# Preface

The information technology revolution that has swept across the world has changed the way the governments work and interact with their stakeholders. This explains why digital government or electronic government (e-government) has become one of the most important topics in the public sector reform agenda. Such an e-transformation in government and public governance has its roots in the 1950s when some few professionals and academics started to speak about the computerization of public organizations. For several decades the discussion was meek, concerning mainly the use of computers in internal operations of public administrations, such as accounting and recordkeeping. Wider perspectives started to gain ground as late as 1980s in the wake of the introduction of personal computers and the merge of computers and telecommunications. Yet, the most fundamental recent turn in the information technology revolution was the Great Internet Explosion of 1993-1994 and the increased popularity of World Wide Web (WWW) in particular. Since then the transformative power of e-government has been generally recognized. *The Encyclopedia of Digital Government* discusses topics that are at the core of this ongoing transformation.

When Dr. Mehdi Khosrow-Pour of Idea Group Inc. in late 2003 invited us to edit a new encyclopedia on electronic government or digital government, we were eager to grab the opportunity. We had, together with our colleague Professor Reijo Savolainen, just edited a book titled *eTransformation in Governance: New Directions in Government and Politics* (IGP, 2004) and were keen to continue our ongoing intellectual journey towards the better understanding of e-transformation in government. With the continuously increasing interest in this topic all over the world, we felt that the time was ripe for such an endeavor. This is how the project got started.

Let us remind here that in spite of the slight differences in their connotations, we use the terms "digital government" and "electronic government" (e-government) synonymously. Our starting point has been to avoid one-dimensional or too narrow conceptions of digital government. This has allowed us to provide an open forum for academics and experts to present their views of digital government and related topics, which in turn has made it possible to create a collection of articles that reflects the richness of topics, concepts, approaches, and contexts in this new interdisciplinary research field.

Another reason for applying fairly broad conception of digital government was the paradigm shift in the political and administrative sciences themselves, sometimes expressed by the phrase "from government to governance." This refers to a general transition from hierarchical, command-and-control-oriented government toward citizen- and stakeholder-oriented, initiate-and-coordinate practices of public organizations. Such new orientations and practices have had their direct implications to digital government discourse. Thus, digital government is used here as a flexible umbrella concept that depicts the dynamic relationship between new trends in public governance and constant technological development.

The concept of digital government may be further divided into various subcategories, including such internally-oriented categories as e-administration, e-management, and e-organization and more externally-oriented areas such as e-service, e-governance, and e-democracy. It includes also more recent technology-driven conceptions, like u-government (ubiquitous government), m-government (mobile government), and g-government (GIS and GPS applications in government). E-government-related terminology is strongly interrelated, which has led to blurring of conceptual boundaries and caused occasional conceptual confusion. A good example is an occasional confusion between concepts of e-government and e-governance. In order to bring clarity to this field and to provide a coherent structure of the publication, we have paid special attention to the systemization of the conceptual field of digital government. The list of contents of this encyclopedia reflects this endeavor. It is our conceptual roadmap of the field in question and serves in placing articles in the most appropriate sections within a comprehensive structure. It goes without saying that many of the topics are closely interrelated, and similarly, many contributions fall into several categories. However, we believe that the structure we have used here— as seen in Contents by Section and Category—serves this publication well enough and possibly also contributes to a better understanding of the conceptual field of and discourses on digital government.

This encyclopedia is divided into 12 sections and over 50 categories. Key topics include: The concept of digital government; e-transformation in government and public governance; e-government policy and regulation; international e-government; state and local e-government; public e-management; IT management and planning in public organizations; e-administration; office systems; work processes; e-human resource management; knowledge and information management; e-government project management; e-commerce in government; evaluation of e-government; electronic service delivery; management of e-services; access solutions; user interfaces; various types of e-services (e-health, e-social welfare, e-school and e-learning, e-law, etc.); e-citizenship; public e-governance; e-democracy; e-participation; e-politics; e-rulemaking; e-voting; technological solutions in digital government; and social issues and dilemmas of digital government (e.g., digital divide, e-inclusion, e-development, access to information, digital rights management, privacy, cyber warfare and terrorism, and ethics of digital government). This is not an exhaustive list, but serves our purposes well enough. Having digital government in focus, generic aspects of information and communication technologies were given a minor role, not least because there are a range of encyclopedias and handbooks available on this topic, such as *Encyclopedia of Information Science and Technology, Vol. I-V* (Idea Group Reference, 2005), edited by Mehdi Khosrow-Pour.

To ensure that this publication provides the best possible coverage and in-depth knowledge of digital government, we invited experts, practitioners, and scholars from all over the world to contribute to the encyclopedia. They represent various academic disciplines (e.g., information science, computer science, management science, administrative science, political science, sociology, economics, communications studies, and business studies), national and regional cultures, and scholarly and practical traditions and approaches. Of hundreds of proposals some 250 articles, written by more than 400 authors, were finally accepted to be published in the encyclopedia. The quality control followed conventional academic review procedure, in which each submission was forwarded to two to four reviewers on a double-blind, peer review basis. Most of the authors of this encyclopedia as well as most of the members of our International Advisory Board contributed to the review process. In addition, more than 100 external reviewers were involved.

All entries are written by knowledgeable, distinguished scholars from many prominent universities, research institutions and expert organizations around the world. What we particularly strived for was a wide geographical coverage of the global scientific and practitioner community involved in the project. We did this to show what are both the development phases and the current understandings of digital government in different parts of the world. This has made it possible to paint an authentic picture of the cultural differences in understanding and approaching digital government and in dealing with the current and emerging context-specific issues of digital government. This also widens the topics discussed in the Encyclopedia, thus making the Encyclopedia a useful publication that will appeal to a wide international readership. What our editorial policy implies is that the final selection of articles reflects not only the most up-to-date academic and practical knowledge in the field, but also the ways in which the various topics are currently discussed and understood around the world.

The *Encyclopedia of Digital Government* is presently the most comprehensive academic publication available in the field of digital government. With more than 500 people involved, the encyclopedia project has been, if not the biggest, at least one of the biggest international collaborative projects ever in the field of digital government.

The *Encyclopedia of Digital Government* offers a broad picture of the issues, concepts, trends, and technologies of digital government. The challenges and future prospects faced by governments at different institutional levels and in different parts of the world are also described in many articles. With some 250 articles, this three-volume set provides a broad basis for understanding the challenges and issues faced by public organizations as they strive for more efficient, responsive and transparent government through the use of emerging technologies. In all, we believe that the *Encyclopedia of Digital Government* contributes to a better understanding of theory and practice of the e-transformation in government and public governance. It is our hope that this publication and its vast amount of information will assist academics, students, experts, developers, managers, decision-makers, and civic actors all over the world in enhancing their understanding of digital government and even in making the world better place for us all.

# Acknowledgments

The *Encyclopedia of Digital Government* is a result of a close collaboration of the publisher, editors, authors, and reviewers. It goes without saying that we are grateful to all the people who have been involved in making this publication a success.

First of all, we want to thank all of the authors for the time and effort they have devoted to this project and for their insights and excellent contributions to this encyclopedia. It has been a true pleasure to work with colleagues and experts from different parts of the world, representing various disciplinary fields and scholarly and practical traditions. We also want to express our special appreciation for the authors who wrote several articles and served the project also as reviewers. You have done a huge work. Thank you all!

Another group that needs to be mentioned here is our International Advisory Board. Its members include Professor Kim Viborg Andersen, Copenhagen Business School, Denmark; Professor Antonio Alabau, Polytechnic University of Valencia, Spain; Professor Ted Becker, Auburn University, Alabama, USA; Professor Subhash Bhatnagar, Indian Institute of Management, Ahmedabad, India; Dr. Lyn Carson, The University of Sydney, Australia; Professor Roger Caves, San Diego State University, USA; Professor Yu-Che Chen, Iowa State University, USA; Professor Stephen Coleman, Oxford Internet Institute, Oxford University, UK; Professor Matthias Finger, EPFL, Lausanne, Switzerland; Professor Patricia Fletcher, University of Maryland, Baltimore County, USA; Professor Shunichi Furukawa, University of Tsukuba, Tsukuba, Japan; Dr. Thomas F. Gordon, Fraunhofer FOKUS, Germany; Professor Åke Grönlund, Örebro University, Örebro, Sweden; Professor Nicos Komninos, Aristotle University, Thessaloniki, Greece; Professor Kenneth Kraemer, University of California, Irvine, USA; Professor Jae-Kyu Lee, KAIST, Seoul, South Korea; Professor Ann Macintosh, Napier University, Edinburgh, UK; Professor Toshio Obi, Waseda University, Tokyo, Japan; and Professor John Taylor, Glasgow Caledonian University, Glasgow, UK. Special thanks to all the members of the Board for their support to the encyclopedia project. We are also happy that so many of them contributed to the publication by submitting their own authoritative articles.

Most of the authors of articles included in this encyclopedia as well as the members of the International Advisory Board served as referees for submissions. Thanks go to all those who provided their constructive and comprehensive reviews, thus contributing to the quality control of this publication project. In addition to this, we used a number of external reviewers. They include: Mr. Hany Abdelghaffar, Professor Jennifer A. Amyx, Dr. Giovanna Anselmi, Mr. Muhammad Hasmi Abu Hassan Asaari, Dr. Parthasarathi Banerjee, Mr. Luiz Carlos Begosso, Dr. Emilia Bellucci, Dr. Paul Beynon-Davies, Mr. Bin He, Dr. Frank Bongers, Mr. Jean-Claude Burgelman, Professor Alain Busson, Mr. David F. Wimmer, Mr. Calvin C. Yu, and Dr. Wolfgang Zuser. This impressive group of academics and experts has contributed directly to the improvement of the quality of individual papers and consequently also to the overall quality of the encyclopedia. We want to thank them all for their cooperation and support.

In a publication project like this the publisher deserves a special mention. We want to thank the publishing team at Idea Group Inc., whose contributions throughout the whole process from inception of the initial idea to final publication have been invaluable. It has always been a pleasure to work with Senior Technology Editor Dr. Mehdi Khosrow-Pour as well as with Managing Director Jan Travers and Associate Marketing Manager Dorsey Howard. During the last two years we have worked closely with three amazing women, Sara Reed, Renée Davies and Michelle Potter, whose professional help made this publication possible. Such great support from the IGI editorial team makes them no less than a group of co-editors of the encyclopedia. Without them, this publication would not have been possible.

Finally, we want to thank our host institutions, the University of Tampere (Ari-Veikko Anttiroiko) and The Police College of Finland (Matti Mälkiä), for their direct and indirect support to the project. Special thanks go to Research Director Antti Kasvio and Ms. Hanna Liikala of the Information Society Institute affiliated to the University of Tampere for setting up the Web site for the encyclopedia.

# About the Editors

Mr. **Ari-Veikko Anttiroiko** is an adjunct professor in the Department of Regional Studies, University of Tampere, Finland. He holds a PhD (Administrative Sciences) and MPhil (Philosophy) degrees, both from the University of Tampere. He has also received a Licentiate degree in social sciences from the University of Jyväskylä. Anttiroiko has conducted and directed several research projects, including The Future of Electronic Services in Local Government and the Local Governance in the Information Society financed by the Academy of Finland. He has worked as an expert in many e-government-related projects and organizations, such as the Regional Information Society Initiative (RISI), the European Regional Information Society Association (ERISA), the UK-Nordic Initiative on ICTs, and the DemocrIT of Örebro University. He has collaborated with local government and e-government experts all over the world and has conducted expert work in different countries, recently in a capacity building project (CABLE) in Namibia, in the Expert Advisory Group of UNDP Democratic Governance Practice Network, and in the Executive Master in e-Governance coordinated by EPFL, Switzerland. His academic contributions include in a nutshell some 27 monographs and 40 articles and numerous conference/seminar papers. He is a co-editor of *eTransformation in Governance: New Directions in Government and Politics* (IGP, 2004) and *e-City—Analysing Efforts to Generate Local Dynamism in the City of Tampere* (Tampere University Press, 2005) and the editor of the *Special Issue of IJTM on Global Competition of High-Tech Centres* (IJTM, Vol. 28, Nos. 3/4/5/6, 2004). He has memberships in several scientific organizations and editorial boards, including membership in the Program Committee of IRMA (since 2003) and in the editorial board of *Electronic Government—An International Journal*.

Mr. **Matti Mälkiä**, M. Soc. Sc., is a senior lecturer (Administrative Science and Leadership) at The Police College of Finland, situated in Espoo, Finland. He has worked there since 1999, and is responsible for strategic management and leadership education and training for senior police officers. Before moving to the College he has worked about 12 years at the University of Tampere, Department of Administrative Science, in different research and teaching positions. Mälkiä has about 100 publications, including 10 monographs, 4 edited books and about 35 research articles. Most of these have been published in Finnish language, covering various aspect and themes of public administration, public organizations and public management. During 1993-1998 Mälkiä served first as a co-chair and then as a chair for International Social Science Council, Committee on Conceptual and Terminological Analysis (ISSC/COCTA)—an international and interdisciplinary research program focusing on conceptual and terminological analysis and social science communication. Mälkiä has organized several national and international scholarly conferences, including CIPA'99 —Citizens and Public Administration in the Information Age: Constructing Citizen-Oriented Society for the Future (August 1999) and he is a co-editor of the book *eTransformation in Governance: New Directions in Government and Politics* (IGP 2004). Mälkiä is currently concentrating his research on police administration and police management, including application of ICTs in this field.

# Access to and Use of Publicly Available Information

A

**Philip Leith**
*Queen's University of Belfast, UK*

## INTRODUCTION

Public information presumes that the information is somehow public and, presumably, that this can be utilized by members of the public. Unfortunately, things are more complex than this simple definition suggests, and we therefore need to look at various issues relating to public information which limit access and usage, for example, the nature of privacy, sharing information within government, court records, ownership of public information, and freedom of information. The exemplars dealt with later in the article will demonstrate the legal constraints upon the usage of public information in a digital environment and help raise awareness of such limitations.

Public information cannot be formally defined (as a list of items, say) except to indicate it is that information which has historically been available to the public in print form and/or through some generally open process. No formal definition is possible because this depends to a very large extent upon cultural differences. For example, tax returns are viewed as private documents in the United Kingdom open only to the tax authorities (unless otherwise authorized, e.g., in criminal proceedings) whereas in Sweden they can be accessed by any member of the public. Furthermore, the source of public information may also vary: what information is produced by a public authority in one country may not be so carried out in another.

The legal constraints upon access and use of public information include the following:

- Privacy/confidentiality of public data
- Sharing and processing of public data collected for divergent purposes
- Freedom of information rights to public data
- Copyright and database rights in public data

Access to public information may be enabled through a formal public register, through statutory mechanism, or other less formal means. Note that being accessible does not necessarily mean that users are free to use this information in any way they wish: copyright licenses in particular are not always passed along with access rights, so that the public may inspect a document but may not use it in other ways (such as republishing). Reasons for this are obvious: the collection of data by government can be expensive and there can be opposition to subsidising commercial activity from the public purse. In the United States, federal materials are explicitly excluded from copyright protection, but this is rarely the case in Europe (see www.hmso.gov.uk for the UK situation).

Another example is that it is possible in most countries to attend local criminal courts or peruse local newspapers and draw up a database of prosecutions in the local area. The database could include information on drunk drivers, sexual offenders, and burglars, and it would be possible to include a wide variety of information—all of it, clearly, of a public nature. Indeed, such activities have been common for many years where credit agencies have collected information from courts on debtors and made this available on a commercial basis. But there are questions: Is all court-based information public? What limitations might be found in some countries and not in others to the dissemination of this information? See Elkin-Koren and Weinstock Netanel (2002) for the general tendency toward commodification of information and Pattenden (2003) for professional confidentiality where it impinges upon public service.

On a more mundane level, judgments from most European courts are copyright of the relevant government or agency. In the United Kingdom, differing again, there is some dispute over whether the judge or Court Service owns the judgment, and frequently the only text version of a judgment is copyright of the privately employed court stenographer.

Thus the publicly available information which is being discussed here is that which emanates from a public authority and can be accessed by members of the public, but will usually have some constraint and limitation on how it can be reused by the public. We are interested in outlining these constraints.

## BACKGROUND

Much of what has driven recent legislation concerning publicly available information has been fear of the differ-

ences between print access and digital access—particularly that of ease of access and length of period of access. Even in 1972, the Younger *Report on Privacy* (1972) noted that there was concern discovered in their research over the usage of computers for the collection of data when there were 4,800 computers "in use or on order." The situation has become much worse—to the privacy advocate—since the inception of the Internet and a freefall in the price of storage. Access to information is global and with the rise of systems such as Google's caching mechanism and the *waybackmachine* (www.waybackmachine.org). Once information has been put onto a Web server, it can be difficult to remove it from public view.

In the case of *Lindqvist*, we can see the legal system is having difficulties in treating these new developments as a natural growth from print technologies. Mrs. Lindqvist set up a parish Web site for her church which noted that a member of the local community had hurt his foot. She was prosecuted by the Swedish Data Inspection Board for failure to register her processing of personal data and for revealing sensitive personal data about the owner of the hurt foot. She was also prosecuted for transferring this to third countries by making it available on the Internet. The case was referred to the European Court of Justice (ECJ) for clarification on various matters relating to data protection. The court found that

*The act of referring, on an internet page, to various persons and identifying them by name or by other means, for instance by giving their telephone number or information regarding their working conditions and hobbies, constitutes the processing of personal data.... Reference to the fact that an individual has injured her foot and is on half-time on medical grounds constitutes personal data concerning health. ...* (Case C-101/01, Judgment November 6, 2003)

However, it did not find that Web publishing was transferring this information to third countries. This decision shows the ECJ's perspective on two fronts. First, it shows that it holds that medical information on the individual should usually be protected from data processing unless permission exists; and second, that it sees a distinction between whether Mrs. Lindqvist had produced her local gossip in print or in digital form. This latter point is important: we can expect less and less material to appear in print rather than digital format, so a practical pressure is being applied by data protection law to change the nature of communication within local communities, as well as within the national or international sphere.

It is in this quirky context that European access to digital public information must be viewed.

## THE PUBLIC/PRIVATE DIVIDE IN A DIGITAL ENVIRONMENT

There is much information that is publicly available but that can potentially be problematic in a number of ways when we move into a digital environment. It is clear that this public information access can sometimes be viewed as undesirable: the information is certainly public, but when it is print based it can be difficult to access and—except to the industrious researcher—tends to be hidden from public view. In particular, this is information that relates to a particular individual—say his or her criminal record, ownership of property, grants received from government, his or her tax return, and so forth. In a digital e-government environment the public nature tends to become magnified simply by the ease of storage, processing, and access.

A second kind of public information is that which the public may have a right to know and access in order to ensure that a public authority is carrying out its tasks properly and effectively. Such information is subject to freedom of information legislation (see Birkinshaw, 2005) in many countries. Much of this pubic information necessarily touches upon private information—letters/e-mails from citizens to public authorities, data collected as part of everyday government tasks, commercially sensitive information. Where should the line be drawn between what is public and what is private?

At the heart of the question of what is public and what is private is the philosophical debate over the nature of government, the role of the citizen in government, and the role of government in overseeing proper standards of the citizen's behaviour. Classical theories are well known in the literature and certainly have had effect upon the development of legislation. However, such abstract theories are difficult to put into practice and the legal texts have most usually lacked clarity for obvious reasons. For example, *The European Convention on Human Rights* gives weight to private life in Article 8 (1):

*Everyone has the right to respect for his private and family life, his home and his correspondence.*

But immediately constrains that right in Article 8 (2):

*There shall be no interference by a public authority with the exercise of this right except such as is in accordance with the law and is necessary in a democratic society in the interests of national security, public safety or the economic well-being of the country, for the prevention of disorder or crime, for the protection of health or morals, or for the protection of the rights and freedoms of others.*

For example, the debate over abortion rights has shown the depth of disagreement which is possible with each side drawing comfort from each of the clauses. The problems that we look at below are some examples of this kind of debate over the citizen/state role, and the rhetoric that one finds surrounding these debates are clearly related to these differing philosophical assumptions.

Note that these legal conventions are formally applicable to governments (indeed, they arose from the after effects of the Nazi era) and their relationship to the individual citizen. However, the courts have developed a jurisprudence which has effectively allowed the citizen to use these public laws against other citizens and/or commercial concerns. This is technically known as horizontal effect. For example, in *Von Hannover v Germany* [2004] ECHR 294, Princess Caroline of Monaco succeeded in arguing that the press was enabled to invade her privacy due to the German government not having effective privacy laws in place. The ECHR ruled:

*in the Court's opinion the criteria established by the domestic courts were not sufficient to ensure the effective protection of the applicant's private life and she should, in the circumstances of the case, have had a "legitimate expectation" of protection of her private life.... Having regard to all the foregoing factors, and despite the margin of appreciation afforded to the State in this area, the Court considers that the German courts did not strike a fair balance between the competing interests.* (Paras 78/79)

Given this ruling, it is not simply the German government that has to consider whether its legislation allows an appropriate balance between the press and individual, but all governments who are constrained by the European Convention of Human Rights.

## SHARING INTERNAL E-GOVERNMENT INFORMATION

One form of information is what is processed within a specific government department or departments or agencies: that is, the last in the list of legal problems relating to data sharing. Data sharing simply means that one arm of government is enabled to access information collected by another arm. The reasons for this sharing may be related to efficient processing, fraud prevention, or a number of other reasons. This is the more traditional form of data processing and is generally covered by the European Union (EU) Data Protection Directive (Directive 95/46/EC and the relevant national implementation). This information is much more akin to the internal processing found in business and commerce, and data protection law requires that the government department gives the data subject similar protections to those given in commercial processing of data. Thus, for example, when data are collected from a member of the public for usage by a public authority, they should be used for only the specified purpose:

*Personal data shall be obtained only for one or more specified and lawful purposes and shall not be further processed in any manner incompatible with that purpose or those purposes.* (Third Data Protection Principle, UK Data Protection Act 1998)

This is not to say that internal government usage of information is nonproblematic. Indeed, e-government is about efficiency and effectiveness and the most efficient way of processing information is by sharing data within government, frequently for purposes that differ from those where the data were gathered:

*4.02 Better data use can streamline a citizen's dealings with public services, by enabling a single point of contact to deal with all but the most complicated queries—a similar process already happens in banking, insurance and other telephone call centers. By enabling the service provider to access a range of relevant information, enquiries can be responded to more quickly and efficiently, and services can be tailored to meet the needs of the individual client. Better use of information held in the public sector can therefore deliver a range of personal benefits, such as accessibility, responsiveness, and speed and accuracy of service.* (Cabinet Office, 2002)

Unfortunately, the historical structure and also currently changing structure of government do not easily allow commercial techniques to be transferred over: for example, government is fragmented into central and local authorities; and the new public governance involves private partners carrying out what were originally government tasks. To streamline communications between the diverse parts of the new governance systems involves a consideration of how privacy and data protection law can be complied with as well as discussion of how public/administrative law is changed by such streamlining.

Further, where private partners are involved, there can be significant value in the commercial confidentiality of that relationship between private partner and government (not least against those who may wish to bid for business in the future). The new open governance which freedom of information (FoI) law is developing conflicts with commercial confidentiality and we see a growing

interest in using FoI to access this information, despite (in the United Kingdom at least, and also in the European Commission) there being a commercial defense to providing information. It is also likely that companies will become hesitant about providing information (data sharing) to public authorities which could become the subject of FoI requests by the public: most FoI requests in the United States are by companies wishing to discover information concerning other companies and the latter's relationship to government.

The United Kingdom has been the European leader of this new mode of governance, but we should expect that it will become more dominant across Europe in the future, and these problems of data sharing and FoI access will become more prominent legal aspects of e-government information handling.

## ACCESS TO INFORMATION: COURT RECORDS AND OPEN JUSTICE

The court systems in Europe have traditionally been underfunded and computer provision has been poor. E-government has offered a means to improve the effectiveness of court systems in Europe and also cut costs. The Council of Europe has recognised this and produced two recommendations (Council of Europe, 2001). For most e-government information processing, there are relatively few problems: courts receive and send monetary sums, reports, produce judgments, and so forth, in a manner much like a power company's billing office. However, these new technologies also have the ability to radically change the nature of the relationship between the citizen and the court: rather than being a distant notion where reports on criminal activities are mediated by the press, it is possible now to set up systems whereby the public can gain direct access to criminal records. This is because, as mentioned above, there is a general right to open justice in European countries to attend court and to collect information and publish details on the case. Some countries have routine restrictions on reporting certain courts (e.g., family courts or those dealing with child offences).

In 1965 President Lyndon B. Johnson set up a Commission on Law Enforcement and the Administration of Justice to investigate causes of crime and prevention which looked to computerization of the courts (see Marchand, 1980). This was one of the first instances where privacy was raised as a potential issue—the commission observed that the inefficiency of manual files provided a built-in protection of privacy which would no longer be available with computerization. The systems that were developed in the United States (e.g., the National Crime Information Center) were not, of course, public access systems, but there were accusations that they almost became so. Marchand states:

*Not only did NCIC permit access to the information by federally insured banks and private employers with state contracts but it also permitted a variety of secondary access. Data could be made available to credit agencies and private employers through a "friendly cop." In addition, much of the information supplied to such private individuals or agencies could be wrong or outdated.* (p. 147)

The information on these systems related as much to pre-court (or simply police files with no intention to prosecute). Courts will also have similar kinds of information (defendants who have been found not guilty or where charges were dropped as the case neared) as well as the more formal and public information about successful prosecutions. It is not difficult to imagine that with such latter information in digital format available via the Internet (and available to the public) a few seconds would be sufficient to download the criminal history of an entire town.

Criminal records are thus a good example of one problem of publicly available information—the limits to rights to information. Allowing access is in line with Article 10 of the European Convention on Human Rights and also with notions of open justice, and denying access is perhaps in line with Article 6 (right to a fair trial), but more usually on principles relating to the rehabilitation of the offender. As examples we can cite the freely available information from the Minnesota Department of Corrections (http://www.doc.state.mn.us/). Users of this state Web site can locate offenders (and view images of them) by name and access information on their crime, date of expected release, and so forth. Other U.S. states also have information of this kind available, for example, Illinois (http://www.idoc.state.il.us/), Ohio (http://www.drc.state.oh.us/), and North Carolina (http://www.doc.state.nc.us/).

There are no similar sites in Europe (where there appears to be more sensitivity to the prisoner's plight), but it is perfectly possible that a growing public demand for such information will lead to it being available in future—for example, there remains a desire amongst many in Britain to have access to child abuse registers. For example, the campaign by one UK newspaper to have an equivalent to the Megan's Law of the United States (http://www.forsarah.com/html/mainpage.html). This campaign turned slightly ugly when the newspaper published addresses and details of sex offenders which resulted in vigilante action on the individuals. Of course, in discussion of these kinds of topics, we have to remember there is a class element—sex offenders are usually rehoused,

not in middle-class suburbs, but in lower-class estates. The Sexual Offences Act 2003 details access to the register. See Torremans (2004) for an overview of human rights law versus freedom of expression and copyright.

Furthermore, a UK government report noted:

*About 60 percent of enforcement in the county courts is ineffective because the claimant cannot find the necessary information about the debtor to enable him to take the right method of enforcement, or even to send the bailiffs to the right address. The current enforcement system in the civil courts is reliant on information being supplied by the creditor, and then on the compliance of debtors to provide accurate or truthful information.* (Cabinet Office, 2002, p. 16)

An e-government system implementation that wished to improve effectiveness would surely have to allow public access to this kind of information when it was held by another arm of government.

With the use of technology in prisons to organize prison life and in courts to better administer court processing, it is clear that the digitized information on various elements of criminal and civil records is available. The automatic presentation of such information to the public via a Web site would be trivial—and the site could be designed to remove information as required by rehabilitation legislation (in the United Kingdom this is the Rehabilitation of Offenders Act 1974).

There are clear freedom of expression arguments for making this kind of information public. Article 10 of the ECHR which provides the legal context in Europe deals with access to information (to receive and impart information):

*1 Everyone has the right to freedom of expression. This right shall include freedom to hold opinions and to receive and impart information and ideas without interference by public authority and regardless of frontiers. This article shall not prevent States from requiring the licensing of broadcasting, television or cinema enterprises.*

But Article 10(2) places limits on that freedom:

*2 The exercise of these freedoms, since it carries with it duties and responsibilities, may be subject to such formalities, conditions, restrictions or penalties as are prescribed by law and are necessary in a democratic society, in the interests of national security, territorial integrity or public safety, for the prevention of disorder or crime, for the protection of health or morals, for the protection of the reputation or rights of others, for preventing the disclosure of information received in confidence, or for maintaining the authority and impartiality of the judiciary.*

Why would one want this information? Neighbors of criminals, battered ex-wives, and victims would certainly be interested. There may just be a desire to know, which unpleasant as it may be to some, is not in itself a criminal or morally repugnant activity. We see that information such as outlined previously is available in the United States where freedom of expression (based on the First Amendment to the Constitution) is given priority in many legal arguments. It is perfectly conceivable that such an attitude may develop at some point within European jurisprudence. See Toulson and Phipps (2004) for an opposing discussion of confidentiality.

The development of systems such as are available in Minnesota has raised interest in these issues in the United States. The Minnesota Supreme Court, for example, has published a report on access to court records (Minnesota Supreme Court, 2004). Whilst seeing potential problems in bulk data provision, the report clearly highlights why access to court records is of value to many:

*Perhaps the least discussed, although most widely shared, benefit resulting from accessible judicial records is the use of those records as part of the critical infrastructure of our information economy. Reliable, accessible public records are the very foundation of consumer credit, consumer mobility, and a wide range of consumer benefits that we all enjoy. There is extensive economic research from the Federal Reserve Board and others that demonstrates the economic and personal value of accessible public records, but it does not require an economist to see that lenders, employers, and other service providers are far more likely to do business with someone, and to do so at lower cost, if they can rapidly and confidently access information about that individual.* (p. 76)

Other states, too, have carried out substantial investigation of these issues (e.g., New York State at http://www.courtaccess.org) as has the National Center for State Courts (http://www.ncsconline.org/).

Opposition to opening easy access is not usually made on privacy grounds. Rather, the argument is that for integration into the community—for criminal records in particular—of the criminal:

*A key element of sentencing is the rehabilitation of offenders to reduce re-offending and contribute to safer communities. Employment is an important aspect of resettlement—it can halve the risk of re-offending—yet a criminal record can be a real barrier. Effective*

*arrangements must be in place to ensure that, where it is safe to do so, individuals can put their past behind them.* (United Kingdom Home Office Web Site, 2005)

Open justice also has several possible limitations allowed by Article 6 of the European Convention on Human Rights:

*Judgement shall be pronounced publicly by the press and public may be excluded from all or part of the trial in the interest of morals, public order or national security in a democratic society, where the interests of juveniles or the protection of the private life of the parties so require, or the extent strictly necessary in the opinion of the court in special circumstances where publicity would prejudice the interests of justice.*

The United Kingdom, as mentioned above, has banned public access to family court hearings (R.39 Civil Procedure Rules). There has been significant unease recently due to single issue organizations who argue that this hides biased decisions (usually against fathers) from the public. For example, one litigant Pelling ([2005] EWHC 414 (Admin)) unsuccessfully attempted to have the ECHR rule that public access was necessary for the interests of justice (*B. and P. v. The United Kingdom* [Applications nos. 36337/97 and 35974/97] April 24, 2001). One celebrated instance of the unease was caused by Professor Roy Meadows, "discoverer" of the Munchausen syndrome by proxy, who was struck off by the General Medical Council for his behaviour as an expert in child abuse cases. One newspaper suggested:

*The problem with child protection cases, especially those involving expert witnesses, is that unless and until they result in a criminal trial, they take place in secret behind closed doors. The media has no access and there is therefore minimal opportunity for transparency or scrutiny. If one wants to prevent further miscarriages of justice taking place and for a system that often relies on expert witnesses to sustain, then the answer is to open up that system to scrutiny and let the open justice principle break its way into family courts.* (The Guardian, July 19, 2005)

## COPYRIGHT AND DATABASE RIGHTS: WHO OWNS PUBLIC SECTOR INFORMATION?

There is a second kind of information that is publicly available and at which the European Commission has recently been looking: that of information produced by public authorities where the public authority owns the copyright or the database rights. Such information can be economically valuable and long lasting: for example, UK crown copyright protection is 50 years from publication and databases (Directive 96/9/EC on the legal protection of databases) are protected from extraction for 15 years on a rolling basis.

Who should have access/use/reutilization rights to this information? From one perspective, it is "public" having been produced through the public purse, and from another, it is an asset of the public authority. In a framework where such information has value, should public authorities be able to control its usage? And what, if licenses are to be given, of issues of costing usage/access of such materials? (See Love, 1995 for an overview.)

Governments generate large amounts of information which in Europe is copyrighted and therefore can potentially be difficult for commercial providers to access. Commercial access to bulk data would be very attractive, and indeed has been attractive in the past where voter registration information has been collected and supplied. In the United States, such federal information is specifically excluded from copyright protection and commercial firms can utilize these data without the constraints of copyright law. The Information Society programme of the EU (http://europa.eu.int/information_society) is concerned with building a vibrant information marketplace and—seemingly encouraged by the U.S. model—has attempted to harmonize European access to this governmental information known as Public Sector Information (PSI) so that information products can be built which are cross-border and European in every way. A proposed directive was produced which would have introduced the concept of "a generally accessible document":

*generally accessible document" means any document to which a right of access is granted under the rules established in the Member State for access to documents as well as any document used by public sector bodies as an input for information products or services which they commercialise.* (Art 2(4) Com(2002) 207)

The notion behind the proposed directive was that even if a government department produced a commercial version of documents it held, others would be enabled to use these as the basis of products or services:

*The sheer size of the economic value of public sector information in the European Union shows the potential of this area: the value has recently been estimated at around 68 Billion (Euros). This is comparable to the size of industries such as legal services and printing. A better use of the economic potential of public sector information will lead to increased activity and job-creation in the*

*digital content industries. Many of these jobs will be created in SMEs [small and medium-sized enterprises].* (Pira, 2000, p. 6)

Given that the documents might include geographic data and related information which could be linked together, the commercial opportunities for information providers were substantial (and some research projects in this area have been supported by the Commission under the e-content programme—see http://www.cordis.lu/econtent/home.html). In the event, the concept of generally accessible document was removed from the eventually agreed directive and governments were enabled to control more closely their commercial exploitation.

Why is this important? Because it is clearly the start of a European debate over the ownership and use of public information which can only grow as the importance of the information economy grows. There is no reason why the state should have any more right to these data than the citizen (including the citizen who wishes to undertake commercial activities) excepting that financial pressures are being brought to bare upon government agencies to self-fund themselves. Moreover, the changing relationship in the new government models means that independent agencies are now undertaking tasks that were previously carried out by the state. Who is to own, manipulate, and commercialize this kind of information? Is it the state, the commercial partner of the state, or will that information become a commodity upon which all can base added-value services and products?

## COMMERCIAL CONFIDENCE AND FOI

The new governmentality model is based on the partnership between government as director and agency as task manager. The agency may be a regulator, a semiautonomous government spin-off, or it may be a fully commercial partner. The relationship between these agencies and governments are clearly problematic when it comes to access to information—what may be viewed as of public interest can quickly become private interest: as a private interest the owner can protect this through trade secret law and law of confidentiality generally. Since confidentiality relies upon keeping the reason why something is confidential itself, it is a very powerful tool indeed. The standard UK work on confidence remains (Gurry, 1984).

There has been much debate in the United Kingdom over the value of public finance initiatives (PFI) and public-private partnerships (PPP) which have been the Labour government's preferred tool to invest in the public sector. The basic idea has been that in the past, these large spending contracts (schools, hospitals, etc.) were high risk: usually late and over budget. By using PFI and PPP, the risk is supposed to be transferred to the private sector. Unfortunately—as a host of reports by the National Audit Office (NAO) (http://www.nao.org.uk/) show—the process has not been as effective as the government might have wished. Not only have there been significant problems in costs and completion, but scrutiny of these contracts by the public (and in fact by the NAO) has been difficult due to the commercial confidentiality regime under which they are signed and run. Even supporters of the financing tool have suggested problems:

*As a result of the commercial confidentiality inherent in the PFI process, virtually no informed public debate has taken place on the merits of that scheme. The details have seeped out and the local authority has quashed every request for information or a public debate on the ground that it would breach commercial confidentiality.* (Lock, 1999)

In contrast to rights to confidentiality, there is of course a growing expectation of freedom of information access. Such an FoI approach clashes with rights to keep information in confidence. The guidelines from the UK government on how to treat this clash when dealing with PFI Projects, for example, indicate:

***2.1*** *The "Code of Practice on Access to Government Information" produced by the Cabinet Office (Second Edition 1997) states that: "the approach to release of information should in all cases be based on the assumption that information should be released… except where disclosure would not be in the public interest or would breach personal privacy or the confidences of a third party".*

***2.2*** *To satisfy public accountability and assist in the development of PFI, public sector clients should not misuse the term "commercial confidentiality" as an excuse to withhold information. When public sector clients wish to withhold information on individual PFI projects "for reasons of commercial confidentiality", they should only do so where disclosure would cause real harm to the legitimate commercial or legal interests of suppliers, contractors, the public sector client or any other relevant party."* (Office of Government Commerce, 2005)

However, the FoI Act appears to provide substantial exemptions for commercial partners in the new governmental models:

***43.*** *(1) Information is exempt information if it constitutes a trade secret. (2) Information is exempt information if its disclosure under this Act would, or would be likely to, prejudice the commercial interests of any person (including the public authority holding it). (3) The duty to confirm or deny does not arise if, or to the extent that, compliance with section 1(1)(a) would, or would be likely to, prejudice the interests mentioned in subsection (2).*

The FoI Act in the United Kingdom has not been in force for a sufficiently long period to discover just how this section is being interpreted, but it is one of the most controversial parts of the Act and we might expect it to quite heavily used and, eventually, litigated over in the coming year or two.

## FUTURE TRENDS

There are many reasons to believe that we are only beginning to see trends arising in "public information" access. The value of this information is growing in a number of ways—as economic goods for commercial vendors who wish to add value, as informational goods on citizens who wish to know about their neighbors, and as a valuable resource for government itself as it tries to become more effective and efficient. Thus the value is rising at the same time as is the quantity. And as more becomes available, so the potential value rises again.

While this increase in worth continues, there are pressures to limit access: those who say that the notion of "public" was fine when access was difficult (and that this acted almost as a privacy limitation) are now arguing that we must control access of the public to information, particularly where it concerns individuals.

The worries too about FoI will grow: these rights are based upon knowing what government does, but when government gives orders from above but does less and less, do these rights necessarily apply to the agents of the government?

It is clear that in an information economy where the basic goods are informational they are therefore worth litigating over. It is unlikely that information law will become less complex or have less impact in future years.

## CONCLUSION

Information is the lifeblood of e-government. But while technologists tend to view information as nonproblematical—simply the data upon which they operate and which the new technologies allow to be collected, stored, and processed in aid of efficient and effective government, to the lawyer—viewed through the lens of a variety of legal rights—"information" is a much more complex entity. This is giving rise to the field of information law—the last 10 years have seen significant developments—where the various individual legal rights (privacy, data protection, copyright, etc.) have come together and impact upon the relationship between persons, data about persons, and the processors of that data. Information law thus straddles a gamut of legal fields which are vital to successful e-government implementation. Technologists clearly want to get on with developments and produce systems which work, which are ready on time, and which keep the clients happy. Law, in this view, simply gets in the way of that process, and lawyers are seen as part of the problem rather than part of the solution. However, a different view is that law, particularly with the law of legal information, is an attempt to balance various pressures so that somehow a meaningful and just system is brought into being. This balancing is not easy: the judiciary is not technically competent, it cannot always foresee how its judgments will affect the world or whether they will have wider consequences, and it is too often persuaded by legal fashion rather than empirical evidence.

