that of the demonstrative, numeral, and adjective within simple NPs. Rijkhoff (1997) accounts for the cross-linguistic linearizations of these three modifiers with reference to three principles, namely, the principle of domain integrity, the principle of head proximity, and the principle of scope. All three principles are elaborations

of what is known as Behagel's (1932, p. 4) first law, which is 'what belongs together semantically is also placed together syntactically.' Of the 24 logically possible linearizations of the demonstrative, numeral, adjective, and noun, the three principles define the following eight word-order patterns as potential basic orders.

(a)	(b)
DemNumAdjN	AdjNNumDem
DemNumNAdj	NumAdjDem
DemNAdjNum	DemAdjNNum
NumNAdjDem	NAdjNumDem

Rijkhoff's cross-linguistic data reveal that all these orders, and only these, are attested as basic orders.

2. *Word Order Variation*

Languages are classified not only in regard to their basic order, but also with respect to the amount of word order variation that they display. However, though labels such as rigid or fixed-order language, or free or flexible-order language are commonplace, there is little consensus on what they actually mean. This is not altogether surprising as it is far from clear how word-order variation could be measured.

The major problem in devising a measure of word-order variation is the sheer number of potential variables involved. An alternative order may be conditioned by a wide range of factors—syntactic, semantic, and pragmatic—relating to the nature of the text and/or genre (e.g., written vs. spoken, narrative vs. expository vs. procedural), the properties of the clause (e.g., its illocutionary force or main vs. subordinate status), the features of the verb (e.g., its voice, tense, or aspect) and the characteristics of its arguments and adjuncts such as referentiality, definiteness, givenness, humanness, animacy, semantic role, and morphological and syntactic complexity. Needless to say, there is no obvious reason why changes in order attributable to any one factor or set of factors should be viewed as being more significant than others.

The above notwithstanding, some idea of the word-order flexibility of a language can be gathered by reducing the number of variables and considering the number of word-order permutations in clauses or head/modifier pairs exhibiting the same characteristics as those used for determining the basic order. In terms of such a measure, English emerges as a fairly rigid word order language at the clausal level, as the only variation on its basic SVO order that it permits is OSV. Polish, on the other hand, is a highly flexible word order language, since in addition to its basic SVO order it also has all the other five permutations of the S, O, and V. Applying the above measure of word-order flexibility to a sample of 171 1anguages, Siewierska (1997) found no variation on the basic transitive order in 22 percent of the languages, only one variant in 35 percent, two variants in 17 percent, three variants in 12 percent, four variants in 6 percent, and five variations in 8 percent. Thus languages with no or little word-order flexibility appear to be considerably more common than those with highly flexible order.

Some generalizations can also be made with respect to the type of word order variations that languages are most and least likely to exhibit, namely (a) verb initial languages are least likely to exhibit verb final orders, and verb final languages, verb initial orders, (b) in languages of all word order types, SVO is a more likely variable order than OVS. Thus, an SOV language with fairly inflexible order may be expected to have an OSV variant, or possibly a SVO one, but not a VSO or OVS variant. And a VSO language may be expected to exhibit SOV order only if it also has VOS, SVO, and OVS.

The degree of word order flexibility of a language with respect to the ordering of the verb and its arguments is often seen to be tied to the existence of agreement and case marking. The argument is that, if the subject is distinguished morphologically from the object by case and/or agreement marking, word order is 'freed' from performing this function and can thus be used for other communicative ends. This, however, is not necessarily so. Cross-linguistic data cited by Siewierska (1997) reveal that, contrary to what is often suggested, it is not the presence of case and agreement marking that has an affect on word-order flexibility but rather their absence. Rigid order is associated strongly with lack of agreement and to a lesser extent with lack of case marking, but neither the presence of case nor agreement marking correlates with flexible order.

The investigation of word-order variation carried out to date suggests that languages exhibit more variation in the ordering of constituents at the level of the clause than at the level of the phrase. Significant differences in word-order flexibility have also been observed in regard to specific head/modifier pairs. Bakker's (1997) investigations of the possibility of alternative orderings of the noun and a single modifier among the languages of Europe suggests that the modifiers of the noun can be placed in a hierarchy of decreasing likelihood of exhibiting an alternative order to that of their basic order, namely: adjective > genitive > relative clause > numeral > demonstrative. Whether this will be. confirmed globally remains to be determined.

3. *Discourse-pragmatic vs. Processing, Explanations of Order*

Both the cross-linguistic preferences in regard to the distribution of basic orders as well as the type of variations on the basic order that languages tend to favor have typically been accounted for in discourse-pragmatic terms. Until recently, the dominant principle assumed to underlie linearization has been the

Topic > Comment principle, which defines a preference for placing constituents encoding more topical, predictable, given information before those encoding less topical, unpredictable, new information. The universal applicability of this principle has been called into question by the existence of languages which appear to favor placing the comment not after, but before, the topic. Givón (1988) has sought to reconcile the existence of two opposing principles of order by formulating the principle of Task Urgency, which is: 'Attend first to the most urgent task,' where a communicative task is identified as more urgent if the information to be communicated is either less predictable or more important. Givón suggests that when the topic of discourse is a highly predictable referent, the most urgent task is to present the comment, and when the topic corresponds to a less predictable or unpredictable discourse referent, the most urgent task is to state the topic. Thus the principle of Task Urgency predicts a cross-linguistic preference for placing either less predictable > more predictable and/or more important > less important information.

An alternative unifying principle of order has been posited recently by Hawkins (1994), who sees order as being determined primarily by processing considerations and not discourse-pragmatic ones. Building on the long-recognized tendency to place short constituents before longer ones, Hawkins hypothesizes that the human parser displays a preference for linearization patterns which allow the quickest recognition of immediate constituents of syntactic groupings. This is captured in the Early Immediate Constituent recognition principle (EIC), which is: 'The human parser prefers to maximize the left-to-right IC (immediate constituent)-to-word ratios of the phrasal nodes that it constructs'. The EIC predicts that information about immediate constituency should be placed in the earlier rather than the later part of a string. For relatively heavy categories, such as sentential and NP complements, this prediction entails a preference for short > long linearization in right-branching (VO) languages and for long > short in left-branching (OV) languages. But in the case of single-word categories, an overall preference for placing the light category to the far left is defined.

Strong cross-linguistic evidence for the EIC has been cited from several types of data: real-time psycholinguistic experiments of alternative orderings, of ICs, language-internal text frequency counts, native speaker acceptability judgments, and the cross-linguistic distribution of basic orders. These data show that not only is there an unequivocal preference for orderings defined as optimal by the EIC, but also that there is a progressive decline in the frequency of non-optimal orders directly proportional to the degree of their non-optimality defined by the EIC. Thus, for example, while the EIC defines the presence of both prepositions in OV languages, and of postpositions in VO as non-optimal, the EIC score for the former, e.g., for *with the friends played* is considerably lower (20 percent) than for the later, e.g., *played the friends with* (65 percent). And though both orders are cross-linguistically uncommon, in Dryer's (1992) data, OV languages with prepositions are three times less common than VO languages with postpositions (1.5 percent vs. 4.6 percent).

Whether an EIC account of word order is indeed superior to one based on discourse-pragmatic principles, as Hawkins argues, remains to be seen.

Word Recognition, Cognitive Psychology of

The term 'word recognition' has two senses. Cognitive psychologists use it to refer to a component process of mind that transforms the printed or spoken features of a word into a linguistic representation. Cognitive psychologists must infer component processes from measures of behavior. Word recognition is a measured task performance. Laboratory volunteers perform a task in which they discriminate words from nonwords (the lexical decision task), and measurements of their performance are used to test hypotheses about the nature of word recognition. At one time, performance in the lexical decision task was assumed to provide an unambiguous view of the word-recognition component in operation. For example, 'there is no way to perform this task without [word recognition], we can estimate the time for this operation by measuring the subject's reaction time to make the decision' (Forster 1976, p. 260). As a performance phenomenon, word recognition may or may not imply a distinct component process. Nevertheless, it is intuitive that reading and listening include a component process of word recognition, as the examples that follow may illustrate.

1. Component Processes and the General Linear Model

1.1 Intuitive Word Recognition

Nineteenth century eye movement studies discovered that a reader's eyes make a series of jumps, while moving across a line of text, pausing about a quarter of a second when fixated. Eye movements thus implied the 'fixation' (recognition) of individual printed words in natural reading. A skilled reader can recognize thousands of printed words with no noticeable effort. A dyslexic child, on the other hand, does not easily acquire this skill. Recognizing a printed word, as a particular word, can be effortful to the point of frustration. Dyslexia may plague an otherwise bright and articulate child, which appears to implicate word recognition as the crux of reading. Reading is not exclusively the recognition of printed words, but it is word recognition that distinguishes reading from natural language. In effect, to become a reader is to master this special skill.

A different example illustrates word recognition in spoken language. When listening to speech in an unfamiliar language, people inevitably wonder why speakers 'talk so fast.' All languages are spoken at equivalent rates, but in a familiar language, we perceive breaks between words (although no physical breaks exist), which 'slows down' perception. Unfamiliar languages sound fast because the listener lacks the ability to segment continuous speech and to recognize the words.

In the examples of dyslexia and foreign speech, our intuition that a component of word recognition may exist derives from the absence of competent word recognition. However, the absence of a hypothetical competence tells us little or nothing about whether the hypothesis is valid. This requires scientific investigation, and a logic for the analysis of complex behavior.

1.2 Nearly Decomposable Systems

Herbert Simon proposed a logic of analysis for complex systems, such as cognitive systems. Complex systems can be partly decomposed, if the components interact linearly. The internal dynamics of cognitive components may be complex (nonlinear). If the interactions between components are, nevertheless, linear, then it is possible to identify these components. Cognitive components, described thus, work as a chain of single causes. Single causes entail the familiar notion of domino causality. Push the first domino in a chain of standing dominoes and each will fall in its turn. Linear interactions, between the dominoes, add up to the total behavioral effect. If behavior is the sum of its parts, the total effect can be reduced to component causes. This formal logic justifies behavioral studies to infer underlying cognitive components.

1.3 Additive Factors Method

The most well-known methodological tool to individuate cognitive components is the additive factors method, proposed by Saul Sternberg. Experiments that include several experimental conditions (i.e., factorial designs) allow simultaneous manipulation of several factors, which provides the opportunity for interaction. If the effects of two or more manipulations are strictly additive, the manipulated variables satisfy the assumption of selective influence—they selectively influence distinct components. For example, the total time from first to last domino, in the previous, idealized chain of falling dominoes, is the sum of each domino's falling time. In this idealization, separate experimental manipulations that slow falling times of individual dominoes, but do not change the falling times of dominoes that precede or follow an affected domino, satisfy the assumption of selective influence. A manipulation selectively effects a single domino's falling time, without affecting other dominoes' falling times. Such effects simply add time to the total falling time of the entire chain. Alternatively, when nonadditive interactions are observed, manipulations have not satisfied the assumption of selective influence. Factors that are not additive, influence (at least) one common component. Thus, to Sternberg's lasting credit, his method includes an empirical failure point: ubiquitous nonadditive interaction effects.

2. Word Recognition as Information Processing

The logic of the additive factors method also fits the metaphor of cognition as information processing. For the chain of dominoes, substitute the guiding analogy of a flow chart of information processing, like unidirectional flow charts of computer programs. Information flows from input (stimulus) to output (behavior) through a sequence of cognitive components. In word recognition, input representations from a sensory process—visual or auditory features of a word—are transformed into an output representation—the identity of the word—that, in turn, becomes the input representation for a component downstream (i.e., a component of response production or sentence processing). In this tradition, empirical studies of word recognition pertain to the structure and function of the lexicon. The lexicon is a memory component, a mental dictionary, containing representations of the meanings, spellings, pronunciations, and syntactic functions of words. Structure refers to how the word entries are organized, and function refers to how words are accessed in, or retrieved from, the lexicon. Two seminal findings illustrate the distinction: semantic priming effects and word frequency effects. Both effects are found in lexical decision performance.

2.1 The Lexical Decision Task

In the lexical decision task, a person is presented, on each trial, with a target string of letters, and must judge whether the target string is a correctly spelled word in English (or some other reference language). Some trials are catch trials, which present nonwords such as 'glurp.' (One may also present words and nonwords auditorally, to examine spoken word recognition.) The participant presses a 'word' key to indicate a word and a 'nonword' key otherwise. The experimenter takes note of the response time, from when the target stimulus appeared until the response key is pressed, and whether the response was correct. Response time and accuracy are the performance measures.

2.2 Semantic Priming and the Structure of the Lexicon

Word pairs with related meanings, such as 'doctor' and 'nurse' or 'bread' and 'butter,' produce semantic priming effects. Semantic priming was discovered by David Meyer and Roger Schvaneveldt, working independently (they chose to report their findings together). Lexical decision performance to a word is improved by prior presentation of its semantically related word. Prior recognition of 'doctor,' as a word, facilitates subsequent recognition of 'nurse'; lexical decisions to 'nurse' are faster and more accurate, compared with a control condition. This finding is commonly interpreted to mean that semantically related words are structurally connected in the lexicon, such that retrieval of one inevitably leads to retrieval of the other (in part or in whole).

2.3 Word Frequency and the Function of Lexical Access

Word frequency is estimated using frequency counts. The occurrence of each word, per million, is counted in large samples of text. Lexical decision performance is correlated with word frequency. Words that occur more often in text (or in speech) are recognized faster and more accurately than words that occur infrequently. This finding is interpreted in a variety of ways. The common theme is that lexical access functions in a manner that favors high-frequency words. In one classical account, proposed by John Morton, access to a lexical entry is via a threshold. Word features may sufficiently activate a lexical entry, to cross its activation threshold, and thus make that entry available. Common, high-frequency words have lower threshold values than less common words. In a different classical account, proposed by Kenneth Forster, the lexicon is searched in order of word frequency, beginning with high frequency words.

2.4 Challenges to the Information Processing Approach

Additive interaction effects are almost never observed in word recognition experiments, and, while it is not possible to manipulate all word factors simultaneously in one experiment, it is possible to trace chains of nonadditive interactions across published experiments that preclude the assignment of any factors to distinct components. Moreover, all empirical phenomena of word recognition appear to be conditioned by task, task demands, and even the reference language, as the examples that follow illustrate.

The same set of words, which produce a large word frequency effect in the lexical decision task, produce a reduced or statistically unreliable word frequency effect in naming and semantic categorization tasks. All these tasks would seem to include word recognition, but they do not yield the same word recognition effects. Also, within the lexical decision task, itself, it is possible to modulate the word frequency effect by making the nonwords more or less word-like (and, in turn, to modulate a nonadditive interaction effect between word frequency and semantic priming). Across languages, Hebrew produces a larger word frequency (familiarity) effect than English, and English than Serbo–Croation.

Consider the previous examples together, within the guidelines of additive factors logic. Word recognition factors cannot be individuated from each other, and they cannot be individuated from the context of their occurrence (task, task demands, and language). The

limitations of additive factors method are well known. Because additivity is never consistently observed, we have no empirical basis for individualizing cognitive components. The *de facto* practice in cognitive psychology is to assume that laboratory tasks and manipulations may differ from each other by the causal equivalent of one component ('one domino'). But how does one know which tasks or manipulations differ by exactly one component? We require *a priori* knowledge of cognitive components, and which components are involved in which laboratory tasks, to know reliably which or how many components task conditions entail. Notice this circularity, pointed out by Robert Pachella: the goal is to discover cognitive components in observed laboratory performance, but the method requires prior knowledge of the self same components.

Despite these problems, most theorists share the intuition that a hypothetical component of word recognition exists. When intuitions diverge, however, there may be no way to reconcile differences. Theorists who assume that reading is primarily an act of visual perception discover a visual component of word recognition; theorists who assume that reading is primarily a linguistic process discover a linguistic component of word recognition, in the same performance phenomena. Repeated contradictory discoveries, in the empirical literature, have lead to a vast debate concerning which task conditions provide an unambiguous view of word recognition in operation. The debate hinges on exclusionary criteria that may correctly exclude task effects and bring word recognition into clearer focus. Otherwise, inevitably, one laboratory's word recognition effect is another laboratory's task artifact.

3. *Connectionism*

Context effects seem to occur at all scales at which words may be viewed. For example, just as semantically related prime words (and appropriate sentence contexts) produce benefits for word recognition; words themselves, as contexts, affect letter and phoneme identification. A briefly presented letter is more accurately identified if it is presented within a word than the same letter presented in a nonword, or presented alone. Also, an ambiguous initial consonant, which could be either a /d/ or a /t/, is more likely to be identified as /d/ in the context of /_ash/ (where /dash/ is a word and /tash/ is not), and as /t/ in the context of /_ask/ (where /task/ is a word and /dask/ is not).

3.1 *Interactive-Activation Models*

James McClelland and his colleagues constructed interactive activation models to simulate the previous context effects. The original interactive activation model simulated context effects on letter identification, and was extended in the another model to simulate context effects on phoneme identification. Interactive activation models are connectionist models. In a connectionist model, constraints on response options are implemented as excitatory and inhibitory connections among nodes that behave as idealized neurons. The original interactive activation model included a hierarchy of representations, implemented in three node levels: visual feature nodes, letter nodes, and word nodes. Most important, letter nodes and word nodes have reciprocal excitatory connections, which allow feedback from word representations to excite letter representations. As a consequence, letter nodes that are inadequately activated by feature nodes may benefit from word feedback. This is the hypothetical basis of word context effects on letter (and phoneme) identification.

3.2 *PDP Models*

In interactive activation models, the connection strengths between nodes are preset by the modeler. Parallel distributed processing (PDP) models include learning algorithms capable of covariant learning. Covariant learning shapes a matrix of connection weights to reflect statistical relations between the input and output patterns of a training set. Systematic relations, at a variety of grain sizes, between English spelling and phonology (or phonology and semantics, etc.), may all be construed as statistical relations. For example, consonant spellings are more strongly correlated with consonant pronunciations than are vowel spellings with vowel pronunciations, but in both cases there are statistically dominant and subordinate relations. Regular words, with dominant relations, are named more quickly than exception words, with subordinate relations. Likewise, body-rime relations may be consistently correlated (the body _uck always indicates the same rime, in English, as in the word 'duck'); but other body-rime relations are less strongly correlated (_int pronounced as in 'mint'); and still others are only weakly correlated (_int pronounced as in 'pint')—a rank order that is also corroborated by readers' naming times. The emphasis of PDP models, on learning the relation between spelling and phonology, coincides with the commonly observed failure of dyslexics to sound out words, and pronounceable pseudowords such as 'glurp.' Not all scientists agree, but the most common form of dyslexia appears to be a specific failure to learn the fine-grain consonant and vowel relations between spelling and phonology.

Covariant learning tracks all grain sizes of covariation, simultaneously, in the connection weights of a PDP model. Even word frequency approximates a relative correlation among whole-word spellings and whole-word pronunciations, and high-frequency

words are named faster than low-frequency words. The outcome of covariant learning is determined by statistical relations in the training set, and so a description of the training set is an integral part of the theory. In effect, covariant learning attunes a network to constraints inherent in a literate culture, for example, the relation between spelling and phonology. Consequently, the description of the cultural artifact, implicit in the training set, is as important for cognitive theory as hypothetical, internal, cognitive processes. Debra Jared used this aspect of PDP models to derive a nonintuitive empirical test using a naming study. The aggregate statistical relation of spelling to phonology, in body-rimes of high-frequency words, predicted a statistical advantage for some high-frequency words over others. Previously, word recognition of higher frequency words was assumed to be immune to such statistical relations. Nevertheless, Jared corroborated the prediction: faster naming times to high-frequency words with consistent body-rime relations. She did not observe this effect in the lexical decision task, however.

3.3 Feedback Consistency Effects

Body-rime consistency effects, in lexical decision performance, were predicted using a combination of interactive activation and covariant learning. Resonance models include learning algorithms that induce symmetrical covariant relations, consistent in both feed forward and feedback directions. Consequently, they predict that symmetrical, consistent relations, between spelling and phonology (and phonology and spelling), imply faster and more accurate word recognition. For example, the body-rime (and rime-body) relation in 'duck' is a symmetrical, consistent relation. All words with the body _uck are pronounced to rhyme with 'duck'; all words with the rime /_uk/ are spelled with the body _uck, as in 'duck.' Inconsistent relations, including inconsistent feedback relations, from phonology to spelling, add time and variability to performance of word recognition. The predicted feedback consistency effect is highly nonintuitive. From an information processing view, processes should always flow forwards, as from spelling to phonology. It should not matter in visual word recognition that a pronunciation may have more than one spelling (or in spoken word recognition that a spelling may have more than one pronunciation).

Feedback consistency effects have been found in performance of English and French lexical decision by Greg Stone, Johannez Ziegler and their colleagues. Words such as hurt (in English), with phonological rimes (/_ûrt/) which could be spelled in multiple ways (_urt, _ert, _irt) yield slower lexical decision times and more errors than words with rimes spelled in only one way. Also, a symmetrical feedback consistency effect is found in performance of auditory lexical decision (in English and French). What is feed forward for visual presentation is feedback for auditory presentation, and vice versa—a parsimonious qualitative symmetry. Moreover, once feedback consistency is taken into account, reliable feed forward consistency effects emerge in visual and auditory lexical decision performance, effects previously thought to be unreliable.

4. Recurrent Network Models and Nonlinear Dynamical Systems Theory

Interactive activation models and PDP models were actually proposed as first steps toward strongly nonlinear models that combined their features. This combination was realized in fully recurrent 'neural' networks (resonance models). Recurrent networks are attractor networks simulated as nonlinear iterative maps. An iterative map takes its output at one time-step as input on the next time-step, until it reaches a stable pattern of node activity (an attractor pattern).

Nonlinear iterative maps approximate solutions of systems of nonlinear differential equations. Thus, recurrent network models, as dynamical systems, invoke the mathematical framework of nonlinear dynamical systems theory. A few recurrent network models of word recognition have been implemented, notably by Alan Kawamoto (and colleagues), Michael Masson, and Stephen Grossberg (and colleagues).

Nonlinear dynamical systems theory concerns the complex behavior of systems, produced by components that interact nonlinearly (nonadditively). A few pioneering studies have corroborated empirical signatures of nonlinearity, including multistability in performance of printed word naming, hysteresis in performance of spoken word identification, and 1/f noise in lexical decision.

4.1 Multistability

Multistability is a generic phenomenon of nonlinear dynamical systems. In this case, the same stimulus word reliably produces more than one naming response. Homograph words are an obvious example. Homographs, such as 'wind,' have two or more pronunciations, and are thus multistable by definition. A word like 'pint,' with a statistically subordinate pronunciation (consider 'hint,' 'lint,' and 'mint'), is a more subtle example. Readers produce two systematic pronunciations to 'pint': the correct pronunciation and an error pronunciation that rhymes with 'mint.' Moreover, when readers are encouraged to produce rapid pronunciations, they are much more likely to produce the systematic mispronunciations. In the latter manipulation, a quantitative change in the time available for a naming response produces a qualitative change in the response itself. Qualitative changes consequent on quantitative manipulations are precisely the kind of phenomena that are addressed by nonlinear dynamical systems theory.

4.2 Hysteresis

Hysteresis effects are more elaborate signatures of nonlinearity, which extend the concept of multistability. Betty Tullerand her colleagues have demonstrated hysteresis effects in perception of artificial speech. As in the previous example, of homograph words, an identical pattern of artificial speech may yield multiple (multistable) perceptions. A typical experiment manipulates the presentation order of speech stimuli. Stimuli are constructed to change quantitatively and incrementally in acoustic properties along a continuum, between the words 'say' and 'stay', for example. Each run of an experiment presents the continuum, one stimulus at a time, running from 'say' to 'stay', and back again (or vice versa). Hysteresis is observed when some intermediate range of stimuli is perceived as 'say'—if preceded by 'say' stimuli—but the identical range is perceived as 'stay' if preceded by 'stay' stimuli. This intermediate range is multistable; and the context effect demonstrates hysteresis.

The hysteresis pattern is a generic pattern that is observed widely in physical, chemical, biological, and cognitive systems. Prior to mathematical developments in this century, however, it was considered a nuisance effect. As a nuisance effect, it motivated one of the first methods in psychology—Fechner's method of limits in nineteenth century psychophysics—effectively, a technique to get around the problem of hysteresis. Generic constructs such as hysteresis and multistability provide an analogy to understand ambiguity resolution in natural language. Words are pronounced differently, and have different meanings, in different contexts. Context sensitivity is a defining feature of multistable phenomena (as hysteresis demonstrates), and the mathematical framework of nonlinear systems yields a simplifying formal perspective on context sensitivity in natural systems.

4.3 1/f Noise

David Gilden and his colleagues have observed 1/f noise in the fluctuation of trial-by-trial response times from several cognitive tasks, including a word recognition task. 1/f noise is observed in the residual 'error' variance of individual participants' trial-by-trial response times (the variability that remains after 'treatment effects' are removed). If we graph each residual time, in the trial order of the experiment, the data points fluctuate between fast and slow times. The connected data points form a complex waveform, which may be viewed as a composite of waves spanning a range of frequencies. 1/f noise is an inverse correlation between the frequency of the composite waves and their power (amplitude).

The phenomenon of 1/f noise can be difficult to grasp, because it goes against the grain of a typical psychological analysis. Typically, error variance is discarded, rather than analyzed for structure. In Gilden's data, the error variance is analyzed and found to resemble the mathematically generic pattern of 1/f noise (a construct from fractal geometry). 1/f noise is a signature of processes that have no characteristic measurement scale. It contradicts additive factors logic, which assumes that we may partition response times into additive, independent sources of variance. This practice strictly requires that the response time in each trial is independent of the response times in other trials. The assumption of independence is at the heart of the linear statistical models used to identify cognitive components. The presence of 1/f noise contradicts this assumption. Response time data do not have 'joints' that may reduce to component causes.

4.4 Challenges for Connectionism

A laudable feature of the information processing approach was its explicit logic and method of analysis, derived from the general linear model, and implemented in additive factors method. No comparable logic has gained general acceptance within the connectionist approach (although connectionist models have been used productively in tests of nonintuitive predictions). In large part, connectionism has inherited the methodology of information processing psychology. However, empirical analyses that assume the general linear model, and theories implemented as strongly nonlinear dynamical systems, are incompatible at their root. They entail contradictory notions of cause and effect.

The domino causality of information processing analysis individuates single causes in additive effects—cause and effect relations that allow the morphological reduction of behavior to underlying component causes. In contrast, the circular causality of strongly nonlinear systems allows that all the components of a system may be present in qualitatively different behaviors of the system. Causal properties emerge in the interaction of components, which are not reducible to causal properties of the components themselves. Circular causality requires a strategic (not morphological) reduction. In a strategic reduction, the same, generic, nonlinear phenomena may be observed at multiple levels of a system. One must concede, however, that higher-level phenomena do not reduce to lower-level causes.

The previous contradiction between linear methods and nonlinear models raises questions, as yet unanswered, for the cognitive psychology of word recognition. For example, is it more productive, for scientific purposes, to view word recognition performance as a product of the nervous system (which also appears as a nonlinear dynamical system), a product of inscrutable components of mind (which have combined in nonlinear interaction), an emergent product of interaction between readers and texts, or

some other possibility that is not articulated in the previous alternatives? Answers to such questions await a generally accepted and reliable logic of nonlinear analysis, appropriate to cognitive performance, connectionist models, and nonlinear dynamical systems theory.

Work and Labor: History of the Concept

The concept of work has at least three different but complementary meanings in contemporary Western societies. As an action, it refers to the content and the performing of an activity; as a product, it is part of the organization of capitalist societies; finally, as a status, it constitutes a linchpin of social organization. Work, as the mainspring of economic activity, is also at the crux of the functioning of the political and social world. Affecting the slightest aspects of life in society, it can be viewed as a 'total social fact' (Mauss 1966). This pivotal position has made work a notion that has long been taken for granted as universal, to the detriment of its variability in time and space (Kocka and Offe 2000). Yet the contemporary meaning given to the concept is the result of an eminently historical process, including in capitalist societies in which work constitutes the yardstick. Although various meanings of the word 'work' existed in the nineteenth century (Cottereau 1994), it is on the particularly restrictive concept of labor, in the sense of quantifiable productive activity, that Western capitalist societies have been built.

The development of the concept was concurrent with the evolution of the social sciences. Labor, conceptualized in political economy after Adam Smith in terms of value, came to be seen as the mediator between the individual and the collective. It thus became a focal point of sociological analysis. The transformations of productive activity and their consequences in industrial society have certainly contributed to shaping the main directions of development in social sciences, but the descriptive as well as prescriptive discourse of the latter has also played an essential role since the early twentieth century in establishing the social sphere on the basis of work.

The history of the concepts of work and labor will be examined from this angle of a dual process in which the social sciences and the societies they study mutually engender one another. Thus delimited, the history will not be a total one, but situated in time and space, that is, confined to the question of the reduction of the concept of work to the concept of labor in capitalist European societies from the nineteenth century onward. This rather Eurocentric history is also the history of the statistic and legal codification of labor into a social status, providing access to citizenship within the welfare state. Finally, since the 1970s it has been the history of re-examining the concept, closely tied to a reassessment of paradigms of action in the social sciences.

1. The Semantic Reduction of Work to Labor

Labor, more precisely wage labor, a dominant form in social–economic relationships in today's societies, has not always had this value as a standard. In the Middle Ages, when idleness was the privilege of the aristocracy, labor was synonymous with poverty and social devaluation. Without going back over the history of work (see *Work, History of*), it is important to underline the contradictory heritage that characterizes the notion in the nineteenth century. On the one hand, work was associated with the idea of alienation. This association finds its origins in the Greek conception of slavery, the function of which was to satisfy the vital needs of reproduction of the human species (Arendt 1958). It was further developed by Marx's critique of wage labor, a modern form of alienation through work. On the other hand, work rhymes with accomplishment and self-expression. This opposite aspect, based on the Protestant formalization of an occupation (*Beruf*) as a vocation (Weber 1930), drawing on the Hegelian conception of work as the

essence of man (Hegel 1977/1805), considerably fed the ideology of the welfare state. This tension between alienation and liberation was to mark the concept of labor in the long term and run through theoretical debates in the social sciences even until today (Méda 1996).

1.1 The Invention of Abstract Work

The opposition between work considered as the essence of human existence and the reality of alienating labor provided, in particular, the basis of the Marxist critique of the political economy (Marx 1968/1867) that marked a major turning point in the conceptualization of work. Political economy, of which labor is a key concept, produced an initial swing of the concept of work toward that of labor. This swing occurred in the context of liberalization of work, consecrating the idea of the market through the promulgation of a set of legal provisions abolishing hereditary dependency, establishing the free circulation of individuals, freedom of commerce and free competition. On the theoretical level, Adam Smith's work (1776) some years earlier consecrated labor as a value, as a source of national wealth, and saw freedom of work as the means to maximize this wealth. From Adam Smith to John Stuart Mill, British theorists of political economy made labor a product, a commodity sold according to the laws of supply and demand, on a market held to be the dominant form of regulation. Determined by the principles of economic liberalism, this conception associates work with a manifestation of individual freedom, it is a specific commodity having an exchange value. Boiled down to a commodity that each person theoretically should be able to sell as he wishes by way of freely agreed contracts, work became, through contractual mediation, a general legal and abstract category, separate from the individual who produced it. This was the invention of abstract work, quantifiable and measurable in time and money; this was labor, a founding principle of capitalism (Biernacki 1995).

Marx embraced this conceptualization of abstract work, but introduced at least two new elements. The first was labor power. Marx viewed labor less from the perspective of the resulting product but from the angle of the labor power (*Arbeitskraft*) required to achieve it. Biernacki (1995) sees in this shift the expression of the structuring nature of the German work culture on the development of Marx's thought. But beyond cultural specificities, taking into account labor power provokes a considerable shift in the problematics of work. Work is no longer reduced to the mere economic dimension of selling and circulating goods, it is henceforth associated as well with the condition of the producer in a capitalist market system. The second contribution of the Marxist critique is the introduction of nonwork, a notion previously absent from political economy (Marx 1982, p. 208). Seen from the angle of the economic dependence of the worker, who can only meet his needs through the sale of his labor power, labor cannot be envisaged independently from nonwork and its different individual consequences. Marx thus contributed to a conceptualization of labor as dependent work, that is, seen from the producer's rather than the product side. This Marxist critique of political economy was to be, in the second half of the nineteenth century, a fertile ground for the development of the social sciences. Their particular contribution was, among others, to objectify nonwork by breaking it down into categories of social organization such as old age, disability, illness, unemployment, etc.

1.2 Wage Labor: A New Expression of Dependent Work

The concept of work mobilized in this endeavor for social objectivation meets the dual criteria of quantification and dependence. The reformist social sciences of the early twentieth century and the new categories they contributed to producing thus reinforced the process of dissociation between on the one hand work/*œuvre*, characterized by the independence of the producer and the quality of the product, and on the other hand abstract work associated with dependence and quantity. This social differentiation grew more marked up until World War II, accompanied at the same time by an increased hold of abstract labor over work to the point of assimilating Work with Labor, to the detriment of other possible meanings of the concept. This process went along with the spread of wage labor which was legally codified—in the form of a contract or through labor legislation—and statistically codified—in the form of socio-professional categories—as a response to standardization and mass production in economic activity.

The concept of employment, at the heart of the legal codification of labor, is informed by a dual meaning: from a macroeconomic standpoint it means trading a given quantity of work for a given salary on the market; from the political and social standpoint, it means exchanging individual subordination for security, that is, the worker's subordination to his employer and the security offered by labor legislation and social protection. From this standpoint, employment is not so much determined by the nature of economic activity as by the nature of the social relationships that frame this activity. Employment can thus be defined as socialized labor, insuring protection for the producer, in response to the Marxist critique. But this protection is highly variable geographically, reflecting the different avenues of society building around the integrative virtues of work (Esping-Anderson 1990). As Biernacki (1995) has shown in the case of England and Germany, the historical forms of economic objectivation of labor specific to each country—as a product

for the English, as labor power for the Germans—affect the way in which the concept of labor has been mobilized in the production of the political and social order.

2. Labor and the Constitution of the Social World

Labor has become the nerve center of the social world. As participation in the common good, it was used at the end of the nineteenth century in the definition of a link that could bind together individuals in the broadened framework of the nation-state. Consequently, it was codified as a vector of individual belonging to the collective, thereby insuring the group's cohesion. But although the social world reflects the actual organization of the group, it is also the fruit of competing endeavors at formalization and cannot be apprehended independently from the discourse and knowledge that institute it. Social science discourse as it was institutionalized at the turn of the century is in this respect exemplary. It played an essential role in indexing the social world on labor and in defining labor's relationships to the public concern (Durkheim 1964, Weber 1930). During the first half of the twentieth century, this scholarly activity focused on the production of general categories to organize the industrial society on the level of the nation-state. In other words, it was an activity mainly aimed at stating principles of homogenization and generalization, as if the transformations of the late nineteenth century had at the same time generated social sciences with strong holistic orientations and the organization of society on a large scale, on the basis of principles of standardization referring to labor within the framework of national institutions.

2.1 Labor as a Status

The close connection between work and social status is one of the main features of the concept of labor. This type of connection doubtless already existed in feudal societies and guild organizations in cities, for instance, but its specificity lies in its relation, since the late nineteenth century, to demands of social justice, political equality, and democracy. Labor has thus become the democratic means of access to social status and political integration, a function that for centuries was ensured by property and heredity. As a provider of income and the principle on which the redistribution of wealth is based, labor has become the central social relationship in capitalist societies. A powerful determining factor of each person's position in the social hierarchy, it helps produce individual identities and shapes the ways in which citizenship is exercised. This link between work and politics, in the sense of organization and production of the society on the whole, was not, however, a foregone conclusion even two centuries ago (Arendt 1958). But it has become such a natural fact within the European nation-state that it today seems to be taken for granted historically (Zimmermann et al. 1999).

2.2 Labor, Class and Nation

The socialization of work and nonwork, based on the critique of a strictly economic conception of labor, has been held up to be the promise of the nation-state's order and political legitimacy. This conjunction between providing security for wage-labor—through social protection and labor legislation—and consolidating the nation-state has led to a considerable growth of the social value attached to paid work. The established expression 'social security' suggests to what extent the socialization of nonwork is as much a question of collective as of individual security. This collective security is based on the capital/wage labor dichotomy, in a framework where the social regulation of labor is a partner of economic regulation of the market more than a substitute for it. The encounter of the nation-state, economic organization and labor institutions under the auspices of the welfare state thus appears as the fruit of a historical compromise between capital and labor. This compromise, at the basis of Fordism, is founded on the norm of full employment taken to be a constituent principle of the social world. From such a perspective, the social world can be seen as a collective order produced on the basis of wage labor and codified by a set of rights and duties attached to the salaried class (Castel 1995).

The history of this collective order is, from 1890 to 1960, one of establishing a coherence between individual identities and economic and political practices on the basis of the principles of class and nation (Wagner 1994). It is a movement of widespread standardization aiming to reduce uncertainty as well as the variety of possible actions and interpretations. Statistical and legal methods were the preferred instruments of this standardization and establishment of equivalences. Through the institution of nomenclatures, they gave shape to a national body made homogenous that can be observed and planned thanks to the objective nature of figures. By granting social and political rights guaranteed by the state, they stipulate individual belonging to this body. But today these standardization principles are put to the test by the demands of flexibility and the multiplication of work statuses.

2.3 Transformations in Work and Reconfiguration of the Social Sciences

The quest for generality a century ago has been replaced by the quest for diversity. This holds true for economic and social life as well as for the field of social

sciences. Over the past few years, the issue has been one of producing new equivalencies between situations and persons, able to place increasingly individualizing practices into a collective order that guarantees equity. The demand for flexibility provides an exemplary illustration. Whereas for the employer it is a powerful tool for dealing with the ups and downs of the economy, for the employee it introduces an uncertainty that the rhetoric of risk and predictability at the basis of social protection (Evers and Nowotny 1987) can no longer necessarily control. One of the current challenges is thus to make individual careers secure in the new context of uncertainty that weighs on work (Supiot 1999). But the categories established on the norm of full employment and the model of society that goes with it are having difficulty integrating these imperatives for diversity and flexibility. It is more generally the reduction of the concept of work to that of labor that should be incriminated, to such an extent that an examination of the ongoing transformations entails a need to rediscover the diversity of meanings of work.

In 1958, Arendt undertook a radical critique of this reduction that led to labor invading the political sphere, eventually crushing it in favor of the 'social.' Against the institution of labor as a general category of human action, Arendt reminds us that it is merely one aspect among others of *Vita activa*. She emphasized the major historical differentiation between:

(a) labor, an activity of *anima laborans* governed by the human race's needs of subsistence and reproduction, producing ephemeral things destined to be consumed;

(b) work, an activity of *homo faber*, producing lasting objects aimed at stabilizing human life;

(c) action, *praxis*, which produces things that are inseparable from the actor and which only occur through interaction. Action thus constitutes the eminently public and political aspect of *Vita activa*.

Whereas Arendt deplored the progressive absorption first of work, then of action, by the reductionist concept of labor, the topicality of the question of the relationship between work and action has since been renewed.

Along the lines of the revival of action theories in the social sciences, the concept of work has opened up toward action. Until the 1960s, continental European sociology of work was mainly concerned with the status conferred on individuals by their jobs. Today it has developed the issue of work as action, mobilizing a broader signification of the concept of work. The paradigms of action lead to taking into account a greater diversity of meanings of work (women's domestic work, voluntary and civic work, for instance). They also lead to envisaging work from the perspective of the interactions and conventions that preside over coordination among agents ('L'économie des conventions' 1989). Such an approach indicates a return to work in itself, to work as an action that refers to particular people and situations (Boltanski and Thévenot 1989). After the major movement of standardization that characterized the history of the concept of labor and sealed its hegemony, the concept of work today is being redesigned to integrate the quality of products and people's capacities, and has opened up to the plurality and diversity of configurations of action (Salais and Storper 1997, Boltanski and Chapiello 1999).

By the same token, the uncertainties that weigh on national employment institutions today, under the pressure of globalization and the constitution of supranational political entities (Habermas 1999), have found considerable resonance in debates on postmodernity that run through the social sciences. After the supremacy of the national level, today new scales of regulation and organization of the collective sphere are being explored, both from a practical and theoretical standpoint. Here again, the connection between economic and political transformations and paradigmatic changes in the social sciences is a close one. To such an extent that, where some see the end of work (Rifkin 1995) or the nation-state approaching, others announce both the end of society and the social sciences. But far from this alarmist diagnosis, today seems rather to be an era of revising both the categories of organization of society built around work and the nation, and their principles of intelligibility as they were defined by the social sciences.

Work: Anthropological Aspects

Work is defined as a continuous human activity aimed at producing goods and services. It is a phenomenon that exists in all human societies. In contrast to sociologists, anthropologists primarily have studied work in nonindustrial/noncapitalist societies (hunters and gatherers, cultivators, pastoralists, craftsmen). Unlike historians, they are interested mainly in contemporary societies. Anthropologists recently have started studying work in capitalist enterprises, and the transformation from noncapitalist to capitalist work. Key concerns of the anthropology of work include the interaction between humans and nature, tool use, and the institutional and cultural embeddedness of work. In these contexts, work is treated as part of a system. In another perspective, work is studied as action and performance. The anthropology of work has been delineated by Applebaum (1992), Gamst (1995), and Wallman (1979).

1. *The Origins of the Anthropology of Work*

Many leading scholars became interested in work in the wake of European industrialization. Their main focus was industrial work, but they made comparative reference to pre-industrial work. Marxpraised the high productivity and discipline of capitalist industrial work, but criticized the alienation it caused. Pre-capitalist work was less productive (e.g., the work of craftsmen); nonetheless it had aesthetic character. In a comparative study on religion in Europe, India, and China, Weberwrote about the development of the work ethic and the rationality of work.

Bücher (1893) studied the division of labor and cooperation, and formulated a theory of 'independent household economy,' in which work is subordinate to the autarchy of the household. Bücher (1896) turned his attention to performance: How was it possible to perform constant, strenuous work in pre-industrial societies? In his view, the answer lay in the aesthetics and rhythms of work. In contrast to Marx and Weber, Bücher also drew upon contemporary ethnographic literature, placing him at the forefront of the anthropology of work. He did not, however, conduct any fieldwork personally.

Malinowski, the founder of modern anthropological fieldwork, was a student of Bücher's in Leipzig. Bücher and other German scholars (including Hahn and Weber) inspired his interest in the topic of work, which became the primary focus of his research on gardening practices on the Trobriands (Malinowski 1935). On the one hand, he was interested in the issue of performance: How do the Trobrianders succeed in performing sustained, strenuous work? His findings conclude that generally they were motivated by an interest in food, but were also interested in the aesthetics and social organization of gardening. Malinowski also examined the relationship between work and magic. Unlike Weber, he did not consider magic a hindrance to successful gardening: Magic is compatible with rational work, helping people to cope with the vicissitudes of gardening.

Two of Malinowski's students, Firthand Richards, continued his line of study. In her classic work on the Bemba in Northern Rhodesia, Richards (1939) stressed more than Malinowski the separation of work and needs: Work is not related merely to food requirements, but is embedded in cultural traditions, in this case the warrior past of the Bemba.

Based on intensive fieldwork, the studies produced by Malinowski, Firth, and Richards are still worth reading, mainly due to the diversity of issues and abundance of material. At a theoretical level they were

functionalists, taking into account economic, ecological, institutional, and cultural factors. Subsequent studies on work, however, belonged to more specialized subdisciplines of anthropology.

2. Theoretical Approaches

2.1 Ecological and Technological Approaches

Ecological anthropology investigates work as interaction between man and nature. The studies focus on hunters and gatherers, cultivators, and pastoralists. Quantitative measurements on energy input and output are characteristic of this approach. Lee (1979) investigated the hunting and gathering activities of the Kung San of the Kalahari (Botswana). One interesting finding was that the women—for less work—yielded more calories collecting nuts and plants than did the male hunters.

The Kung spent an average of 17 hours per week (i.e., 880 hours per year) hunting and gathering. The average calorific value of the food yield was 2,355 calories, i.e., it exceeded the daily requirements of the Kung, who are of relatively short stature. These findings triggered off a series of debates in anthropology and other fields. Based on the findings of Lee and other researchers, Sahlins (1972) argued that hunters and gatherers led a life of affluence consisting of little work. Other anthropologists challenged the thesis, provoking a debate that has yet to be resolved.

As a rule, farmers work more hours than hunters and gatherers. This is particularly true of intensive agriculture (Netting 1993). The annual person-hours in shifting agriculture is 480–960, but it is 3–4 times higher in intensive agriculture. This type of agriculture generally is practiced on small, permanently cultivated areas, often artificially irrigated and situated in high-density population areas. The work requires long working hours, and specialized knowledge and skills.

From an evolutionist perspective, many scholars view intensive agriculture as primitive in comparison to the mechanized agriculture practiced in industrial countries, where labor productivity is higher. Netting, however, argues that labor-intensive agriculture is more suited to densely populated regions. It is also more sustainable. In the USA, the energy input–output ratio for rice production is 1:1.55, while in the Philippines it is 1:7.

Herdsmen are often described as lazy in comparison to farmers. This verdict is based on the premise that only manual activities involving tool use constitute work. But in his study on camel herding and goat herding, Spittler (1998) shows that long working hours, complex knowledge and skills, and the strain of a harsh environment (wilderness) are all part of their work.

Technological approaches in studies on work concentrate on tool use. Craftsmen are the main focus of these studies, not hunters and gatherers, or farmers and pastoralists. In anthropology, the study of tools is a traditional one. This is due partly to the accessibility of collections in ethnological museums, and partly to theoretical paradigms. For many years, tool production was seen as the essential human characteristic. Technical and social evolution was also linked to tool development.

In effect, this fixation on tools was a hindrance to research on work. The fact that many types of work require few or no tools was overlooked. Above all, too little notice was taken of the fact that the starting point for any study on work should be human action, not tools. This is especially true of preindustrial tools, the use of which requires considerable skill, strength, and stamina. Bücher (1896) identified this fact, but found no following at first. Later, two Hungarian folklorists, Fél and Hofer (1974), wrote an excellent analysis of work with agricultural tools. Their detailed accounts of working with hoes, scythes, whips, etc. show that such work entails a number of factors (family traditions of work, general work ethic, emic theory of the body and of tool use, and the social life of tools) which cannot be deduced from the study of the tools themselves.

2.2 Institutional Approaches

With the one important exception of housework, work in industrial societies generally is organized in capitalist or public companies. One major feature here is the recruitment of free labor. There exist other types of work institutions. Slavery is a historically widespread form of organizing agricultural and industrial labor, e.g., in ancient Greece and Rome, in precolonial Africa, and in colonial America. Hunters and gatherers often work in loosely organized bands. The most common form of work organization among farmers, herdsmen, and craftsmen is the domestic economy, also known as the domestic mode of production or family economy. The concept was introduced by Bücher (1893), developed by Chayanov (1923), and established by Sahlins (1972) in the field of anthropology.

Domestic economies produce either for private consumption or for the market. The aim is not primarily profit, but to provide for the household. In the pure family economy studied by Chayanov, labor is recruited exclusively from the ranks of the nuclear family. A domestic economy involving additional labor (relatives, servants, slaves) can grow to a considerable size, comprising 100 or more workers (e.g., the ancient *Oikos*).

For a long time, the family was seen as a unit in which decisions were made in the interests of the entire family, a claim that is being challenged increasingly. Gender studies show that the burden of work is often distributed unequally, with women performing the greater share. The same applies to the age-related

division of labor, which is not always decided on the basis of natural abilities. Children are sometimes exempted from work, but more often are forced to work particularly hard. Both work and the fruits of work are often distributed unequally within the family, with elderly men and women enjoying the most privilege.

The term domestic or family economy is misleading, since a household, or family, is not exclusively—or even primarily—geared toward production, performing a range of other tasks as well. The members of a household are usually provided for, both materially and psychologically, irrespective of their work output. Children are reared and marriages arranged. The members of the household cohabit. Due to the diversity of tasks involved, work cannot be separated from other activities as it is in capitalist enterprises. On the contrary, it remains embedded in the multifunctional institution of the household.

In the purely family economy, the number and combination of the workers is determined by biological reproduction within the family. It depends on the family cycle and demographic contingencies. The output of individual workers fluctuates considerably, depending on the number of consumers. Such imbalances can be rectified by a temporary or permanent increase or reduction in the number of workers (e.g., by employing servants or farming out family members as servants). Greater flexibility is also achieved if households work together on a cooperative basis. Since Bücher, anthropologists frequently have studied the formation of work groups extending beyond the individual household. Due to internal competition, such work groups often lead to increased productivity.

In family economies, the division of labor is mainly on the basis of gender and age. This limited division of labor leads to a lack of specialization, since each member has to accomplish a number of tasks. The tasks are learnt at an early age in an informal process of teaching and learning. Work discipline is enforced by parental authority, but also through specific family sanctions (e.g., inheritance law).

What is the level of work efficiency in domestic economies? Inadequate specialization and restricted sanctions are often identified as negative factors. Family workers cannot be recruited or fired. On the other hand, family solidarity and early training can improve work performance. In areas where a large number of workers is no advantage, e.g., in agriculture, domestic economy proves competitive even under capitalist conditions (Chayanov 1923, Netting 1993).

In contrast to domestic economy, apprenticeship prepares people for a specialized activity. Apprenticeships occur mainly in the crafts (e.g., smiths, potters, weavers). Through the apprenticeship itself and the voluntary enrollment of apprentices, work is rationalized more than in domestic economies (Coy 1989). Similar to domestic economy, trial and error, demonstrations, and repetition are more important in acquiring skills than written instructions, explanations, and questions (Keller and Keller 1996).

From a methodological point of view, this implies that work can only be researched partially on the basis of interview. Precise observation and participation are required. These findings apply to both the study of work and to other areas. They challenge the predominance of the linguistic paradigm and the interview as its methodological correlate.

2.3 Cultural Approaches

In the 1970s and 1980s, a cultural (albeit not entirely new) perspective began to appear in anthropological studies of work (Wallman 1979, Godelier 1984, Applebaum 1992). Weber's analyses of the religious foundations of rationality and the work ethic were an excellent precedent. Now, however, new problems emerged and the approach was radicalized.

Semantic analyses of the definition of work in various cultures show that the meaning of any linguistic equivalent to 'work' can be expressed in broad or narrow terms. In most societies, the most arduous subsistence activities are defined by this one word. However, work is not always confined to useful activities, but can include what is good and beautiful. By contrast, intellectual work is rarely placed in the same category as physical work.

Cultural analysis goes beyond semantic analysis and the specification of taxonomies. It investigates models or commonsense theories of work. For example, work is seen variously as the transformation of objects (the prevailing view in industrial societies), as fighting with nature, or as caring for plants and animals. Commonsense theories also express claims about the part that work (in comparison to chance, magic, divine influences) plays in the outcome of action, and how human work capacity (physical strength, knowledge, skills) is created. Cultural analyses also re-explore the question raised by Marx: What are the implications of work for human identity?

Concepts of work differ from culture to culture, but also change over the course of history. However, many analyses of the history of the concept of work since classical antiquity do not address the question of whether the philosophers' concepts were shared by the working population. In contrast, Applebaum (1992) includes in his study contradictory interpretations of work between philosophers and working people.

Ecological, technological, institutional, and cultural approaches are mutually complementary. Although materialistic (ecological, technological) and idealistic (cultural) approaches were once opposed sharply, they have been combined fruitfully in several recent studies. Descola (1986), for example, in his study about the Achuar Indians in Ecuador, combines the structuralist theory of Lévi-Strauss with ecological approaches.

3. New Directions and Future Research

3.1 Work in Capitalist Societies

Since the 1980s, anthropological research on work has shifted increasingly to capitalist societies. The *Anthropology of Work Review*, founded in 1980, focuses almost exclusively on work in capitalist societies. What is the anthropological content of these studies? What distinguishes them from technological, sociological, or psychological work studies? Anthropology focuses on culture. Work culture and the culture of organizations are, therefore, one of the main areas of study. As a result, the anthropological definition of culture is often modified considerably, especially in the case of corporate culture. The methodological approach of these studies is even more important than their cultural perspective. Most anthropological studies are based on participant observation. Many researchers complete an apprenticeship, and often practice their acquired trade for several years. As a result, they practice participant observation far more radically than most classical anthropologists.

Many domains of work in modern societies interest anthropologists. Some concentrate on craftsmen, since their trades are affiliated most closely to classical anthropology. In a study on blacksmiths based on personal job experience, Keller and Keller (1996) showed how closely learning and working practice are based on nonverbal cognitive influences and experiences.

Anthropologists' traditional predilection for exotic themes is confirmed by their interest in kinds of work with a romantic flair (cowboys, and more recently, locomotive engineers, truck drivers) or fringe appeal (hustlers). Recently, however, they have turned their attention to executive management. Industrial work and its transformation is another topic of interest, and some anthropologists spend many years in industrial employment (Burawoy 1979). In recent years, the modern service and information sector has attracted major interest, including, for example, fast food outlets, computer firms, repair services, and science laboratories.

Despite the diversity of occupations and different theoretical approaches, these studies have a lot in common due to their uniform methodological approach. Anthropologists proceed from the actor's perspective, not from the perspective of economic, technical, or cultural systems. They show that an actor's skills are not limited to the specifications of a job description. They also include physical strength, manual skills, knowledge, stamina, energy, and learning ability. In most jobs, more is learned through acquired experience and discussions with colleagues than through formal training.

Performance at work is ensured only partially by checks, incentives, and sanctions. Other motives also play a role, although not necessarily a specific work ethic. In the minimum scenario, people work simply because it is preferable to 'killing time' over a long day. All the investigations show that consistent work performance possesses an inherent structure that is not governed by checks or sanctions. Furthermore, the work world is never determined exclusively by work; it is a life world, providing scope for personal relationships, emotions such as joy and frustration, and a range of other external influences.

3.2 Work in Comparative Perspective

The classical writers of the nineteenth century (Marx, Bücher, Weber) assumed that pure work first evolved in modern times as a result of capitalist wage labor or a process of rationalization. Still today, most social scientists would agree that precapitalist work is embedded in society and culture, and combined with other activities. They also argue that there is more freedom, because there is less rigid control.

However, if we review the research findings of the 100-year history of the anthropology of work, we tend to arrive at the opposite conclusion. Precapitalist, preindustrial work seems determined largely by ecological and technical factors. The actors are merely peripheral. By comparison, the studies of work in capitalist society reveal autonomous actors who not only perform their work but also display emotions, cultivate personal relationships, and see their work as a life world.

Are the old theories wrong? The new research findings partially correct the dichotomously constructed theories on the antagonism between precapitalist and capitalist work. To a large extent, however, these results are research artifacts. Most anthropologists working in capitalist societies accept the structural conditions of work as given, and concentrate on the scope for individual action (but, see, Burawoy 1979). This view is endorsed by the methods of participant observation. The economic and technical framework conditions are already known or being studied by other sciences.

By contrast, the anthropologist, whose research centers around peasants, herdsmen, or foragers, has to investigate all aspects of their work. This includes ecological, technical, and institutional structures. Anthropologists do not measure working time in capitalist societies, since the data are usually otherwise available. In precapitalist societies, however, time-consuming methods are often required for its measurement. On the other hand, the actor's point of view is rarely examined (but see Malinowski 1935, Fél and Hofer 1974, Spittler 1998). The method is also important in this context. Participant observation, which favours the actor's perspective, is practiced more in capitalist than in noncapitalist societies.

The conclusion is that comparison is difficult, since the investigations are based on different presup-

positions. In noncapitalist societies, anthropologists should investigate work performance and the work world far more closely than in the past; in the case of Western society, they should concentrate more on structural conditions, including the latest developments in the international division of labor. Although the social division of labor was once a central theme of the social sciences (Marx, Bücher, Durkheim), anthropologists have largely ignored it, except for the gender-specific division of labor.

Other major comparative research deals with processes of transformation from noncapitalist to capitalist societies. Extensive anthropological literature is now available on the transformation of work in developing countries and Eastern Europe. These transformation processes show that the labor process in capitalist institutions differs considerably from that of noncapitalist institutions. Conflicts about time schedules, labor recruitment, and labor relations not only express the different interests of workers and management but are indicators of a conflict between work cultures. Therefore, we may expect that the transformation process will not result in the enforcement of a pure capitalist work culture but in a hybrid type of labor process.

Work, History of

The concept of work designates certain human activities; however, those activities that are considered to be work and those that are not, vary among different cultures and epochs. Each historical society has its own definition of work, and a variety of different conceptions are juxtaposed to one another within each society. How work is defined is closely associated with the value placed on it, and this in turn is connected with workers' positions in society. The history of work must therefore bring together two themes: the history of the meaning of work and the history of work as a practice. The relation between gender and work cuts across these two themes and shows how strongly they are connected.

1. History of the Concept of Work

The state of research on the history of the concept of work and the meaning of work suffers from three shortcomings. First, it is based upon the reflections of intellectual elites. The ways in which other social groups—above all, the workers themselves—understood and evaluated work have not left much of a trace in historical source material, nor has much research been done on this tissue. The history of the concept of work is a history of ideas, and—in a very few approaches to this field—a history of mentalities as well (Le Goff 1980). Second, research has tended to ascribe a unitary—or, at least, a predominant—concept of work to the respective historical society under investigation. Contradictory or conflicting attitudes have been almost neglected. Third, the history of

the concept of work has remained eurocentric. Despite the pronounced interest in the work ethic of non-European cultures and religions that was already evident in the work of Max Weber, and in spite of the growing interest in global history, a systematic intercultural comparison remains a desideratum (Godelier 1980).

1.1 Concepts of Work in Pre-industrial Societies

The history of the concept of work in Western historiography begins as a rule with the great philosophers of Greek Antiquity (Aristotle, Plato) (Conze 1972). They employed the term work (*ponos, poiesis*) to designate work done manually, and described thereby activities that required physical exertion and strength, that presupposed the use of tools, and the aim of which was to turn out a particular product. The meanings which coalesced to define the word *ponos* included labor, toil, hardship, and suffering. This concept of work had a parallel in the Indo-Germanic languages, which as a rule contain several terms for work and working: *labor* and *opus* in Latin, *travailler* and *ouvrier* in French, *labor* and *work* in English. The first word stem means great effort, travail, and affliction, activities dictated by necessity or constraint. The second word stem refers to the results of this effort—the attainment of a certain goal, the creation of a product.

Most historians agree that philosophical and political thought in Antiquity was characterized by contempt for work. Work was an evil, the activity of slaves, while the élite engaged in art, philosophy, and politics. The connection between abhorrence for manual labor and slavery is confirmed by the contrast provided by non-European cultures. Slave labor did not play an important role in the historical societies of East Asia, in whose great religious-philosophical systems—foremost among them Buddhism and Confucianism—work (the fieldwork of peasants and the handiwork of artisans) had a positive connotation. But European Antiquity was also characterized by contradictory attitudes toward work. Critical schools of thinking such as the Cynics esteemed physical and mental labor and contrasted them to idleness, which they regarded as a vice. In ancient Rome as well, particularly during the Republic, peasant farm work performed by free men was not seen in a totally negative light.

In the Judeo-Christian tradition, the ambivalence of the concept of work is expressed with particular clarity. In the Old Testament God himself appears as a worker, and man was originally meant to care for God's creation. 'And the Lord God took the man, and put him into the garden of Eden to dress it and to keep it' (Genesis 2:15). However, with man's fall from grace, work became penance and punishment: 'In the sweat of thy face shalt thou eat bread.' (Genesis 3:19). The New Testament carried forth this ambivalence. Christian writings of the Middle Ages constitute an 'ideological arsenal containing weapons for the defence of every position, in favour both of labour and nonlabour (…) ranging from (…) contempt and condemnation to a tendency to respectful evaluation' (Le Goff 1980, p. 77). From the tenth century on, a new trifunctional or tripartite social schema took hold; it divided society into 'priests' (*oratores*), 'warriors' (*bellatores*), and 'workers' (*laboratores*). This model assigned all working people to the lowest level of the social hierarchy, but nevertheless made them an indispensable segment of society. The Reformation strengthened the tendencies to enhance the status of work. Luther and Calvin understood work as serving God. The work that each Christian performed was considered a 'calling' or a 'divine calling,' and thus assumed a quasi-religious character. The adherents of certain Protestant denominations—above all, the Puritans—regarded success they achieved in their work as confirmation that they numbered among God's elect. Since the publication of Max Weber's study (1904–5) it is generally accepted that the higher valuation of work during the Reformation legitimated and promoted the spread of a bourgeois work ethic, even if it has important roots in medieval thought.

1.2 Concepts of Work in Modern Western Society

In early modern Europe, work was redefined in two respects. The first definition exhibits anthropological traits. Work came to appear as active human intervention in nature for the purpose of assuring the ongoing existence of the human species. At the same time, work appeared to be a social process based upon collaboration among human beings. This new idea of work played a central role in Enlightenment philosophy and the writing of cultural history done during this period. Man was seen as ruling over nature; division of labor and cooperation as the foundation of human socialization; and increasing domination of nature and further division of labor as the very epitome of social progress. Tools were considered the basis upon which human dominion over nature rested. Man thus appeared to be the 'tool-making animal,' as Benjamin Franklin put it. In the nineteenth century, Karl Marx and other thinkers of the early Industrial Age carried on this intellectual tradition. In his classic formulations in Volume I of *Das Kapital* Marx described this dual character of work: 'Labor is, in the first place, a process in which both man and Nature participate, and in which man of his own accord starts, regulates and controls the material re-actions between himself and Nature (…) By thus acting on the external world and changing it, he at the same time changes his own nature' (Marx 1867, p.192).