## KEY TERMS

**Access to a Fair Trial:** A fair trial is usually one that occurs in public so that it can be witnessed; however, the European Convention on Human Rights (Art. 6) allows this public nature to be set aside in certain situations: "the press and public may be excluded from all or part of the trial in the interests of morals, public order or national security in a democratic society, where the interests of juveniles or the protection of the private life of the parties so require, or to the extent strictly necessary in the opinion of the court in special circumstances where publicity would prejudice the interests of justice."

**Copyright:** Copyright is given to the first author, that is, the person (or employer) who fixes the work. It is a reward for creation. However, copyright law is a maze for the uninitiated. For example, in UK law, a judge who gives a verbatim judgment which produces a taped aural record has fixed the work in one form. However, a transcriber who produces a document from that recording also produces a copyrighted work. This latter is so in the United Kingdom because there is such a low level of creativity required: the United Kingdom is out of step with other common-law countries and also with the rest of Europe. In the United States, the Copyright Act Section 105 specifically excludes government (i.e., federal) materials from copyright protection.

**Database Rights:** If information is not copyright, it is possible for anyone to republish this without constraint. It was felt that this was problematic: companies who expended effort and costs upon building databases could simply see competitors come along and steal the contents of the database. The Database Directive was introduced to resolve this perceived problem. It is not a right that is available in the United States and remains controversial. Part of the criticism is that it is not clear just what is being protected since the contents can change continually and thus protection is basically available on a perpetual basis:

*Art 10(3): Any substantial change, evaluated qualitatively or quantitatively, to the contents of a database, including any substantial change resulting from the accumulation of successive additions, deletions or alterations, which would result in the database being considered to be a substantial new investment, evaluated qualitatively or quantitatively, shall qualify the database resulting from that investment for its own term of protection.*

**Data Protection:** The idea that commercial firms who were selling, storing, and processing information on individuals should be controlled grew in the 1970s and 1980s. The basic idea is that this should only be allowed when consent is given. There is skepticism about the success of these laws, since consent is easily got by, for example, supermarket chains who offer loyalty cards, or by companies who include a consent clause in their contracts. There has been some impact upon public information: in the United Kingdom one must now opt-in to have voter registration data made available to commercial suppliers. This was the result of a complaint under the Data Protection Act. See *R (On the Application of Robertson) V. City of Wakefield Metropolitan Council* [2001] EWHC Admin 915, November 16, 2001.

**Freedom of Expression:** A right to impart and receive information. In Europe this is a weaker right, perhaps, than that of privacy. It is also limited by libel and slander laws, for example. In the United States it is the First Amendment

right and is of much higher importance than in Europe: "Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the Government for a redress of grievances." (See Findlaw at http://caselaw.lp.findlaw.com/data/constitution/amendment01/ for a very useful overview of interpretation.)

**Freedom of Information (FoI):** The basis for legislation is that the more the citizen knows about how government acts, the better will be the government. Thus various laws have been implemented to allow access to information. However, there is evidence that these laws are not used so much by the public as by commercial firms wishing to know about other commercial firms, for example, who are undertaking governmental work.

**Freedom of Information Exemptions:** Those aspects of public information that have been considered should be excluded from public access. For example, in the United Kingdom: Freedom of Information Act 2000. Section 43:

*(1) Information is exempt information if it constitutes a trade secret. (2) Information is exempt information if its disclosure under this Act would, or would be likely to, prejudice the commercial interests of any person (including the public authority holding it). (3) .... Also see Art 4 of Regulation (EC) No 1049/2001 Regarding public access to European Parliament, Council and Commission documents: "... 2. The institutions shall refuse access to a document where disclosure would undermine the protection of: – commercial interests of a natural or legal person, including intellectual property, ..."*

**Horizontal Effect:** The idea that a law which is directed at governments can be used by citizen against other citizen. Thus the "right to a private life" is an example of a public law (the European Convention on Human Rights) which has, through horizontal effect, become available in private law.

**Personal Data:** Personal data is that which refers to sensitive information about a person. There is no formal definition of this (but it usually includes medical information) and research has demonstrated that it has a cultural aspect.

**Privacy:** Developing European law has given us privacy as a fundamental right. Unfortunately, it is not clear just what is meant by privacy since definitions can cover a gamut of approaches—the right to be left alone or the right to control personal information being two. In the United Kingdom, it has been suggested that the judiciary should utilize the law of confidence to implement privacy. See Lord Woolf in A v B [2002] EWCA Civ 337 (March 11, 2002).

**Public Sector Information:** This is information that (usually) has a commercial usage and that third parties would wish to republish, perhaps with added value. For example, map-based information from government departments could be used as the basis of commercial products if this was available. The European Commission, in its support for an information economy, has been keen to see this type of information become available to republishers.

# Accessibility of E-Government Web Sites

A

**C. James Huang**
*The National Taipei University, Taiwan*

## INTRODUCTION

The Internet has emerged as one of the most prevalent forms of communication. The gathering and sharing of electronic information are becoming essential elements of modern life. Therefore, it is important to ensure that people, especially those with disabilities, have equal opportunities to benefit from the Web, especially from online public services.

While many people describe the Web as a low cost, all encompassing, and far-reaching medium (Parker, 1997), it is really not accessible to everyone. The proportion of people with disabilities in society has been increasing due to the demographic trends long documented by many researchers (Barth, McNaught, & Rizzi, 1993; West, 1998). Nevertheless, government leaders have paid little attention to the needs of people with disabilities when planning and implementing Web projects, and hence many critical online public activities and customer services are not readily available to the disabled. In short, a critical challenge facing all governmental agencies is how to make the massive volume of information being published on public sector Web sites accessible to every citizen they serve.

## BACKGROUND

The Web can be considered as a multifaceted mass medium that contains many different configurations of communication (Morris & Ogan, 1996). As Lynch and Horton (1999) pointed out, the originators of the Web intended the Web to be a device-independent method for exchanging documents across many different platforms. The glue that holds the modern Internet world together is the Web programming language, namely HTML (Hypertext Markup Language). The term "Hypertext" was first coined by Theodor Holme Nelson, a recognized ideologist of Hypertext, in reference to a radically new way of storing and viewing information. Instead of gathering or retrieving information sequentially, information recorded with Hypertext is fashioned in multiple layers. An automated index is built into the Web document. The intertextuality and non-linearity of HTML enable Web pages to connect various virtual contents with specific "links" which allow online users to move among points and "nodes" (Howell, 1992).

The use of Web technology often has particular potential benefits for many people with disabilities. For example, for people who are visually impaired, the earlier text-based Internet sites opened a world of information that was previously off-limits. "For the first time in history, it is now possible for many people with disabilities to get information right from its original source (rather than waiting for Braille translations, etc.)" (Christensen, 2001, p. 30).

Unfortunately, with their focus on structuring and sharing documents, the originators of the Web ignored the visual logic or graphic design aspects of Web information delivery that are now stymieing blind users today. Due to the fact that the Web continues to increasingly embrace colors, graphics, motion pictures, audio, and the other dynamic elements, the current Web design practices have caused more difficulties for disabled individuals trying to benefit equally from society. A recent study shows that the usability of most current Web sites is on average three times higher for users without disabilities than for those who are blind or have low vision (Nielsen, 2001). Another research project published by Forrester Research (Souza & Manning, 2000) found that only one in four e-commerce sites it surveyed met even minimum requirements provided by the Web Accessibility Initiative (www.w3.org/WAI/) for disabled Web users, such as providing text descriptions of images for the blind. Waddell (1998) calls the Web "the growing digital divide in access for people with disabilities." Even in the public sector of the U.S., where Web accessibility is legally mandated, a significant number of official Web sites still contain features that do not provide reasonable access to disabled users (Gant & Gant, 2002).

Web pages are more than printed pages posted electronically. The Web offers many new opportunities as well as challenges to modern organizations (Mitra & Cohen, 1999; Parker, 1997). First of all, the Web makes it easy to transmit information in a timely fashion. Changes to a Web site can be published in a relatively short time when compared to the lengthy processes of redesigning, production, and distribution processes that are necessary for most printed media. Secondly, Web pages can

include larger amounts and a greater variety of information without incurring major printing and distribution costs. On the Web, costs do not necessarily increase as the amount of information being communicated increases. Furthermore, multimedia objects, including drawing, photographs, animation, sound, video, and computer applications, can be incorporated into Web pages at a low cost to enhance the Web's communication effects.

One Web characteristic that sets Web development apart from traditional media design is the lack of control. Unlike designers of printed media, a Web designer somewhat loses control over how online users will browse through the pages, the appearance of the fonts and colors used on a page, and the size, proportions, and exact locations of the different Web texts. On the Web, users largely determine their own navigation paths, and they are free to "jump" to any location that interests them. In addition, designers cannot know the exact computer equipment that the various potential users have, or what fonts and software have been installed in the users' computers. The exact way WWW pages present information would be partly determined by the users' own environment.

Therefore, Web content should ideally be designed in a way that the users using different agents (for example, desktop computers, mobile phones, televisions, PDA, etc.), with different Web browsers (for example, Lynx, Netscape Navigator, Internet Explorer…), and under different constraints can all access. In short, Web accessibility is not only concerned with disabilities, but also with the ideal that anyone using any kind of Web browsing technology can access and get full and complete information within it (Letourneau, 2000).

## REASONS FOR PROVIDING WEB ACCESSIBILITY

There are more than 750 million people with disabilities worldwide. As noted earlier, at a time when the number of people with disabilities is increasing as the population ages, our society has become one that depends more and more on computers and digital technology for work, education, and entertainment. Participating in the digital economy by definition requires the ability to access and use the Web. It is hence important to make every possible Web site accessible. As the director of World Wide Web Consortium and inventor of the Web, Tim Berners-Lee (http://www.w3.org/WAI/), stated, "the power of the Web is in its universality. Access by everyone regardless of disability is an essential aspect."

In addition to common human decency, the most obvious reason to make governmental Web sites accessible to the disabled is to comply with the law. The Americans with Disabilities Act (ADA), Section 508, and similar laws and regulations in other countries (Paciello, 2000, p. 39-44) often mandate the establishment of means to allow the disabled access to the same information and use of the same tools as anyone else on the Web. For example, the ADA requires "reasonable accommodations" and "effective communication" in areas of employment, public services, and telecommunication services. With the popularity of e-government and e-commerce, the foci of the law have changed to include the Internet (Sager, 2000). Section 508 of the Rehabilitation Act defines the processes used by the federal government to procure electronic and information technology. One of the most important foci of the law is to ensure access to electronic and information technology made available to people with disabilities who are federal employees or members of the general public. In Canada, the Equity and Diversity Directorate of the Public Service Commission was the first national institution to publish Web accessibility guidelines to ensure that all governmental Web pages and associated electronic data was accessible to every Web user.

Although most countries in the world have not yet developed specific laws or regulations regarding Web accessibility, many have enacted legislations and governmental regulations similar to the ADA of the U.S. Until recently these laws and regulations are mainly concerned with the topics of employment, transportation, and public facilities. However, it is only a matter of time before most governmental Web sites worldwide come under political and legal challenges for not being accessible to the disabled. It seems likely that in time the Web-based services will be held to the same standards as the services or facility architecture of the physical world in the courts.

Moreover, making a Web site so accessible could be a competitive advantage economically. Many companies have found that creating accessibility on their Web sites is cost-effective and generally good business practice (Solomon, 2000). According to a report published by Forrester Research (Souza, Manning, & Dorsey, 2001), Global 3,500 companies are estimated to spend $560 million to retrofit their Web sites to meet W3C Web Accessibility Initiative guidelines. E-commerce companies, such as Amazon.com, are making their Web sites accessible so as to gain a share of the $175 billion in discretionary income controlled by consumers with disabilities (Amazon.com's press release December 6, 2001; Prager, 1999). Sixty-eight percent of consumers between 45 and 54 years old are online and nearly one-fourth have a disability (US Census). The authors conclude: "Companies must plan site design projects keeping people with disabilities in mind. Doing so is cost-effective—especially if accessibility is part of the planning, development, and maintenance process."

Indeed, disabled Web users often become very loyal customers once they find a Web site that accommodates their special needs (Nielsen, 2000; Rogers & Rajkumar, 1999). Accessible Web design also enables low technology to access high technology. More specifically, accessible Web design features enable video and audio elements on the Web to be archived with word search capabilities, and text to be converted into speech by screen readers, and hence senior citizens, people in underdeveloped countries, and even those who are illiterate are also likely to benefit from accessible Web design, since the Web text can be simultaneously presented auditorily through a voice synthesizer. On the other hand, organizations that do not make their Web sites accessible to people with disabilities are not only missing out on marketing opportunities but also facing further financial pitfalls from civil rights organizations pursuing litigation (Kautzman, 1998).

Once the large commercial Web sites in the private sector are accessible, people with disabilities will come to expect the same online relationship with government agencies as that they have with businesses. For agencies at all levels of government, the Internet provides an ideal medium to the citizens who used to be relatively alienated from many public services. However, the current government Web site planners and production staff are often not aware of the critical importance of this issue and hence erect various barriers between their online services and the disabled constituents (Gant & Gant, 2002; Office of Government Services, 2002).

## FUTURE TRENDS

To promote interest in Web accessibility, several hardware and operating system developers, non-profit assistive technology developers, and application software manufacturers have worked to make equal access to the Web possible. The World Wide Consortium (W3C) launched the Web Accessibility Initiative (WAI) in April 1997. Under the direction of The WAI International Program Office director, the WAI team has developed an in-depth and detailed set of Web Content Accessibility Guidelines (WCA Guidelines 1.0; http://web1.w3.org/TR/WAI-WEBCONTENT/), and associated checklists.

The WCA Guidelines address two general themes: ensuring graceful transformation to accessible designs, and making content understandable and navigable. They are composed of fourteen specific guidelines, with each including the rationale behind the guideline and a list of checkpoint definitions. Each checkpoint is assigned a priority level by the WAI Team based on the checkpoint's impact on accessibility. Specifically, Web pages must meet the requirements of priority 1 guidelines. **O**therwise, one or more groups of users will find it impossible to access the information in the Web page. Priority 2 indicates that Web content developer should satisfy this checkpoint or one or more groups will find it difficult to access information in the document. Finally, Priority 3 means that a Web content developer may address this checkpoint to improve access to Web documents.

The WCA guidelines are recognized as the authority for designing and creating accessible Web sites, and have been used by several software developers to develop accessibility authoring and checking tools (Tillett, 2001). For example, BOBBY (www.cast.org/bobby/), whose design is based on the W3C Accessibility Guidelines for Page Authoring, is provided as a free online service to analyze single Web pages for their accessibility to people with disabilities. Macromedia also joins the effort by providing an online checking tool to help Web producers create accessible Web sites.

Overall, making a Web site accessible does not mean minimal Web page design. "The focus is to promote the design of Web sites that are highly usable for the greatest number of surfers" (Paciello, 2000, p. 50). A Web site designed for accessibility usually enhances its usability for all people, regardless of ability.

## KEY TERMS

**Assistive Technology:** Software as well as hardware for people with disabilities who find operating a computer difficult. As examples, these technologies include speech recognition, screen reader, touch screen, mouse alternatives, keyboard with large print keys, etc.

**Dimensions of Web Accessibility:**

a. Web sites and applications on the Web
b. Web browsers and media players
c. Web authoring tools, and evolving Web technologies

**Priorities of Web Accessibility Conformance:** The WCA Guidelines are composed of fourteen specific guidelines, with each including the rationale behind the guideline and a list of checkpoint definitions. Each checkpoint is assigned a priority level by the WAI Team based on the checkpoint's impact on accessibility. Specifically, Web pages must meet the requirements of priority 1 guidelines. Otherwise, one or more groups of users will find it impossible to access the information in the Web page. Priority 2 indicates that Web content developer should satisfy this checkpoint or one or more groups will find it difficult to access information in the document. Finally, Priority 3 means that a Web content developer may address this checkpoint to improve access to Web documents.

**Web Accessibility:** It can be defined as usability of the Web for people with disabilities, or, using the definition of World Wide Web Consortium, "access to the Web by everyone, regardless of disability."

**Web Content Accessibility Guideline (WCAG):** WCAG was developed by the World Wide Web Consortium (W3C) to explain how to make Web content accessible to people with disabilities and to define target levels of accessibility.

# Accessible E-Government through Universal Design

**Ulrike Peter**
*Institut für Informationsmanagement Bremen (ifib), Germany*

## INTRODUCTION

The accessible design of e-government ensures that these offers can also be used by people with disabilities (accessibility). Moreover, experience shows that clarity and comprehensibility of the offers benefit from their careful and deliberate design and structuring while keeping in mind accessibility requirements. Therefore, accessibility is useful for all citizens who want to attend to their administrative issues via the Internet (universal design).

Accessibility as a cross-sectional subject has to be considered holistically: On the one hand, following the "universal design" principle, it becomes clear that all users benefit from an accessible solution, independent of their abilities and independent of their situation, environment or conditions.

On the other hand, especially in e-government, the complete business process has to be considered: An offer accessible in itself may not be usable if an installation routine or plug-in has to be loaded from a non-accessible page or if the work procedure involves a media break.

## BACKGROUND: ACCESSIBLE E-GOVERNMENT AND HANDLING OF MEDIA BREAKS

Handicapped citizens as well as handicapped employees of the administration benefit from accessible e-government. When implementing e-government applications, there are three substantial areas of requirements where the principles of accessibility have to be considered.

1. **Access:** It has to be ensured that all citizens are generally able to use the application, at home, the workplace or a public access place. It has to be ensured, for example, that a person with a walking impairment can enter a public access location. For a Web site, it is crucial to make the pages accessible for people with disabilities and compatible with assistive technologies. Besides these criteria, which concern hardware, software and constructional issues, an important question is whether the citizens are sufficiently competent to use the media: Do they know what the application offers? Can they judge if the application is trustworthy concerning privacy and security? This means that media competence trainings should also be designed for persons with disabilities.
2. **Vertical Integration:** This area of requirements deals with processing in the administration. E-government makes it possible to think over and change traditional processes. Probably, people with disabilities could take over new tasks at their workplace, which may mean more independence from work assistance or help by colleagues.
3. **Horizontal Integration:** Up to now, normally you will have to visit several administrative agencies and fill in various forms if your life changes; for example, if you move or a child is born. E-government is a genuine added value for citizens if the services are offered in a bundle. From the point of view of the citizen and especially the handicapped citizen, the successful horizontal integration of services clearly is a facilitation and reduces the effort required now.

## TARGET GROUPS

Users with different abilities and skills strongly benefit from the accessible design of Internet offers; respectively, they are excluded from use if their requirements are disregarded.

Blind people depend on screen readers reading the monitor content to them, and a Braille display can give additional help. As the information on navigation and orientation can mostly be understood auditively—that is, linearly—a Web site must be structured very clearly. Therefore, all graphic elements must be accompanied by descriptive texts; it should be possible to use every Web site via keyboard.

Visual impairments can differ significantly. They range from diffuse vision, only light-dark contrasts, tunnel vision and sensitivity concerning lighting conditions to color blindness. Transition into the group of the blind is fluid. Often, magnification software and voice output are combined. With software products, it is important that the font is scaleable and that colors can be individually adjusted. In case of strong magnification, large monitors support orientation.

People with mobility impairments—for example, spasticity—can hardly use a mouse or standard keyboard. Persons who are not able to fully use their arms or hands rely on alternatives; for example, special keyboards, head mice, buttons. Clear design and reasonable input linearization are indispensable also for this group.

People with hearing impairments encounter barriers when audio services and videos are provided without a text version. A great difficulty is an overly complex language, especially when the "mother tongue" is sign language and the spoken (respectively, written) language has to be considered as a foreign language. Therefore, it is important to present the relevant information in sign language films or in easy language.

People with cognitive impairments need a memorable page structure, a manageable navigation and easy language (e.g., plain English). Graphic and animated objects support attention.

People who need more orientation—for example, the elderly or people without Internet experience—also need a clear page structure and manageable navigation.

In principle, people who are temporarily handicapped experience the same barriers by a certain situation, such as the handling of a machine, strong backlight or noise. With alternative output units, such as PDAs or mobile phones, orientation and navigation requirements also have to be considered.

Knowing and understanding users' needs facilitates the use of existing standards and guidelines.

## GUIDELINES

With the support of a European Union (EU) research program, the Web Accessibility Initiative (WAI) of the Worldwide Web Consortium (W3C) developed the WAI Guidelines (www.w3.org/WAI). In 1999, the Web Content Accessibility Guideline 1.0 (WCAG 1.0), with 66 checkpoints, was adopted (Chisholm, 1999). It is mainly concerned with the design of Hypertext Markup Language (HTML)-based Internet offers (e.g., the handling of tables, strict separation between presentation and layout, handling of graphic and acoustic elements). Further WAI guidelines deal with authoring tools, user agents and Extensible Markup Language (XML). Additional guidelines of associations, self-advocacy groups and individuals are normally based on the WCAG 1.0.

Discussion of the WCAG 2.0 is still in progress (see Caldwell, 2004; Peter & Schulte, 2005). With its four principles (perceivable, operable, understandable, technically robust), it is more clearly structured than the WCAG 1.0 and independent from technology when formulating criteria. Checkpoints substantiate the principles; for example, to ensure that the Web site is perceivable, it includes checkpoints concerning the requirements of people with low vision as well as those with hearing impairments.

Besides, there is the international standard ISO/TS 16071 (Ergonomics of human-system interaction—guidance on accessibility for human-computer interfaces), which has not attracted much attention until now. It deals with software products in general. Currently, a further standard is being prepared.

The standards on software ergonomics, especially DIN EN ISO 9241 (Ergonomics requirements for office work with visual display terminals), contain requirements concerning accessibility; respectively, design for all. But in the implementation of the norm, these requirements are not sufficiently considered nor adequately operationalized.

Due to legal framework conditions, especially U.S.-American companies developed in-house guidelines following the WCAG 1.0 and offer functions and APIs that make their products more accessible.

## LEGAL BACKGROUND

The objective of accessible information and communication technology (ICT) has been laid down by law in many countries: in the US, the Rehabilitation Act, Section 508; in Europe, for example, the Communication of the European Commission from September 25, 2001. From the end of 2001 on, all member states and the European institutions take the WCAG 1.0 into account for all public tenders. So the WCAG 1.0 is used for making concrete regulations at the legislative level.

## FUTURE TRENDS: ACCESSIBILITY IN PROGRESS

Ensuring accessibility is a difficult demand due to the complexness of the subject. Therefore, it is necessary to focus on the process. A good method is dialog with and among the people with disabilities and the joint development and dissemination of innovative approaches.

In Europe, the European Design for All e-Accessibility Network (EDeAN) coordinates the activities of member states (www.e-accessibility.org). Several activities inform the public about the importance of the subject. One example is the BIENE Award organized in Germany (www.biene-award.de). This award is given to best-practice cases of accessible Web applications in the fields of e-commerce, e-government, media, education, science and research, as well as culture and society. The evaluation process comprises complex expert reviews and final practice tests with users with different disabilities. The popularity of this purely ideal award clearly shows that awareness has increased (see Pieper, Anderweit, Schulte, Peter, Croll, & Cornelssen, 2004).

## CONCLUSION

It is necessary to design Internet applications according to the requirements of target groups to make them attractive for heterogeneous user groups. To reach this aim, guidelines and laws are required, but not sufficient. Only the knowledge of what people with disabilities need and the continuous communication with users accompanying the process will ensure accessible design. Applications in the field of e-government are examples. There are several best practices of information offers, but the transfer is still missing. Moreover, the subject of applications including complex transactions is a question of present and future research.

## KEY TERMS

**Accessibility:** An information and communication offer is barrier-free and accessible if it does not—by its design, programming or using inappropriate technologies—exclude anybody from its use.

**Universal Design/Design for All:** The principle of the universal design involves more than just the effort on accessibility for people with disabilities. It means that products are designed flexibly so they can be used by everybody. It should be possible to use the product independently of a person's abilities, situation and environment without additional assistive technologies.

**Assistive Technologies:** All kinds of help tools—hardware and software—required for people with certain disabilities.

**Web Accessibility Initiative (WAI):** The WAI of the W3C pursues accessibility of the Web through five primary areas of work: technology, guidelines, tools, education and outreach, and research and development. The W3C develops interoperable technologies (specifications, guidelines, software, and tools) to lead the Web to its full potential. W3C is a forum for information, commerce, communication and collective understanding.

# Accessing Administration's Information via Internet in Spain

**Agustí Cerrillo i Martínez**
*Universitat Oberta de Catalunya, Spain*

## INTRODUCTION

Information in the hands of public administrations plays a fundamental role in developing democracies and carrying out daily tasks—not only the public administrations' tasks, but also those of the general public and companies (European Commission, 1998). New information and communications technologies (ICT) are vastly increasing the range of information in the hands of the general public and considerably diversifying both quantitatively and, above all, qualitatively the tools for conveying this, with the Internet being the means chosen by Organisation for Economic Co-Operation and Development (OECD) Member States to provide the general public with access to the information held by the administration (OECD, 2003).

Nowadays, public administrations create, collect, develop and disseminate large amounts of information: business and economic information, environmental information, agricultural information, social information, legal information, scientific information, political information and social information.

Access to information is the first step towards developing e-governments and is something that has grown most in recent years, not only from the viewpoint of supply but also of demand. At present, most people using e-government do so to obtain information from public administrations.

Throughout history, information has not always had the same relevance or legal acknowledgement in the West.

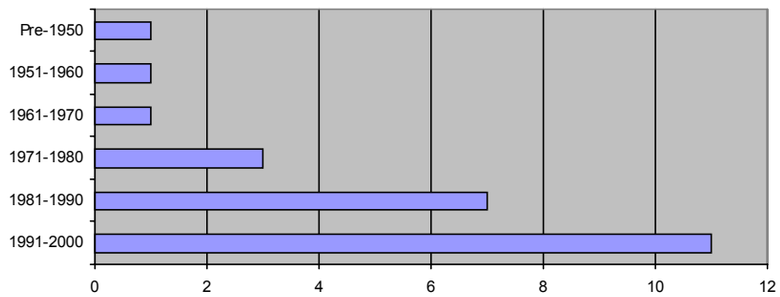
Bureaucratic public administrations had no need to listen to the general public nor notify citizens of their actions. Hence, one of the bureaucratic administration's features was withholding the secret that it had legitimized, since this was considered the way to maintain the traditional system of privileges within the bureaucratic institution—by making control and responsibility for information difficult, and also by allowing the public administration to free itself of exogenous obstacles (Arteche, 1984; Gentot, 1994). In most European countries, except the Nordic countries (Sweden, Norway, Finland), secrets were the dominant principle. For instance, it was not until 1978 that France passed a law concerning access to public sector information; in 1990, Italy did likewise.

Crises in the bureaucratic model of public administration have brought with them the existence of new models. Receptivity, focusing on the client and quality management, have been some responses to the crisis of this model in the 1980s and 1990s, since the advent of the post-bureaucratic paradigm ( Mendieta, 1996; Behn, 1995). The process of modernizing Public administrations has meant that those governed have come to be considered clients of these administrative services (Brugué, Amorós, & Gomà, 1994). Citizens, considered as clients, now enjoy a revitalized status as seen from public administrations, which provides citizens with a wide range of rights and powers in order to carry out their needs, including obtaining information from the administration (Chevalier, 1988). This process has coincided over the years with the rules regulating access to public-sector information being extended in countries of the West.

But the evolution does not stop here. Societies that are pluralist, complex and interdependent require new models of public administration that allow the possibility of responding and solving present challenges and risks (Kooiman, 1993; OECD, 2001b). Internet administration represents a model of public administration based on collaboration between the administration and the general public. It has brought about a model of administration that was once hierarchical to become one based on a network in which many links have been built between the different nodes or main active participants, all of whom represent interests that must be included in the scope of general interest due to the interdependence existing between them (Arena, 1996).

The way the administration is governed online requires, first and foremost, information to be transparent, with the aim of guaranteeing and facilitating the participation of all those involved (European Commission, 2001). It is essential that all those involved in the online process are able to participate with as much information as possible available. Information is an indispensable resource for decision-making processes. The strategic participants taking part in these will consider the information as an element upon which they may base their participation online. Information becomes a resource of power that each participant may establish, based on other resources

*Figure 1. First introduction of regulations concerning access to information in OECD member countries (Source: OECD, 2001a)*



he or she has available, and this will influence their strategies in the Internet. This allows us to see that the networks distributing information may be asymmetrical, which leads to proposing a need to adopt a means to confront this asymmetrical information. In this task, ICT can be of great help with the necessary intervention of law.

Public-sector information has an important role in relation with citizens' rights and business. Public administration also needs information to achieve its goals.

## E-GOVERNMENT AND PUBLIC SECTOR INFORMATION

The use of the Internet has increased access to information held by public administrations. Any citizen, regardless of where they are, can access any information in the hands of the public administration 24 hours a day, 7 days a week just by accessing the public administration's Web site (OECD, 2003a).

This is not exclusive to just one country, but throughout Europe and, generally speaking, worldwide, where considerable efforts are being made to raise the amount and quality of administrations' information in Internet. This has also happened when adopting strategies and further documents related to the administrations' information on the Internet. Thus, for example, on January 16, 1998, in France, the Interministerial Commission for the information society put forward a document entitled *Préparer l'entrée de la France dans la société de l'information* in which it was highlighted that the state, as the leading producer of information in the country, had to extend the distribution of information via Internet. Other documents of the same sort are the *United Kingdom's White Book on the Freedom of Information* and the memorandum from the Netherlands, *Towards the Accessibility of Public Information*. The relevance of access and the use of information from the public sector has been widely highlighted also in the sphere of the European Union. For example, in the Council's Decision 2001/48/EC, dated December 22, 2000, which adopted a Europe-wide program spanning several years that aims to stimulate the development and use of European digital information in the World Wide Web and promote the linguistic diversity in the information society, it has led to the approval of rules, such as Directive 2003/98/EC, regarding the reutilization and exploitation of documents from the public sector.

Access to information in the hands of public administrations allows the general public to exercise its rights and activities. Furthermore, access to information allows an introduction into the market of an asset with a high economic content, which may be the object of commercialization and reutilization.

However, in order that the information the general public accesses fulfils these functions ideally and thus be seen by the general public likewise, it is essential that this information fulfil certain standards. In particular, information must be thorough, objective, trustworthy, reliable, relevant and easy to find, understand and use (OECD, 2001a).

The OECD has confirmed the general use of new ICT on an international level, stating that the options most used by public administrations with the aim of making this information available are Web sites (the number of governmental bodies with Web sites has reached around 80% in the countries taking part in the survey carried out by PUMA in 2000), portals (many OECD countries have created single points of access to facilitate access to information for the general public), search engines, minutes from meetings, kiosks (some countries offer the possibility of accessing the Internet by installing access points in public offices) and CD-ROMs for consultation off-line (OECD, 2001a).

*Table 1. Have you ever contacted the public administration via Internet? (more than one answer possible). (Source: European Commission [Flash Eurobarometer 125])*

## THE LEGAL REGIME CONCERNING ACCESS TO INFORMATION VIA INTERNET IN SPAIN

Analysis of the legal regime concerning access to information in the framework of e-government poses a difficulty from the outset: At present, there have not been any generally adopted regulations regarding access to information using new technologies. In fact, there are very few regulations that entirely cover access to public-sector information using new technologies. Perhaps the first and best known of these is the one developed by the United States (U.S.) Congress in 1996 with the amendment of the *Freedom of Information Act*, known as the *Electronic Freedom of Information Act* (EFOIA).

This has given rise to the fact that there is no clearly defined legal regime in Spain allowing the means to be determined whereby information can be accessed, what type of information can be offered to the public and the characteristics and conditions of this access and use, and the means providing guarantees, price and responsibility for the contents of information, among other items.

This lack of defining important details in the legal regime and, in many cases, the non-existence of a suitable means to guarantee compliance with the right to access administrative information, could lead to inefficacy, inefficiency and asymmetry which, in the end, may prevent it from fulfilling the functions information is expected to provide in this present day (Torrijos, 2001; OECD, 2001).

In spite of this, analyzing the present legislation in Spain will allow us to contribute some details regarding what kind of legal regime should exist concerning access to information in Spain. Law 30/1992, November 26, concerning the legal regime of public administrations and common administrative procedures (hereinafter LRJPAC), acknowledges a list of rights of the general public regarding its relation with public administrations. From the list of citizens' rights provided, four refer to citizens' public-sector information (Cerrillo i Martínez, 2000):

- The right to ascertain the stage at which the documents are being processed.
- The right to know the identity of the authorities and personnel working for public administrations.
- The right to obtain information regarding legal or technical requirements.
- The right to access administrative files and registers.

Without going into great detail by evaluating the extent of these rights, it can be seen that we are faced with real subjective rights (Cerrillo i Martínez, 2000). The acknowledgement of these rights to obtain public sector information implies, on the one hand, the particular obligation to provide information held by the administration, following a relevant request by a citizen and, on the other, the general duty is established for organizing the relevant services to provide this information to the general public (Cerrillo i Martínez, 2000).

Their contents are focused, on the one hand, on general public-sector information (information concerning legal or technical requirements regarding projects, actions or applications and information concerning docu-

ments in archives and registers). Accessing this information does not require any special legitimization. Any citizen can access this information. On the other hand, private administrative information that concerns specific procedures is only available to interested parties (Cerrillo i Martínez, 2000).

Following the approval of the LRJPAC, the regulation concerning information has been increased; first, with rules being introduced in certain sectors involved in this activity (health, education and environment, to mention a few) (Cerrillo i Martínez, 1998) and, in addition to this, rules have been passed establishing the necessary infrastructure to carry out this function.

On a state level, the Royal Decree 208/1996, February 9, regulating services concerning administrative information and attention provided to citizens, establishes the organization, operation and coordination of administrative services, which focuses its work on the tasks of providing information to citizens (Cerrillo i Martínez, 2000). The Royal Decree 208/1996 provides for different means citizens can use to access information by specially highlighting the means of supplying information personally without specifically incorporating the use of the Internet as a means for making information public. However, this regulation makes no mention either of the legal position of the citizen regarding this information or the characteristics or conditions in which the public administrations must carry out this task concerning the information, or other aspects, such as the quality of this information or the service provided.

The rules regulating e-government in Spain do not allow us to overcome the aforementioned lack of resources. On reading the rules regulating e-government, both on a state level and in regions that have already passed some regulations on this matter (Aragón, Valencia region, Madrid region, Extremadura or Catalonia), this will allow us to see that more than simply establishing new citizens' rights in their relationship with the public administrations, they provide new means to exercise the rights previously recognized under other regulations (see article 45 of LRJPAC). There is no general law for the general public to contact the public administration via data transmission and, in particular, to gain access to information in the hands of the administration via this system (Torrijos, 2001).

## FUTURE TRENDS: TOWARD A NEW LEGAL REGIME

Over the years, access to information has grown and been extended until reaching the present situation, which is mainly characterized by the fact that it is the public administration that offers or distributes the information without citizens having to request or apply for it. In other words, passive access to information is now becoming active access. Following article 1 of Directive 2003/4/EC, January 28, on public access to environmental information:

- Passive access is that which arises when a request is made by a citizen for the public administrations to provide a document or item of information. Directive 2003/4 establishes that "Member States shall ensure that public authorities are required … to make available environmental information held by or for them to any applicant at his request and without his having to state an interest."
- Active access is that which is guaranteed via generalized distribution of information through the creation of information distribution systems carried out by the public authorities. Directive 2003/4 establishes that, as regards the distribution of information, "Member States shall take the necessary measures to ensure that public authorities organize the environmental information which is relevant to their functions and which is held by or for them, with a view to its active and systematic dissemination to the public, in particular by means of computer telecommunication and/or electronic technology, where available."

The transition from one type of access to information to another may be seen, to a certain extent, as being caused or even highlighted by the general use of new ICT, since these offer means for searching, selecting, integrating and distributing large quantities of information in the hands of the public administrations as well as facilitating the presentation of the findings in such a way that it may be used by citizens (OECD, 2001a).

From the legal viewpoint regarding access to information, if passive access was sufficiently guaranteed with the recognition of the right to access this public-sector information as a subjective citizens' right, active access also means that it is necessary to establish a service in charge of distributing and making the information public with thorough guarantees for citizens provided by the use of new ICT.

But the public administrations' duty to create information services is not enough in itself. We believe that at present, active access cannot be exclusively guaranteed by creating infrastructures services concerning the distribution of information (in the organic or functional sense); it is also necessary to recognize these as being a service of general interest (Lasserre, 2000; European Commission, 2004). In this way, a minimum content can be guaranteed that may be summarized by the following details: universal service, continuity, quality of service, accessi-

bility and protection of users (European Commission, 2004). But, on the whole, it will allow a guarantee that the distribution of this information fulfils certain characteristics that will allow citizens, in the end, to exercise their rights and companies to carry out their business activity, thereby overcoming most of the difficulties and limits the acknowledgement of the right to access as a subjective right has had so far.

This situation has been reached in a number of countries. For example, in France, Law 2000/321, April 12, regarding citizens' rights covering contacts with the administration, has provided for the distribution of information via Internet to be considered a public service.

The conclusion above, however, does not stem from the public administration being the only one that can distribute information to citizens. Although it is true that public-sector information is important for a civil and democratic society, it is also potentially important from a financial viewpoint. That is why public administrations can distribute *information linked to public service missions* (legal information, information concerning the services it provides) and also information with added value (weather forecasts, statistics, tourist information, for example) that could compete with companies and citizens, as in the case, for example, of Directive 2003/98/EC regulating the reutilization and commercial exploitation of documents belonging to the public sector.

In Spain, information services regulation is not only a power of the state, but also a power of the autonomous communities (regions) and municipalities that can develop their own information services within the framework laid down by the state.

## CONCLUSION

Access to information plays an important role since, on the one hand, it allows democratic legitimacy of governments to be increased and, on the other hand, helps citizens to become active participants, and not just reactivating citizens, in public affairs. Furthermore, and as a consequence of the points mentioned above, access to information is based on a means by which is highlighted the principle of the public powers' accountability.

New technologies facilitate access to information held by public administrations, making large amounts of information available to citizens and companies. However, it is necessary for the citizen to be sure that all information is included and that public administration does not fail to provide information that may cause itself problems.

Law plays an important role in this by establishing the framework in which the information is provided by the public administrations; guaranteeing effective access, available to all, with a minimum level of quality and also easily accessible; and avoiding the existence of asymmetrical information between different participants.

## KEY TERMS

A

**Access to the Administrations' Information:** The right to acknowledge information held by a public administration.

**Active Access:** Access to information made available and disseminated to the public by the public administration to achieve the widest possible systematic availability and dissemination of administrations' information. To this end, the use, in particular, of computer telecommunication and/or electronic technology.

**Information Held by a Public Administration:** Information in its possession that has been produced or received by that authority.

**Passive Access:** Access to information that provide the information regarding public administration after it has been requested by a citizen.

**Public Administration:** Government or other public administration, including public advisory bodies, at national, regional or local level.

**Service of General Interest:** Covers both market and non-market services the public authorities class as being of general interest and subject to specific public service obligations; in particular, universal service, continuity, quality of service, affordability, as well as user and consumer protection.

**Transparency:** Quality of public administration when citizens are able to know what is happening inside.

# Adopting and Implementing Telehealth in Canada

## INTRODUCTION

Canada spans 9,976,140 square kilometers and has an approximate population of 32 million people (Statistics Canada, 2001). More than 90% of Canada's geography is considered rural or remote (Government of Canada, 2001). Despite the highly dispersed population, and, indeed, because of it, Canada is committed to the idea that a networked telehealth system could provide better access and equity of care to Canadians. Growing evidence of the feasibility and affordability of telehealth applications substantiates Canada's responsibility to promote and to develop telehealth.

Telehealth is the use of advanced telecommunication technologies to exchange health information and provide healthcare services across geographic, time, social, and cultural barriers (Reid, 1996). According to a systematic review of telehealth projects in different countries (Jennett et al., 2003a, 2003b), specific telehealth applications have shown significant socioeconomic benefits to patients and families, healthcare providers, and the healthcare system. Implementing telehealth can impact the delivery of health services by increasing access, improving quality of care, and enhancing social support (Bashshur, Reardon, & Shannon, 2001; Jennett et al., 2003a). It also has the potential to impact skills training of the health workforce by increasing educational opportunities (Jennett et al., 2003a; Watanabe, Jennett, & Watson, 1999). Therefore, telehealth has a strong potential to influence improved health outcomes in the population (Jennett et al., 2003a, 2003b).

Fourteen health jurisdictions—one federal, 10 provincial, and three territorial—are responsible for the policies and infrastructure associated with healthcare delivery in Canada. This article presents a telehealth case study in one of Canada's health jurisdictions—the province of Alberta. The rollout of telehealth in Alberta serves as an example of best practice. Significant milestones and lessons learned are presented. Progress toward the integration of the telehealth network into a wider province-wide health information network also is highlighted.

## BACKGROUND

Canada's province of Alberta has a geography that is well suited to using telehealth technologies. Previous telehealth pilot projects throughout the province provided evidence of potential benefits from telehealth applications (Doze & Simpson, 1997; Jennett, Hall, Watanabe, & Morin, 1995; Watanabe, 1997). Alberta is the westernmost of Canada's prairie provinces with a total area of 661,188 $km^2$. Approximately 3 million people live in this western province, with two-thirds of the population living in two major cities in the lower half of the province; 19.1% of the population is distributed over the northern remote areas and southern rural communities (Figure 1) (Alberta Municipal Affairs, 2004; Statistics Canada, 2001).

In Alberta, health regions assume responsibility for acute care facilities and continuing and community-based care facilities, including public health programs and surveillance. The population sizes of health regions vary, as do their service census populations (Figure 1). The province has approximately 100 hospitals and more than 150 long-term care facilities. Health professionals are located largely in the urban centers, leaving many rural and remote areas with limited access to a variety of healthcare providers and services. In the mid-1990s, there was a physician-to-population ratio of 1:624 (Alberta Health, 1996). Most

physicians are compensated on a fee-for-service basis by the provincial government (Alberta Health, 1997).

During the last decade, health reforms and restructuring have taken place in Canada, both at the federal (Kirby, 2002; National Forum on Health, 1997; Romanow, 2002) and provincial (Clair, 2000; Fyke, 2001; Mazankowski, 2001; Ontario Health Services Restructuring Commission, 2000) levels. These reforms were conducted in response to important trends challenging the Canadian Medicare system, such as escalating costs for new technologies and drugs, aging population, and increasing public expectations. Furthermore, health reforms addressed the issue of access to healthcare services for some groups, such as Aboriginal people and populations living in rural and remote parts of the country (Romanow, 2002).

Major challenges include the scarcity and isolation of healthcare professionals in many communities because of Alberta's large landmass; varied, extreme, and unpredictable climate; and population dispersion. Such realities were recognized as principal factors motivating the consideration of a provincial health information network. Alberta began to plan such a network in the mid-1990s, with the objectives of exploiting health information technologies and linking physicians, allied health professionals, hospitals, clinics, health organizations, and Alberta Health and Wellness (the provincial government's department of health) (Government of Alberta, 2003; Jennett, Kulas, Mok, & Watanabe, 1998). This network, entitled Alberta Wellnet, was a joint initiative by Alberta Health and Wellness and stakeholders in the health system. Initially, a core set of priority initiatives consisted of a pharmacy information network, telehealth, a healthcare provider office system, continuing and community care services, service event extract, population health and surveillance, and diagnostic services information sharing. This article describes the development of the provincial telehealth network in Alberta.

## THE PROVINCIAL DEVELOPMENT OF THE TELEHEALTH NETWORK

Just prior to the establishment of Alberta Wellnet, an anonymous philanthropic foundation expressed interest in exploring the feasibility of developing an integrated, province-wide telehealth network based on need, capability and support. One of the authors (ES) initiated discussions with the foundation through an intermediary, and a small team of content experts was assembled to begin dialogue. The foundation requested a letter of intent and a presentation of concept to substantiate the benefits of allocating funds to telehealth. Following internal review and external consultation, the foundation allocated $525,000 for the preparation of a telehealth business plan. A project planning team was formed to serve as the province-wide planning group and to oversee the preparation of the business plan. This team incorporated representatives from the RHAs, the health sector, the universities, and the community. Two province-wide focus groups were held with representatives from the stakeholder groups to discuss content and approach, and a number of meetings were held between the CEOs (chief

*Table 1. Donor foundation conditions*

- Funds to be used for capital purposes only
- 2 to 1 matching funds required ($7,000,000)
- Province-wide network (a minimum of 75% of the population, at least 12 Health Regions)
- Improve access (remove distance, especially for remote, isolated rural)
- Incorporation of all current pilot projects
- Sustainable, integrated into the Health Information System

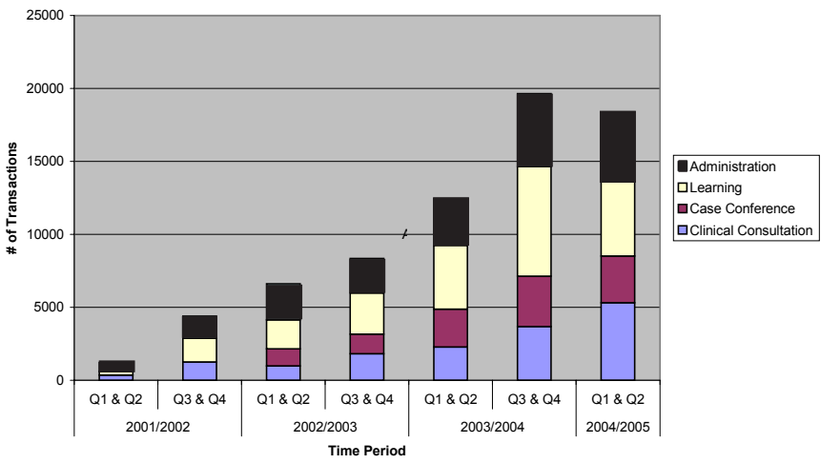
*Table 2. Milestones*

| | |
|---|---|
| 1994 | Health reform and restructuring in Alberta established 17 Regional Health Authorities (RHAs), down from >200. |
| 1995 | An anonymous philanthropic donor foundation expressed interest in exploring the feasibility of developing an integrated province-wide telehealth network based on need, feasibility, and support. |
| 1996 | Initial Business Plan supported the concept of a provincial telehealth plan. Potential allocation of $14 million, provided that a number of conditions could be met. |
| 1996 | Initial plans for a provincial health information network (Alberta Wellnet) began. |
| 1997 | Telehealth Coordination (ATCC) and Implementation Planning Committees (ATIPT) formed with action plans regarding policy, infrastructure implementation, and operational solutions. Vision and overall management report produced by the Telehealth Working Committee, with input from all stakeholders. |
| 1997 | $7 million one-time commitment, plus $1 million operating costs commitment from Alberta Health. |
| 1997 | Provincial Health Authorities' Association reestablished a charitable foundation to receive and to administer funds. |
| 1997-1998 | The Alberta Medical Association's Committee on Fees and Alberta Health opened the way to potential payment for telehealth services. |
| 1997-1998 | Telehealth handbook compiled to provide guidelines for regions initiating telehealth activities. ATIPT merged with ATCC. |
| 1998 | Joint Planning Committee held with Alberta Telehealth Coordinating Committee (ATCC), the RHAs, and the Provincial Boards resulting in four priority telehealth applications: psychiatry, emergency care, radiology, and continuing education. Frameworks for three issues were discussed: (1) needs assessment models, (2) funding models, and (3) provincial telehealth infrastructure and network. |
| 1998 | Decision Document produced for the Minister of Health, the RHAs, the anonymous philanthropic foundation, and the Alberta Medical Association. Business models for the four priority areas evolved, along with working groups assigned to each. |
| 1999-2000 | Establishment of Provincial Telehealth Committee and coordinator. |
| 1999-2004 | Central support services were initiated and deployed, including an interoperability standard testing framework for vendors, a scheduling system, followed by bridging and gatewaying services, core evaluation and costing frameworks, processes, and tools. |
| 2003 | Alberta's RHAs reduced from 17 to 9 health regions. |
| 2003 | Thirty clinical disciplines included in Telehealth. |
| 2003-2006 | Provincial Telehealth Strategic Business Plan approved. Five critical success factors were articulated. A number of proposed initiatives were put into place. |
| 2003-2006 | Telehealth Clinical Grant Fund established. Two calls for proposals have occurred, resulting in the funding of approximately 20 clinical projects and anticipated approval for an additional 20 projects. |
| 2004 | 10,000th telehealth clinical consultation occurred. |
| 2004 | Clinical telehealth service extended to First Nations Communities. |
| 2004 | Telehealth scheduling system extended to the Territory of Nunavut. |
| 2004 | First provincial clinical telehealth forum held. Second one approved for 2005. |

executive officers), their RHAs, and boards. The 17 regions and the two provincial boards at that time indicated their support in principle for a provincial telehealth network. The foundation's acceptance of the Provincial Telehealth Business Plan provided a commitment of up to $14 million to fund a provincial telehealth network pursuant to the satisfaction of a number of conditions (Table 1). The milestones associated with the development of the network are outlined in Table 2.

Specifically, the provincial telehealth network began its rollout in 1999 and continues to evolve and develop. A Provincial Telehealth Committee (PTC) comprised of health region, physician, and Alberta Health and Wellness representatives was formed in 1999 to provide strategic direction to this provincial initiative. Figure 1 outlines the current status of the network. In October 2004, there were 261 active telehealth systems that were networked and centrally connected through a network consisting of

*Figure 2. Growth of Telehealth—Increased administrative, learning, case conference, and clinical consultation transactions*



a combination of ISDN, SW56, and AGNPac. Applications were clinical, educational, and administrative in nature, and sessions were charted between 2002 and 2004 (Figure 2). In 2004, the network's 10,000th clinical consultation occurred, and clinical services were extended to the First Nations' communities.

Since 2001, central supporting services have been established to support all stakeholders. For example, an Internet-based telehealth scheduling system initially was deployed in 2001 to facilitate coordination of telehealth activities throughout the province and has been used successfully to support approximately 30,000 telehealth events. The system now is being shared with several other jurisdictions (Nunavut, Saskatchewan, some mental health sites in British Columbia, Alberta First Nation's and Inuit Health Branch sites). Other core services included an interoperability standards testing site for vendors at Alberta Research Council, bridging and gatewaying services as well as costing models and core evaluation frameworks. For example, a home telehealth business case template was completed to facilitate health region analysis of this mode of service, while a newly developed site-based costing model provided support for further research and the development of a sustainable economic model for telehealth in Alberta. Further, a comprehensive provincial evaluation process is in development. To this end, an Inventory of Telehealth Evaluation Activities in Alberta was completed in order to establish a baseline and to inform refinements to the existing evaluation framework. Associated indicator standards are being aligned with the Alberta Health and Wellness Quality Framework. The Health Information Standards Committee of Alberta recently approved a new Alberta telehealth videoconferencing standard, as technological standards are continuously evolving.

A Provincial Telehealth Strategic Business Plan (2003-2006), developed by the PTC on behalf of health regions and approved by the Council of CEOs, articulates five critical success factors to realize the full potential of the Alberta Telehealth network. These five foci include (1) providing timely access to quality care, (2) collaborating effectively, (3) securing and effectively managing resources, (4) creating a culture that fosters change, and (5) formalizing the evaluation process and enhancing telehealth research.

At present, all of Alberta's Health Regions have telehealth programs in place. Due to required health system and provider buy-in rate, the clinical applications were slightly slower to evolve. As a consequence, a project that established incentives for the development of clinical telehealth applications was initiated. Alberta Health and Wellness funded a Telehealth Clinical Grant Fund (overseen by the PTC) resulting in more than 20 clinical telehealth projects, including cardiology, emergency, diabetes, urgent mental health, and pediatric services. A recent call for proposals is expected to result in funding of 20 additional projects, some of which will be extended to First Nations Communities.

## SIGNIFICANT LESSONS LEARNED AND OBSERVATIONS

There were many lessons learned during the development of the Provincial Telehealth Program. They fall into two broad categories: (1) Business, Funding, and Sustainability

(four items) and (2) Policy, Operational, and Infrastructure Issues (15 items) (Table 3). A number of key observations also emerged. These included the need to:

- Understand the nature and the implications of health reform and restructuring;
- Identify and clarify policy and operational issues around specific applications;
- Incorporate adequate telecommunications infrastructure;
- Respect diversity in priorities as well as preparedness and state of readiness among Health Regions;
- Ensure provision for sustainable operational support; support preparation of business models for shared telehealth needs in the Health Regions;
- Pay special ongoing attention to human factors, including the reengineering and business change management work place processes; and
- Involve end users, including physicians, nurses, and administrators, early in the planning process and conceptual design.

## FUTURE TRENDS AND DIRECTIONS

Today, a major focus for the province is integrating the provincial telehealth program with other provincial health information initiatives. These include the Electronic Health Record Initiative, the Physician Office Support Program (POSP), and the Pharmacy Information Network (PIN). A second focus is on migrating from the current platforms to a high-speed, high-capacity IP broadband backbone (i.e., the SuperNet project) (Government of Alberta, 2002). In parallel, the province is continuously examining new evolving technologies and partnerships that can optimize the use of ICTs within the health sector, with a focus on quality of care, patient safety, and evidence-based decision making at the point of care.

*Table 3. Lessons learned*

**Business, Funding, Sustainability**

- The preparation of business models for shared telehealth needs in the health regions was helpful to ensure buy-in and progress.
- There is a great deal of work remaining after program initiation.
- Funding opportunities to cover the initial and ongoing operating costs of Telehealth require ongoing vigilance.
- Accountability for all network components required articulation.

**Policy, Operational and Infrastructure Issues**

- Raising awareness of Telehealth and its potential continues to be challenging, as Telehealth encompasses a variety of areas and technical complexity, which is difficult to reduce to simple language.
- A number of policy and operational issues around specific applications were identified and required further study and clarification.
- Cross-jurisdictional policy work is extremely time-consuming. For example, the number of editions of the consent policy framework was extremely high.
- Respect for diversity of state of readiness, priorities, and partners/collaborators among regions was required.
- A representative governance structure was required. All stakeholders needed to participate in the planning and decision making during the early stages of rollout.
- A decision document for the Minister of Health, the Health Authority, the anonymous philanthropic foundation, and the Alberta Medical Association was a tool to enhance successful integration and buy-in.
- A clear understanding of the nature and implications of health reform and restructuring are required before telehealth can be integrated into a regional health system. Telehealth must align with and support major health reform initiatives in order to continue to be supported by and to be successful in the provincial funding structure. It also must take into consideration the convergence of technologies as it evolves.
- Alberta Health, the Ministry of Health, was a key player in initial successful implementation.
- Consideration of the province's overall health information approach was important. Multiple reporting requirements are needed.
- In early stages, policy and integration committees were helpful to move agendas along. Commitment was central as expertise, time, and expenses were volunteered.
- Continual revisiting of critical issues with RHAs and Provincial Boards, along with ongoing active participation, was required. Perseverance in planning and development is rewarded.
- Adequate infrastructure (telecommunications, trained staff, etc.) for a network was critical.
- Identification of pressure points, along with provincial barriers and obstacles, was difficult but essential in order to move the agenda along.
- Implementation requires close attention to human, system, and workplace factors.
- Ongoing evaluation and monitoring is required for continuous quality improvement.

## CONCLUSION

The deployment of the provincial telehealth network continues to grow and to strengthen. Many milestones were encountered in the development of the Alberta Telehealth Network (Table 2). Several significant lessons learned also were documented (Table 3). While significant progress has been made, challenges and impediments remain for the creation of a functional, sustainable, and integrated province-wide telehealth network. Specifically, the successful integration of telehealth into a broad provincial health information and health system demands attention to human, system, and workplace factors. The significance of several critical factors cannot be ignored: different degrees of regional and sectoral readiness to adopt telehealth as well as diversity in selected telehealth priorities, potential cultural shift in the way providers work and learn, training needs, and required public/private/academic sector collaborations.

It also was observed that telehealth and e-health initiatives make substantial impacts in key areas of health reform. Integration requires close attention to the ongoing healthcare restructuring movements as well as to the convergence of technologies. There is a tendency to simply add technology to existing processes; however, some of these processes need to be reengineered in order to realize the full potential of telehealth. Further, changing funding processes to better accommodate telehealth is extremely difficult; the amount and quality of evaluation research on the impact of investments in telehealth must be increased to support the decision makers.

The provincial telehealth network initiative provides ongoing progress reports as health reform and restructuring continue and as integration with other provincial health information initiatives continues.

## ACKNOWLEDGMENTS

The authors wish to acknowledge the commitment and many volunteer hours of members on the various committees, planning teams, and working groups associated with the rollout of the Alberta Telehealth Initiative. The authors acknowledge the assistance of Winston Teo, Heidi Brandstadt, and the Health Telematics Unit in the preparation of this manuscript. The authors also wish to acknowledge both the foresight and generosity of the anonymous donor foundation that served as the catalyst for this initiative.

## KEY TERMS

**AGNPac:** AGNPac is a government of Alberta IP network.

**Bandwidth:** The range of frequencies transmittable through a transmission channel. If the channel is unique, the band is called baseband. If the channel is made multiple through a process of multiplexing, the band becomes wideband and can support data, voice, and video at the same time. (1) The difference between the highest and the lowest frequencies in a data communication channel. (2) The capacity of a channel. (3) A measure of the amount of information and, hence, its transfer speed, which can be carried by a signal. In the digital domain, bandwidth refers to the data rate of the system (e.g., 45 Mbit/sec) (Beolchi, 2003). Bandwidth is a practical limit to the size, cost, and capacity of a telehealth service.

**Broadband:** A popular way to move large amounts of voice, data, and video. Broadband technology lets different networks coexist on a single piece of heavy-duty wiring. It isolates signal as a radio does; each one vibrates at a different frequency as it moves down the line. Its opposite is baseband, which separates signals by sending them at timed intervals (Beolchi, 2003). Future networks, like those being deployed in Alberta, will carry these higher speed communications (i.e., Broadband ISDN).

**E-Health:** An emerging field in the intersection of medical informatics, public health, and business, which refers to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development but also a state of mind, a way of

thinking, an attitude, and a commitment for networked, global thinking to improve healthcare locally, regionally, and worldwide by using information and communication technology (Eysenbach, 2001). The Commission of the European Communities (2004) declares that e-health tools or solutions include products, systems, and services that go beyond simply Internet-based applications and include tools for both health authorities and professionals as well as personalized health systems for patients and citizens.

**IP:** Internet Protocol is the network layer protocol for the Internet (Beolchi, 2003).

**ISDN:** Integrated Services Digital Network is a set of international digital telephone switching standards that can be used to transmit voice, data, and video. It offers the advantages of error-free connections, fast call setup times, predictable performance, and faster data transmission than possible when using modems over traditional analogue telephone networks. Basic ISDN services combine voice and data, while broadband services add video and higher-speed data transmission. ISDN offers end-to-end digital connectivity (Beolchi, 2003).

**SW56:** Switch56 is digital telecommunication that transmits narrow-bandwidth digital data, voice, and video signals.

**Telehealth:** Encompasses the use of advanced telecommunications technologies to exchange health information and to provide healthcare services across geographic, time, social, and cultural barriers (Reid, 1996). Telehealth refers to all healthcare or social services, preventative or curative, delivered at a distance via a telecommunication, including audiovisual exchanges for information, education and research purposes, as well as the process and exchange of clinical and administrative data (Quebec Ministry of Health and Social Services, 2001). Homemade systems or systems used outside of official health information networks are included in the latter definition.

# African Regional Case of E-Government

## INTRODUCTION

New developments in information and communication technologies (ICTs) over the past few decades, especially the establishment of the World Wide Web in the early 1990s, have created an unprecedented capacity for people to access and retrieve information on the Internet. Such developments have also affected the way public institutions, particularly governments, provide services to their citizens in addressing the challenges of improving government efficiency, effectiveness, transparency and accountability (Allen, Juillet, Pacquet, & Roy, 2001; Allen, Juillet, Miles, Paquet, Roy, & Wilkins, 2004; Holliday, 2002; La Porte, Demchak, de Jong, 2002; UN, 2004). In addressing these challenges, applications of ICTs have been considered as one of key components in the various public sector reforms, and to some extent associated with the coining of "reinventing government" (Heeks, 2001; Ho, 2002). Thus, by the late 1990s many governments were already delivering Web-based services as "an integral and significant part of a new 'e-government' " (Ho, 2002, p. 434).

All over the world, therefore, countries and states are at the various stages of implementing e-government or digital government to improve delivery of government services to their citizens and at the same time to provide increased avenues for direct participation of citizens in addressing with their governments the citizens' development needs. In general, in all respects of implementing e-government strategies, developed countries are far ahead of developing countries (Basu, 2004; La Porte et al., 2002; Nath, 2003; Netchaeva, 2002; Singh & Naidoo, 2005; UN, 2001, 2002, 2004) due to a number of reasons that will be highlighted later in this chapter.

## E-GOVERNMENT IMPLEMENTATION IN AFRICA

Many African countries are also e-government players at different levels of e-government development (Heeks, 2002; Kaaya, 2004; Mutula, 2002; Panagopoulos, 2004; Singh & Naidoo, 2005; UN, 2004). They have presumably been driven by current social, economic, political, and technological conditions—including public sector reform programs that were tied to structural adjustment programs—to adopt the strategies (Benjamin, 2001; Cain, 2001; Heeks, 2002). Or else, these countries were motivated by benefits that other already-implementing countries have reported, such as greater and more direct interactions with their citizens and business community (Allen et al., 2001; Silcock, 2001; Stowers, 2004; UN, 2001, 2004), enhancement of civil democratic participation (Garson, 2004; Netchaeva, 2002; Panagopoulos, 2004; Silcock, 2001), possible savings in terms of service running costs and time due to speedy processes (Garson, 2004; Heeks, 2002; Whitson & Davis, 2001), improved government accountability (Alan et al., 2004; Cook, La Vigne, Pagano, Dawes, & Pardo, 2002; La Porte, et al., 2002), and the promise of more access (Garson, 2004).

Conversely, these motivating factors might not be sufficiently attractive to some African circles, as they wouldn't like to see changes to the status quo. Moreover, Heeks (2002) argues that the issue of cost savings might not hold water in Africa because salaries of the civil servants in that region are so low that it might be more costly to invest in ICTs than maintaining cheap personnel to perform various government tasks. This is contrary to the situation of developed countries where replacing costly government staff with relatively cheap ICTs might seem more attractive. But levels of African e-government participation in terms of Web content and access are closely associated with the use of the Internet and related infrastructure (For statistics about telecommunication infrastructure in Africa—including telephone lines , ISPs, bandwidth capacities, and so forth—see the UNDP's World Development Reports at http://hdr.undp.org/ and Jensen's Report at http://www3.sn.apc.org/africa/afstat.htm). Therefore, it is important to get the general picture of Internet usage in Africa before dwelling on the situation of e-government services.

According to the latest estimates from the Internet World Stats (2004), there are 12,937,100 Internet users in Africa. These figures represent only 1.4% of the continent's population, indicating low penetration level. The number of users in Africa represents 1.6% of the world's users even though the continent's population represents 14% of the world's population. However, Internet use growth between years 2000 and 2004 was 186.6% compared to the world's use growth of 125.2%;

*Table 1. Number of Internet users in Africa in comparison with other world's regions (Internet World Stats, 2004)*

| Region | Population (2004 est.) | % of World Population | Internet Users (2004) | % Use Growth (2000-2004) | Penetration (% Population) | % Users in the World |
|---|---|---|---|---|---|---|
| Africa | 893,197,200 | 14.0 | 12,937,100 | 186.6 | 1.4 | 1.6 |
| Asia | 3,607,499,800 | 56.5 | 257,898,314 | 125..6 | 7.1 | 31.7 |
| Europe | 730,894,078 | 11.4 | 230,886,424 | 124.0 | 31.6 | 28.4 |
| Latin America and Caribbean | 541,775,800 | 8.5 | 55,930,974 | 209.5 | 10.3 | 6.9 |
| Middle East | 258,993,600 | 4.1 | 17,325,900 | 227.8 | 6,7 | 2.1 |
| North America | 325,246,100 | 5.1 | 222,165,659 | 105.5 | 68.3 | 27.3 |
| Oceania | 32,540,909 | 0.5 | 15,787,221 | 107.2 | 48.5 | 1.9 |
| World | 6,390,147,487 | 100.0 | 812,931,592 | 125.2 | 12.7 | 100.0 |

*Table 2. Top ten countries in Africa in terms of number of Internet users (Internet World Stats, 2004)*

| Country | Population (04 est.) | Internet Users 2000 | Internet Users 2004 | % Use Growth (2000-2004) | Penetration (% Population) | (%) Users in Africa |
|---|---|---|---|---|---|---|
| South Africa | 47,556,900 | 2,400,000 | 3,523,000 | 46.8 | 7.4 | 27.2 |
| Egypt | 68,648,500 | 450,000 | 2,700,000 | 500.0 | 3.9 | 20.9 |
| Morocco | 30,552,000 | 100,000 | 800,000 | 700.0 | 2.6 | 6.2 |
| Nigeria | 154,491,100 | 200,000 | 750,000 | 275.0 | 0.5 | 5.8 |
| Tunisia | 10,001,400 | 100,000 | 630,000 | 530.0 | 6.3 | 4.9 |
| Zimbabwe | 14,712,000 | 50,000 | 500,000 | 900.0 | 3.4 | 3.9 |
| Algeria | 32,080,000 | 50,000 | 500,000 | 900.0 | 1.6 | 3.9 |
| Kenya | 33,520,700 | 200,000 | 400,000 | 100.0 | 1.2 | 3.1 |
| Tanzania | 36,581,300 | 115,000 | 250,000 | 117.4 | 0.7 | 1.9 |
| Cote d'Ivoire | 18,946,700 | 40,000 | 240,000 | 500.0 | 1.3 | 1.9 |

this shows that Africa is far from reaching the critical point of Internet penetration. Table 1 compares these figures with those of other world regions.

From the data, Africa is far behind all other regions whether in terms of total number of users or Internet penetration, or even the continent's contribution to the number of users in the world. The world's average Internet penetration is nine times that of Africa. Within the continent itself, South Africa has the largest number of Internet users, but its penetration of 7.4% is far below the world's average of 12.7%. Table 2 shows top ten African countries in terms of Internet usage (including North African Arabic countries).

Internet penetration figures (Table 3) provide a clearer picture of the situation, since the order of countries by total numbers of users (Table 2) tends to favor countries with relatively high population. A good example is Nigeria with 750,000 Internet users but its Internet penetration is only 0.5%, which is about one-third of Africa's average. Seychelles, which does not feature among top ten countries in terms of the Internet usage numbers, has the highest penetration in the continent (14.1% of the population has access to the Internet). Thus, if the countries are rearranged according to their levels of Internet penetration instead of the total number of users, then the top-ten list is altered as shown in Table 3 (excludes colonies). Only Seychelles is above the world's average by 1.4 percentage points.

These figures, which The Internet World Stats obtained from a variety of sources, provide the general picture of Internet usage in Africa. It is hard to obtain precise figures in Africa due to the nature of usage in

*Table 3. Top 10 Internet users in Africa in terms of penetration (% of population with access) (Internet World Stats, 2004)*

| Country | Population (04 est.) | Internet Users 2000 | Internet Users 2004 | % Use Growth (2000-04) | Penetration (% Population) | (%) Users in Africa |
|---|---|---|---|---|---|---|
| Seychelles | 81,600 | 6,000 | 11,700 | 95.0 | 14.1 | 0.1 |
| Mauritania | 1,265,000 | 87,000 | 150,000 | 72.4 | 11.9 | 1.2 |
| Sao Tome and Principe | 139,000 | 6,500 | 15,000 | 130.8 | 10.8 | 0.1 |
| South Africa | 47,556,900 | 2,400,000 | 3,523,000 | 46.8 | 7.4 | 27.2 |
| Tunisia | 10,001,400 | 100,000 | 630,000 | 530.0 | 6.3 | 4.9 |
| Cape Verde | 463,600 | 8,000 | 20,400 | 155.0 | 4.4 | 0.2 |
| Egypt | 68,648,500 | 450,000 | 2,700,000 | 500.0 | 3.9 | 20.9 |
| Zimbabwe | 14,712,000 | 50,000 | 500,000 | 900.0 | 3.4 | 3.9 |
| Morocco | 30,552,000 | 100,000 | 800,000 | 700.0 | 2.6 | 6.2 |
| Algeria | 32,080,000 | 50,000 | 500,000 | 900.0 | 1.6 | 3.9 |

which individual ownership of the Internet accounts is minimal and many users share single access points—especially public and institutional networks (Heeks, 2002; Jensen, 2002). Jensen underlines this point:

*Because of the large number of shared accounts, and the high use of public access services, it is difficult to measure the total numbers of Internet users. While the number of dialup subscriber accounts is readily available, these figures are only a partial indicator of the size of the Internet sector and should be looked at along with other factors such as the quantity of international traffic each country generates and the extent of the local Internet infrastructure…large scale sharing of information resources is a dominant feature of the African media landscape* ... (http://www3.sn.apc.org/africa/afstat.htm)

Despite the dismal situation of the Internet, usage in Africa there is an overall increase in the presence of Africa's Web content although the continent's share of such content is still low, reflecting trends of Internet usage caused by a multiplicity of factors (Heeks, 2001, 2002; Jensen, 2002; Mutula, 2002; Sy, 1999). Still, most of the countries have official government Web sites (UN, 2004) in addition to several other Web sites created by different government agencies, but most of them are in their early stages of development.

In his discussion of the status of African Web content, Mutula (2002) underlines the importance of the quality of information posted on the Web and such quality can be assessed using such measures as interactivity with the users, currency, accurate and rich downloadable materials, and community-oriented content. The measures can be used to determine the status (development stage and quality) of government Web sites by matching the results with existing models. One of the models, developed by the United Nations, Department of Economic and Social Affairs (DESA), Division for Public Administration and Development Management, describes five stages of e-government development (UN, 2002, 2004) as (1) emerging presence, (2) enhanced presence, (3) interactive presence, (4) transactional presence, and (5) seamless or fully integrated/networked presence (see the article on development stages of e-government for details). In 2002, 20 African countries were in the first stage, 16 in the second stage, four (Egypt, Mauritius, Morocco, and South Africa) in the third stage, while no African country had its e-government services matured enough to go beyond the third stage. The 2004 report shows that Mauritius has reached the fourth stage, as the country now provides many online services and transactions including tax filing (UN, 2004).

The UN-DESA has also benchmarked the member states of the UN using the status of their Web sites, telecommunication infrastructure and human resources to develop the e-government index (UN, 2002) or e-government readiness index (UN, 2004). The report on the e-government readiness index was accompanied by the results of an assessment on e-participation that deals

*Table 4. Regional comparison of e-government readiness indices (UN, 2004)*

| Region | E-Government Readiness Index | Region | E-Government Readiness Index |
|---|---|---|---|
| North America | 0.875 | Western Asia (incl. Middle East) | 0.409 |
| Europe | 0.587 | South & Central Asia | 0.321 |
| South & Eastern Asia | 0.460 | Oceania | 0.301 |
| South & Central America | 0.456 | Africa | 0.253 |
| Caribbean | 0.411 | **Global Average** | **0.413** |

*Table 5. E-government readiness indices of the top ten African countries (UN, 2004)*

| Country | E-Government Readiness Index | Country | E-Government Readiness Index |
|---|---|---|---|
| Mauritius | 0.5055 | Cape Verde | 0.3442 |
| South Africa | 0.4902 | Uganda | 0.3290 |
| Seychelles | 0.4259 | Namibia | 0.3272 |
| Botswana | 0.3827 | Lesotho | 0.3250 |
| Swaziland | 0.3647 | Algeria | 0.3248 |
| **African Average** | **0.2528** | | |
| **Global Average** | **0.413** | | |

with involvement of citizens in decision-making processes via e-government activities. In these assessments, African countries are behind other countries; the situation is reflected in the average figures of the world regions on the e-government readiness index (Table 4). Table 5 shows the top ten African countries in terms of their e-government readiness indices.

The UN has also classified various regions and sub-regions according to progress of their government Web sites. Although the groupings of sub-regions of Africa is debatable (e.g., placing Zambia and Zimbabwe under eastern Africa, and Angola under "middle Africa" while these three countries are in the southern African region), the scores reflect the real regional disparity in e-government development: the African region had the lowest average score of 31.9, which is only 13% of the highest scoring region, North America (Table 6).

Furthermore, the UN has benchmarked its member nations in terms of percentage utilization of the five development stages of e-government, and classified the countries into three categories: High Range (average percentage utilization 67-100%); Mid Range (34-66%) and Low Range (0-33%). With the exception of Mauritius and South Africa, all of the African countries fall under the Low Range category. Globally, there are 16 countries in the High Range category, 48 in the Mid-Range, and 114 in the Low Range category. Mauritius utilizes the stages of e-government at 100% (stage 1), 73.6% (stage 2), 69.0% (stage 3), 17.1% (stage 4), and 7.4% (stage 5), with an average utilization of 51.1%. South Africa's utilization scores are 100% (stage 1), 80.5% (stage 2), 55.4% (stage 3), 0% (stage 4), and 16.7% (stage 5), with an average score of 48.7%. The United States leads the world in utilization: 100% (stage 1), 97.7% (stage 2), 94.0% (stage 3), 92.7% (stage 4), and 77.8% (stage 5), with an overall average of 92.0%. Forty-five out of 54 African countries have national official Web sites while, according to the UN, seven African countries—the Central African Republic, Equatorial Guinea, Eritrea, Guinea Bissau, Liberia, Libya, and Zambia do not have government Web sites.

Countries that have e-government have adopted the strategies as a result of a number of factors, both internal and external. The external factors have been associated with donor-funded projects that attempt to streamline government structures to improve its efficiency. There are mixed reports on the levels of success of specific implementation programs of individual countries (Benjamin, 2001; Cain, 2001; Heeks, 2002; Kenhango, 2003). Kenhango (2003) reports a project initiated by the Cameroonian Government through its tax department using a Web-based system to improve its tax system. The project aimed to provide the citizens and the business

*Table 6. Government Web site scores of Africa and its sub-regions in comparison with other regions of the world (Adapted from UN, 2004)*

| Region/Sub-Region | Representative Countries | Total Score | Average Score |
|---|---|---|---|
| Eastern Africa | Burundi, Comoros, Djibouti, Eritrea, Ethiopia, Kenya, Madagascar, Malawi, Mauritius, Mozambique, Rwanda, Seychelles, Somalia, Uganda, Tanzania, Zambia, Zimbabwe | 534.0 | 31.4 |
| Middle Africa | Angola, Cameroon, Central African Republic, Chad, Congo, DRC, Equatorial Guinea, Gabon, Sao Tome and Principe | 163.0 | 18.1 |
| Northern Africa | Algeria, Egypt, Libya, Morocco, Sudan, Tunisia | 226.0 | 37.7 |
| Southern Africa | Botswana, Lesotho, Namibia, South Africa, Swaziland | 359.5 | 71.9 |
| Western Africa | Benin, Burkina Faso, Cape Verde, Côte d'Ivoire, Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, Togo | 407.5 | 25.5 |
| Africa | 53 countries | 1690.0 | 31.9 |
| Asia | 47 countries | 3513.0 | 74.7 |
| Caribbean | 13 countries | 598.0 | 46.0 |
| Central America | 8 countries | 757.5 | 94.7 |
| North America | 2 countries | 485.0 | 242.5 |
| South America | 12 countries | 1350.5 | 112.5 |
| Europe | 42 countries | 5487.0 | 130.6 |
| Oceania | 14 countries | 728.0 | 52.0 |

community with the information on tax regulations; reduce the cost and improve the precision of tax collection processes; enhance transparency, hence reducing corruption; and initiate dialogues between the tax department and its stakeholders, notably, citizens, businesses, and scholars. The first step in that project was the establishment of a Web site in November 2001 with all the information needed to facilitate tax related activities for both parties. Kenhango notes that the project registered some progress in educating taxpayers about various tax procedures and that after some six months the Web site had received 3,500 hits and 150 downloaded documents. However, its impact was not felt much because of low internet penetration in that country (less than 3%), lack of skills, lack of online interactivity with the taxpayers, and resistance from some of the tax department's staff.

Benjamin (2001) reports several projects in South Africa that endeavored to use information technology to enhance community development and democratization as part of wider public reform strategies that also aimed to improve efficiency and accountability. Throughout that country, multipurpose community centers (equivalent to telecenters) have evolved as important access points for information, including government information in electronic form, by the general public. The projects had varying degrees of successes and failures, though I think it would appear too early for the ICT-government-based strategies to have matured enough for concrete evaluation of their impact (Gupta & Jana, 2003) have also observed this in India). Failures occurred when the services offered did not address community needs and when they lacked sustainability strategies. There are other projects that can be considered as types of e-government strategies in Africa, such as those reported by Cain (2001) in Ghana, Uganda, and Zimbabwe, Heeks (2002) in several countries, and ongoing telecenter development along with community-based initiatives in promoting ICTs for good governance in Tanzania, but the experiences reported are more or less similar because most African countries share similar problems and challenges (These projects are under the coordination of the Commission for Science and Technology of Tanzania; see http://

www.costech.or.tz for details). Problems, challenges, and possible strategies for solutions will be discussed in the next section.

## CHALLENGES FACING AFRICAN COUNTRIES

To realize potential benefits associated with the implementation of e-government strategies, African countries need to address many challenges associated with prevailing conditions in the continent. Some of the problems have been previously highlighted in the brief descriptions of e-government case projects. Although many of the African problems are related to poor economic conditions, one can also argue that problems of access are related to poor priority setting when it comes to investment plans. One of the fundamental requirements for successful implementation of e-government and related services is to ensure that essential infrastructure is in place, including reliable telecommunications services and power supply for connectivity, as well as necessary hardware and software for implementation. Those must go hand in hand with human resources that are sufficiently skilled to collect, organize, disseminate and preserve government information, and, above all, to maintain a system that should also have sufficient archival and security infrastructure (Abie et al., 2004; Adam, 1996; Jaeger & Thompson, 2003; Jensen, 2002; Probir & Chau, 2004; UN 2001, 2004; Yee et al., 2005). Fulfillment of these requirements, along with users' education, will improve delivery of, and citizen's access to government information.

As clearly signified by the Internet usage statistics at the beginning of this article, as well as the stages of e-government and the only partial successes of the case studies, access barriers are more pronounced in Africa than in other developing countries (Adam, 1996; Akst & Jensen, 2001; Basu, 2004; Jensen, 2002; UN, 2001, 2002, 2004). Mutula (2002) discusses the contribution of Africa to global Internet content and cites such problems as poor telephone and power supplies; disparity in infrastructure development between urban and rural areas; English dominated Web content which is only understood by a minority elite (the UN's 2004 survey shows that 60% of government Web sites are in English); low literacy levels; and uncoordinated e-government activities, as key problems facing Africa. Similar problems have been noted by Kenhango (2003) in the case of Cameroon described above, as well as Cain (2001), Benjamin (2001), Heeks (2002), and Jensen (2002). If not addressed forcefully they will exacerbate the digital divide problem both nationally and internationally.