The second redefinition originated in the seventeenth century in the field of political economy, which linked the concept of work with the idea of value. Work was defined as an activity that created value,

and value-producing activities were considered to be all those that were for pay or that generated income. This led to equating work with paid labor. In industrial capitalism, paid labor became the very epitome of work.

These new definitions were associated with the greatly enhanced status of work. 'The modern age has carried with it a theoretical glorification of labor and has resulted in a factual transformation of the whole society into a laboring society' (Arendt 1958, p. 4). Paid labor became the basis of self-esteem, social recognition, and political participation—in short, the admission ticket to civil society. However, attitudes toward work were ambivalent in modern society as well. The classic works of political economy of the eighteenth and nineteenth centuries, beginning with Adam Smith, feared the brutalizing and stultifying effects of extreme division of labor and repetitive mass production. For Marx, work in capitalism was exploitation and alienation; his communist utopia vacillated between self-realization by means of work and liberation from it. These ambivalencies were expressed in increasingly multifaceted views of work. The esteem accorded to work referred to a specified type of work in contrast to its polar opposite, which was assessed negatively; mental vs. physical work, planning and supervision vs. actually performing tasks, skilled vs. unskilled work, a steady job vs. 'casual labor,' 'proper' work vs. housework. A complex hierarchy of work is an essential component of the modern concept of work.

2. *Work as Practice*

Which activities were taken into consideration by scholars compiling the history of work as practice is closely connected to the development of the concept of work. Three perspectives emerge in the historiography of work: work as production and application of technology; work as economic activity; and work as culture.

2.1 *Work as Production*

The conception of work as dominion over nature that had emerged in the seventeenth century began to exert an influence on the history of work in the nineteenth century. Benjamin Franklin's characterization of man as the 'tool-making animal' was cited approvingly by Marx. Tools, or, in more general terminology, instruments of labor, were for Marx, fundamental to the periodization of history and a yardstick of human progress: 'It is not the articles made, but how they are made and by what instruments, that enables us to distinguish different economic epochs' (Marx 1867, p. 194). Proceeding on this basis, Marxian historians and archeologists developed a world historical perspective on work that focused on two (or three) 'revolutions in the forces of production' (Childe 1936, Bernal 1954).

The first of these was called the Neolithic Revolution. Its point of origin was the Near East (Southern Anatolia, Mesopotamia, the Jordan Valley) and between about 8000 BC and 3000 BC it spread over large portions of South, East, and South-east Asia, North Africa, Europe, and Central America. The essence of this revolution was the transition to agriculture and animal husbandry as the most important basis of human existence, and in the emergence of agrarian (farming) societies. According to this view, this was the beginning of goal-oriented human intervention in nature and was thus, in an alternate formulation, the beginning of work. 'Early men did not work at all in the true sense (…) real work, steady work, labor for one's livelihood, came into being when agriculture was invented' (Williams 1976, p. 335).

The second great revolution in the forces of production was, from this perspective, the Industrial Revolution, which began during the second half of the eighteenth century in Western Europe and encompassed large parts of the world over the course of the nineteenth and twentieth centuries. Now, the tools employed in performing work were no longer operated manually by the human hand, but rather by a machine that was driven by artificially produced energy. Thus, production became independent of the skillfulness, endurance, and physical strength of human beings. In capitalist fantasies, as in Andrew Ure's *Philosophy of Manufacturers*, 1835, machinery even functioned as the most perfect means to control and to discipline the workforce, as the final victory over the obstinate spirit of the workers. Factory, mass production and conveyor belt became the symbols of work in industrial society.

The increasingly important role played by microelectronics and the computer in industrial production since the 1960s appeared, in this perspective, as the third great revolution in the history of work. Now, human beings withdrew from the process of controlling production and turned over mental activities as well to a machine, the computer. Automation, or flexible communication between humans and computers—a 'man–machine dialog'—seems now to be the defining characteristic of a new world of work. The amount of human labor necessary for direct production is on the decline. The production process is increasingly becoming the activity of a 'collective worker' (Marx), in which technology and science play an important role.

This 'grand narrative' was subjected to critique and developed further by scholars working in the history of technology, a field that became over the course of the twentieth century an independent academic subdiscipline (cf. *History of Technology*). Its early practitioners were engineers and technicians with their own narrow understanding of technology, who were not interested in human agency, but in the interaction of

material objects. As early as the 1930s (Bloch 1967) though, economic, social and cultural historians were beginning to get involved in this field, and making the effort to conceive of technology as an integral part of society, and thus to conceive of work in an all-encompassing sense. In contrast to Marxist 'history of the forces of production,' they emphasized the numerous small technical innovations made in all historical epochs. An evolutionary perspective predominated in the history of technology. What the two approaches have in common is the tendency to represent the history of work as developing along a path rising in linear fashion, and as the history of progress.

2.2 Work as Economic Activity

At around 1900, with the newly awakened interest in economic and cultural history, there was also increased demand for a history of work, which then proceeded to emerge as a not-very-clearly delimited subdivision of general economic and social history of various different cultures and epochs. Since then, the history of work as an economic activity has been focusing on work as wage labor; on working hours, wages, and working conditions; and on the history of the modern work ethic and work discipline.

Wage labor was widespread in many pre-industrial societies. In Europe, it took on increased significance from the late Middle Ages. Over the course of the Early Modern Period, the population became increasingly dependent upon wage labor. In the economically most highly developed regions of Europe, the 'proletarization' of the populace was a pre-condition and not a consequence of the Industrial Revolution. In the industrialization process of the nineteenth century, wage labor in its 'pure' form ultimately established itself as the predominant type of labor relationship. Among the features that typically characterized it were the standardization and regulation of work, including a high intensity of labor, a regular working rhythm, and a highly pronounced working discipline; a high degree of specialization of work along occupational lines; a clear demarcation of time spent at work and time off (over the course of a day, a week, a year, and a lifetime); the separation of the workplace from home; and a complex system of institutional and legal regulation.

The developmentf wage labor, however, was not a linear process. Recent research has shown that diversity of labor relationships was characteristic of the period from the late Middle Ages to the eighteenth century. A growing number of men and women earned their daily bread from a combination of agriculture, crafts and trades, and commercial activities, and by combining self-employment with wage labor. A high degree of flexibility and increased readiness to undertake labor migration were preconditions called for by this mixed economy. Flexibility, however, was not only a voluntary practice, but was enforced by the instability of the economy, by necessity and misery. The French historian Fernand Braudel suggested that commercial capital and industrial capital, small workshops and large-scale enterprises, rural home industry and centralized manufacturing during this period should not be regarded as sequential phenomena, but rather as a pool of possibilities, as co-existing labor relationships and modes of production, among which men and women could choose and switch.

An ongoing point of discussion is the question of why men and women of the Early Modern Period increased the intensity of their work. Was this attributable to the exigencies of hardship in an increasingly polarized or proletarianized society, as mercantilist economists of the seventeenth century presumed? Was it the capitalist entrepreneurs who used shop regulations and penalties to turn up the pressure upon their employees? (Thompson 1967). Was the transformation of the world of work simply a part of a general disciplining process—including workhouses, prisons, and schools—to which men and women were forced to submit (Foucault), or to which they—as part of the process of civilization (Elias)—subjected themselves? Or was it the transformation of material culture—namely, the brave new world of consumer goods that expanded so rapidly in the Early Modern Period—that made working harder acceptable, or even desirable? Are the beginnings of consumer society thus also the historical roots of the laboring society? (de Vries 1994) (see *Consumption, History of*). Which role was played by the changing perception of time, by which—from the fourteenth century on—Europeans began to adapt to the abstract rhythm of mechanical clocks? No matter how these questions are answered, it is clear that the role of the Industrial Revolution and mechanized factory labor as factors giving rise to the modern world of work have been devalued, whereas more emphasis is now placed on the long history of capitalism.

The industrialization process, too, became a field of revisionism. As it is conceived now, it was not represented by the factory alone; handicrafts, skilled work done by hand, and small-scale enterprises continued to play a key role (Sabel and Zeitlin 1997, Samuel 1977). The diverse branches of the service sector, such as transportation and shipping, retailing, education, entertainment, and the widely varied world of office work would very soon be employing more men and women than the manufacturing sector. In most industrial states, a majority of the workforce has never been employed in the secondary (industrial) sector. And ultimately, factory work has proved to be more varied than it had long appeared to outside observers.

The concentration of research on the 'ideal type' of paid labor in modern society has caused too little attention to be paid to forms of labor that deviate from that model. This applies, for instance, to various

forms of unfree or forced labor. In European history since the Middle Ages, slave labor has not been widespread, but as a basis of the Atlantic economic system from the sixteenth to the nineteenth century, it was indeed an essential component in the emergence of industrial capitalism. However, forced labor was widespread in the totalitarian political systems of the twentieth century. Seen from a global perspective, 'free' and 'pure' wage labor has (still?) not become the predominant form of work. Today, both agriculture as well as a combination of different activities and forms of work—as was characteristic of European history during the Early Modern Period—provides work and a living to a majority of the world's population.

2.3 Work as Culture

Since the 1980s, a new way of looking at the history of work has become widely accepted. A growing number of historians consider work as culture. As far as the concrete practice of research is concerned, this means a micro-historical perspective focusing on the workplace itself. Particular attention has been paid to two types of workplaces: first, the small workshops of artisans in the Early Modern Period and in the nineteenth century, that represent, on one hand, 'traditional' work, and, on the other hand, their increasing integration into capitalist relationships of production (Kaplan and Koepp 1986); and secondly, the factories of industrial enterprises of the late nineteenth and early twentieth centuries, as symbols of the modern industrial world of work (Lüdtke 1993). The chief focus of these micro-historical studies is upon day-to-day working processes themselves and on social relationships in the workplace. They show the enormous diversity of practical labor and thus constitute a much-needed corrective to the generalizations yielded by the macro-historical perspective. Scholars investigating the cultural history of work have also attempted to reconstruct the meaning of work for, 'common, everyday people' by using 'ego documents' such as autobiographies and diaries; iconographic and pictorial sources; and oral-history interviews (cf. Passerini 1982).

There has also been great interest in the symbolic and ritual forms in which solidarities and conflicts are carried out and resolved on the workplace (cf. Darnton 1984). In investigating these phenomena, the micro-historical perspective also extends beyond the immediate confines of the workplace. Work gives rise to social relationships that retain their significance beyond the workplace, the term 'world of work' is used to connote this expanded meaning.

Often, work's significance becomes clearly evident only when it is absent. The implementation of the working norms of industrial capitalism also led to a redefinition of being out of work. Between 1880 and 1910, a new term describing involuntarily not working, became widespread: unemployment (*Arbeitslosigkeit, chômage*) (Topalov 1994). The first microanalysis of work and unemployment that became one of the classics of twentieth-century social science is the study *Die Arbeitslosen von Marienthal*. In this small Austrian factory town in 1932, the textile mill that dominated the village's economic life shut down, so that practically the entire population was thrown out of work overnight. As a result, the rhythms of everyday life became slower and slower, and the unemployed were able to summon less and less energy for activities that they had previously pursued enthusiastically during their free time (Jahoda et al. 1933).

This draws attention to the fact that leisure is, on one hand, the antithesis of labor, though on the other hand, it is also part and parcel of the world of work. In pre-industrial societies, there was no strict dividing line between working and not working. The peasants of the Occitanian village Montaillou, who in about 1300 were interrogated by envoys of the Inquisition about their way of life, interrupted their labors at the slightest opportunity—to chat with neighbors, to hang around the village square, to have some fun playing a game (LeRoy Ladurie 1975). It was only Industrial Society that drew a clear distinction between working and not working, thereby changing the character of not only the world of work but of leisure as well. The concept of leisure refers less and less to merely not working and rather more to an ensemble of activities pursued by specific classes at certain times, such as games, sports, watching TV, going to bars or symphony concerts. In this sense, leisure seems to some historians to be a cultural practice that was not 'invented' until the Early Modern Period (Burke 1995).

3. Work and Gender

The relation between work and gender is a field of scholarship in which the reciprocities between the concept and practice of work, between work as economic activity and as culture, can be seen with particular clarity. Early studies of women's work conducted up into the 1970s almost exclusively treated gainful employment on the part of the women. Initial interest was focused upon factory labor, and then increasingly on 'specifically feminine' occupations like maid, governess, midwife, teacher, secretary, and salesgirl. The aim of this research was to reintegrate women into the male-defined world of paid labor. Beginning in the 1970s, feminist historians increasingly criticized the prevailing modern concept of work. Housework became the subject of theoretical discussions and of empirical investigations. Increasingly, studies on the history of women's work focused both on gainful employment and domestic activities (Tilly and Scott 1978, Simonton 1998).

The issue of the division of labor between the sexes has become a much-favored field of interdisciplinary

research. Anthropologists, historians, and sociologists have shed a great deal of light on the variability of the division of labor. One and the same activity can be a typical man's job in one culture and woman's work in another. Which work is done by men and women does not depend on the 'nature' of their respective sex, but upon socially constructed gender roles. Recent theoretical approaches oppose biological or 'biosocial' as well as cultural determinism. Emphasis is in the variety of options taken in the sexual division of labor and the contesting definition and redefinition of norms.

In European history of the late Middle Ages and the Early Modern Period, the economic significance and the symbolic meaning of the respective activities assumed decisive explanatory power. One research approach emphasizes the exclusion of women from market-oriented activities in agriculture, crafts, and trades. Work that promised to yield profits, was learned and practiced according to formalized rules, coalesced into formalized occupations and had organized politically along occupational lines became the domain of men. Early 'classical' studies of women's work and some recent research proceed under the assumption that up to the beginning of the modern period women also took part in artisanal market production and were organized in guilds—either in exclusive women's guilds or mixed guilds (Wiesner 1989). According to this perspective, it was not until later that there occurred a gradual exclusion of women, be that as a consequence of 'male bonding,' the spread of capitalism, or the Industrial Revolution. Other historians have stressed the continuities of the gender-based division of labor since the twelfth century, which placed women in the domestic sphere or in low-skilled, low-status and low-paying occupations (Bennett 1988). Most historians emphasize the fluctuating boundaries between men's and women's work, which are continuously redefined and renegotiated (Honeyman and Goodman 1998).

Another research approach emphasizes the cooperation between men and women. In this perspective, the 'working couple' formed the economic backbone of the agrarian and the artisanal economy (Pahl 1984, Wunder 1992). This can be seen even more clearly in the 'family economy' of the lower classes. Women played a central role in efforts to exploit and combine as many of the available income opportunities as possible. The 'industrious revolution' which preceded the industrial one in the view of many historians, was based on the cooperation of men and women in the family economy (de Vries 1994). Conflict and cooperation are not necessarily antagonistic but rather complementary perspectives on the gender-specific division of labor in pre-industrial Europe.

With respect to the nineteenth century, the focus of research has been on the 'male breadwinner model' and the emergence of 'separate spheres,' which made paid labor the exclusive domain of the male and, conversely, explained domesticity and care of children as being appropriate to the female nature (Janssens 1997, Hausen 1981). This was an effective model, even if there are diverging assessments of its effective range and the extent to which it actually did determine practice. Indeed, it was a short-lived model. The proportion of women pursuing paid labor began to climb again in the 1960s, including highly qualified professional work and lifelong careers. The history of the division of labor between the sexes shows that 'the division of labor is an effect of the social hierarchy, not its cause.' (Godelier 1980, p. 170).

The feminist critique of the concept of work in modern society has considerably widened the boundaries of the history of work. Since generally applicable definitional criteria are not in sight, they have to be developed from case to case. 'In this widest sense' the English historian Penelope J. Corfield wrote, '"work" is whatever people consider as work (…) the boundaries between "work" and "non-work" are in practice very often obscure' (Corfield and Keene 1990, p. 208).

Work, Sociology of

Work is central to the panhuman existence. In the twin disciplines of sociology and sociocultural anthropology, the study of work has thus long been a central interest, and it pervades much of the disciplines' published research. 'Work' has perhaps the widest meaning of any word in English. It is a culture-bound, scholarly concept, and folk idea regarding both a process and its accomplished state. In this article, the value-laden meanings and the dimensions of 'work' are examined. Also a brief history and salient conceptual issues of the sociology of work are reviewed.

1. *A Brief History of the Sociology of Work*

Few ethnographic monographs about nonwestern societies exclude information on work. In the twentieth century, the twin disciplines depicted the centrality of work in community studies in the USA and Canada. Employment and its access are a vital interest of the fieldworker studying a community, often from an ecological perspective. Pioneering research on work and workers in North America apart from community studies includes that of Whiting Williams, beginning in 1918, on the human relations of employees and employer. With the advent of the experiments and observations regarding workers in the Hawthorne plant of Western Electric, by 1930, the twin disciplines entered their phase of industrial social science, often having a social psychological bent. Studies of work received legitimization in 1946, when the American Sociological Association formed its Section on Industrial Sociology and again, in 1951, when Delbert Miller and William Form wrote the first textbook, *Industrial Sociology*. Work-studies are a variety of empirical emphases not having a characteristic conceptual framework or methodology. Workers display the ordinary range of social behavior. Organizations of work, from corporations to cliques on the job, are components of the greater human society. Nevertheless, in studying modern societies, work relations are part of most conceptualizations of social structures, and social information is most frequently collected in a workplace.

The research on work broadened to encompass many emphases and overlapping subtopics, from gender issues to division of labor. Work research gradated into investigations conducted across disciplines such as on organizations, social control, industrial relations, and role theory. What, then, is 'work'?

2. *Work as Culture-bound Idea*

Knowledge does not exist supra culture; thus, one must first examine the Anglo-Saxon cultural context of work. Work is the broadest English word for both

the process of doing something and the state of something done. Work is viewed ambivalently. It is a moral necessity and the deity's curse of travail upon humankind ('in the sweat of thy face...'). As etymologically rooted and in folk views, work is conceived broadly, as all endeavors.

Many social scientists, however, attempt an analytically useful narrowing of definition to the creating of goods and services valued in a society. But valued by whom? As Melville Herskovits explains, the phenomena of value regarding things exchanged are understandable only as a part of a specific culture or a subculture (Herskovits 1952). Adriano Tilgher informs, because economic value is always relative, so too is the work creating it (1958).

The social value of work then, depends upon the socialized view of the observer, varying even within a specific society. Managers of ante-bellum Southern railroads and their corporate slaves had differing views on the nature of value created.

As with other issues in the sociology of work for example, the management-oriented studies spawned by Hawthorne, definition of value in work resolves into whose ox is being gored, or fed (Carey 1967). A social disruption, however, could be eufunctional for at least part of a society. Thus an intensive strike after which workers lose their employment is not always dysfunctional to labor overall. Locomotive engineers and switchmen decisively lost the bitter strike on the Burlington road in 1888. Management's 'victory', however, proved so costly to shareholders that other railroads quickly began recognizing the labor organizations of the on-train operating crafts. If not definable by value, work could be usefully viewed in various dimensions.

3. *The Dimensions of Work*

Work has a personal dimension in defining the self and obtaining positive affect from community members. This dimension has a strong hold on all humans, in nonmarket and market societies. In the Horn of Africa, the Wayto hippopotamus hunter seeks his village's recounting of his prowess as a killer of game; the Qemant plowman seeks community recognition as a good husbandman.

For the street-corner man of Washington, DC, job experiences and consequent job fears constantly assault him. Terrified of an opportunity to work, he stands defeated by experience, with self-worth destroyed and fear thereby validated. Work greatly affects the integration of personality.

Work also has a social dimension, concerning interpersonal relations' as much as productive output. Many behaviors at work are comprehensible at the collective level. Individual self-interest is dampened by behavioral prescriptions including norms and etiquette. Moreover, in industrial society, with its atrophied bonds of kinship and limited ties of community, work in groups provides opportunities for the close interactions that all primates require, including humanly exchanging positive affect and releasing tensions in a 'support group.'

Each culture structures work in its own particularized dimension of time. To coordinate industrial transportation, standard time zones were created. For modern production and communication, the microsecond was created. Even in so-called timeless foraging and agrarian societies, space cannot be used effectively without some kind of reckoning of time for coordinating activities. A number of temporal modes including frequency, synchronization, and duration time an industrial society. Without such timing, society's work becomes dysfunctionally independent instead of functionally interdependent. The clock, more than the steam engine, was the serpentine machine in the garden of agrarian America.

Anglo-Saxon folk and intellectual thought about work exclude much laboring activity. Some activities are not considered work when the time and exertion seem sporadic and little planned, the activities are only somewhat or unrelated to an institutional product (purpose), or these activities are commonplace. For utility in theory, a concept of human work must be valid across cultures and not bound by Anglo-Saxon culture. Need work be purposeful and gainful, and how is livelihood cross-culturally viewed?

4. *Work as Concept*

Perhaps useful is contrasting a biological exertion involving energetic activity of motor acts and thought with their expression in culturally patterned work. A purely mental activity such as planning a task becomes work. Work, as solely a motor act apart from related thought probably does not occur.

Because work is social, even when done in isolation from other humans, it is enmeshed in the collective conventions of a society. A person's work activities ordinarily intertwine with activities of others in role sets for producing, exchanging, and consuming goods and services. A work role is a cluster of attributes and expectations for a work status, a social position in a society occupied by a person. Even when work is performed apart from other persons in a set, it is enacted regarding a reference group for such activities. Shipwrecked, Robinson Crusoe remained a member of his tinkering British society.

Should exertion be purposeful to qualify as work? Purpose overlaps with relative social value. The issue remains, purpose from whose perspective?

Canadians each perform the same exertion in felling trees: an employed lumberjack, a thieving 'timber pirate', and a gang of vandals. In economic parlance, the first two persons purposefully 'add value', the third group does not. To the extent that defining work

depends on purpose, this characteristic is (sub-) culturally relative.

Work could be defined as gainful; a livelihood earned in a nonmarket, transitional, or market economy. Broadly considered, gainful work does not require market exchange or money. It could be coerced. The gain could be either an increment or a saving of something valued, incorporeal or material. A shaman reciprocates séances for sundry services from community members. A chief collects part of all produce and redistributes some to the chiefdom's members in kind and some as political administration.

In modern societies, an individual has multiple gainful statuses of varying duration. A woman might be a monetarily unpaid homemaker, corporate executive paid in the market, communities volunteer given positive affect, and administrator of a food cooperative compensated in kind. Livelihood work thus supports a human's life (one's biological requisites) and life way (one's sociocultural requisites). With such a broad conception of livelihood, less kinds of exertion become excluded as work.

5. *Work in Modern Societies*

Although a conception of work must be cross-culturally valid, much of its investigation concerns industrial and industrializing societies. In industrial society, few remain primary food or craft producers. Instead, people consume goods and services created outside their local community. They gainfully work mainly for increments and savings to enhance their standard of consumption. Devices enormously multiply exertion in work with a consequently great personal productivity. By hoe, a Plains Indian tilled 0.1 of an acre annually, but, with machines, a Plains farmer tills 2,000 acres annually. Although a concept of work does not depend upon money, in today's market economy, it is the acme of activity. Sufficient money allows great independence from kinship bonds and community ties.

Because monetarily paid work is a central identifier of the self; the characteristic used as a person's overall social label and assessment is occupational status. After the ritualistic 'How do you do?' comes the meaningful, 'What do you do?' Work furnishes a person's basis of social power and economic and other welfare.

In its concomitants, loss of work could mean the severing of one's mooring in society. The largest medium of monetary savings, the house, can be lost. In the USA, vital health insurance is terminated and retirement credits are not accrued. Also concomitantly, the job delimits the kind of neighborhood along with the personal safety and property security obtainable.

It determines the quality of housing inhabited. It influences the kind of education and opportunity for children. It also restricts who will be friends, neighbors, and co-workers. Above all, the job allows a reassuring, predictable routine in an otherwise hectic life.

6. *Social Control of Work*

Coherence in science rests on a central notion. In the twin disciplines, the notion might be social control, their most widely used concept but about which no agreed definition exists. The term could mean an underlying social process, a social mechanism delimiting behavior, or a scholarly model for analysis. Most conceptions, however, concern norms (a culture's prescriptive 'shoulds' and 'oughts') and related sanctions, and the ways in which social organizations change while preserving some societal stability (Gibbs 1994).

Control maintains social relations not equally beneficially to all the involved actors, depicted in the innumerable studies of work and reactions to controllers of work.

Industrial relations constitute contests for social control between employers and employees. Social control of work has a number of forms. These include bureaucratic, by formal rules and procedures; technological, by devices limiting or monitoring action; and occupational, by grouped workers defining, in some part, the terms, conditions, and content of work. The pivotal question in studying control is, 'in what ways are persons made to act in a manner not serving personal self-interest but, instead, society's collective interest?'

6.1 *Employee Participation*

In the 'new industrial relations', the strong control of work by managers is reclad with 'cooperative' programs such as: quality circles, team concept, and employee involvement. For unionized workers, participation in the programs necessarily broadens the character of their labor-management relations. A cooperative program, if fully developed and controlled through bilateral negotiations, could foster mutual benefits. Participation programs, however, are frequently created in trendy public relations, (naively?) overlooking the opposing goals and highly consequential exercises of social control in the relations between labor and management. A large business organization possesses great social power, alone and in coordination with similar firms united in associations having special access to government.

Unorganized employees, and sometimes those organized, are at a great disadvantage regarding power relations and abilities to exercise social control in the market. In its traditional adversarial role of countering union social control, through cooperative programs management can usurp union responsibilities and pose as a benefactor of employees. Cooperation could allow

a transition from powerful collective to powerless individual bargaining for employees. A true employee participation means management must surrender some of its social control of workers. Genuine co-operation in work is fully bilateral, thus a partnership. It can only be effected by near equals in social control. This has not yet been the case. The global market pressures on wages and conditions of employment are inexorably downward.

6.2 Social Control of Technological 'Progress'

Business practice in North America, includes a sectarian, *laissez-faire* ideology promoting technological 'progress.' A tenet of such practice is a view that workers, their families, and fellow community members must suffer the consequences of progress without redress or complaint. Technology, however, is not a neutral force, or impartial hand of advance in an industry, for shaping society and inclining an individual's life. Technological change for work receives guidance from visible hands, according to goals of private firms, public agencies, and other organizations including unions and advocacy groups. In business, only rarely does management effect social control solely through technology. Ultimate control comes through the bureaucratic mechanisms of a firm, thus from managerial norms. The high value North Americans place on technological change masks what seldom changes, the social controls shaping technology and its policy and, thereby, society.

7. Gender

In foraging societies, occupational Jacks- and Jills-of-all-trades exist, respectively, hunters and gatherers. As technologies of plant and animal domestication free some persons from primary food getting, a true division of labor, with occupational specialization, develops in addition to the universal natural division of labor, by age and sex.

Despite a true division—including specialization of work technology within segments of a society or separation of a particular technology into its component techniques, or both—division of labor by sex remains everywhere.

A specific culture assigns to each biological sex a number of gender roles that are mainly learned culture. The roles are normative results of socialization, including for work. Not only do the conventional roles delimit what is 'male' and 'female', but also what is appropriate work for each sex.

Because a great overlapping range of somatic and mental characteristics exists for males and females, a similar range of tasks performed equally well by each sex obtains. Cross-culturally, almost no work roles are exclusively men's roles. Among the Hopi, women do the construction of multistory houses; among the Dahomey, women were the assault troops; and, in many African societies, women have apical political statuses. Whatever a man can do a woman can do equally well, with few exceptions, mainly related to somatic strength.

Nevertheless, work-role and occupational sex typing is dominant even in industrial democracies. At Christmas time, a boy customarily receives a black doctor's kit and a girl a pink nurse's kit. Such socialization for conventional aspiring to statuses of work is multi-stranded, from throughout the fabric of a culture. Some feminist scholarship explores the relations among capitalism, patriarchy, and job segregation. Although these neo-Marxist studies are illuminating, they do not explain similar segregation in the patriarchal, plow-agricultural societies, which might additionally feature other sex typing such as, clitorectomies, infibulations, and familial honor killings of females.

In industrial societies, occupational sex typing of women not only limits their kinds of work and levels of compensation allowable but also the range of beneficial concomitants of work. Perhaps the overcrowding hypothesis accounts for the lower compensation achievable by women compared to men.

With large numbers of women channeled and competing in relatively small numbers of 'pink-collar' work statuses, their compensation rates are driven downward in the market. Restricted compensation opportunities foster women's dependence on men, with increased exploitation by men.

Focus on the workplace ignores the importance of an unpaid wife at home supporting a successful husband at work. Such economic exchanges between social unequals are at odds with the folk category of the self-made man. Not only is the workplace a site of male exploitation of women, sexual and otherwise, but also it is a locale for behaviors from flirting to consensual sex. Not just sexual harassment but additionally sexual pursuits have a workplace arena, not surprising among highly sexual primates. The full range of organizational sexuality, its relations to job benefits and harm, and its resistance to social control are among little studied dimensions of work (Williams et al. 1999).

8. The New Nature of Work

In late industrial societies, the future of work could include not enough of it for permitting the earning of middle-class compensation. Competition in the global market engenders a massive de-industrialization with the loss of adequate jobs for those with high-school levels of education or less.

American production workers must compete with Chinese prison and South Asian child labor. In today's job market, employee loyalty has become a one-way street. Overnight, jobs can be eliminated in the thousands by a single firm. Some terminations are psychologically brutal.

The era of lifetime jobs gradually erodes, replaced by insecure contingent work, including part-time, contract and temporary persons—all workers who are not full-time with full benefits. Conditions of employment not obtained by contingent workers include job training and career advancement with a firm. Such workers become employed only with an immediate demand for them. Of course, some persons desire contingent work. Automation and reorganization of work created a controversy about the existence of deskilling, under capitalism, a continuous lowering of levels of skill throughout a national economy, leading to an unskilled proletariat.

De-skilling in neo-Marxist theory is a form of social control of workers through a minute division of labor, with organizing work into simple, repetitive tasks involving few mental reflections. Although a good number of crafts and some professions were deskilled during the twentieth century, no deskilling throughout an overall industrial economy exists.

Trade unions contest management for social control in some workplaces. In America, for unionized employees in private industry, the overall pay is one-third higher and for blue-collar workers about 70 percent more than in nonunion companies. Unionization provides a wage advantage to workers.

The future of the labor movement, however, is clouded. In the USA and Canada, trade unions have diminished in union density, organizing success, level of labor actions, and political influence. Reasons given for this decline include: union sloth; the law as enacted and then interpreted by the courts; globalized competition; 'cooperative' programs; and a neo-liberal philosophy embraced by the large political parties. For union success, new forms and policies in the labor movement must be created including, multi-employer bargaining, removal of legal impediments to organizing, and coordination with community, advocacy, religious, and ethnic organizations to further mutual goals (Clawson and Clawson 1999).

Working Classes, History of

1. The Working Classes: Origins of the Concept

The concept of the working class emerged in Western Europe during the nineteenth century. Originally, the term was used as a plural, denoting a heterogeneous conglomerate of social groups performing various forms of wage labor. The working classes were considered to be a fraction of a larger 'proletariat,' that is, the estate of people without property, beyond honor. The wage earners were only a part of this amorphous mass. According to the French nobleman Granier de Cassagnac (1838, p. 30), the proletariat formed 'the lowest rank, the deepest stratum of society,' that consisted of four groups: 'the workers, the beggars, the thieves and public women'. 'The worker is a proletarian, because he works in order to

live and earns a wage; the beggar is a proletarian, who does not want to work or cannot work, and begs in order to live; the thief is a proletarian, who does not want to work or beg, and, in order to make a living, steals; the prostitute is a proletarian, who neither wants to work, nor beg, nor steal, and, in order to live, sells her body.' As capitalist relations crystallized more and more, the desire arose among the 'respectable' workers to distinguish themselves from the rest of the 'proletariat.'

Over the course of the nineteenth century, social theorists and the emerging labor movements began to redefine these notions: (a) the working classes became homogenized as a singular working class; (b) this working class was identified with the proletariat; and (c) this proletariat/working class was marked off in three ways: from the petty bourgeoisie, from the so-called lumpenproletariat (the criminal and unsteady 'dangerous classes'), and from the unfree workers (slaves and serfs). An early example of this development was the *Manifesto of the Communist Party* of 1848, which emphatically distanced the proletariat/working class on the one hand from the 'lower middle class, the small manufacturer, the shopkeeper, the artisan, the peasant,' and on the other hand from the '"dangerous class," the social scum, that passively rotting mass thrown off by the lowest layers of old society' (Marx and Engels 1973, p. 77). A similar sharp distinction was drawn between 'free' workers and the slaves in the South of the United States and in some colonies.

Moreover, the notion of a working class was a gendered abstraction, based on the assumption that workers' families exist mainly on the wages earned by the male head of the household and perhaps the additional income of other household members. From 1900 or so scholars of various theoretical orientations seemed to have reached an agreement on what a worker is. In 1926 the German social-christian sociologist. Briefs summarized this *communis opinio* as follows: 'The worker is *personally free*, i.e., his physical and spiritual-moral powers are completely at his own disposal. […] He *has no property*, i.e., he has no exclusive material power over capital as a secure basis with relative permanency. […] He has neither a stock of consumer goods that enable him to live, nor permanent interests of capital. […] He lives in economic circumstances in which means of subsistence can be obtained only through *economic returns*. […] He is forced to offer personal capacities with an economic exchange value in return for means of subsistence (Briefs 1926, p. 149).

2. *Origins in the 'Core Countries'*

Detailed surveys of the living and working conditions of the working classes date from the first decades of the nineteenth century. A relatively early example was the *Tableau de l'état moral et physique des ouvriers employés dans les manufactures de coton, de laine, et de la soie*, written by Villermé (1840), a medical doctor with a great interest in the social and physical condition of 'the people'. Many writings of this kind were intended partly as moral and political indictments of social abuses. One of the best known instances is Engels's (1845) *Die Lage der arbeitenden Klasse in England* [*The Condition of the Working Class in England*], which gave a minute description of the working classes in English industry, mining, and agriculture. During the second half of the nineteenth century social surveys became a quite common genre, especially in industrializing Western Europe. Highlights include the many studies of Frédéric Le Play and his school which covered all of Europe, beginning with *Les ouvriers européens* (1855); Henry Mayhew's *London Labour and the London Poor* (1851–61) with the significant subtitle 'a cyclopaedia of the conditions and earnings of those that will work, those that cannot work, and those that will not work'; Charles Booth's *Life and Labour of the People of London* (1892–97); Alphons Thun's detailed monograph *Die Industrie am Niederrhein und ihre Arbeiter* (1879) on the industrial and working classes in West Germany; and numerous publications of the German Verein für Sozialpolitik (Social Policy Association), including Max Weber's famous study of agricultural laborers in East Prussia (1894).

All these works were mainly contemporaneous, though they have by now themselves become important historical sources. Truly historical studies of working classes followed at the beginning of the twentieth century. A pathbreaking effort was the trilogy written by John Le Breton Hammond and his wife Barbara Bradby. *The Village Labourer, 1760–1832* (1911), *The Town Labourer, 1760–1832* (1917), and *The Skilled Labourer, 1760–1832* (1919). Together these studies provide a rich survey of the British working class during the Industrial Revolution. In other countries similarly wide-ranging works usually were published much later, generally after the Second World War.

3. *Classical Debates*

The study of the working classes has always been central to social and labor history. But different aspects have been studied and emphasized.

The concept of the working class has been used in many different ways. Somewhat simplifying, one might distinguish three main patterns of interpretation. The structural approach uses the notion of the working class in a restrictive sense as a term merely characterizing the common socioeconomic location of a group of wage earners. The historical study of a particular working class then boils down to the reconstruction of their joint 'class position.' How this

class position is analyzed depends on theoretical assumptions (Marxist, Weberian, or otherwise) and on the various ways in which research is operationalized (models of social stratification).

A second approach focuses on agency and emphasizes culture, mentalities, consciousness, and social and organizational behavior. Numerous variations on this theme have developed over time. Perhaps the most influential approach was presented by Edward P. Thompson in his *The Making of the English Working Class* (1963). Here, he argued that. 'The notion of class entails the notion of historical relationship. Like any other relationship, it has a fluency which evades analysis if we attempt to stop it dead at any given moment and anatomize its structure.' Class, according to Thompson is an outcome of collective experience, and workers are active participants in their own class formation.

While the first approach has been criticized for its 'objectivism' and the second approach for its 'culturalism,' a third approach considers working-class formation as 'an outcome of temporal conjuntures between multiple causal structures' (Sewell 1990, p. 73). In this view, class formation results from a combination of economic and technological changes on the one hand and of cultural, political, and discursive developments on the other hand.

The debate on working-class formation is paralleled by an extensive debate on working-class devolution: Does it still make sense to speak of working classes in advanced capitalist countries? Or have these classes dissolved? And if there has been a process of devolution, how and when did it start? Naturally, everything depends again on one's conceptualization of the working class. What does one consider as decisive: structural issues (free wage labor, etc.), collective behavior (e.g., trade unions, strikes), or cultural features? Whichever position one takes, it is evident that the condition of wage earners in advanced societies has changed profoundly during the twentieth century. Research has not given equal attention to all these developments. Especially the cultural shifts after the Second World War remain underexplored.

Most early contributions to working-class history focused on work, industrial relations, and labor markets. At a later stage the field of research was expanded and historians began to pay serious attention to other aspects of working-class existence, including labor processes, family life, religion, etc. Over the course of time the first approach has become more sophisticated and the second approach has gained influence. The historiography of the workers as a class is now increasingly merged with the historiography of race, ethnicity, and gender. While earlier historians considered race and gender as mere adjuncts of class, it is now generally becoming accepted that class, race, and gender are thoroughly interpenetrating, and that they shape each other. As a result of these developments, working-class history increasingly overlaps into women's studies, ethnic studies, anthropology, institutional economics, sociology, or social psychology.

Now that there exists a huge and still growing body of literature on the various historical aspects of working-class existence first attempts are made to integrate the history of various aspects of working-class life and to write comprehensive syntheses. The most spectacular example of such an endeavour is the ongoing project on the '*History of the Workers and the Labor Movement in Germany since the End of the Eighteenth Century*,' co-ordinated by Gerhard A. Ritter (see Kocka 1990, 1991, Ritter and Tenfelde 1992, Schneider 1999, Winkler 1984, 1985, 1987).

4. *The Rise of the 'Periphery'*

The growth of working classes outside the advanced capitalist countries has, especially since the Second World War, caused an increased interest in the working classes of Africa, Asia, and Latin America. From a contemporary point of view this field was first explored by anthropologists and students of industrial relations, who were interested in the problems accompanying the integration of rural migrants into the emerging wage-earning economies. Early examples were A. L. Epstein's ethnographic *Politics in an Urban African Community* (1958), on copper miners in Northern Rhodesia, and industrial relations studies driven by the question how processes of social change could be controlled and how the 'commitment' of the workers could be intensified (e.g., Moore and Feldman 1960; see also Breman 1999).

Simultaneously, historiographical studies emerged; initially these were often based on official sources and looked at the workers through the eyes of employers and authorities. Such was for instance the case in J. Norman Parmer's thorough *Colonial Labor Policy and Administration* (1960) on the rubber plantation industry in Malaya during the last decades before the Second World War. Since the 1960s and 1970s the historiography of the 'peripheral' working classes has changed too. First there was an upsurge of classical labor movement history. Many of the major early studies of this genre were written by radical intellectuals, like Jean Chesneaux's *Le mouvement ouvrier en Chine de 1919 à 1927* (1962) or Guillermo Lora's *Historia del movimiento obrero Boliviana* (1967–70). Second, gradually the perspective broadened and everyday life, mentalities, etc. of working classes received more attention, just as had been the case in the historiography of the high-income countries. Early attempts in this direction were still heavily influenced by Western models of historical development. Morris D. Morris's *The Emergence of an Industrial Labor Force in India: A Study of the Bombay Cotton Mills, 1854–1947* (1965) is a major example of this approach, despite its rich empirical basis. Later attempts

often tried to develop a less Eurocentric approach. Pathbreaking works include Charles van Onselen's *Chibaro* (1976) on mine labor in Southern Rhodesia or Ranajit Das Gupta's *Labour and Working Class in Eastern India* (1994) on plantation workers, miners, and textile workers in Assam, Bengal, and elsewhere. These new developments have been covered by a series of consecutive collections of essays (Sandbrook and Cohen 1975, Gutkind et al. 1978, Cohen et al. 1979, Munslow and Finch 1984, Agier et al. 1987, Amin and Van der Linden 1996). While the traditional historiography of the high-income countries focused primarily on artisanal and factory labor, the new working-class historiography of the peripheral countries reflected the peculiarities of colonial exploitation and unavoidably paid much attention to the labor in agriculture (including plantations), mining, and the transport sector (docks, railways).

5. *Global Insights*

The rise of working-class history in low-income and medium-income countries has made necessary a rethinking of old concepts. First, in the periphery, the larger part of the wage earners is not 'free' in an economic sense. According to the classic definition, wage earners, as 'free persons' are free in a double sense because they alone market their own labor as a commodity and have no other commodity for sale. A 'free' worker is, strictly speaking, someone without obligations to any particular employer. He or she can cancel employment at will and apply for a job with another employer. In reality, however, such a completely uncommitted relationship with the boss is rare, occurring for example, among some forms of casual labor. Many workers are tied to their employer, for example through debts or nonmaterial obligations. There can also be all sorts of cultural or geographic reasons why it is difficult to change employers. Somewhat better-placed personnel can be tied to a firm through superannuation provisions. Frequently, the accommodation of workers is part of the labor contract, etc. In short: what formally seems like a free labor relation is in practice often much less free. A 'free' worker, moreover, does not possess his or her own means of production at all. But in reality there are many types of labor relations in which the employee contributes at least part of the means of production himself. One thinks here of factory workers who own (part of) their own tools, but one can also think of agrarian share-cropping arrangements. Still clearer is the case of self-employed workers, who formally are wholly independent, but who in fact often form a very flexible labor force for enterprises. We can also mention here the case of home workers.

Second, there is wage labor integrated throughout in households and families whose survival always remains partly dependent on other activities. Not only does a great deal of subsistence labor take place every day in every family (especially, but not exclusively performed by women), but there are usually also several forms of activities remunerated with money. Already in the early 1970s Allen observed, for example: 'Cash crops and wage employment are simply alternative methods of coping with the encroachment of capitalism on the traditional way of life. A fall in the demand for labour increases the emphasis on subsistence or cash-crop production, whereas a drought or a bad harvest, for instance, forces Africans to enter the labour market (Allen 1972, p. 181). Within these arrangements with multiple coping methods the 'roles' different family members have are often not fixed permanently, but instead signify a transient social relationship, which can be replaced rather quickly by other sources of income.

Third, the new working class does not mainly or exclusively exist in the industrial sector. The agricultural sphere is proportionally more important in this sphere rapidly advancing proletarianization has created a large stratum of agricultural laborers and share tenants.

Fourth, in the so-called Third World and even in the East- and Southeast Asian newly industrializing countries, permanent employment relationships have always been the exception rather than the rule. Insecure employment relationships, underemployment, and long-term unemployment are the reality there.

6. *Implications for Future Research*

The new insights offered by Third World historians have implications for the advanced countries as well.

First, the dividing line between wage labor and small entrepreneurship is much more obscure than was originally thought. In both the 'Third' and 'First' worlds there are gray zones of (ostensible) self-employment, in which individuals formally work on their own but in reality are dependent on one or two customers. This type of self-employment has been widespread in peripheral capitalism for decades, but lately, it has been increasing rapidly in the centers as well, such as in the construction business. Generally, there seems to be a historical connection in highly developed capitalism between phases of rising unemployment, on the one hand, and stagnation or the growth of 'small-scale' self-employment, on the other.

Second, the border between wage laborers and the marginal groups is not nearly as obvious as older theories would have us believe. In times of desperation, regularly employed wage earners may indeed exhibit behavior characteristic of the *Lumpenproletariat*, such as begging and prostitution, as a way to survive. They will also steal at the workplace, which represents thoroughly criminal behavior from the entrepreneurial viewpoint. Yet, the experience in the Third World has drawn our attention to a lower social class that can be characterized neither as the industrial reserve army in

a Marxist sense nor as the classic *Lumpenproletariat*. Inevitably we need to come up with a new concept to apply to insecure employment relationships in this respect.

Third, the concept of the 'free' laborer is less precise than is usually assumed. Fourth and last, the strict differentiation commonly made in advanced countries between urban and rural life must be revised. Contrary to what modernization theories like to tell us, the ties of urban migrants to their home villages often do not weaken but strengthen over time. Most likely, the reason for this is the lack of social insurance systems. Therefore, the villages become safety nets during times of economic crisis. Recently, though, many villages have not been able to fulfill this task, since the rise of a commodity economy has drained their capacity for subsistence.

What it means to be classified as 'working class' is changing; the category is becoming especially multifarious. We could even flip our intellectual problem and ask why a 'full-time proletarian' in capitalism should have existed or can now even exist at all. From the entrepreneurial standpoint, part-time proletarians are cheaper by far. Part-time proletarians (who belong to a household in which there are other sources of income, e.g., from agricultural work or from self-employment) lower the bottommost, barely acceptable wage threshold because they have other forms of real income (Wallerstein 1983).

Working Memory, Neural Basis of

In experimental psychology, the term 'working memory' has been used to refer to the temporary storage of information that is necessary for cognitive processing underlying the comprehension and learning of new material, reasoning, mental arithmetic, etc. This theoretical construct emerged in the 1970s out of earlier experimental behavioral work on short-term memory (see Baddeley 1986 for a review). The term working memory has been defined variously to refer not only to the transient maintenance of information but also to its processing. For instance, one of the most popular working memory models in cognitive psychology assumes the existence of a central executive system

supplemented by 'slave' systems that are specialized for the maintenance and processing of verbal and visual material (see Baddeley 1986). Such an expanded concept of a working memory system becomes tantamount to the entire neural processing of information that occupies current awareness. Naturally, any system defined so broadly will be the result of processing in multiple areas of the brain. This article will focus on research that aims to identify the role of several cortical structures in what has been termed working memory at the cognitive level of analysis.

1. The Frontal Cortex and Working Memory

There is considerable evidence that the frontal cortex plays a major role in working memory although its precise role remains a matter of debate. The frontal cortex occupies a very large area of the primate cerebral cortex. Its posterior part, which lies immediately in front of the central sulcus, consists of the motor and premotor cortex (see Fig. 1). The vast area that lies further forward is often referred to as the 'prefrontal' cortex. The prefrontal cortex has expanded enormously in the primate brain and comprises many distinct areas. These areas differ in terms of their cytoarchitecture (i.e., the arrangement of the neurons within them) and have their own distinct connections with other parts of the brain (Pandya and Yeterian 1985). These anatomical facts imply that there must be some differences in the local neuronal computations occurring within particular areas since both the local circuitry and the inputs and outputs are distinct.

The first evidence that suggested that the prefrontal cortex plays a major role in working memory came from work in the 1930s by Jacobsen and co-workers who examined the performance of monkeys with lesions restricted to the prefrontal cortex on the delayed response task (Jacobsen 1936). This work showed that frontal cortical damage rendered animals incapable of performing the delayed response task which was introduced by Hunter in 1913 to study transient memory in animals. This task typically is conducted in the following manner. The experimenter attracts the monkey's attention and, in full view of the animal, a reward (i.e., a piece of food) is placed under one of two identical stimuli (e.g., cups, plaques, etc.). The stimuli are then hidden from the animal's view by an opaque screen and, after a delay of a few seconds, the screen is raised and the animal is allowed to choose one of the two stimuli to obtain the reward if, of course, the choice is correct. In interpreting the impairment on delayed response by monkeys with frontal cortical damage, Jacobsen (1936, p. 52) argued that the behavior of such animals 'instead of being directed by a balance of immediate, recent and temporally remote stimulation, is dominated by present external stimuli and the stable habit systems derived from earlier training; the mnemonic influence of past experience is lacking.'

The demonstration that adequate performance of the delayed response and related tasks is severely impaired by lesions of the prefrontal cortex has been

Figure 1
Outline of the left hemisphere of the human brain to illustrate the location of some of the major cortical regions

the starting point of a large amount of experimental work on its possible role in working memory. The lesion investigated in Jacobsen's work involved the entire prefrontal cortex. Subsequent work in the monkey by Pribram, Mishkin, Gross, Weiskrantz, and others showed that the lateral surface of the prefrontal cortex was critical for delayed response performance. Furthermore, the deficit on the spatial version of the task was localized around the sulcus principalis (a prominent sulcus that runs longitudinally in the middle of the lateral frontal cortex of the monkey). It also became clear that the delay was a critical variable for the impairment on these tasks (see Petrides 1994 for a review).

By the early 1970s, the method of recording the activity of single neurons in alert monkeys as they performed various cognitive tasks was perfected and a number of studies appeared that recorded the activity of single neurons in the prefrontal cortex during delayed response performance. Fuster and Alexander (1971) in the United States and Kubota and Niki (1971) in Japan were the first to record such neuronal activity. This work demonstrated that certain neurons in the lateral prefrontal cortex respond specifically when a particular location is indicated as the one to be remembered and continue to discharge during the delay period until the choice has been made. Thus, these neuronal responses appear to maintain temporarily the processed information. This early work and several later studies by Goldman-Rakic, Miller, and co-workers clearly established the existence within the prefrontal cortex of sustained neuronal activity during the delay period of various tasks (see Fuster 1997 for a review).

Thus, both the lesion and the single-neuron work indicated the involvement of the prefrontal cortex in some aspect of working memory. But what exactly is the role of the prefrontal cortex in working memory? One of the theoretical interpretations of the above data was to assume that the prefrontal cortex is a critical region for the short-term maintenance of information and to conceive the different prefrontal cortical areas as specialized working memory modules for the maintenance of different types of information (Goldman-Rakic 1996). For instance, it was argued that the dorsolateral prefrontal area is specialized for spatial working memory (i.e., the maintenance of spatial information), whereas the ventrolateral prefrontal area is a specialized module for nonspatial visual working memory (Goldman-Rakic 1996).

An alternative theoretical model of the role of the different lateral prefrontal cortical areas in working memory was proposed by Petrides (1994), based on work that further analyzed the nature of the impairments on memory tasks by human patients and monkeys with prefrontal lesions. It was argued that the existence of delay neurons in the prefrontal cortex, although implying that some neuronal computations are occurring there during the delay, does not require the conclusion that the primary role of the prefrontal cortex is the short-term maintenance of information. For instance, neurons with sustained activity during the delay in memory tasks can be observed in virtually every part of the cerebral cortex, as well as in several subcortical structures. In addition, there is the major puzzle that patients with damage to the lateral prefrontal cortical region can perform well on several standard short-term memory tests, such as simple recognition, digit span, and story recall. These patients, however, are impaired on the self-ordered working memory tasks in which successful performance cannot be based simply on the maintenance of information in short-term memory but requires, in addition, the executive process of monitoring that information. In the self-ordered working memory tasks, the subjects are presented with different arrangements of the same set of stimuli and, on each trial, they have to select a different stimulus until all have been selected once. Successful performance requires the subjects to compare carefully those stimuli that they have already selected with those still remaining to be selected. In other words, events in working memory must be monitored closely. It was, therefore, argued that the problem of patients with prefrontal lesions lies not in memory per se, but in the application of executive processes on certain memory tasks (Petrides 1994, 2000).

In work on the monkey, where lesions can be restricted with precision within particular regions of the brain, it was demonstrated that damage to the mid-dorsolateral part of the prefrontal cortex results in severe impairments on these self-ordered tasks and related tasks that require the monitoring of externally ordered stimuli (see Petrides 1994). Further evidence of the importance of the mid-dorsolateral prefrontal cortex to the monitoring of information within working memory comes from functional neuroimaging studies on normal human subjects that have consistently shown increased activity in the mid-dorsolateral prefrontal region when the monitoring requirements of a memory task are high (Petrides 2000). In a study by Courtney et al. (1998) in which monitoring and manipulation were minimized, activity related specifically to the maintenance of an active mnemonic representation of spatial information was observed in a region that was posterior to the mid-dorsolateral prefrontal region, suggesting that posterior dorsolateral frontal cortex may play a role in the focussing of attention on information that is held in posterior cortical regions.

2. *The Temporal and Parietal Cortex and Working Memory*

A large number of studies with patients who had sustained lesions limited to posterior cortical regions have documented impairments in short-term memory,

thus providing evidence that the temporary maintenance of information may be occurring in posterior cortical regions (see Vallar and Shallice 1990). There are several reports of patients with a selective impairment in auditory–verbal short-term memory after lesions in the inferior parietal region of the left hemisphere. These patients may be able to maintain and repeat single numbers, letters, or words presented auditorily, but their span (i.e., the number of items that they can maintain after a single presentation) is severely limited (e.g., Warrington and Shallice 1969). Patients with severely impaired short-term memory spans for visual verbal material usually have lesions in the occipitotemporal region of the left hemisphere (e.g., Shallice and Saffran 1986). De Renzi et al. (1977) have investigated visuo-spatial span using the Corsi blocks test. In this test, the patient observes the examiner tap, in sequence, a number of randomly arranged blocks and has to reproduce this sequence. Patients with right posterior hemisphere lesions were particularly impaired on this task, suggesting that the occipitoparietal cortex of the right hemisphere may be a key region for the maintenance of visuo-spatial information (De Renzi et al. 1997).

This notion that posterior cortical regions may play a role in the maintenance of information in working memory receives additional support from work in the monkey. For instance, there is considerable evidence that the anterior part of the inferior temporal cortical region, which is known to be the final stage in the occipitotemporal neural system underlying visual object perception, is also critically involved in short-term visual memory. This evidence comes both from investigations of the effects of lesions (Mishkin 1982) and from studies in which the activity of single neurons was recorded in monkeys as they performed visual short-term memory tasks (Fuster and Jervey 1982, Miller et al. 1991). Similar evidence exists in other sensory modalities. Lesions of certain parts of the superior temporal cortex have been shown to lead to a serious impairment in auditory short-term memory (e.g., Colombo et al. 1990).

How can the evidence for impairments in working memory both from posterior cortical regions and prefrontal cortex be conceptualized? In one theoretical model, the temporary storage and processing of incoming and recalled information is seen as an integral part of neuronal computation in modality specific and multimodal posterior association cortical areas (Petrides 1994). In other words, neural activity in these posterior cortical areas underlies not only perceptual processing and long-term storage of information, but also short-term memory of recently processed information which may be currently provided by the environment or re-activated from long-term storage. The prefrontal cortical areas are considered to play a role in working memory as distinct executive processing modules that allocate attention to different types of information, and monitor the contents of information in posterior cortical regions. Thus, if working memory were to be viewed as the multicomponent workspace of current cognitive activity, then this workspace can be construed as the local computations occurring within specialized posterior cortical regions for the maintenance and processing of modality-specific information, within frontal cortical regions for different aspects of executive processing and the bi-directional interactions between them.

Working Memory, Psychology of

Working memory (WM) can be thought of as the desktop of the human brain, a set of cognitive functions that allows humans to keep track of what they are thinking, what they are doing, or where they are moment to moment. It holds information long enough to make a decision, to acquire vocabulary, to mentally image the layout of a home, to support creative thinking, or remember what to do next. This article describes the theories that have been developed to explain these human abilities and some of the experimental evidence for these theories that has been derived from empirical studies of healthy adults and children and of individuals who suffer from cognitive deficits as a result of brain damage.

1. *Why is the Concept of Working Memory Useful?*

The concept of working memory (WM) has figured prominently in theories and explanations for human on-line cognition, as well as offering a basis for understanding how humans accomplish a wide range of everyday tasks. It can be thought of as a mental tool that aids survival; if an organism is to interact successfully with its environment, then clearly there must be some means to record, on a temporary basis, its own most recent actions and to have some means to plan actions for the immediate future. This gives a significant advantage over organisms entirely driven by automatic responses to external stimuli that signal basic needs. Examples of how this mental tool is used in everyday interaction with the environment highlight its utility. Humans use WM every time they have to solve a problem, to perform a mental calculation, to recall where an object has just been laid down, or to repeat a strange foreign word that has just been heard.

From these examples, it is clear that the concept is much broader than the more traditional idea of short-term memory. Indeed, the concept of WM arose from the need to provide a theoretical account of a wide range of everyday tasks that require both temporary memory and on-line cognition. Until the early 1970s the focus of research on this topic was on retention of random sequences of words, letters, or digits, with the everyday example of recalling telephone numbers while dialling. However a mental faculty would not have evolved to deal with these relatively artificial tasks, and therefore WM is intended to encapsulate on-line cognition and temporary verbal and visuo-spatial memory in both laboratory tasks and in everyday life.

2. *Theoretical Views of Working Memory*

Most memory researchers consider WM to be a useful concept that uses relatively few assumptions to explain a wide range of experimental evidence as well as important aspects of everyday cognition: it is a system with limited capacity, which loses information over periods of seconds, whose contents are subject to displacement by new input, and which interacts and is supported by other parts of the cognitive system such as stored knowledge or the products of perception. Most theories of WM include these features, however, there remains a debate as to its precise characteristics. Some theories view memory as a largely unitary system with WM as the sum total of what is currently activated from the store of knowledge, skills, expertise, and past events. Others view WM as separate from the long-term store of knowledge and events, but even among these latter theories there is some discussion as to whether the cognitive functions are supported by a single flexible system that provides both temporary storage and on-line processing, or comprises multiple components, each specialized for a particular function. A recent book edited by Miyake and Shah (1999) provides a comprehensive discussion of the different theories of WM.

The first type of theory, that WM is simply currently activated knowledge, can account for a wide range of data from experimental psychology with healthy adults, including the ability to bring rapidly to mind information related to areas of personal expertise. Theories of this kind can very successfully explain why chess masters can play several games simultaneously, expert waiters can recall details of meal orders from large groups, and why burglars can recall better than householders, or indeed the police, details of houses related to their crime. Expertise extends the apparent capacity of WM, but there is some recognition among proponents of this theory type of the need for a temporary memory system to deal with completely novel or unfamiliar material. Such theories additionally assume inhibitory processes that serve to prevent activation of information that is not strictly relevant to the task in hand. A breakdown in these inhibitory processes has been suggested as one of the corollaries of normal aging, with elderly people more prone to be misled by irrelevant information or to wander off the main topic in a conversation.

The strict view that WM is no more than the sum total of currently activated experience and memories for events runs into difficulty when considering dissociations that are apparent from studies of healthy adults performing more than one task at the same time. There is substantial evidence that healthy adults can perform two quite demanding tasks concurrently (such as holding a sequence of digits and following rapid random movements of a target). There is very little impact on the performance of either task, and this can be accomplished without any particular expertise or training. Complementary studies have shown that placing a heavy demand on temporary memory places few if any restrictions on retrieval of stored knowledge about past events or that is linked to expertise. These findings suggest that the human cognitive system may comprise several components, each specialized for particular kinds of tasks and which may operate in parallel. The findings also point to the idea that WM is best considered as being separate from the system that stores knowledge of the world and of experiences.

The unitary view of memory also has difficulty explaining patterns of impairment and sparing in individuals who suffer from cognitive deficits as a result of brain damage. The cognitive impairments are often selective, for example, with very poor performance on immediate memory tasks (such as repeating back a random sequence of digits) coupled with normal performance on long-term retention (such as recalling events that occurred weeks, months, or years previously). The converse dissociation also occurs, namely normal immediate memory contrasting with very poor retrieval from long-term memory or difficulties in long-term learning. Theories assuming that working memory comprises temporary activation of relevant information from long-term memory would predict that if long-term memory access is impaired then temporary activation should also result in poor performance. Theories that assume WM to be a functionally separate part of the cognitive system can account more readily for the neuropsychological dissociations as well as the data patterns from healthy adults, and therefore may be more useful.

3. *The Case for Multiple Memory Systems*

During the first half of the twentieth century the prevailing view in North America was of human memory as primarily the result of observable learning of associations, and theories of learning dominated. During the same period in Europe, memory as a cognitive concept was more salient, for example in the work of Bartlett, Broadbent, and Zangwill. By the mid-1950s, the latter became the more generally agreed view, and a cognitive approach to memory gave rise to major new avenues of research. Very quickly it became clear that memory was best thought of as comprising at least two elements, with one focusing on temporary or short-term retention and the other on long-term retention. This reflected a dichotomy proposed in the seventeenth century by the British philosopher John Locke who suggested that the 'faculty of retention' comprised 'contemplation' or 'keeping an idea in mind,' and that this was separate from 'memory' or the 'storehouse of these ideas.' This distinction appeared again in the late nineteenth century when the North American philosopher and psychologist William James referred to primary memory which he contrasted with retention.

During the 1960s, the contrast between primary memory and what then became secondary memory was demonstrated experimentally. For example, when healthy adult volunteers are asked to retain sequences of words for immediate recall in any order, omissions tend to occur among words from the middle part of the list and much better recall is observed for items close to the beginning or close to the end of each list. If instead, the volunteers are asked to recall the items following a delay, performance on the last few items is no better than it is for items in the middle of the list. However, initial items in the list retain their advantage despite the delay. These contrasting patterns were thought to support the idea that two memory systems are reflected in recall of different parts of the list: the early list items are thought to be rehearsed and transferred into a longer term memory system. As the list progresses, rehearsal becomes more difficult and therefore few items are transferred to a long-term store. The final items are thought to be held in a temporary memory system whose contents are lost unless recall is immediate. The advantage for the final items with immediate recall is known as the 'Recency Effect.'