Thus, any successful implementation of e-government services should go hand in hand with strategies to narrow the digital divide, which entail addressing the many challenges and problems mentioned in this section.

Poor infrastructure and associated high tariffs have also resulted in high access charges in Africa. For instance, Jensen (2002) notes that, in Africa, the average charge of a local dial up Internet service for 20hr/month is about $60, compared to $22 in USA and $33 in Germany, where per capita income is more than ten times that of African. Many people resort to public access points since they can not afford equipment and connection charges.

Committed leadership and political will are important because they reflect government's willingness to commit enough resources in support of e-government services for their sustainability, let alone the creation of suitable environments for infrastructure development. In this connection, some leaders might resist the adoption and implementation of e-government strategies in fear of changes in existing government structures (Allen et al., 2001).

Addressing the above challenges is just a step toward full-fledged e-government strategies since there are other factors that influence the use of Web-based and other services. These include user-friendliness; currency, accuracy, and reliability of information provided; availability of back information; privacy of user-submitted data and data on individual citizens; and general interactivity of such services as Web-based transaction facilities and prompt responses from government officials in answering users' queries (Gilliland, personal communication; Holliday, 2002; Kaaya, 2004; Silcock, 2001).

## LOOKING FORWARD AND CONCLUSION

This author often cites Silcock's (2001) remark that, "One of the fundamental differences between e-government and e-business is that whereas business can, by and large, choose their customers, government cannot. For e-government to succeed fully, the dream of Internet access for all has to become a reality" (p. 94). Indeed, African countries need to work harder than ever before to realize that dream and the promise of digital government (as outlined by Garson, 2004). There are various initiatives taking place in individual countries as well as among regional and international groupings to address problems of access. For instance, the UN's Economic Commission for Africa, through the African Information Society Initiative (AISI) and other related initiatives is encouraging African countries to develop and implement national plans for information and communication infrastructure. Nearly half of African nations have developed such plans

and the ministerial statement of the 34th session of the Commission states, "Information and communications technologies hold the promise of enormous positive influence on our countries' economic and social development" (See http://www.uneca.org/aisi/nici/country_profiles/default.htm, accessed on October 17, 2005.) Additionally, Jensen (2002) observes that the African Union in collaboration with the international community under the program, New Partnership for African Development, is addressing many issues in order to speed up development. Observers hope that the program will accelerate adoption of ICT-related strategies and thus improve access to information. Jensen reports that key issues being addressed include erratic (or non-existent) power supply; tax regimes that render such devices as computers, telephone connections, cell phones, and other ICT-related equipment, peripherals and services unaffordable by average citizens; brain drain, low education and literacy levels, and lack of skills; and an unfriendly business environment for increased investment in the ICT sector caused by poor policies and institutional structures.

Several other initiatives related to training on Internet applications. These are offered by universities and private companies in Africa, or supported by various international organizations such as the UNDP and other UN agencies, USAID, IDRC, the World Bank, and various NGOs. There are also several intergovernmental regional and international agencies that have incorporated ICT-related initiatives in their strategic development plans to benefit member nations. These include the African Development Bank, COMESA, IGAD, the East African Community, the West African Economic Cooperation, and the Commonwealth Secretariat, to mention but a few.

One promising trend in Africa is increasing access to wireless telecommunication technology, which is opening up the potential for accessing the Internet and associated services via the mobile phones (Minges, 2004). In many countries of Africa, the density of cell phones outnumbers that of fixed telephone lines. The use of short message service or SMS on mobile phones is now popular in many African countries; this is a precursor to full Internet access via cellular technology. With the advances in the third generation (3G) of the cellular technology, the potential for more access to the Internet—including people's interaction and use of e-government services—is imminent, even from remote rural areas.

It is generally presumed that adoption and implementation of e-government strategies will continue to be a gradual or evolutionary process, and that levels of service provision will differ from country to country and from one government agency to another in the same country. Thus, the prevailing e-government services in Africa are unlikely to include the whole range of services that exist in developed countries. The gradual development of e-government services will be complementary to traditional provision of government services. This is because there are services that will continue to be more effectively provided through traditional means—especially in the printed paper media and face-to-face communication—which is a deeply-rooted culture that will take years to disappear, not only in Africa (no wonder many voters in the United States want the printed versions of electronic ballots).

Finally, along with the promise of e-government in Africa, it is also necessary to keep in mind the limitations of electronic media from the perspective of preservation and persistence of information, along with security and privacy issues. These issues pose challenge to all of the countries that have adopted e-government strategies worldwide and are a subject of debate among scholars in this subject (Collada, 1999; Gilliland, personal communication; Karim & Khalid, 2003). Such limitations require clear policies on the necessary infrastructure to address them. Of particular interest to researchers focusing on the emerging e-government services in developing countries including Africa, this researcher has raised1 the following important issues for discussion: (a) A shift from paper to electronic media and more government control—what will happen if the Web-based information disappears? Are there institutions that are providing parallel paper-based information? (b) What is the degree of political stability and will it affect e-government services? (c) Is there a safe harbor for information—free from hacking? What is the ability of the governments to deliver e-government services (e.g., in terms of equipment, power supply, skills, etc.)? (d) Are there standard methods of assessing the status of e-government services? (e) Are there reliable methods of determining the Internet usage in both the urban and remote areas (owing to the magnitude of use via public access points)?

Strategies to overcome the digital divide should initially focus on improving and expanding public access points, since individual ownership of the facilities for access is not feasible for the majority of the African population in the near future. Heeks (2002) goes further to suggest the need for intermediaries to assist in bridging the digital divide for many people who "are not direct owners nor direct users of ICTs." As noted in the preface of the *Global E-Government Readiness Report 2004: Towards Access for Opportunity* (UN 2004),

*The challenge for development today is to find ways and means to surmount the inequality in development benefits from new technologies.*
*The new paradigm of development requires a re-visitation of the way countries think about ICT and e-government. It needs innovative approaches to government and the*

*public sector; business and the citizen; and culture and society. A holistic approach is required which fully exploits the centrality of ICT for the vision of a future knowledge society.* (p. i)

Furthermore, the UN calls on governments to adopt "access for opportunity" as a policy goal, to direct efforts on knowledge societies, and to recognize the importance of ICTs for development by including them in their national plans.

## KEY TERMS

**Adoption:** A decision to make full use of an innovation as the best course of action available (Rogers, 2003).

**Digital Divide:** The gap between those who can effectively use information and communication tools such as the Internet, and those who cannot (Digital Divide Network).

**E-Government Implementation Strategies:** All of the activities involved in executing e-government services such as hardware/software acquisition and installation, personnel and user training, creating government Web sites, e-government service delivery, and so on.

**Information and Communication Technologies (ICTs):** "The technology used to handle information and aid communication." (Hyperdictionary.com)

**Information Technology (IT):** "Applied computer systems—both hardware and software, and often including networking and telecommunications, usually in the con-

text of a business or other enterprise" (hyperdictionary.com)

**Internet Penetration:** The proportion of a population, usually expressed in percentage, that has access to the Internet.

**Multipurpose Community Centers (MCC):** Organizations offering a range of development services (including information services) to a specific community with a large degree of community involvement (Benjamin, 2001)

**Telecenter:** "A multifunctional office area outfitted with communication and information processing equipment using computer assets with access to telecommunication networks" (Telecentro)

**Teledensity:** The number of telephone lines per number of people.

# Alive and Interactive through Streaming Media

**Mindy Anneli Lassila**
*Indian and Northern Affairs Canada, Canada*

## INTRODUCTION

The advent of new technologies in organizations has created unprecedented challenges for professionals and managers alike to explore several cost-effective technology solutions aimed at improving communications among their target audiences. One such technology, which is gaining popularity, is streaming media. Streaming media has been around for approximately 10 years, but only now is becoming the fastest growing IT sector, with real revenues and a bright future (Alanko, 2004).

Streaming media is a delivery technology that has great potential for enhancing the way people communicate and share information. The evolution of streaming media has made huge strides in the world of the Internet, from a medium which delivered unstable video streamed very slowly through inadequate networks, to one today that rivals the reach in some cases of small cable television channels and local market radio stations.

The use of streaming media is becoming a mainstream communications tool in the public sector. It has the ability to enhance communications both internally and externally (i.e., important announcements, bulletins, community outreach, online learning, training, etc.). Many government departments have started offering live and archived Webcasting of numerous government meetings and programs via the Internet. Whereas outreach has previously been strictly limited to certain individuals, information is now being made available to a wider audience through the use of streaming media.

## BACKGROUND

In general, the terms Webcast and streaming media are used interchangeably. Webcasting covers all the steps in producing an online broadcast from capture and encoding of content through to delivery. A Webcast is a presentation in which a live event is recorded and streamed over the Internet, or archived for viewing at a later time. Streaming media refers to the software that actually delivers the Webcast to the user's desktop media player over the Web. Streaming media was developed to compress and transfer video and/or audio data through a computer in such a way that the file could start to play while downloading (Improvement and Development Agency & Xpedita Limited, 2003). Similar to a live newscast, a live Webcast has the capability to dynamically communicate information and ideas in real time. Unlike media files that are downloaded as large units and saved to your hard drive where they take up disk space, streaming media is sent in a continuous "stream" and played piece by piece as it arrives.

Streaming media as a delivery method allows people across the country and around the world with Internet access to participate in an event. The vast majority of new model PCs come equipped with everything required to view a Webcast. Users require an Internet connection, a sound card and speakers, and a media player program which is downloadable from the Internet. A media player program enables viewers to see and hear streaming media content. These players stream prerecorded and live media over the Internet, and can play back media that has been saved to disk.

## HOW DOES STREAMING WORK?

Although streaming media may seem quite complex to those who are not technologically savvy, it is all really based on these four simple steps (Adobe Dynamic Media Group):

1. The end user selects a media file, causing a request to be sent to the Web server.
2. The Web server relays the request to the media server.
3. The media server streams the media file back to the end-user's computer.
4. The client, or "player," decodes and plays back the media file.

## WHO IS USING STREAMING MEDIA?

Demand for Webcasting has increased widely in the past 2 years from government departments to large private sector corporations wishing to reach shareholders and organizations over vast areas. With the development and growth of the Internet, media delivery has been revolutionised making distance and location irrelevant.

Government departments are faced with the considerable task of communicating important policy, program and security information to internal and external clients. As a result, many government departments have started to Webcast key presentations, speeches and conferences on their Internet and intranet sites. This is possible largely due to boosts in broadband connections across government departments, organizations, educational establishments and households, along with advances in digital compression and video production technology.

Indian and Northern Affairs Canada (INAC) implemented streaming media as an in-house service for departmental employees in early 2002. Prior to implementation the department profiled target audience members to determine application needs and quality requirements. The profile showed a strong growth potential for streaming media within the department.

INAC projects have been aimed at conveying messages to both internal and external audiences. Messages from senior management, national workshops and training sessions are a few of the internal Webcast projects that have been undertaken. Connecting Youth in Canada was a Webcast project targeted for external audiences, specifically high schools, educators and other government departments. It encompassed a series of four, 30 minute live Webcasts streamed from Aboriginal communities across Canada (some remote). The project was aimed at getting Aboriginal and non-Aboriginal youth talking about issues and concerns that matter to them. Viewers were able to interact and express their thoughts with students in real time via e-mail.

From a market that was nonexistent, huge strides have been taken to make streaming media a success within INAC. The latest advances in audio and video streaming technology have been utilized to deliver conferences, seminars, speeches, corporate meetings and other business presentations over INAC's departmental Intranet and corporate Internet sites.

In August 2004, an online survey was posted to the departmental Intranet Web site to help determine the perceptions and experiences that INAC employees have towards Webcasting. Survey responses show that Webcasting is a tool that most INAC staff believes would be of benefit to them and their sectors/branches. Furthermore, many responded that Webcasting is an inevitable technology, which they would like to learn more about.

## BENEFITS

Streaming media is gradually emerging as the cornerstone of effective enterprisewide communication and knowledge sharing. There are several benefits of streaming media, one of which is the use of the technology as an e-learning tool. Streaming media has great potential value for creating interactive and engaging presentations, training applications and business communications. Users have the ability to capture and synchronize audio, video, slides and imaging to create rich-media presentations, which can be made available to the desktops of live target audiences.

*Table 1. Benefits of streaming media*

- Easy to understand and use
- Integrated and interactive
- Conducive to cooperative work environment
- Flexible
- Supportive of a large audience
- Improved information experience
- Unmatched knowledge sharing
- Consistent messaging delivered to multiple audiences
- Decreased travel, communication, and training costs
- Increased productivity
- Improved customer service
- Stronger, more developed corporate culture
- Direct transmission of communications to the desktops of targeted audiences
- Quick (do not have to wait for complete download of video)
- Continuous feed without interruption
- Video is not saved to hard drive
- Video and/or audio can be delivered live and archived simultaneously
- Video and/or audio can be delivered live and translated simultaneously

People using this technology have the opportunity to promote their organization, department or product online. The media player is an excellent place to post graphic identifiers, Website links and contact information, resulting in increased awareness and recognition. Furthermore, Webcasts give viewers more opportunities to express themselves via e-mail. Viewers have the opportunity to e-mail questions, concerns and suggestions during live and on-demand events. Viewer participation bonds users to the event by giving them a sense of importance and membership. It also gives viewers the sense that they are right there in the studio. Televised events are generally cut down to fit the scheduled time window of the network. Webcasts can portray a live event in its entirety, unedited, so viewers feel like they have a front-row seat on the action (ClearStreaming, Inc. & NeuronBroadCasting.Com, 2001). Additionally, streaming media provides event organizers with the potential to capture a worldwide audience without the associated costs of conventional broadcasting. Streaming media is a very effective and affordable marketing tool (Rhodes). A number of other benefits are listed in Table 1.

Although there is no replacement for in-person interaction, streaming technology is rapidly emerging as the next best alternative.

## SOME RELUCTANCE STILL EXISTS

With the introduction of any new technology, reluctance to adopt it is frequently observed. Although Webcasting has been present in the IT sector for many years now, there is still a high percentage of potential consumers who are not aware that the technology exists. Potential customers do not know, nor do they always have time to find out, how to make Webcasting work, especially when they are not familiar with the technology. Therefore, many potential Webcasting consumers find it easier to have a teleconference or have an on-site seminar no matter how much more expensive it is (Alanko, 2004). Moreover, some people may feel intimidated by the technology. It is quite possible that potential users simply overestimate the complexity of streaming media.

Another reason people may be reluctant to use streaming media stems from the conception that it costs too much. Because streaming media is a relatively new tool in corporate communications, it is often misunderstood as a service that is too expensive, or only for larger companies. In many cases streaming media can be less expensive and more effective than its print, broadcast and telecommunications counterparts. It all depends on the scope and objectives of the communications strategy.

As streaming media continues to capture larger segments of public sector and corporate environments, awareness and acceptance of the technology will increase. The good thing is that the technology necessary for successful Webcasting already exists and is quite well developed (Alanko, 2004). Streaming media has evolved immensely since its introduction to the Internet. There have been vast improvements in both compression and quality that will have positive effects on consumers' experiences. The quality of standards-based streaming video now rivals, and sometimes surpasses, conventional broadcast television. The three principle technology standards for streaming—MPEG-1, MPEG-2, and MPEG-4—are all capable of delivering high-quality streaming media over virtually any network today (Mavrogeanes, 2004).

## FUTURE TRENDS

Webcasting will have an important part to play in the way institutions communicate with their audiences in the future. Already, the growth of Webcasting has been far greater than expected. As high-speed Internet becomes more prevalent and the quality of Web-based video improves, it is expected that Webcasting will become even more popular in the home and work environment. Research conducted by various companies indicates that more people are watching video online than ever before. Research has concluded that:

- By 2006, 80% of the top 2000 businesses worldwide are expected to deploy video applications to employees' desktops
- By 2006, video streaming at work will be worth $200 million
- By 2005, worldwide revenue for streaming media services will exceed $5 billion (Brainware TV, 2004)

## CONCLUSION

Today's computer systems are far more than computational and text processing tools. Internet streaming and broadband markets have seen tremendous growth since 1995, and they continue to grow. The Internet market grows by at least 85 million users per year, with about 5% to 10% of that number accessing broadband Internet at work, at school, or at home (Multimedia Research Group, 2001). As people become more comfortable with Internet Web technology, an increase in the demand for streaming media services will almost certainly be observed. Many government departments have already embraced the power of streaming media to deliver corporate communications and training directly to users' desktops. Streaming a wide variety of announcements via the Internet is quickly becoming the new standard for the dissemination of government related information.

Streaming media is no longer a minor player in the world of technology. Statictics show it is being used and consumed on a broad and ever-expanding scale (Tyler, 2005). Many corporations have considered introducing streaming media into their work settings for quite some time; however, it is something that must be implemented carefully in order to obtain acceptance from users. With a video camera, some imagination and the proper equipment, streaming media can deliver leading edge interactive communications within a global context, and, in fact, it is not even limited to this planet.

## KEY TERMS

**Broadband:** This refers to any telecommunication including Internet access in which a wide band of frequencies are available to carry information. The large number of frequencies means that information can travel at faster speeds than narrowband access.

**Broadcast:** When data is sent to all work stations on a network at the same time.

**E-Learning:** The delivery of a learning, training or education program by electronic means. eLearning involves the use of a computer or electronic device in some way to provide training, educational or learning material. eLearning can involve a greater variety of equipment than online training or education, for as the name implies, "online" involves using the Internet or an intranet. CD-ROM and DVD can be used to provide learning materials.

**Encoder:** A software application or a device (hardware) used to encode – that is, compress and format digital video or audio.

**Encoding:** A technical term used to describe the compression of media files into specific formats (i.e., Real Media, Quicktime, Windows Media)

**Information Technology (IT):** The branch of technology devoted to (a) the study and application of data and the processing thereof; that is, the automatic acquisition, storage, manipulation (including transformation), management, movement, control, display, switching, interchange, transmission or reception of data, and (b) the development and use of the hardware, software, firmware, and procedures associated with this processing.

**Internet:** A worldwide system of computer networks in which any one computer can get information from/or talk to any other connected computer using the TCP/IP protocols.

**Intranet:** A private network inside a company or organization that uses the same kinds of software that you find on the public Internet, but which is only for internal use.

**Media:** A term with many different meanings, in the context of *streaming media*, it refers to video, animation, and audio. The term "media" may also refer to something used for storage or transmission, such as tapes, diskettes, CD-ROMs, DVDs, or networks such as the Internet.

**Media Player:** An application that enables users to play audio and video files on their PC.

**Media Server:** Specialized server software that takes advantage of appropriate Web transfer protocols such as RTSP (real time streaming protocol), as well as special communication techniques between clients and servers, to facilitate the continuous playback of synchronized audio and video in real time, adjusting the streams transmitted to the actual bandwidth available. Media server software may be running on discrete hardware, or can be deployed in combination with Web server software running on the same device.

**MPEG:** Motion Pictures Expert Group of the International Organization for Standardization (ISO) has defined multiple standards for compressing audio and video sequences. Setting it apart from JPEG which compresses individual frames, MPEG compression uses a technique where the differences in what has changed between one frame and its predecessor are calculated and encoded. MPEG is both a type of compression and a video format. "MPEG-1" was initially designed to deliver near-broadcast quality video through a standard speed CD-ROM. Playback of MPEG-1 video requires either a software decoder coupled with a high-end machine, or a hardware decoder. "MPEG-2" is the broadcast quality video found on DVD's. It requires a hardware decoder (e.g., a DVD-ROM player) for playback. "MPEG-4" is a relatively new standard, now being used in some architectures for streaming media.

**Network:** A network is a number of computers connected together to share information and hardware.

**Streaming Media:** A technology developed to compress and transfer video or audio data through a computer in such a way that the file can start and play while it is downloading.

**Teleconference:** Live, two-way audio transmission between two or more locations. Usually includes speaker phones and microphone amplification systems that allow audio volume balancing for people at different locations from the microphone.

**Video-on-Demand:** Describes video content which may be viewed by the end-user whenever they want, any time of the day or night. A prerecorded Webcast.

**Webcast:** A presentation in which a live event is recorded and streamed over the Internet, or archived for viewing at a later time.

# American E-Government Service Sectors and Applications

**Donna Evans**
*Miami University, USA*

**David C. Yen**
*Miami University, USA*

## INTRODUCTION

Citizens routinely use technology to increase the efficiency of their transactions in every area of their lives. It is, therefore, logical that citizens expect technology to be used to improve the efficiency of their transactions with their government. In response, the United States government has developed electronic interfaces combined with the Internet called electronic government or e-government. E-government is the communication between the government and its citizens, businesses or itself by the use of computers and a Web-enabled presence.

## BACKGROUND

Government departments were once commonly held to be inefficient because they had little motivation to please the citizen, and the citizen did not have an alternative provider available for these services. E-government represents an opportunity to serve the interests of the government and the citizen because it allows one point of contact at a convenient time. In addition, it allows the government to process information more efficiently and collect data while doing so.

As the scope of government increases, so does the tax burden on the citizen. One of the greatest opportunities to reduce costs is by increasing the efficiency of services delivered. Given that 60% of all current Internet users interact with government Web sites, e-government represents a logical way to reduce transaction costs (E-Government Task Force, 2002). These savings can be realized with virtually no cost to train the citizen, as many citizens are already Internet proficient and have provided the equipment in their own home at no cost to the government. The purpose of this study is to investigate the state of e-government in the United States by examining sectors served by e-government and by reviewing a sample of applications currently in use.

## E-GOVERNMENT SERVICE SECTORS

Creation and maintenance of e-government structures will result in significant technology spending for the foreseeable future. In order to focus these efforts the president of the United States has announced the following e-government goals: increased ease of access for citizens, increased responsiveness to citizens, and increased government efficiency (E-Government Task Force, 2002). The United States government organizes service sectors into four service opportunities as presented in Table 1 (E-Government Task Force, 2002).

*Table 1.*

| Service Opportunity by Sector | Acronym |
|---|---|
| Government to Citizen | G2C |
| Government to Business | G2B |
| Government to Government | G2G |
| Intra-Government<br>Internal Efficiency and Effectiveness | IEE |

### Government to Citizen (G2C)

This service sector focuses on the ability of the government and citizen to communicate information to each other in an efficient electronic manner. One of the most popular benefits of G2C is the simple posting of forms and registrations that were previously available only to those who were willing to wait in line or await mail delivery. Another benefit is the ability to monitor performance such as public schools testing results. Other examples of benefits are prisoner security, voting and jury selection.

### Government to Business (G2B)

This sector focuses on the transactions between government and business with the objective to reduce cost and gather more accurate information. The purpose of this category of service is to allow the government to purchase items, pay invoices, and conduct business more cost effectively, as well as to assist in obtaining data to analyze to assist in decision-making. A goal for this sector is the posting of online regulations for agencies and increasing the electronic tax capabilities for business (i.e., filing W2s on the Internet). Another objective is to consolidate trade information for export/import data, and create a "business compliance" information center. This center will help businesses to check in one place for health, safety, employment, environment, and tax rules (United States International Trade Commission, 2002).

### Additional Private Business Issues

The government-to-business relationship can be extended beyond the need for the government to purchase services. Businesses, such as healthcare or pharmaceutical companies, may need to monitor research or rulings posted by the Federal Drug Administration or may need to examine employment requirements, tariffs and other general information required for business support. Such information could be posted online for easy access.

### Government to Government (G2G)

The government-to-government sector strives to improve the efficiency of service when transacting information between local, state, and federal levels of government. E-government applications benefit this sector by increasing capabilities in terms of crime detection, emergency response systems, law enforcement, and homeland security. An example of this government to government transaction would be to coordinate disaster site information during a crisis by using technology at local, state and federal levels of government.

### Intra-Government Internal Efficiency and Effectiveness (IEE)

This sector concentrates efforts on creating efficient and cost effective systems, particularly supply chain issues. IEE differs from G2G sectors in that its focus is coordination of resources to increase the efficiency of back-office systems. Recent examples of success in this sector were the Department of Transportation Online University that was implemented to reduce training expenses and the creation of an E-payroll system that is projected to save over $995 million in expenses. Other current projects are recruitment one-stop, enterprise HR integration, e-clearance, e-travel integrated acquisition environment and e-records management (White House E-Gov-Internal Effectiveness, 2004).

## SECTOR ANALYSIS

The four service sectors are a form of organization, and specific applications may combine elements of more than one sector. For example, jury selection application could involve all four sectors of service delivery. Jury selection involves the G2C sector (contacting citizens), the G2B sector (using software from the business community), and the G2G sector (coordinating information with the Justice Department and Bureau of Motor vehicles) and the IEE sector (ensuring that jury selection was completed efficiently).

## CURRENT APPLICATIONS

United States e-government applications are multiplying as electronic transactions become the norm. The United States information technology budget was $50 billion in 2004, and it is hoped that this will cause increased efficiencies, thereby driving down costs (Resources for the President's Team, 2004). The context of American e-government is best understood by reviewing the following examples of specific applications.

## Education

Publicly funded education is an important service provided by the United States government (White House E-Gov-Internal Effectiveness, 2004). The enhancement of education with e-government is an important opportunity to improve the educational experience, increase access and accountability while reducing expenses. Public school information is compiled on a national, state, school district, and building level and will give parents the ability to understand how well their school is performing compared to others. Another opportunity for e-government enhanced education is distance learning. All age groups could benefit from new applications that permit access to education despite geographic location or physical disabilities. Distance learning will also assist senior citizens who have difficulty leaving their home but wish to continue their learning. Many universities have distance-learning proposals being developed at this time.

## Prison Guard Systems

Some prisons are now equipped with electronic monitoring systems that track the location of its inmates. Each prisoner wears an electronic bracelet that transmits a unique radio signal every two seconds. If the inmate approaches an area that is forbidden to him, alarms go off. A display monitor shows the identity and location of all inmates and officers. The information is recorded and archived so information can be retrieved as necessary (Wong, 2002). This application of e-government increases efficiencies as citizens do not want tax money to be spent on prison personnel, but want prisoners safely contained. The archived record of activity between prisoners and guards allows clear analysis of any problems and may prevent frivolous and expensive lawsuits (Wong, 2002).

## Tracking and Money Laundering Systems

The ability to track currency and securities movements translates into more information available for investigators but raises substantial personal privacy issues. As more citizens engage in online transactions the potential for abuse grows. Studies show in the year 2001, 30% of Americans have checked bank information online, 16% have moved money between bank accounts online, 8% have bought securities online, 12% have paid with credit cards online (Colby & Parasuraman, 2001).

The Financial Crimes Enforcement Network (FCEN division) sifts through information obtained from the Bank Secrecy Act of 1970 which requires all financial institutions to report large transactions of currency with bank secrecy reporting forms. Data mining techniques that incorporate artificial intelligence algorithms are used to sort through the information. (Daukantas, 2000).

## Voting

The proper administration of voting is essential to the citizen's acceptance of government in the United States. Voting is a labor-intensive process, fraught with opportunities to cheat or manipulate the results. Technology provides an opportunity to automate, reduce labor expenses and provide accountability. Many proposals for voting have been introduced including online voting.

A study by the California Institute of Technology in conjunction with the Massachusetts Institute of Technology Voting Project claims that electronic voting is less effective than actual paper voting (Evans, 2001). The key finding is that wrong vote counts (under or over) are increased with technology. The research refers to these votes in error as residual votes. They claim that paper ballots and lever machines have 2% residual error. Surprisingly, more technical systems have a higher error rate of 3% residual error. Despite this, electronic voting is increasing in popularity and usage. It was estimated that 2% of the population used electronic voting in the 1980's. During the 2000 election, it is estimated that 11% of the voting population used some sort of electronic voting. (Evans, 2001).

## Jury Selection

Companies that provide information technology services to the government have products that enable the government to generate jury lists. Software programs create and maintain jury lists based on voter registration lists provided by the Bureau of Motor Vehicles. Duplicates are eliminated by the use of a unique key such as social security numbers and birth dates. The system provides a jury pool that is representative of age and location requirements. Those who have recently served on a jury are eliminated from the list. This random selection is useful in preventing jury tampering (Maximus: Jury Management, 2004).

## Social Security Administration

The Social Security Administration has the goal of becoming a paperless organization by the year 2010. The Social Security Administration is considered one of the most paper intensive agencies especially because of the need to review original documents in processing claims of death or disability. Citizens may apply online to determine if they are eligible for services and obtain explanations of benefit services. The site allows the user to log on to a previously registered account to get more information about an ongoing issue, or to request notification about changes in pre-selected issues. A searchable database of questions is available as well as calculators to help citizens analyze events such as retirement, disability and survivor benefits (Social Security Online, 2004).

## Bureau of Motor Vehicles

The Bureau of Motor Vehicles is a state controlled registration, but it has links to the federal government. The automation of this department represents time savings for employees and citizens. The federal government Web site "FirstGov.gov" contains direct links for each state's Bureau of Motor Vehicles Web site, available with the intent of accommodating their citizens. The ability to obtain forms and information online is an important benefit for many citizens who do not have time to physically visit an office to obtain a form.

## Law Enforcement Agencies

Law enforcement agencies, faced with technology barriers, have often been unwilling silos of information. E-government structures that link local, state, and federal government agencies reduce costs and enable agencies to share information in order to eliminate redundant activities. Law enforcement agencies are linked in a regional alliance system called regional information sharing systems, and agencies include the Drug Enforcement Agency, the Federal Bureau of Investigation, the Internal Revenue Service, and the Secret Service (Institute for Intergovernmental Research, 2004).

## Emergency Response Systems

The United States focus on homeland defense has heightened interest in improving emergency response systems. Improved systems could help rescuers to find victims sooner and see that appropriate resources are properly allocated. Appropriate e-government applications focus federal aid agencies' responses to those in need of financial help by reducing paperwork and decreasing time required to respond. In a major disaster many inspectors are in the field but there are only limited personnel to handle the influx of paperwork, creating a bottleneck that slows down responses. Proposed systems would use a wireless system to evaluate and report damage in a format that meets federal requirements. The finished product could use hardware such as a personal digital assistant (PDA) to automatically file information into the agency database from the disaster site. Applications of this type could help rapidly deliver funds and resources to where they are needed most (Accela Inc. Government Software, 2004).

## Military Defense

The ability to communicate in the military chain of command in a secure manner is essential to security. The United States Navy and the Department of Defense have created a business plan that will be funded by some portion of the defense budget for information technology improvements. The command has set up a $20 million budget each year to enable the Navy to be an e-business prototype (Onley, 2001). E-government applications certainly fit nicely with military defense as citizens expect economy of resources but demand accuracy with life and death decisions.

In the short term, there is likely to be a slowing of growth of e-government because of recent terrorist attacks (Chiger, 2002). Certain Web sites like the Los Alamos National Laboratories, a government backed nuclear weapon facility, have blocked access to certain documents. It is unclear whether there will be a decrease in the types of information available. The Freedom of Information Act requires that information be made available to the public unless the information falls under the exception of a Special Exemption 2. This exemption says the Department of Justice can block information if it is deemed a vulnerable critical asset. The exemption is amplified by a memo from the Department of Justice in the wake of recent terrorist attacks on the United States (United States Department of Justice Office of Information and Privacy, 2001).

### Mail

The United States Postal Service NetPost.Certified program was developed to authenticate electronic correspondence using smart cards and readers. After a pilot phase it became available to all customers. The customer registers online and then presents himself once at the post office with a photo ID and another document containing their name and address that has been sent through the mail (like a bill that has been mailed to his home address). While there is no charge for the digital certificate, there was initially a $0.50 charge for each email downloaded using the service (Johnston, 2001). The program has expanded to offer multiple services such as: greeting cards, flyers, and post cards. The cost per unit is determined by item and volume and is listed on the Web site (United States Postal Service, 2004).

### Space Exploration

E-government applications are used to organize resources for international space exploration. Current projects involve an international community in multiple locations with highly technical requirements. Project management is complicated by the international aspect of the space program, adding a complicated mix of technology, politics, culture, and interdependence. Coordination is now accomplished using a project management development program from the German software company, SAP. NASA uses this program to manage the financial, human resource, and technology aspects of planning and delivering the launch on time. (SAP Global, 2004).

## E-GOVERNMENT-STRATEGIC CONCERNS

While the benefits of e-government are considerable, it presents new and unexpected concerns such as the widening of the digital divide and the resultant impact on a democratic society. The older, and potentially more conservative, voter may be discouraged from using e-government structures. Older adults in particular are a concern because part of that population may be unfamiliar or reluctant to use technology, or simply may have physical difficulty in reading screens or manipulating keyboards (Becker, 2005). The digital divide may manifest itself in terms of international security when digitally disadvantaged countries fall further behind in the technology race they will have greater difficulty in competing in the global marketplace. Care must be taken to minimize the national and international digital divide at every opportunity through grants, education and the marketplace.

## FUTURE TRENDS

Recent difficulties in maintaining the security and privacy of computer users have slowed the acceptance of e-government by potential users (Mercuri, 2005). While the rate of e-government progress has slowed in recent years more citizens are using e-government as a way to obtain information and governments are gaining real cost savings from the structures (Gov Slowly Gaining Acceptance, but Must Mature, 2004). It is hoped that, as citizens realize the cost savings of back-office reforms, consumer acceptance of e-government will increase.

## CONCLUSION

E-government structures have generated many important benefits, but at the same time have raised some justifiable concerns. An important advantage of e-government is that the government becomes more accountable to its citizens because of increased transparency and the ability to audit transactions. The ability to access e-government from virtually anywhere ensures equal access to services despite geographic location. Automation of government services creates fairness by eliminating barriers to information. Conversely, e-government structures present some disadvantages, such as the considerable expense required to develop and maintain such systems. It is unavoidable that certain citizens have a lower level of comfort and experience with technology, and this could lead to groups of citizens who do not feel they have the opportunity to fully participate in their government. Continuing research may make it possible to develop new and improved applications while guarding against invasions of privacy and security. E-government's success will be dependent on continuing gains in efficiency and consumer confidence.

## KEY TERMS

**E-Government:** See electronic government.

**Electronic Government:** E-government is the communication between the government and its citizens, businesses or itself by the use of computers and a Web-enabled presence.

**Electronic Voting:** The method by which a citizen casts his vote electronically instead of manually.

**E-Voting:** See electronic voting.

**Government to Business (G2B):** The e-government sector of service in which the government communicates with businesses. This communication can include tax payment by the business, or purchase from a vendor to the government.

**Government to Consumer (G2C):** The e-government sector of service in which the government communicates with its citizens. The word consumer is used instead of citizen because the citizen is treated as a consumer where transaction satisfaction is important.

**Government to Government (G2G):** The e-government sector of service in which the government communicates with other governments. This communication often refers to coordination between state and federal levels of government or coordination between various agencies.

# Application for Comprehensive E-Government

## INTRODUCTION

E-government forms an essential part of the tendency toward administrative modernization as it embraces the optimization of intra-authority processes; the interface between the authority, citizens, and companies; and interauthority processes, thus leading to the realization of an e-driven informed society. The complexity of the theme results from the doing of authorities; their communication partners like citizens, companies, and other authorities; and the social and legal framework. The growing distribution and the increasing maturity of these e-government applications pose new issues calling for scientists and economists to deliver immediate solutions.

Within the frame of the new public management strategy, the one-stop-shop principle—a central contact-oriented service aimed toward solving problems—has also been in the focus. The portal architecture serves to realize one-stop government for citizens, who are now able to access most various online services of different authorities from one single point to present their concerns. Apart from this, the interconnection between the internal (file) administration through online services rendered to citizens, companies, and other administrative facilities leads to an increased procedural transparency for citizens and companies and forms the basis for one-stop government.

## ONE-STOP GOVERNMENT

The idea to create an e-government pool is heading in the same direction. The pool of portals represents a uniform frame for access to cross-authority Web applications and the administration of related rights. This allows users logging onto their home portals to use additional applications outside their home portals in so-called application portals.

The pool of portals facilitates the incorporation and utilization of external databases (GIS cards, book of prime entry, directories, etc.), which finally provides a continuous cross-linkage.

Thus, the citizen and the officials are able to settle all their issues at a central (virtual) point.

*Figure 1. Flowchart of e-government processes*

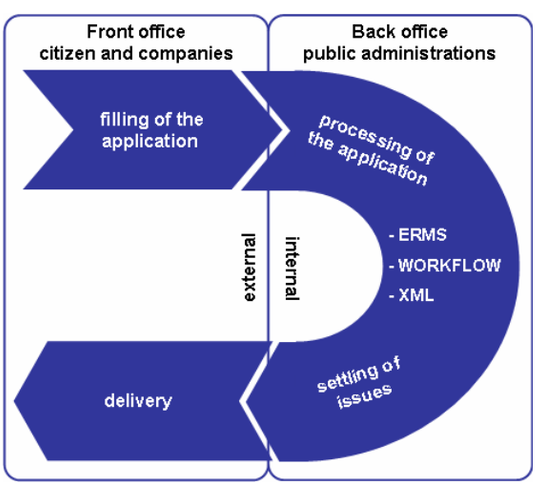

*Figure 2. Communication partners of an authority*

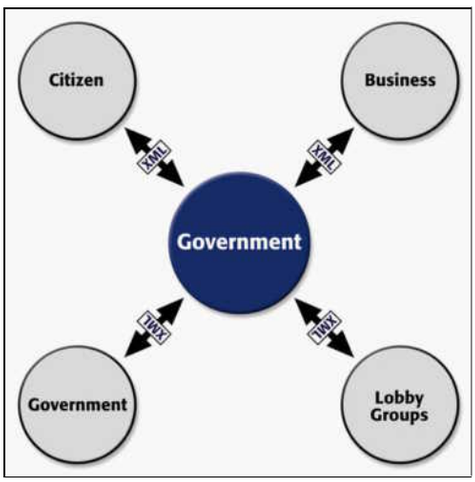


- Through a Web portal, online services, and online delivery, the citizen settles all his or her public issues in a comfortable fashion through the Internet.
- At the authority's site, the citizen is notified of the respective status of the ongoing processing of his or her issue from a central service point.
- A call centre can access the status data of the procedure and is thus able to notify the applicant at any time via phone or SMS if requested to do so.
- Via mobile devices, officials can, at any time and in any place (for instance, through a pool of portals), access electronic files and special applications.

## INTERNAL VS. EXTERNAL E-GOVERNMENT

Typical e-government processes are initiated by citizens and companies (e.g., by way of applications submitted via the Internet), processed within the scope of the internal flow of files of an administrative organization (e.g., using an electronic records-management system [ERMS]) before they are returned to the external applicant (e.g., via the electronic delivery of the administrative decision).

Administrative external e-government means processes that are not part of intra-administrative action in a narrow sense but still fall within the scope of administrative issues. These include above all application processes initiated by citizens and companies, and the participation in processes by other administrative facilities and organizations associated with quasi-administrative tasks.

Administrative internal e-government processes comprise all intra-authority processes (flow of files) in the respective field of work, and cross-authority cooperation in settling issues.

Both the internal and external components are calling for careful planning, monitoring, and control. Different requirements and angles resulting from the external, internal, and cross-authority processing of business objects lead to the separate presentation of problems regarding the required interfaces, standards, and safety requirements. The dual characteristic of e-government processes requires a comprehensive solution in order to provide an implementation of e-government projects as effectively and efficiently as possible. The desired increase of efficiency cannot be achieved unless it is done by means of electronic projection and the linking of all process items, that is, continuous and coordinate electronic processing embracing the complete scale of the filing of an application, intra-authority processing, and delivery.

The concrete adoption of e-government processes and the resulting requirements from an intra-authority and extra-authority angle in the form of software products and their continuous further development are the core contributions of software producers to a holistic approach to e-government-related issues.