Further support for the dichotomy comes from amnesic patients, that is people who, following brain damage, suffer from severe memory impairment that is characterized by an inability to learn new material. When such patients are tested for immediate free recall of word lists, their pattern of recall lacks the advantage for the initial items in the list but retains a normal recency effect. This suggests damage to the memory system responsible for retention of the early items but normal functioning of the memory system responsible for the recency effect.

A second experimental paradigm demonstrated that different memory codes are used in immediate and delayed recall. In one set of experiments, volunteers were given lists of words that were similar in meaning (e.g., tall, broad, wide, fat, huge, big, great) or were similar in sound, that is they were phonologically similar (e.g., man, mad, mat, map, cap, can, cat), for immediate recall or for recall after a delay. Recall of both lists was compared with memory for lists of words that were neither semantically nor phonologically similar (e.g. car, lock, spoon, book, chair, pen, dog). With immediate recall, phonologically

similar words were recalled more poorly than were words from the other lists, a phenomenon known as the acoustic similarity or the phonological similarity effect. It is interesting to note that this effect appears even when the words were read by the volunteers, suggesting that the visually presented words were translated into a sound-based or phonological code in memory. In contrast, with delayed recall, the semantically similar words led to poorest recall. Because phonological similarity affected short-term but not long-term retention, while semantic similarity showed the converse, this led to the conclusion that acoustic or phonological codes were a signature of a temporary memory system (for visual or auditory presentation) and semantic codes were characteristic of the use of a longer term memory system.

4. *Developing the Concept of Working Memory*

The idea of primary and secondary memory provided a useful framework to account for the accumulating body of experimental data in support of a two-component memory system. However, it was limited by the fact that virtually all of the research relied on experiments with presentation and recall of words, letters, or digits over relatively short time periods. It is clear that we can also retain information about the appearance of objects and scenes as well as their names and descriptions. Therefore, from the late 1960s, primary memory began to be seen as a system that could support temporary retention of different kinds of material as well as offering a means to process and manipulate that material. The dominant or 'modal' concept then became that of a short-term, or WM processing and storage system. This 'modal model' retained the notion that information was transferred from the senses, via WM to secondary, or long-term memory. It also incorporated the assumption that the system has a maximum capacity that could be employed by storage, by processing, or by elements of both.

However, a number of features of this model came under pressure from the 1970s onwards. The recency effect, once thought to be a major source of support for a temporary memory system, was also demonstrated in longer term recall. For example, when recalling visits to movies, where the car was parked, or attending rugby matches, individuals can often recall details of very recent events but have rather poorer recollection of experiences that are more remote. This demonstrated that recency was not unique to a temporary memory system. Also, there were demonstrations that semantic coding, thought previously to be the prerogative of long-term storage, could be used to help support short-term retention. For example, immediate free recall of real words is better than recall of nonsense words, suggesting that the additional stored information about the real words (such as their meaning) can support immediate memory. These findings did not wholly undermine the traditional view of a short-term memory, because there was other evidence that a unitary model of memory could not readily explain, such as that mentioned above from dual task performance and from brain damaged individuals. However, the findings of long-term recency effects suggested that recency might be a property of any human memory system (short- or long-term), and the evidence for short-term semantic coding showed that the memory systems interact, with any one memory task probably drawing on several different aspects of the cognitive system depending on task demands.

Another core assumption of the modal model has come under increasing strain in recent years, namely the idea that information from vision or hearing could reach long-term memory only through WM. For example, one famous neuropsychological case is that of patient 'PV' who, following a stroke in the sylvian region of the left hemisphere, presented with a very severe deficit in retaining sequences of words or digits for immediate recall, but had no difficulty in retrieving details of autobiographical events and proved well able to learn new material. The pattern for PV and other similar patients suggests that access to long-term memory does not depend on normal function in short-term verbal retention, either for new learning or for recall of past events (e.g. Vallar and Shallice 1990).

Additional evidence comes from patients who suffer from a neuropsychological disorder known as unilateral spatial neglect. This arises most commonly from damage to the right parietal cortex of the brain, and such patients typically are unable to report details of scenes or objects to their left, despite having normal vision. A few patients show unilateral neglect only for information in their mental image or immediate memory for scenes. For example, one patient 'NL' (Beschin et al. 1997) could quite readily report details of everything in his immediate environment. However, if he was asked to close his eyes, he could only report from memory details that were on his right. Moreover, if asked to recall details of a familiar scene such as the square in his home town he could recall only those details that were on his imagined right. This was not a problem of accessing his long-term memory, because when asked to imagine himself standing at the opposite end of the square, he could then report details that were now on his imagined right but had been omitted before from a different imagined viewpoint. This pattern demonstrates a clear dissociation between the processes of perception, which for NL were perfectly normal, the contents of his long-term memory, which again was normal, and the operation of his visual working memory which was dramatically impaired. It suggests that WM may not act as a gateway between perception and long-term memory as assumed by the modal model and by many recent introductory textbooks on memory.

Figure 1
Example drawings plus names generated by volunteers in a mental discovery task involving combinations of geometric shapes (upper) and object shapes (lower)

Studies of healthy adults are pointing in a similar direction. Research over the last decade has explored the possible constraints on creative thinking or mental discovery. In one form of these experiments, volunteers are asked to imagine a set of shapes such as a triangle, a horizontal line, and a circle. They are then to manipulate and combine these shapes in their mental imagery to form a recognizable object which they then name and draw. There is no correct answer except that all the shapes must be included, and they must retain their original shape (e.g., a circle is not to be used as an oval). One possible response generated by a volunteer in these experiments is shown in the upper part of Fig. 1. This demonstrates that working memory can be used for mental discovery. However, if instead, volunteers are asked to combine the shapes of real objects rather than generic shapes, they have much greater difficulty in doing so. One successful drawing from a volunteer is shown in the lower half of Fig. 1 which is an attempt to combine the shapes of an apple, a banana, and a comb. The problem with object shapes was not their complexity, but the fact that they have a meaning associated with them. This made it difficult, for example, to think of an apple as anything other than an apple, because this requires reinterpretation of the shape. This suggests that the contents of working memory have meaning, and they can only have meaning if the perceived shape is interpreted in the context of stored knowledge. That is, it appears that information from the senses goes through and activates the contents of long-term memory before it becomes available for retention or manipulation in working memory, quite the reverse of the traditional flow of information in the modal model of memory.

Figure 2
Example of the duck-rabbit ambiguous figure

A final, rather convincing demonstration that the contents of working memory are interpreted comes from experiments with ambiguous figures. Figure 2 can be interpreted in one of two ways, as a duck or as a rabbit, and if we continue to inspect the figure then our interpretation 'flips' between one and the other. However, in some ingenious experiments, Chambers and Reisberg (1985, see Cornoldi et al. 1996) showed this figure for only a brief time to a large number of volunteers who were asked to report from their memory what the figure depicted. All of the volunteers reported it as either a duck or a rabbit, but none of them could then reinterpret their image in memory and see the figure as anything other than their first interpretation. Nevertheless, they could do so when asked to draw their image on paper moments later. In other words, again, the contents of working memory are interpreted and under some circumstances are very difficult to reinterpret unless we can use the processes of perception with a physical drawing. This offers quite convincing evidence that perception feeds into long-term memory which activates relevant knowledge for manipulation with working memory (for discussions see Cornoldi et al. 1996, Helstrup and Logie 1999).

A second assumption of the modal model was that of WM as a single, flexible, limited capacity system that could undertake both temporary storage and some processing of the material being stored. This theme remains in one contemporary strand of WM research that has focused on measures of individual differences in cognitive capacity. In a typical task,

healthy adult volunteers are presented with a series of sentences. The requirement is to recall the last word of each sentence after all the sentences have been presented. The number of sentences is gradually increased until the participant can no longer accurately recall all of the final words, and the maximum number of words that can be recalled is taken as a measure of the individual processing and storage capacity. The measure in various forms has been shown to correlate well with other measures of cognitive ability such as reading comprehension or mental arithmetic performance. These correlations are then used to argue that WM is a mental capacity for processing and storage that can be applied to a wide range of both laboratory and everyday cognitive tasks. In this sense, the sentence 'span' (or WM capacity) measure has been quite useful, and offers the basis for a standardized test of cognitive ability. Set against its pragmatic value, the underlying theoretical assumptions are that there is a single flexible cognitive system supporting performance. One possible alternative view is that the task taps several aspects of cognition, and that this same range of cognitive functions is employed for other complex cognitive tasks such as reading comprehension. A further limitation is that the test provides only a measure of memory in the context of processing (retention of the final words while reading). In a recent test of the above assumptions, a separate measure was taken of processing capacity by asking volunteers to verify each of the sentences for their semantic content without a memory requirement. Memory ability was measured independently by asking volunteers to recall lists of individual words. Participants were then asked to combine verification with recall of all of the final words, and the task demands were set at the maximum that had been determined for each task component separately. If WM were a single flexible, limited capacity system, we might expect performance to be very poor when these two demanding task elements were combined. Results showed that despite the high processing demand and high memory demand, performance on both elements of the task remained very close to those obtained when the subjects were performing the tasks independently.

These results point to the notion that temporary memory might be served by different aspects of the cognitive system from those used to support on-line processing. This argument in turn suggests that WM might be best thought of as the orchestrated operation of multiple cognitive instruments, each one with a specific role for temporary memory or for processing.

5. *Working Memory as a Multiple Component Workspace*

The most influential model of multicomponent WM was proposed in 1974 by two British scientists, Alan Baddeley and Graham Hitch. The model included some elements of the modal model by incorporating processing and memory, however, these were viewed as distinct. Three components were originally proposed to provide, respectively, temporary verbal storage, temporary visuospatial storage, and a coordinating or 'executive' function. The verbal storage component was originally named the articulatory loop, although subsequently it has been referred to as the phonological loop, and to consist of two components, a passive phonologically based temporary store and a mental verbal rehearsal process. The visuospatial component was originally referred to as the visuospatial scratch pad, but has subsequently been thought to comprise a specialist temporary memory store (or visual 'cache') for retaining the visual appearance of objects and scenes linked to a system (an 'inner scribe') for retaining, and possibly rehearsing, sequences of movements and more dynamic properties of scenes. The coordinating mechanism is referred to as the central executive, but in more recent years has been thought of as a collection of executive functions, including the coordination of multiple task performance, the allocation of attention, and the implementation of strategies and heuristics used in problem solving and mental discovery or when learning and retrieval are demanding of attention.

A schematic representation of a recent version of the multiple component model is shown in Fig. 3. The diagram illustrates the various specialist subcomponents in addition to the suggested flow of information from perception through a long-term knowledge base into working memory. In the latter sense the contents of WM comprise some of the products of perception and of subsequent mental processing. WM can then be considered as a multicomponent workspace that stores and manipulates information which has been activated from the long-term store, rather than as a primary route into long-term memory from the environment. Detailed discussion of the evidence for the features of the model can be found in Logie (1995), Miyake and Shah (1999) or Richardson et al. (1996).

This conception of WM fits neatly with the notion that people are strategic in how they use their cognitive functions. For example, recalling a list of words can be accomplished by rehearsing the sounds of the words, thinking about their meaning, organizing them into groups, or imagining the objects or concepts to which they refer. As a result, a phenomenon such as the phonological similarity effect (see above) with visually presented words only appears if the participants rely on mentally rehearsing the sounds of words prior to recall. There is evidence that some participants in these experiments spontaneously use other strategies that might rely on visual or semantic codes, and for them the phonological similarity effect does not appear (e.g. Logie et al. 1996). The same argument holds for other well-established phenomena such as the recency effect. Such strategic use of different aspects of WM would not arise if the material did not

Figure 3
Schematic diagram of a recent version of the multiple component model of working memory

activate knowledge stored in long-term memory prior to it being held in WM for the period until recall is required.

6. *Applying the Concept of Working Memory*

The idea of a multiple component WM has proved useful in understanding some of the cognitive deficits suffered by individuals with brain damage as well as accounting for important aspects of healthy cognition. Discussed above are some of the insights into cognitive deficits arising from the use of the model, and how studies of patients with such deficits help the understanding of normal cognition. The application of WM theory to some aspects of mental discovery and creative thinking has also been mentioned. There have been several other areas of application, including the use of the phonological loop in explaining important aspects of vocabulary learning and mental arithmetic. For example, one feature of the phonological loop is that it can retain a recently heard word, mentally rehearse the word, and then generate the word as articulate speech. A number of studies have examined the ability of young children to repeat aloud new or nonsense words that they have just heard. Their ability to do so correlates well with their general competence in language and predicts their language ability several years later. Patients with severe verbal short-term memory deficits also appear to have difficulty acquiring new foreign vocabulary. These findings have led to the suggestion that the phonological loop is a cognitive function that has evolved to support the acquisition of language, and that has the emergent property that it can support temporary verbal memory.

Among the acquired skills that appear to depend on the phonological loop are counting and mental arithmetic. Keeping track of a running total in counting relies on subvocal rehearsal of the counting sequence, while keeping track of partial solutions in mental arithmetic again appears to rely on subvocalization of the subtotals involved, unless the solution is already well learned. For example, for most people the answer to $4+5=?$ would be available without the need for mental calculation, because it would be recalled as an arithmetic fact. However, the answer to $23+19+48+34=?$ would require a series of operations with temporary memory for the subtotals (held in the phonological loop) as each part of the sum is completed. Evidence for these conclusions arises from

studies in which volunteers perform counting or mental arithmetic while suppressing articulation through repeating an irrelevant word. Accuracy in counting and in arithmetic is disrupted by this procedure but is not disrupted by performing other irrelevant tasks such as tapping the table in a regular pattern or even when being presented with irrelevant speech sounds. The phonological loop therefore seems to support accuracy in counting and arithmetic.

The visuospatial resources of WM can support a wide range of other everyday cognitive tasks such as remembering where we are on the page while reading, maintaining and updating a representation of objects in our immediate environment, mental scanning to plan a route around a familiar town, or imagining the configuration of furniture in an empty room.

7. Conclusion

WM is an evolving concept which may be subject to change in the light of new evidence or questions as to its detailed characteristics. Nevertheless, it allows the interpretation of a great deal of evidence and phenomena from both laboratory tasks and from everyday experience.

Workplace Environmental Psychology

Workplace environmental psychology focuses on the role of physical environments in workers' experience, performance, and interaction in buildings that serve as workplaces, especially offices and factories. This subfield of environmental psychology (see *Environmental Psychology: Overview*) studies the influences of physical features of workplaces on workers and their relationships, and how workers and groups use, modify, and adapt to their environments. Also a subfield of industrial– organizational psychology (see *Industrial–Organizational Psychology: Science and Practice*), workplace environmental psychology overlaps with engineering psychology (see *Engineering Psychology*), but deals with larger-scale environmental features, including some studied by architectural psychology (see *Architectural Psychology*).

Workplace environmental psychology developed during the 1980s, though the underlying empirical research dates from the early 1900s (Sundstrom 1986).

1. Scope

Table 1 illustrates the scope of workplace environmental psychology. It emphasizes the individual and interpersonal levels of analysis, although the scope also extends to the organizational level (see Fischer 1997, Sundstrom 1987).

1.1 Individual Level of Analysis

The individual or psychological level of analysis focuses on objectively measurable ambient conditions—temperature, air quality, illumination, and sound—and features of workstations, or areas designed to accommodate one worker. It also focuses on features of supportive environments such as restrooms and walkways. Research and theory of the subfield concern the influences of these features on individual performance, job satisfaction, health, and other outcomes via psychological processes listed in Table 1.

1.2 Interpersonal Level of Analysis

The interpersonal or social–psychological level of analysis examines the social implications of psychological influences of workplaces, such as an adverse effect of noise on attention to social cues. The

interpersonal level of analysis also applies to features of workspaces (individually assigned workstations) that communicate status, personal identity, or other meanings, and to features of work settings that limit or facilitate access among workers for casual, face-to-face interaction, meetings, or conferences. This level of analysis extends to elements of physical settings with roles in the development and effectiveness of work teams (interdependent collections of individuals who share responsibility for specific outcomes for their organizations; see *Teamwork and Team Training*).

Features of physical environment shown in Table 1 can serve multiple functions at both individual and interpersonal levels, and one function can be served by multiple features. For example, a fully enclosed ('private') office can symbolize rank, limit noise, and aid in regulating interaction. Each element of a workplace can have a role in a larger system, so analyzing them calls for a systems perspective.

1.3 Organizational Level of Analysis

Because of its roles in interpersonal relationships, the physical environment is a factor in organizational development and effectiveness, although relevant research is sparse. Facets of physical environments can support, reinforce, and complement organizational structure. Consequently, interventions to promote organizational development include changes in work environments. Designing buildings for work calls for mapping organizational structure to optimize the fit (Becker and Steele 1995).

2. State of the Art

Workplace environmental psychology, a relatively new subfield, draws on parent fields, environmental and industrial–organizational psychology, for research and theory. Empirical research on topics listed in Table 1 includes over 100 studies conducted in offices, factories, and other workplaces, and hundreds more in laboratories.

The research shows that the physical workplace, as a whole, represents a significant factor in individual job satisfaction, health, and performance, and group formation and cohesion. Findings on specific facets of the workplace are summarized in the following sections at the individual and interpersonal levels of analysis, along with accepted theoretical explanations.

3. Individual Workers and Ambient Conditions

Ambient conditions are the most intensively studied facets of the workplace. Evidence concerning individual satisfaction and health comes mainly from research in workplaces, including postoccupancy evaluations (assessments of new buildings using multiple measures; see *Architectural Psychology*). Evidence concerning performance comes mainly from laboratory experiments.

3.1 Temperature

Thermal comfort in workplaces depends on ambient air temperature and relative humidity, air movement,

radiant heat sources, activity level, clothing, and individual differences. In offices, temperature represents a common source of dissatisfaction with the physical environment. Up to 20 percent of office workers report feeling too cold or too warm at temperatures the majority finds comfortable.

Effects of temperature on performance reflect arousal (generalized physiological/psychological excitation) which increases during initial exposure to heat, and eventually falls below normal after continued exposure. The arousal hypothesis (see Sundstrom 1986) predicts optimum performance at moderate arousal and poorer performance if arousal is too high or low. Optimum arousal is higher for simple or practiced tasks, and lower for complex tasks and learning.

Consistent with the arousal hypothesis, laboratory experiments show that warm temperatures briefly boost performance of simple tasks. Other research shows no effect on performance of moderately demanding cognitive tasks. Exposure to heat for 30 minutes or more without rest periods degrades performance of complex and demanding tasks such as manual tracking, vigilance (monitoring displays for change or irregular signals), and dual tasks (simultaneous primary and secondary tasks). Decrements in dual tasks appeared in secondary tasks, often as errors of omission, suggesting that heat contributes to sensory/cognitive overload and prompts the usual coping responses: narrowing of attention and ignoring low-priority inputs. Early studies in factories found adverse effects of heat on output and accident rates ameliorated by ventilation.

3.2 Noise and Sound

Noise (or unwanted sound; see Kryter 1994) ranks high among sources of dissatisfaction with offices, particularly coworkers talking and telephones ringing. Dissatisfaction correlates with peak sound levels above background, not with background levels, consistent with evidence that noise is most irritating when irregular or unpredictable. Some research finds overall job satisfaction significantly and inversely correlated with annoyance by noise.

Loud background noise initially elevates arousal, which diminishes with adaptation (decrease over time in responsiveness to a feature of the environment, via perceptual change, altered metabolism, or active coping). Performing a complex or demanding task during noise slows adaptation. Laboratory research shows that adaptation can have psychological costs or adverse aftereffects in the form of temporarily impaired capacity immediately after working during loud, unpredictable, uncontrollable noise.

Individual health may suffer when prolonged exposure to noise is combined with an additional source of job stress. Working in a noisy environment correlates with physiological symptoms of stress among employees dissatisfied with their jobs, working on rotating shifts, or facing high job demands (see Evans et al. 1994).

Noise affects performance through arousal, overload, distraction, and masking of helpful sounds. Consistent with the arousal hypothesis, continuous loud noise over 100 decibels (dB) produces a brief increment in performance of some clerical tasks. Short-term exposure to noise has no effect on performance of some moderately complex tasks, such as reading. However, noise as loud as 90dB degrades performance of complex motor tasks, vigilance, mental tasks, and dual tasks. Decrements in performance of complex tasks intensify when the loud noise comes in irregular or intermittent bursts.

Music—sound intended for enjoyment—accompanies work in some offices and factories. Of published studies conducted in workplaces, many found no effect of music on performance. Those that assessed employees' attitudes about music found them generally favorable. A few studies reported positive effects of music on output or quality; none found decrements. Laboratory research found no effects of music on performance of clerical tasks or reading, but some beneficial effects on vigilance. Performance increments are consistent with the capacity of music to increase arousal or postpone its usual decline during prolonged, monotonous work.

3.3 Air Quality

Key variables related to air quality in workplaces include ventilation (flow of fresh air) and air pollution (gas, dust, mist, vapor, fiber, or other ingredients besides the natural constituents of air). In factories, a small fraction of complaints about working conditions concern air quality. In offices that allow smoking, a substantial fraction of nonsmokers report annoyance with tobacco smoke. In office buildings, poor ventilation has been associated with elevated rates of respiratory illness.

3.4 Illumination

Laboratory research indicates that the intensity of illumination influences performance through its effects on visibility of details. In tasks requiring visual discrimination, performance increases with intensity of lighting, but performance gains diminish as lighting intensity increases. As light becomes brighter, glare (uncomfortably bright light in the visual field) can pose problems. Research in offices has generally found employees satisfied with the lighting. Employees tend to prefer 'natural' light from windows, a preference that could reflect other desirable features of windows such as the view outside.

4. Individuals and Features of Workstations

Analysis of relationships between individuals and workstations relies on models of the human–machine system (see *Engineering Psychology*). Related research yields guidelines for designing displays, controls, and other features such as seating and positioning of equipment.

Research on a common type of equipment in many workstations, computer video displays, illustrates a typical sequence. When video displays entered workplaces, early studies found problems with visibility and complaints of symptoms such as headaches and eyestrain. New designs that reduced or resolved the problems soon appeared in offices; later research found fewer problems. Similar research/redesign/re-evaluation cycles occurred for other common elements of workstations, such as keyboards and chairs. Early studies of office chairs found complaints of discomfort and symptoms of strain. New chair designs incorporated guidelines based on the research; later research found most office employees satisfied with chairs that usually had padded seats, lower back support, and adjustable seat height.

Employees may personalize their workspaces by decorating them with photos, memorabilia, artwork, plants, and other unique objects—as allowed by company policies and features of the workspace. Some research in offices found satisfaction with the work environment positively correlated with personalization of workspaces.

5. Interpersonal Effects of Ambient Conditions

5.1 Noise

Noise interferes with conversation by masking the sounds of coworkers' voices. In noisy workplaces, coworkers move closer and shout to be heard. (They may also talk less.) In uncomfortably loud noise, people pay less attention to social cues, possibly as a response to a form of overload from noise. Participants in a laboratory simulation assigned lower salaries to fictitious job applicants in noise than in quiet, but this finding has not been replicated in actual workplaces.

5.2 Temperature

Research from social psychology has found a correlation of moderately uncomfortable heat and aggressive behavior, but this finding has no demonstrated parallel in workplaces. A multination study found national, ambient temperature positively correlated with reported role overload (Van de Vliert and Van Ypersen 1996).

6. Interpersonal Relationships and Workplaces

6.1 Workspaces as Status Markers

Characteristics of workspaces that signify rank, or status markers, include a private office, privileged location, exterior windows, floor space, guest seating, and others. Research in offices shows that employees consistently recognize status markers within their organizations. Status markers communicate the occupant's rank to visitors. Research in offices has found that among those with supervisory responsibility, status markers are associated with satisfaction with the work environment.

6.2 Proximity and Communication

In offices and factories where individuals have assigned workspaces, research has consistently found the frequency of casual or informal conversation correlated with the physical proximity of the employees' workspaces. The relationship of formal communication (required by work roles) with proximity of workspaces is more complex. Coworkers whose jobs call for frequent, face-to-face interaction tend to be assigned to workspaces near one another. As walking distance between workspaces increases, preferred means of communication shift from face-to-face conversation to telephone calls or written messages, except for certain kinds of meetings seen as requiring face-to-face interaction.

6.3 Physical Enclosure and Regulation of Interaction

Perceived privacy (selective control over access by others to oneself) in a workspace correlates with enclosure by walls or partitions. Privacy facilitates regulation of workers' interaction. Some research in offices found privacy correlated with job satisfaction among employees of similar rank.

Enclosure of workspaces is important to performance because it restricts accessibility, limits noise and visual distraction, reduces interruptions, and possibly limits overload. Enclosure may also limit social facilitation (motivating effect of the presence of others) and spontaneous conversation with coworkers located nearby. Research points to a complex relationship of enclosure with performance depending on task complexity and personality traits like ability to 'screen' social input (see Oldham et al. 1995).

In the 1970s and 1980s many organizations adopted 'open-plan offices,' with minimal enclosure of workspaces and few signs of rank. Reduced enclosure was expected to aid communication. Some evaluations of open-plan offices found no change in communication;

some found increases only in casual conversation; others found declines in confidential conversation, friendship opportunity, and supervisor feedback. Privacy declined, usually along with satisfaction with the environment.

6.4 Room Layout and Face-to-face Conversation

Research in offices finds greater 'psychological distance' in face-to-face meetings over a desk than without a desk, although meetings last just as long in either arrangement. Recent research found 'stand-up' meetings as effective, but faster and less personal, than 'sit-down' meetings.

In laboratory research on face-to-face meetings of three or more people, conversation follows lines of eye contact. Leaders emerge in places affording eye contact with the most members. Circular tables avoid this 'head of the table' effect.

7. Physical Environments and Work Groups

Informal groups tend to form among employees in adjacent or nearby workspaces in offices and factories. Work groups physically enclosed or isolated from their organizations develop cohesion (attraction/commitment of members to the group) often along with unique group norms (shared habits and attitudes).

In the 1990s, many organizations adopted team-based organizations (with groups as primary performing units). Facilities supportive of effective work teams ideally incorporate colocated workstations, shared group workspace, conference space, informal gathering places, and other features, depending on the type of group (Wineman and Serrato 1999).

Some organizations use 'virtual teams' (work groups with geographically dispersed members who collaborate via electronic communication; see Mittleman and Briggs 1999). Facilities for virtual teamwork include videoconference facilities and computer-based 'group decision support systems,' which can also be used face to face.

8. Workplace Trends and Evolution

Issues for workplace environmental psychology evolve along with the technology of workplaces. Factory automation requires fewer workers, who spend more time at computer workstations. Increasing use of manufacturing teams calls for more conference space. As technology makes knowledge work more portable, more of it occurs in workers' homes as 'telecommuting' (Christensen 1988). Work at home reduces office costs, but raises issues concerning home workspaces. Numbers of full-time office occupants may decline. Other trends point to increasing needs temporarily to accommodate part-time employees, contractors, visitors from elsewhere in the organization, and employees of supplier or customer organizations. Increasing use of work groups brings corresponding increases in needs for conference space in offices.

As workplaces evolve more toward conference centers, workplace environmental psychology may focus more on physical support for work groups and collaboration.

Workplace Safety and Health

1. Definition of Workplace Safety and Health

Workplace safety and health refer here to all practical actions taken at the shopfloor level to promote the safety and health of workers. Such actions should be theory-driven because accident theories help to pinpoint dangerous factors in the company, and they offer directions for practical solutions. The focus of these actions is the behavior and attitudes of the workers subject to the highest risk of occupational accidents and diseases.

2. Short History of Occupational Safety and Health

The history of occupational safety and health starts in the fourth century BC, when Hippocrates described the occurrence of lead poisoning among miners. Later, another Roman physician, Galen, wrote about various occupational diseases (Fraser 1989). However, the first written source to mention a disease as actually being occupational in origin was Agricola's *De Re Metallica* (1556), which ends with a note on diseases and accidents among miners. At that time a woman could be married to as many as seven miners, one after the other. Eleven years later (1567) Paracelsus published *Von der Bergsucht und anderen Bergkrankheiten*, describing the diseases of smelter workers and metallurgists (Hunter 1955).

Finally, in 1700, Ramazzini published a book entitled *De Morbis Artificum Diatriba*, in which he examined the health conditions of over 50 occupations. Because of his success, he is called the Father of Occupational Medicine.

Observations on occupational diseases did not lead to legislative action until 1802, when the Health and Morals of Apprentices Act was confirmed in England. This act was then improved by the Factory Acts in the middle of the nineteenth century. The first compulsory social security system for wage-earners was also set up about that time, in Germany in 1883. The Workmen's Compensation Act followed in Britain in 1897. It provided for automatic compensation to an injured worker. In 1919 occupational safety and health became a truly worldwide concern when the International Labour Organisation (ILO) was founded in Geneva to establish International Conventions and International Recommendations for the development of standards and procedures for occupational health and accident prevention (Fraser 1989).

3. Theories on Occupational Accidents

A feature common to different definitions of an occupational accident is the unexpected and unintentional nature of the incident. When physical injury is added, an occupational accident can be defined as an unexpected and unintentional series of events leading to the physical injury of a person at work. The other precondition for an occupational accident is a contractual relationship between the employer and the employee (Figlio 1985).

Until the end of the nineteenth century, people thought that accidents were brought on by their sins or were 'God's will.' This idea was based on the fact that most hazards were caused by natural phenomena. People had very limited means with which to resist the forces of nature. The onset of industrialization in the twentieth century meant that production moved from homes to factories. Since people had built these environments, most of the hazards were also man-made. Thus the idea of accident prevention fell on fruitful ground.

3.1 Theories on Accident Causes

The first scientific theory attempting to explain accidents was the theory of accident proneness. Greenwood and Woods (1919) insisted that 'accidents occur to a limited number of individuals who have a special susceptibility to accidents' (preface). Accident proneness was presumed to be a stable personality trait. The theory assumed that some people have an inherent tendency to be involved in accidents (Shaw and Sichel 1971).

The theory of accident proneness has been criticized on both theoretical and empirical grounds. The studies published have displayed conceptual confusion, however, surrounding the meaning of accident proneness. Accident proneness is understood as a unitary trait, as a general characteristic, and as an innate and unmodifiable characteristic, and it is thus used as an explanatory concept. The statistical criticism of the accident proneness theory culminates in the question of whether the entire population has the same risk to be involved in an accident or not. Because the accident proneness theory is based on an incorrect assumption of homogeneous exposure to risk, it should be substituted by the concept of accident liability, which is based on the assumption of the inequality of exposure (McKenna 1983).

According to the danger factor theory, an accident happens when a worker and a danger factor meet so that the worker injures him/herself. The accident is a

stochastic event, the probability of which is determined by the number of danger factors. The most critical danger factors are those with the highest energy content (Skiba 1973). This theory is mostly based on practical experience.

A more sophisticated version of the danger factor theory is the ergonomic approach to the causes of accidents. The ergonomic approach assumes that disturbances in the flow of information increase the risk of accident occurrence. The exchange of information between a worker and his or her environment, or between a worker and co-workers or supervisors are preconditions to accident avoidance (Saari 1984).

3.2 Theories on Risk Taking

The recent theories related to accidents are those on risk taking. They have been developed in research on traffic safety. Most of the authors have thought that their theories can be applied to risk-taking situations in worklife as well.

The risk compensation theory assumes that people have a constant level of risk that they are ready to accept. If the risk level decreases due to safety measures (e.g., seat belts in cars), people tend to adjust their goals (e.g., try to arrive sooner at their destination) so that the risk level returns to exactly the same level as before. The effects of safety measures are thus eliminated in the long run (O'Neill 1977). Because the assumption of exact compensation is criticized, the concept of risk compensation is often replaced by the concept of behavioral adaptation.

According to the risk homeostasis theory, the risk of traffic accidents is determined by the homeostatic system, which is analogous to the room temperature system. The main assumption of the theory is that the target level of risk is the only factor determining accident rates. Perceived benefits and costs of risk taking and cautious behavior are the factors controlling the level of target risk. The risk homeostasis theory argues that the effect of a safety measure depends on its motivational nature for the people who use it. The effect of a measure (e.g., mandatory seat belt use) which does not motivate its users will be eliminated in the long run as the drivers take more risks. However, safety can be enhanced by measures that motivate people to desire safety (Wilde 1982). If such motivation can be achieved, the effect of the measure may be greater than technical calculations show.

A complementary theory for the risk homeostasis theory is the risk motivation theory (Trimpop 1994). This model assumes that both personality and situational factors influence one's risk perception, which is divided into physiological, emotional, and cognitive components. Each one has its own target level of risk, which contributes to the total target level of risk. Based on the rational calculation of costs and benefits, a risk taker is motivated to act. These acts influence the environment, which then gives either positive or negative feedback. The actor can then perceive the risks in a new and better way.

The theory of zero risk received its name from the assumption that drivers of motor vehicles adapt to the risks involved in driving to the point that they do not generally feel any risk in a traffic situation or their subjective risk assessments approach zero. People avoid the feeling of risk just as they avoid pain. There is a risk threshold, however, above which risk is experienced as aversive. A driver tends to satisfy his or her motives in traffic, as well as in other areas of life. This need to satisfy motives pushes him or her to drive faster and more hazardously. Both excitatory and inhibitory motives influence the decision making of a driver. The most hazardous excitatory motives are 'extra motives' (i.e., those outside traffic, such as the saving of time and effort) which prompt the driver to increase speed. The increased risk of an accident is related to the strength of these extra motives (Näätänen and Summala 1976).

If the psychological portrayal of a human being with respect to accident theories is analyzed, a change can be seen. The first theories assumed that a human being is a passive accident victim who has an inherent tendency to be involved in accidents. In the more recent theories, a human being is an actor who actively searches for information from the environment. The theories, however, accept that a human being is not perfect and does make mistakes and errors. As technology becomes more reliable, a human being will be the greatest risk factor for him/herself (see *Health Risk Appraisal and Optimistic Bias*).

4. The Behavior Modification Approach

The approach of behavior modification is based on operant learning behavior. Behavior is seen as a function of its relation to various prior and current events. The preceding events are called antecedents, and the events following the performance are consequences. If an act has increased in rate after a particular consequence has reliably followed it, the consequence is reinforcing. But if the rate has decreased, the consequence is aversive. Last, if a behavior disappears when a prior reinforcing consequence is continued, the situation is called extinction (Sulzer-Azaroff et al. 1994).

4.1 Interventions

The training of workers is usually the first form of intervention included in a behavior modification program. The aim of training is to teach safe work habits. The training must be as illustrative as possible, for example, showing photographs of workers using

safety glasses. It is also possible to show unsafe scenes and ask workers to point out the unsafe actions. The important point in training is to repeat the safe habits in different ways for the workers. Several studies, however, have shown that training alone is not sufficient to improve safety performance (Sulzer-Azaroff et al. 1994).

The alternative method for traditional classroom teaching is an informational safety campaign. The first prerequisite for an effective informational campaign is to set a clear objective with a specific message that is positive, simple, plausible, and comprehensible. The campaign material should be designed to attract attention. Posters should be placed at crucial points of action, for example, on the wall of the canteen at a construction site. The effect of a campaign is usually short-lived. The types of intervention used in informational safety campaigns have not influenced the number or the seriousness of accidents (Saarela et al. 1989).

The other alternative method is to utilize small groups in accident prevention. This idea is based on experiences from quality circles, which are problem-solving groups largely used in the manufacturing industry. As in the case of quality circles, small accident prevention groups consist of members of the same organization meeting regularly to solve safety-related problems. In a Finnish shipyard the small groups had from 4 to 13 members, and they met 5 to 11 times during one year. The two tasks of the groups were to eliminate the obstacles to good order and safety and establish new housekeeping practices—behavior modification. The program was successful both in improving housekeeping and in reducing accidents (Saarela 1990).

Goal setting is the other main method with which to improve performance. The first requirement for successful goal setting is that the workers who are to be the subjects of the intervention participate in the setting of the goals. Difficult goals inspire better performance than easy goals do. The best goals are difficult, but achievable. The utmost goal should be divided into subgoals that are easy to understand. The first goals should be rather concrete, such as 'we should use hard hats all the time at the construction site' (Locke and Latham 1990).

4.2 Positive Reinforcement

Positive reinforcement refers to an increase in the frequency of a response following the presentation of a positive reinforcer. Whether or not a particular event is a positive reinforcer is determined empirically. The effectiveness of the reinforcer depends on several factors. Reinforcement given immediately after the response is more effective than feedback given after a long delay. The greater the amount of a reinforcer, the more frequent the response. Reinforcers that are highly valued lead to greater performance. A continuous schedule of reinforcement, where a response is reinforced each time it occurs, is the most effective (Kazdin 1975).

Figure 1
TUTTAVA information board

Positive reinforcement should be given soon after the observation of a desired behavior. It ought to be given regularly, for example, once a week. The feedback should be visible and given to all workers at the same time. One way to fulfill these requirements is to place a special information board on the wall so that a curve illustrates the development of the safety score on the experimental area from one observation to another. One example of such an information board is the TUTTAVA-board developed at the Finnish Institute of Occupational Health (Fig. 1), TUTTAVA being a Finnish acronym for a program to help improve production, quality, and safety.

One form of positive reinforcement is the use of a token economy. A token is a tangible object, for example, a lottery ticket, which can become a conditioned reinforcer. The use of tokens may shorten the delay between the behavior and the consequence, reinforce the behavior any time and any place, and provide a visible record for evaluation. The weakness of the token economy is that it pictures behavior as a simple series of stimuli and reactions. The token economy is, however, rather inexpensive for companies to operate (Brown 1978).

4.3 Measurement of Safety Behavior

It is useful to start a behavior modification program with accident analysis. The analysis of accidents during the previous three to five years pinpoints the hazardous sites of the workplace. It is worthwhile classifying accidents as unpreventable and preventable, that is, as whether or not workers could avoid a similar accident if they changed their behavior. The

researcher should then discuss the actions that could prevent accidents with the on-site personnel. Using the results of this analysis, the researcher collects 10–20 safety practices which should be phrased positively (Komaki 1986).

The next step is to prepare the measurement of safety performance. Generally an observation method is used for this purpose because the object of measurement is the external behavior of the subjects. The researchers should select observation periods at random (Tarrants 1980). When the observation is done at different times of the day, the workers behave normally and do not avoid the most hazardous tasks. The observation can be done from a single observation point or by walking through the observation area; the latter method is more common.

The observation sheet includes at a minimum a list of the desired safety practices. Usually it is constructed with only a dichotomized classification. The behavior of the observed worker is either safe or unsafe, as defined by the criterion of behavior included on the observation sheet. The third possible category is 'not observed,' under which the practice does not occur (Komaki 1986).

One example of an observation method is ELMERI (Fig. 2), ELMERI being the Finnish acronym for a workplace safety and health observation method. It has been developed through cooperation with safety authorities, safety managers, and safety representatives from selected workplaces. The observation method consists of 26 items, divided into 7 groups: (a) safety behavior, (b) order and tidiness, (c) machine safety, (d) industrial hygiene, (e) ergonomics, (f) walkways, and (g) first aid and fire safety. For each item, the observer makes a decision as to whether the item is correct according to the safety criteria defined in the handbook of the observation method. The alternatives for the observer are 'correct,' 'not correct,' or 'not observed.' The 'not observed' alternative is used, for example, when there are no machines with permanent means of access in the workplace. It takes about 15 minutes to observe one work station with the ELMERI method, and only a few hours of training are needed to reach an acceptable level of interobserver reliability. It has been shown that a high safety index from ELMERI is related to a low accident rate (Laitinen et al. 1998).

The walkthrough observation rounds should be repeated once a week during five to ten weeks. The suggested time for each round is 30–60 minutes. The minimum number of observations during one observation round is 100. The results of the observations are calculated as a safety score as follows:

$$\text{safety score} = \text{correct}/(\text{correct} + \text{not correct}) \times 100.$$

The higher the value of the safety score, the better the safety situation within the workplace (Komaki 1986, Tarrants 1980).

The reliability of the observation is based on interobserver agreement. Therefore, two observers should independently assess the behavior of the same workers. It is desirable to conduct reliability checks when both the observers and the observed workers are unaware that checks are being conducted. The reliability is calculated by dividing the smaller frequency by the bigger frequency and multiplying by 100. The reliability should be at least 80 percent to be acceptable (Kazdin 1975).

4.4 Experimental Designs

The effect of the intervention is demonstrated by the experimental design. It has two tasks. First, it should show that the change in behavior is permanent. Second, it should prove that the change in behavior is due to the intervention. There are three main types of experimental designs.

4.4.1 Reversal or ABAB design. The reversal design demonstrates the effect of the intervention by alternating the presentation and removal of the program over time. The purpose of the design is to demonstrate a functional relationship between the target behavior and the intervention. The first task in a reversal design is to measure the baseline rate of behavior, which describes the behavior in a normal situation before the intervention. The baseline period (referred to as phase A) is continued until the rate of the response becomes stable.

Then, in the experimental phase (referred to as phase B), the intervention is carried out. This phase continues until the behavior reaches a stable level or diverges clearly from the baseline level. Now the change in behavior is evident, but the cause of change is unclear.

In the reversal phase (phase A) the intervention is withdrawn. The target behavior usually returns to or near the original baseline level. The purpose of the reversal phase is to determine whether the behavior would have remained unchanged if the intervention had not been introduced. When the behavior reverts to the baseline, it is possible to reinstate the intervention (phase B). The design is called the ABAB design because the phases A and B are alternated (Kazdin 1975).

4.4.2 Control group design. Another way to demonstrate the effect of intervention is the classical experimental design with experimental and control groups. The intervention is done with one group (the experimental group) and not done with the other group (the control group). Immediately before and after the intervention the behavior of the workers is assessed. The basic requirement of the study design is the similarity of the groups. The best procedure to control for systematic differences between the groups

is to allocate the workers to groups at random (Kazdin 1975).

At the shopfloor level a random classification of workers is not always possible for production reasons.

Then two departments, which are as similar as possible, are selected as experimental and control groups. In addition to nonrandomness, overlapping of the information between the departments may be a problem in the comparison of departments.

4.4.3 Multiple-baseline design. The third experimental design to show the effect of interventions is the multiple-baseline design. The aim of this design is to demonstrate that the change in behavior is associated with the introduction of the contingency at different time points. This design requires the use of two or more interventions. After the baseline reaches a stable rate, one of the interventions is introduced, while baseline conditions are continued for other interventions. When the rates are stable once again, the second intervention is introduced. The effects of each intervention are established only after it has been introduced.

One problem that can occur with the multiple-baseline design is that changes in behavior take place too early. If behavior changes before the intervention is introduced, it is not clear whether the intervention is responsible for the changes or not (Kazdin 1975). Another problem is that the effects of the different interventions could be confused.

4.5 Analysis of Intervention Data

Intervention studies often require the use of statistical tests appropriate for single-case experimental designs. Conventional t and F tests can be used in the statistical analysis of intervention data if the data are not serially dependent. This practice requires that the autocorrelation (i.e., correlation between data points separated by different time intervals) not be significant (Kazdin 1984). The other statistical method is to use tests for time series. The best for a short time series ($n < 10$) is Kendall's tau, which analyses the mean trend.

It is possible to complement the quantitative data of the effects of the intervention study by qualitative data. Qualitative methods are the most useful for analysing the meanings and symbols of the culture or subculture. In an intervention study, the most useful qualitative method is perhaps a discourse analysis. With this method, a researcher can analyse the possible change in the attitudes of the workers participating in the intervention.

In the reports of behavior modification studies, graphs should be used to illustrate both the study design and the results. It is easy to show the development of a safety score with a line graph (Gillan et al. 1998). In some cases it is possible to use the same graph to give feedback to workers and to illustrate the results in the report, as the TUTTAVA curve does (Fig. 1).

High-quality intervention studies help to avoid the wasting of time, money, and effort. Shannon et al. (1999) have presented eight criteria for an intervention study of high quality. First, the objectives of the study or its underlying hypotheses are clearly presented. In the experimental design the subjects are randomly allocated to experimental and control groups. The study has external validity and therefore its results can be generalized to other workplaces. The outcome measurement with acceptable reliability and validity should be appropriate to the objective of the intervention. Qualitative data can be used to supplement quantitative data. Diffusion of intervention manipulation from the experimental group to the control group (overlapping) or improper randomization are the main threats to internal validity. Appropriate statistical analysis should be applied in the analysis of the data set. The conclusions should address the program objectives and the limitations of the study and be supported by the analysis. These criteria are useful both in the assessment of other studies and in the planning of one's own study.

5. Future Recommendations for Workplace Safety and Health

The fatality rate in Finland has fallen from 7.2 to 3.2 deaths per 100,000 workers from 1975 to 1994 (Statistics Finland 1997). Most of this positive development is due to technical solutions to prevention and improved safety inspections. Nowadays most of the technical solutions are in use and simple accidents can be prevented. Only the more complex accidents need to be tackled nowadays; they are due to the interaction between technical failure and human error.

Occupational accidents cause disturbances in production. When a serious accident occurs, all workers stop their work and go to help. According to Finnish calculations of accident costs, this participation forms the highest costs to the employer. Some customers therefore demand that the number of occupational accidents should stay under the acceptable limit.

Traffic research in Sweden has produced an idea called Vision Zero. According to this idea, no one should be killed or sustain an injury resulting in permanent impairment (Tingvall 1997). Some workplaces, at least in Finland, have already accepted the idea of Vision Zero. In other words, they follow the principle that no accident is acceptable and that all accidents are preventable.

These trends increase the expectations for safety modification behavior. Workplaces require more effective ways of changing the attitudes of workers to a more positive direction and activating them towards work safety. Alternatively, a deeper understanding of human behavior based on the advances of social and behavioral sciences makes it possible to respond to these increased requirements.

Worksite Health Promotion and Wellness Programs

1. Introduction and Historical Development

Organizational efforts to improve employees' health began with an almost exclusive concentration on worksite safety and progressed rather slowly to broader areas of concern, which today include health promotion. In the 1920s, concerns over employees' safety and health grew with industrialization. This was, to a large extent, due to organized labor's concerted efforts to improve unhealthy and dangerous work conditions. These concerns led to the development of a broad range of occupational safety and health initiatives which, for the most part, dealt with physical, chemical, and biological hazards in the work environment (Wolfe et al. 1994).

Health promotion initiatives gained a new lease of life in the late 1970s and 1980s (for a typical review, see Parkinson et al. 1982). Shain et al. (1986), based on a sample of historical case studies, suggested that health promotion programs are really just a modern expression of an old idea, namely employer paternalism. It was criticized that these programs communicated the view that deteriorating health is a moral failing for which the individual worker is responsible. With the move to a more comprehensive approach to worker health, the adoption of the health promotion philosophy by a number of employers in the 1970s represented a move away from the previous industrial medicine (occupational safety and health) orientation in three ways. Firstly, the primary concern shifted from preventing injury and disease to the active promotion of health. Secondly, the newly-adopted health promotion model heavily emphasized employee or personal behavior instead of workplace conditions as the primary focus. Thirdly, health promotion programs which traditionally had been initiated by

management and tended to be used primarily by white-collar staff were now extended to blue-collar workers as well (Wolfe et al. 1994).

2. Definition and Domain of Workplace Health Promotion Programs

The terminology used to label employee health promotion initiatives varies. Terms such as fitness programs, worksite health promotion programs, employee health management programs, health promotion programs, health enhancement programs, disease prevention programs, and wellness programs are only some of the most commonly used. Over the years, not only the name and content of workplace health promotion (WHP) programs have changed, they have also gradually broadened. For example, Elias and Murphy (1986) regard health promotion as 'art of a broad spectrum encompassing all health services and activities. This spectrum consists of health promotion, health maintenance, and health restoration.' Katzman and Smith (1989) defined health promotion programs as 'various combinations of in-house activities initiated by a company with the intent of enhancing the overall physical and psychological health of its employee population.' Kizer et al. (1992) refer to the definition of Parkinson et al. (1982) as they regard health promotion as 'a combination of educational, organizational, and environmental activities designed to support behavior conducive to the good health and wellbeing of employees and their families.' Wolfe et al. (1993) define WHP programs as 'ongoing organizational activities designed to promote the adoption of personal behaviors and organizational practices conducive to maintaining and/or improving employee physiological, mental or social well-being.'

The common vision of WHP programs is that of an integrated approach of a total package of activities, targeting not only the individual and organizational levels, but also environmentally-focused strategies and community-based resources. Such an interactive approach would offer the possibility of remedying problems of a physical and mental nature, promoting and maintaining good physical and mental health among employees, and developing an environment and tapping into the community to facilitate successfully sustaining positive changes achieved by the WHP programs.

3. Why Promote Health at the Worksite?

There are a number of advantages and disadvantages associated with the use of the worksite for health promotion initiatives. From the employees' perspective, they are convenient, affordable, and provide the opportunity for social support. These strengths may also be disadvantages where the timing of meetings may interfere with other valued activities, and/or individuals may not wish to disclose certain behaviors in front of their peers. For employers, potential benefits include better employee morale and public relations (Cataldo and Coates 1986, Everly and Feldman 1985); improvements in employees' performance; positive influences on morale, absenteeism, turnover, recruitment and productivity (Robison et. al. 1992); as well as reduced healthcare costs, particularly in the USA (e.g., Harvey et al. 1993), and reduced absenteeism (Bertera 1990). However, as many programs focus on individuals rather than organizational structures, there is a danger of 'victim blaming' and the development of ineffective programs.

One of the attractive aspects of WHP programs is their potential to reduce the rapidly increasing healthcare and health-related costs incurred by 'unhealthy' organizations. With WHP programs, substantial savings can be achieved by the organization. For example, cost savings may be associated with reductions in the cost of heathcare insurance, disability payments, and workers' compensation. In addition, a healthier workforce would absent themselves less frequently from work, thus reducing health-related costs. Of perhaps greater importance than a health promotion program's ability to control potential healthcare costs is its potential to improve employees' performance. Research has found that such programs can positively influence morale, absenteeism, turnover, recruitment, and productivity (Robison et al. 1992). Research has shown that generally, employees are satisfied with health promotion programs (Davis et al. 1984), and programs contribute to improvements in employee morale and job satisfaction (Pelletier 1991, Wolfe et al. 1993).

From a theoretical perspective, the worksite offers an excellent opportunity to maximize behavioral change through long-term individual programs, and the potential for environmental policies and manipulations to foster and maintain such change. However, not all programs have utilized the full potential of the worksite. For example, worksites which provide health screening clinics with no provision for followup or support through other environmental changes gained no advantage over similar interventions conducted in other settings (e.g., Erfurt et al. 1990). Accordingly, while the worksite provides an excellent setting for health promotion, its benefits can only be maximized through programs that utilize its environmental and social resources to the full.

4. The Environment—Challenges for the Working World in the Twenty-first Century

Clearly, a range of new challenges are confronting the world of work today. The world of work is undergoing major changes—a process which will continue for some time to come. A few random examples include genetics, the widespread of use of new technologies,

Table 1

and demographic change. More general socioeconomic developments are also generating tremendous pressure on innovation, which also impacts on the field of work and health. Some of the key issues to be confronted are:

4.1 Globalization

As more firms become global in their operations, organizations will have to take into account the diversity in the workforce when deciding on wellness issues and programs. Some issues involved are differences in customs, language, and communication styles; differences in attitudes toward time; and the effects of labor laws, ethical standards, and the political climate.

The global workforce is anything but homogeneous. Employees' attitudes and value systems vary greatly in a wide variety of important ways. Table 1 summarizes some of the major differences in the workforces around the world. For example, about 7 percent of the Western population suffers from hypertension in such a measure that it needs to be treated in order to prevent cardiovascular problems. Another 7 percent has moderately heightened blood pressure which also needs to be attended to. Only a small number of people are being treated for this condition. Several studies which offered non-medication therapy (e.g., reduced smoking, losing weight, better nutrition, relaxation exercises, and stress management) reported success in the hypertension programs (Baier et al. 1992, Fielding 1982, Glasgow and Terborg 1988).

4.2 Unemployment

Millions of workers at all occupational levels have lost their jobs in recent years as a result of reorganizations and the inability of some industries to remain competitive in the world market. Retrenchment is traumatic, not only for the incumbent but also for those who remain in the job. Organizations involved in layoffs have found reduced morale, job commitment, and job involvement among their remaining workers (Seppa 1996).

4.3 Increasing Use of Technology

Of the 20 fastest growing occupations, one-half are related to the health and computer fields. Bezold et al. (1986) have cited data indicating that computers and robots will probably affect 7 million factor jobs and 38 million office jobs. The projected effects of this will include job displacement, deskilling, and lower paying jobs.

4.4 Changes in Employment Practice

With the advances in personal computers, telecommunications, and fax machines, flexibility has come to characterize the workplace. In recent years, flexibility in work scheduling (e.g., short-term and part-time employment) has become more widespread. Telecommuting—the decentralizing of work—is already in effect at more than 600 US companies. Increases in productivity of up to 30 percent have been reported (Becker and Steele 1995).

4.5 Change in Organizational Size and Structure

Due to the huge changes in company structures, new production and management concepts are introduced. The 'classic' company with its stable and predictable structures is heading towards a new flexibility involving ever smaller core workforces, new forms of work, and greater mobility between jobs. Overall, there is an increase in the number of small- and medium-sized enterprises. These companies are subject to special conditions, particularly with regard to occupational safety and health and workplace health promotion.

4.6 Changing Demographics

The demographic development must be observed as regards its effects on workplace health promotion.

Figure 1
Workplace health promotion grid: a multitier strategy

4.6.1 Gender composition. According to Fullerton (1985), of every 10 new jobs between 1985 and 1995, six would be filled by women, and the proportion of women would continue to increase to 46 percent of the workforce. Because of role demands and constrained occupational opportunities, this trend may have an adverse impact on physical and mental health.

4.6.2 Ethnic composition. Another emerging demographic trend is that of an increased participation of minority-group members in the workforce. Data from the USA identifies a strong association between ethnicity and health status. Blacks have higher age-adjusted mortality rates for heart disease, cancer, liver disease, diabetes, and pneumonia than whites. They are also more likely to die from violence (Markides 1983). In the UK, rates of ill health and mortality amongst ethnic minorities differ from those of the native (white) population, but there are also marked differences between them (see Balarajan and Raleigh 1993). As differences in health behaviors are associated with both race and gender, health promotion programs will do well to take these factors into consideration. According to Narang and Murphy (1994) and Doyle (1991), ethnic minorities experience more problems in gaining access to health services such as cancer screening and antenatal care, and have lower survival rates following diagnosis of cancer or AIDS, than their white counterparts (Primm 1987). They are also more likely to experience environmental stressors such as poverty, poor housing, and poor working conditions.

4.6.3 Age composition. The change in health structure has, on the one hand, resulted in a higher proportion of older employees in the working population: on the other hand, this change also requires longer working lives to safeguard the 'agreement between the generations'. This demographic development means that the group of older employees is growing in relative terms. While at risk from poorer health and from sometimes outdated qualifications, these older employees offer a large but frequently untapped potential of experience and qualifications.

5. The WHP for the Twenty-first Century—A Multitier Strategy

It is generally agreed by health promotion researchers that in the twenty-first century, mental health problems in the workplace are prevalent. These problems have high human and economic costs (both direct and indirect) and are related to overutilization of general medical care and increasing healthcare costs. Unfortunately, mental health problems are not yet sufficiently addressed at the worksite. Today, the objective of WHP is therefore more than just protection against accidents and occupational diseases. It includes all the activities that serve to maintain and promote the physical and mental performance and motivation of the employees. A 'biobehavioral,' multidimensional perspective to WHP programs is recommended—that of examining occupational-related stress and/or health factors in combination with life-style factors (e.g., sedentary behavior, smoking, poor diet). Such life-style factors affect the health of the individual worker and collectively affect the wellbeing and

productivity of the entire workforce. These concerns should be addressed collectively through comprehensive disease prevention and/or health promotion efforts.

In modern companies, strong involvement of the employees in this process is essential, taking into consideration the changes in the communication and information conditions in society and within companies. Successful WHP is not feasible without intensive communication and constructive cooperation at all levels. The future success of organizations is dependent on having well-qualified, motivated, and healthy employees. Worksite health promotion has a significant role to play in preparing and equipping people and organizations to face these challenges. In view of the multiple issues faced by organizations in the twenty-first century, a multitier approach is suggested. Workplace health promotion programs need to be implemented strategically and with some permanence. To ensure that this happens, there is a need to disregard the notion of creating 'programs,' which are temporary by definition. Change must begin with policy; thus, a need to involve both the micro (individual and environmental) and macro (organizational and community) levels are essential. These will include:

1. *Individually-focused strategies* of health risk appraisal, clinical preventive services for employees and their dependants, and employee life-style change (including physical exercise, good nutrition, avoidance of tobacco products and excessive alcohol consumption, safe driving practices, safe sexual behavior, safe work practices, and the application of sunscreens when exposed to direct sunlight).
2. *Environmentally-focused strategies* of ergonomic workplace design, industrial hygiene and occupational safety (e.g., removal of chemical and environmental hazards, maintenance of good indoor air quality), and effective facilities design and management practices.
3. *Organizational efforts* to promote employee wellbeing and healthful workplaces, for example, policies that establish smoke-free worksites; efforts to facilitate flexible work schedules; provision of employee health benefits and insurance plans that incorporate disease prevention and health promotion services; managerial efforts to cultivate socially supportive and responsive organizational climates and to offer worksite violence prevention programs; and corporate compliance with occupational safety and health regulations.
4. Beyond the workplace, *community programs and resources* that enhance the health of employees and their dependants, including the development of 'healthy city' programs and effective healthcare delivery services at local and regional levels. The community also includes employee groups, the private sector, healthcare providers, health insurance companies, unions, educational institutions, and the federal and state governments.

6. *The Future of Work and Health Programs*

Based on the above, one of the goals of future WHP programs should be understanding the rapidly changing nature of work and its impact on the health of employees. In addition, sophisticated program evaluation activities need to be incorporated in the planning phase of such programs. Employees must have a primary role in the conceptualization of the research questions and methodologies in order to anticipate limitations and ensure that the findings can be assimilated into corporate policies. A change towards a culture in which it is seen as normal and positive to be concerned with improving health and maintaining good health at the workplace causes a change of attitude and social norms with regard to healthy behavior. An important part of the health program is that information reaches employees through different channels, thus raising the level of knowledge of health promotion and, importantly, influencing the existing culture with regard to health-promoting activities at the workplace. Evaluation should be an integral part of the program. In order to attain good evaluation, the aims of the program should be described in terms of clear, quantifiable, and feasible goals. These goals should be formulated in such a way that they are recognizable and in accordance with the needs of the participants.

Many organizations are currently investing considerable resources in WHP, with the expectation that it will produce substantial organizational dividends. This presents a window of opportunity for health and organizational scientists to develop WHP programs based on sound scientific principles that will meet both public health goals and organizational objectives. This will extend the benefits of WHP programs to reach not only the working population, but also the population at large.

World Systems Theory

World Systems Theory (WST) is the intellectual descendant of Marxist theories about imperialism and of Latin American Dependency Theory. It uses a holistic methodology that claims to incorporate all the social sciences and to look at the entire globe as a unit. It is meant to overcome the narrow specialization by discipline and geographic area that has yielded much specific knowledge but few general theories to explain the extreme differences in wealth between various parts of the world. WST does this by saying that under capitalism poorer or 'peripheral' countries have been systematically underdeveloped by the rich and powerful 'core' countries, and as such, they stand little or no chance of escaping without some sort of world revolution. In between peripheral and core countries are 'semiperipheral' ones that act as a kind of global middle class stabilizing the world capitalist system. On the other hand, it is precisely in semiperipheral countries that the strains and contradictions of the world system are most evident, and therefore, that is where revolutions against the world system are most likely. Because of its ideological radicalism, WST has been somewhat marginalized, but if divorced from its ideological bias, it has the potential to become a valuable tool for the analysis of social change.

1. *The Intellectual History of the Theory*

The theory was developed primarily by the sociologist Immanuel Wallerstein (1974, 1979) in the 1970s, and it quickly became popular in sociology and anthropology, as well as among some historians and political scientists trying to explain both historical inequality between nations and the international situation of the 1970s, particularly the war the United States lost in Vietnam. But it has older antecedents.

The notion that capitalist growth and therefore successful industrialization can only occur through the ruthless exploitation of an impoverished working class was Marxist. Though Karl Marx himself concentrated primarily on the internal workings of class conflict within rather than between different societies, he also stressed the global nature of capitalist expansion and its effects on colonial or semicolonial societies. This became an important aspect of later Marxist theories of international relation. Rosa Luxemburg's and V.I.