## FROM REQUEST TO FULFILLMENT

As we already mentioned above, e-government can be divided into an internal and external scope of activity; in doing so, the internal scope of activity (back office) is generally understood to comprise the processing of business issues using ERMSs and other special applications. The external view of e-government (front office) deals with the communication of an authority with external partners. In this case, the communication partners can be citizens, companies, and nonprofit organizations, but also other public administrations.

The great diversity of external communication partners and the general legal setup provided by public administrative bodies require a very complex technological implementation of e-government systems and call for innovative technologies needed to cope with the resulting demands. The Internet provides the basic communication platform for the transfer of information between citizens, companies, and the authorities as it forms the base for Web-based e-government applications and tools such as online services, online delivery, and mobile devices.

This allows the applicant to submit his or her application on a home PC (personal computer) using online forms in a most comfortable fashion. Field staff officials access the required intra-authority data via mobile terminal devices on the Web. In a similar fashion, external authorities can review the ongoing issue to the required extent, plus the necessary authority can process the respective business issue, if needed, according to specific access mechanisms. Finally, the applicant is sent the settled issue in an electronic form through a delivery server.

## ONLINE SERVICES

In processing an application filed, the incorrect collection of basic business-related data and the resulting information gap tend to cause process delays. In order to avoid this risk, the planning of form sequences forms an essential part of e-government processes, thus serving mainly an improvement in the quality of external data collection as to accuracy and completeness. Form sequences have the task to ensure a clear structuring of the data to be collected on the one hand, and to guide the applicant through application processes including the enclosure of documents, the payment of fees, and the confirmation of the particulars provided via a digital signature on the other.

For example, for the design of online forms in Austria, the Chief Information Office (CIO) published directives within the frame of the e-government style guide (current version 1.2). These directives are designed to ensure a high quality and uniform presentation of the online services of Austrian administrative units. In handling online forms, modular forms have proved effective in the past. This is due to an increased serviceability, structured and more flexible design options, and the application of form layout tools by persons without programming skills.

The subdivision of the application form into form pages and form blocks allows one to save as a temporary file only the blank sections of the application form on the form server in XML (Extensible Markup Language) format. Filled-in and signed parts of forms are submitted to the internal ERMS immediately. This ensures that personal data do not need to be stored temporarily on the DMZ form server.

The involvement of external authorities in the settlement of applications is another vital issue in interauthority cooperation. This means that information needed from an external authority (e.g., registration office) can be incorporated into the proceedings as soon as the citizen has submitted the application without the authority responsible being required to make active contributions.

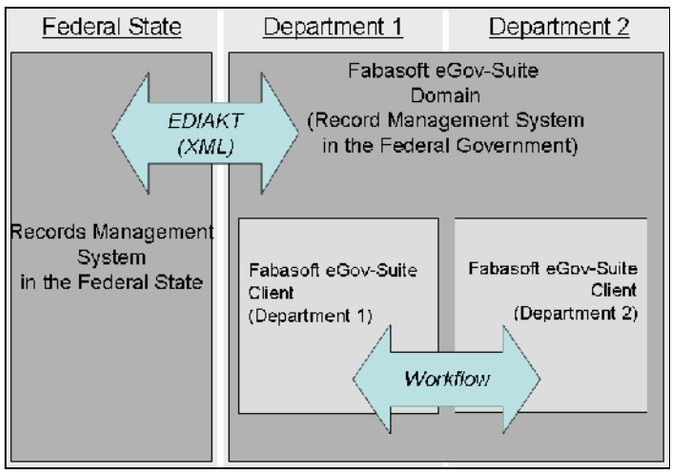
This happens by communicating with the external authority via e-mail after the submission of the application. In doing so, the external authority is requested to check and, if needed, correct or complete the missing particulars within the scope of its sphere of responsibility. For this, it receives special access to the application data receiving only those particulars relevant to its sphere of responsibility. Once the external authority has checked or completed these data, it confirms their accuracy by giving a digital administrative signature.

## FROM THE REQUEST TO ELECTRONIC RECORDS MANAGEMENT SYSTEM

For the acquisition of the data contained in an XML-format application, a flexible and configurable mechanism is required allowing one to control the creation of the case paper (electronic record) containing the application document and the initialization of the work flow for the case paper in the electronic records-management system of an administrative authority. Being controlled by SOAP actions and thus forming the interface between external and internal e-government processes, the data acquisition is substantially effected in three steps: the creation of a case paper, the creation of the application from the XML data, and the initialization of the work flow.

The management of electronic records is one of the most important elements in the government's modernization program and is the base of the government target for online service delivery by 2005. By 2004, all central government organizations should be able to store and retrieve their public records electronically.

*Figure 3. Cross-client exchange of files: EDIAKT and ELAK work flow*



For electronic file and case processing and archiving, the European countries have adopted their national concepts. These concepts differ as to the structural and procedural organization. Electronic records-management systems usually offer functionality for document management, content management, work flow, and the archiving of documents and files, and they involve other special applications like digital signatures or conversion services. Examples of specific ERMS concepts are the following:

- DOMEA in Germany
- ELAK in Austria
- GEVER in Switzerland
- The National Archives in the United Kingdom

An example of an electronic records-management system is the standard software product Fabasoft eGov-Suite. Fabasoft eGov-Suite offers a document-management system with work flow and consists of a functional core applicable throughout Europe plus tested and certified country-specific modules complying with the national requirements and regulations.

## CROSS-AUTHORITY EXCHANGE OF FILES

The electronic handling of records offers the huge advantage of several users able to access the same file. This facilitates intra-authority but also interauthority processes. The joint utilization of electronic resources and the avoidance of redundancies help to provide synergy effects that reduce cycle time and costs of proceedings.

For example, the interface underlying the cross-authority exchange of files in Austria is called EDIAKT. Another example is the interface XDOMEA in Germany. For both, the base technology offers XML.

Files and documents are exported from the system using predefined XML patterns and are then ready to be sent off via electronic media such as e-mail or Web services. Thus, EDIAKT allows cross-authority cooperation through various channels such as the exchange of files or access to files on a cross-community, -state, or -ministry scale.

In Austria, the project ELAK im Bund (EIB; Electronic Records Management in the Federal Government) is an example of this, where cross-authority processes have been implemented through an XML interface. If a case paper transported in an EDIAKT-conforming manner is imported into the internal ERMS through a known XML pattern, the existing file is updated or, in the event of a new file, a new file is created. All metadata contained in the file, the documents stored in the file, and work-flow information are applied before the work flow is started according to the subject area as a predefined process or with a start activity in case of ad hoc processing.

In the event that several authorities use one system in a multiple-client environment, the functionality of EDIAKT

is not indispensable as all persons dealing with a case are working within one and the same work-flow system. The implementation and configuration of several clients within one domain allows client-specific settings and coordinate access rights without affecting the handling of other clients.

The implementation of ELAK im Bund with the European standard software Fabasoft eGov-Suite is also an example of the cross-authority exchange of files through work flow. The ministries are assigned states as own their clients and are within one EIB domain. All documents and files are handled depending upon the individual client. However, these documents and files can be handed over to other ministries through the work flow. Access is controlled through an ACL (access control list). In doing so, the processing rights can be assigned actively for the process period through orders issued to other ministries and organizational units.

## ELECTRONIC DELIVERY

Electronic delivery means the supply of documents via electronic channels. Citizens will no more receive administrative decisions by post, but will get the documents via the Internet through an electronic delivery service.

In Austria, the last step of comprehensive e-government has been made possible by the concept for the electronic delivery server ZUSE (current version 1.0). The model of the electronic delivery server of the Austrian Chief Information Office describes the foundations and the process model of electronic delivery. While doing so, the directives defined recommend the use of a modular, universal, and efficient delivery service regarding interfaces, infrastructure, the submission of supporting documents, and signatures on the part of both the citizen and the authority. This includes the process description and information format of electronic delivery, one LDAP pattern description, one XML specification of the data structure, and the utilization of the online application container (OLAPP). Within the frame of the model of electronic delivery, the digital signature given by the authority is worked on by the development of another MOA (modules for online applications) model for generic server signature components.

An example of an electronic delivery system according to ZUSE 1.0 is Fabasoft Delivery, which fulfils all requirements and directives for the electronic delivery of administrative decisions.

## EXAMPLES FOR STANDARDIZATION AND INTEROPERABILITY

Scenarios of this kind require highly developed networks in intra- and interadministrative communication. In order to accomplish this, tools based on well-established technological standards are an indispensable means to use. Technological standards, directives, and recommendations for communication via the Internet are primarily specified through global organizations such as XML, WAI conformity standards, or the SOAP recommendation issued by W3C (World Wide Web Consortium). These endeavours directed toward standardization must be supported by all sides because no lasting interoperability can be ensured if the development pursued fails to orient itself by standards.

### W3C WAI Conformity

WAI (Web-content accessibility guidelines) issued a directive for the design of Internet presentations that can also be visited by disabled persons without additional barriers, thus ensuring free access to the Internet for any person.

Applications for online services work according to the principle of the separation of content, layout, and structure. This allows the creation of online forms and Internet presentations for different types of publications and presentations (Internet, WAI, print view, WAP, etc.)

### Interworking of MOA Modules

The MOAs specified by the Austrian Chief Information Office offer basic services, for example, in the field of the electronic signature for creating safe online procedures. In the MOA-SP basic module, all functionalities for signature verification are enclosed, thus enabling online applications to access these (basic) functionalities. In doing so, both security-layer conform signatures and XMLDSig and CMS signatures are supported. By analogy, the MOA-SS basic module encloses the entire functionality for the server-based creation of signatures. In MOA-SS, security layers and XMLDSig conform signatures are supported.

### Identification by Smart Card (Citizen Card)

The use of a smart card for identification (citizen card) calls for the definition of an interface between the smart

card and the application. An example of such an interface is the security-layer specification in Austria. It is the interface between the Austrian citizen-card environment and the applications and has been implemented as an XML interface.

## Style Guides

The electronic applications submitted on the Internet that are being developed within the frame of e-government projects of the federal government, the federal states, and communities should be based upon a nationwide regulation and maintain one uniform structure independently of the authorities they are operated by. This applies to the handling of the electronic application procedure, the structure of standard data, and the layout, which should be largely uniform.

## CONCLUSION

From a technical view, a comprehensive e-government scenario can be resolved accomplishing international and national concepts, standards, and guidelines. However, due to heterogenic hardware and software infrastructures, successful implementations are difficult and complex, which only can be solved by further international standards.

E-government projects must be understood primarily as organizational projects and not only IT projects. E-government presupposes a different thinking in processes, which leads to a cultural change from traditional paper filing to electronic filing and work flows. Additional clear directives from management are needed as well as the creation of a proper legal framework. Nevertheless, e-government must be seen as an alternative distribution channel that offers public authorities other service possibilities.

## KEY TERMS

**Citizen Card:** Smart card for citizens for electronic identification when using e-government online services.

**Comprehensive E-Government:** Official channel through which activities from the filing of an application through electronic records management to electronic delivery is done only through electronic systems without paper.

**Electronic Records Management:** Management of electronic files and documents.

**Interauthority Processes:** Processing of business issues using electronic records-management systems and other special applications between different administrative authorities.

**Intra-Authority Processes:** Processing of business issues using ERMSs and other special applications within one administrative authority.

**One-Stop Government:** A central contact-oriented service aimed toward administrative concerns.

**Online Services:** Services offered through the Internet.

# The Application of Single-Source Publishing to E-Government

A

**Lucas Walsh**
*Deakin University, Australia*

## INTRODUCTION

The following article provides an introductory overview of Extensible Markup Language (XML) and how it may be applied to certain processes of e-government to improve accessibility to government services as well as to make governments' services more widely available. In particular, this discussion explores how the kind of single-source framework used in digital publishing can be used to drive the storage, delivery, and exchange of e-government information and services. The first section of this article provides a basic introduction to XML. The second part illustrates how content is prepared and disseminated using XML, providing some existing and hypothetical examples of this single-source approach. The final section looks at future trends as well as some of the challenges that may be encountered when using this XML-based single-source framework.

## BACKGROUND

A central technical dimension of e-government continues to be the dissemination of information to citizens, as well as between government agencies, stakeholders, and other groups. The most visible and largest growing area of e-government in recent years is the use of the Internet and World Wide Web to deliver government information and services. Between 1996 and 2001 alone, the number of official government homepages throughout the world grew from less than 50 to over 50,000 (Ronaghan, 2002, p. 5). As Abramson and Morin point out, it is now expected that public, private, and not-for-profit organisations will have a Web site: "the key question today is not whether organisations, including those in the public sector, have Web sites, but what is the quality of those sites and the scope of services being provided online" (Abramson & Morin, 2003, p. 4).

From a user's perspective, this technology makes it easier for people to gather documents about government and politics, become involved in political discussion groups and collaborate to organise certain political activities (Davis & Owen, 1998). From a content provider's perspective, the scope and scale of e-government activities, ranging from any official government online presence to the full integration of e-services across administrative boundaries (Ronaghan, 2002), necessitates the need for effective and efficient ways of disseminating content to this range of users across a variety of contexts.

With the diffusion of information and communications technology, such as the Internet, e-government faces three closely related imperatives:

1. The need to disseminate information to different outputs (e.g., Web, print);
2. The need for citizens and other stakeholders to access this information from a variety of contexts (e.g., work, home, public kiosk); and
3. The need to be able to share this information with different individuals and groups (e.g., government agencies, NGOs, multi-stakeholders) in an efficient and effective way.

XML has been developed from the experiences of commercial and government organisations seeking to store, display, and disseminate large volumes of information. It is a metalanguage used to mark up content[1] for delivery across multiple platforms and to different kinds of users. XML is used to describe how different kinds of data are stored, exchanged, and presented. XML has been particularly successful in digital publishing and certain areas of e-learning.[2] In its application to digital publishing, XML "provides a well-defined, broadly accepted syntax for creating markup schemes to [enable] the development of tag sets focused on projects as small as a single book or journal ... or whole collections or classes of books or journals ... or to achieve a particular functionality" (Kasdorf, 2003, p. 87).

The use of XML within a single-source publishing approach to the production, storage, and exchange of information is by no means new and has a wide range of applications to e-government. A single-source approach

involves a process in which a master source of information is prepared using XML to make that information available to end-users through print, the Web, and a variety of other platforms as necessary. The major advantage of this single-source approach is to make content reusable and accessible via a range of media.

The following discussion seeks to provide an introduction to XML and outlines how it can be used to encode a single source of content in such a way that it can be used in different ways and formats for online, printed, and other delivery platforms according to the needs of end-users.

## XML: An Overview

XML is a text-based metalanguage that is "extensible," or customisable, enabling users to construct their own specialised markup languages to transmit data (Bray et al., 2004; Bradbury, 2001). XML serves a rule-based system "designed for marking up content of all sorts (text, graphics, computer code, commercial information, intellectual information) in order to specify what the component parts of that content are, and to describe them" (Kasdorf, 2003, p. 91). XML users can create their own tags to act as hidden labels to annotate the content, be it for a Web page or sections of a text within a page (Berners-Lee, Hendler, & Lassila, 2001).

Development of XML began in 1996 under the auspices of the main standards body for the Internet, the World Wide Web Consortium (W3C), as a subset of Standard Generalised Markup Language (SGML) that would be easier to implement on the Web (Bray et al., 2004; Bosak & Bray, 1999). XML originated in the commercial and governmental use of SGML and Hypertext Mark-up Language (HTML). XML's designers drew from: (1) the positive aspects of SGML; while (2) seeking to address some of the limitations of HTML as a mark-up language (Kasdorf, 2003).

XML is a restricted form of SGML (Bray et al., 2004). SGML (Goldfarb, 1990) has been widely used in manufacturing, medicine and aerospace industries, as well as public administration, such as the US Department of Defence and Internal Revenue, to enable contractors and suppliers to exchange large technical documents, and for other large publishing applications (Bosak & Bray, 1999; Kasdorf, 2003, Salminen, 2005). As a subset of SGML, XML provides a standard basis for industries, organisations, and individuals to exchange information, using their own vocabularies and structures, as well as a data interchange between software applications.

Rather than replace HTML, which is primarily a presentational format designed for a specific way of viewing content on the Web, XML is "in its best use, a *source* markup, designed to be transformed into something else, to be archived and used in different ways…XML retains the information about what the elements in the source content *are* and how they *relate*; HTML typically loses that information, focussing instead on what the content should *look like* in a given presentation" (Kasdorf, 2003, p. 91).

Like HTML, XML makes use of tags (words bracketed by "<" and ">") and attributes. Unlike HTML, which has a fixed set of tags, XML has a potentially infinite number of tags. It enables users to define and use their own tags but "has no built-in mechanisms to convey the meaning of the user's (i.e., content providers) new tags to other users" (Berners-Lee, Hendler, & Lassila, 2001, p. 32). Users of XML can assign explicit meaning to data stored in an XML file, using tags to delimit portions of data without having to specify how that data will be interpreted by the application processing it. HTML, on the other hand, specifies the meaning of tags and attributes, and how a browser will display the text between tags.[3] For example, using a "<p>" tag in XML does not necessarily have to define a paragraph, as it does in HTML, but can signify any attribute created by content providers to suit their specific needs and in a language that they understand.

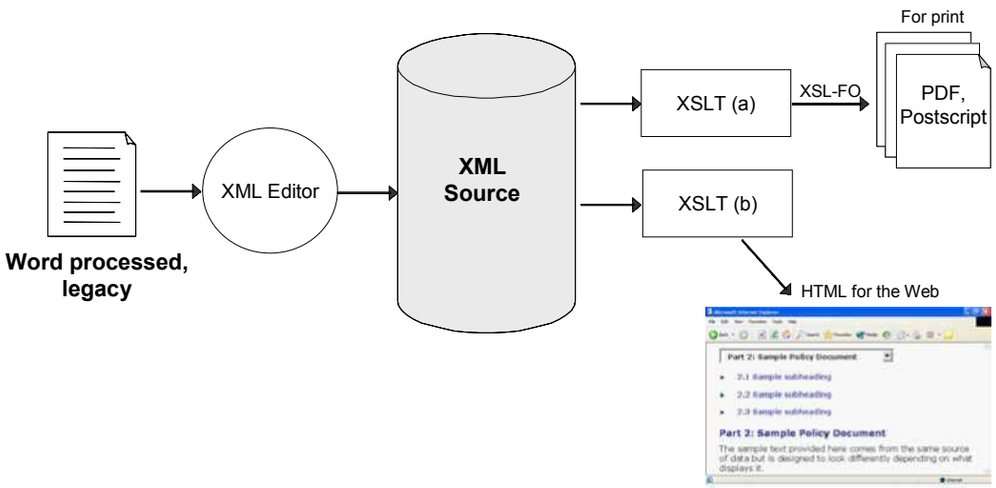
## How XML Works: A Sample Workflow

It is not uncommon for government information to be made available online in a Portable Document Format (PDF), Microsoft Word (DOC) or Rich Text Format (RTF) in the form of a single file suited to printing in hardcopy. Often, the file displayed online is text-based, static, and identical to the printed version, because the content is taken directly from printed source files stored in PDF, RTF, and/or Word. Alternatively, data is stored in multiple sources and formats (e.g., PDF, HTML, RTF, and MS Word) leading to inefficiencies in data management and unnecessary duplication of labour.

Generating single-source content using XML involves a multi-stage process that may take place in a number of ways. For example, the initial document may be created directly in XML or repurposed from RTF or Word and then exported into a source XML file. This source file may then be transformed into other XML vocabularies for print, the Web, or other outputs. A single-source approach requires that content be 'captured' early on at the authoring and formatting stage so that content can be marked up for multiple outputs in a unified process.

This source XML file may be structured and tagged according to a Document Type Definition (DTD) suited to the type of content intended for storage and dissemination (Bray et al., 2004). A DTD is a kind of template for the XML file. It is a separate file that defines what goes where

*Illustration 1. Using XSL to Transform a word processed document into multiple outputs—a basic example*



within an XML document and in what order, what the attributes of the content are and how they are structured in relation to each other. The XML file is written to comply with a DTD to ensure that the document can be effectively processed in XML.[4] Once the DTD has been written for one set of generically structured content, it can be applied to a range of similar documents featuring a similar structure.

While there is no definitive approach to structuring XML documents, the construction of DTDs requires a carefully planned process of modelling to identify the structure of the content. The model depends on the type of content; however, a number of generic DTDs have been defined and released to the community to use, such as DocBook, which is a general purpose XML DTD specifically suited to book and journal publishing. DocBook features a schema in a relatively simple format that is freely available. While DTD syntax is fairly straightforward to understand, the challenge is to create a model that is applicable to the type of content being disseminated.

Extensible Stylesheet Language (XSL) can then be used to transform the XML source into various outputs. XSL is the standard stylesheet language for XML that includes a vocabulary for specifying how content can be used to transform a source XML file into various XML vocabularies or to other formats (e.g., HTML) (Bosak & Bray, 1999). This process of transforming XML into other formats uses Extensible Stylesheet Language for Transformation (XSLT) (Clark, 1999).

XSLT can be used to transform a single-source XML document into a multitude of outputs for the Web, for print, as an image file, a new XML document, or any number of outputs. It is one of the most important aspects of an XML environment because it enables tagged content to be interpreted by a stylesheet and rendered in way that end-users can understand (e.g., via a Web-browser). Illustration 1 provides a basic example of a workflow using XSLT, in which one XSLT is used to produce a print document format (PDF), while another XSLT is used to produce a Web-based output.

The previous example illustrates the process in which a source file is exported to XML from a master or legacy document authored in a standard word-processing software package (e.g., MS Word) using an XML editor[5], and then converted to two outputs—PDF and HTML–using separate Extensible Stylesheet Transformations.

As shown in Illustration 1, one XSLT (a) is used to generate a printed version from a source XML file. A process for Extensible Stylesheet Language Formatting Objects (XSL-FO) creates a paginated print version of the data stored in that source file. XSL-FO is a page

description language which tells a formatter how to structure text on a page (e.g., specifying the size of margins). The source XML document is transformed into FO using a stylesheet and rendered as a file format suitable for printing, such as PostScript and PDF.

Within this single-source framework, the paper-based version generated from the XML source file can look like and be structured as a normal paper-based document; however, the online version of that same content can be dynamically generated and reformatted in an automated process to be more "Web-friendly," interactive and customised to end-user needs. The second stylesheet (b) in Illustration 1 specifies that only online features tagged in the XML source file are recognised when the file is transformed for online display in HTML.

Stylesheets can be applied to transform a single-source of content into formats suitable for a wide range of outputs to expand and enhance access. For example, stylesheets can be used to filter, reorder, and render the data in print or with graphics on a Web page, as text on a handheld organiser (e.g., personal digital assistant [PDA]), into Braille or as audible speech on a telephone, or other platform as necessary (Bosak & Bray, 1999). Further examples and illustrations of this are provided.

## Using XML as a Storage medium

The ongoing need to find more inexpensive and environmentally-friendly ways of storing, maintaining and disseminating information is an important consideration of e-government. XML is useful for content management because it can be used to tag data for customised storage (Bradbury, 2001).

It is possible to store different kinds of information about information, or "metadata," within a source XML file. In a single source approach, the source XML file serves as a container for metadata. Metadata consists of attributes and values that identify, for example, the language in which the document is written, the author, publication date, security, rights information and revision version. Metadata adds value and utility to data by enabling the information within the XML document to be understood, manipulated and customised by others. For example, when a specific type of user requests a document online, the database driving the Web site can be programmed to find the data tagged at the level and covering only the subject matter required by the end-user (e.g., as a citizen, policy specialist or parliamentarian). Metadata may be added so that selected parts of the document are automatically extracted from the single source in the form of an executive summary featuring key topic headings. Metadata can also make the data more searchable, depending on how much metadata is used to describe the content. (A practical example of this is the Tasmanian Legislation Web site, which is described in further detail as follows.)

## Minimising the Duplication of Data and Labour

Specific tags and metadata can be used to break the content up into modules that are easier to update. A key strength of using XML in a single-source approach is to reduce the duplication of labour and data. Generic information that remains the same across a number of contexts such as copyright information need only be tagged once.

Rather than modify each different version for specific outputs, it becomes possible to edit and manipulate one source of content. For example, a group of policy documents may feature the same standard copyright page. This page would only need to be marked up once and automatically generated and inserted into the group of policy documents as necessary.

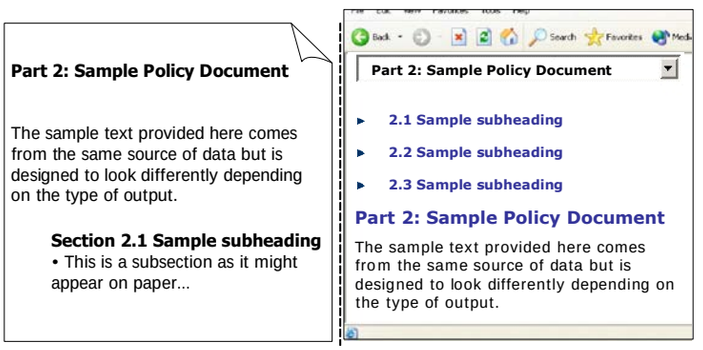
Despite these longer-term benefits, a lot of work is required to develop XML elements within a scheme of data management and formatting for a given source of content. Deciding on which content is generic requires careful consideration (e.g., determining which content is common to all output versions of a given document, as well as potentially used in other documents). As a corollary of this, considerable effort is required in determining the "granularity," or level of detail, to which a given chunk of content should be tagged.

Creating a customised language for the encoding, storage and display of data involves organisational challenges in keeping track of the variants in language and how they work. Those involved in the production/delivery of content have to implement the languages describing this content according to a common standard.

## Making Data Exchangeable through Standards

XML is designed for document exchange. Since 1998, W3C (2003) has recommended XML as a standardised approach to data-handling. XSLT was one of the first XML standards to be established by W3C, making it possible for changing vocabularies to be incorporated into the life-span of a given document by using this method of transformation to convert one set of data description into another. According to Bosak and Bray (1999), "XML bridges the incompatibilities of computer systems, allowing people to search for and exchange scientific data, commercial products, and multilingual documents with greater ease and speed" (p. 83).

*Illustration 2. Divorcing display from content—two outputs from the same source*



A major advantage of XML is its openness. XSLT and XSL-FO are based on open standards, and the software to work with these technologies is freely available. Because XML has become a standard for open information interchange, content providers do not have to depend on commercially developed proprietary, closed standards; nor do they have to depend on specific vendors or software[6] to apply them, which can be extremely expensive.

This is one of the reasons why XML has been adopted as a data interchange format in areas such as digital publishing. This openness is important to digital democracy as governments increasingly mandate the use of open standards in the development and use of ICTs for administration and service provision. On an international scale, open standards are critical to the effective exchange of information by multi-stakeholders across diverse contexts and systems.

Another benefit arising from standards is the capacity to "future-proof" data against changing needs and technologies. As XML is useful for storing information that will be presented in a variety of formats, it can also be useful as an intermediate step for transforming from one format to another. XML can be converted to other formats relatively easily, so that even if XML becomes obsolete, the source XML file can, in principle, be converted to the new standard.

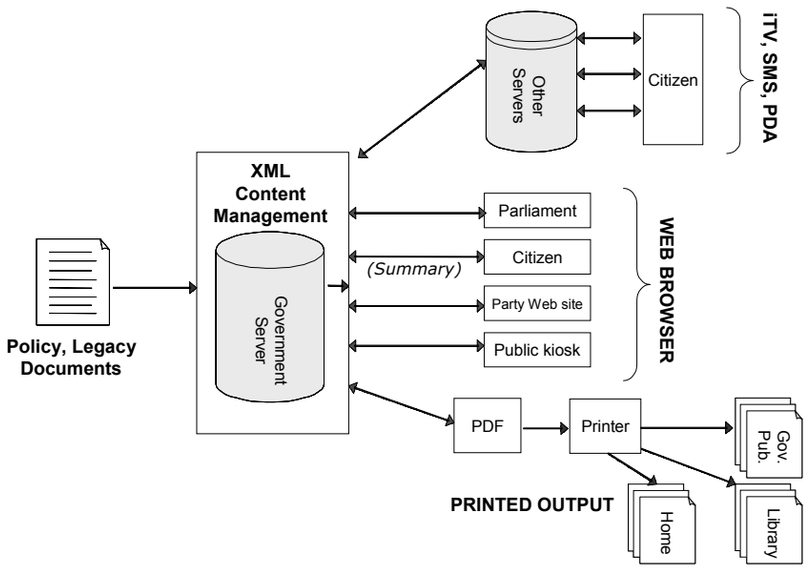
## Using XML to Display across Multiple Platforms and Devices

Effective e-government necessarily involves the dissemination of information and services to users with different needs, and who access information and services from a diverse range of contexts and platforms. XML can be used to define how the content is stored without having to specify how it will be displayed (Bradbury, 2001). Source-content marked up with XML tags can be displayed on a variety of devices (Bosak & Bray, 1999).

This ability to divorce display from content is possible using separate stylesheets. As previously mentioned, the same source of content used for the printing process can be used for the Web; however, each output uses its own XSLT so that they look and function differently. Illustration 2 offers a visual comparison of how a printed and online version derived from the same source of content can appear differently according to the means of output.

XML can be used for multi-channel display systems, such as interactive television, personal digital organisers, and mobile phones. The same source of content can be made available to speech-based applications, Braille and Wireless Markup Language (WML) for mobile devices, by writing another XSLT transformation to convert the

*Illustration 3. An example of single-source publishing*



source to the required output. Content can therefore be made more accessible to users with special needs.

The multi-output capabilities of a single-source approach are shown in Illustration 3 in a model based on the kind of centralised content aggregation framework used in digital publishing (see Merceica, 2001, p. 81). This illustration shows how a single source of content can be used across multiple outputs using XML.

Selective versions of a given document can be dynamically created on demand in response to an end-user's request. It is possible to also specify that only parts of a given document appear on certain Web sites and other outputs. The same content can then appear differently through different outputs according to the needs of users and according to the design motif of that output.

## Two Examples of this Single-Source Approach

The Tasmanian Legislation Web site (www.thelaw.tas.gov.au) provides a good illustration of this single source approach. First developed in 1998, this Australian State Government Web site uses a single-source approach legislative drafting and maintenance system to enable extensive searching and browsing facilities. Underpinning this system for the automatic consolidation of legislation is a database system that supports the import and export of documents marked up in SGML/XML. All legislation in the database is broken up into chunks for each Section or Schedule of legislation, which contain information such as the dates for which each particular fragment of legislation is in force. When legislation is amended, the system automatically joins these fragments on demand as/when the legislation is affected by amendments. (The old fragments are archived for historical reference. A complete history of Tasmanian principal legislation has been maintained in the system since implementing the database in 1997.)

The system enables legislation drafters to mark up an electronic version of any given consolidated Act and provide access to electronic searching facilities to aid in the preparation of consequential amendments.[7] Whereas legislation was traditionally drafted using manually pasted-up copies of legislation in conjunction with manual indexes (Arnold-Moore, Clemes, & Tadd, 2000), this approach offers a number of benefits, such as: "drafters can work from consolidated legislation to prepare amendments; a version of the Principal Act can be printed showing how it will be affected by amending legislation (the marked up changes can be read in conjunction with the amending legislation); and standardisation of wordings for amendment legislation improves overall readabil-

ity" (Department of Premier and Cabinet, Tasmania, 2005). Another benefit is the automation of processes, such as the consolidation of amendment legislation on commencement, and multiple format delivery for the publication of legislation (e.g., to paper-based printed documentation, CD ROM and HTML publishing via the Internet, along similar lines to Figure 3).

A number of similar developments in the management of legislative documentation have taken place elsewhere, such as Estonia (Heero, Puus, & Willemson, 2002) and the US House of Representatives, which has initiated plans to draft the vast majority of bills in XML (Carmel, 2002; Salminen, 2005).

To provide a more sophisticated hypothetical example of how the framework shown in Illustration 3 may be applied in a more sophisticated way, consider the following scenario: a piece of constitutional reform under debate in parliament is marked up using XML to be presented differently according to who is reading it. A citizen, whose information and communication needs differ to those of the parliamentarian, may require only a summary of the document. Furthermore, this summary is integrated into other media, such as net casts of parliamentary debate and related online discussion forums so that the end-user can refer to the summary as she watches and discusses the debate through her home PC entertainment system or interactive television or public kiosk. She can access the content through other means, such as an electronic handheld organiser or networked public information kiosk.

## FUTURE TRENDS AND CHALLENGES

### Implementing XML

Bosak and Bray (1999) rightly point out that "Unlike most computer data formats, XML markup also makes sense to humans, because it consists of nothing more than ordinary text" (p. 81; see also Bray et al., 2004). Nevertheless, adopting XML involves an extensive process of implementation. The initial outlay of human resources and finances can be considerable, not only because of the technical requirements for XML, but also because development of a single source of content intended for multiple outputs may present a radical departure from conventional processes and workflows.

Familiarisation with the basic standards of XML is necessary for those involved in the process of content development and dissemination. From a document management perspective, for example, users have to conform to the strict rules stated in a DTD. This presents challenges to conventional approaches by authors of content, as law-writers working within the Estonian legislative system have encountered (Heero, Puus, & Willemson, 2002). Extensive in-house and external training may be required in handling content markup in XML.

A major challenge in developing an XML source is granularity; that is, to what level of detail should the content be tagged. Careful thought needs to go into why levels of tagging need to take place, how content is best structured and what naming conventions are best suited to the current and future use of data. For example, will the use of a certain XML tag in one area of governance make sense to other users of the data, both now and in future?[8]

### Developing and Maintaining Standards

Continued support is required from standards bodies and their contributors. While standards for data vocabularies and the methods of tagging and describing information have progressed significantly in recent years, there is an ongoing challenge to implement, develop and maintain them because they require close cooperation between parties seeking to share and use the data (who may be in competition with each other) (Kasdorf, 2003).

Central to the effective sharing of information is the development and consensual adoption of common standards. Currently, there are a number of initiatives to define common metadata terms in document publishing (e.g., Dublin Core, 1999); however, there are a variety of different industry-specific standards currently in place. Because standards are still in their infancy, methodologies for the efficient exchange of information articulated in a common vocabulary are currently underdeveloped. Crucial to the effectiveness of standards is agreement and conformity between content providers and users to ensure that these standards are formalised. It also important for vendors to produce software that enables these standards to be effective and maintainable.

### New Technologies

Three developments in XML are worth highlighting in relation to the single-source approach outlined in this article. Firstly, there is a stricter reformulation of HTML that is compatible with XML called Extensible Hypertext Mark-up Language (XHTML). Secondly, a number of XML schema languages have been developed to replace the use of DTDs with more straightforward, compact, and easily manipulated forms of XML syntax. Like DTDs, these schemas describe the structure of XML documents

but allow for advanced forms of data-typing. Thirdly, is the importance of XML to the development of the Semantic Web (Berners-Lee, Hendler, & Lassila, 2001, p. 32), which has been promoted as "a next-generation Web designed to make more kinds of data easier for computers to locate and process" (Associated Press, 2004). Where current search engines for the Web are designed to be browsed by people, the designers of the Semantic Web are seeking to improve the automation and therefore speed, efficiency and search-ability of the Web by developing a system that is browsed by computers *for* people. A definition of Semantic Web is best left to its architects and advocates:

*To date, the World Wide Web has developed most rapidly as a medium of documents for people rather than of information that can be manipulated automatically. By augmenting Web pages with data targeted at computers and by adding documents solely for computers, we will transform the Web into the Semantic Web ... Computers will find the meaning of semantic data by following hyperlinks to definitions of key terms and rules by reasoning about them logically. The resulting infrastructure will spur the development of automated Web sources such as highly functional agents* (Berners-Lee, Hendler, & Lassila, 2001, p. 30).

Also central to the development of the Semantic Web is the resource description framework (RDF). This system for describing relationships between data resources can be expressed in XML to build the kind of metadata that will make the Semantic Web possible. RDF, it is argued, will enable faster and more accurate data retrieval (Bosak & Bray, 1999, p. 81).

## CONCLUSION

XML is useful because it provides a set of rules, guidelines, and conventions for encoding, structuring, and manipulating data. This discussion of XML is only introductory and covers just a few of the technologies available to content providers seeking to enhance the storage and dissemination of government information and citizen resources to users across different outputs and contexts. Indeed, several solutions similar to the frameworks outlined above have been already been built already before XML using SGML. Nevertheless, the single-source approach proposed in this article has potential application across a number of levels and processes of e-government. It could be used to disseminate a range of information, such as a constitution, the development, and consultation of policy, to legislative development.

While data storage, exchange, and dissemination form only one dimension of digital government, developing effective technologies is a keystone to building a sustainable, usable, and effective information society.

## KEY TERMS

**Document Type Definition:** A specific syntax and vocabulary for formalising an XML document in a language that enables a computer to interpret it (Kasdorf, 2003, p. 97). It provides a grammar for a class of documents (Bray et al., 2004).

**Extensible Hypertext Markup Language:** A stricter reformulation of HTML, compatible with XML.

**Extensible Markup Language:** A meta-language that provides a set of rules, guidelines and conventions for encoding, structuring, manipulating and exchanging data. The acronym "XML" refers to the language itself and to a whole family of standards that have developed around it, such as XSL (Bray et al., 2004; Kasdorf, 2003, p. 88).

**Extensible Stylesheet Language for Transformation:** Used to transform XML into a multitude of outputs for the Web, for print or any number of outputs. XSLT enables tagged content to be interpreted by a stylesheet and rendered in way that end-users can understand (e.g., via a Web-browser) (Bray et al., 2004).

**Extensible Stylesheet Language Formatting Objects:** A page description language that tells a formatter how to structure text on a page (e.g., specifying margin sizes).

**Extensible Stylesheet Language:** A standard stylesheet language for XML stylesheets, which includes a vocabulary for specifying how content can be used to transform an XML file into XML vocabularies or to other formats (e.g. HTML) (Bosak & Bray, 1999, p. 83).

**Hypertext Markup Language:** The first version of HTML was published in 1992 as an SGML-based language to describe Web pages. HTML is a "language used to encode formatting, links and other features on Web pages" that uses standardised tags whose meaning and interpretation is set universally by the World Wide Web Consortium (Berners-Lee, Hendler, & Lassila, 2001, p. 32).

**Portable Document Format:** A widely adopted page description language.

**Rich Text Format:** A specification by which formatted text and graphics is encoded for transfer between applications.

**Standard Generalised Markup Language:** Developed "for supporting the management of heterogenous information resources of the Internet and to facilitate communication between various software applications" (Salminen, 2005). (See Goldfarb, 1990.)

**World Wide Web Consortium:** Founded by Tim Berners-Lee, inventor of the World Wide Web, W3C includes Member Organisations ranging from product vendors, service providers, publishers, corporations, academic institutions to governmental bodies, who seek to evaluate and develop proposed technologies for the Web, such as HTML and XML.

## ENDNOTES

1 The author uses the term "content" to encompass all text, illustrative and audio-visual materials made available for delivery via print, the Internet and other media.

2 This article derives its applied understanding of XML from work conducted between 2001 and 2003 at the International Baccalaureate Organisation's Online Curriculum Centre (IBO). An overview of this work within an educational context was presented by the author as a paper entitled: "Using extensible markup language for the single source delivery of teaching resources via print and the Web: A practical example" at the conference of the Australasian Society for Computers in Learning in Tertiary Education, 5-8 December 2004, Perth: Western Australia.

3 For example, HTML uses standardised tags such as <H1> and <BODY> whose meaning and interpretation is set universally by the World Wide Web Consortium (Berners-Lee, Hendler and Lassila, 2001, p. 32).

4 Unlike HTML, which will typically attempt to display a Webpage even though it may be missing certain tags, XML is far less tolerant of missing tags or other encoding errors. This "draconian error handling" is deliberately designed to promote stability in data-handling (Kasdorf 2003, p. 91).