Lenin's work as well as that of many non-Marxist critics of late nineteenth and early twentieth century European imperialism stressed the internationally exploitative nature of capitalism and its seeming need to control ever growing markets and resources. Lenin's theory of *Imperialism* (1939), written in 1916, claimed that World War I was the logical outgrowth of the competition between capitalist powers for colonies, because without dependencies, the internal contradictions of capitalism would produce growing worker immiseration and eventually, revolutions. The consequence of this theory, if it is to be believed, would be that revolutions outside the core capitalist societies can deprive the core of easily exploitable human and material resources, and therefore lead to worldwide revolution. This belief remains at the heart of Wallerstein's ideas, except that whole societies act as members of a class. Class conflict within societies remains important, but its ultimate direction is determined by the global struggle between exploiting and exploiting societies. For Wallerstein, no revolutionary movement within a single society, or even several of them, can succeed in bringing down capitalism without a global revolution.

The theory's other intellectual parent was early twentieth century right wing nationalism. Joseph Love's work (1996) traces the development of nationalist economic theories of underdevelopment from the German Friedrich List in the nineteenth century, through the Romanian fascist-corporatist Mihail Manoilescu, and to the Latin American right in the 1930s. The relative backwardness of these societies (they were what Wallerstein would call 'semi-peripheral' at the time they produced the relevant theorists) was explained mostly by the dominant market position of the most developed capitalist powers of those times, first England, and later, the major West European powers and the United States. The implications were that in order to develop, the poorer societies had to shield themselves from the world market, to somehow exclude the world system. Nationalism justified such policies as essential in order to protect the self-interest and integrity of the less developed nations.

World War II discredited fascist-corporatist notions of development, but the theory retained its attractiveness, and it gradually migrated leftward. In Latin America, Raul Prebsich, Celso Furtado, and Fernando Henrique Cardoso became the chief spokesmen for what came to be called 'Dependency Theory.' The explanation of backwardness remained essentially the same, that the developed capitalist powers impeded the development of those who were more backward, but it no longer seemed necessary to carry out protectionist theories within the framework of an authoritarian, ultranationalist, fascist-corporatist state (Cardoso and Faletto 1979). It should be noted that Cardoso, who eventually became Brazil's president, abandoned most of the implications of his theory long before achieving power in his own county. Meanwhile, the theory became increasingly popular within the revolutionary left.

The problem was that a high degree of protectionism in an increasingly powerful and advanced world economy required heavy state intervention to block market forces and popular demand for the consumer goods produced by the world capitalist system. Therefore, some sort of authoritarian, state centralizing mechanism was required to carry out such policies rigorously enough to permit escape from the world system. If the theorists were right, the capitalist core, now led by the United States, would use its economic, diplomatic, and even military power to force open recalcitrant nations. This was the theoretical explanation of American intervention in Vietnam and throughout the Third World. Thus, to motivate their people and mount a defense, the leaders of anti-capitalist regimes would have to use nationalism as the glue binding their people together in struggle, because they would be unable to provide the kind of consumer rewards offered by world capitalism. For those hostile to right wing, authoritarian nationalism, this led inescapably to the conclusion reached by Wallerstein and his followers, that Leninism in its most autarkic, closed Stalinist or Maoist forms was the only way to protect antisystemic nations until the world revolution achieved its goal of destroying the world capitalist system and replacing it with a more equitable, redistributive world socialist system.

This created an intellectual quandary recognized by many of WST's early followers who did not relish the ideological conclusions reached by Wallerstein and those who remained with him. Could something be saved from the comparative, holistic methodological approach advocated by Wallerstein without having to accept the extreme leftism he and his closest followers, such as Christopher Chase-Dunn (1989) were also promoting? The problem became all the more acute in the late 1980s and 1990s as communism collapsed and Marxism–Leninism was largely discredited throughout the world.

2. *The Uses of World Systems Theory*

Despite its shortcomings a world systemic approach to the study of social change remains a powerful antidote to narrow specialization. It also addresses problems that will remain with us far into the future, and it offers insights absent in other theoretical models.

2.1 *World Systems Theory is not a Substitute for but a Supplement to Economics*

First, we are obliged to admit that WST cannot claim to be a substitute for sound economics. While many development economists recognize that perfectly free

trade policies by poorer economies may indeed have detrimental effects, few if any accept the notion that autarky is a reasonable development policy, whatever the type of political regime. The import-substitution policies followed by many Latin American countries from World War II until the 1980s, as well as by India and many other countries, slowed economic growth, led to entrenched, corrupt domestic interest groups that blocked innovation and reform, and ultimately provoked economic and financial crises that threatened economic catastrophe. On the other hand, trade protectionism and developmental policies that fostered export-led industrialization in East Asia produced robust economic growth (Ray 1998). But beyond this, the truly extreme forms of withdrawal from the world capitalist system, that is the autarkic communist states, have all produced economic disasters. Furthermore, economic historians have shown that in the nineteenth century, as least, if not before, capitalist development did not rely on colonial markets, so that the economic argument in favor of imperialism turned out to be largely specious (Bairoch 1993). Yet, no matter what their strengths, there remains something unsatisfying about purely economic models of economic development.

In the hands of comparativists who place the societies they analyze in a global context and understand capitalism's transformative power, but who also recognize the importance of domestic social structures and the variations caused by specific historical experiences, world systemic ideas help account for some of the differences in rates of economic modernization. Peter Evans (1995) has done this in explaining the success of certain state led industrialization projects. Though somewhat suspicious of core power, especially American hegemony in the contemporary world capitalist system, Evans recognizes that development within that system remains possible for those who know how to combine effective bureaucratic leadership with local entrepreneurial talent, and who remain oriented to succeeding within the world system and using its advanced technology and market opportunities rather than revolting against capitalism.

Historical studies such as the one by Resat Kasaba (1988) also show how WST can provide important insights as long as it is not used dogmatically. He proves that in the mid-nineteenth century local merchants within the Ottoman Empire were able to use growing trade relations with the capitalist world to strengthen their own position against both the Ottoman state and the interests of the hegemonic core powers. But later, the Ottoman bureaucracy, helped by some powerful foreign, core financial institutions regained its strength, and this reduced the economic power of the domestic merchant class. Far from being 'compradors,' that is, subservient tools of the capitalist core (which is what conventional WST and most Marxists contemptuously call them), these local entrepreneurs might have spearheaded an economic and social modernization that would have made Ottoman society more open, tolerant, and progressive. The world capitalist system did indeed play an important role in peripheralizing late Ottoman society, but not in the expected way, and only because it was successfully manipulated by an increasingly nationalistic, Turkish, anticommercial state elite.

2.2 World Systems and Premodern Social Formations

Wallerstein believes that the capitalist world system began in the sixteenth century, with the European explorations and expansion around Africa to Asia and across the Atlantic to the Americas. But some of those inspired by WST have extended his model to precapitalist social and economic formations, arguing that notions of core and periphery based on economic and cultural exchanges explain social dynamics in a much wider array of societies than merely modern ones.

Janet Abu-Lughod (1989) argues that there was a large pre-European world system in the thirteenth and fourteenth centuries, linking China, India, and the Middle East, and that it was only bad luck that subsequently weakened this particular system and allowed Europe to become dominant. Her book, while historically somewhat at odds with Wallerstein, is faithful to his general world view.

Thomas Hall (1989) has used his research on the Southwestern United States from the fourteenth to the late nineteenth centuries to show that its many societies were interconnected in ways analogous to those specified by Wallerstein long before the arrival of Europeans, and such links continued in modified form under Spanish and Mexican rule. Looking at the shifting geographical distribution of ancient cores and peripheries has led Hall and others to reinterpret archeological data to better understand prehistorical social change.

3. Theoretical Limitations and Methodological Promises

WST's methodological approach reaffirms an old but often neglected concept. All societies have operated within larger systems, and without placing them in that context, our understanding of how they work is severely limited. There can be no general laws of social behavior that do not take this into account.

Beyond this, WST has shed light on the nature of modernization, even though that is a term it avoids in order to show it rejects the functionalist theories proposed by 'Modernization Theory' in the 1950s and 1960s. WST has shown that there is indeed a capitalist world system, and its rules, largely determined by the core powers, affect everyone. Furthermore, this capi-

talist world is itself an evolving, changing structure. It is subject to periodic waves of prosperity followed by economic downturns. Even economists need to take such large systemic factors into account in order to perfect their models. So do the other social scientists who, by and large, limit comparisons to discrete cases rather than incorporating system wide variables.

3.1 Limitations

A world systemic approach to social science, however, must admit the limitations of the theory as it now stands. Aside from its tendency to neglect economic theory, mentioned above, WST has also relegated technology and science to an almost insignificant role. Thus, Wallerstein, Abu-Lughod, and most others refuse to admit that Western European capitalism's early dynamism depended on the religious and scientific transformations that occurred during the Renaissance, Reformation, and Enlightenment. Max Weber remains a better guide to this process of change than any of the contemporary practitioners of WST, and by neglecting him, and the cultural issues he raised, they have weakened their paradigm.

Ideas generated by the core, from science and technology to various political ideologies such as nationalism and Marxism, have affected the rest of the world as much if not more than the economic and military power of the core. These ideas have been transformed in many ways within the periphery, and have stirred up particularly disruptive ideological currents of resentment and antimodernism in what Wallerstein has called the semiperiphery. There is no theoretical reason why WST could not use its model to expand our understanding of how this has worked. There is no need to continue to adhere to the simplistic materialism so many of its practitioners now follow.

It is precisely because the core, still led by the United States, retains its cultural vitality and historically unusual ability to innovate that the world capitalist system is still thriving. The repeated assertions that world capitalism is or will soon be in some sort of terminal 'crisis' has marred WST's ability to understand the present, just as the failure to take into account the cultural specificity of Western Europe has weakened its explanation of the rise of the modern world. But these theoretical deficiencies should not obscure the merit of using a world systemic approach.

3.2 Methodological Promises

When he first presented his theories, Wallerstein declared himself to be a disciple of Fernand Braudel and the French *Annales* school. Indeed, Braudel's vast comparative sweep in which entire regions, and ultimately the globe, are studied as a system of interdependent parts, is entirely compatible with WST.

Many more recent first-rate social scientists have adopted a similar, world systemic approach, though usually without acknowledging their methodological kinship with it. For example, the historian Anthony Reid (1988/1993) has presented a daringly new vision of Southeast Asian economic, cultural, and political history by putting it into the kind of comparative and global perspective that WST has always championed.

Ken Jowitt's analysis of the failed attempt to create a Leninist world system (1992) also adopts a world systemic approach without admitting it. He points out that the communists actually were more successful at creating a cultural and ideological world system of their own, with a powerful core struggling to keep its peripheries under control, than at creating a system based on economic links. He then predicts that the collapse of Leninism will have a globally destabilizing effect because it will leave the resentful losers in the world capitalist system without any constructive or predictable revolutionary alternative.

Sociological theories about the spatial distribution of cities, or trade, or global networks could all benefit from adopting a world systemic perspective. So far, judging from the literature in the articles on these subjects assembled by Neil Smelser and Richard Swedberg in *The Handbook of Economic Sociology* (1994) this has not happened. But if it did, it could yield important results. On the other hand, some geographers interested in these issues as well as by problems posed by environmental degradation already have used a WST in a fruitful way (see Taylor 1993).

Other examples and promising avenues could be spelled out, but the important point is that WST's potential is far from exhausted. Flexibly used, it still has lot of new insights to offer, and it is likely that in the early twenty-first century, in response to increasing globalization, continuing inequality, and uneven prosperity, it will undergo a creative rebirth that will take it beyond its sectarian origins.

World Trade Organization

1. Background/Objectives

The World Trade Organization (WTO) was formed in 1995 as an outgrowth of earlier arrangements set up by the governments of 23 countries under the General Agreement on Tariffs and Trade (GATT) in 1947. The objectives set for the WTO largely mirror those which emerged in the postwar years for the GATT. Prior to 1947, when the GATT was formed, there had been substantial discussion between governments of the appropriate postwar financial and trade arrangements which would govern the global economy. In the area of international finance, the International Monetary Fund had been formed with a mandate to maintain exchange rate parities, and to do this by extending loans to countries coming under exchange rate pressure. These, in turn, were to be repaid when such pressures subsequently receded. In the area of international development and infrastructure financing, the World Bank had been founded with the objective of providing financing for roads, bridges, dams, and other forms of infrastructure through concessional financing.

These arrangements were put in place at the 1944 Bretton Woods Conference but in the trade area things were left hanging for some time further. By early 1946, however, there was movement to also negotiate a charter for a wide-ranging new international trade organization which would lay down rules concerning the conduct of international trade and allowable interventions in trade by national governments. This negotiation was initiated in Havana, but as 1947 advanced it became clear to a subset of countries that this negotiation was in some difficulty in being too broad, and having a focus which was excessively interventionist. In the fall of 1947, a number of countries therefore decided to engage in a separate negotiation which, among other things, would provide a framework for the recording of the results of an initial tariff cutting conference which had been planned. The GATT was born of this separate negotiation, and as a temporary arrangement pending the ratification of the wider International Trade Organization (ITO).

The ITO charter was not ratified by the US Congress in 1951 on the grounds that it contained too many compromises with free trade principles. So the GATT, born as a temporary arrangement, was left as the major arrangement in the postwar years between national governments available to guide the conduct of global international trade policy. At first seen as a minimalist organization, with only limited expectations of it, it subsequently grew through a series of successful negotiating rounds which were fueled in the1950s by the creation of the European Community and, to a lesser degree, the entry of Japan into the GATT in 1955. This Round-based liberalization reached its high point in the 1960s with the Kennedy Round (1964–7) of trade negotiations, during which there were substantial reductions in tariff barriers, largely attributed at the time to the cooperation negotiated with the framework of the GATT. The later Kennedy Round (1973–9) was to a large degree an echo of the Kennedy Round, and the ambitious and still controversial later Uruguay Round (1986–94) was driven by the perceived need to broaden trade negotiations beyond now low tariffs.

2. Basic Elements of the WTO Structure

In essence, the GATT as it evolved after 1947 and became permanent in the World Trade Organization in 1994 embodies three key elements which each contribute to oversight of the conduct of world trade and the ways in which national governments allow each other to intervene in that trade. The first is a series of mutually agreed limits (or rules) on the use of trade-restricting measures by national governments. These were initially set out in the General Agreement itself, but have been interpreted and elaborated on both by further negotiation and through the dispute settlement process within the GATT. The second is progressive liberalization, to be achieved through negotiations on trade barriers and reductions in trade barriers. These negotiating Rounds, guided by reciprocal exchanges

of concessions between member governments, occurred in the 1960s and 1970s (in the Kennedy and Tokyo Rounds), and in the 1980s through to 1994 (in the Uruguay Round).

The third element in the GATT structure, and subsequently incorporated into the WTO, is an institutional presence maintained through the operation of its Secretariat. Importantly, the Secretariat largely oversees the conduct of dispute settlement panels, which, in effect, define the enforcement mechanism for the rules of the trading system within the WTO system. These dispute settlement panels have accelerated greatly in their use in recent years, culminating in decisions in a number of key areas, including recently in banana trade (see the statement by the WTO Director General to the WTO General Council, March 8, 1999).

3. *Broader Objectives*

While these three elements of rules, progressive liberalization, and dispute settlement define the structure of the WTO, at a broader level its objectives reflect a firm belief that it is important to restrict the use of new trade measures globally so as to prevent outbreaks of retaliatory trade wars that some people think characterized the 1930s. At this time, there was a rapid increase in trade barriers in the United States mandated under the 1930 Smoot-Hawley Tariff Act, and through the retaliation which followed in Europe. In the 1930s depression, world trade volumes shrank rapidly, some suggest by as much as 70 percent over a two year period (Kindleberger 1973). A central objective therefore set for the GATT was to prevent the world economy from going back to anything reminiscent of the 1930s, fueled by breakdown in international cooperation in the trade area.

Another broad objective relates to the potential gains from progressive global trade liberalization. It is widely believed in many circles that international trade represents the engine of growth for many economies around the world. While this is still contested by some, those involved with the WTO often point to the much more rapid growth of trade than income in the world economy since 1945, and the accelerating growth of trade in recent years. In the mid-1990s, for instance, trade growth was approximately three times income growth in the global economy, and many attribute this to the liberalization achieved within the trading system under the WTO in these years (*UNCTAD Handbook of International Trade and Development* 1999, 1993, 1995).

While these two overarching objectives, preserving international cooperation and going further with new liberalization, are generally agreed to be those underpinning the GATT/WTO system, there has been much debate over other objectives for global trade policy. One concerns the relationship between trade and development and whether the rules of the trading system through WTO should be designed so as to help fuel the growth and development of developing countries, and facilitate their wider participation in the trading system, and hence the achievement of growth and development. The developing countries generally believe that growing trade is an important part of their developmental process, and have aggressively pursued their interest in this set of issues in the WTO in recent years. At the same time, many cling to longstanding positions that the WTO (and the GATT) has *de facto* operated as a rich man's club, and that poorer countries do not actively participate in it because they are effectively excluded from it because of the structure of GATT bargaining (Srinivasan 1998).

Another area which has taken on a high profile recently concerns the use of trade policy to achieve nontrade objectives. These considerations came into play in the Uruguay Round with the introduction of intellectual property into the trade negotiations. The idea was that international norms and standards could be agreed in intellectual property protection which could then be enforced through dispute settlement allowing retaliatory actions covering trade in goods. The discussion of international trade policy instruments in this case was not so much to achieve liberalization and new growth of trade as to enforce arrangements in a nontrade area through the use of trade threats and sanctions. Some trade economists have expressed concerns over these developments since they raise the prospect of higher rather than lower trade barriers from the WTO because of the linkage of trade to nontrade areas.

Beyond intellectual property, a similar structure of linkage prevails in other related proposals which are now before the WTO. These were at the heart of the conflict at the 1999 Seattle Ministerial meeting last autumn, and involved the proposed use of trade measures to achieve environmental objectives and the use of trade measures to enforce labor standards (UNCTAD 1999).

In summary, the WTO reflects a structure based on three pillars which is widely believed by many economists to have been extremely successful in most of the postwar years in both promoting world trade and preventing any increases in trade barriers. The broadening of the WTO agenda in the Uruguay Round, however, has converted it into much more than a trade organization. It now deals with the new issues which were introduced into the Uruguay Round (services, investment, and intellectual property) and threatens to broaden further to also cover environmental issues and labor standards (Crome 1998).

4. *Current Issues in the WTO*

The WTO currently faces a range of issues, many of which have their origins in previous negotiations and, to a large degree, the Uruguay Round, while

others span the openness of WTO processes (transparencies), the political acceptability of WTO decisions and NGO participation, even to the survivability of the WTO itself. Shorter term, key issues lie in the area of agriculture; a key sector for global trade, insofar as it was effectively excluded from the GATT/WTO system in 1947 by provisions included in GATT Articles 11 and 16. GATT Article 11 specifies that all use of import quotas is to be banned, but special provisions apply to allow these to be used in agriculture; GATT Article 16 has similar provisions applying to export subsidies. The reasons for these exemptions for agriculture reflect a belief in 1947 that the agricultural sector had been vital to the war effort and cultural identification with the family farm and the agricultural sector as central to national identity justify protection. In addition, some countries (such as Japan) held the view that national security objectives implied that countries should be allowed to be self-sufficient in agriculture through trade protection.

For all these reasons, agriculture was initially outside the framework of the GATT structure and subsequent developments in the trading system including a special GATT waiver for the United States in 1955 and the 1957 European Common Agricultural Policy further intensified this situation (Ritson and Harvey 1997). Europe, which was a net food importer of large proportions in the 1950s, first excluded imports under the Common Agricultural Policy. Then with high prices in their domestic support programs and stockpiles, Europe became a significant net food exporter. This led to global export subsidy wars and major conflict more generally in agriculture in the 1980s.

The Uruguay Round represented the first attempt to deal with agriculture in a substantive way in the GATT, and introduced new disciplines. These left the original concessions in place but put in place an overarching structure which aimed to reduce levels of support to farmers, to cut export subsidies, and to convert all existing trade restrictions into transparent border measures (tariffication). Agriculture, however, was left as an area after the Uruguay Round for further negotiation (Hathaway 1987). Approaching the Seattle Ministerial meeting, agriculture and services largely define the so-called 'built-in agenda' for future negotiations under the WTO. (For information on built-in agenda, see WTO Secretariat's note. Implementation of the provisions for Review, Future Work or Negotiations in the WTO agreement and related decisions and Declarations of 7 May 1998 (WTO document WT/L/271).) New conflicts cover such matters as to whether or not there should be a ban on export subsidies, a ban which given the European structure of agricultural supports would be difficult for them to implement. The issue of and the rationale for agricultural protection on existence value grounds is a further source of conflict.

Another area of current discussion is textiles and clothing. In the Uruguay Round, the developed countries agreed to terminate their use of textile and clothing trade restrictions under the Multifibre Arrangement (Trela 1994). These restraints go back to the early 1960s, when a series of short-term agreements between the US and Asian exporters became subject to mutually agreed trade restraint on the grounds of allowing time for domestic adjustments which would accompany free trade to take place in the United States. The initial time agreed was one year, but this was first renewed and then converted into longer term agreements of five years, and subsequently multilateralized to include other OECD countries in 1974 (Whalley and Hamilton 1996).

In 1994 under the Uruguay Round decisions, the developed countries agreed to terminate the Multifibre Arrangements (MFA), but at the same time have been effectively tightening their trade restrictions they are committed to eliminate, despite an agreed phase-out plan for the MFA. Many developing countries are therefore skeptical over what may happen in the year 2004. Developing country negotiators have compared the developed country position on MFA elimination as akin to walking off a cliff (Nguyen et al. 1993). How this is to be resolved is yet another issue.

New issues also pose future issues for the WTO despite their inclusion in the Uruguay Round agreement. These include services, investment, and intellectual property. In the case of intellectual property, the phase-in period is long with special delays on implementation given for certain types of developing countries. Its full impact will be felt in the twenty-first century. In services, a whole structure of restraint on trade measures was agreed, but very little substantive liberalization to include in the structure, and hence, what happens next is very much an issue of debate.

Future issues also include the trade and environment and later standards issues which have been at the heart of a lot of the discussion and debate in Seattle. In the environmental area, the issue is the extent to which trade-restricting measures can be used to achieve environmental objectives. The trade and environment conflict was greatly accelerated in the early 1990s because of a dispute between the United States and Mexico over the use of trade restrictions on tuna which had been caught in ways which generated large incidental kills of dolphin (the activities of the GATT (1990)). The measures mandated by US courts in response to actions taken under US law by various environmental NGOs in the US were subsequently not deemed to be GATT compatible by a GATT dispute panel (Seattle Ministerial Conference—Trade and Environment: Proposals on the Possible Implications for Developing Countries). The GATT and subsequently the WTO acquired a reputation among environmental groups as being environmentally unfriendly and hostile to environmental considerations. This perception persists and was in part behind some of the conflict which prevailed in Seattle. How this is

all to be worked out in the future is now a central issue for the WTO, who in turn would perhaps like to see the trade and environment issue diffused with the environmental problems dealt with in another forum.

The trade and labor standards is also another high-profile issue because of the claim in some circles and primarily in Europe that imports occur from factories where child labor is used in unacceptable conditions: long working days, poor lighting, children who could be subject to deformities as a result of their activities in carpet factories and other locations. The free traders, however, see this as a dangerous form of new protectionism which will be supported by labor groups in OECD countries who have an incentive to show opposition to imports from countries with low wages.

All of these, then, are current issues, and current matters for the GATT and the WTO. The overarching issue, however, remains one of the contribution of the WTO to global economic performance. In the 1930s, Ragnar Nurkse posed the question of whether or not trade was the engine or handmaiden of growth; did trade drive growth as being a major, perhaps even sole, determinant within national economies or did trade merely grow because the wider economies themselves were growing? This question posed by Ragnar Nurkse has never been adequately resolved in the research community, but strong views prevail on these matters nonetheless. Free traders generally believe that strong economic performance requires an open trade regime. This is despite the performance in Japan in the 1950s and 1960s and in some other countries that have adopted more protectionist trade for them, and the fact that some countries have liberalized and not grown. On the other hand, it seems clear that countries such as Korea who have generally moved towards strong outward orientation and Taiwan have grown rapidly as a result of their trade orientation.

The stance one takes on the issue of the role of trade in future global growth largely determines how much importance one attaches to the WTO. As a vehicle for preventing the world economy reverting to the 1930s, as part of the mechanism which avoided the major cataclysmic recessions in the 1940s and 1950s comparable to the 1930s, and as a vehicle for fueling substantial liberalization through the 1960s and 1970s, it seems clear that the GATT and the WTO have much pride that they can claim in their actions. However, issues such as whether or not the system favors rich countries over poor countries, whether the system is inequality enhancing at the expense of the poor, and whether the system is closed and highly nontransparent and hence not in accordance with principles of good governance, remain. How these issues are to be worked out will largely determine both the acceptability and the profile of the WTO in the years which follow. The attempts that follow in the next few years to move forward from the Seattle Ministerial of December, which in the short term has proved to be destructive for the WTO, will largely determine both the acceptability and the profile of the WTO in the future.

Wright, Sewall (1889–1988)

Sewall Wright was born December 21, 1889, in Melrose, Massachusetts, and died in Madison, Wisconsin, March 3, 1988. Before his third birthday, the family moved to Galesburg, Illinois, where his father, Phillip G. Wright, had accepted a teaching position at Lombard College. Wright graduated from Lombard College in 1911 and, after a year at the University of Illinois, went to Harvard University as a student of William E. Castle. After receiving the

doctorate in 1915, he was employed as senior animal husbandryman by the US Department of Agriculture (USDA) in Beltsville, Maryland. He remained there until 1925, when he accepted a position as Professor at the University of Chicago. Upon retirement in 1954 he moved to the University of Wisconsin, where he stayed for the rest of his long life. Wright remained intellectually and physically active until his death at age 98, caused by his slipping on an icy sidewalk during one of his regular long walks.

1. *Early Life*

Wright was a precocious child. He could read and kept a diary before starting school. He also learned arithmetic and astonished his first-grade teacher by extracting cube roots. Later he and his brothers printed the first poems of Carl Sandburg, who was a student in their father's composition class. At Lombard he took several courses from his father, including calculus. But, despite his later reputation as a formidable mathematician, Wright never took advanced courses; his mathematics was largely self-taught. His interest in genetics was kindled by reading Punnett's article on Mendelism in the Encyclopedia Britannica.

Between his junior and senior years of college, he used his mathematical and surveying skills to work on a railroad construction in the Standing Rock Reservation in South Dakota. It was an exciting time for him. In his 90s he enjoyed telling about the rough frontier life with cowboys, Indians, and outlaws, and he still recalled a large number of words in the Sioux dialect. This work was cut short by a lung infection. While confined to a caboose, he used the time to study Tait's book on quaternions. As a result of the damaged lung, he later had trouble getting life insurance, something that he found increasingly amusing as he continued to live far beyond the usual life-expectancy.

Wright's father, Philip, was a man of many talents. He taught courses in astronomy, mathematics, economics, surveying, English composition, and physical education. He loved poetry and music, and was disappointed that his son did not take to them. Later he moved to the Brookings Institute where he published a number of books on economics. Wright had two brothers who also attained distinction. Quincy became a leader in international law and Theodore was an aeronautical engineer and acting president of Cornell University.

A full length biography of Wright is available (Provine 1986), with full details of his life and scientific accomplishments. His scientific papers span the period from 1912 to 1988, an astonishing 76 years. His bibliography comprises more than 200 articles, including a four volume set published during his retirement (Wright 1968–78).

2. *Animal Breeding*

Wright's thesis at Harvard analyzed interaction of coat colors in guinea pigs, a subject which he pursued throughout his USDA and Chicago years. He enjoyed guinea pigs and spent many hours taking care of them. Only the non-availability of an animal house prevented his continuing this after his move to Wisconsin. While at Harvard, he also began his theoretical studies of population genetics. On moving to the USDA, he inherited a colony of guinea pigs that had been inbred for many generations. His analysis of the effects of inbreeding and crossbreeding set a standard for careful analysis; the paper could be written today with hardly a word changed. During this time he invented the inbreeding coefficient, with a simple algorithm now standard textbook material (Wright 1922a). Also during this period, he formulated the basic principles for analysis of quantitative traits. Wright, along with R. A. Fisher (see *Fisher, Ronald A (1890–1962)*), converted animal breeding into a quantitative science.

Wright was especially proficient in manipulating correlation and regression coefficients. One of his earliest papers (Wright 1917) foreshadowed the analysis of covariance. His major statistical contribution was developing the method of path analysis. This is a way of measuring the relative contribution of different causal paths to a quantity of interest, such as size or performance. This was presented in a diagram in which causal paths were designated by arrows and correlations by curved, two-headed arrows (Wright 1921). A path coefficient, measuring the influence of a path, is a standardized partial regression coefficient. Wright formulated a set of simple rules that made the analysis easy to apply. This method enjoyed great popularity among livestock breeders, although recently it has been largely replaced by more sophisticated, computer-driven techniques that permit analysis of large bodies of data, and measurement of the precision of the estimates.

The technique is most useful for nonexperimental situations and in recent years has found its greatest use in the social sciences. Wright himself used the method in the late teens to analyse 510 correlations of 42 variables involving corn yields and prices and hog production. He could not get this monumental paper published because an animal husbandryman was not supposed to know about economics. It was not published until several years later, and only after the intervention of Henry A. Wallace, son of the then Secretary of Agriculture.

3. *Evolution*

After moving to Chicago, Wright changed his emphasis from animal breeding to evolution, although he still retained his interest in the physiological genetics of guinea pigs. Three people, R. A. Fisher (1929) and

J. B. S. Haldane (1932) in Britain, and Sewall Wright (1931) in the USA are mainly responsible for the 'new synthesis,' the welding of Mendelian inheritance and Darwinian natural selection into a coherent mathematical theory. Wright's particular contribution was the 'shifting balance theory.' He thought that a major difficulty in evolution was the frequent inability of a well-adapted organism to evolve into a better adapted one without passing through maladaptive intermediates. In Wright's metaphor, a population at an adaptive peak could not move to a higher peak without passing through less well adapted intermediate stages.

Wright thought that a way out of this dilemma was to have a population broken up into partially isolated subgroups. Within a small subgroup random gene-frequency changes can occur and occasionally these may produce a combination of genes that is close to that of the genotypes at the higher peak. Then, selection could take over and carry the population to the peak. This highly adapted subpopulation would then expand and send migrants to upgrade the whole population, and the process could start over.

Wright's theory became very popular among biologists. Its emphasis on gene interactions and its offering a way of putting together adaptive combinations of genes that might be deleterious in other combinations had a wide appeal. On the other hand, the theory was less popular with mathematical theorists. Wright's model required a delicate balance of population size, selection, and migration, which would be rare. It also required that the population spend much of its time, during the trial and error period, in a less than optimally adapted state. Finally, there is a question as to whether the theory is really needed; perhaps mass selection usually suffices for adaptive evolution.

Wright's theory was steadily refined during the rest of his life, but the essence remained unchanged. The theory became almost an obsession with him and he delivered many talks on the subject and wrote paper after paper. It is fair to say that, as to the importance of his theory, the jury is still out. Wright's latest paper (1988) was spirited defense of his idea, while still noting the importance of the contributions of Fisher and Haldane, and of Kimura (see *Kimura, Motoo (1924–94)*) who argued for the importance of mutation-driven, neutral evolution of molecular differences. He concluded that 'all are valid.'

4. *Retirement Years*

After moving to Wisconsin, Wright spent the first few years finishing the analysis of his extensive guinea pig studies. These were masterful analyses, but by that time the molecular revolution had changed the nature of developmental genetics, and Wright's methods were out of vogue. When this was completed, in his 70s he began his monumental four volume set, the last volume of which was published when he was 88 (Wright 1968–78). Although his shifting balance theory is conspicuous throughout, the book is far more than this. It summarizes, in four densely packed volumes, not only his life's work, but the whole field of population genetics. For the last decade of his life Wright's eyesight became progressively worse, and he used a reader that projected a greatly enlarged picture onto a television screen. He continued to read and to enjoy conversations, but in his last years he found it increasingly difficult to keep up with molecular advances and turned more to reading history and biography.

As a person, Wright was quiet, shy, and introverted. He had no small talk, and was hard to converse with. Yet, once the conversation turned to a subject on which he had an interest—and there were many—he could go on at great length. His lectures were always full of details and regularly ran overtime. He had a charming sense of humor and was excessively generous with his time. His students and colleagues held him in great affection.

5. *Social Sciences and Philosophy*

Wright's greatest influence in the social sciences is his method of path analysis. It was taken up by several social scientists, such as Dudley Duncan in sociology and Arthur Goldberger in economics, and has become a standard part of the statistical methodology. One of Wright's earliest applications of path analysis used adopted children to separate genetic from environmental influences on IQ scores, and there have been many follow-up studies extending his methods to more complex analyses of behavioral traits with better data. Finally, with the increasing interest in behavioral evolution, especially among psychologists, mathematical theories of evolution are becoming increasingly common and Wright takes a place in this, along with Fisher and Haldane.

Wright was unusual among biologists in taking an active interest in philosophy. He had a somewhat Leibnitzian view. He disliked any idea of emergence. He found no sharp borders between different levels of complexity, such as between embryo and adult or between mind and no mind. Thus if the mind does not emerge by magic, it must trace its development into a continuous process back to the embryo, the egg and sperm, and ultimately the DNA molecules. He called his concept 'dual-aspect panpsychism.' Mind is everywhere; so is matter.

The biological community either disagreed with Wright's view, or was indifferent. Most regarded mind as a natural outgrowth of appropriately organized matter. Wright held on to his dualistic view, however, and found a few kindred spirits among philosophers, particular his long time colleague at the University of Chicago, Charles Hartshorne.

Writing, Evolution of

Writing is mankind's principal technology for collecting, manipulating, storing, retrieving, communicating and disseminating information. Writing may have been invented independently three times in different parts of the world: in the Near East, China and Mesoamerica. In what concerns this last script, it is still obscure how and when the Olmec symbolic system, first attested from 600 to 500 BC, was transmitted to the Mayas and other Mesoamerican cultures (Marcus 1992). The earliest Chinese inscriptions dated of the Shang Dynasty, c. 1400–1200 BC, consist of oracle texts engraved on animal bones and turtle shells (Keightley 1985). The highly abstract and standardized signs suggest prior developments presently undocumented.

Of these three writing systems, therefore, only the earliest, the Mesopotamian cuneiform script, invented in Sumer, present-day Iraq, c. 3200 BC, can be traced without any discontinuity over a period of 10,000 years, from a prehistoric antecedent to the present-day alphabet. Its evolution is divided into four phases: (a) clay tokens representing units of goods were used for accounting (8000–3500 BC); (b) the three dimensional tokens were transformed into two-dimensional pictographic signs. Like the former tokens, the pictographic script served exclusively for accounting (3500–3000 BC); (c) phonetic signs, introduced to transcribe the name of individuals, marked the turning point when writing started emulating spoken language and, as a result, became applicable to all fields of human experience (3000–1500 BC); (d) with two dozen letters, each standing for a single sound of voice, the alphabet perfected the rendition of speech. After ideography, logography and syllabaries, the alphabet represents a further segmentation of meaning.

1. *Tokens Precursor of Writing*

The direct antecedent of the Mesopotamian script was a recording device consisting of clay tokens of multiple shapes (Schmandt-Besserat 1996). The artifacts, of mostly geometric forms such as cones, spheres, disks, cylinders and ovoids, are recovered in archaeological sites dating 8000–3000 BC (Fig. 1). The tokens, used as counters to keep track of goods, were the earliest code—a system of signs for transmitting information. Each token shape was semantic, referring to a particular unit of merchandise. For example, a cone and a sphere stood respectively for a small and a large measure of grain, and ovoids corresponded to jars of oil. The repertory of some three hundred types of counters made it feasible to manipulate and store information on multiple categories of goods (Schmandt-Besserat 1992).

The token system had little in common with spoken language except that, like a word, a token stood for one concept. Unlike speech, tokens were restricted to one type of information only, namely, real goods. Unlike spoken language, the token system made no use of syntax. That is to say, their meaning was independent of their placement order. Three cones and three ovoids, scattered in any way, were to be translated 'three baskets of grain, three jars of oil.' Furthermore, the fact that the same token shapes were used in a large area of the Near East, where many dialects would have been spoken, shows that the counters were not based on phonetics. Evidently, the goods they represented were expressed in any language. The token system showed the number of units of merchandize in one-to-one correspondence, in other words, the number of tokens matched the number of units counted: x jars of oil were represented by x ovoids. Repeating 'jar of oil' x times in order to express plurality is unlike spoken language.

2. *Pictography: Writing as Accounting Device*

After four millennia, the token system led to writing. The transition from counters to script took place simultaneously in Sumer and Elam, present-day western Iran when, around 3500 BC, Elam was under Sumerian domination. It occurred when tokens, probably representing a debt, were stored in envelopes until payment. These envelopes made of clay in the shape of a hollow ball had the disadvantage of hiding the tokens held inside. Some accountants, therefore, impressed the tokens on the surface of the envelope

before enclosing them inside, so that the shape and number of counters held inside could be verified at all times (Fig. 1). These markings were the first signs of writing. The metamorphosis from three-dimensional artifacts to two-dimensional markings did not affect the semantic principle of the system. The significance of the markings on the outside of the envelopes was identical to that of the tokens held inside.

About 3200 BC, once the system of impressed signs was understood, clay tablets—solid cushion-shaped clay artifacts bearing the impressions of tokens—replaced the envelopes filled with tokens. The impression of a cone and a sphere token, representing measures of grain, resulted respectively in a wedge and a circular marking which bore the same meaning as the tokens they signified (Fig. 2). They were ideo-

grams—signs representing one concept. The impressed tablets continued to be used exclusively to record quantities of goods received or disbursed. They still expressed plurality in one-to-one correspondence.

Pictographs—signs representing tokens traced with a stylus rather than impressed—appeared about 3100 BC. These pictographs referring to goods mark an important step in the evolution of writing because they were never repeated in one-to-one correspondence to express numerosity. Besides them, numerals—signs representing plurality—indicated the quantity of units recorded. For example, '33 jars of oil' were shown by the incised pictographic sign 'jar of oil, 'preceded by three impressed circles and three wedges, the numerals standing respectively for '10' and '1' (Fig. 3). The symbols for numerals were not new. They were the impressions of cones and spheres formerly representing measures of grain, which then had acquired a second, abstract, numerical meaning. The invention of numerals meant a considerable economy of signs since 33 jars of oil could be written with 7 rather then 33 markings.

In sum, in its first phase, writing remained mostly a mere extension of the former token system. Although the tokens underwent formal transformations from three- to two-dimensional and from impressed markings to signs traced with a stylus, the symbolism remained fundamentally the same. Like the archaic counters, the tablets were used exclusively for accounting (Nissen et al. 1993). This was also the case when a stylus, made of a reed with a triangular end, gave to the signs the wedge-shaped 'cuneiform' appearance (Fig. 4). In all these instances, the medium changed in form but not in content. The only major departure from the token system consisted in the

creation of two distinct types of signs: incised pictographs and impressed numerals. This combination of signs initiated the semantic division between merchandise and numerosity.

3. Logography: Shift from Visual to Aural

About 3000 BC, the creation of phonetic signs—signs representing the sounds of speech—marks the second phase in the evolution of Mesopotamian writing, when, finally, the medium parted from its token antecedent in order to emulate spoken language. As a result, writing shifted from a conceptual framework of real goods to the world of speech sounds. It shifted from the visual to the aural world.

With state formation, new regulations required that the names of the individuals who generated or received the registered merchandise were entered on the tablets. The personal names were transcribed by the mean of logograms—signs representing a word in a particular tongue. Logograms were easily drawn pictures of words with a sound close to that desired (for example in English the name Neil could be written with a sign showing bent knees 'kneel'). Because Sumerian was mostly a monosyllabic language, the logograms had a syllabic value. A syllable is a unit of spoken language consisting of one or more vowel sounds, alone, or with one or more consonants. When a name required several phonetic units, they were assembled in a rebus fashion. A typical Sumerian name 'An Gives Life' combined a star, the logogram for An, god of heaven, and an arrow, because the words for 'arrow' and 'life' were homonyms. The verb was not transcribed, but inferred, which was easy because the name was common.

Phonetic signs allowed writing to break away, finally, from accounting. Inscriptions on stone seals or metal vessels deposited in tombs of the 'Royal Cemetery' of Ur, c. 2700–2600 BC, are among the first texts that did not deal with merchandise, did not include numerals and were entirely phonetic. The inscriptions consisted merely of a personal name: 'Meskalamdug,'

PUABI, QUEEN

Figure 5

or a name and a title: 'Puabi, Queen' (Fig. 5). Presumably, these funerary texts were meant to immortalize the name of the deceased, thereby, according to Sumerian creed, insuring them of eternal life. Other funerary inscriptions fostered even further the emancipation of writing. For example, statues depicting the features of an individual bore increasingly longer inscriptions. After the name and title of the deceased, followed patronymics, the name of a temple or a god to whom the statue was dedicated (in a dative form), and, in some cases, a plea for life after death, including a verb. These inscriptions introduced syntax and, therefore, brought writing yet one step closer to speech.

After 2600–2500 BC, the Sumerian script became a complex system of ideograms mixed more and more frequently with phonetic signs. The resulting syllabary—system of phonetic signs expressing syllables—further modeled writing on to spoken language. With a repertory of about 400 signs, it could express any topic of human endeavor. Some of the earliest syllabic texts were royal inscriptions, and religious, magic and literary texts.

The second phase in the evolution of the Mesopotamian script, characterized by the creation of phonetic signs, not only resulted in the parting of writing from accounting, but also its venturing out of Sumer to neighboring regions. The first Egyptian inscriptions, dated to the late fourth millennium BC, belonged to royal tombs (Bard 1992). They consisted of ivory labels and ceremonial artifacts such as maces and palettes bearing personal names, written phonetically as a rebus, visibly imitating Sumer. For example, the Palette of Narmer bears hieroglyphs identifying the name and title of the Pharaoh, his attendants and the smitten enemies. Phonetic signs to transcribe personal names, therefore, created an avenue for writing to spread outside of Mesopotamia. This elucidates why the Egyptian script was instantaneously phonetic. It also explains why the Egyptians never borrowed Sumerian signs. Their repertory consisted of hieroglyphs representing items familiar in the Egyptian culture and that evoked sounds in their tongue.

The phonetic transcription of personal names clearly played an important role for the dissemination of writing to the Indus Valley where, during a period of increased contact with Mesopotamia, c. 2500 BC, writing appears on seals featuring individuals' names and titles (Possehl 1996). In turn, the Sumerian cuneiform syllabic script was adopted by many Near Eastern cultures who adapted it to their different linguistic families and in particular, Semitic (Akkadians and Eblaites); Indo-European (Mitanni, Hittites, and Persians); Caucasian (Hurrians and Urartians); and finally, Elamite and Kassite. It is likely that Linear A and B, the phonetic scripts of Crete and mainland Greece, c. 1400–1200 BC, were influenced also by the Near East (Chadwick 1990).

4. *The Alphabet: The Segmentation of Sounds*

The invention of the alphabet about 1500 BC ushered in the third phase in the evolution of writing in the ancient Near East. The first, so-called Proto-Sinaitic or Proto-Canaanite alphabet, which originated in the

region of present-day Lebanon, took advantage of the fact that the sounds of any language are few. It consisted of a set of 22 letters, each standing for a single sound of voice, which, combined in innumerable ways, brought an unprecedented flexibility to transcribe speech (Healey 1991). This earliest alphabet was a complete departure from the previous syllabaries. First, the system was based on acrophony—signs to represent the first letter of the word they stood for—for example an ox head (*alpu*) was 'a,' a house (*betu*) was b (Fig. 6). Second, it was consonantal—it dealt only with speech sounds characterized by constriction or closure at one or more points in the breath channel, like b, d, l, m, n, p, etc. Third, it streamlined the system to 22 signs, instead of several hundred.

The transition from cuneiform writing to the alphabet in the ancient Near East took place over several centuries. In the seventh century BC the Assyrian kings still dictated their edicts to two scribes. The first wrote Akkadian in cuneiform on a clay tablet; the second Aramaic in a cursive alphabetic script traced on a papyrus scroll. The Phoenician merchants established on the coast of present day Syria and Lebanon, played an important role in the diffusion of the alphabet. In particular, they brought their consonantal alphabetic system to Greece, perhaps as early as, or even before 800 BC. The Greeks perfected the Semitic alphabet by adding letters for vowels—speech sounds in the articulation of which the breath channel is not blocked, like a, e, i, o, u. As a result the 27-letter Greek alphabet improved the transcription of the spoken word, since all sounds were indicated. For example, words sharing the same consonants like 'bad,' 'bed,' 'bid,' 'bud,' could be clearly distinguished. The alphabet did not subsequently undergo any fundamental change.

5. *The Modern Alphabets*

Because the alphabet was invented only once, all the many alphabets of the world, including Latin, Arabic, Hebrew, Amharic, Brahmani and Cyrillic, derive from Proto-Sinaitic. The Latin alphabet used in the western world is the direct descendant of the Etruscan alphabet. The Etruscans, who occupied the present province of Tuscany in Italy, adopted the Greek alphabet, slightly modifying the shape of letters. In turn, the Etruscan alphabet became that of the Romans, when Rome conquered Etruria in the first century BC. The alphabet followed the Roman armies. All the nations that fell under the rule of the Roman Empire became literate in the first centuries of our era. This was the case for the Gauls, Angles, Saxons, Franks and Germans who inhabited present-day France, England and Germany.

Charlemagne (800 AD) had a profound influence on the development of the Latin script by establishing standards. In particular a clear and legible minuscule cursive script was devised, from which our modern day lower case derives. The printing press invented in 1450 dramatically multiplied the dissemination of texts, introducing a new regularity in lettering and layout. The Internet catapults the alphabet into cyberspace, while preserving its integrity.

6. *Writing: Handling Data in Abstraction*

Beyond the formal and structural changes undergone by writing in the course of millennia, its evolution also involved strides in the ability to handle data in abstraction. At the first stage, the token system antecedent of writing, already abstracted information in several ways. First, it translated daily-life commodities into arbitrary, often geometric forms. Second, the counters abstracted the items counted from their context. For example, sheep could be accounted for by an administration, independently from their actual location. Third, the token system separated the data from the knower. That is to say, a group of tokens communicated directly specific information to anyone initiated in the system. This was a significant change for an oral society, where knowledge was transmitted by word of mouth from an individual to another, face to face. Otherwise, the token system represented plurality concretely, in one-to-one correspondence. Three jars of oil were shown by three tokens, as it is in reality. At the same time, the fact that the token system used specific counters to count different items was concrete—it did not abstract the notion of item counted from that of number. (Certain English numerical expressions such as twin, triplet, quadruplet and duo, trio, quartet, to refer to particular sets are comparable to concrete numbers.)

When tokens were impressed on the envelopes to indicate the counters enclosed inside, the resulting markings could no longer be manipulated by hand. In other words, the transmutation of three-dimensional counters into two-dimensional signs constituted a second step in abstraction. By doing away with tokens, the clay tablets marked a third level of abstraction since the impressed markings no longer replicated a set of actual counters. The invention of numerals, which separated the notion of numerosity from that of the item counted, was a crucial fourth step in abstraction. The signs expressing the concept of oneness, twoness, etc., allowed plurality to be dealt with in fully abstract terms. In turn, the phonetic units marked a fifth step of abstraction, since the signs no longer referred to the objects pictured, but rather the sound of the word they evoked.

Phonetics allowed writing to shift from a representational to a conceptual linguistic system. That it to say it enabled writing to leave the realm of real goods in order to enter the world of words and the ideas they stand for. Finally, the process that started with ideograms expressing concepts and phonetic signs

referring to the sound of monosyllabic words reached the ultimate segmentation of meaning with letters. As Marshall McLuhan (1997) defined it, the alphabet consisted of semantically meaningless letters corresponding to semantically meaningless sounds. The alphabet brought data handling to a final double-stepped abstraction.

7. *Conclusion: The Stability of Writing Systems*

The origin of the Chinese script and the development of Mesoamerican writing are still obscure. The Mesopotamian script, however, offers a well-documented evolution over a continuous period of 10,000 years. The system underwent drastic changes in form; gradually transcribed spoken language more accurately, and handled data in more abstract terms. The most striking universal feature of all writing systems, however, is their uncanny endurance, unmatched among human creations. The Chinese script never needed to be deciphered because the signs have changed little during the 3400 years of its recorded existence. It also always remained ideographic, merely inserting rebus-like phonetic complements in some characters. The Mesoamerican Maya phonetic glyphs preserved the symbolism initiated by the Olmecs over one millennium. Finally, when the last clay tablet was written in the Near East, c. 300 AD, the cuneiform script had been in use for three millennia. It replaced an age-old token system that had preceded it for over 5000 years; it was replaced by the alphabet that has prevailed for 3500 years.

Writing Instruction

The term 'writing' covers a huge range of activities, from, at one extreme, the motor processes in forming letters, to, at the other extreme, the creative mental processes involved in writing a novel. For present purposes, the term 'writing' will be restricted to referring to the cognitive and social processes involved in writing, and 'instruction' to referring to educational practice as it has been informed by research into these processes.

Contemporary approaches to writing instruction have their origins in the 1970s (see Nystrand et al. 1993 for a review of the development of writing studies during this period). Before this period, the overwhelming emphasis was on the text as a linguistic product, with research and instruction concentrating largely on identifying the distinctive features of exemplary texts and teaching these to students. In contrast, the defining feature of more recent research has been its emphasis on understanding the processes by which text is produced, and in particular, on the processes involved in creating the knowledge embodied in text. Writing, in this view, is not just a means of communication, but a vital tool for learning and thinking. During this period, understanding of the nature of the processes involved has expanded and, in some respects, changed considerably. Research has moved from an initial, almost exclusive, concern with the cognitive processes

within individuals, through a broader view of text as the product of social processes, to a mixed view, in which writing is seen as the product of an interaction between conflicting processes differing in the extent to which they involve adapting to the social context.

1. Writing as Problem Solving

Cognitive research on writing has been dominated by a view of writing as a form of problem solving, in which writing skill depends on the ability to think strategically about how best to achieve communicative goals. The most widely cited model in this area is Hayes and Flower's (1980) descriptive model of the cognitive processes in writing. Based largely on protocols of writers thinking aloud as they composed, the model identifies three basic components of the writing process, each of which can be further analyzed into more basic processes until they 'bottom out' in the basic cognitive operations studied by cognitive and experimental psychologists. The three processes are: planning, which involves setting goals, and generating and organizing ideas to satisfy them; text generation, which involves encoding ideas in language; and revision, which involves reading and editing the text that has already been produced. These basic processes are controlled by a monitor or central executive which is responsible for coordinating the processes as they operate on information stored in long-term memory, in response to the demands of the task environment. The key feature of the model is that the basic components of planning, translation, and revision are recursively applied processes rather than stages in a sequence of activities. Thus, each of the processes can, in principle, be called on just as much while jotting down notes before writing as while writing or rewriting the text itself. In consequence, the model is able to capture the dynamic interplay between different components at different points in writing. Hayes and Flower's subsequent work, with a variety of different collaborators, involved more detailed studies of the different subcomponents of the writing process. A useful review of the basic findings from this research, and a heavily revised version of the original model, can be found in the chapter by Hayes in a volume edited by Levy and Ransdell (1996).

Perhaps the most important consequence of this research was that it enabled a characterization of differences between expert and novice writers. (See Hayes and Flower 1986, for a review of their own findings, and Bereiter and Scardamalia 1987, for an influential model examining the development of children's writing, and procedures whereby this could be developed.) Bereiter and Scardamalia characterize the difference between novice and expert writing as a contrast between a knowledge-telling model of writing and a knowledge-transforming model of writing. Knowledge telling is typically employed by children and less experienced writers and is essentially a 'think-say' method of composing in which ideas are retrieved associatively from memory and then translated directly into text. Typically, there is little differentiation between components of the writing process, so that text is produced in a single draft with little preplanning or revision of the text. Even when explicitly instructed to plan before writing or to revise a text, planning tends to be restricted to the direct listing of content as it comes to mind, and revision to cosmetic changes to surface features of the text. The result is a text, which, although it may cover relevant material, is lacking a distinctive point of view or evidence of reflection upon ideas. By contrast, the kind of knowledge-transforming strategy employed by expert writers involves actively designing a text to satisfy communicative goals. Experts spend more time planning, both before and during writing, and develop more elaborate representations of the rhetorical problem to be solved, with the result that ideas are not just retrieved directly from memory but are actively constructed and evaluated with respect to this richer representation of the rhetorical problem. Similarly, revision becomes a goal-directed process involving global changes to the structure and content of the text, as well as correction of its surface features. The result is more reflective text, which shows more evidence of design, and in which ideas are selected and presented in the service of higher-level communicative goals. Moreover, in the process of working out how to communicate effectively with a reader, writers are also actively transforming their own knowledge.

According to this view of writing expertise, one of the main factors affecting writing performance is cognitive overload, arising from the fact that a complex set of processes has to be carried out in a limited-capacity working memory. In particular, the demands of translating ideas into well-formed text may consume resources required for higher-level reflective thought. Although this is particularly true for children, for whom even the basic mechanics of forming letters may be resource consuming, it is a pervasive problem stemming from the nature of the process itself. Research in this area has suggested that individual differences in performance are associated with differences in working memory capacity, and also that writers with greater knowledge of the different components of the writing process (metacognitive knowledge) are better able to manage the conflict between processes, and to switch attention between planning, translation, and revision at appropriate points. More specifically, Kellogg (1994) has shown that outlining before writing improves the quality of text compared to producing text in a single draft, and that this is because it enables writers to focus attentional resources on either planning or translation at different points in writing, rather than dividing up their mental resources among both processes. (For a

review of Kellogg's work on drafting strategies, see Kellogg 1994; for a model of working memory in writing, see Kellogg's chapter in Levy and Ransdell 1996.)

The second main strand of research in this area has focused on the reflective processes involved in the knowledge-transforming strategy itself. Bereiter and Scardamalia describe these in terms of an interaction between a content problem space, in which the writer works out the content to be included in the text, and a rhetorical problem space, in which the rhetorical problem is represented, and in which goals for the text are developed. In this view, while novice writers have the procedures for turning content into text, they lack the executive procedures required to translate problems encountered in rhetorical space back into goals to be achieved in content space. Accordingly, the crucial ingredient of writing expertise that the novice needs to learn is how to incorporate communicative goals into the writing process. Bereiter and Scardamalia suggest two broad ways in which this can be done.

First, the processes involved can be made visible by providing models of the writing process. For example, a teacher thinking aloud as they compose a text can demonstrate the formulation of goals during writing, and the search for, and evaluation of, content relevant to these goals. Second, children can be helped to incorporate more goal-directed thinking into their own writing using the technique of 'procedural facilitation.' This involves providing external prompts suggesting goals, possible courses of action, or relevant evaluatory criteria which the writer can consult moment by moment as they write a text. Gradually, as such procedures are internalized, this scaffolding can be removed, leaving the writer capable of carrying out the appropriate procedures unaided.

Teaching programs designed to increase metacognitive awareness of the components of writing and using methods such as modeling and procedural facilitation to develop more goal-directed thinking have shown strong effects on children's writing compared with control groups. (For examples of effective programs based on these ideas, see Englert et al. 1991, and the chapter by Graham and Harris in the collection edited by Levy and Ransdell 1996.)

2. *Writing as Social Action*

In both Hayes and Flower's original model and in Hayes's more recent revision of the model, the social nature of the writing process is represented by the inclusion of the audience and topic specification as features of the task environment, and by the inclusion of audience knowledge and more general discourse knowledge as part of the information stored in long-term memory (see Hayes's chapter in Levy and Ransdell 1996). One might expect, therefore, that there would be a complementary relationship between cognitive and social research on writing, with cognitive research focusing on the processes by which information is manipulated, and social research focusing on such factors as the relationship between the writer and their audience, or on elaborating on the nature of the conventions which make up the writer's discourse knowledge. In fact, social research has developed in part as a reaction against cognitive models of writing, and has led to the development of alternative theoretical approaches to the writing process which have had a strong influence on approaches to writing instruction.

Social critiques of problem-solving models take a variety of forms (see Cooper and Holzman 1989 for a fairly representative example). But at the heart of them all there is an underlying disquiet with the way in which problem-solving models treat individual elements of text as being constructed out of a stable set of cognitive processes and representations which can be explicitly manipulated by the writer. In particular, they question the extent to which content knowledge is stored independently of discourse knowledge, and dependent on explicit goal-directed processing, if it is to be realized as a complete social act. Instead, they treat each part of the text as an indivisible 'social act,' which cannot be further broken down into components which can be explicitly manipulated.

Within social approaches, then, the elements of a text are defined as social acts, and analyzed in terms of the functions they serve within a particular context, rather than in terms of the processes by which they are cognitively constructed. The direct determinant of the form of the text is the social environment in which writing takes place, and variations in writing performance are treated as variations in the way the writer responds to that environment. In this view, writing is not a uniform set of mental procedures, but rather a repertoire of practices, which varies widely across different contexts. This has a range of implications for research and instructional practice. First, research into writing takes a fundamentally different form, more like that of natural history, and involves predominantly qualitative methods, aimed at identifying the different kinds of act which are employed in specific contexts, relating these to the environment in which they occur, and examining how they vary across different contexts. Second, learning to write is no longer treated as a matter of learning to write in general, but rather of learning what practices or social acts are appropriate in a variety of particular contexts. Finally, the teaching of writing becomes a matter of creating authentic contexts that draw out approximations of the relevant social acts, which can then be shaped with practice into the appropriate form.

The most dominant of the various social approaches to writing is the field of genre studies. The fundamental idea here is that texts are not produced by individuals working in isolation, but rather by individuals as

members of communities employing a characteristic set of discursive practices to achieve the goals shared within the community. A genre in its most general form is a repeated set of social acts produced in response to a recurrent situation. It specifies the shared set of communicative purposes within a group or academic discipline, and shapes the schematic structure of text, as well as influencing choices of content and style. It provides conventions about what issues are appropriate, the forms of reasoning which are typically employed, and assumptions about the different roles of readers and writers within the community. Because these practices are conventional in form and vary widely across groups, novice writers cannot work them out from first principles, or from their experience within other discourse communities, but instead have to internalize them by immersion within the community. As they gain experience and begin to be able to use the genre as a guide to their own text production, so the genre also becomes a tool enabling them to construct their knowledge in the way characteristic of the particular discipline to which they are trying to gain membership. (See Freedman and Medway 1994 for an overview of work in the field.)

Research in this field has had a number of effects on writing instruction. First, it has led to a move away from the teaching of writing as a general skill by 'writing experts' toward the teaching of writing within disciplines by disciplinary insiders. Second, the content of teaching focuses on explicating the goals of the discipline and identifying the social acts within the text which enable the discipline to achieve its goals. Third, in line with the principle that text is a response to the social environment, a great emphasis is placed on designing tasks and creating environments which recreate as authentically as possible the social conditions and purposes of the community as it is in the 'real world.' (See Swales 1991 for a detailed example of the ways in which a genre approach can be applied to writing instruction.)

3. *Writing as a Knowledge-constituting Process*

Problem-solving models and social approaches to writing have both had a significant impact on writing instruction, and in many cases writing instruction draws eclectically on insights from both traditions. However, the theoretical conflict between them has not yet been resolved, with the result that research has tended to progress in parallel, with the two traditions using fundamentally different vocabularies to describe the writing process. There have been some attempts to combine the two traditions (see, for example, Flower 1994 for a relatively cognitive view, and Brandt 1992 for a more social-interactive approach), but these have not been generally accepted. More recently, however, there have been signs of a more integrated approach based on an alternative cognitive framework.

This has developed from a strand of research focusing on the implicit processes involved in text production itself, rather than on higher-level problem solving or social negotiation. (See Torrance and Galbraith 1999 for a collection of papers describing some of the empirical research involved, and for discussions of their theoretical implications for models of the writing process.) Galbraith, for example, has proposed a dual process model of writing, in which the more implicit and involuntary kinds of processing implied by social approaches to writing are combined with the more explicit and deliberate processes proposed by problem-solving models. In particular, this model invokes connectionist principles—involving parallel constraint satisfaction within a distributed representation of knowledge—to explain how 'social acts' can be formulated in the text as it is produced, without the need for the deliberate manipulation of separate components of information assumed by traditional problem-solving models. In this view, text production is an active knowledge-constituting process in its own right. Furthermore, and crucially, although the model accepts that the more explicit problem-solving processes assumed in traditional cognitive models of writing play an important role, it stresses that these operate on the output of the knowledge-constituting process, and highlights the potential for conflict between these two different processes.

This emphasis on text production as an active knowledge-constituting process, and on the conflicting nature of the writing process as a whole, is compatible with what has become a highly influential, although not universally accepted, approach to writing instruction, associated, in particular with the work of Elbow (1998; and see Belanoff et al. 1991 for a more recent review of work in this tradition). Elbow advocates the use of a multiple drafting strategy, in which the writer is encouraged to start writing by producing a spontaneous draft of their thoughts as they come to mind, without preplanning or attempting to impose organization on the text. Once a draft has been completed, revision involves identifying the main ideas that have emerged in the text, and these are used as the basis for a further draft of the text. This process of alternating between spontaneous drafts and more reflective revision continues until the text achieves a satisfactory form. Writers are also encouraged to engage in regular 'free-writing' exercises, as a means of providing them with direct experience of the generative properties of this form of writing, and to participate in peer feedback groups to gain direct experience of the effect of their writing on their readers.