5 A number of software packages available which plug in to desktop publishing and word processing applications, such as Microsoft Word, enabling users to tag content from within the application.

6 As Kasdorf (2003) points out, it is useful to remember that while PDF is a widely adopted page description language, it remains a *de facto* standard controlled by Adobe Systems.

7 For an example time-line of legislation, see Figure 2 in Arnold-Moore, Clemes, and Tadd (2000).

8 For a more detailed examination of some these challenges within the context of the Estonian legislative system, see Heero, Puus, and Willemson, 2002.

# Applications of E–Commerce in Government

A

**Genie N. L. Stowers**
*San Francisco State University, USA*

## INTRODUCTION

Electronic commerce, or e-commerce, is simply business that is conducted over the Internet. Government e-commerce applications are those e-commerce applications utilized by some level of government, whether it is federal, state, or local. In this article, we will distinguish between interactive transactions and e-commerce transactions. Strictly speaking, e-commerce applications are only those in which a financial transaction of some sort takes place. Interactive transactions would involve interaction with a Web survey or some other application like filing an online form requesting services or submitting a complaint, but financial transactions are not included. Electronic commerce applications are an important segment of the growing e-government service delivery field. Government e-commerce applications may involve G2B (government-to-business), G2G (government-to-government), or G2C (government-to-consumer or, in this case, citizen) mechanisms.

Table 1 provides examples to illustrate the differences between e-government activities like information provision, non-e-commerce interactive transactions, and e-commerce transactions.

## IMPORTANCE OF E-COMMERCE APPLICATIONS IN THE PUBLIC SECTOR

E-business and e-commerce has grown very rapidly throughout the U.S. and international economies, along with the Internet itself. In 2005, there were an estimated 604 million worldwide Internet users; 159 million were estimated to reside in the United States (U.S. Central Intelligence Agency, 2005). This increase and the rapid change and growth in technology led to a burgeoning of interactive service delivery and retailing over the World Wide Web, or e-commerce. The U.S. Census Bureau estimated e-commerce activity in the third quarter of 2005 at $22.3 billion in adjusted dollars, an increase of 5.7 % from the estimates of the third quarter of 2004. In the third quarter of 2005, e-commerce sales had grown to 2.3 % of total retail sales and was still growing (U.S. Census Bureau, Economics and Statistics Administration, 2005).

In 2002, the U.S. Department of Commerce found that 30.9 % of all Internet users over the age of three had used the Internet to search for government services (U.S. Department of Commerce Economics and Statistics Administration, 2002). As more recent data from the Pew

*Table 1. Examples of e-government information provision, interactive transactions, and e-commerce transactions*

| | Information Provision | Interactive Transactions | E-Commerce Transactions |
|---|---|---|---|
| **G2C (Government to Citizen)** | Provision of information and forms via .html pages, .pdf files or forms | Complaint forms to be completed by citizens | Online purchase of birth and death certificates, hunting or fishing licenses, or renewal of drivers licenses |
| **G2B (Government to Business)** | Provision of procurement RFPs and RFBs by business plus other information on how to do business with government | Service completion forms to be completed by businesses | Online purchase by businesses of government data such as census or GIS data, maps |
| **B2G (Business to Government)** | Business provides government online information on goods and services available to agencies through vendor/procurement sites aggregated together | Businesses register as vendors using interactive transactions | Business sells government goods online from vendor "mall" set up to capture economies of scale |

*Table 2. Selected Internet activities from the Pew Internet and American Life Project Survey (Pew Internet and American Life Project, 2004)*

| Internet Activity | Percent of Those with Internet Access Who Do Each Activity | Month and Year of Survey |
|---|---|---|
| Research a product or service before buying it | 78 | February 2004 |
| Look for information from a government Web site | 66 | August 2003 |
| Buy a product | 65 | February 2004 |
| Buy or make a reservation for travel | 55 | May-June 2004 |
| Bank online | 34 | June 2004 |
| Participate in an online auction | 23 | February 2004 |
| Buy or sell stocks, bonds, or mutual funds | 12 | February 2004 |
| Buy groceries online | 12 | March-May 2003 |
| Make a donation to a charity online | 7 | December 2004 |
| Play lottery or gamble online | 4 | March-May 2003 |

*Table 3. Selected government e-commerce activities from the Pew Internet and American Life Project, "Rise of the E-Citizen"Pew Internet and American Life Project (2002)*

| Internet Activity | Percent of Those Who Use Government Web Sites Who Have Ever Done Each Activity |
|---|---|
| *Information* | |
| Get tourism and recreational information | 77 |
| Do research for work or school | 70 |
| Find out what services a government agency provides | 63 |
| Seek information about a public policy or issue of interest to you | 62 |
| Get advice or information about a health or safety issue | 49 |
| Get information about potential business opportunities relevant to you or your place of employment | 34 |
| Get information about elections such as where to vote | 22 |
| Get information that helped you decide how to vote in an election | 21 |
| Get information about a lottery | 21 |
| *Transactions* | |
| File your taxes | 16 |
| Renew a driver's license or auto registration | 12 |
| Renew a professional license | 7 |
| Get a fishing, hunting or other recreational license | 4 |
| Pay a fine | 2 |

Internet and American Life Project have confirmed, many more users now use the Internet to look for information from a government Web site (66 %) and roughly the same number are now using the Web for e-commerce applications (see Table 2) (Pew Internet and American Life Project, 2004). Table 2 illustrates how often those with access to the Internet engage in e-commerce or government-related activities. Table 3 illustrates the fact that most users still use the Internet to search for information from government agency Web sites rather than make an

e-commerce transaction. The Pew Internet and American Life Project found that 16% of government Web site users used the Internet to file their taxes, 12% of government Web site users used these sites to register or renew their car registrations, 7% renewed a professional license, only 4% got a fishing, hunting, or other recreational license and even fewer—only 2%—used it to pay a fine (Pew Internet and American Life Project, 2002). These rates increase with experience with the Internet and with income levels (Pew Internet and American Life—Project, 2002). Far more citizens evidently trust and use government Web sites to get tourism and recreation information (77%) than to get information about the lottery (21 %).

## BASICS OF SUCCESSFUL E-COMMERCE APPLICATIONS

Several elements are necessary for successful e-commerce applications, including those utilized by government. The electronic storefront provides an interface seen by users while the "backend" is where applications like databases reside:

- **The Agency Portal Complete with User-Friendly Interface:** Government agencies must provide an interface that users can navigate and successfully utilize on their own. Typically called the storefront, the user-friendliness of this interface is crucial for the public sector, as many who use public applications could lack experience with computers, the Internet, or both.
- **The Ability to Acquire and Store Information:** Government agencies, like private sector companies, must be able to digitize and manage information about goods available, effectively and efficiently. For e-commerce applications, this means being able to manage the items for sale, orders, and customer information. This is accomplished through database-based catalogs and other database applications.
- **Shopping Cart:** Government agencies typically also utilize the concept, if not the actual software, of the shopping cart. This software application is a virtual space where goods to be purchased are accumulated until checkout.
- **Search and Discovery Engines:** Not only must agencies be able to manage their information in large databases, but citizens must also be able to access and find the information that they need. Therefore, effective search engines are crucial for e-commerce sites and are typically part of e-commerce software suites.
- **Electronic Payment Capability:** Secure systems must be available to allow citizens to pay for services and goods and provide a vehicle for citizen confidence in those systems. Beyond secure credit card systems, digital cash systems are being developed to ensure that money can be transferred smoothly and effortlessly between parties with a high degree of security. These capabilities are also typically part of e-commerce merchant server software.
- **Provisions for Secure Systems:** Confidentiality, authentication of identity, and integrity of transactions. Important requirements for any online transaction include that transactions remain confidential, that all parties be able to verify the identity of all other parties, and that no one else is able to interfere with those transactions. This means that some cryptographic system or a vehicle like digital signatures must be utilized.
- **Connectivity:** All systems need to be accessible and must contain adequate bandwidth to handle the transfer of large amounts of information and communication.
- **Legal and Policy Context:** The entire policy universe surrounding e-commerce is continually evolving and changing. Some of the issues being debated in state legislatures and in Congress are digital signatures, privacy, intellectual property, and Internet taxation. The result of these legislative decisions will have an enormous influence upon e-commerce applications in both the public and private sectors in the near future.
- **Agency Back-End:** The agency back-end activities are also important for the success of a governmental e-commerce application. These activities include inventory management, accounting and finance, delivery mechanisms, and customer service activities that would exist without e-commerce but must be even more efficient since e-commerce is moving the agency towards 24/7/365 operation and citizen service.

For simple implementations, agencies could purchase e-commerce merchant server software to implement their system, which would typically include the user interface or portal, database-based catalog system, a search application and shopping cart with payment capacity. These features entail the front-end of the e-commerce application and are often provided by outside vendors or ASPs (application service providers). Today's (2005) e-commerce models are established within a Web services environment of distributed applications and several different Web protocols—SOAP (simple object access protocol), WSDL (Web Services Description Language),

and UDDI (universal description, discovery, and integration) (Elsas, 2003).

As e-commerce continues to develop, one of the most critical issues for the public sector to resolve is to establish a common e-commerce architecture so that applications can be interoperable, scalable, and, ultimately, useful for the agency and citizens (Oscar, 2001).

## TYPES OF E-COMMERCE MODELS AND APPLICATIONS FOR GOVERNMENT

Several different types of e-commerce models are being implemented in the public sector today.

### Simple Financial Transactions/Classic Shopping Cart Model

The first of these models are the simple financial transactions that are the most common e-commerce sites found on the World Wide Web today. These straightforward transactions allow consumers to access goods from vendors' sites at their own convenience—24/7/365. For simple financial transactions, most sites utilize a classic shopping cart model to store and then move to checkout.

Government agencies do not engage in as many straightforward financial transactions as does the private sector but there are applications which are well-known and are comparable to private sector activities. These include:

- The purchase of goods like stamps or Amtrak reservations from quasi-public agencies in straight-forward transactions that operate exactly like those in the private sector.
- The purchase of birth or death certificate, another important financial transaction in which citizens interact with their governments.
- Online fee, permit, and license payments are one of the most frequently used public sector e-commerce services. Many states currently offer the capacity to purchase hunting and fishing licenses as well as many types of professional licenses.
- A more specific type of license payment and renewal are drivers' license and vehicle registration renewals. Many states currently offer the capacity to renew drivers' licenses and vehicle registration as well as pay parking and traffic citations online.
- Many states have now developed and implemented online tax submission applications where citizens pay fees to submit their tax returns online.
- Finally, many jurisdictions and agencies offer the ability to purchase maps, data, or other "products" produced by the public sector. Census or statistical data is but one example that is either now offered free for download or is available for charge online.

### Portal Sites/Aggregators

In important public procurement efforts, gateway sites or portals have been developed to bring together numerous vendors and retailing opportunities at one site. The goal is to provide one site to which users can go to obtain everything they need and want in order to capture economics of scale and efficiency for agencies. They are based on sell-side one-to-many architectural models in which vendors provide information and the opportunity to purchase goods from their Web sites or independent portal sites with buyers and sellers integrated together (Moon, 2002). These procurement efforts, often run by ASPs, are important e-commerce activities since they utilize the Internet to facilitate B2G transactions. Each vendor's catalog is available for search for merchandise selection, also creating convenience opportunities for government procurement agents.

There are several major procurement projects in the public sector involving vendor aggregator sites. Projects like the U.S. Department of Defense's Emall and the Multi-State Emall project, which once allowed Massachusetts, Idaho, New York, Texas and Utah to participate together in procurement efforts, are collections of sites brought together with a common database and user interface (Stowers, 2001). These e-commerce applications have already proven their enormous potential for dollar savings and productivity improvements for public sector agencies working together. At one time, Massachusetts reported savings of from $52 to $108 per procurement transaction and a 72% reduction in time spent on managing the procurement function (Moon, 2002, p. 28).

### Online Auctions

Online auction or reverse auction sites provide more and more governments the opportunity to interact and bargain with others interested in buying and selling. Auctions operate on the eBay model with many buyers competing for the same goods; governments now often utilize these models to sell surplus or confiscated goods. Along with reverse auction sites, these sites have diffused throughout government agencies. Reverse auctions occur when government agencies identify the goods they want to purchase and vendors bid to supply them. There is evidence that both have saved money for government agencies.

Wyld (2004) has identified several important cases of successful online auctions or reverse auctions and makes the case that this implementation of e-commerce technology is an important new resource for effective and efficient asset management and developing new sources of revenues. Some jurisdictions have successfully sold surplus goods on eBay while the U.S. Defense Department has created a partnership with GovLiquidation.com to get rid of its surplus goods and make money doing it. Bid4Assets is another online private sector site that specializes in the auctioning of tax-forfeited properties. Many law enforcement agencies are also getting involved with online auctions in order to dispose of seized, lost, or forfeited property and goods. The potential for growth in this area is enormous.

### Online Premium Service Areas

Finally, many state governments (examples are Virginia and Georgia) have established password-protected premium services areas that provide services, information, and e-commerce activities—for a fee transacted online. Typically, these sites allow access to protected databases and other information, such as state corporation databases and access to drivers license records which are useful to those in some professions but not to everyone.

## ISSUES AND FUTURE TRENDS

An essential difference between public and private sector e-commerce is that governments serve only their own citizens—a limited number—and a limited geographic area, not a potentially world wide market. Except when jurisdictions are large enough (states or the federal government), this makes any e-commerce efforts far less efficient than for private sector firms. It also makes it more difficult to earn benefits over a broader scale and scope of customers and does not allow smaller jurisdictions to take advantage of economics of scale and positive externalities. Governments obviously also have limits to what can be sold online; most e-commerce applications are found in the limited areas where funds do exchange hands—taxes, licenses and permits, and procurement.

Governments have additional constraints that are confined to the public sector and make e-commerce and e-government efforts infinitely more challenging. These include the absolute need for privacy and confidentiality of client information, their need to be accountable to their citizenry, their duty to provide access to all (not just those with discretionary income), and their duty to provide public rather than private goods. Governments are also more likely to be providing services rather than goods and are therefore less likely to have goods available for e-commerce opportunities.

Because of these restrictions and challenges, governments have moved more slowly towards e-commerce than the private sector and e-commerce transactions are more likely to be found on the largest public sector Web sites like those found for federal agencies, states, and large cities. However, in a very short period of time, many federal agencies, states and cities have developed some extremely innovative applications that provide very useful services to the public.

The potential in some of these innovative areas of e-commerce is great. It is clear that e-commerce in the public sector will grow along with the growth of e-government itself and with e-commerce—although more slowly than e-commerce growth in the private sector. However, the potential for auctions and reverse auctions and other procurement applications is quite exciting (Moon, 2002; Wyld, 2004). In addition, with mobile government (m-government) also beginning to expand, potential e-commerce applications exist for wireless applications as well (Moon, 2004)—the newly emerging field of m-commerce (mobile commerce).

## CONCLUSION

There is an exciting future ahead in e-government and e-commerce, fueled by technology and our imagination. Government processes can be improved and e-commerce can assist in that process. E-government and e-commerce will not replace face-to-face government, but it can definitely enhance it. There are many challenges ahead for e-government and the e-commerce applications that will more and more often fuel those efforts. A careful examination of potential applications, viewed within an agency's own mission and goals, and an examination of the experiences of other agencies' experiences and lessons learned (such as those presented here) will help to enhance the chances of eventual success.

## KEY TERMS

**Application Service Provider (ASP):** A separate party that manages software-based services for customers. Governments often utilize ASPs to provide e-commerce capabilities.

**Auction or English Auction:** An auction or English auction is the traditional one where customers bid at the lowest price possible and, as demand increases, the price increases also, with bidders anonymously bidding against one another.

**Digital Cash System:** A system that lets users transfer funds back and forth over the Internet and operates like cash or credit cards in face to face transactions. These facilitate e-commerce transactions online.

**Digital Signature:** A digital signature is an encrypted code sent along with Internet messages that uniquely and securely identifies the sender. Since the identity of the

sender can be established, the digital signature enables e-commerce transactions to occur securely.

**Reverse Auction:** Operates the opposite. Suppliers are the ones who bid, after the buyer establishes the auction to receive goods. The suppliers bid down against one another in order to be able to provide the service or goods.

**SOAP:** Stands for simple object access protocol. An XML-based message protocol assists in Web service requests by structuring the communication of data between systems.

**UDDI:** Universal description, discovery, and integration. Dynamic online directory that lists online Web services available on the Web.

**WSDL:** Web Services Description Language, an XML based language describing Web services available in transactions between users.

**XML:** Extensible Markup Language is a Web-based markup language used to tag, or identify, the data used in Web services.

# Applications of Geographical Information System in E-Government

## INTRODUCTION

Geographical information system (GIS) is one kind of information system that handles spatial data. It is difficult to give one definitive definition about GIS (Heywood, Cornelius, & Carver, 2002; Maguire, Goodchild, & Rhind, 2001). This variety of definitions can be explained by the fact that any definition of GIS will depend on who is giving it, and their background and viewpoint (Pinkles, 2002). The complete definition of GIS is selected here as: "a set of tools for collecting, storing, retrieving at will, transforming, and displaying spatial data from the real world for a particular set of purposes"(Burrough, 1986, p. 6). As an important part of e-government, is that it has functions of cartography, manages spatial data and spatial analysis.

## BACKGROUND: THE ROLE OF GIS IN E-GOVERNMENT

All types of data are needed in e-government, among which spatial data are perhaps the most important information, reflecting the distribution rules of spatial entities (e.g., property boundaries, roads, etc.). Therefore, e-government cannot do without GIS, and therefore, the management of e-government cannot be successful without analyzing spatial information. With the advantage of handling spatial data, GIS can provide many services concerning spatial analysis, such as, geographical location information, location-based services, route tracing, and the analysis of spatial structures. This can be especially valuable when incorporating social and economic attribute data.

### Functionality of GIS in E-Government

There is a wide range of functions for data analysis available in most GIS packages. According to the top-down hierarchical classification of the major types of functions that characterize GIS, there are ten major categories to define the functions of GIS: capture, transfer, validate and edit, store and structure, restructure, generalize, transform, query, analysis, and present (Dangermond, 2001; Maguire & Dangermond, 2001). In any GIS project, not all of the GIS functions or even all of the major categories need be employed. Generally, with the functions like measurements, attribute queries, buffering, map overlay, spatial interpolation, analysis of surfaces, and analysis of networks, GIS can provide mapping, spatial data management, and many other functions for various managing in public sector.

For example:

- GIS could handle and provide relative maps. Since GIS provide spatial information with maps, it can make the necessary information much clearer and obvious at first glance.
- GIS can collect, handle, store and manage spatial data. Managers can obtain more complex spatial information for making decisions through query functions of the system.
- Spatial analysis function of GIS can be used in simulating and analyzing (creating what if scenarios) of the stored spatial data. With GIS software, various description programs for spatial processes are provided as decision-making support system for management.

### Applications of GIS in E-Government

GIS can play a role in all aspects of spatial information management. In governmental management, GIS application becomes more and more intensive. Some cases are shown next to illustrate applications of GIS in governmental management.

- **Regional (or Urban) Planning—Both General and Physical Ones:** By combining graphic and property information effectively, GIS can provide immediate

and bidirectional data operation. This can provide services such as inputting map data, editing topographic map, setting up attribute data and querying planning information. With the proper system, both general urban planning and physical plans can be created, as well as comparing and simulating the different results of the planning. Meanwhile, GIS can provide assistance via decision-making support tools for selecting land blocks, examining and approving architecture licenses, evaluating demolition and relocation projects. Most importantly, the planning programs can be described by maps.

- **Land Management—Managing Land Resources, Land Record, Land Classification, and land Using:** All the land management process can be fulfilled by operating spatial data stored in GIS. Generally, GIS provide tools such as data inputting, querying land block alteration, analyzing land quality, and automatically measuring land areas for the end users. When doing land management, GIS can also be integrated with office automation (OA) system into an integrated land management information system, which involves many subsystems such as data handling, windows office, and cartography, and so forth. With the system, the users can query the distribution of land resources, alter the record of stakeholders, and make land use plans in the network.
- **Municipal Facilities Management—Managing Pipelines of Water, Electricity, Gas, and so forth:** By combining pipeline databases of municipal facilities, customer location information and property, GIS can provide graphic displaying and query functions for managers and inspectors; by using network analysis model and information about valves and switches of municipal pipeline network, GIS can provide inspection data and emergent repairing programs for work process handling, detect field construction, and analyze the areas where there are, or have been failures or that are prone to failure in the pipelines.
- **Traffic Management—Managing Vehicles and Roadways:** Constructing city traffic information system with GIS, the system can query and analyze the traffic conditions through spatial and attributes data. At the same time, the system can be connected with other equipment, such as road sign controllers, vehicle information systems and global position systems (GPS), etc. In this way, close loop control system is created to manage traffic information, roadways situations, and vehicles effectively.
- **Hazard Monitoring and Controlling—Emergency Management:** A large variety of data elements involved in the assessment of risk and emergency management can be collected by GIS. Once a database of potential hazards has been set up using GIS tools, specific hazards or emergency situations can be displayed by query and other spatial analysis functions of GIS. The system can also help to make special assessments for emergency preparedness by being integrated with social-economic and traffic databases (and other data), assisting in making the decisions for response, and for the process of recovery.
- **Real Estate Management—Managing Housing and Property:** By using GIS, we can manage data of district boundaries, street networks, municipal facilities, architecture, and the various types of public facilities, as well as the characteristics of private properties in order to make good housing policies. For example, providing more housing opportunities for poor people, etc. GIS has very rich functions such as editing, developing overlays and creating complex displays from disparate data. As a result, property information, housing age, housing prices and surrounding infrastructure information can be queried using GIS tools. In addition, the spatial analysis of building locations or property alterations can be done by setting up many kinds of analytical models.

## KEY ISSUES OF GIS APPLICATION IN E-GOVERNMENT

GIS applications will meet various issues in different governmental sectors. Because the governmental roles are multi-sectored and complex, the system has to manage the different data formats, and operate in various environments in order to meet data sharing and exchange requirements between different sources. Therefore, interoperability of spatial databases, the unification of multi-department application systems, and integration of GIS into management information systems (MIS) and other non-spatial systems are critical issues in GIS application.

### Interoperability of Spatial Database

Managing spatial data is the key issue of GIS application. Many kinds of GIS software have been employed over time and some remain as legacy systems. In some cases, software was independently developed. There are lots of differences among these various GIS software platforms, especially because of various data formats. As a result, some data might be lost when it is used with software it wasn't designed for. Hence, data sharing between GIS

software can become difficult. In order to resolve the data sharing problems as above, those managing data should adopt standards, and if possible, have common, shared data store in a database that is designed to accommodate spatial data. The objective is to have data stored in one place, available to everyone that needs it.

### Unifying Various Departments

Governmental management is a vertical and horizontal networked system, which involves multiple levels and departments. In the historical periods of application development, some information systems were built uniquely for different departments. Many of these systems would not work together making communication and collaboration between different departments difficult. When communication and collaboration exists among different departments (systems working together), the sharing of spatial data has played a significant role in constructing of e-government. For example, modern civil traffic commanding system involves city planning, traffic management and environmental departments. All these systems have to work together and be used cooperatively. How to construct such synthesized set of applications is a critical problem in the digital city. The first issue is to set up multi-departmental information system based on spatial data and GIS technology, with data standards and hopefully, common spatial data storage.

### Integration of GIS with MIS and Other Non-Spatial Systems

GIS is one part of e-government. Effective management could not be done without integrating GIS with MIS, OA, a multimedia image processing system, and a communication and image processing system. At present, the lack of a common interface and transparent data access can become the bottleneck of e-government, GIS will play more important role in governmental management system, as the integration problems are resolved.

## MANAGING DATA FOR GIS APPLICATION

Data is the core of GIS. The expense for data can account for more than 80% of the entire system cost, and data needs to be maintained and updated for the life of the system (Chen, 2004). The success of the system is closely related to database architecture and construction. Data segmentation (grouping data relative to users' needs and required access) is developed from administrative segmentation and from different administrative units. The issues of GIS database architecture and construction are listed as follows.

### Unifying Standard of Database Construction

All existing and legacy GIS software may have their own data formats and data structure standards. In many systems, it is impossible to read and use the data directly from other GIS software without translating data formats and structures. Therefore, data formats and structure standardization to enable data sharing, is a key problem, which should be addressed in the process of GIS construction and development to insure the ability to share of data.

### Integration of Databases

The data sources of GIS come from widely different methods of collection, from different time periods, different regions, different departments and different systems, etc. The level of precision, data formats and quality of each set of data also may be quite different. How to organize such data and allow them be shared is a difficult and important job. In order to resolve these problems, data integration must be given the highest priority when designing and constructing an enterprise-wide GIS, using shared data by organizing all existing data, creating standard contents, scales, precisions, and coordinate systems. The benefits are divergent departments and end users, all working with the same information, using the same data standards, the same data precision, and the same data quality, making the management of the system easier and more uniform across the entire organization.

## CONSTRUCTION OF LOCAL GOVERNMENTAL GIS

A local government using a common GIS platform is an important part and phase of an e-government information system.

### Characteristics of the Governmental GIS platform

A governmental GIS platform should be a cooperating GIS based on a Web environment. It is logically unified (central access via the Web), but physically dispersed. The government is the organizer, creator, and user of the GIS platform. The objectives of the technology and data of a government GIS platform are to meet the planning

and managing needs, using governmental and other related spatial information.

The objectives of a governmental GIS platform require that:

- The planning, design and constructing must accommodate existing Web and office platforms
- Different application systems can be set up separately, yet always with a view to eventual integration
- The system needs to be continuingly updated and enhanced. Therefore, the initial system design must look toward the future and accommodate future anticipated requirements

As Governmental GIS is especially valuable when used with urban emergency systems, the initial design should consider being integrated with the various emergency support systems. For example, police, fire, traffic, hazard preparedness, public health, and so forth, so that from the onset, a unified emergency management system can be designed and created.

## Principles of the Platform Solution

- To construct governmental GIS platform for inputting data and making digital maps
- To redefine system functions, including personnel, organization, user rights, map layers, attribute fields, data quality, and so forth.
- To integrate databases seamlessly, setting up a simple interface using real time information, and make the platform into a real time multimedia data display
- To design dynamic and flexible structures in order to satisfy governmental leaders, official members and the public
- To combine distributed application system structure and component structure together (Zhang, 2004)

## System Functions of the Platform

As a platform of governmental management, the system should have more adequate attribute data (from across departments), easy to use queries besides the basic functions of spatial analysis. The main functional areas as follows:

- **Basic Map Maintenance:** This function includes map viewing controls, layer maintenance, map maintenance tools, cartography, saving, printing, and so forth.
- **Signin:** With this function, the user can mark related sites or buildings on map layers within their allocated access rights and input related data.
- **Roaming, Dragging, and Zooming:** For example, the user can index useful information by dragging, zooming, and roaming around the map.
- **Querying and Displaying:** The desired spatial and attribute data can be conveniently obtained, by the user, through the robust graphic functions of GIS. As a result, combined queries for maps, graphs and data can be obtained. For example, the location map can be obtained when the user inputs an address, post-code, unit name, or any other attribute data contained within the system. In the same manner, the surrounding areas' information can also be queried, such as points of interest, hotels, businesses restaurants, shopping malls, hospitals and schools, and so forth.
- **Data Collecting Based on OA:** Data is the lifeblood of a system. Database architecture and design is integral in system construction. Because the existing data is dispersed, may be out-of-date, and come from different sources and formats, it makes the system harder to construct. Therefore, standards and quality criteria of data should be defined from the onset.
- **Doing Statistic and Analysis with the Attribute Data:** If a user creates a histogram using certain data, or identifies certain information such as population density and educational degree, etc., with specific colors, as in a thematic representation, these separate analyses can be displayed in different layers.
- **Releasing Map Information:** Weather forecast, pollution monitoring, municipal infrastructure constructing, development important events and traffic conditions can be mapped and distributed via GIS00

## Technological Features of the Platform

Governmental management platform needs to be compatible with all types of data and systems. Therefore, the technological characteristics are listed as follows:

- The system should support at least 100 users accessing the system at the same time.
- Managing spatial data with a relational database should have spatial data and non-spatial data integrated in the same database.
- The application of GIS controls and components can provide GIS functionality within non-GIS applications.

- The system should support all kinds of attribute data, such as population, economic growth and pollution data. It should also allow for attributes defined by users themselves.
- The system should integrate multimedia data, support graphics and other information, such as characters, pictures, voices, and images, and so forth.

## THE IMPACT OF GIS TECHNOLOGY DEVELOPMENT IN THE APPLICATION OF E-GOVERNMENT—FUTURE TRENDS

From a technological development point of view, Web-GIS, and mobile GIS are the most advanced GIS technologies to date. More and more governmental offices have begun to use GIS, which have created new challenges to GIS technology. New GIS techniques are also appearing in many governmental offices, For example, multiple-dimension data interfusion, three-dimensional information representation (3D CAD), several software techniques that bring maps, data, text and imagery into one system and of course, Web-GIS.

### Web-GIS Technology

Since the internet became popular, the Web browser has been accepted more and more by the publics, because it is a universal client application and used everywhere. Because of the browser as a universal platform, the browser has formed the fundamental tools of Web-GIS. The communication protocols being adopted for Web-GIS are totally different from PC operation system or IP network. The spatial database of Web-GIS is openly designed and combined with standard database technology to form a foundation for Web-GIS.

This technology was naturally incorporated into e-government systems when governmental office automation systems were linked with the Internet.

### Development of Mobile GIS

Mobile GIS plays an important role in an overall GIS system. Terminal devices such as wireless application protocol (WAP) telephone, personal digital assistant (PDA), or even the common telephone can obtain spatial information (Dong, 2004). This makes the possibility of obtaining multi-dimensional spatial information on a mobile device a reality. Mobile GIS is a new field of GIS and should have great market potential. The main application fields in governments for mobile GIS include urban infrastructure management, object-location and resource detection and object tracing, real time data updates from field personnel, and so forth.

### Interfusion of Multiple-Dimension Data

When topology relationships, location relationships and attribute relationships between two or more digital maps are set up, a vast amount of data can be interfused to establish foundations for the management and analysis functions of GIS. These digital maps (from this interfusion) formats are digital line graph, digital raster graph, digital elevation model, digital building model, and digital thematic map, and so forth. (Hao, 2002).

The interfusion technology makes map more convenient to be viewed and operated. It allows non-GIS professionals understand and implement GIS. Importantly, it can take advantage of multiple dimension data to promote planning efficiency and accuracy. The system can be operated in a three-dimension (3D) computer environment, which makes regional (urban) plans much richer and simulate reality.

### Three-Dimension Representation Technology

When 3D information is obtained in the form of vehicle data, mobile data and laser-scanned data, 3D modeling methods can be created using Automatic Computer Assistant Design (AutoCAD, 3D design programs) modeling, 3D image modeling, GIS attribute modeling and laser-scanned modeling. Using these techniques, spatial information can be used within a 3D computer workspace. As a result, information can be configured within a GIS system in order to construct regional (urban) 3D models.

Because it is richer and creates visualizations that are closer to reality, three-dimension representation can be used in monitoring, urban planning and design, and the construction of public 3D viewing platforms.

### Software Integration

Traditional software and new technologies, as well as special purpose software have been integrated with the evolutions and enhancement of the IT technological environment. For example, new techniques such as Web-GIS, 3D-GIS and Component GIS, have all evolved from traditional GIS technology; Multimedia, Work-Flow, and OA software technology has been evolved from traditional MIS; Internet Web technology has been evolved from the traditional local area network. One interesting trend of software integration is the integration of CAD

and GIS and 3D software. There will be more integration of 3D GIS, Web GIS, and VR technology in the future as we move toward more realistic display of data.

With more coordination and integration among governmental departments, there will be more integration of GIS in government. This integration will be mainly done using technologies from MIS, GIS, CAD, OA, Web-GIS, 3D GIS, and virtual reality (VR). Where they will be employed in planning management, real estate management, basic geographic information system, pipe lines management, and urban OA, and so forth.

## CONCLUSION

GIS has strong functionality in the ability to handle spatial data, with which, it can provide a visualization of reality on the computer for the manager. By using GIS software, the manager can view spatial entities and create powerful analysis for decision-making. This makes managing more efficient and effective, because the manager can visualize and harness powerful sources of information.

However, while spatial analysis is the special function of GIS, and is a powerful tool, there is much more to be developed. Both the engineers of GIS and application professionals are trying to develop even more powerful spatial analysis functions for e-government. GIS will become more and more a standard tool in the field of e-government.

## KEY TERMS

**Attribute Data:** It is one kind of data about the nature of the real-world future that the spatial entity presents in GIS. There are two kinds of data in GIS, which are attribute data and spatial data.

**Buffering:** It is used to identify a zone of interest specified distance around an entity, or set of entities.

**Digital Elevation Model:** Digital elevation model data files are digital representations of cartographic information in a raster form. It consists of a sampled array of elevations for a number of ground positions at regularly spaced intervals.

**Interoperability:** It is the ability of exchanging and sharing data files and programs among

**Location-Based Services(LBS):**LBS is the ability to find the geographical location of the mobile device and provide services based on this location information into the cell network or handset that uses triangulation between the known geographic coordinates of the base stations (with GIS, e.g.) through which the communication takes place.

**Map Overlay:** The ability to take two different thematic map layers of the same area and overlay them one on top of the other to form a new layer.

**Route Tracing:** It is the ability to trace flows of goods, people, services and information through a network in the GIS. Connectivity, the way network links join at network nodes is the key concept in route tracing. Once a directional network has been established, tracing the links downstream or upstream of a point on the network is simply a question of following or going against the flow, respectively.

**Spatial Analysis:** Modeling spatial process with spatial data by identifying the spatial features, representing the concept model and selecting an appropriate spatial data structure.

**Spatial Data:** Data which describe the spatial dimension with mathematical spatial reference.

**Spatial Interpolation:** It is the procedure of estimating the values of properties at un-sampled sites within an area covered by existing observations (Waters, 1999).

A

# Applying ICTs in Juridical Decision Making by Government Agencies

**Marga Groothuis**
*Leiden University, The Netherlands*

## INTRODUCTION

Electronic government is developing throughout Europe. Increasingly, central, regional, and local governments use ICT applications to perform their tasks. In the 1970s and 1980s, computers were mainly used to perform administrative tasks (including word processing). In the 1990s, *juridical expert systems* were introduced within government organizations: software programs which can solve juridical problems, either without any human interference or with limited human interference, by means of a reasoning mechanism and a "knowledge database" (Groothuis, 2004). Furthermore, government agencies started to use new ICT applications such as the Internet and e-mail to communicate electronically with citizens.

This article examines the juridical aspects of automatic decision making and electronic communication by government agencies in The Netherlands and addresses the following questions:

1. What is the legal framework for automatic decision-making by government agencies in The Netherlands?
2. What is the juridical quality of decisions made by expert systems in practice?
3. What is the legal framework for electronic communication between government agencies and citizens in The Netherlands?
4. To what extent does *electronic government* exist in The Netherlands and what are its prospects for the period 2005-2007?

## AUTOMATIC DECISION MAKING BY GOVERNMENT AGENCIES

Increasingly, government organisations in The Netherlands use expert systems to make juridical decisions in individual cases under the Dutch General Administrative Law Act (*Algemene wet bestuursrecht*). Examples of juridical decisions that are made by expert systems are tax decisions, decisions under the Traffic Law Act (traffic fines), decisions under the General Maintenance Act (maintenance grants), and decisions under the Housing Assistance Act (Bovens, Groothuis, & Van den Hoogen, 2003).

There are two categories of juridical expert systems. Expert systems in the first category support the process of juridical decision making by a civil servant. The decision is taken in "cooperation" between the computer and the civil servant. Expert systems in the second category draft juridical decisions without any human interference. In these cases the decision making process is fully automatic.

### The Legal Framework

To what extent and under which conditions is automatic decision making by government agencies legal? Under Dutch administrative law, there are no specific rules for automatic decision making.[1] Therefore, government agencies are entitled to use expert systems, or other ICT applications, in their decision-making processes if they wish to do so. This does not mean, however, that the use of ICT is not bound by any rules. When government agencies make decisions, the general rules of Dutch administrative law apply. Most of these rules can be found in the *General Administrative Law Act*. Among them are several *general principles of proper administration*: rules which administrative bodies should observe in all their acts. The *justification principle*, for example, holds that an administrative body should give grounds for its decision, and that these grounds must be mentioned in the decision itself (article 3:46 and 3:47 of the General Administrative Law Act). If a decision is made by an expert system (or another ICT application),

the *justification principle* requires that the reasoning (or logic) behind the automatic decision be explained. This means that the working of the ICT tool has to be transparent.

Besides the *general principles of proper administration* a second set of principles has been developed in Dutch jurisprudence: *general principles of proper use of ICT.* According to some scholars (Bovens, 1999; Franken, 1993) these principles—accessibility, confidentiality, integrity, authenticity, flexibility, and transparency—should be respected when government organizations use ICT. If, for example, a government agency uses an expert system in its decision-making process for residents permits, this system should be accessible for applicants and other citizens (principle of accessibility), function correctly (principle of integrity), and its working should be transparent (principle of transparency).

Finally, the Dutch Privacy Act (*Wet bescherming persoonsgegevens*) contains a specific provision on automatic decision making (article 42). This provision, which applies equally to government and nongovernment organisations and which forms the implementation of an EU directive[2], holds in its first section that:

*every person has the right not to be subject to a decision which produces legal affects concerning him or significantly affects him and which is not based on automatic processing of data intended to evaluate certain personal affects relating to him.*

The second section of this provision gives an exception to this main rule. It states that a person can be subject to a decision as referred to in the first section if—in short—suitable measures are taken to safeguard his legitimate interests, such as allowing him to put his point of view. This provision implies that automatic decision making by government agencies is allowed under the condition that citizens who have a legitimate interest in the decision are given the opportunity to present their views (e.g., in a public hearing).

## Quality of Electronic Decision Making: Two Case Studies

What is the juridical quality of automatic decision making by government agencies in daily practice? In the period 1999 to 2002 I performed empirical research on the quality of automatic decision making by government agencies.[3] In two case studies I examined whether automatic decision making meets the requirements of the applicable statutes and rules of unwritten law. The first case study examined the daily use of an expert system in the field of housing assistance in the Dutch Ministry of Planning. The second case study investigated the daily use of an expert system in the field of general assistance in one Dutch municipality.

In each case study, three steps were taken. First, a *checklist* was developed. Next, this checklist was *applied* to a selection of individual decisions. Third, the *results* of this application were categorised and interpreted.

Each of these individual decisions involved intensive file research. For each of the selected decisions the pertinent file was obtained and studied with respect to the criteria in the checklist. It was determined whether each decision fulfilled all of the requirements in the checklist. Below, the results of the two case studies are summarised.

## Case Study I: An Expert System for Housing Assistance

The first case study examines the daily use of an expert system in the field of housing assistance: *IHS*. This expert system was developed by the Dutch Ministry of Planning in the late 1980s and has "produced" millions of decisions since then. The system is run on a "mainframe", which is connected to a number of personal computers.

Seventy-five percent of all application forms for housing assistance are processed fully automatically by *IHS*: in these cases the decision is made without any interaction by a human being. In the remaining 25% of the cases, a civil servant is involved in some part of the decision-making process. In those cases the decision is made by "cooperation" between the expert system and the civil servant. An *interface* enables communication between the expert system and the civil servant. Via the interface the expert system asks the civil servant to enter specific data. After each question the expert system presents an intermediate conclusion on the computer screen.

In all cases, the reasoning mechanism of *IHS* formulates a decision in the individual case. No human being is involved in the formulation of the text. Each decision is automatically printed out and put into an envelope. No human being reads the decisions before they are sent.