This more recent research on text production can be seen, in part, therefore, as providing a theoretical rationale for some long-standing practices within writing instruction. But, in addition, in promising a deeper understanding of the implicit processes involved in text production, it may help to resolve the

division between social and cognitive approaches to writing.

Writing Process, Psychology of

The psychology of the writing process treats the cognitive and emotional dimensions of expressing private thoughts as public written symbols, including their neural basis and development. The kinds of writing done in schools, the workplace, the home, and elsewhere are diverse. Signing one's name, completing a form, drafting a routine letter, and composing a novel differ in their cognitive demands, but these and other writing tasks draw on common production systems. In this article, three aspects of the psychological processes underlying the production of an extended coherent text will be considered in turn. These are thinking, language, and memory.

1. Writing as Thinking

Writing involves systems for formulating, executing, and monitoring text. The seminal model of the writing process proposed that formulation involves planning content and generating sentences based on knowledge drawn from the writer's long-term memory (Hayes and Flower 1980). Planning a text entails generating ideas, organizing them, and setting goals to be achieved in the text. Translating ideas or sentence generation includes the subprocesses of speech, such as selecting appropriate lexical entries and assembling the constituents in the proper order. Reviewing the text involves reading and editing operations that detect faults at multiple levels of text structure, ranging from local mechanics to the coherence of the whole text. The writer must monitor whether the processes are successful and decide which writing process to engage at a given moment.

If one focuses on the reflective cognition seen in planning and reviewing, then writing looks like thinking. Composition studies in rhetoric and education in the 1970s stressed the similarity of writing to problem solving. Later composition studies shifted the focus to social cognition and stressed that thinking is situated within a community of other writers and readers.

1.1 Problem Solving

Planning, translating, and reviewing are constrained by the task environment and the writer's long-term memory. The topic, the type of text, the intended readership, and the text produced thus far constitute elements of the task environment, as do the writer's tools, collaborators, and deadlines. The task environment and long-term memory together pose the problems of content (what to say) and rhetoric (how to say it) that must be solved in order to produce a text.

Mature writers seek solutions to both the content and rhetorical problems posed by the writing task at hand, using a strategy called knowledge transforming (Bereiter and Scardamalia 1987). The writer gains insight into the ideas being formulated as a consequence of expressing them as text, actively transforming what they know about a topic as a result of

trying to write about it. Unlike the reflective problem solving of mature writers, young children fail to elaborate their thinking through the act of writing. They instead engage in knowledge telling. The task environment automatically cues children to retrieve an idea from long-term memory and then translate it into sentences. Writing continues in this manner until retrieval fails to provide relevant material. During adolescence, knowledge transforming begins to emerge as a complement to knowledge telling.

Data based on verbal protocols and other forms of introspection indicate that adult writers recursively attend to planning, translating, and reviewing processes. Although planning generally occurs more frequently in the beginning stages of a first draft and reviewing later, all three operations may be called upon at any point. One effective strategy for coping with the multiple demands of writing on working memory is to delay concerns about how ideas are expressed and focus on planning. This increases the number of ideas generated during planning (Glynn et al. 1982). Another effective strategy is to prepare an outline of ideas and their organization before composing a first draft. Advance outlining permits the writer to focus on translating ideas into sentences and can increase the fluency and quality of writing at least for short texts on familiar topics.

There are individual differences in the strategies preferred by adult writers (Kellogg 1994). Some prefer to plan and review in advance in careful detail, perhaps creating diagrams, outlines, and notes, before starting a first, relatively polished draft. This has been called by several names, such as the Planner or Mozartian strategy. Such writers transform their knowledge about the topic by tackling the content and rhetorical problems as part of prewriting. Others prefer to discover ideas and develop their thinking on a topic by actually writing about them in a rough draft and then later doing extensive revision. This goes by the name of Discoverer, Reviser, or Beethovian strategy. Surveys of faculty and graduate students have revealed that planning carefully and revising little is associated with higher productivity in academic writing. However, it is unknown whether particular kinds of texts are generated more readily with a discover and revise approach (e.g., creative writing), or why some writers prefer one approach to another while others adapt their strategy to the task at hand (e.g., personality traits).

Writing exposes not only the content of our thoughts but also our ability to think, remember, and articulate. Avoidance of writing can be a means of coping with the anxiety and other emotional reactions to expressing thoughts as public symbols. In writer's block, text production halts altogether, although reading and thinking about the task may continue. The prewriting phase can be lengthy and a useful time for reflection for any writer. But in writer's block, the prewriting activities become a way to procrastinate and no longer serve any useful purpose. Procrastination, excessive worrying, impatience, perfectionism, and evaluation anxiety characterize writer's block.

1.2 Social Cognition

Besides an act of problem solving, writing is inherently a social act. Texts are created to be read within a discourse community (Rafoth and Rubin 1988). The social aspects may be explicit, as in collaborative writing, or they may be implicit, as in the way an imagined reader shapes the writer's ideas and manner of expression.

Expert writers conform their texts to the expectations of their readers. This point is well illustrated in the publication style requirements of the American Psychological Association. The style demands an allegiance to the empirical method and so defines the psychologist's task as a writer. Conclusions must be hedged so as to avoid stepping beyond the limits of the data, creating an air of uncertainty atypical in the humanities. Disagreements are couched in terms of differences about appropriate methods or interpretations of data, never in the personal terms at times seen in literary criticism.

It is often through revision that writers make their texts accessible to readers. Immature writers fail to take their audience into account and revise effectively. Reading and editing the text are highly effortful for young writers, in part because of working memory limitations. The lack of thorough revision also stems from a failure to establish clear plans in the first place. Without explicit goals that include the needs of potential readers, young writers cannot detect problems in meeting those goals. Revising becomes little more than editing errors in spelling, punctuation, and other writing mechanics. Besides needing explicit representations of what they wrote and what they intended, writers further need a representation of how the text appears to their readers. Skilled writers can see their work from another person's perspective. Taking the perspective of another individual is an important milestone in social cognitive development in many domains, including written language production.

2. Writing as Language Production

Writing is an act of language production, too. However, speech production has received far more attention in psycholinguistics than writing, largely because the field of linguistics stressed the spoken over written word during the twentieth century. Psychological studies of literacy are also lopsided in that reading outweighs writing (for example, see *Reading Skills*). This asymmetry derives from the methodological difficulties of studying language production compared with comprehension.

In experiments on language comprehension, the inputs to the system can be controlled and the outputs carefully measured. What someone says or writes in response to an experimenter's prompt is, by contrast, unpredictable. Rather than experimentation, the natural observation of speech errors or slips of the tongue guided theories of speech production, and slips of the pen have likewise informed us about written spelling. Observations of pauses in handwriting—both their location and duration—have provided insights into writing as language production. Another alternative to experimental manipulations has been the use of neuropsychological case studies that correlate lesions in brain structure with difficulties in speaking, writing, or both.

From slips of the tongue and neuropsychology, much is known about the translation of ideas and their motor execution in speech (for example, see *Speech Errors, Psychology of*). Five levels of processing must be distinguished in sentence production. The message level corresponds to the planning of the ideas or propositions to be conveyed. Writers may start with only inchoate feelings or images that must be mapped onto propositional representations suitable for sentence production. Functional processing reflects the translation of propositions into the words or lexical items along with the grammatical roles to be played by various phrases. Positional processing continues translation by retrieving the lexical (e.g., phonological segments) and grammatical morphemes (e.g., inflections), and positioning these constituents in a hierarchical syntactic structure. Next, the phonological component completes translation in speech by specifying all aspects of the sound structure of the sentence, including its prosodic features such as stress patterns. Unlike speech, writing requires a graphemic representation (Caramazza 1991). Graphemes can be computed either from the visual appearance or orthographic code of a whole word or by applying rules for converting phonology to orthography in spelling out the word. The order of graphemes for spelling a word and the motor programs for controlling the musculature in typing or handwriting must be specified. In handwriting, for example, the size of the letters and their allographic form must be selected.

In crafting a written sentence, more care may be given to correctness and precision than in speech. Whereas sentence fragments are characteristic of speech, written language is expected to be well formed. The motor execution process, particularly with handwriting, is markedly slower than typical rates of speech production, and the writer is freed from the social awkwardness of pauses, allowing for both more intensive formulation and editing than would be found in most speech. The production of a single sentence in writing, then, is an intricate affair, dependent on multiple neurological structures. The inability to express a thought in writing, agraphia, usually occurs to some degree as a consequence of significant brain damage, regardless of its location. Specific disorders of central language systems, as in aphasia, or of motor systems, as in Parkinson's disease, cause agraphia, as does widely spread pathology, as in Alzheimer's disease.

But written language production entails more than the production of a sentence, more than appropriately arranged letters and words. A text is made up of multiple sentences that must be coherent at both a local level and a global level (for example, see *Memory for Text*). Local coherence is achieved by cohesive ties that link one sentence to another. To illustrate, anaphoric pronouns form a link between the pronoun and the noun to which it refers in the previous sentence (e.g., The *dog* chased the thief down the street. *He* barked fiercely all the way.). Local cohesion is necessary but not sufficient, however. All the sentences in a text must relate to one another so that the text is also globally coherent. An extended text must be organized both at the level of its microstructure and its macrostructure.

3. *Writing as Memory*

Without knowledge, writers cannot succeed at their task. Diverse kinds of knowledge must be available in long-term memory, retrieved when needed, and maintained in working memory as the writer plans, edits, and so on. In particular, writers must know much about their topic, content knowledge, and about the requirements of a well-structured text, discourse knowledge.

3.1 *Long-term Memory*

Content knowledge guides the generation of informative and interesting ideas. To develop a theme, writers must be able to retrieve ideas from long-term memory throughout the course of prewriting, drafting, and revising. An inadequate stock of content knowledge is one reason why student writing fails and professional writing succeeds. Just as expertise in a domain improves a reader's ability to comprehend a text, it also improves their ability to write in an interesting manner. For example, a high degree of knowledge about baseball enables writers to generate many more game relevant propositions in a narrative about a half inning of play (Voss et al. 1980). Although less knowledgeable writers are able to generate macrostructure propositions well, they fail to supply the necessary detail for the microstructure of the text. Including sufficient detail improves the reader's comprehension and opinion of the text.

Discourse knowledge guides the selection of relevant ideas and the organization of these ideas. The writer must know how to link clauses together using conjunctions, how to use pronouns so that their

reference is unambiguous, and how to choose between the use of the same word or a synonym in linking clauses. These and other cohesive devices must be learned for a writer to produce text that is locally coherent. Although it is often emphasized that people acquire the syntactic rules needed to support spoken language before a child enters school, learning to use cohesive links among clauses in a written text develops throughout the primary grades.

To create global coherence in narrative or other kinds of text, each of the individual sentences must help to develop the story, theme, or argument. Narrative schemas are acquired at a young age and are heavily practiced throughout childhood in listening to and telling stories. Knowing the typical sequence of events in a story helps the writer to select ideas that need to be included and provides an organizational format for expressing them. Teachers draw on the writer's knowledge of discourse by giving narrative assignments, and students show their strongest writing skills in the narrative mode. In contrast, schemas for argumentation and persuasion are weakly developed in all but the highest ability college students, and the quality of the average student's expository and persuasive writing is correspondingly poor (Britton et al. 1975). Regardless of the type of discourse being written, the more one knows about the requirements of global coherence, the better prepared one is to actually produce an effective and memorable text.

3.2 Working Memory

Representations must be not only retrieved from long-term memory, but they must be maintained in an active state for writers to plan, translate, and review. The details of how verbal, visual, spatial, and central executive components of working memory support writing processes are still unclear. But it is known that if working memory resources are diverted away from writing, then performance suffers. For example, when adult writers try to maintain a set of five words in working memory and concurrently transcribe orally presented sentences in French, they make subject–verb agreement errors (Fayol et al. 1994). The limitations of working memory are especially problematic for children learning to write. Planning suffers because they often forget the ideas recently generated and so repeat them again. Sentence generation suffers because the number of linguistic units that may be coordinated is limited. Furthermore, handwriting or typing are not as effortless in children as they are in adults. Children must divert working memory resources from formulation and monitoring to motor execution.

Finally, the extensive interactions among planning, translating, and reviewing processes found in mature writing are highly effortful. For example, in planning a text, an experienced writer sets rhetorical goals that are shaped by the intended audience. Such high-level planning has consequences for the selection of ideas to be included and even the choice of words in a given sentence. It is not the case that the writer plans the ideas of the text and then automatically translates them into sentences. The formulation and monitoring processes typically require working memory resources even when motor execution has been automatized. Given its demands, learning to write effectively requires instruction and practice throughout childhood and young adulthood. Whereas learning to speak occurs universally to a remarkable degree of mastery by five years of age, the demands of literacy greatly extend the language acquisition period.

Writing Systems

The term 'writing system' specifically denotes a set of symbols which is used for the graphic (written) recording of language. Its use is commonly synonymous with that of the term 'script,' and the two are used interchangeably; however, the notion 'writing system' may additionally include the conventions (or spelling practices) which dictate how the symbols of such a system can be used. Forms of graphic expression which may have some semantic content—such as cave drawings, petroglyphs, icons, and even sophisticated picture messages—but which do not or could not record a linguistic utterance directly, are thus excluded from the realm of *writing*. This is not to suggest that all writing systems are capable of recording language with equal precision, but that by definition writing systems are fundamentally linguistic.

1. *Types of Writing System*

Writing systems are of three fundamental types. Logographic systems consist of symbols, called logograms, which represent entire words. In opposition to the two remaining types, a logographic system is said to be nonphonetic to the extent that its minimal elements record the pronunciation of an entire word, rather than representing the individual phonetic components (consonants and vowels) which make up the word. The reality of the phonetic opacity of a logographic system becomes obvious when, for example, one works with an ancient language written with logograms. It may be possible to identify the meaning of a logogram by its context and other clues, but if the word which it represents is not also attested by a more revealing, phonetic writing system, its pronunciation will remain uncertain or unknown.

In contrast to logographic scripts, syllabic and segmental writing systems are said to be phonetic. A syllabic system consists of symbols, syllabograms, which have the value of a single syllable (although the syllables of a word spelled with a syllabic script may not actually line up with the syllabograms used in a one-to-one fashion). Syllabaries most commonly possess symbols of the value V (vowel) and CV (consonant + vowel); CCV, CVC, VC, among still other permutations, also occur, though less frequently.

Segmental writing systems are those which are composed of symbols representing individual sounds, and are themselves of two types. Consonantal scripts (or alephbeths) have symbols for consonants only. Alphabets are characterized by both consonant and vowel symbols.

The relationship of the three types of writing system to one another is in large measure of a historical, developmental nature. Consequently, the ensuing discussion will roughly follow a chronological scheme. As will be seen, most writing systems are not purely logographic or phonetic, but display some degree of hybridization.

2. *The Birth of Writing*

On the basis of presently available evidence, it is clear that human beings first began to record language in the ancient Near East. Until quite recently, the very earliest examples of writing were to be found among the archaeological remains of ancient Mesopotamia. However, recent discoveries may place the appearance of writing in Egypt at approximately the same time as its first attestations in the Fertile Crescent.

2.1 *Mesopotamian Writing*

Writing appears among the Sumerians of southern Mesopotamia in the late fourth millennium BC, and it is the Sumerians who are usually credited with the invention of writing, although it appears to be attested not much later in Syria (at Tell Brak) and in Iran (in texts preserving the poorly understood language of Proto-Elamite). The events which led to the advent of Sumerian writing are of course unknown, although there are various theories regarding its appearance. In the view of some scholars, the Sumerian invention of writing was a deliberate act, probably occasioned by the needs of palace administrators, and most likely in the city of Uruk where it is first attested. Others would see the process as being more of an evolutionary, in effect accidental, nature.

Regardless of the nature of the crucial step which led to the appearance of a system of writing on the Sumerian Plain, it seems undeniable that a precursor of the script is to be found in the clay tokens which had been in use for record keeping in Mesopotamia since at least 8000 BC. Some of these tokens actually resemble the commodity which they depict; others are of an arbitrary shape. By the latter half of the fourth millennium BC, some tokens had begun to be used as stamps, being impressed into moist clay tablets to produce administrative ledgers. Other tokens, those of more complex design, began to be etched freehand in the clay using a stylus. Schmandt-Besserat (1996) has argued that the appearance of Sumerian logographic writing was a natural evolutionary step following from the practice of inscribing token images (a process

linked, she argues, to the development of symbols for abstract numerals).

As suggested by their conjectured association with tokens, the earliest Sumerian symbols are pictographic; in other words, the symbols have a picture-like appearance. The curved lines of the pictographic characters began, however, to give way to more angular, conventionalized shapes. Such conventionalization of symbols is a common process in the evolution of writing systems, but in this instance that process and the direction of development were dictated by the medium and instruments of writing. The chief medium used throughout the history of Sumerian writing was clay. Sumerian scribes incised their pictographic characters in wet clay tablets using pointed styli. These, however, were replaced by a stylus with a triangular-shaped head which was simply pressed down into the clay, allowing for more efficient production of the symbols. Characters produced in this way have a characteristic wedge-shape (quite pronounced by the middle of the third millennium BC), and are hence called cuneiform (from the Latin *cuneus*, meaning 'wedge').

The value of early Sumerian symbols is logographic: each symbol represents an entire word. This logographic system is characterized by extensive homophony and polyphony. Homophony refers to the existence of multiple logograms having the same pronunciation, as they spell phonetically identical but semantically different words (homophones). Polyphony is, in a sense, the very opposite; the term denotes the practice of using a single logogram to spell two or more conceptually related but phonetically different words. For example, a single logogram is used to spell both DINGIR 'god' and AN 'heaven' (by Sumerological convention, Sumerian words are transcribed using capital letters).

A subset of the Sumerian logograms did double duty as semantic markers, called determinatives. These were written in conjunction with another logogram and were used, in effect, to provide the reader with a clue as to the meaning of that logogram, although their use is both conventionalized and optional. For example, the logogram GIŠ, 'wood,' is used as a determinative with logograms denoting items made of wood and tree names, such as ^{giš}ERIN, 'cedar' (determinatives are commonly transcribed as superscript). Similar devices also occur in the logographic Egyptian and Maya scripts, and in a somewhat different form in Chinese writing as well.

Sumerian is an agglutinating language with complex word structure involving the joining of multiple affixes in sequence. Logographic spelling thus obscures much word-internal morphology. Perhaps it was chiefly this inherent shortcoming which led to a significant typological alteration in the Sumerian logographic writing system—the introduction of syllabic symbols (by about 3000 BC). The method employed in devising such symbols was that of a rebus. Just as in an English rebus, a picture of the sun, for example, could be used to 'spell' the word 'son,' so Sumerian logograms began to be used to represent syllables having the same sound. Sumerian scribes used the syllabic symbols not only for representing grammatical elements but also as phonetic complements, syllabic characters used to distinguish between polyphonous logograms. For example, the logogram KA was used to spell 'mouth' as well as related notions such as 'word,' 'speak,' 'voice,' and still others; attaching the phonetic complement *-ma* (i.e., KA-*ma*) signals that the logogram is being used to spell INIM 'word.'

Late in the third millennium BC, texts begin to appear in the Mesopotamian archaeological world which are written in the cuneiform script of the Sumerians, but which are composed in a completely different language, the Semitic language Akkadian. The Assyrians and Babylonians, speakers of Akkadian, greatly extended the use of syllabic symbols, but continued to utilize Sumerian logograms and determinatives as well. The Akkadian cuneiform script was transmitted to other peoples of the Near East, providing writing systems for the Hittites and Luvians, the Hurrians and Urartians, the Elamites, and, in a significantly streamlined form, the Persians. The latest known Akkadian cuneiform texts were produced in the first century AD.

2.2 Egyptian Writing

While the pictographic symbols of the Egyptian hieroglyphic script are clearly graphically distinct from those of Sumerian, and the internal operation of the two scripts shows appreciable differences, similarities are undeniable. Both possess a logographic component; both have a phonetic component, which is commonly used for phonetic complementation; both expand the use of symbols through the rebus principle; both use a subset of logograms as determinatives. As it has appeared that the Egyptian script is first attested a bit later than the Sumerian (about 3100–3000 BC), as there is evidence for a precursor to the Sumerian logograms, and as Egypt was otherwise being influenced by Mesopotamia at the end of the fourth millennium BC, it has been commonly conjectured that at least the idea of writing, if not a writing system itself, came to the Egyptians from Mesopotamia. One possible difficulty with this scenario is that the Egyptian writing system appears well developed at its earliest attestation, perhaps suggesting some earlier, undocumented period of use.

Quite recently, moreover, small tags of bone and ivory, about postage-stamp size, have been discovered on which are carved symbols that, in some cases, bear similarity to later-known hieroglyphs. These have been dated to around 3400–3200 BC by the German archaeologist, Günter Dreyer, who discovered them,

and the symbols have been interpreted by Dreyer as writing. The dating of the tags and, perhaps more crucially, the interpretation of their markings as writing requires further investigation.

The most striking difference between the Egyptian and Sumerian systems is the nature of the phonetic component. In Egyptian writing the phonetic symbols do not have syllabic value, but represent consonants—either single consonants or sequences (although not necessarily phonetically contiguous strings) of two or three consonants. Twenty-six monoconsonantal symbols occur (including two variant forms), representing the individual consonants of the language; there are almost 100 biconsonantal symbols, and somewhat fewer triconsonantal. Biconsonantal and triconsonantal phonetic symbols are often themselves accompanied by one or more monoconsonantal phonetic complements. For example, the triconsonantal symbol *nfr*, spelling the Egyptian word meaning 'good,' is commonly used in conjunction with one or two monoconsonantal complements, as in the spelling sequence *nfr f r*.

3. *Consonantal Writing Systems*

During the early second millennium BC, a Semitic people living and laboring in Egypt developed a script for their own language by exploiting a single component of the Egyptian writing system. With the inspiration provided by the monoconsonantal Egyptian symbols, these people designed a fully phonetic and greatly simplified writing system which consists entirely of symbols for individual consonants. The first evidence of the script, called Proto-Sinaitic, came to light in the early twentieth century with Sir Flinders Petrie's excavations of Egyptian turquoise mines at Serabit el-Khadim in the Sinai; hence the name. Quite recently, additional examples of Proto-Sinaitic writing have been discovered near the ancient city of Thebes, at Wadi el-Hol, perhaps dating back to as early as 1900 BC.

The method which the adapters employed in turning the Egyptian script to their own use was dubbed the acrophonic principle by the British Egyptologist Sir Alan Gardiner. The values assigned to the phonetic characters of this earliest Semitic script—characters of pictographic form—were determined by the initial consonant of the Semitic word for the symbol depicted, rather than by any phonetic value associated with a corresponding Egyptian symbol. For example, the Egyptian hieroglyphic symbol resembling waves of water and used in the Egyptian system as a monoconsonantal symbol with the value /n/ was assigned the value /m/ in the Proto-Sinaitic script, as the word for 'water' in the Semitic language of that script began with /m/. The Proto-Sinaitic character for /n/, on the other hand, was based on the Egyptian symbol representing /dŽ/, a hieroglyph depicting a serpent, and received its Semitic value from the initial consonant in the Proto-Sinaitic word for 'snake.'

Proto-Sinaitic is one particular form (the earliest by the interpretation of an origin within Egypt) of a more broadly, if meagerly, attested consonantal script called Proto-Canaanite, found at several sites in Syria-Palestine. This Proto-Canaanite script is the immediate ancestor of the Phoenician script (appearing in the eleventh century BC), which is in turn the source of the ancient Hebrew (*ca.* ninth century) and Aramaic (*ca.* eighth century) writing systems (the Hebrew language began to be written with the Aramaic script during the sixth century BC, although the Samaritan sect continued to use the old Hebrew letters, and continues its liturgical use to the present day). The Aramaic script gave rise to the writing system of Syriac (*ca.* first century AD, and late enough to be influenced by the Greek alphabet) and, through the particular Aramaic script used by the Arab Nabateans, to the Arabic writing system (*ca.* fourth century AD).

Proto-Canaanite writing also served as the inspiration and model for the script of the ancient Levantine city of Ugarit. The Ugaritic writing system, however, departs markedly from the other Canaanite scripts in that its symbols are of cuneiform shape. It thus represents something of a hybrid writing system, combining the consonantal nature of Proto-Canaanite with the graphic form of the Mesopotamian scripts, although some scholars have argued that the shapes of the Ugaritic consonantal characters were themselves modeled on the Proto-Canaanite symbols but executed with the cuneiform stylus. The Ugaritic writing system also differs from other Canaanite scripts to the extent that it does not consist wholly of consonantal characters, but includes in its graphemic inventory three CV syllabic symbols, representing a glottal stop followed by the vowels /a/, /i/, and /u/.

Yet a different Semitic writing tradition would descend from the Proto-Canaanite script. In the south of the Arabian peninsula a distinct consonantal script had appeared by at least the sixth century BC, and certainly had begun to develop several hundred years earlier. An interesting feature of the Old South Arabian script is that the order of its letters departs from that of Phoenician and the consonantal script of Ugarit. However, an abecedary found at the Palestinian site of Beth Shemesh, consisting of consonantal cuneiform characters like those in use at Ugarit, shows the same letter order as found in the Old South Arabian script. The consonantal script of South Arabia spread northward to be adapted for use by early North Arabian languages (distinct from Arabic) and westward to the horn of Africa, where it was employed for writing the Semitic language of Ethiopic. Interestingly, the consonantal script of Ethiopic had undergone a significant metamorphosis by the fifth century AD, becoming a syllabary of almost 200 CV symbols.

4. Mediterranean Syllabaries

4.1 Crete

At about the time a Semitic people resident in Egypt were fashioning a consonantal script out of Egyptian hieroglyphs, three writing systems emerged among the Minoans of Crete. Probably the first to appear was the pictographic script called Cretan Hieroglyphic. Dating back to about the eighteenth century BC is a second Minoan script, attested on only a single document, the Phaistos Disk. A third script, also appearing in the eighteenth century and likely to be descended from Cretan Hieroglyphic, is the one that was dubbed Linear A by Sir Arthur Evans, the British archaeologist who excavated the Minoan city of Knossos early in the twentieth century. The name refers to the linear nature of this script's symbols in contrast to the pictographic quality of symbols in the other two Minoan scripts. None of these ancient Minoan scripts has yet been deciphered by modern investigators, although recent work on Linear A may suggest that it records an Indo–European language of the Anatolian subfamily (an idea first proposed in the mid-twentieth century by the British classicist and linguist L. R. Palmer). Cretan Hieroglyphic is possibly a syllabic script, as is probably that of the Phaistos Disk; Linear A is certainly a syllabary.

In his excavations at Knossos, Evans unearthed documents written in yet a different script. Bearing an obvious similarity to Linear A, this writing system was labeled Linear B. In 1952 the Linear B script was successfully deciphered by Michael Ventris, a British architect working in collaboration with the classicist John Chadwick. The language of the Linear B documents turned out to be Greek—that dialect used by the Mycenaean Greek culture of the second-half of the second millennium BC. The identification of the language of the Linear B script was made particularly difficult by the seeming unsuitability of the script for spelling that language. The great majority of the symbols of this syllabic writing system are of the type CV. As Greek has many word-internal CC sequences and word-final consonants, spelling practices were devised which in some cases required the use of CV symbols for spelling consonants only (with no following vowel), and in some cases resulted in a consonant not being spelled at all. The basic strategy for spelling consonant sequences is one which coopts a phonological property of the Greek language, namely the relative sonority of consonants. It is the general case that a consonant is written when it precedes a consonant of greater sonority (such as a stop occurring before a fricative), utilizing the CV symbol whose vocalic component is identical with the vowel which follows the consonant sequence, but is not written if the ensuing consonant is of less sonority (such as a fricative before a stop). In either case, the second consonant is written (with the appropriate CV symbol). Word-final consonants are not written and this practice appears to be a further expression of the sonority-based strategy.

4.2 Cyprus

There is evidence for writing on the eastern Mediterranean island of Cyprus as early as the middle of the second millennium BC. The writing system in use is preserved in distinct forms called Archaic Cypro-Minoan, and Cypro-Minoan I, II, and III (although the last type is actually attested in the documentary remains of the city of Ugarit, on the neighboring Levantine coast, and not on Cyprus itself). In spite of the fact that none of the three has yet been deciphered, the formal similarities between these scripts and those of Minoan Crete clearly suggest that the Bronze Age Cypriot writing system had its origin in the Cretan scripts.

Cyprus was a key locale lying along the trade routes which stretched from Greece to the east, and certainly for this reason there had been a Greek presence in Cyprus during the Mycenaean era; however, the Greek population of Cyprus increased dramatically as refugees fled the conflagration which brought an end to the Mycenaean civilization in the Greek homeland. The earliest remains of Greek writing in Cyprus come from the middle of the eleventh century BC, and the system of writing used was that of the Cypriot Syllabary. This syllabary, while probably based graphically upon Cypro-Minoan 1, is obviously closely affiliated with the Mycenaean script. Like Linear B, the Cypriot Syllabary is composed predominantly of symbols having the value CV. The same problems of representing word-internal consonant sequences and word-final consonants which Linear B scribes faced also plague the Cypriot Greek writing system; and the solutions to these problems are virtually identical to those utilized by the Mycenaeans, being based upon the relative sonority of Greek consonants. The notable difference between the two systems in this regard is that the Cypriot writing system makes much more limited use of the CV-deletion strategy than does Linear B. In most instances in which the first of two consonants is of greater sonority, the Cypriot strategy is to write that consonant (and not to refrain from writing it, as in Linear B) using a CV symbol whose vocalic component is identical to the vowel which precedes the consonant sequence.

5. The Alphabet

5.1 The Greek Origin

It was the Greeks who created the first segmental writing system to represent not only consonants but vowels as well. The raw material for the Greek

alphabet was provided by the consonantal script of the Phoenicians. As there was both a significant Phoenician presence on the island of Cyprus, and a vibrant tradition of Greek literacy, Cyprus is a *de facto* likely candidate for the place at which the Greek alphabet came into existence, probably in the early eighth (or possibly late ninth) century BC. There are, moreover, particular features of the early Greek alphabet which are not motivated within that segmental script, but which are motivated within the Cypriot Syllabary. For example, the biconsonantal symbol *xi*, representing the sequence of /k/ + /s/, is unnecessary within a segmental script that has both a *k*-symbol (*kappa*) and an *s*-symbol (*sigma*). Within the Cypriot Syllabary, however, *ksV* symbols are idiosyncratically required by the strategy of consonant cluster spelling which is based upon the relative sonority of consonants. Cypriot Greeks appeared to have transferred this and other features from their syllabic script to the newly devised alphabet.

For vowel symbols, the Greeks utilized Phoenician consonantal characters which were not required for writing Greek. Thus, Phoenician *aleph*, symbol for a glottal stop (which sound Greek did not possess phonemically) was assigned the Greek value /a/ (the Greek letter *alpha*). Phoenician *he*, spelling the glottal fricative /h/, was used by the Greek adapters to record mid front (*e*) vowels (*epsilon*; for writing Greek /h/, Phoenician *ḥet* was employed, the symbol for a voiceless pharyngeal fricative /ħ/). To write mid back (*o*) vowels (*omicron*), the Greeks tapped Phoenician *ayin*, which represented a voiced pharyngeal fricative /ʕ/. Phoenician *yod*, spelling the palatal glide /y/, and *waw*, representing /w/, were assigned the Greek values /i/ (*iota*) and /u/ (*upsilon*) respectively.

5.2 The Etruscan Alphabet

Following rapidly upon its creation, the alphabet was widely disseminated throughout the Greek world, developing many local varieties. In the south of Italy, Greek colonists passed their western Greek alphabet on to a non-Indo-European people of Italy, the Etruscans, in the seventh century BC. As the Etruscan language lacked voiced stops, the Greek letters representing such sounds, *beta* (/b/), *delta* (/d/), and *gamma* (/g/), were not needed for that purpose. The first two letters would disappear from the Etruscan alphabet, although *gamma* was retained and used for spelling the voiceless stop /k/ when it occurred before a front vowel. The Etruscans used Greek *kappa* for /k/ before /a/ and Greek *qoppa* for /k/ before the high back vowel /u/. In turn, the Etruscans transmitted the alphabet to other peoples of Italy.

5.3 The Roman Alphabet

Among those places to which the Etruscan writing system came was the city of Rome—a singly significant step in the history of the alphabet. For a time, the Romans continued the Etruscan practice of using three different symbols to represent the velar stop /k/ in its various phonetic contexts. However, *C* (from Greek *gamma*) was eventually used regularly for /k/ as well as for /g/ (*K*, Greek *kappa*, continued to be used for a very few words and *Q*, Greek *qoppa*, was employed before *V* for spelling /k^{w}/). By the third century BC, a variant form of *C* had been introduced, namely *G*, for writing the voiced velar stop /g/. However, as *G* was assigned the alphabetic position held by Greek *zeta* (spelling the early Greek sequence /zd/, later /z/), which was not required for spelling Latin, it has been argued that *zeta*, not *gamma*, provided the raw material for the creation of the new letter *G*. Later, in the first century BC, with the influx of much Greek vocabulary, both *Y* and *Z* (for Greek /ü/ and /z/ respectively) were appended to the Roman alphabet.

5.4 The Alphabet Abroad

The alphabet would make its presence known, directly and indirectly, throughout the European continent and beyond. The fragmentary remains of Celtic writing from continental Europe are attested in alphabetic scripts—Etruscan, Roman, or Greek (aside from the Hispano-Celtic inscriptions written in a curious script which is part syllabic, part alphabetic). Moreover, the 'native' writing systems of both the ancient Celts of Britain and Ireland, and of the Germanic peoples of Europe are alphabetic traditions, although formally distinct from both the Greek and Roman scripts, and strikingly so in the case of Celtic Ogham, with its characters of oblique and right-angle lines. Nevertheless, it is undoubtedly the case that both Ogham and the Germanic runes found their inspiration and model in the Mediterranean alphabets. When in the fourth century AD the Gothic Bishop Wulfila translated portions of the Bible into his Germanic language, he used an alphabetic script of his own design, based chiefly on the Greek alphabet.

The spreading of the Christian faith and the effort to ground believers in the biblical texts were—far beyond Wulfila—fundamental factors in the evolution of alphabetic writing systems. The Roman Catholic Church played a key role in the introduction and eventual establishment of the Roman alphabet across much of the European continent. Carried by the colonizing European nations, this writing system would be transported around the world, being utilized for writing European languages on all six of the populated continents, and adapted for spelling indigenous languages of Asia and Africa, as well as providing raw material for the symbols of the Cherokee syllabary of North America.

In the ninth century AD, Greek missionaries led by Saint Cyril and Saint Methodius developed writing

systems, based on their own Greek alphabet, for translating the Bible into the language of south Slavic converts. One of these scripts, the Cyrillic alphabet, thrived and is the predecessor of the alphabetic scripts of various modern Slavic languages, most notably Russian.

The alphabets of both Armenian and Georgian are traditionally attributed to the fifth-century cleric, Saint Mesrop. These writing systems were based at least partially on the Greek alphabet, but their creator may have also drawn upon a Semitic consonantal script.

6.1 *The Indian Syllabaries*

The earliest attested writing system of India is the script of the Indus Valley civilization, dating back to *ca.* 2500 BC. Many of the symbols are of a pictographic nature, and the number of symbols identified suggests that this writing system is logographic, possibly partially syllabic. It is, however, presently poorly understood and does not appear to have been the source of the Indian syllabaries which appear in the third century BC. These scripts, Kharoshthi and Brahmi, probably developed from the Aramaic consonantal writing system. Of the two, only Brahmi appears to have survived late antiquity; its perhaps best-known form being Devanagari, the writing system of Sanskrit, as well as that of Hindi and other modern Indo-Aryan languages.

Devanagari differs notably from the Mediterranean and Mesopotamian syllabic writing systems in that rather than having a distinct symbol for each possible consonant + vowel combination, Devanagari consists of a basic set of CV symbols having the vowel value -a (i.e., Ca symbols). These CV symbols can be assigned different vowel values (Ci, Cu, etc.) by the addition of diacritic strokes (this is essentially the same strategy utilized by the Ethiopic syllabary, which traces its origins to a Semitic consonantal writing system, as apparently do the Indic scripts). Devanagari also has the capacity to transform basic CV symbols into ones representing more complex consonantal components (CCV, CCCV, etc.) through the use of conventionalized ligatures. Such ligatures consist essentially of a Ca symbol (representing the final member of the consonant cluster) to which a form, often highly abbreviated, of one or more other Ca symbols is attached. Word-final consonants are spelled utilizing the appropriate Ca symbol beneath which a diacritic mark, called virama, is placed, revealing to the reader that the symbol is to be read with no vowel component.

The Indian syllabaries were spread through much of Central and Southeast Asia, giving rise to writing systems for numerous languages. Not only does the Tibetan script trace its roots to India, but also the writing systems of Javanese, Thai, Burmese, Lao, and Khmer.

6.2 *Chinese Writing*

The earliest evidence for writing in China is provided by the Shang-dynasty oracle-bone inscriptions of *ca.* 1200 BC. There is no clear evidence that writing developed in China under the influence of any then existing writing system; as in Mesopotamia (and perhaps in Egypt), writing seems to have appeared *de novo*. Like the earliest Mesopotamian writing system, the early Chinese script is pictographic with each

symbol representing an entire word. Moreover, as in both Mesopotamia and Egypt, the Chinese writing system is one which multiplies the value of its characters utilizing the rebus principle; and one which utilizes semantic markers to minimize graphic ambiguity. In China, however, these markers were commonly combined with the associated characters to produce compound symbols of two components—one signaling pronunciation, the other meaning. The fundamental logographic nature of Chinese writing has been preserved to the present day, and the inventory of logographic characters has steadily increased. While approximately 60,000 distinct characters are currently identified, about 2,500 occur in common use.

6.3 Japanese Writing

The modern Japanese writing system is quite complex, probably the most so of modern scripts. The earliest attested examples of Japanese writing (*ca.* eighth century AD) are executed in Chinese script. However, by the end of the ninth century, two Japanese syllabaries had appeared, evolving out of the practice of using certain Chinese characters as phonetic symbols. Both of these syllabaries remain in use alongside kanji, essentially logographic symbols originating in Chinese characters; in the contemporary script, a single such symbol can have multiple values. The syllabary called katakana is utilized for scientific terms, for foreign loans, for indicating emphasis, among still other uses. Modern hiragana is used for spelling grammatical particles and affixes associated with kanji.

6.4 Korean Writing

As in the case of Japanese, the Korean language was first written with Chinese characters. It was in the fifteenth century AD, according to Korean tradition, that the Korean alphabetic writing system of Han'gul was invented. Credit for this script—the world's only alphabetic writing system which may not trace its roots to the Greek alphabet—is given to Sejong, a Korean king. Han'gul is a highly efficient and phonetically transparent script. Its various consonantal symbols are purported to have been designed to represent schematically the articulatory position of the tongue in producing the consonant sounds of Korean. While Han'gul is alphabetic, consonant and vowel characters are written together in such a way as to form orthographic blocks corresponding to phonetic syllables.

7. Writing in Mesoamerica

There is at least a third region of the world, in addition to China and the Near East, where human beings appear to have designed a means of writing without prior knowledge of any such thing, namely Mesoamerica. While the study of ancient Mesoamerican writing is still at an early stage, significant strides have been made since the 1970s. Of the several Mesoamerican scripts currently known, the best attested and best understood is that of the Maya, who were writing by at least the third century AD. In its fundamental characteristics, the Maya writing system is much like those of the Sumerians and Egyptians. The script's pictographic symbols, or glyphs, are logographic and syllabic in value. The latter type is used both in conjunction with logograms as well as for the phonetic spelling of words. In addition, the Maya system makes use of determinatives, like the Sumerian and Egyptian systems, to provide semantic guidance to the reader.

Writing Systems, Psychology of

Although the psychological study of *reading* and the psychology of *language* are well established domains of research and theory, the *psychology of writing systems* and their uses, *literacy*, are relatively recent additions to the cognitive sciences. The central goal of the psychology of writing systems is to bring these two, hitherto independent, fields of study into conjunction, allowing both to be seen in a new light.

Writing systems have been neglected in psychology for two reasons. First, twentieth century linguistics has focused almost exclusively on speech, consigning writing merely to a way of recording. The study of writing was left to specialist domains such as epigraphy and classical studies. Nonetheless, important studies of writing were produced, that by Gelb (1963) providing the foundation for more recent work. Second, only the alphabetic writing system was the object of psychological studies of reading, leaving the impression that other writing systems were primitive and scarcely worth careful study.

In the period since the 1960s, the two fields, the psychology of reading and the psychology of language, have begun to converge to produce several lines of new research and theory. These relations make up the major sections of this article.

1. Relation Between Speech and Writing

Making marks which can serve mnemonic and communicative purposes is as old as human culture itself. Writing systems are a subset of such marks which, typically, represent aspects of linguistic form. Sampson (1987) provided an abstract classification of types of writing system. Some systems, *semasiographic* systems, represent meanings without any direct link to spoken form. Historical examples include the so-called 'picture writing' of American Indians, more modern ones include systems of highway signs and mathematical symbols. Some writers (Coulmas 1989, Harris 1995) consider such nonspeech sign systems as full writing systems, claiming that what makes a writing system is its adequacy in conveying information visually rather than its purported links to speech.

Logographic scripts are linguistically based but the spoken elements represented are meaningful units, primarily words and morphemes. A clear example of such a script is Chinese in which morphemes which sound identical are often represented by entirely dissimilar graphic characters, although some theorists (de Francis 1989) insist that any full writing system is phonologically based, at least to some extent.

Syllabaries are scripts which represent spoken patterns by signs for syllables. Thus *ka*, *ke*, *ki*, *ko* would be written with the same graphic sign. Arabic and Hebrew are modern examples.

Finally, *alphabets* employ a separate mark to represent the consonant and vowel segments of a syllable, roughly, the phonemes of the language. These categories of writing systems are generic types; no living writing system is based exclusively on one type of sign. Thus in English script, signs represent both phonemes by means of letters and words by means of spaces between letter groups. Japanese writing uses Chinese logographs (Kanji) to represent the stems of content words and a completely different syllabic script (Kana) to represent grammatical morphemes and inflections (Taylor and Taylor 1995).

In one sense, the history of scripts reflects the discovery of increasingly subtle aspects of speech, going from meanings to analytical constituents of speech. Yet contrary to the evolutionary view (Gelb 1963), many researchers (Gaur 1987, Sampson 1987, Olson 1994, Harris 1995) have argued that these so-called progressive changes merely reflect the impact of borrowing a script invented for one language to represent a completely different language. The consequence of such borrowing was the discovery of previously ignored properties of speech, word signs, syllable signs, and phoneme signs.

2. Writing Systems and Reading

As different types of writing systems bear distinctively different relations to speech, learning to read and write

them call upon different cognitive activities. Semasiographic systems found in Ancient Mesoamerica, namely the Mixtec and Aztec systems used until the conquest for record keeping, depended highly on rich factual knowledge; one had to know what the inscription was about before one could read it. Further, it depended heavily upon interpretation as the inscriptions allowed variable readings. Indeed, there is no categorical difference between the writing and drawing. Nineteenth-century Canadian Blackfoot Indians, for example, depicted 'the year that horses got drowned' by means of a circle (representing a lake) and four stick-drawings of horses superimposed on the circle. Such a chronicle records an important cultural event but not the linguistic form of its description. That is why it allows such variable readings.

All other so-called full writing systems map on to or represent spoken forms and learning to read each of them requires a somewhat different orientation to the script. Scribner and Cole (1981) found that their Vai subjects in Liberia in learning to read a syllabic script became adept at analyzing their speech into syllabic units but failed to analyze their speech into words. Others have found that the ability to manipulate phonemes was tied to learning to read an alphabet. Read et al. (1986) found that Chinese readers of traditional character scripts could not detect phonemic segments whereas those who could read Pinyin, an alphabetic script representing the same language, could do so.

Ample empirical evidence exists to show that it is acquaintance with an alphabetic script that is critical to the acquisition of awareness of the phonological properties of the language (Morais et al. 1979, Vernon and Ferreiro 1999). Concepts of words as lexical entities, similarly, have been shown to be tied to concepts of words as written entities (Olson 1994). Concepts of sentences, needed for the mastery of punctuation, are acquired at even more advanced levels of literacy. Conceptual development in children is, in part, the consequence of the acquisition of these systems for representing language (Vygotsky 1986).

Much confusion about the cognitive and social implications of writing and reading arises from a failure to recognize that modes of reading and interpretation do not inevitably arise from simply learning to identify words and letters. The history of writing is largely a history of inventing devices, such as punctuation and text structures, as well as rules for interpretation that have taken sometimes millennia to develop. A dictionary itemizing all the words of a language is a recent, literate invention. The very idea of fixity of a text is not inevitably attributed to writing and printing but to a specialized set of conventions for interpreting texts and institutional structures for preserving them (Johns 1998). However, once procedures had been developed for the systematic interpretation of Scriptural texts, it was found that such procedures were also suitable for the interpretation of the 'book of nature.' Scientific epistemology, it has been argued, is a form of applied hermeneutics (Olson 1994).

3. *Theories of Reading Alphabetic Scripts*

Assumptions about the relation between script and language have given rise to considerable, well-publicized, differences of opinion and differences in reading theory. One group emphasized the recognition of meaning of written expressions in ways analogous to the recognition of meaning in oral forms. That is, written language is seen as an alternative to spoken language each with their peculiar and distinctive perceptual and cognitive processes but with a common goal of meaning construction, hence the label Whole Language.

The other group, credit for which is often given to Alvin Liberman and Isabel Liberman of the Haskins Group at Yale University, is that reading is essentially a metalinguistic activity in which readers must find mappings from the written form to aspects of their implicit knowledge of speech (Olson 1994, Adams et al. 1998). Evidence on the importance of word and phoneme segmentation, two forms of metalinguistic knowledge, to learning to read and write tends to favor the metalinguistic theory of reading (Stanovich 1986, Lundberg et al. 1988), that is, the theory that reading is not a matter of mapping signs to meanings but rather a matter of mapping visual signs to aspects of oral speech and hence on to meaning. It is this metalinguistic theory of reading that helps to explain not only why learning to read brings aspects of speech into consciousness but also why reading and writing may contribute to a new and distinctive mode of thought in certain social and institutional contexts.

4. *Writing Systems and Thinking*

Nineteenth-century theorists took the view that writing and literacy had the general effect of making thought more logical and formal. The recognition of the fact that there are many types of writing systems and that even those different types may be read in very different ways (Saenger 1997) has made such general claims problematic, as has the dispute as to the meaning of literacy, some identifying it with the basic skills of reading and writing (Scribner and Cole 1981) and others with the evolved products of particular literate cultural traditions (Goody 1968, Olson 1994).

Although there is wide agreement on the 'psychic unity of mankind' ('They are just like you and me,' as Jack Goody once put it), and there is wide agreement that all languages are *in principle* capable of expressing all nuances of meaning, nonetheless patterns of thought vary widely from culture to culture and context to context, so much so that it is not uncommon

to despair of finding interesting cognitive differences attributable to writing or to a written tradition. Mathematics, the epitome of a written tradition, is sometimes seen as basically equivalent to practical computations, so-called street math.

On the other hand, cultural historians have asserted the cultural and psychological implications of writing and literacy, arguing, for example, that the medium of representation is the most important aspect of the message (McLuhan 1962), that writing separated the knower from the known (Ong 1992), that scriptal changes caused the origins of modern silent reading (Saenger 1997), and that writing allowed the formulation of modern conceptions of logic and mathematics (Goody 1968).

The metarepresentational theory of reading gives new credence to these more radical views. Writing and reading a linguistically based script, on this view, are an exercise not only in meaning, but also in consciousness and discourse about language, that is, about units of sound, units of meaning, words and structural units, sentences. Literacy on this view is seen as instrumental to discourse about word meaning, sentence meaning, and to other aspects of form which may be *mentioned* rather than *used* in discourse. This metarepresentational shift invites talk not only about particular words and sentences independently of their use, but also about other metarepresentational properties, such as *truth*, *logical form*, and *aesthetic goodness*. Furthermore, it allows mathematics to be clearly distinguished from 'street math,' the former being concerned with number rather than quantity. In the former, a number is expressed in the singular: *five* is more than *four*. In the latter, quantity is expressed as plural: I have seven apples, *five* are red. Only the former is metarepresentational, that is, mentioned rather than used, and consequently an object of thought in its own right.

Furthermore, writing is instrumental to thinking in general as a form of metalinguistic knowledge, that is, knowledge 'about' the lexical, grammatical, and logical properties of the language.Vocabulary knowledge, for example, is both greatly extended by reading (Anglin 1993), and reflective knowledge about words, as required for judgments of synonymy, for example, serves as a major aspect of measured intelligence in a literate society (Stanovich 1986). Formal reasoning tasks which require judgments of validity rather than truth or agreement, too, appear to be related to literacy, especially the specialized literacy of schooling (Ong 1992).

In order to account for such effects ranging from phonological awareness to awareness of sentence meaning (as opposed to what a speaker means by the sentence), Olson (in press) has proposed that writing be seen as quoted speech, and that reading and writing be viewed as learning to deal with quoted utterances rather than with ordinary direct utterances. This associates writing with a special feature of language known as reflexivity and as roughly equivalent to the use–mention distinction and language–metalinguistic distinction. Thus, in writing and reading one is not merely using an expression but quoting and thereby mentioning a linguistic form. The special interpretation called for in such a context depends upon the special properties of the form, its 'linguistic meaning' or 'sense,' rather than its referential meaning as well as allowing for judgments of similarity of meaning and judgments of logical entailments. Some writers such as Havelock (1982) and Ong (1992) argue that 'all elaborate, linear, so-called 'logical' explanation depends on writing' (Ong 1992 p. 312). Admittedly, not every culture and/or every reader exploits these distinctions as they rely heavily on particular institutional arrangements such as schools, professions, and academic disciplines. However, no reader reading a word- and sentence-segmented alphabetic text can fail to acquire the special metalinguistic concepts of sound, word, and sentence. The remainder comes with more specialized study, normally in schools.

5. *Writing as Normative Practice*

Writing does not merely transcribe speech but presents speech in terms of an idealized model. When learning to write, one is taught not to transcribe speech but rather to edit the speech by removing false starts, correcting errors, and adding needed qualifiers to make the transcription more complete, correct, and formal than the more spontaneous oral utterance. Writing in a literate culture is a normative practice, which is to say it involves the correct, authorized forms of words, sentences, and texts. Admonitions to 'speak grammatically' are in fact admonitions to speak as one would write. Although linguists abhor so-called prescriptive grammars, claiming that all utterances of a native speaker are grammatical, schools are regularly charged with teaching 'proper English.' In this way, writing comes to serve as a model for speaking.

Reading texts and composing them provide a special forum for coordinating the content of a domain with the syntactic and rhetorical demands of the written models available. van Dijk and Kintsch (1983) showed how readers coordinate linguistic form with conceptual structure in interpreting texts and Scardamalia and Bereiter (1986) showed how in writing, students coordinated their ideas with available discourse forms.

6. *Writing and Knowledge*

Although all of the peoples of the world know a great deal about nature, themselves, and the social world, writing systems in the modern world have largely preempted such local knowledge, overwriting it with institutional forms of knowledge based on textual archives and specialized interpretive practices. Have-

lock (1982) suggested that writing was responsible for divorcing the knower from the known, allowing the latter to accumulate and become the subject of research and revision when the social conditions were suitable. Contemporary forms of knowledge are without exception text based, with access to these forms limited to those willing to undergo years of specialized training in the formulation and interpretation of the principle documents of the tradition. Stock (1983) called such traditions 'textual communities' and Smith (1990), a sociologist, characterizes the organization of power in contemporary society in terms of objectivized forms of text-based knowledge: 'The primary mode of action and decision in … business, government, the professions … are textual. The realities to which action and decision are oriented are virtual realities vested in texts and accomplished in the distinctive practices of reading and writing' (Smith1990 pp. 61–2). Psychologists have only begun to explore the implications of living and working in such text-based environments.

7. *Literacy and Social Development*

Because literacy plays such a prominent role in modern societies, it is often assumed that the route to social development is through teaching people to read and write, a view supported by UNESCO. Research and practice have shown that in order to bring about cultural and social transformation, literacy must be seen as an activity embedded in social and cultural practice. Literacy, bureaucratic institutional structures with explicit procedures and accountability, and democratic participation are mutually reinforcing. Rather than being seen simply as a goal, literacy has come to be seen as a means to fuller participation in the institutions of the society, whether in law, science, or literature (Street 1984), as well as a means for their transformation.

Wundt, Wilhelm Maximilian (1832–1920)

1. Life and Times

Wilhelm Maximilian Wundt was born on August 16, 1832 in Neckarau, Germany. From 1844, he attended secondary schools in Bruchsal and Heidelberg. He enrolled at Tübingen for medical study in 1851, then went to Heidelberg, where he earned his doctorate in 1856 with a work 'On the Behavior of Nerves in Inflamed and Degenerated Organs.' In Heidelberg, neuroanatomist Friedrich Arnold and the clinician and pathologist Ewald Hasse guided his interest toward neuroanatomical and neurophysiological problems. During the summer of 1856, he worked under Emil Du Bois-Reymond (1818–96) at the famous physiological laboratory founded in Berlin by Johannes Peter Müller (1801–56). Returning to Heidelberg, he became Hasse's assistant. He completed postgraduate work in physiology in 1857.

In 1858, Hermann Helmholtz (1821–94) was made professor at Heidelberg. Wundt was made professor of Anthropology and Medical Psychology in 1864. For 16 years, he worked alongside Helmholtz at the Physiological Institute in Heidelberg. During this period, his orientation shifted from experimental physiology to physiological psychology, and finally to philosophy. From 1864 to 1868 he was a representative to parliament in the state of Baden, where he advocated social integration for workers. He was appointed professor of Inductive Philosophy (philosophy of science) in Zurich, Switzerland in 1874. On October 18, 1875 he accepted a professorship in Leipzig in Philosophy ('with a natural scientific orientation'). In Leipzig, he founded the world's first Institute for Experimental Psychology, which soon attained international renown. Students came to Leipzig from many countries, including Bulgaria, the UK, Japan, Canada, Poland, Romania, Russia, and Hungary, and especially from the USA. Many students went on to establish institutes in their home countries, using the Leipzig Institute and its course of study as their model. In 1881, Wundt founded one of the world's first journals of psychology, *Philosophical Studies*. Wundt died on August 31, 1920 in Großbothen near Leipzig, and was buried in the professors' section of the South Cemetery in Leipzig.

What kind of an era did Wundt live in? In the year of his birth (1832), the celebrated writer of German classical literature Johann Wolfgang von Goethe died. In 1848, the revolution that sought to achieve democratic process in Germany failed. In 1871, the Second German Reich was born after the violence of Prussia's wars against Denmark (1864), Austria (1866) and France (1870–1), and Austria was excluded from the German states' centuries-long common political development. By the time Wundt died (1920), the Second German Reich had lost World War I in 1918 and the Weimar Republic had been established. Looking back, Wundt wrote in his memoirs: 'Lived experience is the most immediate of what the gods have bestowed, but knowledge is the better portion of what he has been granted' (Wundt 1920, p. iv).

2. Work and Influence

2.1 An Overview

Early in his career, Wundt focused on the experimental analysis of physiological and then psychophysiological problems. Somewhat later, he attempted to provide a philosophical foundation for his experimental work. The titles of his works published in Heidelberg vividly illustrate his path: *Contributions to the Science of Muscle Movements* (1858), *Contributions to the Theory of Sense Perception*' (1859–62), *Lectures on the Mind of Humans and Animals* (1863), *Textbook of Physiology* (1864), *Physical Axioms* (1866), *Handbook of Medical Physics* (1867), and *Principles of Physiological Psychology* (1874). In 1902, one of his first biographers summarized: 'Evidently, it was involvement with questions of sensory physiology that first awakened in Wundt the need for a philosophical orientation' (König 1902, p. 23).

In Heidelberg, Wundt also developed the fundamentals of his ethnopsychology (*Völkerpsychologie*), stimulated by the work of Moritz Lazarus (1824–1903) and Hajim Steinthal (1823–99) in their *Journal for Ethnopsychology and Linguistics* published from 1859. Decades later in Leipzig, Wundt elaborated these fundamentals into a 'general psychology' and a 'general developmental psychology.' After 1875, he wrote the works that would bring him world renown as a methodologist, experimental psychologist, and ethnopsychologist. This progression, too, can be traced in the titles of his books: *System of Philosophy* (1889), *Logic: An Investigation of the Principles of Knowledge and Methods of Scientific Research* (finally a three-volume work, 1906–8), *Introduction to Philosophy* (1901), and the 10-volume work *Ethnopsychology* (1900–20). Between 1908 and 1911, he also expanded *Principles of Physiological Psychology*, his standard work on experimental individual psychology,' to three volumes. His students in Leipzig carried out the psychological experiments that would fill the 20 volumes of his *Philosophical Studies* and those of the subsequent *Psychological Studies*.

2.2 Wundt's Major Work—Individual Psychology and Ethnopsychology

Wundt's major work was devoted to psychology, which was for him the basis of philosophy. His psychology had a twofold basis, consisting of a scientifically oriented experimental 'individual psy-

chology' and a humanistically oriented comparative 'ethnopsychology.' About his individual psychology, he wrote, 'The concept of individual psychology covers investigations whose subject are the psychological processes of individual human consciousness, inasmuch as these possess a *typical*, generally valid significance for normal consciousness' (Wundt 1908, p. 162). He added, with regard to methodology, 'In truth, there are … for individual psychology … *two* aids available: casual self-observation and experimental method. The former assumes both a preparatory and a supplementary function; the latter, however, is the sole tool for analysis of elementary psychological processes' (Wundt 1908, p. 163). 'Ethnopsychology,' in contrast, had '… the task of complementing individual psychology with information about the general mental products of social life' (Wundt 1908, p. 163). 'The principle domains of ethnopsychology … are: *language*, *art*, *myth* and *customs*. They signify for the consciousness of cultures what imagination, feeling, and will signify for individual consciousness' (Wundt 1908, p. 232). Clarifying the main aspects of ethnopsychology he continues, 'So the psychological value of language consists primarily in expressing laws of *thought*, therefore various forms of language correspond to specific steps in the development of this basic mental function. In the same way, *myth* is intimately connected with the activities of fantasy in *art*' (Wundt 1908, p. 232). Finally, he describes the psychological value of (social) customs, writing, 'As myth does for art and religion, so do *customs* possess a central significance in their relation to two other important areas of life' (Wundt 1908, p. 233). 'One of these areas is *society* … It is society that first makes possible the formation of customs, the prevailing embodiments of norms of will within a society … The other area deriving from customs is *law*' (Wundt 1908, p. 234). He adds finally: 'Language, art, myth and customs are thus not the sole objects of ethnopsychology, but they are the ones that from the beginning express social life' (Wundt 1908, p. 234). On methodology in ethnopsychology, he wrote, 'The fundamental method of ethnopsychology … is … *comparison* in the ways it is generally used in the humanities' (Wundt 1908, p. 240). And he adds, '… ethnopsychology … is conducted … by assembling for comparison a collection of facts about psychological viewpoints, and through this close and direct connection to psychological analysis, comparison itself leads to the establishment of psychological laws … In this manner, the correct use of the comparative method here gains a significance similar to that of experimental procedure in individual psychology' (Wundt 1908, p. 240).

With these ideas, Wundt created a conceptual framework that would have great consequence in the history of psychology: a scientific psychology of elementary psychological phenomena and a humanistic psychology of higher psychological phenomena. Scientific psychology is an 'individual psychology' since it gets its data from the experimental investigation of individuals. Humanistic 'ethnopsychology' is a 'general psychology,' since it examines general psychological objects. As such, it is also a 'general developmental psychology' since those objects also develop throughout history. Methodologically, ethnopsychology gets its data from the ethnological analysis of historically developed products of mind (i.e., language, art forms, myths, customs). From these, conclusions can be drawn about the psychological processes involved in their emergence. Such processes include thinking, feeling, or willing. The view that a methodical humanistic approach was the only way to study higher psychological processes was momentous in the history of psychology. According to this concept, there could be no experimental psychology of thinking, emotion, or volition. From today's standpoint it should be noted that Wundt did recognize that psychological methodology could not be solely experimental. It must also be a quasi-experimental and historical methodology. On the other hand, his view that higher psychological processes were inaccessible to experimentation proved to be false. Wundt's methodological quarrel at the beginning of the twentieth century with members of the Würzburg school around Oswald Külpe (1862–1915), which concerned the role of experimentation in the psychology of thinking, had already shown that his critique of their method as 'interrogation experiments' was untenable.

3. *Wundt and the Genesis of the Discipline of Modern Psychology*

Wundt made fundamental contributions to the genesis of the discipline of modern psychology in the nineteenth and twentieth centuries, in Germany and beyond. This genesis may be described generally in terms of six phases and their corresponding developmental features.

First, Wundt had a lasting impact on the development of the subject matter and methods of empirical psychology since the beginning of the nineteenth century with his 'individual psychology.' This is also true to a certain extent for his 'ethnopsychology', if historically developed products of mind are regarded as historical empirical experience.