To make correct decisions under the Housing Assistance Act, the Minister of Planning in The Netherlands needs to follow two sets of rules. The first set is the rules from the Housing Assistance Act. The second set consists of the general rules of administrative law, most of which can be found in the General Administrative Law Act. Among these are several *general principles of proper administration*: rules which administrative bod-

*Table 1. Categorisation of the 21 errors detected in the study of 200 decisions made with the support of IHS*

| | Type of quality criteria | | | |
|---|---|---|---|---|
| **Level of support by HIS** | **Content** | **Wording** | **Procedure** | ***Total*** |
| **Full support** | 0 | 16 | 3 | *19* |
| **Incomplete support** | 0 | 0 | 2 | *2* |
| **No support** | 0 | 0 | 0 | *0* |
| ***Total*** | *0* | *16* | *5* | *21* |

ies must observe in all their acts. A small number of general principles of proper administration have not been codified in the General Administrative Law Act; they are considered part of unwritten law[4]. These rules (or criteria) together formed the checklist.

For the purpose of the investigation the criteria contained in the checklist were divided into three subgroups:

1. Criteria with regard to the *content* of the decision;
2. Criteria with regard to the *wording* of the decision;
3. Criteria with regard to the *procedure* of making a decision.

The above checklist was applied to a selection of decisions made with the help of *IHS*. The period of investigation for the case study was 1999 to 2000; the decisions under investigation were made between July 1, 1997 and July 1, 1998. In this time span the Ministry of Planning made 1,031,000 decisions on a first application for a benefit under the Housing Assistance Act. Of those 1,031,000 decisions, 200 decisions were selected randomly and became the object of further investigation.

The investigation of the 200 cases revealed 21 errors which can be divided in the three categories of quality criteria in the checklist. These 21 errors can, however, also be categorised with respect to an important second dimension: level of expert system support, where three categories are distinguished:

1. Tasks for which the expert system offers full support
2. Tasks for which the expert system offers incomplete support
3. Tasks for which the expert system does not offer any support

Thus, the 21 errors detected can be categorised according to the criteria and according to the level of support delivered by the IHS system (Table 1).

As Table 1 shows, in none of the 200 cases was an error made with regard to the *content* of the decision. This result is remarkable. It can be explained by looking at the way *IHS* works. In this expert system, the provisions of the Housing Assistance Act have been translated into algorithms. In these algorithms, as in the Provisions of the Act, the rules for calculating the sum of housing assistance have been laid down. These rules are complicated, but they are all closed norms: there is no space for judgment during the decision-making process. The algorithms clearly prescribe step by step how the sum of housing assistance must be determined. The expert system—an application of ICT—never fails to apply the rules. In each case it applies the same algorithms, without ever making a mistake.

Table 1 further shows that in 16 out of 200 cases an error was made with regard to the *wording* of the decision. In each of these 16 cases, there was a breach of the justification principle, which holds that an administrative body should give grounds for its decision, and that these grounds must be mentioned in the decision itself (article 3:46 and 3:47 of the General Administrative Law). Decisions on housing assistance are formulated automatically by *IHS*: no human being is involved in the formulation of the grounds for the decision. The errors with regard to the wording of the decisions were caused by the way the expert system works. It produces standard text blocks for standard situations. A few standard text blocks, however, are incomplete: some steps of the reasoning process are left out. Thus, the grounds for the decisions become incomprehensible.

Finally, Table 1 shows that five errors were made with regard to the *procedure* for the decision-making process. In three of these cases, the error was caused by the expert system: it failed to check whether data were correct in situations where the General Administrative Law prescribes that such verification should be performed. In the other two cases, the error was made

*Table 2. Categorisation of the 25 errors detected in the study of 30 decisions made with the support of MR-ABW*

| | Type of quality criteria | | | |
|---|---|---|---|---|
| **Level of support by MR-ABW** | **Content** | **Wording** | **Procedure** | ***Total*** |
| **Full support** | 1 | 0 | 0 | *1* |
| **Incomplete support** | 5 | 11 | 0 | *16* |
| **No support** | 2 | 1 | 5 | *8* |
| ***Total*** | *8* | *12* | *5* | *25* |

by the human factor. In these cases, (typing) mistakes were made when a civil servant entered data from the application form into the expert system. These mistakes, however, did not affect the final outcome of the decision-making process (the calculated sum of housing assistance was correct).

## Case Study II: An Expert System for General Assistance[5]

The second case study investigates the daily use of an expert system in the field of general assistance in one Dutch municipality. This expert system, *MRE-ABW*, was developed by a Dutch software company in the 1990s and is now in daily use in about 20% of the Dutch municipalities. The system, which can be run in a network environment and on a personal computer, contains three parts: (1) a *database*, (2) an *interface*, and (3) *a reasoning mechanism*.

The *database* contains rules from the General Assistance Act, additional local regulations, case law for general assistance, rules from the General Administrative Law Act, and unwritten rules of general administrative law. Thus it offers the user the legal information with which to make decisions under the General Assistance Act.

The *interface* enables communication between the expert system and the user. In most cases the user will be a civil servant working in the social security department of a municipality. Via the interface the expert system questions the user, asking him or her to enter specific data (for example: date of birth and income of the applicant, etc.). After each question the expert system presents an intermediate conclusion on the computer's screen. The system can also generate an advisory report and a draft text for the decision in each individual case.

The *reasoning mechanism* or core of the expert system, is a set of algorithms into which all the steps that the expert system takes to deal with individual cases have been programmed. The reasoning mechanism applies the input data to the rules stored in the database. Thus it formulates intermediate conclusions, which are presented to the user via the interface. After asking a number of questions, the reasoning mechanism formulates a draft advisory report and a draft text of the decision in the individual case and exports both texts via the interface to a word processor, after which the user can either adjust them or print them as is.

In order to make correct decisions under the General Assistance Act, a municipal executive in The Netherlands needs to follow two sets of rules. The first set consists of the rules from the General Assistance Act itself. The second set is made of the general rules of administrative law, as described under case study I. These rules (or criteria) together formed the checklist.

For the purpose of the inquiry these criteria were divided into three subgroups:

1. Tasks for which the expert system offers full support
2. Tasks for which the expert system offers incomplete support
3. Tasks for which the expert system does not offer any support

The above checklist was applied to a selection of decisions made with the help of MR-ABW in one municipality. The period of investigation for the case study was January to December 1999. In this time span the social security department of the municipality in question made 1145 decisions on a first application for a benefit under the General Assistance Act. Of those decisions,

30 were selected randomly and became the object of further investigation.

The investigation of the 30 cases revealed 25 errors with respect to the three categories of quality criteria in the checklist[6]. These 25 errors can also be categorised as to the "level of expert system support", similar to case study I.

Thus, the 25 errors detected can be categorised according to the criteria and according to the level of support delivered by the MR-ABW system (Table 2).

As Table 2 shows, only a single error was made while performing a task for which the expert system offered full support. This error concerned article 43 (m) of the General Assistance Act. According to this provision, part of the work income of parents with children under the age of five may be disregarded (which leads to a higher benefit). The expert system offers full support for the task of interpreting whether a person qualifies for this provision. However, although the person in this case qualified, article 43 (m) was not applied. This was not the result of an error in the expert system. The civil servant probably did not give a correct answer to all the questions of the expert system. Based on wrong input, the system could only conclude that the provision did not apply.

Sixteen errors were made in performance of a task for which the expert system offered incomplete support to the civil servant. In 11 of the 16 cases, the decision did not fulfill the requirements for the wording of the decision. In all these cases, there was a breach of the justification principle, which holds that an administrative body should give grounds for its decisions, and that these grounds must be mentioned in the decision itself (article 3:46 and 3:47 of the General Administrative Law). In each case, the expert system offered a draft text for the decision, which contained grounds, but this draft text did not meet the requirements of the principle. In some cases the reasons that were given in the draft text were incomplete, with only some of the reasons specified in the decisions. In other cases, a calculation of the assistance allowance was given, but this calculation was incomprehensible, because important steps were missing. The civil servants could have amended the draft text for the decision manually, but they failed to do so.

In 5 of the 16 cases, the decision did not meet the requirements for the content of the decision. These cases all showed the same type of error in the application of article 14(2) of the General Assistance Act. This provision specifies the circumstances that must be taken into account when imposing a sanction upon the person applying for or receiving an allowance. The expert system offers support for the application of this provision, but its support is incomplete. That is, the system offers a draft text for imposing a sanction, but it does not support how the civil servant takes into account the circumstances specified in article 14(2). It appeared that the civil servants skipped the unsupported part of the task: the relevant circumstances were not taken into account.

Eight times an error was made in performing a task for which the expert system did not offer any support to the civil servant. Here the civil servant had to rely on his or her own knowledge. Without the help of the expert system, errors were made in all categories: errors in the content of the decision (two cases), errors in the wording of the decision (one case), and errors in the application of procedural rules (five cases).

To my knowledge this is the first investigation into the extensive use of expert systems in the daily practice of handling a complex juridical task within government organizations[7]. The results of these case studies show the problems that may arise when expert systems are put into practice, as well as their ability to improve the quality of the decision-making process. Expert systems may indeed be useful to improve the quality of decisions, especially when they make complex calculations. More specifically, the use of expert systems can further compliance with the principle of legal equality and the prohibition of arbitrariness. However, the use of expert systems does not guarantee juridically correct decisions. Errors—especially breaches of the justification principle and breaches of the principle of due care—are made if the system offers only limited support to its users. There is a risk that users will rely too much on the expert system and will not use their own knowledge when necessary.

These results underline the need for users of juridical expert systems to be aware of their limitations and to know how to use them. Government agencies that decide to use expert systems should take additional measures to maintain control over the quality of the decisions in fields which are not, or not completely, covered by these systems. Such measures may include:

- analysis of complaints by citizens and case law and, where necessary, adjustment to the expert system or the instructions to the users;
- additional training for the users of the expert systems in order to make them more aware of the risks of too much reliance on the expert system.

## ELECTRONIC COMMUNICATION BETWEEN GOVERNMENT AGENCIES AND CITIZENS

Increasingly, government agencies and citizens communicate with each other by electronic means. Citizens send e-mails to government agencies to apply for permits and grants and to submit objections or appeal against government decisions which affect them. Government agencies, in turn, open Web sites on which citizens can download forms, collect government information, submit applications, and so forth. To what extent and under which conditions is electronic communication between government agencies and citizens legal under Dutch administrative law?

In April 2004 the Dutch parliament adopted the Electronic Administrative Communications Act (*Wet elektronisch bestuurlijk verkeer*). This Act, which entered into force on July 1, 2004, regulates electronic communication in administrative procedures. This law is aimed at removing the legal obstacles for electronic communication between government agencies and citizens[8].

A key issue in this context is the term "in writing". Under Dutch administrative law, several acts are required to be in writing. Applications for individual decisions and objections against those decisions, for example, have to be submitted in writing. How should this term be interpreted in an electronic context: are electronic letters (e-mails) considered in writing? Since the late 1990s—when e-mail and Internet became common means of communication—there has been uncertainty about these issues under Dutch law.

The new Electronic Administrative Communications Act removes this uncertainty. It leaves the term "in writing" as is, and indicates in its explanatory memorandum that this term should be interpreted as "expressing signs on a data carrier". The data carrier can, according to the memorandum, be paper, but also an electronic carrier, such as a computer disk. Thus, the legislator has adopted a wide interpretation of the term "in writing". The requirement that applications for decisions have to be submitted in writing, for example, means that applications can be made by a letter on paper, but also via e-mail. The same applies for the submission of views, objections, and so forth.

The new Act further regulates under which conditions electronic communication between government agencies and citizens is allowed. Two principles are central in this context. The first principle is that electronic communication is allowed if both the government agency and the citizen(s) involved agree to permit it. Citizens are not obliged to communicate electronically with government agencies; on the other hand they have no right to do so if the government agency chooses not to use electronic ways of communication. The second principle is that the electronic message meets requirements of "reliability" and "confidentiality": an electronic message may be sent if the electronic system by which it is sent is sufficiently reliable and confidential, given the nature of the communication.

The Electronic Administrative Communications Act also contains a provision on *electronic signature:* art. 2:16. This article holds that the requirement of "signature" is met by an electronic signature "if the method which is used for authentication is sufficiently reliable, taking into account the nature and the content of the electronic message and the object for which it is used." The provisions on electronic signature in the Dutch Civil Code (art. 15*a*, section 2-6, and art. 15*b* of Book 3) apply to the extent that the nature of the message does not oppose to this. These provisions of the Dutch Civil Code are part of the Dutch Electronic Signature Act which forms the implementation of Directive 1999/93/EC of the European Parliament and the Council of the of 13 December 1999 on a Community framework for electronic signatures.[9]

## PLANS AND PROSPECTS FOR E-GOVERNMENT IN THE NETHERLANDS

### Plans for E-Government: An Overview of the Government Program 2004-2007

In September 2004 the Dutch government published the report "Towards the Electronic Government" (Ministery of the Interior and Kingdom Relations, 2004), in which it presented its policy program for e-government in the period 2004 to 2007. In this program the government has formulated four targets:

1. Companies and citizens should be required to submit certain information to the government only once.
2. There is to be an electronic system which enables all companies and citizens to be uniquely identified for official purposes.
3. In its communication, both internal and external, the government is to use open standards, thus

decreasing reliance on any one supplier or platform.

4. By the year 2007, 65% of all public services (at national, regional, and local authority levels) should be provided via the Internet.

In order to reach these targets the Dutch government has started a number of policy programs since 2004. These include a program to develop an infrastructure for electronic identification and a program for electronic authentication.

The object of the program for electronic identification is to enable all persons to be identified with just one type of document. At present, identification relies on various official documents such as a passport or National Identity Card for those persons registered with local authorities, a *SoFi card* for EU residents, and a *Foreign Citizens Card* for others. All such documents carry a unique number. The introduction of the new electronic identification—a chip card—will enable information to be read from the document electronically. Such information shall include the unique biometric characteristics of the holder. The chip card will enable government agencies to provide a wide range of public electronic services for which unique identification is required.

The object of the program for electronic authentication is that users—government agencies, citizens, and companies—can be certain that information can only be accessed in an authorized manner, and that it is impossible for anyone to assume another person's identity. To reach this goal, the government has started the development of a *Universal Government Access Facility*. This facility will have three layers of security:

1. A high security level, providing an electronic signature as defined and required by art. 2:16 of the Electronic Administrative Communications Act
2. A medium security level, in line with the current tools used for Internet banking and the software certificates (as proposed by the Chambers of Commerce)
3. A basic security level, requiring an identification number and/or password, as currently used by the Tax and Customs Administration

The *Universal Government Access Facility* shall enable government agencies to offer a range of "services" (e.g., maintenance grants, parking licenses, building licences) *online* to citizens and companies, rather than in offices.

The program "Towards the Electronic Government" has not yet been completed: the targets which the Dutch government has set for itself are for 2007. It is too early to estimate whether the goals will actually be reached. At present (2005) both the program for electronic identification and the program for electronic authentication are at an early stage of development. Plans have been presented and pilot projects have started in several municipalities.[10] At a national level, however, there is not yet an electronic identification or a means of electronic authentification for electronic transactions between government agencies and citizens.

## Prospects for E-Government: Challenges and Opportunities

What are the prospects for e-government in The Netherlands in the near future? We can conclude from the above paragraphs that the legal infrastructure for e-government is ready but the practical infrastructure is not yet. The new *Electronic Administrative Communications Act* regulates under which conditions electronic communication between government agencies and citizens is allowed. The new Act also contains a provision on "electronic signature", clarifying under which conditions an electronic signature can be qualified as a signature under the Dutch Administrative Law Act. However, in practice there is not yet a national infrastructure for electronic identification and authentication. It will last a few more years until each citizen in The Netherlands has his or her own electronic identification card which can be used in contacts with all government organizations. It will also last a few more years until there will be a national infrastructure for electronic authentication—available for electronic transactions with all local, regional, and national public organizations.

If the goal of a national electronic identification card and a national infrastructure for electronic authentication is reached in 2007, the prospects for e-government in The Netherlands in the period thereafter are positive. Empirical research in 2003 already showed that there is a demand for electronic government services among citizens and companies (Bovens et al., 2003; Groothuis, 2004). All municipalities in The Netherlands and nearly all other government agencies have Web sites. Already now citizens use e-mail to apply for grants and licenses and to submit objections against decisions by government citizens. Many municipalities and other government organisations develop plans for electronic transactions and have started implementing them at a small scale

in daily practice. The main challenge for the Dutch government in the period until 2007 will be to develop and implement a national—harmonized—infrastructure for electronic identification and authentication.

## CONCLUSION

The use of ICT by government agencies offers, from a legal point, both challenges and opportunities. A first opportunity is that ICT facilitates communication between government agencies and citizens. Citizens now have a new choice in their contacts with government agencies: they can communicate not only orally (in an office) or in writing (on paper) but also via e-mail and other new forms of electronic communication. Government agencies, in turn, can use Internet and other ICT applications to actively involve citizens in the process of developing new policies, prepare decisions, and so forth. This means that the interests and opinions of citizens can be better taken into account. An important condition for electronic communication between government agencies and citizens is that it meets requirements of reliability and confidentiality. These requirements have been laid down in the new Dutch *Electronic Administrative Communications Act*, which entered into force on July 1, 2004. To meet these requirements the Dutch government has started to develop a national infrastructure for electronic identification and authentication.

A second opportunity is the use of juridical expert systems in the process of decision making by government agencies. Investigations into the extensive use of expert systems by government agencies indicate that expert systems can indeed be useful to improve the quality of decisions, especially when they make complex calculations.

However, expert systems do not guarantee juridically correct decisions. Empirical research in The Netherlands has shown that errors are especially made if the system offers only limited support to its users.

There is a risk that users will rely too much on the expert system and will not use their own knowledge when necessary. These results underline the need for users of juridical expert systems to be aware of their limitations and to know how to use them. Government agencies that decide to use expert systems should take additional measures to maintain control over the quality of the decisions in fields which are not, or not completely, covered by these systems.

## KEY TERMS

**Algorithm:** A series of instructions for the performance of tasks and their sequence.

**Automatic Decision Making:** Decision making based on automatic processing of data.

**Electronic Signature (under Dutch Law):** An electronic method for authentication which is sufficiently reliable, taking into account the nature and the content of the electronic message and the object for which it is used.

**General Principles of Proper Use of ICT:** Principles which should be respected when government agencies use ICT (e.g., principles of accessibility, confidentiality, transparency).

**In Writing (under Dutch Law):** Expressing signs on a data carrier (paper or an electronic carrier).

**Juridical Expert Systems:** Software programs which can solve juridical problems, either without any human interference or with limited human interference, by means of a reasoning mechanism and a knowledge database.

**Universal Government Access Facility:** A means of authentication which enables government agencies to offer a range of services (e.g., maintenance grants, parking licenses, building licences) on line to citizens and companies.

## ENDNOTES

1 There are two provisions of European Union law on automatic decision making, the articles 12 and 15 of Directive 95/46/EC of the European Parliament and of the Council of 24 October 1995 on the protection of individuals with regard to the processing of personal data and on the free movement of such data: Official Journal 23/11/1995, L 281/31. These provisions, and their implementation into Dutch law, are addressed in this article.

2 Art. 15 and 12 of Directive 95/46/EC of the European Parliament and of the Council of 24 October 1995 on the protection of individuals with regard to the processing of personal data and on the free movement of such data: Official Journal 23/11/1995, L 281/31. An analysis of these provisions of the directive is made in Bygrave (2001).

3 This empirical research was part of my PhD studies into the legal aspects of electronic decision making by government agencies (Groothuis, 2004).

4 These rules of unwritten law, such as the principle of legal equality, were developed in the Dutch case law and jurisprudence.

5 This overview, which is part of my PhD studies, was earlier published in Groothuis and Svensson (2000).

6 Each of the 25 errors, as well as the overall results of the case study, were discussed with the manager of the social security department of the municipality. The manager agreed with the finding that there had been errors in these cases.

[7] Experiments with juridical expert systems in laboratorium settings were described in Nieuwenhuis (1989), De Bakker and Wassink (1991), and De Vey Mestdagh (1997).

[8] An analysis of the new Act can be found in Groothuis and Voermans (2001). A comparative law study on electronic communication and its impact on administrative law can be found in Prins, Eifert, Girot, Groothuis, and Voermans (2002).

# An Assessment of the Open Government Web Site in Mongolia

**Lkhagvasuren Ariunaa**
*Intec Co. Ltd, Mongolia*

## INTRODUCTION

The open government Web site was initiated and developed under the direct guidance and support of the prime minister of Mongolia in 2002. The project was initially supported by USAID (United States Agency for International Development) and The Asia Foundation from 2004. The main purpose of the Web site is to strengthen the linkage between the private sector and government and to facilitate public contribution of opinions to state policies and laws. The Web site has four major sections namely: legislation (draft laws, Parliament agenda, and links to laws); discussion (forum, online conference, questions, and answers); links; and search engine. Moreover, there is an opportunity to subscribe to the Open Government newsletter.

This article describes the current status of the open-government Web site in Mongolia, its strengths and weaknesses and provides a framework for future action in order to improve service delivery

## BACKGROUND

The concept of e-government was introduced to Mongolia in 2001 (Enkhargal & Ariunaa, 2001) when government organizations were furnished with computers, networks and necessary equipment and some locally and internationally developed software. At the workshop on public administration reform, one of the sessions was dedicated to the use of technology for delivering government services. The concepts of what is e-government and e-governance were introduced, the former described as the opportunity for government to provide government information to citizens and the latter described as providing government services online to the public. (Heeks, 2001). Although there are different definitions of e-government and e-governance, there were no major debates or discussions held on their definite distinctions.

Information and communications technology (ICT) in the government of Mongolia refers mainly to the use of hardware, the internal organizational network setting, use of different software and applications, and access to the Internet. Apart from the physical hardware, the important issue is how to utilize investments in ICT to better serve citizens of the country. There are a number of ways to do that: (1) by developing an office management system; (2) by setting up Web sites and providing information; (3) by providing opportunities for strengthening linkages between the private sector and government; and (4) by facilitating communication with the public on matters of policies and laws.

The open-government Web site of Mongolia was referred to by the *World public sector report 2003* of the United Nations as one of the examples of "listening to citizens." (UNDP, 2003, p. 174). Since its launch in 2003, the open-government Web site has been highly promoted and publicized. It is seen as the best means to bring the voices and concerns of the public and the private sector to the government. The front page of the Web site has welcoming remarks by the prime minister of Mongolia, who says that "24/7 (meaning the Web site is accessible 24 hours a day and 7 days a week) running Web site will enable YOU to express your opinions to the government with transparency and to co-rule the country with us." The prime minister also assures citizens that the government will take into consideration their "valuable, comments, initiatives, and support." (Open Government, 2005.)

Currently, there have been over 124,270 visitors to the open government Web site which translates to over 100 visitors per day (Open Government, 2005). The forum discussions are highly popular and account for most of the visitors to the Web site. The rules of discussions require that users should "express their opinions freely, without using insulting or offensive language and must respect others' opinions" (Open Government, 2005). The Web site administrator has the right to delete comments when rules are violated and he or she is "not responsible

for the content of people's comments" (Open Government, 2005).

The open government Web site has links to Web sites of 17 governmental organizations, 10 media, eight international organizations, seven NGOs, 11 IT companies, and four others, including reference to CNN and BBC. In addition, there is a "Frequently Asked Questions" (FAQ) section, which provides preset answers to questions commonly asked by visitors. The prime minister visits the Web site regularly; and also gets comments in abbreviated format every two weeks. Visitors to the Web site are not expected to write directly to the prime minister, but the Web site performs the function of the messenger.

## STRENGTHS OF OPEN GOVERNMENT WEB SITE

The open government Web site of Mongolia has a number of strengths namely that:

1. The prime minister has been personally involved in supporting and promoting the Web site. Without his leadership role in developing the Web site content and without his encouragement to government officials to regularly visit the Web site and provide their input, the open government Web site would have remained static.
2. It publishes draft laws for public discussion on the Web site, which provides citizens with the opportunity to make their input to the draft laws.
3. The regular visitations of government officials at the open-government Web site provide opportunities for them to give quick feedback on issues and concerns raised by the public.
4. Every two weeks, the prime minister and ministers are informed of the progress made at the open-government Web site. Issues raised on the government Web site are discussed at the meeting and given recommendations for follow-up by line ministries, agencies and other governmental organizations.

## WEAKNESSES OF OPEN GOVERNMENT WEB SITE

The Mongolia open government Web site also has a number of weaknesses, such as:

1. The local area networks at the ministries and agencies are not operational in the true sense of LANs. This in effect hampers individual government officials in providing information and services from their desks.
2. The process of getting input on laws and regulations from the public is complex. Such inputs are received by the ministry/agency representative on duty, passed on to his or her boss, then further to the prime minister before it is affected into the draft law or regulation after it has been discussed.
3. Apart from the discussion forum, which is the most visited part of the Web site, the other parts are not regularly maintained.
4. There is little information or feedback to the public about which of the suggestions were considered for integration into draft laws and regulations.

Despite its strengths and weaknesses, the open-government Web site has had an impact on citizens and businesses. They are realizing that there is a new way of reaching the government, using computers and networks; that the government is willing to open up to public through this Web site and that the citizens and businesses could contribute to draft laws—a new tendency in the relationship between citizen and government. Although, it is difficult to say how much businesses use this Web site, the information available on the site seems important to them, such as the linkages to the Web sites of government organizations and the opportunity to contribute to the draft laws. Still, many challenges lay ahead. This includes the opportunity for accessing this Web site not only from the capital city, but also from different parts of Mongolia as well as by representatives of different groups of society, especially those who do not have computers at home or have no access to Internet (or cannot afford to pay for this kind of services). Mongolia is a largely dispersed country with few citizens (1.5 million square kilometres and 2.6 million population) (Statistics for Mongolia, 2001). Around 1 million people live in Ulaanbaatar and the remaining 1.5 million are widespread throughout the huge territory of Mongolia with limited access to information and technology. How to reach these one and half million people outside the capital is one of the great challenges for open government in Mongolia. Although Mongolia is considered a highly educated country with a high rate of literacy (97% by 2001 figures) (Human Development report of Mongolia, 2001), the infrastructure still is an issue for people from the rural part of Mongolia preventing them from having

access to government and directly to the prime minister himself. There is a telecommunications backbone reaching out to major settlements—aimag and soum centers, but there are few soum centers that have access to the Internet and its services. Fewer opportunities are open for herders who lead the old nomadic lifestyle of moving from one place to another following pastureland for their livestock, and consequently are cut off from information services and resources. It is important to open up opportunities for both rural and urban parts of population of Mongolia and initiate activities to reduce the increasing digital divide in Mongolia. Even in the capital city itself, there are differences between people living in the centre and on the outskirts of Ulaanbaatar. The more things are done, the more problems need to be resolved. However, it is important that the government is not giving up and is looking for ways and means to overcome these challenges.

## RECENT E-GOVERNMENT INITIATIVES

The government of Mongolia has recently given a higher priority to the ICT sector by establishing the Information and Communications Technology Authority (ICTA) in November, 2004. Over only 6 months, the ICTA has initiated the "E-Mongolia" program (www.icta.gov.mn) to foster development of ICTs in Mongolia. As part of this program, the Internet Service Providers joined their efforts in the establishment of the Mongolian Internet Service Provider Association (MISPA) (www.mispa.mn), through which they started negotiations with satellite providers to reduce costs and increase bandwidths for the whole of Mongolia. This gives the ISPs much more power to negotiate better prices than when they leased lines separately from the satellite providers. This is expected to result in the reduction of the costs for Internet access for individual citizens and organizations. Moreover, a "Computers for all" program is being developed which would enable citizens to purchase high-quality computers for the cheap price of 250USD. The computer companies established their own association, so called Mongolian Association for Computerization (MASCO). Within framework of e-government program, the government organizations started not only providing information through their Web site, but also started governmental services online. Among those leading organizations is the Mongolian Taxation Authority (MTA), which has a Web site with information about taxes in Mongolia and downloadable taxation forms, which were required to buy from taxation agents at the submission of tax forms (www.mta.mn). With this Web site, the private companies can download around 40 taxation forms and bring filled out forms to the taxation office. This is one step towards e-governance development in Mongolia.

These and other initiatives provide increased incentives for government to provide information and services online to citizens and businesses. This, in turn, would evolve into the next developmental phase for the open government Web site, when it will provide services to enable citizens to perform online transactions. Although the people in urban areas seem to have access to a broad variety of information services and resources, the people in rural parts of Mongolia still lack this opportunity. Because of the insufficient telecommunications infrastructure, the people in the rural parts of Mongolia will likely not be able to take advantage of these new developments in the near future.

## FUTURE TRENDS

There are a number of suggestions that would improve the operations of open government Web site which are discussed next.

1. **Improving the Content of the Web Site:** Despite the popularity of the open government Web site, the content of the Web site needs to be enriched further. For example the Web site should have information on all government officials including—their positions, issues they handle, room numbers, phone numbers, email addresses, and Web sites if available. This would make the government more open and transparent, providing grounds for two-way communications.
2. **Increasing the Visibility of the Web Site to the Public:** One of the main points of having government Web site is to make it more visible to citizens, the private sector, NGOs and others. Over the past year, the promotional activity of the project seems to have been reduced. The people who know about open government Web site regularly visit it and provide their inputs on the site. However, for new comers, the situation may be difficult. There are linkages to the open government Web site from other organizations, such as MIDAS/MONITA (Mongolian Information Development Association/Mongolian Information Technology Association) NGO, Open Society Forum NGO, the Governmental portal site, and at sites of international organizations. Awareness should be created among

potential users to use all available means of communication—Internet, Web, newspaper, television, radio, and so forth.

3. **Enhancing Information and Services Provided to Citizens:** If the Web site made provision on how inputs from citizens were integrated or taken to improve draft laws and regulations, this would provide excellent grounds for people to visit this Web site and become active participants in government affairs. Currently, there is no information provided on whose inputs were taken or not. Moreover, it is essential to keep the content of the Web site up-to-date, and also regularly monitor and evaluate Web site visits. For example, it is important to know which content is visited more often. In addition, regular surveys of visitors and their comments on the Web site, itself, not just the discussions, should be undertaken.
4. **Strengthen further the Linkage between Private Sector and Government:** The private sector is driven by profit-making and rarely moved by social missions. If the Web site had information, for example, on government procurements at least from Cabinet Secretariat, this would attract the private sector to this Web site. For example information on private companies providing ICT services to government, such as hardware maintenance, solving technical problems, providing consultancy services, supplying hardware, software and applications would enhance private sector participation in government. This information would be necessary to service procurement.
5. **Linking Open Government Web Site with Actual Operation of the Government:** Within the framework of public sector reform, there is a need for linking up public reform initiatives with ICT. The decision needs to be done at the level of senior government officials to achieve the goal of providing adequate public services to citizens, to make government open, transparent and accountable.
6. **Establishing Public Access Points to the Web Site:** Considering that not everybody has computers or access to Internet, the setting up of public access points would at some extent decrease digital divide in the country and thus would enable broader participation of the citizens in the decision making process.

## CONCLUSION

Although the open-government Web site has some weaknesses, the fact that (1) it is visited by over 100 people per day; (2) the forum discussions are continuing for days on different issues and (3) government is paying great attention to it—prove that the Web site has more opportunities in the future. These include linking citizens directly with individual government officials, increasing the awareness of this site among a broader audience, and establishing public access points for citizens. More can be done, but the fact, that the government initiated, opened up and uses this Web site as a main gateway between government and citizens and businesses and plans to develop it further, shows the importance of these first steps and the necessity for further action. Businesses and citizens from their side should support, use and benefit from this initiative. One thing is definite, that the open-government Web site has had an important impact on citizens and businesses in their relationship with government.

## KEY TERMS

**Accountability:** Quality of being accountable, responsible. The ability to call state officials, public employees, or private actors to account, requiring that they be answerable for their policies, actions, and use of funds. Access to information and analysis about the performance of services and policies builds pressure for accountability.

**Forum:** An information interchange regarding a specific topic or product that is hosted on an Internet newsgroup, online service, or BBS. It can include the latest news on the subject, a conferencing capability for questions and answers by participants as well as files for downloading fixes, demos and other related material.

**Government of Mongolia Web Site:** A single point of access to major programs, services, and organizations of the Government of Mongolia. Its address is www.pmis.gov.mn

**Hardware:** Machinery and equipment (CPU, disks, tapes, modem, cables, etc.). In operation, a computer is both hardware and software. One is useless without the other. The hardware design specifies the commands it can follow, and the instructions tell it what to do.

**Internet:** The largest network in the world. It is made up of more than 100 million computers in more than 100 countries covering commercial, academic and government endeavors. Originally developed for the U.S. military, the Internet became widely used for academic and commercial research. Users had access to unpublished data and journals on a variety of subjects. Today, the "Net" has become commercialized into a worldwide information highway, providing data and commentary on every subject and product on earth.

**Online Conference:** Conference organized online through Internet. It runs on a real-time schedule, however it is not tied into specific geographical location, does not require physical presence of the participants, and provides opportunities for interaction with other participants, presenters, keynote speakers as well as presentations, forums and discussions held during online conference are available at any time virtually.

**Public Access Points:** Points of access to government information and services by citizens without computers and no access to Internet. Usually those access points are established in aimags' centers of Mongolia to enable citizens raise their voices and concerns to the government through ICT and actively participate in government policy development.

**Transparency:** Clarity and openness regarding activities and relationships.

# Assisting Users Seeking Medical Information through Government Portals

**Jane Moon**
*Monash University, Australia*

## INTRODUCTION

There has been an explosion in the number of different types of portals in the last decade, and at the same time there has been a lot of confusion with them, especially in relation to the enormous number of portals and their differences from Web sites or Web-pages. This coincides with increased use by consumers seeking medical information on the Internet, and with the important role played by medical portals for evidence based medicine.

This article explores current portal technology available from an evaluation of market leaders in the industry and identifies important functional components that are necessary in building an intelligent portal to assist users seeking information on the Internet.

The emphasis will be on government to consumer portals (G2C) and uses two reputable government portals Betterhealth and Healthinsite as examples to discuss issues involved with those.

## BACKGROUND: INCREASED USE OF PORTALS FOR SEEKING MEDICAL INFORMATION

Reliance on portals for medical information is high, and recent statistics show that this trend is growing. At the same time medical information is widely dispersed and information retrieval is inadequate (Shepard, Zitner, & Watters, 2000). There is an urgent need to develop portals that help users to retrieve quality information.

The National Health Medicine Advisory Council reported that better health outcomes are predicted when users are better informed, suggesting the need for digitization of health services (Bodenheimer, Lorig, Holman, & Grumbach, 2002; Kennedy, 2002; National Health Information Management Advisory Council, 2001). However this is yet to be confirmed, as Internet content has not yet proven to be satisfactory. There is a lot of concern about the materials found on the Internet (Ciolek, 1997, Moon, 2005).

Modern portals are built with the aim of better catering for the different needs of users. Portal technology is improving and features such as knowledge management, content management, and search engines, along with effective Web site design, help users to find information more effectively, and yet portals remain ineffective in information retrieval (Clarke & Flaherty, 2003; Elias & Ghaziri, 2004; Quirk, 2001; Rao, 2001). An effective evaluation tool to assess the validity and effectiveness of the portal is quintessential in assisting both users and portal builders.

## PORTALS

Portal terminology has been loosely used in the industry and the term "portal" means different things to different people. Some argue that the word "portal" should be used as an adjective—"portal framework," "portal structure," and "portal architecture"—rather than as a noun as it is commonly used (Roth, 2003). Others are confused by the difference between a Web-page or Web site and a portal. The same confusion is applied to health portals vs. medical portals. The following sections seek to clarify these terms.

### Definition of Portals

For the purpose of this research, the working definition of a portal is an Internet-based information system providing uniform access to different sources of information in an enterprise and maintaining dynamic links to information resources (Moon & Burstein,

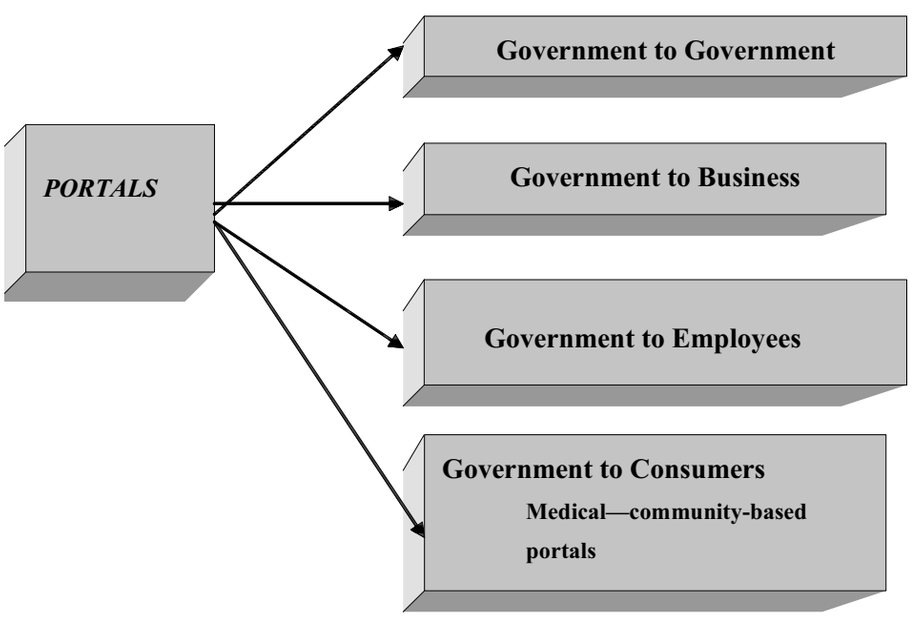
2004). A portal supports communication within the enterprise, and connects people with information and applications they need for performing tasks. Unlike a conventional Web site, portals should support both push (subscription) and pull (search) functions in assisting users to gain access to essential contextual information (Probst, Raub, & Romhardt, 2002; Shepard et al., 2000).

## Portals vs. Web sites

The word "portal" is often confused with Web sites. The difference between Web sites and portals is that the former are static and the latter are dynamic. Portals are Web-based, have dynamic links to the information resources, effective information and document managers and connect people with information. A portal is dynamic, can have personalisation features built into it and has the ability to bring together "business professionals involved in their area of interests" (Hazra, 2002, p. 623). A portal is a mechanism to deliver content, using a Web browser. It runs on an application server, and can integrate with knowledge management and workflow. It must unify a large range of applications, services and information flows.

A Web site is static, and is a collection of Web pages relating to a given subject, including and beginning with the home page; for example, a company Web site. A portal is often confused with a Web server where many different Web sites can be stored on a single machine. Companies generally have many Web sites that are stored by commercial Web servers

*Figure 1. Government portal market segment diagram (Adapted from Collins, 2003; Clarke and Flaherty, 2003; Shepard et al. 2000)*



in different locations, sometimes worldwide.

For the purposes of this chapter, any Web sites which have at least one of these listed features is referred to as a "portal."

## CLASSIFICATION OF PORTALS AND FUNCTIONALITIES

There was an explosion in the number of different portals in the late 1990s. A great multitude of terms are used to describe different types of portals. Some examples are: EIP (enterprise information portal), corporate portal, community portal, employee portal, business intelligence portal, horizontal portal, vertical portal, public portal and private portal, to name just a few. These names are dependent on who the stakeholders are (Collins, 2003; Portals Community, 2004).

A government portals can be categorized broadly into four types depending on the stakeholders (government to government, government to business, government to employees, and government to consumers).