Second, Wundt was influential in institutionalization, that is, founding institutes for experimental psychology and anchoring them in the university system, as well as other forms of institutionalization, such as the founding of scholarly journals and scholarly societies. Active in scientific policy making, Wundt made a definitive contribution to institutionalization by founding the world's first psychological laboratory, the Institute for Experimental Psychology at the University of Leipzig in 1879. He

also founded one of the first experimental journals in psychology, *Philosophical Studies* in 1881.

Third, Wundt can be said to have contributed to the temporary division into major schools during the period between about1890 and 1940, inasmuch as his institute became a model for psychological institutes in many countries. But he did not found an actual school in the strict sense of the Berlin school of Gestalt psychology, the Würzburg school of cognitive psychology, or the Vienna school of psychoanalysis.

The fourth phase is the development of applied psychology, that is, through the inclusion and development of fields of praxis outside the universities and higher education after about 1890. Wundt had an ambivalent, rather negative relationship to the development of applied psychology. In his opinion, psychology should attempt a transition to practical applications only after its foundation has been systematically constructed (Wundt 1913).

Fifth, with his twofold psychology and with numerous students from many countries, Wundt made a definitive contribution to the development of a pluralistic system of psychology and to the gradual integration of the major schools after about 1930.

The final phase is professionalization, that is, the establishment, social anchoring, and state certification of standards for academically educated psychologists active outside of the university system around the time of World War I. With his early work in developing a curriculum for the education and training of psychologists, Wundt contributed indirectly to professionalization. This curriculum, with further contributions from other psychologists, was adopted in 1941 in the form of the first state diploma examination regulations in Germany.

The genesis of the discipline described above was initially, in the nineteenth century, determined primarily by experimental psychology. This constituted the first phase of methodological development in which experimental methods, the technical apparatus and the mathematics of experimental physics and of experimental physiology were transferred to psychology. Wundt's 'individual psychology' is an expression of this development. It thus becomes understandable why many of the 'pioneers' of modern psychology, Wundt's contemporaries in nineteenth-century Germany, were trained as experimental physicists or experimental physiologists. They include Ernst Heinrich Weber (1795–1878), anatomist and physiologist, Gustav Theodor Fechner (1801–87), doctor and physicist, and Hermann von Helmholtz (1821–94), physiologist and physicist.

During the second half of the nineteenth century a second phase of methodological development began. More or less standardized nonexperimental methods were added step by step to the experimental procedures. These methods were initially analytical documentary procedures that Wundt called methods of 'comparison' within his 'ethnopsychology.' Later they also included the preexperimental empirical methods based on the paradigms of assessment, achievement, arrangement, and interpretation. These methods contributed significantly to the development of psychodiagnostic procedures. Both groups of nonexperimental procedures today constitute elements of 'historiographic' and 'quasi-experimental' methodology in psychology. Wundt's work and its influence may be categorized within these two phases of nineteenth-century methodological development: his experimental 'individual psychology' falls within the first phase and his nonexperimental 'ethnopsychology' within the second.

4. *Review and Outlook—What was Transitory, What Endures*

Four achievements of Wundt's life's work must be especially emphasized. First, he contributed, in the politics of science, to the genesis of the discipline of modern psychology, that is, to its independence as an empirical psychology with its own subject matter and methods. Second, he constructed a system of psychology as an experimental 'individual psychology' and as a humanistic 'ethnopsychology.' Third, he founded the world's first Institute for Experimental Psychology, which gave impetus to the institutionalization of psychology and fourth, he founded one of the first scientific journals for psychology, *Philosophical Studies*.

Critically it should be noted that Wundt's concept of the experimental inaccessibility of higher psychological processes played a limited role for a time in the discipline's development. However, even some of his contemporaries did not share this idea. They included Gustav Theodor Fechner (1801–87), Carl Stumpf (1848–1936), Hermann Ebbinghaus (1850–1909), Georg Elias Müller (1850–1934) and Oswald Külpe (1862–1915). Nor did many experimental psychologists of the next generation, such as Narziß Ach (1871–1946), Karl Bühler (1879–1963), Max Wertheimer (1880–1943) or Otto Selz (1881–1944), share Wundt's view.

Wundt's writings and activities attained worldwide influence, especially because of his many students. It was them, most of all, who spread the tradition of experimental 'individual psychology.' Granville Stanley Hall (1844–1924), who established the second psychological laboratory in the USA at Johns Hopkins University in Baltimore in 1883 and in 1887 founded the *American Journal of Psychology*, was a prime example. Another was James McKeen Cattell (1860–1944), Wundt's first assistant in Leipzig, who occupied the first chair in psychology in the USA at the University of Pennsylvania in 1887. He became known primarily as the cofounder of the field of psychological diagnostic testing. Edward Bradford Titchener (1867–1927) who left Oxford, England in

1890, spent two years in Leipzig and went on to promulgate Wundt's teachings as structuralism at Cornell University in the USA. Another student was Dimitrij Nikolaevich Uznadze (1887–1950), founder of the Georgian school of psychology and known for his theory of set. Notable among Wundt's German students were Emil Kraepelin (1856–1926), one of the founders of modern psychiatry, psychopharmacology, and experimental psychodiagnostics; Ernst Meumann (1862–1915), founder of experimental pedagogy; Theodor Lipps (1851–1914), an exponent of experimental esthetics; Hugo Münsterberg (1863–1916), founder of industrial psychology and cofounder of applied psychology ('psychotechnics'); and Karl Marbe (1869–1953), one of the founders of forensic psychology.

Western European Studies: Economics

1. Background

In many respects, economic Western Europe looks very different today from what it was in the Cold War years of the early 1980s. In these two eventful decades, the Western European economy underwent radical transformations, with deep structural changes and complex institutional reforms affecting the working of both markets and policy authorities.

Since the second half of the 1980s, after a long period of sclerosis, an ambitious process of economic integration was launched and successfully implemented. It first took the form of market enlargement in real and financial assets aiming at the perfect mobility of goods and productive factors. The idea of a single European market was significantly reinforced by the decision to introduce a common currency and to design a new set of European institutions and procedures. Consequently, economic convergence within the area increased while, following German reunification, integration with Eastern European countries also proceeded at a very rapid pace. Projects for a further widening and deepening of European integration, ranging from a more complete economic and political union to the Eastward enlargement of membership, are now in an advanced stage of elaboration or just about to be implemented.

The decisive steps toward greater integration were taken under the influence (which occasionally became a threat) of world trade globalization, the new technological revolution, and the generalized liberalization of capital movements. In Europe, accepting these external challenges brought about a decisive retreat of the nation-state from the effective control of a series of domestic policy instruments and the public ownership of industrial concerns. Traditional theories on market failure were replaced by a number of alternative approaches based on incentives and mechanism design. State-owned enterprises have been affected by a massive wave of privatizations, while new procedures to deal with anticompetitive behaviors were elaborated by the European Union. The European Commission has now acquired increasing powers in this respect and some commentators have argued that latecomer Western Europe has one of the most developed antitrust policies in the world.

In this process, regulation was critically scrutinized as a source of market inefficiency and systemic degeneration. Politicians and academic scholars often wondered whether Government intervention had become a powerful obstacle to employment and economic growth. The pressure to have common labor legislation and economic regulations going from a harmonization of tax rules to the redefinition of social benefits opened new fields of investigation on the traditional theme of the optimal relationship between markets and authorities.

Major transformation processes such as these often impose heavy adjustment costs on societies or specific groups. Western Europe was no exception to this rule of history. It would probably be an exaggeration to talk of a long recession of the European economy in the 1990s, but it remains true that, in comparative terms, the century closed with a long series of weak economic performances that have not been reversed by the introduction of the new currency. The unwelcome consequence of this rapid transition toward a more integrated and competitive economic system was the upward convergence of unemployment rates and the increase of social inequalities. Double-digit figures were a permanent feature of the European labor market in the 1990s, and remained quite unaffected from cyclical fluctuations in output and investment.

Quite understandably, integration, unemployment, and regulation were among the economic issues that attracted a great deal of intellectual energies. Although the richness of Western European studies in economics is obviously far greater, considerable work was done on these general topics, and this explains the decision to restrict this discussion to them.

2. Integration

Generally speaking, integration in Western Europe has been interpreted as the outcome of sovereign actions of politicians and bureaucrats, rather than a market-induced process (Streit and Mussler 1994). Ever since the Treaty of Rome (1957), a long series of 'interventions from above' produced substantial results in the fields of trade policy, agriculture, the monetary system, competition, industrial policy, and social cohesion. The Maastricht Treaty (1992) strictly followed this functional approach, extending the Community powers over new sectors and policies, and establishing a rigid set of criteria for the creation of a monetary union. Policies for redistribution and compensation within the area were also significantly reinforced after Maastricht. Many more recent features (like Sweden's large majority rejection of the monetary union in September 2003 that strengthened the anti-Euro sentiments of the Northern fringe of Scandinavian countries and Britain) corroborates the view that European integration is an elitist project with rather limited popular support.

Before the approval of the Delors report (1986), agriculture and exchange rates dominated the agenda. The Community Agriculture Policy turned out to be a 'subsidized folly' (Petersmann 1993), burdening the European taxpayer and consumer with extremely high costs. It still absorbs most of the Community (modest) financial resources and instead of winning

approval it provoked loud protests even among its beneficiaries. It turned out to be a permanent source of conflict, both within and outside the Community, and was particularly detrimental to new trade creation and growth opportunities with Less Developed and Eastern European Countries in transition.

The European Monetary System (EMS) worked as an exchange rate mechanism, which was built on fixed but frequently adjustable parities, enhanced central banks cooperation, and an anti-inflationary bias. Flexibility, new financial facilities, and a strong dollar were the main factors for its first successful stage (1979–87), while rigidities, frictions, a weak dollar, and the economic consequences of German reunification marked its tumultuous end (1992). In terms of a monetary union, the EMS was unsuccessful and steps in that direction (the creation of a European monetary fund and the issue of a 'parallel' currency) did not evolve.

However, the actual working of the EMS stimulated fresh analysis on the interaction between monetary arrangements on the one hand and the functioning of real markets and the efficacy of policy decisions on the other. European economists refined such concepts as credibility, reputation, time consistency, or the games between governments and central banks, and applied them as analytical tools to explain the new road to integration. They also showed that asymmetries and rigidities were the result of choice rather than constriction. New theoretical models were framed to speculate on the advantages of 'tying one's hands' in the conduct of domestic monetary policy: the EMS, so it was argued, allowed member states to import credibility and acquire stability from the core country (i.e., Germany) and its central monetary authority. Therefore, by the end of the 1980s, the loss of monetary independence was almost complete, thus easing the way toward greater monetary integration (Giavazzi and Pagano 1988).

The EMS collapsed due to its incapacity to target simultaneously fixed exchange rates and use interest rate policy in pursuit of other domestic economic objectives (i.e., employment growth). While this is possible when capital movements are prohibited, in a global financial market the 'trinity' becomes inconsistent. Thus, a monetary union or, conversely, flexible exchange rates, remained the alternate options to overcome the 'open economy trilemma,' given the freedom of capital flows. After some discussion and popular reactions, Western European countries decided for the former (Giavazzi and Giovannini 1989).

The European Monetary Union (EMU) remains the world's most advanced experiment in moving beyond national economic sovereignty. The transition to monetary union was accompanied by widespread skepticism and criticism. Particularly, American observers thought that the likely effects of monetary union on macroeconomic fundamentals would be adverse even though they might be somewhat compensated by closer political ties (Feldstein 1997).

Debates on EMU focused on what prerequisites real markets of goods and productive factors ought to possess for monetary integration to generate net welfare gains. The Maastricht schedule of events and convergence criteria, relying on arbitrary quantitative ratios, was attacked for having nothing to do with the economics of optimal currency areas. Requisites for the 'sustainability' of EMU were strongly influenced by the prevailing German view and were defined in terms of nominal convergence of inflation and interest rates, monetary independence, and fiscal policy restraints.

Economists emphasized that the real properties for monetary integration simply did not exist in Western Europe: local markets were not efficient enough to guarantee low adjustment costs and offset the loss of exchange rate changes. Mobility, flexibility, and social integration were other indispensable factors that Western Europe did not possess. Common monetary policies with no exchange rate adjustments rendered the absorption of asymmetrical shocks more difficult. The inclusion of restrictions on fiscal policy in a treaty that set the timetable for monetary union was a further source of considerable debate. Many felt that the road to monetary unification needed to be supplemented by some forms of fiscal coordination in order to absorb country-specific shocks and avoid migration of taxpayers. However, while nation-states were all quite reluctant to surrender or harmonize their fiscal stance, Germany imposed stringent rules in order to discipline high deficit countries and avoid negative spillovers that would threaten the dogma of price stability and interest rate convergence. The economic rationale of this 'stability pact,' however, was thought to be very weak, particularly if rigidly applied over the business cycle.

On the whole, the (almost) unanimous verdict was that Europe did not constitute a 'natural' monetary union, and that imposing a new single currency would be detrimental mainly for cyclical unemployment. On the positive side of the balance sheet, the European countries' significant degree of openness to mutual trade remained, mainly intraindustry. This feature rendered adjustment through exchange rates less effective and less compelling. Moreover, a single currency was thought to provide further expansion to intra-European trade and investment, because of lower transaction costs, less discrimination, and no currency risks. The ensuing regionalization of the European economy was expected to reduce the likelihood of country-specific asymmetric shocks.

Therefore, within the economics profession, EMU is still receiving favorable support, despite the difficult start of its new currency and widespread

manifestations of anti-Euro public opinions. On the one hand, it created a safety net against such outcomes as trade wars, competitive devaluations, and discriminatory practices that are always likely to be implemented as it was experimented in the aftermath of the 1992 EMS crisis. On the other, dynamic efficiency gains might be obtained by integration in terms of more perfect competition, economies of scale, productivity growth, and a more efficient allocation of loanable funds.

Building up on these advantages, new studies show that currency integration is indeed a very dynamic process that cannot be (exclusively) predetermined by some set of exogeneous criteria (whether the Maastricht ones or other more theoretically sound ones). In Europe, the lack of mobility and flexibility is a regional, not national, phenomenon, and there is no reason why monetary integration should make things worse. The classic Mundell criteria have thus been substantially revised. Research efforts have recently been directed to the study of the intertemporal balancing of the benefits against the costs (Padoan 2000). Monetary integration must then be analyzed in an endogeneous growth model. In the process toward more complete integration, public confidence in the system may grow, some new benefits may emerge, and existing benefits may rise; alternatively, expected costs and the occurrence of asymmetric shocks may diminish as integration proceeds.

Recent manifestations of anti-Euro sentiments have been sustained by bad economic performance in the Euro area. At the current stage of European monetary integration, Europe oddly resembles more a multi (rather than an optimal) currency area, while economists have raised serious doubts on whether European policy rules have been efficiently designed and properly managed.

Finally, empirical research has shown that Eastern and Western Europe have integrated faster than it was commonly expected. Eastern European firms are now participating in Western Europe-centered production hubs, and have actively organized cross-bordered corporate networks. Intraindustry trade and input sourcing boomed together with foreign direct investments, just showing the growing complexity and maturity of economic integration between the European Union and the transition economies.

3. *Unemployment*

Western European unemployment has increased dramatically since the early 1970s, moving up from 2% to more than 10%. Compared to other countries, European unemployment is suffering from higher duration rates (relating to those who are unemployed for one year or more), higher rates of open unemployment (which considers discouraged workers and involuntary part-time jobs), and low participation rates among particular classes of individuals, such as prime-age men, married women, and the elderly. Economists often talk of the existence of a 'dual' labor market in Western Europe, one formed by very protected (male) workers (the so-called 'insiders'), the other by an army of unemployed for which market mechanisms and incentives no longer seem to be functioning (the 'outsiders').

Debates on rising European unemployment have focused on three main issues: (i) the effects of globalization with growing imports from low-wage countries; (ii) the effects of the German way to monetary union; and (iii) the effects of a rigidly constrained labor market structure. According to the former, increased international trade from LDCs may have something to do with European unemployment. Although analysts often disagree of the real magnitude of these effects, demand for unskilled labor has been dramatically reduced in developed countries as a consequence of globalization, and changes in the structure of foreign trade provide a plausible explanation (Davis 1998). As to the second argument, meeting the Maastricht criteria for EMU membership has led in some countries to substantial short-term increases in unemployment. This reflected the contraction of aggregate demand due to tight monetary and fiscal policies that all countries implemented in order to meet the deadline. However, the greatest attention has been devoted by far to the study of the labor market, which has been mainly developed in comparative terms. Particularly, the North America versus Europe dichotomy has been featured in a variety of works (Siebert 1997, Nickell 1997, Layard et al. 1991).

Conventional wisdom states that European unemployment is now comparatively higher because of the more powerful interactions between local factor market institutions and global goods markets. In other words, greater openness of the European economy to trade and external competition in the goods market was unaccompanied by greater openness and competition in the factor markets, where the downward wage rigidity is the main source of unemployment. Local institutional features (such as the minimum wage, workers immobility, or high firing costs) introduced important asymmetries that affect the level of wages and have a negative impact on labor demand and supply.

The contrast between Western Europe and North America is more complex than this stylized picture. Economists, for instance, have begun to question the description of America as a flexible wage economy and of Europe as a rigidly constrained and overly institutionalized economy. Furthermore, it is quite inconvenient to talk of Western European unemployment since the structure of labor markets is hardly homogeneous, while their performance is even more markedly different (Siebert 1997). European rates of job turnover are quite satisfactory while overall wage

flexibility is not dramatically lower compared to North American standards (Nickell 1997). Consequently, economic analysts have been trying to disaggregate the European labor market in order to understand as to what are its main structural weaknesses that generate high unemployment rates. One of the more challenging questions is whether there are any specific institutional features that are more responsible than others and what practical remedies can be introduced.

The review of the empirical evidence shows that Western Europe has strong legislation both on employment protection (relating to the legal framework governing hiring and firing) and other aspects of the labor market (from working time to fixed-term contracts and minimum wages). Unemployment benefits are also fairly generous even though, beyond the short term, they tend to adjust toward the lower North American coverage. While extremely variable across countries, nonwage labor costs (which are mainly responsible for the so-called tax wedge) appear extremely burdensome. Hence labor productivity is financing social insurance benefits to a greater extent than in other labor markets. Finally, in most European countries, trade unions play an important role in wage determination and even when union density is quite low the coverage rate is always substantial. One possible generalization from these institutional features is that, in Western Europe, the wage elasticity of labor needs more time to determine the necessary quantitative adjustments, while the long-term response of wages to unemployment is satisfactory and even higher than in other contexts (Siebert 1997).

Among the remedies, together with greater wage flexibility, the high fiscal wedge is considered to be the most important single explanation to European unemployment, regardless of how the tax burden is redistributed. Extension of social insurance is the main reason for the increase in the overall marginal tax wedge, which has particularly depressed the demand for labor. Lowering payroll and income taxes has thus become a very popular recommendation for reducing unemployment. Moreover, there seems to be an increasing awareness that job protection rules must be softened in order to increase firms' incentives to create new labor opportunities. Serious implications are also associated with unemployment benefits, especially if they have no time limit and are combined with a decreased willingness to search for a new occupation. The so-called 'reservation wage' (which guarantees minimum social welfare and unemployment benefits) needs to become more negotiable, thus reducing distortions in the market mechanism that are familiarly indicated under the heading 'unemployment traps.' As far as trade unions are concerned, centralization of wage bargaining is thought to increase efficiency if the process is coordinated with strong employer associations and negotiated within the more general macroeconomic compatibilities imposed by policy authorities. However, centralization leads, almost by definition, to less wage differentiation: in Western Europe, equity reasons have again prevailed to market clearing equilibrium, mainly at the expense of low-skilled workers. Finally, increasing investments in education are generally recommended as a remedy against structural unemployment.

4. *Regulation*

The great claim for perfect competition is that it leads to efficient results in the allocation of resources. From the production side of the economy, a perfectly competitive market solves two problems. First, production is allocated in such a way that desired output is produced at a minimum cost (i.e., efficient cost structure). Second, given that prices are equal to marginal costs, desired output is supplied by a sufficient number of (viable) firms (i.e., efficient price structure). Thus, production efficiency is a desirable objective of public policy.

Unfortunately, the competitive model may fail to be satisfied in the sense that markets are neither always complete (some may even be missing) nor are all markets perfectly competitive. The theory of market failures and the rationale for government intervention have been pioneered by such European economists as Lindahl (1919), Pigou (1920), and Wicksell (1896). Then, starting in the 1930s, in Western Europe the question of how deeply the government should be involved in the national economy has strongly been debated with economists divided between advocates (Robinson 1933) and critics (Hayek 1944) of government intervention. After World War II, market failures together with the difficulties of price controls, subsidies, taxation, and nonprice regulation were the major considerations that, with slight differences across countries, turned out the answer in favor of regulation and/or granting governments ownership and operation of selected activities. Some have argued that the role of government should have been that of acting as a 'welfare state' and thus modifying the actions of the market that would not produce vital (or public) goods and services at an acceptable cost (Briggs 1961). In this vein, most Western European countries adopted the so-called *public interest* view of regulation in which positive theories are based on normative considerations: to improve (maximize) social welfare the government needs to respond to market imperfections, and the extent of its action, subjected to various constraints, varies accordingly with the extent of those imperfections. Moreover, abstracting both from positive and normative rationales, state ownership of certain 'strategic' industries like steel, defense, airlines, automobiles, and banks has been

perceived as necessary to promote economic growth. However, this interpretation is perhaps too idealistic. As we shall see later, it is often inappropriate to assume that a benevolent government would make decisions solely in the interests of citizens.

From the 1980s, the very idea of a single European market has shifted policy from using regulation and state-owned enterprises (SOEs) to a greater reliance on the market mechanism and on incentive systems to improve consumer welfare as well as pursue industrial and employment goals. The promotion of competition has been one of the pillars of the European Union since the treaty of Rome, and governing bodies of the Union have acquired increasing powers to deal with noncompetitive behavior, both by private firms and public agencies, that distort competition and inhibit integration of markets across Europe. Empirical analysis raised concerns about the cost, price, and quality performance of regulated firms, and the policy arena became increasingly aware of the possibility of regulatory failures. Theory advancements also showed how, although market failures remain an argument for government intervention, the 'unnecessary' and/or the 'wrong' intervention may worsen the situation.

The existence of market failures, however, is not a sufficient reason to grant government intervention in markets. This insight was provided some 20 years before by Ronald Coase, a British economist working in the US. In the seminal paper 'The Problem of Social Cost,' he paved the way for the economic profession to realize that some market failures may be solved by redefining property rights and creating markets. Moreover, in choosing regulatory policies one should take into account the fact that informational limitations may raise the possibility of strategic behavior both by the regulated firm and of the regulator itself. Thus, rather than on command-and-control provisions, regulatory enforcement should be based on incentive mechanisms. This was made clear by a French economist, Dupuit (1844). In his pioneering contribution on marginal cost pricing, he was perhaps the first to take up the problem of how to design incentive-compatible regulatory mechanisms. These issues, which were largely absent in the traditional regulatory theory, have been brought up by developments in the literature on game theory, principal-agent, information economics, and the new institutional economics. The introduction of informational and institutional constraints showed how second-best optimization of social welfare is not straightforward while the set of feasible regulatory instruments is rather limited (an excellent account of most of the issues of the 'new regulatory economics' is provided by Laffont and Tirole 1993).

In the last two decades, European Union public policy reform has been mainly concerned with liberalizing prices and access to restricted markets as well as transferring SOEs to the private sector, and/or contracting out activities previously run directly by governments (i.e., privatization). These phenomena have been reinforced by developments in the product and capital markets, changes in the level and structure of demands, and a sharp decline in the cost of certain products and services. Although the pace and extent of liberalization have been quite different across countries, the policy objectives of the European Union can be summarized as follows:

- setting rules that make access to industries possible for a plurality of efficient providers,
- unbundling vertically integrated monopolies, thus creating new markets to replace transactions that previously took place within firms,
- restructuring tariff structures in ways that reflect underlying costs,
- ensuring that noneconomic public interest may be attained in a competitive environment,
- designing regulatory mechanisms that reflect the possibility of 'capture' by regulated firms or other interest groups,
- replacing regulation through public ownership with arm's length regulation,
- ensuring independence of the regulator from the executive branch of the government, and
- imposing constraints on regulator's discretion.

Looking at selected industries, such as services and utilities, makes it possible to highlight some of the features of the reform process.

Regulation of *network industries*, such as the local loop in telecommunications, electricity distribution, water pipelines, and rail track, has been based on two kinds of market failures: natural monopoly and externalities. In a natural monopoly a single supplier could serve the entire market at a unit cost lower than any industry configuration with two or more firms (Baumol et al. 1982). Hence, the case for natural monopoly is based on the fixed and costly infrastructures needed to deliver services to users. Externalities are effects of jointness of production/consumption not priced by the market. Here, externalities are mainly related to network effects: the demand for the product or service increases with the increase in the size of the network, since there are benefits in being connected to a larger network.

Restricted entry and extended price regulation have been sought to prevent: (a) that the single unregulated firm would not produce the desired output level, making impossible the fulfillment of social or universal service, (b) unstable prices, and (c) excessive investments. However, as Coase (1960) put it, 'all solutions have costs, and there is no reason to suppose that governmental regulation is called for simply because the problem is not handled well by the market or the firm.' Take, for example, the case of telecommunications. Here, the existence of both scale and scope economies has been used to justify vertical integration of the provider of the local service (a true natural monopolist) with potentially competitive

activities such as long distance and mobile services. In these multiproduct industries socially optimal second-best (Ramsey) prices, which permit a natural monopoly to break even, resulted in cross-subsidization. In other words, prices of competitive activities (i.e., long-distance calls) higher than those based on 'stand-alone' costs subsidized the costs of noncompetitive activities (i.e., local access). Hence, high prices in potentially competitive services prevented consumers from reaping the benefits of technical progress.

Increasingly aware of these pitfalls, the European Union moved toward regulatory reform that involved the privatization of state monopolies, the elimination of entry restrictions, and the adoption of incentive-based regulatory techniques. An example is the so-called 'Full competition' directive (96/19), which required the elimination of all remaining legal barriers to entry in telecommunications markets by January 1, 1998.

Where competition *within* the market is not feasible an alternative competition *for* the market has been introduced (Demsetz 1968). For example, auctions for the franchise right to operate the mobile telecommunication services have been used in the United Kingdom, Germany, Italy, and the Netherlands. Provided that (a) inputs are competitive available to all bidders, and (b) there is no collusion among bidders, auctions compel prospective entrants to reveal private information on their services, thus reducing the agency problem that characterizes the relationship between the government and the regulated firm. Regulated firms almost always have superior information concerning costs, demand conditions, products quality, and technological possibilities than the regulator. Indeed, this asymmetric information plagues the whole (multi)principal–(multi)agent relationship of the regulatory problem. Informational constraints limit both the control of the regulator over the firm and the set of feasible instruments to exert such control.

In traditional rate-of-return regulation, prices are set so that the regulated firm can cover its costs plus a reasonable rate of return for capital. Here, the regulator suffers heavily for informational limitations on costs and demands. Thus, where possible, rate-of-return regulation has been displaced by more fruitful incentive-based techniques. For example, to increase the available information, the regulator may make use of external information, such as the performance of other firms as a benchmark by which to compare the performance of the regulated firm (Shleifer 1985). *Yardstick competition* is increasingly used by European agencies in assessing efficiency and/or evaluating performance. It has strongly been recommended by the European Commission for the regulation of interconnections prices in telecommunications. Another type of incentive-price regulation—one that avoids continuous and detailed information on costs and demands—is *price–cap regulation*. In price–cap regulation, the regulator fixes caps on the prices that firms can charge for their products (or basket of products) for a given period of time. Then, firms choose to price at or below the caps—that are reviewed over time. Since firms have the incentive to minimize costs, price–cap regulation induces price structures to be more in line with underlying costs than rate-of-return regulation.

Traditionally, in Europe, regulatory objectives such as quality of service, price control, and universal service obligations were thought to be more easily implemented by state-owned firms than through regulatory schemes. However, several European governments—most notably Britain, France, Germany, Italy, and Spain—have launched large privatization programs in the 1990s, which have been widely used to raise revenue and to reduce public debt without raising taxes or cutting other government services. Nevertheless, in some industries, state control through share ownership remains widespread and the dominant role of incumbents (former monopolists) is still an obstacle to full competition.

Positive theory suggests that politicians are reluctant to privatizations because they have to give up their ability to operate SOEs in ways that provide economic benefits for their political constituencies (Shleifer and Vishny 1994). Regulators have the power to generate and redistribute rents across interest groups and/or may use this power to gain, or maintain, support from their political principals. At the same time, regulated firms have incentives to 'capture' regulators and influence regulatory outcomes (Stigler 1971). Indeed, the European Union has strongly criticized regulatory agencies of member states for delaying the implementation of its directives aimed at liberalizing markets.

Xenophobia

Although the term xenophobia is well established in the language of politics, the media, and the sciences, as a concept it has only a weak theoretical foundation. This is due not least of all to the ambiguity of the term. The word xenophobia comes from the Greek words *xénos*, meaning both 'the stranger' and 'the guest,' and *phóbos*, meaning 'fear.' Strictly speaking, then, xenophobia means 'fear of the stranger,' but it is usually taken to mean 'hatred of strangers.' This contradiction is particularly clear in German, where xenophobia and 'Fremdenfeindlichkeit' (i.e., hostility towards strangers) are used consistently as synonyms. The semantic discrepancy between fear and hatred of strangers can be illustrated in the following way: the stranger whom one fears can be welcomed as a guest, but not so the stranger whom one hates.

1. *The Origin of the Term*

The concept of the 'stranger' exists in premodern European societies as well as in practically every existing culture worldwide. Usually strangers are considered to be foreign, strange, unfamiliar, uncommon, unusual, and extraordinary. One cannot expect a relationship with a stranger to be good from the outset: only time can tell whether it will be a friendly or inimical one. As a result, attitudes towards strangers are characterized by ambivalence. This is particularly the case for strangers who live 'amongst us'—in our village, our city. While the concept of the stranger can be thought of as a universal category, this is not the case for xenophobia. Xenophobia is a concept of recent coinage: it was first used by Anatole France in his 1901 novel *Monsieur Bergeret à Paris*. The term anti-Semitism of the Dreyfus affair, which shook domestic politics in France at the turn of the twentieth century, provided a social and political background for xenophobia, as did the virulent form of nationalism that was emerging at the time (Villard 1984). In 1906—the very year of Dreyfus's rehabilitation—xenophobia was listed for the first time in a French dictionary: the *Nouveau Larousse illustré*. But only many years later could the word be found in English and other dictionaries. While the scientific world hardly took notice of the concept, 'xenophobia' was all the more present in the press. Attempts to account for the phenomenon of xenophobia included the explanation that it is the result of prejudice against strangers (*Athenaeum*, March 13, 1909) or that it is related to imperialist attitudes (*Nation*, May 11, 1912). The peoples of foreign countries—for example, the Afghans (*Mail*, May 24, 1922)—were accused of xenophobia, and so were nationalist movements in Egypt, China, Persia, and Turkey (*Nation*, December, 20, 1919). Finally, the phrase 'xenophobic outburst' was coined to describe the rising wave of anti-Semitism that was the precursor of German fascism.

While 'xenophobia' slowly became an established term in the French and English-speaking worlds, it was rarely used by speakers of German. The reason is that a conceptual pair already existed in the German language: 'Überfremdung' ('overstrangerization,' infiltration with foreign elements, foreign control) is a direct expression of xenophobic attitudes, and 'Fremdenfeindlichkeit' (hostility against strangers) clearly describes such attitudes. 'Überfremdung' had already emerged as a concept in the German-speaking world towards the end of the nineteenth century. The use of the term reveals anxieties about a loss of national identity due to a massive increase of immigrants.

2. *Theoretical Framework*

One reason why xenophobia was given virtually no theoretical foundation is probably because the phenomenon cannot be discussed without taking into account normative concepts that focus on attempts to mark 'one's own' off from 'the other.' Race, nation, ethnicity, and culture are such concepts. In social and political reality, xenophobia manifests itself in accordance with the division of the world into one's own race, nation, ethnic group, and culture, and other races, nations, ethnic groups, and cultures. This type of symbolic and normative worldview promotes self-centeredness, and constitutes precisely the kind of cognitive framework within which xenophobia is spawned, articulated, and disseminated. Since fear and hatred, the two emotional states contained in xenophobia, are qualities that rely on subjective experience, they require cognitive signposts and social values to allow them to focus on their object. Focus on an object is less relevant when one fears something, than when one hates. Hatred of what is strange or foreign, therefore, always calls for naming and objectification. Labeling is the first step towards constructing

the object against which xenophobic hate can be directed. Social valuing of the object then modulates the intensity of xenophobia; it triggers the change from fear of the other—i.e., latent xenophobia—to hate of the other—i.e., virulent xenophobia.

Two scientific fields in particular deal with xenophobia: social psychologists examine forms of ingroup/outgroup behavior in which xenophobia can appear in its latent form, while researchers in the social sciences and humanities explore and interpret the social construction of xenophobia as well as its effect in modern societies.

3. *The Concept of Xenophobia in Social Psychology and Sociobiology*

In social psychology, research on xenophobia primarily explores groups rather than societies. Social psychological approaches start by dealing with questions such as 'how is group membership established?' and 'how does the ingroup distinguish itself from the outgroup?' Research shows that the self has to align with the group in order to establish group membership. To allow such alliances to be formed, group-related categories and identities must be available and used. If they do not yet exist, they are generated through the process of alliance itself. Intergroup comparisons allow the emergence of the kind of psychological distinctiveness which can lead to upgrading of the ingroup and downgrading of the outgroup.

Intergroup behavior is usually valued as a response to real or imagined group interests. At the heart of this theory is the proposition that group members' intergroup attitudes and behavior will tend to reflect the objective interests of their group vis-à-vis other groups. Where these interests conflict, their group's cause is more likely to be furthered by a competitive orientation towards the rival, which often is extended easily to include prejudiced attitudes and even overtly hostile behavior. At the same time, the success of the ingroup in achieving the goal is likely to be furthered by very positive attitudes towards other ingroup members, thereby engendering high morale and cohesion. Where, on the other hand, the groups' interests coincide it is more functional for the group members to adopt a cooperative and friendly attitude towards the outgroup. If this is reciprocated, a positive joint outcome is more probable (Sherif 1967). The social psychologists associated with Tajfel (1981) even proved experimentally that the mere fact of perceiving the existence of group categories suffices to generate an ingroup response: neither past hostility nor an objective conflict is necessary. Mere categorization is sufficient to produce intergroup discrimination. Categorizations that generate intergroup discrimination are intimately related to education and the use of stereotypes (Macrae et al. 1996) and prejudices (Lippmann 1922).

According to social psychology, then, xenophobia is a specific ingroup response that uses categorization in the form of stereotypes and prejudices, articulates real or imagined group interests, and pursues the goal of enhancing ingroup cohesion through discrimination against the outgroup.

Both in social psychology (LeVine et al. 1971) and in other scientific disciplines, as in sociobiology (Reynolds et al. 1987), xenophobia is either directly equated with ethnocentrism or at least interpreted as the logical extension of an ethnocentric frame of mind. The concept of ethnocentrism was first used by William G. Sumner, one of the key representatives of American Social Darwinism. In his definition of ethnocentrism, Sumner (1911) took up the concepts of 'codes of amity' (referring to internal cooperation) and 'codes of enmity' (referring to self-defence) defined by Herbert Spencer in the *Principles of Ethics*. His definition is still accepted today in several scientific disciplines, for which ethnocentrism is the technical name used for the feelings of cohesion that generate internal fellowship and devotion to the ingroup, which in turn lead to a sense of superiority to any outgroup.

4. *The Concept of Xenophobia in the Social Sciences*

In the social sciences, the focus of research is on social values, norms, historical developments, and structural factors, rather than on biological or psychological constants which provoke xenophobic behavior. The social sciences ask how these factors support the existence of latent xenophobia, as well as allow xenophobic outbursts within specific social and political contexts. Unlike sociobiologists, social scientists do not consider xenophobia to be a universal phenomenon; instead, they describe it, first, as one among several possible forms of reaction generated by anomic situations in the societies of modern states. Second, social scientists agree that xenophobia grows out of the existence of essentialist symbolic and normative systems that legitimate processes of integration or exclusion. Xenophobic behavior, therefore, is based on already existing racist, ethnic, religious, cultural, or national prejudice. However, social scientists usually fail to make clear distinctions between such systems of categorization and xenophobia.

Attempts were made at an early stage to understand differences between manifestations of xenophobia in different nations. Lapierre (1928), for example, gave four possible answers to the question of why racist prejudice and xenophobia are stronger in England than in France. Apart from the answer—common at

the time—that biological differences may play a role, he formulated three hypotheses that are still in use today. First, differences between the two countries may result from different forms of colonial involvement. Second, they may be determined by differences between the processes of political socialization in metropolises. Third, possibly, no radical difference exists between the two countries with respect to this issue, because manifestations of xenophobia can be interpreted as short-term, periodically variable reactions to immigration and group competition. Post-World War II research on xenophobia and racism has continued to develop these three approaches. The social sciences, however, show a preference for the second hypothesis, which is why political socialization is given particular attention. Research has indeed shown that in states which are comparable with regard to immigration, both the intensity of xenophobia and racism and their forms and organization develop differently (Banton 1996). Thus, empirical research has revealed that in France, the social distance between native North Africans and the French is significantly smaller than the social distance that separates Germans from native Turks in Germany. An important indicator is the number of mixed marriages in these two countries (Todd 1994). This discrepancy is not thought to be caused by a supposed greater inclination towards xenophobia among the Germans than among the French. Differences between processes of political socialization rooted in the conditions of the nation–state are considered more meaningful. The French model of the nation is based more on a universalist–assimilationist approach, while the German one is inspired more by a differentialist–culturalist approach. In the first model, barriers against naturalization are low because the principle of *jus solis* is still partly valid. In the second model, where the concept of the nation is rooted in the principle of *jus sanguinis*, the barriers against acquiring citizenship are high. In the French model, particular cultural identities are submitted to discrimination, while the German model favors such identities. At the same time, cultural categories are formulated negatively and constitute the basis for latent xenophobia and racism. This is a phenomenon that is currently particularly visible not only in Germany, but also in East-European and Southeast-European countries. Positive expressions of cultural categories, however, lead to multiculturalism. From the point of view of social sciences, racism and multiculturalism, therefore, are two sides of the same coin. Both forms of discourse are particularly developed in societies where there is a large social gap between ethnic groups.

At the beginning of the 1990s, xenophobic outbursts led to an increase in acts of racist violence in several Western countries. This was the culmination of a sudden rise of xenophobia in the West that began in the 1960s, and that can be distinguished from the old form of racism which led to Nazism and Fascism, with respect to both ideological roots and causes. Some researchers believe that it is possible to speak of a 'new racism' (Barker 1981) that began to develop slowly in the postwar area, as racism was no longer based on biological but on cultural differences.

Two interrelated causes are thought to have provoked the resurgence of xenophobic and racist movements. First, new migration patterns developed during the postcolonial era as a consequence of the gradual internationalization of the labor market. In the 1950s and 1960s, under the influence of recruiting programs such as the American *bracero* program and the *Gastarbeiter* (guest workers) policies developed by Germany and Switzerland, the kind of spontaneous migration which links low-wage and high-wage countries soon developed. In the countries of immigration, social groups with little access to resources considered newcomers as competitors who contended with them for jobs and public services (housing, education, social welfare). This easily fostered a social and political climate that generated xenophobia and racism—i.e., defensive reactions against migrants—as well as nationalism—i.e., demands that the state provide better protection against foreigners for its own population. This is the background that gave strength to those right wing parties which certainly now argue from a 'new racist' point of view and are particularly attractive to social groups who feel threatened by migrants.

The second cause that is believed to reinforce xenophobic and racist trends is globalization. Growing internationalization and more flexible markets of all kinds (for products, services, and labor) have led to intensification of competition between and within states. In turn, such competition has put pressure upon states, inducing them to reduce their services. Neoliberalism is the ideological foundation for globalization, and requires not only lean production but also a lean state. The reduction of state services in the areas of social welfare, education, and healthcare also hits those segments of the population who already live on the margins of society. The social groups whose livelihoods are menaced by the dismantling of the welfare state are the main breeding ground for xenophobic and racist ideologies, since these groups are placed in direct competition with migrants for welfare services (Wrench and Solomos 1993). Of course, outbursts of racist violence in various countries illustrate that xenophobia need not be caused by strong immigrant flows of the cultural other. Social decline of specific groups and right-wing political organization are sufficient preconditions for the emergence of xenophobia.

Y-chromosomes and Evolution

For several decades now, genetic studies have been used as a complement to more traditional anthropological approaches in the study of human origins and diversification (see *Modern Human Origins*). Most genetic analyses have used autosomal and mitochondrial (mtDNA) markers and such data provide a global picture of human evolution (Cavalli-Sforza et al. 1994, Ruiz-Linares 1999). Two major findings are that African populations show a higher level of genetic diversity when compared with other continents and that the greatest differentiation between human populations is seen between African and non-African populations. Both these observations are in agreement with paleoanthropological data showing that humans originated in Africa. Interestingly, the overall level of genetic differentiation between human populations is small relative to the diversity observed within populations, suggesting that the differentiation of human populations occurred relatively recently, possibly around 100,000–200,000 years ago. Based on paleoanthropological evidence two general models of human origins have been proposed: a multiregional and a Garden of Eden model. Under the first scenario the diversification of human populations is very old, tracing back to the initial differentiation of regional *Homo erectus* populations. The Garden of Eden model proposes that the differentiation of human population is recent (of the order of 100,000 years) and dates to the migration out of Africa of a fully modern human species. Genetic data have been found to be mostly consistent with a recent out-of-Africa model.

Until recently, little was known about the extent and distribution of diversity in the Y-chromosome. This problem stemmed from a basic difficulty in identifying genetic variation on this chromosome. None of the traditional genetic markers are found on the Y and attempts at identifying molecular variation progressed slowly until the late 1990s. A major breakthrough came about in 1997 when a novel technique known as Denaturing High Pressure Liquid Chromatography (DHPLC) was developed and allowed the rapid screening of a large number of DNA fragments from the Y-chromosome, leading to an increase in the speed of identification of new molecular variants. Recent developments resulting from the Human Genome Project, such as the availability of a draft sequence of the human genome and the activities of the so-called SNP (single nucleotide polymorphism) consortium are leading to an even faster identification of molecular variants on the Y-chromosome. The recent availability of a large number of genetic markers on the Y-chromosome has led to an increasing interest in the use of this chromosome in human evolutionary studies, both to explore human origins and ancient diversification as well as to examine recent population history.

1. *Transmission of the Y-chromosome*

Part of what makes the Y-chromosome of special interest for human population genetic studies is its peculiar mode of transmission. The passage of the Y from one generation to the next is immediately apparent: it determines the male sex. In other words, it is only transmitted from fathers to their male offspring. The fact that the Y-chromosome is transmitted between generations only by one sex means that if one reconstructs a genealogy of ancestors, only a single line of inheritance needs to be followed. Another type of DNA that shows a uniparental mode of inheritance is mitochondrial DNA (mtDNA), which is transmitted only by females (see Mitochondria and evolution). Thus, the Y-chromosome and mtDNA allow respectively the reconstruction of the male and female lines of inheritance or lineages (Jobling and Tyler-Smith 1995).

2. *Variability of the Y-chromosome*

Although the Y-chromosome determines the male sex, very few genes have been identified on the Y and none of the classical genetic markers are encoded by this chromosome. There is considerable cytogenetic variability of the Y but such variation is difficult to interpret for evolutionary studies. Similarly, most of the variants identified by molecular methods before DHPLC consisted of complex molecular rearrangements that were difficult to characterize and interpret in a population setting. The increasing number of variants that are now being identified can be categorized into two basic types: biallelic and multiallelic. The biallelic markers consist of nucleotide substitution or small insertion/deletions while the multiallelic markers generally consist of regions of the DNA in which a variable number of Short Tandem Repeats (STR) of a

Figure 1

DNA motif occur (for example a variable number of the tetranucleotide CATG). One basic difference between these two types of markers is that biallelic polymorphisms generally represent single evolutionary events while mutations at the STR loci occur at a relatively higher rate and the mutational process is frequently reversible. This means that identical STR alleles might have a different evolutionary history, as the same allele might be generated by independent mutational events, thus potentially erasing an evolutionary signal when probing too far back in time. However, the combination of these two types of markers actually increases the power of evolutionary analyses based on the Y-chromosome. Slowly evolving biallelic markers can be used to define the basic relationships between Y-chromosomes in an unambiguous form. The rapidly evolving STR markers can then be used to assess the relationships of Y-chromosomes within the basic lineages defined by the biallelic markers. Both kinds of markers can also be used to estimate the age of Y-chromosome lineages based on different evolutionary models, with the consistency of the two estimates thus providing greater confidence in such estimates (Pritchard et al. 1999, Thomson et al. 2000).

3. *The Origin and Diversification of Human Populations*

3.1 *Human Origins*

As biallelic markers on the Y-chromosome generally represent events that occurred only once in human evolution it is possible to examine the relatedness of Y-chromosomes worldwide and represent their ancestral relationships on a phylogenetic tree. The analysis of 167 genetic markers in 1,062 males from 21 populations around the world recently allowed the identification of 116 Y-chromosome types (Underhill et al. 2000). Based on the common ancestry of certain types, it is possible to group human Y-chromosomes into ten basic lineages (Fig. 1). Interestingly, the most ancient splits on the tree separate lineages I and II, which are

almost exclusively seen in African populations, from all other lineages which have a wider geographic distribution. This observation is in agreement with an origin of human populations in Africa followed by a migration out of that continent of a sample of African men. Descendants of these initial migrants would have founded small populations outside of Africa that would have remained small in size until the end of the last glaciation (around 16,000 years ago) when they would have expanded in numbers, spreading geographically to all inhabitable areas. Such an expansion is clearly evidenced in the Y-chromosome by the large proportion of mutations that are specific to a particular chromosome type. Estimates of the age of Y-chromosome lineages indicate that their initial differentiation is about 59,000 years old with a migration out of Africa around 44,000 years ago (Pritchard et al. 1999, Thomson et al. 2000). These findings are more in agreement with a model of recent African origins of modern humans; however the dates obtained with these data are considerably younger than those estimated from mtDNA and autosomal markers (Horai et al. 1995, Goldstein et al. 1995). This inconsistency might be due to natural selection (see *Natural Selection*) acting with variable intensity in different genetic systems or could relate to demographic differences between men and women. Overall, the Y-chromosome shows a reduced level of variation when compared with other genetic systems and such variation is highly structured by geography (Seielstad et al. 1998). This makes the Y particularly suitable for the study of the history of specific geographic regions.

3.2 Human Population Diversification

The analysis of Y-chromosome diversity at 22 biallelic markers in 1,007 males from 25 populations of Europe and the Middle East identified 20 different lineages (Semino et al. 2000). However, over 95 percent of the men examined have one of 10 lineages, several of which are closely related. Examining the distribution of these lineages in European populations it was observed that two closely related lineages showed East–West gradients in frequency, with one of them being particularly frequent in the Basque and the other in Eastern Europe (Poland, Hungary, and Ukraine). Phylogenetic and genetic dating analyses suggest that these two types of Y-chromosomes were brought to Europe by people of the Aurignacian culture, which spread to Europe about 35,000 to 40,000 years ago. The East-West gradient is possibly explained by the demographic contraction caused by the last glacial maximum (20,000 to 13,000 years ago) that would have led human populations to seek temporary refuge in more hospitable areas from which they would have subsequently expanded. A third Y-chromosome lineage is about 20,000 years old and is restricted to Europe (where it is seen at highest frequency amongst central Eastern Europeans) although it is closely related to Y-chromosomes frequent in the Middle East. The age and distribution of this lineage suggest that it was introduced by people of the Gravettian culture that appeared in Europe around 20,000 years ago. These people found refuge in central Europe during the last glacial maximum, after which they expanded into Western Europe. Finally, a group of younger and closely related haplotypes show a gradient in frequency from the Middle East into Europe and might have been spread by the people that introduced the practice of agriculture into Europe about 10,000 years ago. Y-chromosome data thus indicate that two Paleolithic and one Neolithic migrations are at the origin of most of the current European population as manifested by three main population clusters seen when lineage frequencies are compared between populations (Fig. 2). The three clusters observed (Western Europe, Eastern Europe, and the Middle East) correspond to the two major glacial refuges and to the area of origin of agriculture.

4. Male and Female Migration in Human Evolution

A very interesting use of genetic data is in teasing apart male and female demographic history throughout human evolution, by comparing population diversity of Y-chromosome, autosomal, and mtDNA markers in native populations from around the world. In an

initial evaluation it was observed that the level of genetic variability across populations based on Y-chromosome markers was much greater than that observed with mtDNA markers (Seielstad et al. 1998). This means that the distribution of Y-chromosome variants is geographically more localized than that of mtDNA variants. A possible explanation for this global pattern could be that about 70 percent of human populations practice patrilocality, that is women tend to move into the areas inhabited by the males they marry and consequently move more, on an evolutionary scale, than men. A subsequent refined analysis restricted to South American populations failed to confirm the generality of a higher migration rate of women in native populations (Mesa et al. 2000). A detailed evaluation of the proposal that females have generally had a higher migration rate than males awaits the analysis of more genetic markers and populations. However, it is possible that important regional differences in male/female migration rates might be detected and that these differences relate to the frequency with which patrilocality is practiced in different parts of the world.

5. *Maternal and Paternal Origins of Recently Founded Human Populations*

The comparison of mtDNA and Y-chromosome markers is also informative when applied to populations established more recently and such data can be used to refine information obtained from traditional historical sources. Particularly, analyzing different genetic systems can help establish the relative proportion of males and females from particular geographic areas that founded a new population. In the province of Antioquia in Colombia it was seen that about 90 percent of Y-chromosomes were European while 90 percent of the mtDNA lineages were Native American (Carvajal-Carmona et al. 2000). This indicates that the population was founded mostly by European males and Native females. This finding is consistent with the geographic isolation of the province and with historical records indicating that in early colonial times, on average only about 20 percent of the Spanish migrants to the New World were women. However, this result is inconsistent with autosomal markers, which indicate that this population is predominantly of European ancestry. This inconsistency between bi and uniparental markers might relate to the collapse of the Native American population during the first century of Spanish colonization and to the fact that Spanish immigration was a long-term process. These demographic factors might have resulted in a progressive dilution of the founding Native American component as estimated with autosomal markers.

Curiously, the analysis of rapidly evolving STRs indicates that the population of Antioquia seems to have a relatively important Jewish ancestry as evidenced by the finding in this population of Y-chromosome STR lineages seen at high frequency only in Jewish populations. However, no record is available of a Jewish migration to Antioquia. Furthermore, almost simultaneously with the Spanish expansion to America, Jews were expelled from Spain or forced to convert to Christianity. The Y-chromosome findings suggest that amongst the Spanish founders of Antioquia a relative large proportion of converts was represented. No record of such contribution is available probably because the migration to the colonies of converts was considered illegal under colonial rule.

6. *Conclusion*

Developments resulting from the Human Genome Project have recently catapulted the use of Y-chromosome markers into the forefront of the study of human population origins and diversification. The large number of markers currently available together with novel highly efficient technologies enable analyses of an unprecedented resolution and scale. Evolutionary analyses are facilitated by the fact that slowly evolving markers allow the unambiguous assessment of the evolutionary relationship between Y-chromosomes. Rapidly evolving markers can refine analyses within specific lineages or populations. These studies illuminate not only questions related to the origin of our species and its early diversification but also allow the probing of more recent demographic events. The synthesis of genetic data with information obtained from sources including geology, paleoanthropology, archaeology, and historical demography is allowing a refined reconstruction of human evolution stretching from our origins as a species all the way to the exploration of quite recent historical events.

Youth Culture, Anthropology of

The study of youth has often hovered on the relative margins of more central anthropological preoccupations even as it has been inspired by work in such disciplines as sociology and cultural studies. During the late 1980s and over the course of the 1990s, research on this subject, both within anthropology and cognate disciplines, was catalyzed by a growing interest in popular culture and globalization, fields in which youths have often played pivotal roles. In the process of this reanimation, the study of youth within anthropology has moved away from a concern with adolescence as a life course stage to an interest in youths as cultural producers and consumers.

1. Defining Youth

The range of persons anthropologists include in the category of youths has often varied depending on the cultural context in which this position is being defined and on what question the researcher is asking in respect to this field. In a rare early example of a systematic ethnographic focus on youths, during the 1920s Margaret Mead conducted research centering on a group of girls, ranging in age between 10 and 20 years, who were residing in three villages on the Samoan island of Tau (Mead 1928/1968). In carrying out this research, Mead was concerned to answer the question of what 'coming of age' meant in Samoa and how this differed from the experience of growing up in the USA. She claimed that unlike the emphasis on storm and stress which then (and has since) dominated American characterizations of adolescence, growing up in Samoa was a simple, easy matter, a process which involved no special conflicts or dramatic transitions. Beyond the obvious signs of physical maturation, she suggested that there were few differences between Samoan girls still approaching puberty, those who were just passing through this transition, and those already several years beyond it. Given this emphasis, it is hardly surprising that Mead was not concerned with defining the boundaries of adolescence too precisely or distinguishing it sharply from either childhood or young adulthood.

In contrast, Alice Schlegel and Herbert Barry's (1991) much later survey of adolescence in ethnographic accounts of 186 nonindustrial societies was more expressly directed at delimiting this stage cross-culturally. Schlegel and Barry argued that while the social duration of adolescence varied cross-culturally and between genders, it was universally recognized as a social stage of the life cycle and tended to fall between the ages of 11 and 17 or so. When social adulthood was delayed far beyond puberty, a further stage intervened between adolescence and adulthood, a stage which Schlegel and Barry called 'youth.' While adolescence was universal, the stage of youth was only recognized in a minority of societies.

However, this distinction between adolescence and youth as two distinct social stages is not otherwise common in the anthropological literature on youth

culture. In part this reflects an ambiguity in the boundaries assigned to adolescence which is especially common in the Western industrialized settings which have often been the locales for youth culture research but in part this also reflects a set of particular analytical priorities. For example, a cross-cultural collection of articles on youth cultures edited by Vered Amit-Talai and Helena Wulff (1995) included groups ranging in age between 10 and 30 years with considerable variation in the scope of autonomy and social responsibilities represented among them. However, this collection, unlike Schlegel and Barry's or Margaret Mead's studies, was not directed at defining youth (or adolescence) as a stage of human development. Rather it was concerned with the ways in which young people creatively engage with, are affected by, and in turn help to shape the statuses, images, products, styles, and orientations identified, sometimes very broadly, with youth. In short, it was concerned with the experiences and attributions of youth rather than when and how youths become adults. As such it reflects a reorientation of the study of youth which has been as much inspired by influences outside anthropology as within it.

2. *The Cross-disciplinary Antecedents of Youth Culture Studies*

While Margaret Mead was very successful as a popularizer of anthropology, she was not equally successful in provoking fellow anthropologists to continue her focus on adolescents. For many years following Mead's work in Samoa, youths largely remained marginal figures in the anthropological record. Concerted interest in this field was much more evident in other social science disciplines than it was in anthropology. During the 1930s, a little over a decade after Mead's initial research in Samoa, the sociologist William Foote Whtye began participant observation fieldwork in the North End of Boston. Whyte's (1943/1981) classic ethnographic study of the organization of peer relations among second generation young Italian men in a 'slum area' exerted a seminal influence primarily on the development of US urban studies. Yet it was and remains one of the most thorough and sympathetic portraits of youth street life ever produced, effectively countering the notion of social disorganization which had dominated the US sociological literature on inner cities until that point. Not long after Whyte's study was published, the concept of youth culture appears to have been introduced by another American sociologist, Talcott Parsons (1942/1964) and was later taken up more systematically by James Coleman (1961) to denote the circumscription of American youth peer interaction. It was, however, the work of British cultural theorists during the 1970s and early 1980s which did most to develop youth culture as a central field of research on class, subculture, and consumption.

During this period, the Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham, sometimes referred to as the 'Birmingham School,' launched an ambitious collaborative study of British youth subcultures (Hall and Jefferson 1976). For the CCCS scholars, youth appeared to offer a special vantage point from which to consider the more general dislocation and fragmentation of the British working class as the structure of Britain's system of production, labor force, income distribution, and lifestyles was transformed over the course of the post-World War II period. The emergence of a variety of highly stylized British youth subcultures (punks, mods, skinheads, etc.) appeared to crystallize the growing importance of mass culture, consumption, and leisure practices as bases for increasingly fragmented working class identities. The gaze of the CCCS was self-consciously selective, focusing on young British nonconforming white working class males. The larger population of 'ordinary' working class youth who accommodated to rather than visibly resisted institutional controls, middle class youth, and girls, with some notable exceptions, were not accorded similar attention, gaps which were well noted by later critics. The members of the 'Birmingham School' were also criticized for reading ideological undertones of class resistance and consciousness into what sometimes appeared to be fairly trivial instances of adolescent rebellion. In spite of an emphasis on case studies, the CCCS published work was notably slim in empirical findings. Here again, there was a notable exception in Paul Willis' (1977/1981) ethnography, Learning to Labour, which followed a group of boys, the 'lads,' through their last year of high school and onto the industrial shop floor. Yet, in spite of these limitations, the Birmingham School's focus on popular culture, consumption practices, resistance and cultural agency, and their attention to youth as a nexus for broader social change, continue to resonate in research on youth culture both within anthropology as well as in other disciplines.

3. *Anthropology of Youth Culture: Key Features*

Current anthropological research on this subject is characterized by a determined shift away from socialization and human development approaches, which have often entailed less of a focus on youths than on the adults they will eventually become or the adults attempting to direct and socialize them. Instead, contemporary anthropologists are more likely to focus on young people in their own right. While much of this research pays heed to the marginality generally associated with youth, it does not assume that this social location produces a simple helplessness or passivity.

Instead, it often features an insistence on respecting the capacity of juveniles to be active agents creatively shaping their environment even as they contend with a variety of legal, political, economic, and social constraints imposed on them by virtue of their age and liminal status.

These emphases have emerged within the context of a broader reorientation of anthropology away from the notion of unitary and enduring cultural formations which was more common in Mead's day to a contemporary conception of culture that can more easily accommodate internal diversity, fragmentation, and transience. This has made it easier for anthropologists to be comfortable with a notion of youth as eliciting specific kinds of knowledge and cultural competence that are different from rather than incomplete versions of adult cultures. It has also rendered more persuasive the claim that youth cultures can have broader analytical and social significance even when they are highly ephemeral and situationally specific. During the 1980s and 1990s, critical reappraisals of the conventions of ethnographic accounts, in particular of the ways in which the textual authority exercised by anthropologists can silence or distort the perspectives of the people they are studying, provided a broader context for a reconsideration of the ways in which ethnographic representations had effaced the presence and experiences of children and youth. In a cogent illustration of the dialectical nature of intellectual exchange, an essay by George Marcus (1986) in a volume which was particularly influential in this broader anthropological reassessment, focused on Paul Willis' seminal CCCS ethnographic study of working class boys in school. In turn, volumes of this kind and the critical introspection they prompted influenced subsequent anthropological studies and representations of both children and youth.

Notwithstanding this exchange, the study of youth culture remained on the relative fringes of mainstream preoccupations within late twentieth century anthropology. There were more ethnographers conducting research in this field than twenty years previously but their work still only had limited recognition within the larger discipline of anthropology. This is in spite of the fact that youth studies often focused on issues with general salience in contemporary anthropology, particularly the impact of globalization, migration, and popular culture. Hilary Pilkington's (1994) study of Moscow youth focused on the ways in which the production and consumption of music, dance, and dress styles mixed and hence mutually transformed imported Western and local Russian influences. Mark Liechty's (1995) study of youth in Kathmandu explored the media appropriation, dissemination, and reinterpretation of the Western concept of teenager. Livio Sansone (1995) examined the changing and increasingly global nature of youth culture among young Creoles of Surinamese origin living in Amsterdam.

Notwithstanding the broad dimensions of the processes they consider, many of these ethnographies of youth are self-consciously and intentionally intimate in focus. Helena Wulff's (1988) South London study examined a wide range of issues including the symbolic dimensions of black British ethnicity, consumption practices, friendship, femininity, and institutions of family, school, and youth club, but it deliberately and carefully focused on the relationships and lives of 20 girls between 13 and 16 years of age. Wulff's focus was based on her concern to relate cultural process concretely to individual lives and social relationships, a goal more accessible through a concentration on small-scale cultural processes or 'microculture.' Similarly, nearly a decade later, in another study of black British youth in London, Claire Alexander argued that in focusing on a small number of male informants she was 'hoping to portray an alternative vision of black youth; not as a unified and homogenous, externally defined and structurally constrained entity, but a collection of individual lives, choices, and experiences' (Alexander (1996, p. 18). Their capacity to marshal a wealth of detail about relatively few individuals allows these small-scale studies to move beyond stereotypical notions of youthful resistance or undifferentiated peer culture to reveal the fluidity and creativity of cultural processes among young people.

4. *Gaps in the Anthropology of Youth Culture*

In spite of nearly two decades of critiques, the influence of the pioneering work of the CCCS continues to be expressed in a predominant emphasis on leisure activities and peer relations within many youth culture studies. Ironically, given the CCCS interest in class, the focus on leisure has often been at the expense of systematic analyses of the political economy of youth. Problems of unemployment and the gulf between globalized media images of Western consumption practices and the limited economic resources of many youths are alluded to in a number of studies. However, the nature of the economic roles performed by youths, while still students or nominally minors, as workers in service or informal sectors has not received much sustained attention. We are still much more likely to see youths dancing, singing, clubbing, and consuming fashion and media than working. Yet the globalization of production and the growth of service industries has often relied on the availability of cheap, part or full time youth labor. We are also not very likely to see much of the interaction between youths and adults, particularly with their parents. In the concern to move away from adult-based socialization models of adolescence, researchers often appear to have created ethnographic landscapes remarkably devoid of the adult figures who nonetheless figure so largely in the lives of the youths being studied. Not only are such

portraits ethnographically incomplete but, without including adults, it is difficult to see how these studies can adequately address issues of power and subordination, however sensitive they may be to the association between youth and social marginality. Finally, one has to wonder whether the marginality of their youthful subjects has been extended by proxy to this subfield of anthropology. If so, it would be a strange irony in a discipline that has prided itself on its particular attention to poor and marginalized peoples.

Youth Culture, Sociology of

Youth culture refers to the cultural practice of members of this age group by which they express their identities and demonstrate their sense of belonging to a particular group of young people. The formation of youth culture thus implies boundary drawing. Both the youth culture's distinction from mainstream (adult) culture and its internal coherence help define the members' personal identity and enhance feelings of belonging. With the extension of the life stage 'youth' in the later decades of the twentieth century (Buchmann 1989), the boundaries of youth as an age group have been increasingly blurred. The issue of what constitutes authentic and autonomous cultural expressions of youth (as opposed to the mainstream adult cultural practice) has therefore become more complex. Likewise, the internal differentiation of juvenile cultural practice and the proliferation of youth cultures from the late twentieth century raise the question of the relationship between structural location, socialization, and cultural practice. After a brief history of the concept and the presentation of the major theoretical currents, these issues will be discussed.

1. A Brief History of the Concept

The notion of youth culture dates back to the start of the twentieth century. With the development of youth movements in Germany, such as the *Wandervogel*, representatives of the so-called *Reformpädagogik* noticed the distinct ways of cultural articulation shown by this group of young people, for which they coined the term 'youth culture.' The juvenile cultural orientations and styles of behavior were interpreted as signs of authentic and autonomous cultural practices. This fundamental issue—whether the social group of youth may be characterized by a common authentic lifestyle developed within the self-defined community of peers—would accompany the theoretical debates within the sociology of youth over large stretches of the twentieth century. The first input to this scientific discourse can be traced back to the 1920s, when researchers from the Chicago School of sociology engaged in many empirical studies on criminal milieux, especially on delinquent youth groups (e.g., Sutherland 1924). Detailed investigation of groups of juvenile delinquents revealed similarities in their outlook on life, values, and styles of behavior. To characterize these

commonalities, the notion of youth culture was introduced into the scientific literature. But it was not until the 1940s that juvenile cultural practices would be conceived of explicitly in terms of a subculture (Hollingshead 1949). The use of this concept implied, first, the assumption that there is global cultural differentiation between youth and the dominant (adult) society, and, second, the idea of the strong internal coherence of juvenile cultural expressions.

2. *The Cultural Differentiation of Youth from Adult Society*

The two basic assumptions of the early conceptions of youth culture mentioned above can be linked to two influential theoretical traditions within sociology. The first refers to Mannheim's concept of generation (Mannheim [1928] 1997). The second theoretical tradition, linked especially to the name of Eisenstadt (1956), focuses on the peculiarities of the transition between age groups within modern society and related questions of socialization.

2.1 *The Legacy of Mannheim's Concept of Generation*

Even popular conceptions of youth, especially those advanced by the mass media in the second half of the twentieth century, would often refer to the concept of generation to characterize a juvenile way of life. Descriptions of youth, such as the '68 generation,' the 'beat generation,' the 'no-future generation,' or the latest version of 'generation X' document the attractiveness of this concept.

The major input to the scientific debate on generations goes back to Mannheim ([1928] 1997) who developed the generational approach. Mannheim maintains that the formation of a generation is most likely to occur during the life stage of adolescence. During these formative years, the experience of social circumstances and historical events will have especially profound and long-lasting effects. However, the common location in the historical processes, or the generation location (*Generationslagerung*), is not sufficient for the formation of a generation as an actuality. Although the common location in history provides access to a specific range of potential experiences, the generation as actuality (*Generationszusammenhang*) presupposes the '*participation in the common destiny* of this historical and social unit' (Mannheim [1928] 1997, p. 46 [Mannheim's emphasis]). Mannheim acknowledges the possibility that groups of youths exposed to the same generation location may '*work up the material of their common experiences in different specific ways*' (Mannheim [1928] 1997, p. 47 [Mannheim's emphasis]). Hence, these groups constitute separate generation units (*Generationseinheit*). Mannheim's approach has provided two major theoretical contributions to the sociology of youth culture. The first input is the conceptualization of generations in relation to social processes and historical events as opposed to biological age boundaries. The second insight relates to differences in the ways in which young people within the same generation location cope with their common experiences and thus develop different cultural orientations and styles of behavior. Unfortunately, much of the empirically oriented research on youth culture in the second half of the twentieth century, while incorporating the concept of generation, did not make use of Mannheim's fine distinctions.

2.2 *The Role of the Juvenile Subculture in the Transition to Adulthood*

In Mannheim's theoretical frame, the role of socialization processes in adolescence is related to the profound and long-lasting effects of historical events. By contrast, structural functionalism as developed by Parsons and further elaborated by Eisenstadt (1956) focuses on the role of age-homogeneous groups (peer groups) as agents of socialization. According to structural–functional theory, these groups fulfill the function of facilitating the young people's transition to adulthood in modern society. In order to become full members of modern society (i.e., adults), adolescents must undergo a fundamental reorientation. As children, they are predominantly integrated into the family, a sphere of social participation characterized by particularistic relations. The positions and roles in this action sphere are mostly ascribed, and behaviors are scarcely evaluated on the basis of achieved criteria.

In the adult world, however, the range of social participation is much broader, demanding much more elaborate action capacities. Moreover, most spheres of social participation are structured according to universalistic principles. Action outcomes are therefore attributed to individual competencies. In this context, formal and informal age-homogeneous groups of youths may be regarded as 'interlinking spheres' helping to bridge the gap between the demands of the children's world and those of the adult world. Norms and values predominant in peer groups usually show a specific combination of particularistic, as well as universalistic, elements. Hence, participation in peer groups and their culture provides a great opportunity for juveniles gradually to acquire action competencies compatible with universalistic principles. Given the relative absence of direct social control by adults, age-homogeneous groups provide a social space in which autonomous and self-responsible action patterns may be learned without being immediately exposed to adult sanctions. The flipside of such a sanction-free space may be the development of peer cultures that are in more or less stark contrast to the norms and values of the adult world.

Against this background, theoretical thinking about youth culture in the 1950s and early 1960s was largely dominated by the idea that youth as a social group adheres to common values, goals, and behaviors distinct from those of the adult world. Most influential in this respect was the work by James Coleman (1961), who described the independence, the internal homogeneity and coherence of the world of youth, for which he coined the term 'peer culture.' Empirical evidence, however, did not support the global differentiation of youth culture from that of the dominant (adult) society. Various forms and styles of juvenile cultural expression have always existed, displaying some common elements. With the onset of the general critique of structural functionalism within sociology, the focus on the functional necessity of adolescents' orientation towards peers and their culture gradually faded and gave way to theoretical thinking that paid greater attention to the internal differentiation of youth culture.

3. *The Structure of Social Inequality in Modern Society and Class-specific Youth Cultures*

The reorientation within the sociology of youth culture became especially evident with the research conducted at the Centre for Contemporary Cultural Studies (CCCS) in Birmingham, UK (Hall and Jefferson 1975, Willis 1990). Although the concept of subculture remained essential to their understanding of juvenile cultural expressions, this research tradition not only linked it to the dimension of age (generation), but also stressed the connection to the dimension of social inequality, in particular to social class. Within this theoretical framework, juvenile subcultures are regarded as the outcome of class-specific socialization processes. Hence, youth culture is internally differentiated and, most likely, several youth cultures coexist at any given period of time within modern society. The CCCS model assumes that the cultural sphere of modern society is made up of two independent cultures, hierarchically related to each other. The bourgeois culture is the dominant one and the working class culture is the discriminated one. Within these cultural entities, differentiation by age, ethnicity, and sex may occur. The differentiated subcultures show a varying degree of overlap with the superordinate culture, incorporating common, as well as distinct, cultural elements. Moreover, they are characterized by relatively high internal consistency and relative stability, encompassing all life spheres.

Theoretically, the aforementioned characteristics of subcultures are linked to socialization processes. As members of a particular social class, individuals learn the class-specific cultural repertoire and become equipped with particular resources, with which they try to solve the problems of daily life. Given the multiplicity of membership in modern society (e.g., class, gender, age), particular tasks may occur that demand new ways of coping. With respect to the age group of youth, juveniles have to cope with their indeterminate social position—no longer children, yet not full adults. This particular social situation predisposes them to invent cultural practices that help them to define who they are (i.e., identity construction) and to develop social bonds and a sense of belonging. In this influential theoretical tradition, juvenile subcultures are interpreted as class-specific answers to the particular demands of the life stage 'youth.' Although all young people are confronted with these demands, the social milieu greatly determines the material and symbolic resources available to them, thus resulting in class-specific cultural practice.

4. *Structural and Cultural Change Within Late Modern Society: Youth Cultures as Youth Styles*

The basic assumption of the cultural model developed by the researchers of the CCCS maintained that the precise social location was essential to the definition of juvenile subcultures. The cultural practice of youth was conceived to be the symbolic expression of their social existence. Observers of youth culture in the 1980s noticed, however, the proliferation of juvenile cultural expressions characterized by a looser coupling with young people's social positions (Cavalli and Galland 1995, Chisholm et al. 1995, Thornton 1996). The weakening of the linkage between social location and cultural practice, furthermore, was accompanied by the growing importance of the element of style in young people's cultural expressions, i.e., the expressive and esthetic presentation of one's identity and social belonging.

Although the research tradition of the CCCS, focusing on class-specific differentiation of youth cultures, paid particular attention to the element of style (Hebdige 1979), the full meaning of style as the main ingredient of youth culture was not yet recognized. In this tradition, style was conceived mainly to be a particular means by which the unresolved problems and contradictions inherent in the respective adult class cultures could be expressed symbolically. More recent conceptions of the role of style in youth culture stress the intricate relations to several structural changes within late modern society. In particular, three facets of social change have been identified: first, the growing structural differentiation, resulting in the blurring of age boundaries and the changing significance of social standing; second, the increasing importance of the social sphere of leisure; and third, the role of the media in constructing and disseminating symbols of youth style. The three facets of social change and their implications for juvenile cultural practice are discussed below.

Although still hotly debated, social change in late modern society has been associated with the growing

differentiation of the system of social inequality and the concomitant diversification of individual life course patterns (Buchmann 1989). Advocates of this view link these changes to the expansion of the educational system, which provided access to medium-level and higher education for the broader masses. The profound changes within the institution of education resulted in a substantial extension of the life stage 'youth,' and especially in the blurring of age boundaries between youth and adulthood (Buchmann 1989). The massive expansion of the welfare state is regarded as another major element of these changes, making life less dependent on the family. With the broad application of information and communication technologies, profound changes in the economy and the labor market occurred, transforming work roles and occupational careers. Hence, the pathways from school to work, the major role and status change in the transition to adulthood, became increasingly diverse. Under conditions of increasingly differentiated social positions and life course patterns, the ways in which individuals express their identities and demonstrate their sense of belonging is affected as well. The quasi-automatic integration into social milieux and collectivities can no longer be taken for granted. Rather, the individual's identity and his or her group membership become more dependent on action capacities and competencies. Cultural practices, especially those including stylistic elements, therefore advance to particularly suitable means to symbolically present one's self and express one's social affiliation. Hence, juvenile cultural practice crystallizes into particular youth styles.

The structural transformation of late modern society described above also brought about a shift in the relevance of various spheres of life. In particular, the social sphere of leisure became much more important, both as an element of lifestyle and as a means of cultural distinction. Characterized by a strong component of social visibility, leisure-time activities provide ample opportunities to satisfy the needs of the expressive and esthetic presentation of one's self and one's social belonging. With regard to youth especially, cultural practices such as music, dancing, movies, visual arts (e.g., comics), particular sports (e.g., skateboarding), and fashion (e.g., clothing and hairstyles) are preferred means of expressing a distinct way of life that is recognized by others as a sign and signal of a particular identity and group membership (Austin and Willard 1998, Danesi 1994, Epstein 1998). In fact, late twentieth/early twenty-first century youth cultures are mostly integrated into leisure time and oriented toward mass media and consumption. They are to a large degree leisure styles. The heterogeneity of juvenile cultural scenes and styles observed at the beginning of the twenty-first century can be attributed both to increasing degrees of freedom in the individual's scope of action, due to the structural changes in late modern society discussed above, and the great abundance of cultural materials provided in the sphere of leisure. According to the particular needs of social representation, young people may assemble and reassemble stylistic elements of various origins in ever new ways to form distinct styles of juvenile cultural practice.

For the swift circulation and dissemination of the cultural signals of youth styles, media and computer culture play an ever greater role (Kellner 1994). The formation of youth styles and scenes may be regarded as an interactive process with the media. Styles for clothing and hair generated in informal groups of youths, for example, are often quickly appropriated by the media and the market, and turned into fads and fashion. As a result, larger segments of youth may get the opportunity to participate in this style, thus contributing to its dissemination. And, vice versa, cultural materials provided by the media may be appropriated and reinterpreted by young people and utilized in the construction of juvenile styles. The mutual appropriation and simultaneous transformation of cultural signs and signals by groups of young people and the media is the major reason for the rapid fluctuation and swift turnover of youth styles at the beginning of the twenty-first century. As soon as juvenile cultural expressions have become integrated into the mainstream (adult) cultural world, they can no longer serve as means of cultural distinction. However, this is essential for presenting one's identity and expressing a sense of belonging to a particular group of youth.

5. *Future Directions in the Sociology of Youth Cultures*

Scholars of youth culture agree that in recent years the field has been dominated by detailed descriptive studies of the proliferating forms of juvenile cultural expressions. As valuable as these studies are for gaining insights into contemporary juvenile cultural orientations and styles of behavior, theoretically based issues and matters should again become more prominent in future research. To date, it is largely unknown which structural or cultural factors are responsible for the predominance of class-related juvenile cultural expressions and, vice versa, for the predominance of generation-related juvenile cultural styles. Furthermore, the impact of juvenile cultural innovations on cultural change in society at large remains largely unknown. Likewise, the role of the media in the construction, dissemination, and appropriation of juvenile lifestyles is not well understood.

Youth Gangs

1. Introduction

Youth gangs have been a part of the American culture since the eighteenth century (Sante 1991, Sheldon 1898). Gangs are diverse in American society; not all gangs are the same. Traditionally, researchers have identified poverty as a common bond between members of youth gangs (Miller 1958, Cohen 1960, Moore 1978, Taylor 1989, Curry and Spergel 1992). Many gangs today are still largely populated by young people from inner city neighborhoods, characterized by high unemployment, high educational dropout rates, and a general feeling of hopelessness. Yet, today, not all gangs share an impoverished background. Youth gangs are springing up in affluent suburbs and in rural areas (Goldstein and Soriano 1994, Spergel and Curry 1993, Evans et al. 1999). At the start of the twenty-first century, many traditional views about what constitutes a gang are still prevalent. Defining gangs has been, and continues to be, a problem in the USA. The practice of defining a gang has become highly subjective, ranging from disorganized noncriminal to highly organized criminal organizations (Taylor 1989). This diversity continues to be debated by professionals in social work, law enforcement, education, and community organizations.

The following sections include discussions on the difficulty of defining youth gangs (see Sect. 2), as well as covering the diverse ethnic membership of youth gangs in America (see Sect. 3). Myths of gangs and gang members are discussed because society tends to view gangs from a myth-based perspective. In order to understand the problem, define the problem, and prevent the problem of gangs, a reality-based approach must be found (see Sect. 5). These discussions rely on available gang studies for a broader perspective of the gang problem in the USA today. Following the conclusion, an extensive reference list is provided to assist with further review of the topic.

2. Defining Gang

Historically, defining the term *gang* has been a problem in the USA. Early definitions did not focus on criminal activity, but rather on delinquent behaviors. Consensus of definition does not exist today. Many researchers have created their own versions of what constitutes a gang (Klein 1968, Huff 1989, Taylor 1990, Monti 1993). In fact, every organization that comes in contact with gangs has created an operational definition of the term to suit its own needs. Although law enforcement's focus, understandably, is on gangs that are breaking the laws and mores of society, there isn't one definition for all jurisdictions to follow (Cromwell et al. 1992).

Neighborhoods, families, and communities also come in contact with gangs and must find a way to define existing groups. Groups of youth in many communities across America may appear similar to gangs, yet they have no criminal past or future. One researcher called these types of groups adjunct, advocated political groups, and underscored that often they comprise productive young citizens of a particular community (Taylor 1993).

Gangs vary by membership and activity. Generally, researchers agree that there are different degrees of gang involvement and activity (Fagan 1989, Huff 1990, Taylor 1990). Although some young gang members earn a living through drug trafficking, illegal weapons sales, and other criminal activities, others join gangs for noncriminal reasons. For example, a young person may join a neighborhood gang to get protection in their neighborhood; another may join to gain respect they would otherwise not receive at home or in the community; and still others may join for the camaraderie. Whatever the reason, gang members are as diverse as the gangs themselves.

What constitutes a gang to some communities is clearly not always tied to criminal behavior. Some will choose to define gangs by categorizing them as organized or unorganized criminal groups. Yet others will be swayed by images that are often fictional (see Sect. 4).

3. *Overview of US Youth Gang History*

The earliest record of youth gangs in the USA may have been as early as the eighteenth century, at the end of the American Revolution in 1783 (Sante 1991). Some of these gangs were known as Smith's Vly gang, the Bowery Boys, the Broadway Boys, and the Long Bridge Boys (Osman 1992). These gang members were not necessarily criminals who committed violent crimes, although they did fight with rivals.

Redfield (1941) believed the first gangs in the USA migrated from Mexico in the nineteenth century after the Mexican Revolution in 1813. It was around this time that the first criminal gangs were formed. These were youth gangs involved in criminal activity, due in part to the economic situation and the increase in population in urban areas.

The Irish immigrants were the first to form criminal gangs in New York City in the 1820s. The 1850s saw an increase in gang membership as urban government corruption was rampant. During the early years after the civil war ended, migration patterns increased for industrial centers like New York, Chicago, and Detroit. The Irish, Jewish, and Italian immigrants who came were impoverished and formed gangs based on ethnicity. It was also at this time that drugs were introduced to gang life.

The early part of the twentieth century was dominated by economic turmoil. Due to the increase in population of the urban areas and the decline in the economy, the gap between the rich and poor grew. According to Thrasher (1927), there were 1,313 gangs in Chicago in the 1920s. Many of these were ethnic gangs. The increase in the number of immigrants in urban areas continued throughout this century. In particular in the early 1940s large numbers of Puerto Ricans entered New York City. This fact, along with a growing African-American population from the south, contributed to the large minority populations in northern cities. While Irish, Italian, Jewish, and other Eastern European ethnic groups were establishing their communities, Puerto Ricans and African-Americans, including strong pockets of black West Indians, became a strong presence. Racial conflict was clear in northern big cities such as Detroit, Michigan, where one of the worst race riots in American history took place in 1943. Groups of white youth gangs roamed the city attacking black citizens (Shelden et al. 1997). Around the same time in Los Angeles, the Zoot Suit Riots of 1943 were underway. In these riots, white residents and visiting soldiers harassed and beat up young Chicano men who dressed in the popular zoot suit style of clothing (Moore 1978, Shelden et al. 1997).

Following World War II, gangs became more organized. As the population in ethnic ghetto neighborhoods shifted from largely Eastern European in the early 1950s toward African-American and Latino in the 1960s and 1970s, so did the ethnicity of gangs in those areas. Weapons, illicit narcotics, and sexual encounters came with delinquent and criminal street youth gangs in the 1950s and 1960s. Urban cities experienced poverty, crime, and inferior education. Some researchers contend that young people, under-educated and without access to good jobs, become frustrated with their lives and join gangs as an alternative to boredom, hopelessness, and poverty (Shaw and McKay 1942, Cloward and Ohlin 1960, Taylor 1990). Today, the composition of youth gangs is changing with the onset of affluent suburban and rural youth gangs (Korem 1994, Evans et al. 1999).

During the 1960s, the connection between criminal gangs and youth gangs varied from neighborhood to neighborhood, and city to city. Female gangs evolved from male gangs in some of these cities. The media focused on youth culture and its music, dancing, and desire to have its own identity. Youth culture defines itself within the context of hip hop, grunge, and other youth experiences and expressions. Many times gangs were blamed for anything negative or delinquent (Miller 1975). The issue of social class is underscored by how some communities responded to the challenge of gangs. Many middle class communities supported recreational programs for youth. Unfortunately, the concept of positive youth development only applied to the middle class youth in suburbia. Inner city youths were not included in positive youth development, instead youth detention was used to regain and maintain social control.

The Watts Riots of 1965 did for African-American gangs what the Zoot Suit Riots did for the Chicano gangs in 1943. Basically, the outcome was that the media began to portray the youths in a negative light, and the youths began to see themselves differently. They chose to see themselves as defiant rather than defeated, and to 'redefine exclusion as exclusivity' (Shelden et al. 1997).

For the most part, the 1960s saw a decline in gang violence. By the early 1970s, they were back on the front page. At this time, drug use in gangs began to decrease while the use of violence began to increase. The gangs of the 1970s, with greater use of guns, were more lethal in their encounters than previously (Horowitz and Schwartz 1974, Taylor 1989). By the 1980s, the urban ghettos became overcrowded and the youth gangs transformed themselves into entrepreneurial organizations with the crack cocaine epidemic of that decade (Sanchez-Jankowski 1991, Taylor 1989).

The youth gang problem in the USA today affects communities of all sizes. Although youth gangs are

more prevalent in urban areas like Detroit, New York, Chicago, and Los Angeles, they can also be found in affluent suburban and rural areas (Korem 1994, Evans et al. 1999). According to the 1996 National Youth Gang Survey, approximately 31,000 gangs and 846,000 gang members were active in the USA in that year. The survey respondents reported that, especially in rural areas, the gang problem began to effect them in 1994. This study also found that the proportion of Caucasian gang members was especially high in rural areas.

In looking at youth gangs, it is imperative to include not only those in urban centers, but also those in suburban and rural communities. Gang membership today is no longer exclusive to school drop-outs from impoverished, overpopulated urban areas. It can also include affluent middle-class suburban youths and youths from underpopulated rural areas.

While it is easy to see the daily newscast about Latino and African-American gangs, the gangs of skinheads and White Supremacist are not always defined as gangs. Remembering the diversity of gangs, including youth gangs, is important. Highly structured, corporate gangs can be found all around the country; but not all gangs are corporate-style gangs, some are loosely held organizations, having virtually no leadership (Taylor 1990).

The idea of defining the term gang is good in theory. The problem is in gaining consensus among the organizations and communities that are effected by youth gangs. Today, gangs are identified based on the needs of the organization that comes in contact with them. Whether a highly organized criminal corporation or a loose-knit group of friends that comes together for camaraderie rather than criminal activities, gangs are too diverse for one definition. Whatever the definition of choice, in defining gangs it is paramount that the distinction is made between criminal and noncriminal gangs. Juvenile youth gangs could be considered delinquent depending on how their respective communities view delinquency. However, criminal behavior is not automatically part of youth gangs. Some researchers have promoted the notion that all gangs are criminal. One of the shortcomings of literature on gangs is the focus on criminality. Delinquency, continued lifetime criminal behavior, is well documented in many academic studies. Yet, there is little if any attention on youth gangs, gangs, or gang members involved in noncriminal activities. This lack of focus does not conclude there are no other gang types; it does, however, point to the posturing and approach of how society has viewed youth gangs in America.

4. *Role of the Media and Cinema*

The debate about what constitutes a gang has been underscored by the portrayal of gangs and gangsters in the media and cinema. Entertainment has become big business as an industry that promotes and sells gangsters, action heroes, and violence.

The media has been developing a bio-sketch of a gang member since the Zoot Suit Riots of 1943 and using it to keep fear of diversity in the minds of all who are willing to be taken in. The Watts Riots of 1965 gave the media more ammunition for its exaggerated view of a gangster. Thanks to their portrayal, many people today believe that a gang member is a Latino or African-American illiterate youth, who comes from a female-headed household, in an impoverished urban area. The suburban gangster is not seen as a threat because he has been portrayed as a literate youth who comes from an intact family with Christian family values, from an affluent community. Given these choices, who would you be afraid of?

American cinema has a long history of gangster movies. From 'West Side Story' to the more hardcore portrayal of criminal street gangsters today, the cinema has literally been a training ground for gang wannabes. Classic movies such as 'The Godfather' give an excellent example of Thrasher's (1927) evolution of street gangs, rising from neighborhood playgroups and evolving into successful criminal street gangs. From the portrayal of rebelling youth (i.e., 'Rebel Without A Cause,' Blackboard Jungle,' 'Wild Ones'…), to star-crossed love (i.e., 'West Side Story'), and the hardcore reality of street gangsters (i.e., 'Menace II Society,' '187,' 'Heat,' 'Boyz in the Hood'), the youth of America did not have to look far for gangster role models.

Society, and in particular some media forces, has been ready to assign responsibility for brutal acts exclusively to so-called vicious gangs. But the reality is that gang members run the spectrum of angels to demons. According to the Bureau of Justice, only 10 percent of gang members are hardcore, violent members. Researchers have found that most are peripherally involved in violence; more important, there is evidence to show that only a small percentage of gang members are responsible for the violence.

5. *Gang Myths*

In order to gauge properly the gang influence in a community, gang myths must be addressed and dispelled. Although there are many myths in existence today, the following are a selection that tend to crop up in research (Goldstein and Huff 1993, Taylor 1990, 1993).

Myth 1: All street gangs are turf oriented.

Reality 1: There are gangs that claim ownership to a particular territory, but this is not the exclusive reason for gang membership. Others include Scavenger gangs (loose-knit, immoral, noncriminal), Commercial gangs (focused on material gain), and Corporate gangs (well organized, highly structured, focused on financial gain by criminal action).

Myth 2: Females are not allowed to join gangs.

Reality 2: Females are joining gangs in record numbers. One female gang supported research, showed females in autonomous gangs involved in organized criminal activities.
Myth 3: There are no gangs in my neighborhood.
Reality 3: Today, no neighborhood, regardless of economic status, is immune to gang membership. Gangs can be found in rural areas, suburban areas, as well as urban areas.
Myth 4: Gang members wear baggy clothes and athletic team baseball hats.
Reality 4: Baggy clothing has become the 'cool' style of dress and not a uniform that all gang members wear.
Myth 5: All gangs have a single leader and a tight structure.
Reality 5: Some gangs are loosely held organizations, having virtually no leadership.
Myth 6: Gangs are a law-enforcement problem.
Reality 6: Gangs are a problem for every member of society including parents, teachers, and police.
Myth 7: I know a gang member when I see one.
Reality 7: This statement opens the door to racism. Using traditional ideas of gang membership would mean that only Latino and African-American youths would be targeted. It is important to remember that youth gang members are diverse in color, style of dress, activities, and background.

6. *Conclusion*

Historically, youth gangs began as a group of young people coming together with a common bond. Today, ethnicity seems to be the bond that is focused on by the media, the cinema, and society. The youth gang problem continues to grow in the USA. It is no longer an urban issue, as shown by the current and rapid onset of suburban and rural gangs. The gang structure is also changing, with gangs of different sizes engaged in activities ranging from non-criminal to criminal. At the start of the twenty-first century, society needs to define the term gang, taking into account the facts that there are different types of gangs ranging from non-criminal to criminal; loosely knit to highly structured; coming from diverse ethnic backgrounds; experiencing different reasons for joining, as well as choice of activities pursued. Youth gangs should be studied and defined by the behavior that is associated with gangs. As difficult as it will be to come to one definition of the term gang, some consensus must be reached if there is any hope of identifying specific prevention and intervention programs.

Youth Movements

Youth movements are the organized, conscious attempts by young people to bring about or resist societal change. The formal organization and coordinated activities of youth movements distinguish them from brief episodes of youthful unrest and collective behavior. Rooted in generational tensions and specific sociohistoric conditions, the defining characteristic of youth movements is that they are staffed and carried out largely by young people—typically between the ages of 17–30—who join together to protest adult authority and take it upon themselves to transform society. Ranging from a small number of members to hundreds of thousands of active supporters, youth movements have included student movements, cultural (literary, artistic, musical, ethnic, religious, countercultural) movements, peace and antiwar movements, nationalist and political movements, and environmental–ecology movements. Young people spontaneously may initiate their own movements for change, or youth movements may be sponsored by adults to supplement the activities of larger social and political movements (see *Age, Sociology of*; *Collective Behavior, Sociology of*; *Social Movements, Sociology of*).

1. *The Problem of Youth and Youth Movements*

Throughout history, adults have defined young people as 'a problem.' Wedged between childhood and adulthood, it has long been recognized that young people's idealism, energy, impetuousness, and desire for independence draw them to action and put them at odds with adults. Although incidents of youthful unrest and collective behavior have been recorded since antiquity, full-fledged, organized youth movements did not emerge until the early nineteenth century in Europe. The impetus for youth movement activity stemmed from the forces of modernization and from the Enlightenment, which ushered in the new values of freedom, equality, and self-determination (see *Modernization, Sociological Theories of*). Increasing in number and geographic location from the early nineteenth through the twentieth centuries, youth movements occurred on a global scale during the 1960s and 1980s. Youth movements have toppled governments and have been a force for democracy and societal reform as well as violence, terrorism, and bloody revolution.

The study of youth movements ranges from personal and journalistic accounts to detailed descriptions, analyses, and research investigations by historians, sociologists, political scientists, anthropologists, psychologists and psychiatrists throughout the world. As a result, information about youth movements, while plentiful, is fragmented and scattered among many disciplines and countries.

Several theoretical perspectives have influenced the way youth movements are perceived and studied. Advocates of a life-course approach—based largely on Freudian psychodynamic theory—attribute youth movements to generational rebellion, young people's life-cycle characteristics and needs, and deep-seated emotional conflicts between youth and adults (Erikson 1968; Feuer 1969) (see *Life Course: Sociological Aspects*). From a cohort-generational perspective, youth movements are viewed as products of a rapidly changing social order and unique growing-up experiences that exacerbate age-group tensions and relations, and, at times, may heighten young people's generational consciousness and organized behavior. In addition, because of their varying social locations in society, young people may disagree over the direction that change should take and form generation units or competing groups within the larger generational movement (Mannheim 1952; Ortega 1962) (see *Generations, Sociology of*).

According to socialization theory, young people involved in youth movements are not rebelling against their parents but are carrying out values learned in the home. Schools, universities, peer groups, and the media also act as influential sources of socialization that promote or reinforce youthful activity (Flacks 1971; Keniston 1971) (see *Socialization, Sociology of*). Historical conditions are the focus in another perspective on youth movements. According to this view, the formation, structure, and demise of youth movements are affected strongly by specific local, national, and international trends and events. In general, societal dislocations, inequities, and widespread discontent in conjunction with new opportunity structures and resources explain why youth movements occur during certain periods and not others (Esler 1971; Tilly 1975) (see *Historical Sociology*).

2. *Historical Generational Patterns of Youth Movement Activity*

A survey of modern history indicates that youth movements erupt periodically and became global in scope by the 1960s. Moreover, youth movements tend to cluster during particular eras, followed by periods

of relatively little youth unrest. A cluster of youth movements represents a historical generation. Over the last nineteenth and twentieth centuries, there have been five identifiable historical generations or waves of youth movement activity: Young Europe, Post-Victorian, Great Depression, 1960s Generation, and 1980s Generation. Historically, most youth movements have formed over issues of citizenship, including freedom, equality, self-determination, nationalism, and cultural expressiveness (Braungart and Braungart 1989b, 1993) (see *Citizenship: Sociological Aspects*). To provide an overview of the growth of youth movements during this period, the five historical generations are described briefly in Table 1.

Young Europe was the first wave of youth movement activity where young people fought for Enlightenment values. Napoleon's defeat in 1815 ushered in an age of nationalism, romanticism, and liberalism that inspired university students to organize movements for national independence (see *Nationalism, Sociology of*; *Revolutions, Theories of*). First, in Germany and then elsewhere in Europe, students called for an end to absolutism and the *ancien regime* in favor of the modern nation-state. The Post-Victorian Generation reflected another period of upheaval in modern history. A new era of mass democracy and self-determination encouraged young people to organize against colonialism and imperialism. *Fin de siècle* youth mobilized to challenge the last of the great empires (Victorian, Austro–Hungarian, Ottoman, Ch'ing, Meiji, Romanov), and young socialists fought nineteenth-century liberals. The Great Depression Generation reacted against the economic failures of capitalism and waged intense ideological struggles involving totalitarian regimes (communist, fascist), authoritarian states, and liberal democracies. The call for national independence reached developing countries by the 1930s.

The 1960s Generation, rooted in the post-World War II baby boom, faced several international challenges, including the East–West Cold War and the growing economic gap between rich and poor countries. In unprecedented numbers, young people demanded freedom, equality, and peace, while countercultural lifestyles and behavior spread rapidly around the world (see *Counterculture*; *Youth Culture, Sociology of*). The 'revolution of rising expectations' generated youth movement activity in developing countries. The 1980s Generation mobilized over issues relating to human rights, freedom, and democracy. The Cold War was under attack by young people in Western and Eastern Europe; youth in Asian countries demanded greater democracy; the North–South economic gap worsened and spawned youthful protests in developing countries; and ethnic and religious confrontations involving young people erupted in all global regions. What started in Berkeley in 1964 had reached Beijing by 1989.

3. *Intergenerational and Intragenerational Dynamics of Youth Movements*

An examination of several hundred youth movements in history indicates a number of common patterns in generational activity. Specifically, much of the momentum for youth movements is derived from the intergenerational conflict between young people and adult authorities and the intragenerational conflict among competing generation units or youth groups. When the research is pulled together to provide an understanding of youth movement activity, the principal dynamics of generational conflict are identified and suggest a synthesis of the various theoretical perspectives.

Intergenerational conflict is the central dynamic of youth movement activity and plays a significant role in mobilizing young people to transform society. The generational tensions, misunderstanding, and conflict between youth and adults stem from two sources: (a) the life-course differences, needs, and orientations of young people that set them apart from adult needs and interests; and (b) the distinct growing-up experiences of each cohort in a rapidly changing society. During routine times, youth and adults manage to cooperate or at least coexist. However, during certain extraordinary periods, specific historical conditions—especially a large educated youth cohort, institutional discontinuities, and opening-up eras—heighten young people's dissatisfaction with society and desire for gradual reform or total change. These sociohistorical conditions, in conjunction with effective leadership and opportunities for youthful mobilization, facilitate the formation and spread of youth movements.

The dynamics of age-group mobilization involve the intensification of young people's peer and generational identification (see *Identity: Social*). Adults and adult-run institutions are 'deauthorized' or chastised for the mistakes and disappointments they created in society, and young people 'authorize' or empower themselves to bring about or resist the desired change. As a youth movement becomes more active and visible, adult authorities typically react by attempting to curtail youthful protests, using either relatively peaceable methods or violence and repression. The wider adult population may support or oppose the youth movement activity and strongly influences its success or failure.

Once a youth movement challenges adult authority, intragenerational conflict erupts within the youth generation. That is, although young people may concur that society needs reform, youth groups are likely to disagree and compete over the direction, means, and extent of the proposed changes. During each historical generation, youth movements fighting for radical change are countered by youth groups defending the status quo or championing the status quo *ante*. Whether initiated by young people or sponsored by adults, extreme utopian as well as ideologically moderate generation units may organize that reflect an array and intensity of social and political views (revolutionary, progressive, moderate, conservative, and reactionary). The various opposing generation units compete over the control of the larger generational movement (Braungart and Braungart 1989a, 1989b, 1997).

4. *The Impact of Youth Movements*

As youth movements unfold, the dynamics of inter- and intragenerational conflict sustain the momentum and largely determine how the movement is played out—as a positive source of societal renovation and renewal or fraught with injury, destruction, and death. Historically, youth movements have ranged from being mildly disruptive to thoroughly destabilizing; they have been short- or long-lived; and they have been a significant force for extending democracy and citizenship as well as for totalitarian repression and genocide. Over the nineteenth and tweentieth centuries, youth movements have become a powerful means for young people to bring about or resist change in every part of the world.

With their personal identity and future tied to the vitality of the nation or state, young people readily are recruited into movements to reform or revolutionize society by charismatic leaders who are successful in connecting youthful life-course needs to movement objectives. Specific conditions and opportunities account for why youth movements erupt during particular periods in history. In all likelihood, future generations of young people will mobilize over issues that challenge their contemporaries. The question is not whether a new wave of youth movement activity will arise, but when and over what issues?

Youth Movements, History of

While 'youth,' the age between childhood and adulthood, varies from one culture or period of history to another in terms of form, duration, and degree of regulation, the 'young generation' is always an object of the older generations' focused attention, as adults try to prepare young people for their role as full (male or female) members of their society, passing on to them the generally accepted values, norms, and viewpoints by regimes of education and discipline. As history shows, this constellation has again and again led to individual and collective group conflicts. Since ancient times, young people have often found themselves in the front lines of diverse political and/or social movements. However, the 'youth movement' as a form of the 'young generation' more or less violently revolting against the adult world is a 'modern' phenomenon. It first appeared in the 'old' European states around 1800, emerged in such 'young' states as the USA and Australia in the early twentieth century, and has increasingly turned up in countries of the so-called Third World since 1950.

1. Youth Movements as an Expression of Generation Constellations in the 'Modern Age'

Collective revolt by groups of young people against the conditions in which they live may aim for more or less general political, social, or cultural change, essentially telling the older generation to 'move over'; or it may target specific social trends which the younger generation considers outrageous, threatening, or inhuman, such as repercussions of political upheaval, the loss of civil rights, the destruction of the social environment, or the deterioration of economic prospects. In this sense 'youth movements' need to be clearly distinguished from 'youth welfare' and 'youth work,' which are activities led or dominated by adults to socialize the younger generation. These include the youth organizations of established parties and youth organizations with a national or ideological background (such as, for instance, most of the scout organizations), not to mention all types of national youth organizations. It may sometimes be hard to draw a line between a 'youth movement' and ventures for 'youth welfare' in certain instances. As a rule, however, modern 'youth movements' are expressions of a specific form of conflict between generations and as such have spread throughout the world. Since the early nineteenth century, the predominant style elements have been those of male societies, whereas female members have tended to play a minor role. It is only in recent years that this has been changing.

While generation conflict constellations do represent one of the most important roots of youth movements, they are not simply reflections of the natural relations between parental and child age groups. According to the sociologist Karl Mannheim (1928), generation constellations reflect the distinct mental dispositions of each generation, that is the intellectual horizons and emotional needs that the members of an age group develop in their youth in a specific historic context. As a result, the various age groups in a society experience, perceive, and pass judgment in distinctly different ways. The 'Modern Age' uprooted the tradition of passing on experience, as the acceleration of change in the industrial societies of the nineteenth century devalued the knowledge and experience of the older generations as irrelevant, increasingly leading to widespread disregard for the elderly who had previously been held in high esteem. This was accompanied by the development of a youth cult, as industrial production, urban culture, and the capitalist economy began to give preference to youth over old age as stronger, more dynamic, more ready to learn, and more open to change. The older generations meanwhile held sway at the hubs of political power where decisions about future developments are made, rigorously defending their authority and interests. Educational reforms, increasing possibilities for young people to participate politically and to articulate their interests, supported by the universally accessible mass

media, combined to promote burgeoning self-confidence and corresponding expectations among younger and younger age groups. Advertising for consumer goods added to 'youth emancipation,' so that, particularly in times of upheaval, latent constellations between age groups developed into a conscious and distinct frame of reference and identity. Such constellations have been particularly apt to cause individual groups in the 'young generation'—often among students—to develop a strong sense of identity and radical concepts, making massive demands on the 'responsible' older generations including shows of aggression to the extent of using violence, propelled by the belief in a revolutionary mission.

2. *On the History of 'Youth Movements' Since the Nineteenth Century*

Nineteenth century Europe abounds in examples of such generation constellations and the youth movements that they engendered. These include the student fraternities in Germany around 1820 who fought against the reactionary politics of the royal houses after the defeat of Napoleon; Guiseppe Mazzini's 'Young Europe,' which he founded in Switzerland in 1834 along with other national 'youth movements' (including, beside Giovina Italia, La jeune France, Junges Polen and Junges Deutschland); the Narodniki movement of the Russian intelligentsia in the 1860s (where a plan was discussed to exclude all people over the age of 25 from public life in order to enable radical reform); and finally, at the end of the nineteenth century, the 'Young Turks' in northern Greece under Ottoman rule, who did manage to overthrow the Ottoman Empire and come to power in 1909, Ataturk later emerging from their midst.

While the young activists in these movements (male dominated throughout) had mainly political goals, notwithstanding some bohemian excursions, and went as far as to plan and go through with coups and assassinations, the German Youth Movement of the 'Wandervögel' (viz., 'migrant birds') and the 'Freideutsche' (viz., 'free Germans'), which emerged in the urban centers of the German Empire as well as in Switzerland and Austria after 1900, is a unique example of a highly romantic youth movement which was primarily critical of modern civilization, abjured any political involvement, and developed an independent youth culture staking out an autonomous sphere of freedom for itself. Its members were mainly members of the educated classes, whose intellectual leadership was in decline as a result of the rise of a new technical and economic elite. The educated classes propagated 'simple living' to counterbalance the supposedly demoralizing influence of urban mass culture, sought out the folk traditions of bygone days, and dreamed of creating a 'New Man' through a general reform of everyday life. This 'New Man' was to be the leavening in the dough of society to promote greater humanity.

The movement's highly idealistic motto was coined in 1913 at an open-air festival on the 'Hohe Meißner,' a mountain near Kassel: 'The 'Freideutsche Jugend' seek to shape their lives by themselves, responsible to themselves, and true to themselves.' In hindsight, history has shown that anti-political idealism and the fantasy of 'breeding' an improved version of humankind were to be abused by racist demagogues and ideologues in the 1930s to mobilize a new 'young generation' (born in the years around World War I) for totally inhuman and destructive goals, leading directly to World War II and National Socialist genocide. As a movement of youth culture, the German Youth Movement did however manage to promote, firstly, women's emancipation in the ranks of the autonomous girls' movement and, secondly, migration to Palestine and the beginnings of the Kibbutz movement by empowering the Jewish youth groups which split off from other youth groups in response to the latter's frequently nationalist tilt.

This brings the history of youth movements well into the first half of the twentieth century, when throughout the world independent movements of the respective younger generation engaged in at least temporary social and political activism in increasing numbers, criticizing the political situation or giving impulses for political, social, and cultural change. There are many constellations where national politics were influenced by the specific experience of a whole generation. Examples include the Japanese reform circles socialized during the Meiji-Era (the first Japanese constitution being instituted in 1889) and the Spanish 'Generation of 1898,' whose formative experience included the shock of defeat in the Spanish–American War. The greatest influence during the second third of the twentieth century, particularly in Europe, but also for example in Australia, seems to have been that of the 'Generation of 1914' (Wohl 1980), which has been called the 'lost generation.' The way in which this generation dealt with the experience of World War I, particularly in the nations which had lost the war, created explosive constellations of immense historic consequence: Not coincidentally, the fascist movements, particularly in Italy and Germany, styled themselves as revolutionary movements of a 'disinherited' young generation, only to form a dangerous alliance then, with the younger 'Great Depression Generation,' the former leading the latter.

The American 'New Deal Generation' on the other hand, while belonging to this same age group, had totally different aims, seeking a deep-rooted democratization of American society and an expansion of social welfare institutions. While they were propelled by unmistakable self-confidence and a sense of mission, this generation did not develop any discernable forms of youth movement. However, the political

opening of American society that they promoted was to pave the way for the coming independent social movements that were to be carried mainly by young people, including the Civil Rights Movement and Women's Liberation. Beginning in the 1920s, liberation movements emerged in other parts of the world as well, demanding civil rights, national independence, and cultural autonomy for nations or cultures that had lived under colonialism or other forms of oppression (such as the black population in South Africa and the Aborigines in Australia). Whether such movements can be connected specifically to the young generation needs to be studied case by case, but there is no doubt that large groups of young people were among the followers of charismatic leaders or groups.

It is just as difficult to decide whether the subculture of young street gangs and peer group cliques (such as hooligans or skinheads) found in almost all industrialized states since the early twentieth century—primarily among the underprivileged social classes—are actually part of youth movements as defined here. They, too, clearly react in their way to their actual living environment, aim to provoke the older generations, and sometimes encounter massive persecution (as did the 'Edelweiss Pirates' under German National Socialism).

Since World War II, and particularly since the end of the 1950s, when a generation of young people without any first-hand experience of war came into its own, waves of youth movements have become quite common and have developed new forms, peaking in the second half of the 1960s, when student movements began simultaneously in a number of countries, following in the tracks of such predecessors as the Easter March movement and such counter-culture groups as the 'Beatniks' in the USA, the 'Angry Young Men' in Great Britain, and the young 'Existentialists' in France. Beginning in the early 1960s, generation conflicts specific to the different countries began to mesh with the international involvement of young people with problems they considered to be of worldwide importance: the massive rearmament during the 'Cold War,' the growing atomic power potentials, the exploitation and poverty in the so-called 'Third Word,' the military intervention by the major powers in regional conflicts (particularly the involvement of the USA in Vietnam), the destruction of renewable natural resources, and the increasing danger of global ecological catastrophes due to reckless industrialization, the disregard for civil rights in many countries despite UN declarations, the continued inequality between men and women, and so on. Some of the initiatives originally organized regionally managed to become established as large international organizations, such as Amnesty International and Greenpeace. Such initiatives were always attempts to assert new perspectives and political and cultural ideals against those of the older generation (coining such phrases as 'Don't trust anybody over 30'), in the extreme case of the Chinese 'Cultural Revolution' and later the famous events of the Tienanmen Square in Beijing 1989 causing a great deal of bloodshed. The young generation's interest in criticizing prevailing conditions and in replacing the established authorities gave all kinds of ideologues and demagogues a chance to preach new catechisms to the young or to install themselves as their new leaders. The often overblown idealistic expectations pursued with youthful pathos were usually watered down or twisted out of shape in public debate, and in the end were confronted with both the complexity of social reality and with the fact that as their proponents got older and 'wiser,' their attitudes changed, with corresponding consequences for the movements.

3. *Inner Structure, Style, and Mental Consequences of Youth Movements*

Aside from providing a venue for general social self-criticism, reform, and renewal in times of upheaval and an outlet to the young in generation conflicts, youth movements also play a central role in the lives of the young people who have been involved in them at one time or another (sometimes only a small portion of their age group), shaping their life-course and lifestyle. To come back to K. Mannheim's generation model (1928): the development of an emotional bond with a generation at a young and impressionable age as provided by youth movements is an especially intensive experience which creates long-term mental dispositions that give those involved many points of reference with which to define themselves in historical terms and in relationship to the various age groups living together. Such dispositions may include political and philosophical values as well as principles about how people should treat each other, which lifestyle is appropriate, which esthetic qualities are desirable, and so on. This introduces the question of the inner structure of youth movements.

Youth movements, which sometimes develop out of small activist groups or even secret societies (such as the Italian 'Carbonari' in the early nineteenth century), allow young people looking for orientation and adventure the opportunity to broaden their horizon substantially beyond the everyday confines of their families, schools, and apprenticeships. In their 'conspiracy' of like-minded people their own age, usually motivated by charismatic leaders who are often not much older, members of youth movements develop their own morality and dynamics structured by special codes of communication beyond the blatantly stated goals of the movement. Developing their own language, manners, esthetics, initiation rites, rituals, as well as rules to exclude 'defectors' and 'traitors,' they document the difference between the movement and its social surroundings, particularly with regard to the

styles, morality, and values of the older generation. Elements whose importance is not to be underestimated for most of the movements are short populist manifestos on the one hand, and esthetic elements such as songs and other musical elements on the other, which create an exciting atmosphere at ritual celebrations and give the participants a sense of security. Looking and acting provocative in public, using strategies ranging from clothing, beard, and hair styles to massive shows of militancy, is meant to shock outsiders and strengthen the feeling of belonging among insiders, to the point of producing the feeling of being part of a 'chosen' few. Individuals have been known to initiate spectacular actions in such a hyped-up, extremist, sectarian climate, such as assassinating a social figurehead or mounting a kamikaze attack, which then provides the movement with its heroes or martyrs.

The spread of the mass media in the twentieth century has produced a public arena for youth movements. Television in particular has publicized the aims of youth movements worldwide, touching off direct spin-offs, winning the sympathy of 'fellow travelers,' and generating a wide spectrum of both critical and positive resonance. The activists, in turn, have quite conspicuously played up to the media to promote their own goals. This strategy, however, has frequently backfired. Many of the innovative impulses and manners that were provocative at first have been copied massively in a toned down version, effectively taking the 'sting' out of them and making them generally fashionable. It therefore seems rather simplistic to say programmatically that 'young people make their own history' (Gillis 1981). While youth movements have certainly provided impulses for social change again and again and have been able to get things moving by provoking the older generations, they are, of course, subject to the complex reality of society and its generation structures, specific constellations of which, as we have seen, had to be given before the time was historically 'ripe' for political revolution and/or cultural change.

Research should continue to look for the links between mental dispositions and structural constellations, particularly in the context of the history of generations and in regard to the long-term repercussions in the collective biography of individual age groups involved in youth movements in their respective societies. International comparative research has hitherto been sadly neglected. Papers given in 1990 at the International Historical Congress in Madrid (Fauvel-Rouif 1992) have unfortunately remained a very first step in this direction.

Youth Sports, Psychology of

Youth sports are adult-organized sports programs for children and youth, typically between the ages of 7 and 18 years, which have designated coaches,

organized practices, and scheduled competitions (Gould 1982). There is an estimated 22 million youth in the USA who participate in nonschool youth sports programs. There are equally high percentages of children and youth in Australia, Brazil, Canada, and many Asian and European countries, who participate in youth sport programs through clubs or schools (De Knop et al. 1996). Most of these programs are aimed at mass participation rather than focused on developing elite athletes.

The psychology of youth sports, as an area of scholarly inquiry, is relatively new. Research in this field did not start to proliferate until the 1980s. The research developed out of concern by professionals for the educational value of youth sports participation and the well-being of the children involved. The topics that have been most often addressed on the psychology of youth sports include psychological readiness for youth sports participation, the benefits and detriments of youth sport participation, participant motivation and attrition, and adult involvement in youth sports.

1. *Psychological Readiness for Youth Sport Participation*

Although the question of when children should begin competing in sports appears simplistic on the surface, it is very complex. Readiness, in youth sports, is viewed as the ability of a child to handle successfully all the demands presented in competitive sports. Physicians and educators in the first half of the twentieth century believed that the biological maturation of children was the sole determiner of their readiness to perform sport skills. Contemporary researchers, however, view biological, motoric, and cognitive readiness as interacting with psychological readiness to handle the demands of competitive sport. Factors that have been considered include motivational and cognitive readiness to compete, physical maturation and body size, the knowledge and skill level of the child, and the type of sport. Unfortunately, these factors have not been studied together systematically in the area of youth sports.

1.1 *Motivational and Cognitive Readiness*

The research literature has long shown that most children are not capable of consistently competitive or cooperative behavior until the age of five years (Greenberg 1932). Competitive sport involves setting abstract standards and goals for one's performance and this is usually not possible for children under five years of age. Children also need to have sufficient emotional competence to handle stressful situations inherent in competitive sports. Youth sports participation also requires a number of cognitive skills. These include the child's ability to process a considerable amount of information about the sport, such as rules, skill techniques, and strategies. Most children before the age of five have attention spans that are too short to stay on task in sports games. In addition, children are not accurate judges of their competence until they have developed the ability to understand that winning and losing are the products of interactive causal factors such as physical skill, strategy, preparation, effort, opponent difficulty, and luck. This cognitive ability may not be well developed in children before the age of 12 years (Kaley and Cloutier 1984, Nicholls 1978). Thus, children who are not motivationally and cognitively ready to meet the demands of a competitive sports program may not experience the same success and enjoyment as those who have this readiness and could be likely candidates for sport withdrawal. Gibson (1977) found that Australian boys, aged 10 to 13 years, who participated in adult-style football games, lost interest in participation over the course of the season. Whether modified youth sports programs (e.g., those with simplified rules, less emphasis on competition, shorter practices, equal playing time) would attenuate negative experiences for children who are not yet emotionally and cognitively ready for adult-styled games has not been systematically studied.

1.2 *Physical Maturation Readiness*

Even when children have the motivational and cognitive readiness to learn sports skills and to compete, some may not have the physical maturation to be reasonably successful with other agemates in their chosen sports program. Because children mature at different rates, some 10-year-old children will be more like a 12-year-old child physically and some will be more like an eight-year-old child. When sports programs do not classify children by physical maturity or weight (e.g., weight classifications in wrestling), they usually favor the early maturer (boys in particular). The later maturing boy will usually have less strength, endurance, and skeletal maturity than his average peers. This individual variation in biological maturity has a direct influence on the child's self-perceptions in sport and chances of success. For instance, teams that win the Little League World Series comprise players who are maturationally two to three years older than their chronological age.

1.3 *Knowledge and Skill Level*

Children may be physically and psychologically mature enough to compete in organized sports, but unless they have the requisite skills and some knowledge of the activity, positioning, and game rules, they will have little early success. By six to eight years of age, most fundamental motor skills, such as running, jumping, catching, and striking, are reasonably well

developed in the majority of children (Branta et al. 1984). However, a number of six to eight-year-old children have not yet developed movement patterns mature enough to participate successfully in sport. Whether children with immature movement patterns can still benefit from youth sports participation has not been studied, but may quite well depend on the instructional focus and game modifications in a particular sport program. Different coaches and programs place different emphases on the motor, cognitive, and competitive skills of a sport.

1.4 Type of Sport

Different sports require different levels of physical and cognitive/emotional maturity. For instance, to play baseball/softball effectively, a child must be able to throw the appropriate distance, run, bat, and catch, as well as remember where to make the play for a specific situation. Competitive swimming and running require heavy physiological demands on the cardiovascular and respiratory systems. Each sport has its own unique set of rules, strategies, and skills to be learned. Unfortunately, the criteria of readiness for specific sports have not been studied systematically. Tests of readiness exist in school-related subjects, but none exist for youth sports. Most youth sport programs, however, modify the rules, equipment, and game to accommodate the skill levels and lack of readiness of age-grouped participants. These modifications also need systematic and longitudinal study to determine whether they are of any benefit to those participating.

2. Psychological Benefits and Risks of Youth Sport Participation

For children who are ready to participate in competitive sports, there are a number of potential benefits. Proponents of youth sport programs maintain that youth sports provide an effective medium for psychosocial development such as the development of social skills, cooperativeness, persistence, achievement motivation, emotional control, responsibility, self-confidence and self-esteem, sportsmanship, and leadership. Critics, on the other hand, maintain that youth sports place excessive psychological and physical stress on children, diminish the value of play as a free and spontaneous outlet for expression, and tempt participants to violate moral norms. However, little systematic study has been conducted to determine any causal changes, positively or negatively, from participation in youth sports.

2.1 Benefits

The majority of studies examining the benefits of youth sports participation have been correlational. These studies indicate that regular participation in organized sport activities is associated with increases in physical self-esteem, feelings of physical well-being, and peer acceptance (Brustad 1993). Whether participation in sport results in positive psychological effects for children or whether children who already possess these positive characteristics gravitate toward sport is still uncertain. A few studies have examined the influence of coaching behavior on children's self-esteem and ability perceptions and found that coaches' feedback style can influence the self-esteem and perceived competence of children across a season of competition (Smoll and Smith 1996). However, research on the benefit of youth sports to moral development, sportsmanship, and other socialization outcomes has received no consistent support other than from self-report studies. Self-report studies suggest that the positive outcomes outweigh the negatives.

2.2 Risks

The most frequently cited psychological risks to youth sports participation are competitive stress and anxiety, lowered self-esteem, and reduced moral competency. Participation in youth sports has the potential to be stressful to children because of the uncertainty of competitive outcomes and demands imposed on players. However, most of the research on the anxiety levels of children before and after competition found that children typically report rather low levels of stress, and that these levels of stress are no higher than other evaluative activities typically found in school programs (e.g., academic tests, music competitions). Children who tend to have high competitive trait anxiety, low self-esteem, and low performance expectations, report greater stress than children who are low competitive trait anxious, high in self-esteem, and high in their performance expectations. The experience of stress does not imply that competition is necessarily detrimental to children if there are no consequences beyond a temporary unpleasantness associated with the child's emotional state. However, consequences of stress that lead to loss of sleep, loss of appetite, or dropping out of the sport, are considered detrimental to children.

The question of whether youth sports has an influence on children's moral behavior is difficult to ascertain because the experiences children have in sport are not uniform in terms of the social relationships and interactions that shape behavior. The research in this area has also been correlational in nature. The sport and delinquency research has shown a negative relationship between sport participation and delinquent behavior, however, explanations for the relationship are unclear. Most of the contemporary research on moral reasoning and aggression in sport has been conducted by Brenda Bredemeier and her colleagues (Shields and Bredemeier 1995). This research has shown that reasoning about moral issues in

sport is significantly higher for nonathletes than for athletes but not so for moral problems in nonsport settings. Shields and Bredemeier suggest that athletes use a concept they call 'game reasoning,' a unique type of moral reasoning that is legitimized within the sport context. The divergence between life reasoning and game reasoning becomes greater with age and experience in sport. The genesis, developmental course, and behavioral implications of game reasoning await further research.

3. *Participant Motivation and Attrition*

The importance of participant motivation in youth sport relates to beliefs that participation patterns and experiences in youth sports strongly influence overall active lifestyles in adolescence and adulthood and that attrition is the consequence of undesirable psychological experiences in youth sports. The dropout problem in adolescence is common in many countries, especially among girls. Much of the early research in participation motivation and attrition has been descriptive. Investigators found generally that young athletes participate in sports primarily to have fun, for excitement, to improve their skills, to be with friends and make new friends, and for success. These participation reasons can be categorized into enjoyment, competence, affiliation, and competition motives, respectively. These motives tend to generalize cross-nationally. The most common motives, worldwide, for taking part in youth sports are instrinsic (e.g., for enjoyment and affiliation reasons), rather than competitive (De Knop et al. 1996). Although, children are likely to cite multiple motives, there are few age, gender, experience, and sport-type differences.

Fewer studies have documented the reasons for children's discontinuation in youth sports. Those studies have indicated that competiveness of the program, conflicts with coaches, insufficient success, other interests, and lack of fun are the major reason for discontinuing in a sport. However, the most common motive across studies for withdrawal from a sport had to do with conflicting interests on the part of the child, especially during adolescence. The major problems with these studies are their inability to discern whether a conflict of interests is due to a dissatisfaction with their sport experience or is due to more practical reasons. A second problem is the inconsistency among studies in the definition of the term 'dropout.' Some studies have defined a dropout as one who discontinues in the sport in which he or she was previously participating. However, a number of studies have found that these individuals do not drop out of sport altogether, but rather transfer from one sport to another. Even the small percentage of those who have withdrawn from sport altogether have mostly returned to their sport sometime later (Weiss and Gould 1986). Thus, the motives for withdrawal from sport may be based on practical, age-related, or negative reasons.

More recently, theoretically-based studies have emerged to supplement the initial descriptive research on this topic. The theoretical frameworks most commonly used to explain children's sport involvement and withdrawal are competence motivation theory (Harter 1978), achievement goal-orientation theories (Nicholls 1984), and cognitive evaluation theory (Deci and Ryan 1985). These theories regard self-perceptions of competence as central influences on a child's motivated behavior. Children who perceive themselves to be highly competent in a sport should maintain interest in participating and mastering that sport. In contrast, children who perceive themselves to have low competence in a sport should not maintain persistence and interest. In addition, goal-orientation theories also emphasize that children approach their sport participation with different goals and ways of judging their competence. Children having a task-oriented approach to sport participation hold a self-referenced view to judge their achievement. Children having an ego-oriented approach use social comparison information to judge their success. Task-oriented children should be motivated to participate and remain in sport as long as they have an appropriate level of personal challenge. Ego-oriented children should be motivated to persist in sport only if they perceive that they have more ability than their socially comparative others. These theoretical predictions have been supported by a number of empirical studies. Thus, children tend to persist in sport if they perceive they have the competence to be successful, either in their personal challenges or as compared with others in their program.

Very few studies on participation motivation have been conducted longitudinally or prospectively. It is reasonable to assume that a child's motives for participation will be shaped over time by a number of intrapersonal and contextual factors. Second, retrospective studies on discontinued participation in youth sports do not allow for causal inferences. One prospective study (Ommundsen and Vaglum 1991) examined the relationship of low perceived competence in soccer and social skills with later dropout from boys' soccer over a 16-month period. Low perceived soccer and social competence negatively influenced soccer persistence. More prospective studies are needed looking at additional factors such as type of program, type of sport, personal characteristics of the coaches, and achievement orientations of the children.

4. *Adult Involvement in Youth Sports*

There is general consensus that the benefits, negative experiences, and children's motivation surrounding youth sports are influenced strongly by the adults

involved, coaches and parents in particular. Unfortunately this area of youth research has received the least attention. Again, the majority of the work has been correlational and assessed from the child's perspective. In terms of parental influence, parental support is linked to greater initiation and continued participation in sport, as well as higher levels of intrinsic motivation. Parental pressure is linked to greater sport anxiety and lower enjoyment. Parental judgments of their child's competence are related strongly to the child's self-perceptions.

Much of the research on the influence of coaching behavior on children's self-perceptions and motivation has been conducted by Ronald Smith and Frank Smoll (Smith and Smoll 1996). In one of the few experimental studies on coaching behavior, Smith et al. (1979) showed that young athletes, whose coaches were trained to use a positive approach to coaching (frequent encouragement, positive reinforcement, corrective feedback), had significantly higher self-esteem ratings over the course of a season compared with players whose coaches received no additional training. Low self-esteem children who played for the trained coaches showed the greatest increases in self-esteem.

5. *A Biopsychosocial Perspective on Youth Sports*

Researchers in the psychology of youth sports are calling for a more biopsychosocial approach (Smith and Smoll 1996). For instance, in explaining children's motivation and attrition in sport, the influences of training/conditioning, physical growth, and maturation should be considered in concert with self-perceptions and adult influences. Other questions from this perspective include: What are the long-term biopsychosocial effects of competition in youth sports at various intensity levels? and How do the factors of motor development, biological maturity, physiological function, and psychosocial development interact to determine readiness for and success in sport competition? To examine these questions adequately, youth sports researchers have called for longitudinal, systematic research programs that consider development in the design of studies and that focus on a number of interrelated questions.

Youth to Adulthood across Cultures, Transition from

1. *Transition and Psychological Functioning*

Adolescence is a period in life that begins with biological maturation during which people accomplish a series of developmental tasks raised by the many biological–physical changes, cognitive changes, and

social–emotional changes. It begins roughly at 10 to 13 years and ends—depending on cultural and educational conditions—at 18 to 22 years of age. The following period in life, early adulthood, is a time of establishing personal and economic independence, career development, and of selecting social contexts.

In earlier historical times transitions from youth to adulthood were fairly clearly marked with rites. The purpose of initiation rites in preindustrial societies was to cushion the emotional disruption arising from the transition from one life status to another. In the case of the transition to adulthood, these rites formally ended dependence on parents and served as an introduction to the life of an adult. For example, according to some psychoanalytic perspectives, ceremonies related to sexuality and separation from mothers are necessitated by the conflict between fathers and sons over who will dominate the women. To make clear the adults' supremacy and to ensure the allegiance of the young males, adults typically put the youth through a series of trials at which they were superior to the youth. Most trials included tests of strength, endurance, power, and courage, and—depending on tribe—mutilations. Female adolescents were also exposed to physical pain during the transition to adulthood. For example, genital mutilations were meant to sensitize them to the greater role that sex will play in their lives. These mutilations also made them recognizable to the members of the tribe. The ceremonies often ended in giving the new adult member a new name, usually that of a close ancestor. Seebald (1992) delineates three functions that rites of passage serve: (a) informing the individual of his or her new rights; (b) announcing the new status to the community; and (c) anchoring youth to the group emotionally by instilling a profound sense of belonging to that community.

Entry into adulthood is far more complex for adolescents today, largely due to the need for many more years of formal education and hence prolonged dependence on parents. No specific rituals exist in present Western societies to aid youth through this change. Two general types of transition, intrinsic and role transitions, are distinguished. An intrinsic transition involves new skills and competencies and a qualitative change of the representation of the world. A role transition is exclusively bound to chronological age and social roles, and involves a new status, mainly legitimized by the social environment. Both types of transitions can be described as opening opportunities for further development. If, however, a lack of developmental opportunities occurs on a continual basis and if it occurs within important transition domains, then it is detrimental to the individual.

Psychological stress during transition occurs when people are confronted by demands that exceed their capacities. The fact that something important is at stake, and that the situation is uncontrollable, leads them to perceive that the situation as more of a threat than a challenge. Hence, psychological functioning during transitions consists in an interplay between demands and resources on personal, social, and environmental levels. If the demands exceed a person's resources, the level of functioning decreases. A continuous misfit between demands and resources leads to suboptimal or problematic transition from youth to adulthood.

1.1 Four Principles Underlying Transitions

Four principles are crucial in understanding development in a lifespan perspective, especially the transition from youth to adulthood. First, individual development is carried forward in such a way that the earlier development has implications for a person's pattern of functioning at a later time (Rutter 1994). So the question is, which processes and structures are instrumental in increasing stability in behavior and which of them are instrumental for changing this behavior. In both these cases, two patterns are influential: On the one hand, biological processes, social and societal expectations and individual actions play a role, and on the other hand, a person's objective means.

The accentuation principle is a second component. According to Elder and Caspi (1990) stressful or challenging experiences tend to emphasize and strengthen pre-existing characteristics. Negative critical life events and the lack of opportunities have a consequential negative impact, especially on vulnerable individuals. These events accentuate pre-existing characteristics rather than give rise to new behavior. So personal consistency and behavioral stability is increased.

Third, the increasing stabilization of development across the lifespan is founded in the person's self-concept. As many developmental psychologists have pointed out, experiences have effects in life only through a cognitive transformation. People think about themselves and what happens to themselves. The patterns of individual interpretations and thoughts are condensed in a self-concept (Harter 1996). The self-concept has a clear bias toward assimilation, i.e., people act on the world in congruence with their self-concept. Once the self-concept is established it works as an organizer of subsequent experiences and is rather robust against change.

The fourth principle takes into account that individual development always occurs in a specific environment. The environment is crucial in its influence and in the degree to which it is contingent on the individual's actions. Psychological theories about learning and development were for a long time almost exclusively concerned with this respect, i.e., the contingencies between environment and action. The fundamental learning principle assumes that the contingent positive effects of a person's behavior increase the likelihood of the specific behavior.

1.2 Transition as a Turning Point and in a Lifespan Perspective

It follows from such a conceptualization that development is almost stable and invariant across time (Caprara and Cervone 2000). However, there are turning points which call for new behavior (Caspi and Moffitt 1993). A turning point removes a person from the known structure. On the one hand the individual does not have prior experiences to deal with the new situation, but is forced to act in it. On the other hand, the social environment has not provided the specific individual with experiences, but is inevitably connected to the individual. In this respect, a new learning pattern must be established that has the potential for a persistent change. Rutter (1996) differentiates among three categories of possibly lasting turning point effects: (a) those that discontinue or open opportunities; (b) those that involve a lasting change in the environment; and (c) those with a lasting effect on a person's self-concept. A large amount of empirical evidence supports the characterization of early menarche, schooling, geographical displacement, teenage pregnancy and parenthood, marriage, army experiences, and work as typical examples of turning points. It is noteworthy that a turning point in general provokes a chain of experiences. It is not a singular event, but a chain of events that causes an existing developmental path to change direction.

There is another body of literature which refers to lasting changes during transition, i.e., the lifespan perspective in developmental psychology. Within this framework change and stability across the course of a life has been demonstrated as multidirectional in ontogenetic change and is markedly influenced by sociocultural conditions in a given historical period. Empirical evidence exists for a continuous dynamic interplay between gains and losses in adaptive capacities across the life course. Individual plasticity was here demonstrated as a key concept, i.e., the within-person variability and potential for different forms of behavior and development (Baltes 1987, 1997).

2. Domains of Transition: Developmental Tasks

Havighurst (1948) introduced the concept of developmental tasks in order to describe transitions. Developmental tasks are learning tasks across a lifespan. Successfully solved developmental tasks in the context of real demands enable people to learn new skills and competencies which are necessary for the satisfactory and constructive mastering of life within a given society. Success in solving tasks at earlier stages increases the probability of successfully solving subsequent tasks. People are expected to solve a series of developmental tasks across different life periods in order to be accepted in society. However, not all developmental tasks of a specific life period have to be solved at the same time. Within which time range and in which order developmental tasks are solved is subject to individual differences as well as to cross-cultural variations and sociohistorical shifts.

2.1 Three Sources of Developmental Tasks

2.1.1 Physical maturation. Physical maturation is the basis of developmental tasks and varies little across cultures. For example, in most cultures puberty gives rise to the search for new relationships with same- and opposite-sex peers.

2.1.2 Societal expectations. Societal expectations are the main source of cultural relativity of developmental tasks, typically reflected in age norms. This means that a person is expected to solve a specific developmental task within a certain period. Therefore, the individual's developmental stage can be described as one in which he or she is able to deal with culturally set demands. Cultural norms are also reflected in 'early,' 'on time,' and 'late' development in various transition domains, as, for example, deciding on a job or preparing for a family. Expectations of the timing in role transitions exist for the individual as a private person (e.g., reaching emotional and economic independence from parents, taking responsibility for further decisions) as well as a public person (e.g., age-related norms for different civic rights).

Societal expectations of time ranges in solving developmental tasks are subject to historical change. For example, less than 10 percent of youth attended senior high school in the USA at the end of the nineteenth century compared to almost 90 percent 100 years later. Another example: two-parent farm families were by far the most prevalent family type over decades (Hernandez 1993). A decrease of this family type started in the nineteenth century, and in 1990, less than 5 percent of children lived in two-parent farm families. In parallel, two-parent nonfarm families with a full-time working father and a full-time homemaker mother rapidly increased, resulting in the most prevalent family type between 1910 and 1970. This family type almost disappeared in the 1990s, being replaced by dual-earner families. Since the 1970s, one-parent families have become more prevalent. For the rest of the Western world, the pattern of family structures also changed, but in different time frames compared to the USA. It goes without saying that the family structures in non-Western settings changed, too, but in ways different from those described above. These and other patterns of societal change such as the divorce rate, numbers of births to unmarried women, number of siblings, and education had lasting effects

on the timing of the transition from youth to adulthood (Grob et al. 2001).

2.1.3 Individual goals and values. Individual goals and values are the third source of developmental tasks. In general, people try to organize their actions in congruence with their purposes and goals. There are goals that are mainly the same for all individuals, for example to decide on a career or to reach independence from parents, and others which differ across individuals in obvious and important ways, for example becoming expert in petrography.

2.2 Developmental Tasks in the Transition From Youth to Adulthood

For adolescence, Havighurst proposed nine developmental tasks, i.e. (a) accepting one's physique and a masculine/feminine role; (b) forming new relations with peers of both sexes; (c) achieving emotional independence from parents and other adults; (d) achieving assurance of economic independence; (e) selecting and preparing for an occupation; (f) developing intellectual skills and the concepts necessary for civic competence; (g) desiring and achieving socially responsible behavior; (h) preparing for marriage and family life; and (i) building conscious values in harmony with an adequate scientific view of the world. The eight developmental tasks for young adulthood were (a) deciding on a partner; (b) living with a partner; (c) starting a family; (d) raising children; (e) maintaining a (family) household; (f) starting a professional career; (g) taking societal responsibility; and (h) finding an adequate social network.

The superordinate theme across adolescence and young adulthood, however, is what Erikson (1968) calls identity and intimacy. During adolescence individuals begin to search for who they are, what they are all about, and where they are going in life. As part of this search for an identity, the adolescent experiments with a variety of roles, some sexual, others ideological, and still others vocational. Each of Erikson's eight stages of development across the lifespan centers around a salient and distinct emotional concern stemming from biological pressure from within the individual and from sociocultural expectations. Concerns or conflicts may be resolved in a positive or healthy manner or in a negative or unhealthy way. The characteristics for the transition from youth to young adulthood are described by Erikson with two central themes, i.e., identity versus identity confusion in adolescence and intimacy and isolation in young adulthood.

The empirical evidence on how adolescents manage the transition to adulthood stems among other fields in research on identity. Four identity stages were identified which are: identity diffusion, foreclosure, moratorium, and achievement (Marcia et al. 1992). Individuals who achieved identity, for example, are committed to adult roles by having passed developmental work. Identity statuses are seen in developmental sequences, but not necessarily in the sense that the one is the prerequisite of the other. Identity achievers appear to be healthier than other individuals, and score higher on achievement motivation, moral reasoning, career maturity, and social skills with peers (Kroger 1993). The actual formation of an adult identity does not occur until late adolescence. Identity achievement is primarily reached in the sphere of occupation, whereas commitment in the area of political and ideological identity is often not evident for a considerable proportion of young adults. Thus, the challenge of identity forming in given domains is not resolved at one point in time, but continues to re-emerge again as the individual moves through late adolescence and early adulthood.

3. Further Research

Further research is needed to identify which factors generate discontinuity and continuity in transitions from youth to adulthood within *and* across cultures. Factors that may result in discontinuities in the transitional processes are: (a) variations of social expectations at different historical times due to economic and societal shifts; (b) changes in the specific life contexts and life experiences of adolescents and their families; and (c) the emergence of new developmental tasks at different ages and times as, for example, increased pressure on self-determination and individualization. However, there are also factors that may generate continuity, such as; (a) the genetic disposition of the individual, (b) the continuing influence of early experience, and (c) a contingently rewarding social environment. Determining which parts of the pattern—i.e., biological, historical, social, and individual conditions—contribute to which aspect of successful development in various cultural settings and within cultural subsettings is a task for future longitudinal studies.

Zionism

The political structures of Zionism were largely formed through the institutions which emerged in the wake of the first Zionist Congress, convened by Theodor Herzl in Basel in 1897; they were inspired by Herzl's own *Der Judenstraat* (1896) and by earlier tracts like Moses Hess' *Rom und Jerusalem* (1862) and Leon Pinsker's *Autoemancipation* (1882). Yet Zionism's origins are more complex and reflect the impact of modernization and secularization on a traditional Jewish identity which was basically religious. On the one hand, Zionism draws on the traditional Jewish messianic beliefs in a redemptive salvation which would return Jews from their exile to Zion (= Jerusalem) and the Land of Israel. Yet this belief, which greatly enhanced the ability of Jewish individuals and communities to survive two millenia of exile and persecutions, was at its base religious and looked for divine intercession in the historical process, and not for human, practical action; it was thus, basically, passive. It also never led, with some few yet notable exceptions, to concrete steps in the here and now aimed at bringing Jews to the Holy Land or to the establishment of a political commonwealth. Modern, racist antisemitism, which grew towards the end of the nineteenth century in many European societies, did indeed put in question the hopes for the disappearance of anti-Jewish prejudices with the advent of the Enlightenment and secularization, yet did not by itself lead to the emergence of a political movement among the Jewish populations in Europe: those fleeing antisemitism, especially in the Czarist Empire in the 1880s, looked for emigration to the West—mainly to North and South America, but also to England and South Africa.

In other words, neither traditional Jewish religiosity nor modern antisemitism can adequately explain the emergence of Zionism. It can be understood only in the context of modernity—political, social, and economic—which totally transformed Jewish–Christian relations in Europe, which were based on a delicate, and not always stable but culturally deeply anchored, balance which enabled Jews to find a niche for themselves in Christian Europe. For despite theological condemnation, persecution, discrimination, and occasional expulsions, Christian Europe was able to tolerate the existence of a small Jewish minority in its midst. Provided they accepted their marginality and subjugation, as well as their exclusion from public spheres of social life, Jews were allowed a relative free exercise of their religion and could find an economic sphere for highly circumscribed yet permitted activities.

The emergence of the modern nation-state in the wake of the French Revolution totally changed the parameters of this relationship. On one hand, the modern nation-state was based on the ideas of popular sovereignty and equality among all citizens; on the other, it drew on notions of common descent and put at its symbolic core a commonalty of language, history, myths, and institutions: this confronted both Jews and non-Jews with new challenges. It was not anymore a question of religious tolerance or even equality before the law, but the question of identity and belonging: thus liberalism and nationalism posed a new set of questions. While the ideas of the French Revolution emancipated the Jews as individuals and made them, for the first time, into equal citizens and thus broke down the physical and spiritual barriers of the ghetto, new questions of identity arose for which there were no normative answers in traditional, orthodox Judaism. How should Jews behave with regard to Jewish holidays, customs and laws of marriage, preservation of cultural traditions within a society which, for the first time, is now open to them? At the same time, the emergence of modern nationalism in central and eastern Europe posed equally new questions to Jewish individuals and communities: should they view their identity in purely religious or confessional terms, give up their ethnic and cultural identity, and strive to become 'Germans (or Magyars) of the Jewish confession'? And if they choose this option—as many of them did—would their surrounding society, deeply imbued with ideas of national continuity, history, and cultural identity, really accept them as equals and cease to view them as aliens on their national territory? These issues became especially acute in the areas of the Czarist and Habsburg Empires, where most European Jews lived in the nineteenth century: these empires were also challenged by nationalist movements, and Jews living on the fault lines of these various movements were further torn apart by competing claims: should Jews living in Prague identify with German or Czech nationalism, those living in Budapest identify with German or Magyar culture, or those living in Warsaw support Polish nationalism or Russian rule?

Precisely because secularized, emancipated Jews were looking for an anchoring in their surrounding society, when most of those societies in Central and

Eastern Europe were riven with competing claims for allegiance and identity, it became clear that modernity and even equality do not supply answers to questions of this sort: should one send one's child to German or Polish or Hungarian or Czech schools? Whatever the choice it sometimes raised more questions than it answered. The emergence of the Hebrew *Haskala* (Enlightenment) in Central and Eastern Europe raised a new challange. Under the impact of Herderian ideas, Hebrew became once again a vehicle for literary and cultural creativity beyond its traditional use as a language of prayer and rabbinical discourse. The study of the history of the Jewish people appeared for the first time among Jewish secularized intellectuals, with scholars like the German-Jewish historian Heinrich Graetz following a historiography inspired by Ranke and Michelet making Jewish people much more aware of their own history than the mostly atemporal religious discourse tended to do. This development led to a modern, literary-historical and national new interpretation of the Bible which was now seen by nonpracticing Jews not as a religious text but as a repository of poetic, ethical, literary, and historical sources.

The Haskala created a new Jewish intelligentisia—relatively free from religious observance, yet deeply aware of its history, cultural heritage, and specific contribution to world history: thus the Exodus from Egypt was turned from a story of divine redemption to the first revolt of slaves in history and the Maccabeans became the first fighters for religious freedom. All this was a specific Jewish response both to ideas of political liberalism and national romanticism emerging from the complex heritage of the French Revolution.

This was the context within which the Zionist Organization, founded by Herzl, flourished, developed, and found its adherents. Initially Herzl believed that the acquisition of a Jewish homeland in Palestine could be achieved through diplomatic means and the instrumentality of the European Great Powers bearing upon the Ottoman Empire to grant his organization a Charter for Jewish settlement. It became clear, however, that this was not to be, and that without a demographic change in the population structure of Palestine, no real results could be achieved. The few and sporadic Jewish settlements established in Palestine prior to the emergence of political Zionism became the nucleus of a much wider and organized attempt to create a social, economic, and political Jewish infrastructure in Palestine. After World War I, Palestine became a British Mandate under the League of Nations, with a vague and ambiguous British commitment to support 'a Jewish national home' in the country (the 1917 Balfour Declaration). Between 1918 and 1939 the Jewish population in Palestine grew, through immigration, from 60,000 to almost 600,000, accompanied by a sustained effort at creating an agricultural Jewish class, representative institutions, and relatively autonomous economic sector. Zionism always viewed it as an 'anomaly' of Jewish life that Jews lived not only in exile and under conditions of political powerlessness, but also that their social and economic structure differed widely from that of the populations in whose midst they were living: because Jews were not allowed to own land, they became a mainly urban population; because certain economic activities were barred to them, they were limited to a narrow range of financial or petty trading activities. One of the first aims of Zionism was to change this so-called 'inverted pyramid': hence the emphasis on settling on the land, supported by strong social solidarity and national institutions: it was this which gave the Zionist Left, greatly inspired by Russian socialist revolutionary and populist (*Narodnik*) ideas, its great impetus towards creating new forms of communal living (kibbutzim, moshavim) and the emergence of the Labour Federation (Histadruth) as an overarching 'Community of Labor' combing trade union functions with aims of social transformation and economic development.

As a national movement anchored in its relationship to what it considered the historical homeland of the Jewish people in Palestine, the Zionist movement found itself confronted by the emergence of Arab nationalism, both in Palestine and in the surrounding countries: this at a time when with the demise of the Ottoman Empire in World War I, Arab Nationalism became a major force among Arabic-speakers in the Middle East. Arabs in Palestine saw in Zionism and the influx of new immigrants a danger to their status in Palestine, which in Arab national thought was seen as integral a part of the Arab homeland as the surrounding countries of Syria, Lebanon, Egypt, etc.

The fear of becoming a minority in their own land drove Palestinian Arabs in 1921 and 1929 to anti-Jewish riots and then, during 1936–9, to the Arab Revolt against the British which was aimed at stopping Jewish immigration at a time when the tides of antisemitism in Europe made Palestine sometimes into the only option available to Jews fleeing Nazi persecution. After 1945, Jewish resistance to the British—which still did not allow free Jewish immigration to Palestine, even after the Holocaust—caused the issue to be brought to the United Nations which in 1947 proposed the partition of British Mandatory Palestine into two states, one Jewish and one Arab. While the Jewish community in Palestine and the Zionist organization accepted the idea of partition, it was totally rejected by the Arabs of Palestine and by all member countries of the Arab League. This led to the War of 1948, when the Arabs of Palestine and Arabs armies that came to their help were defeated in their attempt to prevent the establishment of a Jewish State in a partitioned Palestine and the Palestinian refugee problem was created.

Arab countries continued to reject the acceptance and legitimacy of Israel, and this led to the wars of

1956, 1967, and 1973; Israeli occupation in the war of 1967 of the West Bank and Gaza caused the Palestinian intifada against Israeli military rule. President Sadat's visit to Jerusalem in 1977 led to the first Arab–Israeli peace treaty, in which Egypt accepted the legitimacy of Israel in return for the return of Egyptian territories occupied by Israel. Further agreements with the Palestinian Liberation Organization (PLO) in 1993 and with Jordan in 1994 paved the way for a wider reconciliation and for the possibility of an eventual emergence of a Palestinian state living side by side with Israel—basically the 1947 UN formula.

On the ideological level, Zionism encompasses a variety of tendencies—from rightwing nationalistic Zionism (mainly represented by the Likud Party) through religious Zionism to a variety of socialist and social-democratic parties (now mainly represented in the Labour Party). The mass immigration of almost a million Jews from the lands of the former Soviet Union since the late 1980s, as well as the immigration of almost 60,000 Jews from Ethiopia during the same decade, suggest the basic dilemmas out of which Zionism grew are still a reality in some regions of the world. In the democratic West, on the other hand, an identification with Israel is the only hallmark of a Zionist Jewish identity. In Israel itself, relative security and the feeling that the main tasks of Zionism have been fulfilled, albeit under conditions of warfare and siege, now give rise to a less nationally-centered public discourse, sometimes called post-Zionist, which suggests an attempt to substitute the national ideology by one focused more on ideas of civil society. The more the peace process succeeds, the more these new and not always coherent ideas will become much more central to the public discourse of the country.

Zionism, History of

1. Historiographic Premises

Israel is one of those modern societies whose institutions were clearly shaped by an ideological movement. Thus, Israel is similar to other new states whose political institutions directly derive from the nationalist movement that won their independence. But, in addition, a wide variety of social, economic, and cultural institutions of the new Jewish state were initially developed by the Zionist organization and its associated bodies. In these respects, Zionism had an impact unusual among nationalist movements. It must rather be compared with social revolutionary and radical reform movements. Anthony D. Smith contrasts 'ethnocentric nationalism' in which the dimensions of 'power and culture inhere in [a single] cultural group' and 'polycentric nationalism' in which the group's chief desire is to 'join the "family of nations" becoming a nation like all others in a condition of dignified equality.' He further refines this differential with respect to 'diaspora nationalism' citing Garveyism, Zionism, Lebanese, Liberians, Greeks, and Armenians as 'classic cases' (Smith 1983).

A national liberation movement typically arises among a people oppressed by foreign rulers in its own land. Elie Kedourie argues that this conceptual approach actually has roots in the French revolution and the toppling of the *ancien regime*. (See Kedourie's classic essay, especially his comments on 'Politics in a New Style' in *Nationalism* (Kedourie 1985).) To this generalization, the Zionist movement and the rise of Israel are exceptions. Jews did not face the common nationalist situation of being oppressed in their own land by a foreign ruler. Rather, the Jewish people lived as a minority in numerous countries throughout the world, among many different ruling nations and under different regimes. The oppressions they suffered were different in kind, varying from intense to imperceptible, and no single foe could plausibly be held responsible for all Jewish frustrations.

Hence, when Jewish nationalism arose, rival ideologies such as Jewish liberalism, socialism, autonomism, and anti-Zionism did not succumb to it (see Laqueur 1992). They engaged instead in a sharp polemic through which their own positions became more fully elaborated and well defined. Nor did the whole nationalist movement concentrate upon the primary objective of national sovereignty. Numerous nationalist factions arose, each insisting that its goal was most important and all others secondary (see Halpern 1969, Chap. 1, Shimoni 1995).

2. Origins of Zionism

In the eighteenth and nineteenth centuries, the Jewish communities of Europe were traditional in character. This period witnessed a complex phenomenon known

as Jewish emancipation: the process by which the Jews, especially those in Western and Central Europe, were propelled towards new social and economic opportunities and became engaged in gentile society. The prospect of emancipation gave rise to the ideology of Jewish liberalism, which sought to redefine the Jews as a religious community, aware of and responsive to the norms of gentile society. Jewish liberalism was especially strong in Western Europe—England, France, and Germany—where the numerical insignificance of the Jewish population, the speed of social and economic modernization, and the relative ease of legal emancipation all appeared to legitimize the pro-emancipation viewpoint.

While Jewish liberalism dominated the thought of the emancipated Western Jewish leadership, there was a broad body of Jewish public opinion that objected to the loss of a specific Jewish identity. Both traditionalists and defectors from the camp of Jewish liberalism shared this perspective. The typical opponents of Jewish liberalism were born and educated in areas outside the Western liberal mainstream, in Eastern and South Eastern Europe, where traditional values held strong, antisemitism was a palpable reality, and Jewish integration did not appear to be a viable option.

Although Zionism was, in part, a response to modern antisemitism, a number of factors forced the retention of a residual Jewish communal consciousness and national identity. As integral to Zionism as its negative reaction to antisemitism, was its positive assertion of belief in messianic prophecy and the historic destiny of the Jewish people (see Schweid 1985, Chaps 1, 3). Two leading precursors of Zionism, Rabbi Zvi Hirsch Kalischer (1795–1874) and Rabbi Judah Solomon Hai Alkalai (1798–1878), were moved to create a Jewish settlement in Palestine by sociopolitical forces and a deep religious conviction that the time for the biblical injunction of the 'ingathering of the exiles' had arrived—the prophecy was to be literally acted upon.

Similarly, the socialist Moses Hess (1812–1875) rediscovered Jewish nationalism after a distinguished radical career in Central Europe. His book *Rome and Jerusalem* (1862), was an eloquent appeal for the reassertion of Jewish national identity. The work of Hess, and of his contemporary, the Hebrew publicist and editor Perez Smolenskin (1840–1885), demonstrates that even before the Russian Jewish crisis of 1881–1882, Western Jewish liberalism was under attack from Jews with a nationalist perspective.

The term Zionism was probably coined by Nathan Birnbaum (1864–1937), an Austrian leader of Hovevei Zion [Lovers of Zion], a loose federation of groups devoted to the promotion of national resettlement of the Jews in their ancestral homeland. The Hovevei Zion viewed resettlement as the solution to the Jewish question, which it variously defined as the problem of antisemitism or the problem of Judaism in a modern, secular world. Significantly, the term Zionism reflects both traditional sentiment (the longing for Zion) and a modern political orientation.

3. *Ideological and Political Evolution*

The assassination of Tsar Alexander II by revolutionaries, the pogroms of 1881–1882 and 1903–1905, and the ensuing the Russian Revolution provoked despair and panic and eventually prompted the massive flight of East European Jewry. Many young Jews considered options such as emigration to and the colonization of Palestine. An immediate rivalry developed between the Amerikantsy, represented by such groups as Am Olam [Eternal People] who saw the United States as the obvious safe haven, and the Palestintsy who desired resettlement in Palestine.

In 1882 scattered groups of Palestine-minded students united to found the Bilu movement, a secular Zionist group dedicated to creating exemplary rural colonies in the Land of Israel. Their most celebrated publicist was the young journalist Moshe Leib Lilienblum (1843–1910). Although the movement failed to generate mass migration to Palestine, it did lay much of the ideological groundwork for Russian Jewish pioneers in this period (Frankel 1984, Chap. 2).

The movement for a new exodus received ideological justification from Leon Pinsker (1821–1891), who in 1882 published an influential pamphlet entitled Auto-Emancipation. Pinsker headed the Russian movement known as Hibbat Zion [Lovers of Zion] from 1884 until his death. The efforts of the Russian Zionists were largely ineffectual. They managed to establish a few agricultural colonies in Palestine, but many of them became dependent on the largesse of the important French Jewish philanthropist Baron Edmond de Rothschild (1845–1934). Though deeply committed to the development of the Land of Israel, Rothschild was not a Zionist (Halpern and Reinharz 2000, Chap. 4).

There was a significant growth in the Jewish population of Palestine in the decades before World War I, largely due to Zionist immigration. Estimates for the beginning of the nineteenth century indicate that only about 7,000 Jews lived in Palestine, about 2.4 percent of the whole population, and mostly concentrated in the four Holy Cities: Jerusalem, Tiberias, Safed, and Hebron. At the end of the century the number of Jews had grown to about 43,000, about 8.1 percent of the total population. Well over 90 percent of these Jews lived in the cities. 5,000 Jews lived in Jaffa, half of the total population of the city. Furthermore, by 1890 Jews were already a majority of 60 percent of the population of Jerusalem, and their proportion was due to grow even more in the following years. Before World War I they comprised half of the Jewish population of the country, but these were

mostly Orthodox Jews who had little to do with the developing Zionist movement (Friesel 1972, 1990).

Zionist ideas also found fertile ground on American soil (Raider 1998). As early as the beginning of the nineteenth century, prominent American Jews expressed the view that the Jewish people should be allowed to return to the Land of Israel. Mordecai M. Noah (1785–1851), a well known publicist and former consul in Turkey, following an ill-fated attempt to found a Jewish colony called 'Ararat' near Buffalo, New York in 1825, turned to Palestine as an ultimate haven for the Jews. So, too, did Warder Cresson (1798–1860), a former American diplomat who converted to Judaism and established a settlement near Jerusalem.

4. *Modern Political Zionism*

The fortunes of the fledgling Zionist movement changed dramatically with the appearance of Theodor Herzl (1860–1904), the father of modern political Zionism. Herzl was an Austrian Jewish writer and journalist and, until the Dreyfus Affair of 1894, a typical, assimilated, middle-class Jew. Shocked to the core by the virulent display of antisemitism surrounding the Dreyfus Affair, Herzl subsequently turned his efforts to the implementation of a Zionist solution to the so-called 'Jewish problem.'

In 1896, after unsuccessful attempts to enlist the support of Franco–Jewish philanthropists, Herzl sought a wider audience with the publication of *Der Judenstaat* (The Jews' State). In 1897 he launched a Zionist weekly called *Die Welt* (The World) and presided over the First Zionist Congress in Basel, Switzerland. A total of six congresses were held between 1897 and Herzl's death in 1904, and they created the organizations and institutions of the Zionist movement: the World Zionist Organization, the Jewish Colonial Trust, and the Jewish National Fund.

Herzl pursued his goals through diplomacy aimed at the rulers of European states and the Ottoman sultan. In 1903, the Zionist movement underwent a crisis when the British government offered Herzl a tract of land in East Africa for Jewish colonization. Herzl recommended the acceptance of this territory to his followers as a temporary 'safe haven' for the Jews. This 'Uganda Project,' as it came to be known, ultimately failed, foundering on the hostility of the Russian Zionists led by Menahem Mendel Ussishkin (1863–1941). In the event, the militant rejection of Herzl's flirtation with territorialism assured the Zionist movement's enduring commitment to settlement in Palestine alone (Vital 1975, 1982).

Some years after Herzl's premature death in 1904, the leadership of the movement was captured by the 'practical Zionists' who subordinated the long-range, diplomatic and social goals of Zionism to the task of building up the Jewish settlement in Palestine. Another important influence was that of Ahad Haam (the pseudonym of Asher Zvi Ginsburg), a Russian Jew who emerged as the foremost critic of both Hibbat Zion and Herzlian Zionism. Ahad Haam (1856–1927) rejected the concept of Zionism as a mass movement, arguing instead for a concept generally characterized as 'spiritual Zionism.' In his view, the Jewish people required cultural revival and modernization, objectives best carried out by a small elite based in Palestine. This was a clear rejection of the idea of immediate, mass resettlement. Although never part of the Zionist mainstream, the writings of Ahad Haam had a profound influence on many of the younger leaders of the Zionist movement (Zipperstein 1993).

The differences between Herzl and Ahad Haam reflected the differences between West and East European Jewry, stemming from their contrasting political and cultural situations. The multiethnic character of some of the states and political parties of Eastern Europe theoretically presented the Jews with the possibility of a secular national culture within the context of modern society. However, East European Jewry was forced to face the brutal nature of antisemitism in a much more violent fashion than West European Jewry, and because of the exigency of this problem East European Zionists were pressed to develop a program of immediate, practical solutions that involved alternatives that did not require the restoration of sovereignty in Palestine. In contradistinction to East European Zionism, Western Zionism until the rise of the Nazis was largely a philanthropic movement devoted to the welfare of persecuted Jews in Eastern Europe. It did, however, contribute significantly to the intellectual and ideological fermentation of Zionism in the East and the West.

In the decades that bridged the nineteenth and twentieth centuries, socialist ideas merged with East European Zionism to produce a number of socialist Zionist parties, some of them with a Marxist orientation, some not. The left-wing Zionist groups produced many of the members of the Second Aliyah, the wave of Jewish immigration to Palestine between 1904 and 1914 that had a profound impact on Zionist politics and ideology (Halpern and Reinharz 2000).

5. *Zionist Policy and the British Mandatory*

The outbreak of World War I opened up new possibilities for the Zionist movement. Some of the leading Zionists, among them Chaim Weizmann (1874–1952) and Vladimir (Zeev) Jabotinsky (1880–1940), decided that the future of the movement laid in the Entente camp. Their hopes were indeed realized with the great political success of the Balfour Declaration in 1917, wherein the British government expressed its commitment to the establishment of a Jewish national home in Palestine. The Balfour Declaration, which generated tremendous excitement among diaspora Jews, was received by the Arab

community in Palestine with profound misgivings. But the hopes and fears the Declaration stirred respectively in each camp were equally exaggerated.

After World War I, when the British Mandatory regime's policy unfolded, it became clear that it had neither the will nor the intention to establish a Jewish national home in Palestine in the sense envisaged by the Zionist Movement. Instead, during the interwar years, the British government issued a series of White Papers stressing that the Balfour Declaration had not intended to create a sovereign Jewish state in Palestine. The principle of the 'double obligation' to Jews and to Arabs in equal measure, became the cornerstone of British policy in Palestine in the years from 1922 to 1939. Unappeased, however, Arab political leaders continued to view Zionism as an extension of Western imperial aims and Arab opposition to the Jewish community in Palestine intensified (Stein 1985).

In the 1920s and 1930s, Palestine's Jewish society-in-the-making (known in Hebrew as the *Yishuv*), grew gradually in numbers and developed a political structure, communal institutions, and an economic foundation. There were 85,200 Jews in Palestine in 1922 (11.1 percent of the total population), and 175,100 in 1931 (17 percent of the total population). Due mainly to significant increases in the 1930s, the number of Jews reached in 1947 to 630,000, close to one-third of the total population. In 1946, over three-quarters of the Jewish population lived in cities. With over 180,000 inhabitants, Tel Aviv became the major Jewish center of the country (Friesel 1990, Hersch 1948).

Chaim Weizmann, the architect of the Balfour Declaration, emerged as the leader of the Zionist movement in the years after World War I (Reinharz 1993). Despite Weizmann's secure diplomatic standing, the new Zionist hierarchy led to a somewhat anomalous situation. On one hand, the Zionists in the cities and the settlements in Palestine, many of them religious, others secular, an influential segment imbued with a particular socialist ideological agenda, lived all according to the specific dynamics dictated by the life in Palestine. On the other hand, the individuals who retained ultimate political control of the Zionist movement lived in a totally different milieu thousands of miles away. The ambivalent attitude of the British authorities toward the Yishuv and Zionism only accentuated this division.

The geographic distance separating the Zionist leadership in London from the movement in Palestine and elsewhere caused misunderstandings, ideological quarrels, and eventually a power struggle in world Zionist politics. A rift emerged between the traditional European-based Zionist leaders and the stewards of the movement in the United States. Louis D. Brandeis (1856–1941), an associate justice of the United States Supreme Court and head of the American Zionist movement, believed that the political era of Zionism had ended with the Balfour Declaration. By contrast, Chaim Weizmann believed that the political struggle was far from over, and he continued to view Zionism, as officially represented by the Jewish Agency for Palestine, as representing the national will of the Jewish people. In fact, Brandeis and Weizmann did not differ significantly in their programmatic positions. However, they did differ over a principle of fundamental importance: the notion of exile and the Land of Israel as the authentic home of the Jewish people. Weizmann eventually emerged supreme in this clash of ideologies, defeating Brandeis at a convention of the American Zionists held in Cleveland, Ohio in 1921 (Halpern 1987).

6. *Labor Zionism and Palestine*

In the 1930s the Labor Zionist movement rose from its minority status in the World Zionist Organization to a position of political dominance. Despite Labor's initially meager size, the movement had always played a critically important role in Zionist efforts aimed at immigration, land acquisition, and permanent Jewish settlement, particularly the process of organizing and training young Zionist pioneers abroad. Notwithstanding the British Mandatory's restrictive policies, the Arab community's steadfast and even violent opposition to Jewish settlement, and the economic fragility of the region as a whole, the Labor movement gradually developed a sound socioeconomic, country-wide infrastructure.

At the heart of the Labor enterprise stood the Histadrut, the General Federation of Jewish Labor, created in 1920 by a conference of socialist Zionist parties in Palestine. The Histadrut commanded a broad network of agricultural settlements, educational institutions, trade unions, self-defense groups, a workers' press and a workers' health organization. This web of social, economic, cultural, and political interests consolidated Labor's position in the World Zionist Organization and enabled the Yishuv to cope with different crises through broad measures of cooperative organization.

Labor never attained a political majority in the Jewish community in Palestine, and had always to form coalitions with other parties, especially with the Mizrahi national-religious party and the middle-class liberals, known as the Progressives. The ensuing political experience of power-sharing, which continued for most of the time of the British Mandate in Palestine, created patterns of political collaboration that were to continue later on, after the establishment of the State of Israel (Halpern and Reinharz 2000, Medding 1990).

Labor Zionism's most serious political challenge came from Revisionists, the right-wing dissident movement created by Vladimir Jabotinsky in 1925. Jabotinsky originally created the Revisionist party to counteract what he viewed as the corruption of Herzlian political Zionism under Chaim Weizmann's

leadership. He also emphasized the primacy of private capital in developing the Yishuv and insisted on maximal nationalist and antisocialist principles.

A critical juncture factor in determining the Yishuv's future was reached in the late 1920s and early 1930s when a coalition of Zionist and non-Zionist forces united behind the objective of attaining a secure Jewish national home in Palestine. To this end, the World Zionist Organization initiated a series of negotiations with organized Jewish bodies in various countries, which culminated in 1929 in the creation of what came to be known as the Expanded Jewish Agency and was regarded as an expression of the growing interest in Palestine of the entire Jewish people (Halpern 1969, Chap. 6).

The Arab riots of 1929, which resulted in the massacre of Jews in Hebron and other places, dramatically changed the Yishuv's internal debate over the issues of Jewish sovereignty and security. The pretext for the riots was a clash over conflicting Arab and Jewish rights in Jerusalem. In fact, the tension between Arabs and Jews had been steadily mounting since the previous wave of riots in 1921. Shortly thereafter, the uncertainty of the Mandatory's short- and long-range goals was further compounded by the eruption again of Arab riots in 1936–1939. The latter initially prompted the Royal Peel Commission of 1937 to recommend the partition of Palestine and the creation of a small Jewish state—a plan reluctantly adopted by the Zionists and rejected by the Arabs.

But the stillborn Peel proposal ultimately led to a complete reappraisal of Mandatory policy and a retreat from the Balfour Declaration-inspired policy. In its place came the MacDonald White Paper of 1939, which acquiesced to Arab demands. The White Paper established a limit on Jewish immigration of 75,000 between 1939 and 1944 (when immigration would cease), curtailed drastically new purchases of land by Jews, and established a ten-year transition period after which Palestine should become an independent country, meaning, an Arab state with a Jewish minority of about 30 percent of the population. The Jewish Agency and Zionists everywhere believed this to be a clear breach of past British pledges. In the face of this turnabout, exacerbated by the onset of World War II, David Ben-Gurion (1886–1973), the leader of the Zionist movement after 1935, declared a new Zionist policy agenda: 'We must support the [British] army as though there were no White Paper, and fight the White Paper as though there were no war' (Shapira 1992, Chap. 7).

7. *World War II, the Holocaust, and Combative Zionism*

During the course of World War II, Britain received assistance from the Zionist organization, including the Haganah, the military arm of the Jewish Agency. The British military received assistance from the Palmah (Hebrew acronym for *plugot mahaz*, shock troops), for example, in the campaign against the Vichy French authorities in Syria in 1941. The Palmah had originally been formed to help defend Palestine against a possible German or Italian invasion of Palestine.

While the British Mandatory was ambivalent about the Haganah and the Palmah, it was plainly negative toward the Revisionist fighting force known as the Irgun Zvai Leumi (National Military Organization, also known by the acronym Ezel). Created in the midst of the 1936–1939 riots, the Irgun was dedicated to undertaking retaliatory action against Arab terrorists. When Menahem Begin (1913–1994) assumed command of the Irgun in 1943, he was convinced that the only effective strategy for gaining Jewish control of Palestine was to exert so much pressure through selective terrorism—such as the bombing in 1946 of the King David Hotel in Jerusalem—that the British would eventually be forced to choose between total repression or complete withdrawal.

Zionist terrorism was unacceptable to the leaders of Jewish Agency. After the assassination in Cairo, in 1944, of Lord Moyne, the British Minister for the Middle East, by members of another Zionist terrorist organization, the Stern Group or Lohamei Herut Israel [Freedom Fighters of Israel, also known by the acronym Lehi), the Haganah and the Palmah were given orders to 'neutralize' the Irgun. This led to the so-called 'Open Season' during which Haganah and Palmah operatives interned and handed over right-wing Zionist activists to the British, causing considerable bitterness in the Yishuv. As this clash reveals, global events at the height of World War II brought about a steady radicalization of Zionist ideology and activity in the Yishuv.

The outbreak of World War II resulted in the complete dislocation of Jewish life on the European continent that had been the backbone of much of Jewish life since the eighteenth century. The constitutional pattern of the World Zionist Organization and the Expanded Jewish Agency became unfeasible and in practice responsibility for the Zionist enterprise fell to the Yishuv and American Jews. In May 1942, a wartime conference was held in lieu of a Zionist Congress at the Biltmore Hotel in New York City. The Biltmore Conference symbolized the strengthening of the position of Zionist leaders in the Yishuv and America and united most of world Zionism around the call for a Jewish state in Palestine (Laqueur 1992). This juncture also signaled the displacement of the Zionist movement's veteran leadership, notably Chaim Weizmann and Stephen S. Wise (1874–1949), and the ascendance onto the world stage of a younger generation led by David Ben-Gurion in Palestine and Abba Hillel Silver (1893–1963) in America (Teveth 1987, Raider et al. 1997).

The election of the British Labour party in 1945 raised expectations that Palestine's partition and

Jewish independence would soon follow. These hopes were dashed, however, when British Foreign Secretary Ernest Bevin announced, in effect, that the White Paper policy of 1939 would continue and that Britain was committed to a Jewish 'home' in Palestine, but not a Jewish state. Set against the catastrophic tragedies that befell European Jewry during the war—but, in fact, before the full magnitude of European Jewish destruction was known—British policy was received with mixture of anger and alarm by Zionists of all political persuasions.

8. *Campaign for Jewish Statehood*

The years immediately following World War II were characterized by turmoil in Palestine, intensive Zionist activity worldwide, and ongoing diplomatic initiatives in the Western capitals, especially in London, Washington, and New York. The Jewish Agency spearheaded the postwar campaign for the establishment of the Jewish state. The Agency used three interrelated approaches to the attainment of this goal: first, political negotiation, aimed at securing international recognition for a Jewish state; second, the practical work of immigration, land development, and the building of a strong autonomous Jewish community; and third, the organization of clandestine or illegal Jewish immigration to Palestine during the British Mandate known in Hebrew as *Aliyah Bet* (Ofer 1990).

The latter reached a climax in 1947 against the backdrop of overflowing displaced persons camps in Cyprus when the British decided on a policy of returning illegal Jewish immigrants to their original ports of departure. The most notorious example was the Exodus-1947, a ship carrying nearly 5,000 Jewish refugees. Intercepted off the Palestine coast, the Exodus was compelled to return to Hamburg after a pitiful ordeal in which the British forced the passengers off the ship and beat those who resisted with clubs and hoses—all in the glare of the world's media. The affair demonstrated Britain's inability to deal with the ever-increasing flow of illegal Jewish immigrants and hastened its decision to relinquish the Mandate. It also highlighted the Zionist leadership's postwar strategy for winning the battle for international public opinion. The boatloads of beleaguered European Jewish refugees and determined Zionist activists gradually eroded sympathy for British policy and underscored the urgency of postwar Jewish reconstruction (Laqueur 1992, Sachar 1976).

On November 29, 1947 the United Nations adopted a resolution calling for the establishment of a Jewish state in Palestine. The sudden collapse of the Mandate, the persisting hostility of the Arab states, and particularly the absence of and ensuing conflict with the Palestinian Arabs abruptly and totally altered the conditions under which the policy of the Jewish state would thenceforth have to be formulated. When the state was formally proclaimed on May 14, 1948, the major functions of the World Zionist Organization and the Jewish Agency were immediately assumed by the nascent Israeli government.

The Zionist movement before the rise of Israel proclaimed, in addition to the goal of national independence, the following objectives: to develop Hebrew as a spoken language and as the foundation of a Jewish national consensus; to transfer to Palestine all Jews who could not or did not wish to live in diaspora countries; to establish a Jewish community in Palestine free from the peculiar social, economic, and cultural problems that beset the Jewish status as a minority people scattered throughout the world; and to carry out the transformations in the Jewish social and economic distribution, to create the appropriate social institutions, and to foster the cultural changes that were the necessary means for attaining the above ends. By World War II, the Jewish community in Palestine had indeed secured a socioeconomic infrastructure in conformity with the ideal of a self-sustaining national home and developed institutions capable of realizing its political aims. With the creation of the State of Israel in 1948, the ideal of Jewish national independence was institutionalized in its ultimate form: Jewish political sovereignty.

Zooarchaeology

Zooarchaeology is the subdiscipline of archaeology that focuses on the analysis of animal remains from archaeological sites. The term has a less euphonious twin, archaeozoology, which has less currency in English than it does in other languages. While some have distinguished among the kinds of approaches that might be treated under these two terms (Reitz and Wing 1999), research identical in form and content is published under both names.

A thorough history of zooarchaeological research has yet to be written. It would be a daunting task to do so, since highly relevant literature in a diverse variety of languages extends well back into the nineteenth century. Zooarchaeology has continued to be an inherent part of archaeological research for well over a century for a wide variety of reasons: faunal data can help place archaeological sites in time, provide detailed information on past human diets, provide detailed knowledge of the environments in which past peoples lived and on human impacts on those environments, and, less securely, provide insights into the nature of the social organization of the people involved.

Even though zooarchaeology has always been an integral part of prehistoric archaeology, zooarchaeology as a distinct and recognizable subdiscipline extends no further back than to about 1970. Prior to that time, most research dealing with animal remains from archaeological sites was conducted by people whose primary training and interests lay outside of archaeology itself, usually within zoology or paleontology. The research done by these practitioners was frequently of superb quality and enduring value, but was often poorly-integrated with other aspects of the archaeological research involved.

This situation began to change in the mid-1960s, as archaeology as a whole began to shed its largely descriptive roots and turned toward more explicitly scientific approaches to the past. Within a decade or so, there came into existence a set of scientists with intensive training in both biology and archaeology whose research focused on zooarchaeological matters, and who began developing techniques, methods, and theory relevant to answering those questions (e.g., Grayson 1984, Klein and Cruz-Uribe 1984). Today, most well-regarded archaeology Ph.D. programs in the USA now include zooarchaeology as part of their training program.

Compared with other object-based research realms in archaeology, including lithic and ceramic analysis, zooarchaeology benefits tremendously from the fact that the units studied are provided by biology, and that their biological meaning is never in doubt. These units tend to be of two prime sorts. First, there are taxonomic units, drawn from the Linneaen system—species, genera, and families, for instance. Second, there are anatomical units—the separate parts of the vertebrate skeleton, for instance, or of the insect exoskeleton. As a result, while zooarchaeologists might argue over the identification of a particular specimen, they do not argue about the meaning of their classification systems. This is often not the case in lithic or ceramic analysis—as anyone who has worked

with European Neanderthal stone tool assemblages or with ceramic Poverty Point objects in southeastern USA can attest.

1. Vertical Applications

Much zoological research is directed toward understanding change through time, and relies heavily on the analysis of data from stratified archaeological sites or from sites which, if not stratified, can be arrayed in time. As a result, such research has a strong temporal, or vertical, component, and can differ in approach from zooarchaeological research that focuses on a particular site or set of sites at a precise point in time, and is thus primarily spatial or horizontal in emphasis. These different approaches may be driven largely by the research problems that intrigue a particular investigator, but they may also be driven by the kinds of sites available for analysis. Because vertical zooarchaeological research tends to focus on change through time, it often draws more heavily on biological theory than do horizontally-oriented analyses, which tend to depend more heavily on less-well developed social theory. Even though this is the case, vertical analyses often have horizontal components, horizontal analyses often have vertical components, and either approach can make use of either kind of theory.

In recent years, vertical zooarchaeological research has revolutionized our understanding of the relationship between prehistoric peoples and their biotic environments. It has done this by showing the impacts that even small-scale societies can have on their faunal landscapes, and by showing that those impacts can force changes in the behavior of the people themselves.

Those impacts can be dramatic. For instance, it has long been clear that people caused the extinction of some 11 species of large, flightless moas in New Zealand within a few hundred years of the human colonization of these islands some 1,000 years ago. While it is not known what combination of human hunting, habitat alteration (largely by burning), and human-introduced predators (rats and dogs) caused moa extinction, human activities were certainly to blame (Anderson 1989).

During the past two decades, however, zooarchaeological work throughout Polynesia has shown that bird extinctions followed human arrival in island settings with deadly consistency. While large, flightless birds were particularly vulnerable, smaller, flighted species were lost in high numbers as well (Martin and Steadman 1999), and over half the species that comprised the Polynesian avifauna may have been lost after the initial human colonization of these islands. As is the case with New Zealand's moas, the exact causes of each extinction is unknown, but some combination of human hunting, human-induced vegetational change, and human-introduced predators was involved (Kirch and Hunt, (eds.), 1997).

Zooarchaeological research has detected impacts of this sort, though not necessarily of this magnitude, in other parts of the world as well. In some of these places, the branch of evolutionary ecology known as foraging theory has been used to understand not only why particular species declined in abundance under conditions of human predation, but also the impact of such declines on the people who caused them.

Among other things, foraging theory is designed to answer two apparently simple questions. First, given that resources are not often distributed randomly across the landscape but are instead clumped into patches (like ducks at oases), which of those patches will a predator chose to visit and how long should it stay there? Second, given that multiple prey types, or species, exist in a given patch, which of these prey types should a predator bother to pursue upon encountering it? The former issues are treated with what is called the patch-choice model, the latter with what is called the prey-choice or diet-breadth model, but combinations of the two also exist (Smith and Winterhalder 1992, Stephens and Krebs 1986). Developed in biology for non-human predators, foraging theory has seen wide application in contemporary human contexts, with impressive successes (Smith and Winterhalder 2000).

In recent years, it has begun to be applied to archaeological contexts as well. These applications have assumed that human prey choice is driven by energy returns, and that up to a point, larger animals provide higher returns than smaller ones. From this, it follows that vertical analyses of archaeological faunal assemblages should show that these animals face the steepest decline in the face of human predation. Zooarchaeological research has shown that they do just that.

In the San Francisco Bay area of California, for instance, Broughton (1999) has shown that such large-bodied animals as deer formed an ever-decreasing part of human diets between 2,600 and 2,000 years ago, while such smaller and more costly animals as sea otters became increasingly important. After 2,000 years ago, this pattern changed, and deer began to become more common in the diet—but only because sea otters themselves had become rarer, and it now paid to go further afield to hunt deer. As all this was happening, sturgeon, the largest fish available in the area, not only declined in abundance through time, but even declined in size. All this is predicted by biological theory under conditions of heavy predation.

In fact, it seems that wherever zooarchaeologists look for such effects, and have access to sufficiently fine-grained data, they find them. The moas provide another example. It has been realized for many years that after moas became extinct, human diets in New Zealand became dominated by small prey species, including fish and shellfish. Recently, Nagaoka (2000) has used foraging theory to provide the details of this process.

Foraging theory predicts that, as prey items that provide high energy returns decrease in abundance, the number of species included in the diet may increase in response to the resultant energetic shortfall. Using data from the Shag Mouth archaeological site on the east coast of New Zealand's South Island, Nagaoka has shown that, as the abundance of moas decreased through time here, not only did higher cost, smaller vertebrates become more important in the diet, but the number of species included in the diet increased as well. She has also shown that as moa populations dwindled, the places people went to procure food changed substantially. As time went on, for instance, people began to bring only the meatiest parts of moas back to Shag Mouth, suggesting that they had to go further and further to hunt those moas that still existed. In addition, during the earliest occupations of the site, most prey species came from either inland or coastal settings. Only late in the history of the site did people begin to exploit offshore resources, mainly barracuda, heavily, and this only after the human activities had caused depletion of larger vertebrates available nearer-by. All this occurred within a period of less 200 years, between about AD 1300 and AD 1500.

Zooarchaeologists have thus shown some of the kinds of impacts that even small-scale societies can have on the faunal landscape, and the influence that those impacts can in turn have on the people themselves. These kinds of theory-driven studies are fairly new. More traditional are zooarchaeological analyses that show the influence that 'natural' (i.e., non-anthropogenic) environmental changes can have on human adaptations, but these make far heavier use of, and greater contributions to, biological theory than they did in even the fairly recent past.

For instance, the site of Grotte XVI in southwestern France contains a series of archaeological deposits that date to between 36,000 and 12,000 years ago. Zooarchaeological analyses of the large mammal bones from these deposits showed that the percentage of reindeer that people hunted increased steadily through time, from 47 percent of all the large mammals at about 36,000 years ago, to 94 percent of those mammals at about 12,000 years ago. Comparing the dated archaeological record at Grotte XVI with a reconstructed summer temperature curve for southern France demonstrates that each of these increases was associated with a decrease in summer temperature (Grayson et al. 2001), culminating in a human diet whose large mammal component was almost entirely reindeer. Biogeographic theory shows that the challenges posed to mammals by temperature extremes, either hot or cold, can lead to mammalian communities that are dominated by a small number of species, and Grotte XVI, as well as other sites, show this process in operation through time.

Thus, vertical zooarchaeological analyses have begun to show the complexities of human relationships with their faunal landscapes. In some cases, people caused the abundances of the species on which they preyed to decline dramatically, and both people and prey paid the price. In others, people were forced to react to environmental changes for which they were not responsible, and the results can be readily seen in their diets, and probably in other aspects of their lives as well.

2. *Horizontal Applications*

Horizontal approaches to zooarchaeology focus on fine-scale analyses of faunal material across space within, and occasionally between, sites, though other aspects of faunal data play a role here as well. These distributions are usually used to test hypotheses about social organization, hunting patterns, or other aspects of past human behavior, or to infer aspects of such behavior from the distributions themselves.

Ongoing work at the ca. 12,500 year-old site of Verberie, located in the Oise River Valley north of Paris, provides a simple yet compelling example of such an analysis. Unlike Grotte XVI, which is a cave, Verberie is an open-air site consisting of a series of thin depositional layers, each of which represents a distinct occupation of short duration. These occupations vary in extent from 45 to 250 square meters, and are marked by stone-lined fireplaces, around which stone artifacts are concentrated. The site is also quite rich in well-preserved bone, most of which is of reindeer (Audouze et al. 1981, Audouze and Enloe 1997, Enloe and Audouze 1997). The Verberie bones are distributed across each occupational layer, but many are found concentrated around relatively bone free, circular zones. These concentrations tend to be marked by parts of the reindeer skeleton that do not have much meat associated with them in the living animal, suggesting that they had been left behind after butchering and removal of the meatier parts. In addition, these concentrations are located several meters from the hearths, which are in turn located several meters from one another. Taken as a whole, however, the occupation floors at Verberie contain all parts of the caribou skeleton. Since reindeer are large animals that are not likely to have been transported far when whole, the Verberie occupations would appear to represent hunting camps.

One of the most powerful tools zooarchaeologists have available for studying social organization is provided by what is known as refitting. There are two sorts of bone refitting, the first of which involves reassembling broken bones. Refits of this sort can tell us about the stratigraphic integrity of a site, since fragments of the same bone found in different strata demonstrate that specimens have moved up or down the deposits. They can also provide much more precise information as to the nature of the faunal assemblage as a whole, since small shaft fragments often cannot be

identified to species on their own, but can be identified once reassembled (e.g., Marean and Frey 1997, Marean and Kim 1998).

In the second approach, developed by Enloe (1991), detailed measurements and morphological comparisons allow bones that are highly likely to have come from the same individual animal to be refit to one another. If such refit body parts are found on spatially disparate parts of an undisturbed occupation surface, they have the potential of telling us about such things as food-sharing and other aspects of past social organization.

Bone refitting of this second sort done by Enloe at Verberie shows that bones belonging to the same animal either did not travel very far from the areas in which they are concentrated (and at which initial butchering apparently occurred), or, if they did, travelled to, but not between, the hearths. This situation is quite different from that found at the roughly contemporaneous site of Pincevent, located not far from Verberie. Here, bones traveled from hearth to hearth, suggesting food sharing among the people using those hearths (Enloe 1991). All this, along with a wealth of other evidence from the site, suggests that Verberie, unlike Pincevent, served as a briefly-occupied hunting camp—a place from which hunting was conducted and to which the results of the hunt were brought for processing. Enloe was also able to use tooth eruption data to show that in all likelihood the Verberie reindeer had been killed during the Fall, and thus presumably during migration.

The work done at Verberie provides a remarkably detailed view of what happened at this particular place at about 12,500 years ago. Small groups of people came here to hunt reindeer during autumn. Hearths were constructed and stone tools fashioned or refashioned around those hearths; animals were hunted nearby, then brought back to be butchered, with the meat transported elsewhere.

Not all horizontal archaeology is as firmly-grounded at that which has been done at Verberie and Pincevent. A good deal of it, in fact, is hardly compelling at all, consisting largely of poorly-controlled assertions about the behavioral meaning of a particular set of faunal material. However, when horizontal zooarchaeology is well-done, as at Verberie and Pincevent, the degree of detail it can provide about ancient human behavior can be close to astonishing.

3. Taphonomy

The differences between vertical and horizontal approaches to zooarchaeology are often differences in degree, not kind. Multiple horizontal analyses at a single stratified site can be combined to look at change through time, and many vertical analyses examine the distribution of specimens across space as well.

Both approaches require that we understand the nonhuman factors that may have impacted the faunal material that is under study. Carnivores, for instance, can introduce bones into sites occupied by people, and can modify both the condition and the location of bones deposited by people. Specimens can be destroyed by a roof-fall in a cave, or by chemical action anywhere; they can be moved by water, trampled by large animals (including people), attacked by roots, and in general be affected by a depressingly broad variety of processes that can dramatically transform the assemblage that was originally deposited. Because of this, the area known as taphonomy, the study of the processes that intervene between the time an animal dies and scientists study what is left of it in the lab, has become extremely important in zooarchaeology (Lyman 1994). Most zooarchaeologists are proficient at conducting taphonomic analyses. Without such analyses, there can be a high risk of interpreting as archaeologically meaningful patterns that have been produced in other ways.

In short, the thriving subdiscipline of zooarchaeology provides us with information that can be acquired in no other way on human diet, on human interactions with the environment, on those environments themselves, and on a surprising variety of past human behaviors that are themselves invisible but that leave faunal residues from which they can now at times be fairly confidently inferred.