- **G2G (Government to Government):** Supports work flow between government sectors and assisting and collaborating work, not accessible to consumers
- **G2B (Government to Business):** Supports business flow, activities, suppliers, and partners for distribution and supply chain management
- **G2E (Government to Employee):** Supports the access and availability of personalised information to employees
- **G2C (Government to Consumer):** Supports ordering, service, support, and billing for customers

All of the portals in Figure 1 fall in to the function of the following three types:

- **Knowledge Portal:** Has the ability to combine information, but provides no commercial transaction
- **Decision-Based Portal:** Collection of information from a wide variety of sources, which can be structured or unstructured
- **Process-Based Portal:** Changing focus to delivery, user-centric, collecting information to be distributed to future processes such as business to consumers (B2C) or business to business (B2B), where transactions are involved

Recent development has been on process-based portals, those that promise to deliver information based on user needs. All of the previously mentioned portals are rapidly evolving to support changes in the information needs of customers, businesses, suppliers, and individuals. The names of portals vary according to services and the users they serve (Wege, 2002).

### Portal Server Technology

Portals integrate diverse interactions: access to information, applications, and people. The infrastructure, which is a connection between hardware and software, is critical for the deployment of a portal. The portal server technology items needed are:

- **Hosting Service Provider:** The hosting service provider can be internal (the IT department within the organization), or external (an application service provider (ASP)) or an off-site hosting services vendor. Hosting service providers are responsible for maintaining the portal services. The tasks involve systems management and site administration
- **Platforms:** Several types of platforms have evolved. The most pervasive platform is the Operating System, especially Microsoft Windows OS, Windows 2000, and Windows NT. Others include Macintosh (for client layer), Unix, and its variants (Sun Solaris, Linux, IBM AIX, IBM OS/390) for the servers also. Some traditional main frames are OS/390, OS/400, etc
- **Interoperability:** Interoperability is crucial to the success of the portal. A typical portal would integrate several Web based applications (Microsoft and Sun architecture), XML, and database applications as well as desktop applications (word processors and spread sheets).

*Table 1. Medical portals comparison*

| Australian Medical Portal | Search Engine | Spell Check | Sounds Like Index | Parsing | Ontology | *Personalization* | Thesaurus | Dec. Facilitis |
|---|---|---|---|---|---|---|---|---|
| BetterHealth Channel | Google | X | X | X | X | X | X | X |
| Health*Insite* | Yahoo | X | X | X | X | Yes | Yes | X |
| Rural Health | X | X | X | X | X | X | X | X |
| Health*InfoNet* | Yes | X | X | X | X | X | X | X |
| HealthConnect | Yes | X | X | X | X | X | X | X |
| Medicine Australia (MedAu) | Yes | X | X | X | X | X | X | x |
| HealthNetwork | Yes/ selective | X | X | X | X | X | X | X |

*X = No, absence of the feature*
*Yes = Presence*

A good portal would consolidate all these applications into a single organized desktop

- **Personalization:** Portal personalization can be made at different levels. An individual can have personal settings; a group of people sharing the same function can have group settings. An organization can choose its own settings. These features allow the portal to be customized according to needs
- **Single Sign-On (SSO):** Signing on only once to get access to all the facilities portals offer is crucial. This is a significant time saving in logging on to different sites, and a significant reduction in training and also time saving for administrators in re-issuing passwords for those who have forgotten them (Collins, 2003, p. 39; Portals Community, 2002, p. 12; Wege, 2002).

## Functional Components of Medical Portals

Portals should provide wide functionality to allow users to find information, and to manage, categorize, and use applications. They should ensure that the features needed by employees in the organization are met. The implementation of functionalities will vary depending on the nature of the business. Some of the functionalities that are available and can be implemented in medical portals are as follows:

- **Browse/Navigate Documents:** Allowing users to search for and locate information manually by navigating a directory structure
- **Collaboration:** An important aspect of a portal and a powerful tool. It includes instant messages such as "chat," document sharing, video conferencing, virtual conferencing, and discussion forums
- **Content Management:** A process of approving, authoring, delivering, maintaining, and publishing content integrated with or accessed from a portal or other Web site. This can be implemented as a separate component with a common database accessible through the portal
- **Directory:** A directory within the portal's enterprise taxonomy. It is a collection of data structured into a hierarchy of categories

*Table 2. Evaluation of portal vendors on intelligence features*

| Vendors | CM | KM | Navigation and Search | Personalization | Community Definition | AI |
|---|---|---|---|---|---|---|
| ArtTechnology Group | • | • | • | • | • | • |
| Autonomy | • | • | • | • | • | • |
| BEA systems | • | • | • | • | • | |
| BroadVision | • | • | • | • | • | |
| Citrix | • | • | • | • | • | |
| Computer Associates | • | • | • | • | • | |
| Corechange | • | • | • | • | • | |
| Epicentric | • | | • | • | • | |
| IBM | • | • | • | • | • | |
| Oracle | • | • | • | • | • | |
| PeopleSoft | • | • | • | • | • | |
| Plumtree | • | • | • | • | • | |
| SAP | • | • | • | • | • | |
| Sun Microsystems | • | • | • | • | • | |
| Sybase | • | • | • | • | • | |
| TIBCO | • | • | • | • | • | |
| Vignette | • | • | • | • | • | |
| WebMethods | • | • | • | • | • | |

- **Document Management:** Similar to content management but dealing mainly with control and management of an enterprise's documents. It involves managing electronic files including scanned images of pictures and documents
- **Personalization:** Portal personalization can be made at different levels. An individual can have a personal setting; a group of people sharing the same function can have group settings. An organization can set up its own setting. This feature allows a portal to be customized according to needs
- **Search Engine:** The ability to search is the fundamental implementation of a portal. It allows users to browse the content, retrieve information on a content basis, and link to other repositories for information
- **Subscribe/What's New?:** Allows users to register an interest in a particular aspect of the portal. Portals then notify the user when any changes in the content occur
- **Taxonomy:** A classification scheme to organize information. Additional functionalities, such as metadata added to taxonomy, could help to organize documents into different categories that could make the information easy to browse, search, or navigate ideally.
- **Online Community:** Opportunity for users with similar interests to discuss their medical conditions and experiences. This could range from sharing experiences of treatment to discussing medical conditions and alternative medicine (Collins, 2003; Millen, 2000; Moon & Burstein, 2004; Tushkar, 2000).

## THE IMPORTANCE OF INTELLIGENT MEDICAL PORTALS

The term "intelligent medical portal" refers to a Web gateway environment that allows users with varied medical interests and diversified backgrounds to access medical resources and information to support their decision-making processes, which often involve critical medical problems.

Current medical portals do not provide for people with different educational backgrounds, age, ethnicity, location (urban or rural), and stages of disease.

For example, there is no specific information for a 63-year-old female with early breast cancer or for a 35-year-old mother experiencing advanced breast cancer living in a rural area. The hyperlinks regarding breast cancer seem to employ a "one-size-fits-all" approach (McKemmish, Burstein, Manaszewicz, & Fisher, 2002).

In the case of breast cancer, a third of sufferers in Australia live rurally. For them the quality of information is absolutely critical, often life-threatening (Manaszewicz, Fisher, Williamson, & McKemmish, 2002). The development of an intelligent portal is to some extent a response to this problem. A major concern is that there are no real safeguards and standards concerning the "quality, precision, trustworthiness, currency, and authorship of this information" (Ciolek, 1997, p. 5).

How can a portal be made to behave intelligently so that users can easily gain access to vastly distributed medical information? McKemmish et al. (2002) suggests an intelligent portal "will improve the structure and manage the quantity of information presented" (p. 5). Indeed an intelligent portal should provide information that is high-quality, relevant, and adequate. It should provide for the needs of users by helping them to solve issues that are often critical to life. With the use of intelligent portal technology, combining knowledge management issues of personalization and decision support, the needs of Internet users of medical portals could be improved.

## Intelligence Features

Previous research has established intelligence features that are available technically as follows (Moon & Burstein, 2004):

- Search engine
- Spell checking
- Sounds-like index
- Parsing
- Ontology
- Personalization
- Thesaurus

As medical jargon, treatment and drug names are often very difficult to remember and spell, it seems that it is essential to implement the available technology previously mentioned as much as possible to assist users in their search for medical information.

## Australian Medical Portals

Despite the surge of interest and importance of the Internet for providing users with medical information, users were dissatisfied with the results. The following table illustrates the results of intelligence features against seven Australian medical portals.

All the portals had search engines. In general, most of them lacked in providing any form of intelligence. Health*Insite* is the only portal that provided "personalization" and a "Thesaurus."

## Evaluation of Portal Vendors on Intelligence Features

For the purpose of this research, it was important to look for what was currently available on the market in terms of functionalities for medical portals that make them more intelligent.

To do this it was necessary to explore various vendors of portal software and find the functionality available as well as to compare vendor's views with users' views to check the validity of vendor's claims. Though the technology and the concept of the portal have been around for more than 10 years, the idea of implementing portal solutions as a whole package is still fairly new. Most of the portal solutions that are available are developed to solve commercial problems, and are expensive.

After the evaluation of leading providers of portal software, eighteen high-profile providers were chosen for the analysis of intelligence features.

All the leading portal software packages provided most of the intelligence features. Only two vendors, Autonomy and ATG, provided AI, in particular artificial neural networks, for their search. ATG is in partnership with Autonomy for their search engine.

## FUTURE RESEARCH

The results of this study confirm wide use of Government portals in searching for medical information. However, the study indicates that Australian medical portals have a limited intelligence features and are not meeting the needs of their users despite of the available technology. Further research should be undertaken in:

- **Intelligent Medical Portals:** How intelligence features can be effective in implementing medical portals.
- **Implementing Intelligent Agents:** Implementing intelligent agents such as "digital secretary," which acts as personal secretary, or "digital sister-in-law," which helps users with movie suggestions, make portals smarter (Jafari & Sheehan, 2003).
- **User Profiles:** Better identification of common profiles of information usage and matching these with correct content by employing the best available technology to improve user acceptance of portals.

## CONCLUSION

The research reports that current Australian medical portals are not meeting their users' needs. The research sought to discover the ways to improve the portals technology to assist the users in their search for medical information. From the literature review and analysts reports the definition of portals and of the many different types of portals are identified.

The analysis of portal vendors amongst market leaders, the technical functionality available for portals was identified. All the portal vendors had most of the listed intelligent features with the exception of artificial intelligence (AI). Autonomy was the only vendor that provided with AI that of Artificial neural network.

An intelligent medical portal is one way of meeting consumers' needs. Understanding human search behaviour can help to improve the technology if this understanding is integrated into interface design. Available portal technology such as ANN and fuzzy logic can help to improve information retrieval. Further incorporating intelligence features and portal functionalities such as CM, DM and KM can add value to the service and thereby increase the effectiveness of portals.

## KEY TERMS

**Content Management:** A process of approving, authoring, delivering, maintaining, and publishing content integrated within or accessed from a portal or other Web site. It can be implemented as a separate component with a common database accessible through the portal.

**Health Portals:** Health portals on the other hand, are broad; they cover a very wide range of health and medical topics, anything relating to health (e.g., shampoo products, cosmetics, diets, medicine, and alternative therapy. This research is concerned with the narrower cencept of medical portals.

**Intelligent Medical Portal:** Refers to a Web gateway environment that allows users with varied medical interests and diversified backgrounds to access medical resources and information to support their decision-making processes, which often involve critical medical problems.

**Knowledge Management:** This can be seen as a mechanism for capturing "know-how" and "know-why" in a knowledge repository.

**Medical Portals:** Medical portals provide information such as causes of diseases, medications, treatments, alternative therapies and lists of consultants. Medical portals can be either general or specific. General medical portals provide general medical information, for example Better*Health* or Health*Insite*. Disease-specific portals provide information specific to a particular disease (e.g., cancer portal, breast cancer portal).

**Portal:** In Latin, the word *porta* means a gate or entrance. A portal can be defined as a gateway to information (Golier Inc., 1980). It is Web-based and connects a set of commonly used information or services via a link from a single Web page (Clarke and Flaherty, 2003; Elias and Ghaziri, 2004; Notess, 2002; O'Leary, 1999; Rao, 2001).

# Automated Content-Management Systems

**Neil C. Rowe**
*U.S. Naval Postgraduate School, USA*

## INTRODUCTION

The World Wide Web quickly evolved as a valuable resource for organizations to provide information and services to users. Much initial development of Web pages was done haphazardly. This resulted in many information gaps and inconsistencies between pages. Departments with more available time created more and better-designed Web pages even when they were no more important. Personnel who created Web pages would move to other jobs and their pages would become obsolete, but no one would bother to fix them. Two copies of the same information on the Web would become inconsistent when only one was updated, leaving the public wondering which was correct. Solutions were needed. We survey here the principal solution methods that have been developed.

## BACKGROUND

"Content management" has recently become a popular term encompassing ways to manage Web pages, online databases, and print documents more consistently (Boiko, 2002; Hackos, 2002). "Content" means an organization's information assets. Since Web pages have become the primary means for organizations to publish information today, the primary focus of content management is on Web pages (Goodwin & Vidgen, 2002; Proctor, Kim-Phuong, Najjar, Vaughan, & Salvendy, 2003). Content management is "Web page bureaucracy," imposing a set of policies and rules for creating pages, implementing them, updating them, and reusing their content for new purposes. Bureaucracy is not necessarily bad, since no one wants an organization (especially a government one) that is inconsistent or incompetent. Governments are required by law to provide certain services, and a bureaucracy of Web pages can assure that Web services are delivered properly and fairly. So although content management is not unique to digital government, it is an especially important and essential technology for digital government. But content management, like any bureaucratic innovation, does stifle some creativity, impose additional restrictions, and add time to create and use pages.

A variety of commercial products are available for content management, ranging from standalone applications for Web page authoring to comprehensive systems that control every aspect of an organization's Web pages. The term "content-management software" can refer to any of these. Costs range from free (for open-source software) to millions of dollars, and systems are rarely compatible with one another. So an organization must do a careful study before embarking on content management. Useful case studies of development of systems are available (Dudek & Wieczorek, 2003; Kunkelmann & Brunelli, 2002; Lerner, 2000; Weitzman et al., 2002).

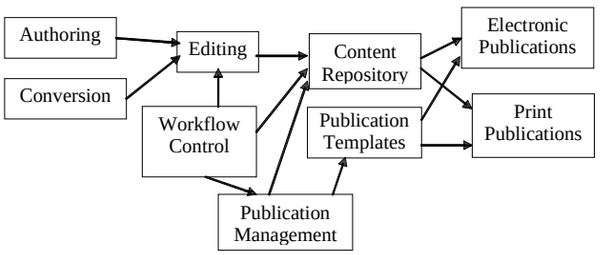
## TASKS OF A CONTENT-MANAGEMENT SYSTEM

Typically content management is divided into collection, management, and publication (Boiko, 2002):

- Collection facilities obtain information ("content") with such things as Web authoring tools, specialized word-processing software, media managers and editors, and format conversion.
- Management facilities control the approval mechanisms and information flow of content. Most systems store content for pages in a database or "repository" along with metadata describing the form of the content. Management facilities ensure that checking and approval is done by specified people before content is made public, and they can also test content errors and track different versions of content.
- Publication facilities convert content into polished public presentations in Web pages, print documents, or various forms of media. They provide templates for selecting information and providing a consistent appearance. Publication management also includes efficient management of Web sites.

We now discuss in more detail the tasks of a content-management system (see Figure 1). Collection facilities comprise authoring, conversion, and editing; management facilities comprise workflow control and the content

*Figure 1. Outline of the content management process*



repository; and publication facilities comprise publication management, publication templates, electronic publications, and print publications.

## Authoring

General-purpose text editors can create content for content-management systems, but editors specifically designed for Web authoring like Microsoft Front Page and Macromedia Dreamweaver are often better, and the more-structured editors accompanying comprehensive content-management systems are even better. An organization can mandate starting templates for its Web pages with such tools, into which the content must be fitted and apportioned. A template can specify the types of information allowed and/or required on a page, general information about the page, and its layout.

Templates require "metadata" information about each chunk of content to manage it properly. This can include (among other things):

- Author
- Who needs to approve it
- The software that created it
- When it was created
- When it was last revised
- When it becomes effective
- When it becomes obsolete
- When update-reminder messages should be sent
- To whom update-reminder messages should be sent
- Fonts needed to display it (if they matter)
- How the text should be aligned and justified (if it matters)
- Links needed to other documents
- Keywords that help describe it
- Classification of the content type

The authoring tool must obtain this information, but it should not need to ask the author for most of it if the tool is designed properly; otherwise, metadata requirements can quickly develop into a serious point of contention between authors and their organization. Author name, software, and special formatting information can be obtained from defaults set when a user first uses the authoring tool. Creation and revision dates can be obtained from the operating system. Effective and obsoleting dates can default to specified durations or times after the revision date (so for instance, class schedules at a university become effective at the beginning of each quarter and obsolete at the end). Formatting can be specific to the type of content selected by the user before starting. Keywords and content classifications can be obtained from authors via menus, but it can still be burden for them, as it has required many hours by librarians for print publications over the years. It helps to have different keyword menus for different types of content, and to use defaults for types where possible. For instance, all content from the purchasing department can have keywords "purchasing," "acquisition," and "contracts." Keywords can also be guessed from page titles and abstracts, and classification can be estimated by text-analysis methods (Varlamis, Vazirgiannis, & Halkidi, 2004), but this is less accurate.

## Conversion

Much important content of organizations comes from sources other than Web pages. So a content-management system needs tools to convert a variety of documents to the format of the system. This includes such things as converting image files from GIF format to JPEG format, and documents from Word format to PDF format. Audio and video often require conversion since several incompatible formats are currently competing with one another. Conversion also includes formatted editing such as stripping blank lines or rearranging the columns of a table from a text-formatted database. When reusing information from other sources, copyright and usage restrictions may apply, so rights management software (Fetscherin & Schmid, 2003) may be necessary to track this, but this is not common with government content.

Electronic publications can also automatically acquire content from across the Internet. This can be done by specialized programs called "aggregators" and "bots" (Heaton, 2002) but they require programming. For example, an organization's Web page can be programmed to automatically show the latest weather report, news headlines, and boss's pronouncement as acquired from other pages.

XML (Extensible Markup Language) is essential today for organizing chunks of content, and most content-management software uses it. It is a generalization of the Web language HTML that allows for structuring and labeling of arbitrary data. So acquisition of content usu-

ally entails a conversion into XML (Surjanto, Ritter, & Loeser, 2000).

## Editing

After content has been created or acquired, an organization normally sends it to someone for checking of style, appearance, coverage, and consistency with organization policy. Style is traditionally checked by human "copy editors," and involves examination of spelling, grammar, usage, rhetoric, and consistency. Content may also need to be edited to conform to organization policy in matters such as length, technical detail, use of color images, and accessibility to disabled users (W3C, 1999). Editing may also address metadata, since while a good authoring tool can fill in some metadata, authors may not be consistent in such metadata as keywords.

Editing electronic content may also involve segmentation and/or aggregation of content into user-friendly pieces, an issue more important than with traditional print documents. The editor may get many small documents (especially if they are generated automatically) and need to combine them into a larger one, as in collecting information for a phone directory. But also an editor may have a document that is too large and need to partition it into subdocuments. Partitioning is essential in formatting for small handheld devices like personal digital assistants (PDAs), but can be valuable with any Web pages since users get lost easily in large documents when they lack the tactile feel of turning pages.

## Workflow Control

Most automated content management manages the chain of approval necessary to publish. If done right, automation of approval management can significantly increase the productivity of a government organization since often much time is wasted in obtaining approvals. It can also eliminate many tedious manual transfers of files and possible errors in doing so. One needs to define, for each category of document or content, the sequence of people who process it (with substitute people when they are absent), what kind of processing they provide, and what time constraints must be fulfilled ("workflow control"). For instance, instructions for completing a new government form could be drawn up by a technical writer, sent to their supervisor for approval, sent to a copy editor for style and language improvements, sent to a Webmaster who controls the Web site, posted on the test site for debugging, and then moved ("migrated") after a time to the public Web server. As examples of time constraints, a department could specify posting of the current version of its forms catalog every three months, and a review of press releases by on-staff lawyers could be bypassed if they do not complete it within two days.

Workflow control also must include procedures for handling mistakes in publications since they can be costly. So it must be possible to return a Web site or electronic publication to a previous version, what is called "versioning control" (Nguyen, Munson, & Thao, 2004). Mistakes can be reduced by posting content to a staging or test server first (not necessarily on a separate machine from the public server); this is important for testing when content is dynamic or requires special software.

## The Content Repository

Most content-management systems use a database, the "repository," to hold the pieces of content after authoring, conversion, editing, and approvals. This can range from a basic file system to a full database system. In many cases this should be a single centralized database for simplicity, but there are advantages in flexibility and robustness to distributing the information over several sites (Cranor et al, 2003; Luo, Yang, & Tseng, 2002); peer-to-peer methods can even be used to distribute content (Hausheer & Stiller, 2003). Methods for object-oriented databases can be helpful because content usually represents a variety of object types. Media files will need to be stored separately with pointers to them since their sizes can vary so much. The database will also need to support versioning and archiving.

Another benefit of automated content management is the ability to systematically check for inconsistencies like links that become invalid or pages that are moved. So deletion or moving of content in the repository should trigger changes to all content pointing to it. Broken external links can be found automatically by systematic periodic checking.

## Publication Management

Finally, content management creates publications automatically or semi-automatically from the content in the repository including its metadata. Templates can be defined to assure consistent presentation style, including how the information is partitioned into pages and cross-linked. Metadata labeling of content permits creation of a diverse set of documents from the same information, including both print and electronic publications. It can also permit personalization of publications to the user using "cookies" and other forms of user tracking. For instance, the system can remember the type of display device the user had last time, the language they preferred, and the topics in which they were interested (Huang & Tilley, 2001).

The structure of publications is critical to usability so content management needs to address this, using feedback from potential users. This includes the partitions into subdocuments, titles and headings, links between documents (hyperlinks in electronic documents), navigation aids to help users locate themselves in a set of documents, and use of dynamic content. Electronic documents also greatly benefit from good indexes to the content, and keyword-based access using the indexes; although search engines such as Google index sites, an index specific to a site helps users find things faster.

Content management also includes management of the hardware and software that supplies content to users. Caching of frequently-requested information helps response time (Candan, Li, Luo, Hsiung, & Agrawal, 2001). Distributing popular content redundantly across different sites can reduce overloading problems and increase reliability. Management can include automated copyright management. It also can include methods for presenting multimedia data such as choosing the size of an adequate window for playing video over a limited-bandwidth Web connection.

## ACCESS CONTROL FOR SECRECY

All governments have secrets they must protect. Examples include secrets to preserve the privacy of citizens (like tax information), secrets to preserve fairness (like early economic data), secrets to facilitate negotiation (like diplomatic secrets), and secrets to protect public safety (like military secrets). Secrecy requires more powerful content control than that of a content-management system, to control who has access to the content and how it can be used. Secret information must be segregated on separate computers and networks where it cannot be accessed or transferred without tight restrictions. It entails many other security measures, like passwords, encryption, access-control lists, monitoring of systems by intrusion-detection software, monitoring for inadvertent electronic emanations, and control of the physical devices on which secrets reside. Declassification or revealing of secrets is needed on occasion but must be subject to stringent safeguards.

Military and diplomatic organizations have elaborate systems for handling such "classified" information (Landwehr, Heitmeyer, & McLean, 1984). The U.S. military is representative, with four basic levels of Unclassified, Confidential, Secret, and Top Secret. In addition, the levels can have "compartments" which designate a subtopic to which the classification applies, such as a compartment for nuclear secrets. An individual must have a "clearance" for both the level and compartment to access the information. All information must be used in appropriate designated facilities and have its classification printed on it.

## FUTURE TRENDS

Content management is becoming increasingly common to all Web sites of organizations. It will soon be unthinkable for organizations to develop Web sites without it, and governments especially need content management to provide reliable and consistent services to their citizens. The current large number of products and vendors will probably decrease as a few products become popular. Few major innovations in the facilities of content-management systems are likely with the exception of multimedia support, but the systems will become increasingly flexible and increasingly well human-engineered as vendors gain experience with users.

## CONCLUSION

Everyone complains about bureaucracy in government, but some bureaucracy is necessary to provide systematic, consistent, and complete service to citizens. Content-management systems extend bureaucracy to an organization's publications by deriving them systematically from stored electronic data that has been carefully checked through a series of approval steps and then presented in a standardized way. As such, they can increase the speed and reliability of government procedures and reduce workloads by permitting reuse of content for many purposes. But like all bureaucracy, content management risks getting out of control and impeding operations if not managed properly since its complexity can encourage growth of a technocratic elite unresponsive to citizens. To avoid this, it is essential to keep content-management systems as simple as possible and to manage them responsibly for the benefit of citizens.

## KEY TERMS

**Aggregator:** Software for automatically creating documents by collecting it from a set of designated Internet sites.

**Classified Information:** Secrets (like military capabilities) that a government protects by special access controls (like identification cards and passwords).

**Content:** Any information formatted primarily for display to humans, as opposed to internal data of a computer.

**Content Management:** Policy and software for managing the electronic publications of an organization.

**Metadata:** Any data describing other data, such as size and type information for a media file; essential to management of databases and other information systems.

**Migration:** Copying content from one site to another, as from a test server to a public server when it has been approved for release.

**Repository:** In content management, the database holding the tagged content from which publications are constructed.

**Versioning:** Software to keep track of versions of publications, different either in date or audience, so that when changes are made to parts of the content those changes will appear simultaneously in all the versions with those parts.

**Workflow Control:** Management of who sees and approves content, and in what order, before it can be published.

**XML:** Extensible Markup Language, a general language for structuring information on the Internet for use with the HTTP protocol, an extension of HTML; currently the most important language for flexibly sharing information between computer systems.

# Automatic Generation of Theories of Coordination in Multi-Agent Systems

**Nicholas V. Findler**
*Arizona State University, USA*

## INTRODUCTION

*Coordination* is defined as the process of managing dependencies between activities. Its fundamental components are the allocation of scarce resources and the communication of intermediate results. Coordination theory can be defined as the set of axioms, constructs and analytical techniques used to create a model of dependency management in multi-agent systems (MAS).

*Multi-agent systems* (MAS) represent a significant interest in a variety of disciplines, such as artificial intelligence (and other domains of activity in computer science), political science, international relations, public health, public policy, social welfare, economics, demography, anthropology, communication studies, geography, history, sociology, urban planning, control theory, electrical engineering, military science, and so forth. The present author and his students have worked on several systems in different domains of MAS, such as:

a. **Manmade Technical Systems:** The technical and economic aspects of distributed automated air traffic control; distributed automated control of urban street and highway ramp traffic signals; learning, planning and collaborating robots; distributed control of nationwide manufacturing operations; distributed decision support systems for optimum resource and task allocation over space and time.
b. **Natural Complex Systems:** The behavior of natural organisms, causality and temporal relations, social structures and coordination.
c. **Human Behavior and its Simulation:** Language development and studies of the properties of dictionaries; behavioral studies on reasoning and decision making; information, fact and knowledge retrieval; automatic teaching and evaluation of control operators; social networks, social and cultural anthropology aids; multi-agent systems simulating human societies.

One important concern is how to verify the correctness of the computer representation of MAS and how to optimize their operations. Theories of Coordination (ToC) should satisfy these requirements. However, such are currently ad hoc and amorphous, in that there is no unified model of coordination, though there exist many constructs describing specific phenomena in MAS. With the current advent of large-scale agent-based societies, there is a need for theories that builders can use in designing MAS, instead of being forced to learn from trial and error every time such a society is built. In addition to such design tools, we generate a trouble-shooting tool to diagnose problems with existing deficient systems. We envisage steady feed-back from this component to the user when the MAS malfunctions.

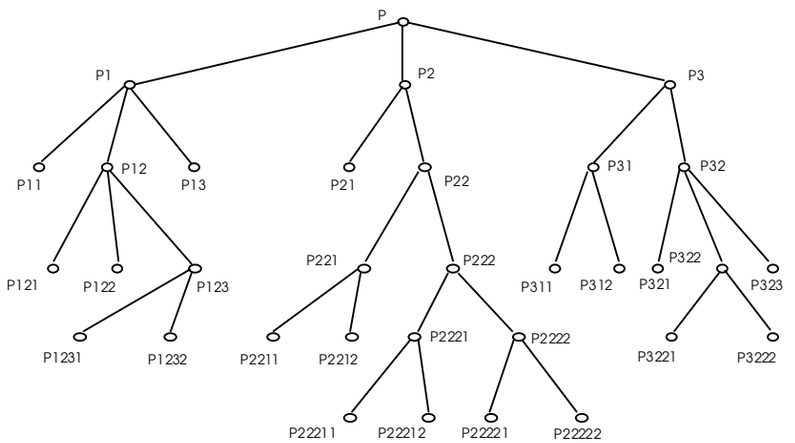
We are creating software tools and formal techniques to be used to analyze and design[1] systems of interacting intelligent agents. The concept is based on our experience gained in many projects, primarily in developing tactical and strategic decision support aids for use in dynamic command and control environments with multiple resources, multiple tasks, multiple sources of information and multiple human and machine decision makers that have different roles and responsibilities and belong to a hierarchy with overlapping jurisdictions. (This was completed during our multi-year collaboration with the U.S. Coast Guard in computerizing their tactical and strategic planning processes.)

## BACKGROUND

Our approach to the above scenarios is to use intelligent agents as aides for human decision-makers, with each agent performing a small number of functions. The complex problem of designing a command and control system for such environments is greatly aided by automated support. A fundamental requirement for such automated support is a framework for modeling coordination in a way that can be used by automated tools. Our ongoing work is intended to satisfy this requirement.

We are adopting an empirical approach in developing theories of coordination. We are creating for benchmark tests a representative, easily modifiable and parametrizable simulation model of three large classes of MAS. We then observe and measure the effect of a set of control variables on the quality of coordination. We then form high-level, orthogonal emergent variables using the multivari-

*Figure 1. The metaphorical production plan, the P-tree, is an AND-tree. Leaf nodes reference raw materials or subcomponents provided. Higher level process nodes correspond to manufacturing/ assembly operations. Each process node may be associated with an OR-subtree (not shown).*



ate statistical method principal factor/components analysis. (Note that nonlinear and cross-product terms are also to be included in the trial functions. The word "trial" has an important, well-meant property, indicating that preconceived artifacts have no a priori role in the approach.) The emergent variables directly and in a statistically significant manner affect the level of coordination, the system structure and functioning. We then produce on this basis theories of coordination applicable to the three classes of MAS to be discussed below. They will contribute to the creation of design tools and guidelines in the construction of new systems, and trouble-shooting tools for existing suboptimal MAS.

We note this method is analogous to theory formation in physics where experimental results may suggest novel conceptual frameworks that have relevance to phenomena beyond those appearing in the original experiments. We hope that the theory to be developed will help in understanding coordination in general as well as in the creation of models of coordination for specific applications.

## THE THREE TYPES OF MULTI-AGENT SOCIETIES

The first experimental environment, the *P-System* (*P* stands for production), is a metaphorical and abstract version of our Distributed Control of Nationwide Manufacturing Operations system and will be used for the first set of benchmark tests. The model also has correspondence to industrial supply networks and has the following characteristics:

- Communication between agents is asynchronous and over limited bandwidth. It includes request for information, resource or action; task or resource allocation to agents; a piece of information; an acknowledgment, and so forth. Messages can be broadcasted at large, or sent to selected groups of agents or to an individual one on the basis of need-to-know and qualified-to-know.
- The sequence of "manufacturing operations" of a given product defines a hierarchical network of tasks, the *P-tree*, which corresponds (is homomorphic) to the problem-solving network needed by the planning process (see Figure 1). All agents share a global goal structure that forms the basis for the generation of individual goal structures. The agent society can assume an organizational structure ranging from a sharply defined multitier hierarchy to an egalitarian flat structure.
- Although the top layer of the P-tree is an AND-tree, each node can also be associated with an OR-subtree (alternative tasks can accomplish the given job at the respective process node).
- *Planning* is equivalent to assigning the (metaphorical) manufacturing/assembly operations to resources over space and time. An agent with a higher priority task (see below) can obtain a needed resource from another agent with a lower priority task. The latter task is performed with a less satisfactory

resource (more expensive or slower) or preempted until the loaned resource is returned.

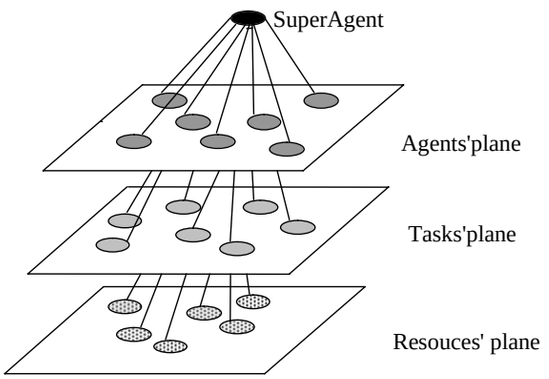
- Tasks may be priority- or deadline-oriented. The former implies that each task associated with the completion of a component must be well-coordinated with the completion of its sibling, ancestor and descendent components. Tasks in the deadline-oriented category have a deadline by which they have to be performed to satisfy the completion constraints of the final product.
- *Resource availability* (tools for the assembly/manufacturing operations) may change intermittently or regularly. Idle allocated resources and the (temporary) storage of components also cost money. The total range of resource availability has four subranges: (1) *infeasible*—the production process cannot function for lack of indispensable resources; (2) *deficient*—the production process can function only if some resources are transferred between process nodes at opportune moments (balancing the costs of transfer and component storage); (3) *scarce*—some tasks must be allocated suboptimal resource types; (4) *abundant*—every task can be allocated the optimum resource type.
- There is *critical dependency*, possible *conflicts*, *incompatibility* and *contests* between subsystems.
- There are three tiers in resource taxonomy: (1) *Resource Category* (every item in it can be used for one or more tasks); (2) a resource category contains one or more *Resource Types* (a given task can be performed at different cost or time levels, depending on the type chosen); (3) one or more *Resource Instances* exist within each resource type—these are actually allocated to tasks.
- *Agents* are associated with process nodes, resource categories and types, are spatially and functionally distributed, assume different levels of autonomy and capabilities in network perception (for reactive behavior), model other agents and the environment (for predictive behavior), maintain network coherence, communication and negotiation, short- and long-term planning, adherence to coordination and cooperation regimes, plan generation and execution for time-critical tasks.
- There are manager agents with different responsibilities. A top-level *Monitor Manager* collects and processes information from the other managers, and stores it in a knowledge base. The *Message Manager* intercepts each message, records the IDs of the agents that originate, transmit and receive it, as well as categorizes and stores them according to their contents type in a *Message Database*. (This is crucial for the trouble-shooting tool.) The *Coordinative Process Manager* is concerned with solution synthesis, reinforcement (such as the support in the coordinator-coworker relationship) and scheduling processes (tasks and resources). The *Manager of Negotiating Processes* assesses how agreements and decisions are made and kept. The *Manager of Neutral Processes* observes the cost and the effect of learning processes. The *Constraints Manager* identifies the cost/benefit ratio of inherent and imposed constraints (capabilities, classes, timing, costs, capacities, resource availability). The collected information is processed by the *Statistical Analyzer Manager*.
- Two objective functions can be used: the P-System is to produce a given number of final products (1) at a minimum cost within a given period of time, or (2) at a given cost within a minimum period of time. Both of these require an optimum allocation of the manufacturing/assembly operations and resources to individual agents over space and time, while satisfying a set of constraints.
- Two objective functions can be used: the P-System is to produce a given number of final products (1) at a minimum cost within a given period of time, or (2) at a given cost within a minimum period of time. Both of these require an optimum allocation of the manufacturing/assembly operations and resources to individual agents over space and time, while satisfying a set of constraints.

We have to define the Quality Measure of Coordination (QMC) to be optimized through experimentation. The P-System is optimally coordinated if subcomponents arrive at every process node simultaneously and at the required rate—while the total production time or cost, respectively, is kept under its allowed level and the total production cost or time, respectively, is minimized. This idea leads to our definition of QMC, based on the concept of synchronization and supply balancing,

$$\mathrm{QMC} = \frac{\sum_{(l)} l \cdot \sum_{(j)} t^{*}_{lj}/t_{lj}}{\sum_{(l)} \left(\sum_{(j)} l_j\right)}$$

Here $l$ is the level number, $l_j$ references the $j$-th process node from the left at level $l$, $t_{lj}$* is the best possible time for assembly/manufacturing at node $l_j$, $t_{lj}$ is the actual time used after local and global optimization (referring to systematic resource exchanges when needed). The weighting factor in the numerator, $S\,l$, expresses the fact that deficient synchronization and supply balance has a detrimental, cascading effect on coordination at the levels above the process node in question. The lower the

*Figure 2. Schematic representation of the connections with the confrontational interactions*



node level, the more serious the effects are. The denominator normalizes QMC to the range [0,1].

The next agent environment is termed the *Confrontational* type and the environment for the empirical study is called the *C- System*. One can visualize it as shown on Figure 2.

The super agent interferes only when the interagent decision making rules, for some reason, are not sufficient – more about it below. The Agents initially have enough "inborn" knowledge to cause each to select the highest priority Task to be accomplished and the best resource type instance needed for the job. (Task descriptors contain the respective Resource needs.) There are three tiers in the Resource taxonomy: (1) resource category—every item in it can be used for one or more specific tasks; (2) a resource category contains one or more resource types (a given task can be performed at different cost or time levels, depending on the type chosen; (3) one or more resource instances exist within each resource type—these are the ones actually allocated to tasks. if the best resource type instance is not available (already assigned to a higher priority task), the next best resource type of the same resource category is looked at if it has an available resource type instance, and so on.

For a given task environment, there are four possible resource availability sub-ranges: (1) infeasible: The production process cannot function for lack of indispensable resources; (2) deficient: The production process functions only if some resources are transferred between process nodes at opportune moments (balancing the costs of transfer and component storage); (3) scarce: Some tasks must be allocated suboptimal resource types; (4) abundant: Every task can be allocated the optimum resource type.

Each task Ti is characterized by a criticality factor, C, which equals the sum of the task's constant importance, I, plus its urgency value that increases over time. When time reaches the critical value,

t=tcr, urgency becomes infinitely large (e.g., *t*cr is the estimated time of impact of an enemy missile).

$$C(T_i) = I(T_i) + \frac{U_0}{t_{cr} - t}$$

The actual generation of the ToC is similar to that with the production-type MAS: We identify a large number of control parameters, each having an effect on the computation and the quality of the runs. The statistical design of the experiments has two phases: (a) the values of the control parameters fall into symbolic ranges, such as *very small*, *small*, *medium*, *large*, *very large*; (b) random selection of numerical values within the appropriate symbolic range. This is necessary since there are no symmetrical, unbiased experimental designs available for such high dimensionality.

We now describe characteristic quality measures to be computed during or after each run of experiments over the time interval $[t_s, t_f]$, $t_s$ being the starting and $t_f$ the finishing time of the run. In the following formulae, the *r*'s reference various rates of events from which the QMC components, *E*'s are formed.

1. **Task Accomplishment:** Let $T_a$ be the number of tasks accomplished, $T_u$ the number of tasks unaccomplished. The first measure is

$$r_1 = \left[1 - \frac{T_u}{T_a + T_u}\right], \qquad E_1 = \frac{\sum_{t_s}^{t_f} r_1}{t_f - t_s}$$

2. **Resource Type Utilization:** In Resource Category C, let the number of unused Resource Types be $N_C(RT_u)$ and the total number of Resource Instances $N_C(RI_t)$. This is summed over all Resource Categories, C:

$$r_2 = \sum_{(C)} \left[1 - \frac{N_c(RT_u)}{N_c(RT_t)}\right], \quad E_2 = \frac{\sum_{t_s}^{t_f} r_2}{t_f - t_s} \quad r_3 = \sum_{(C)} \left[1 - \frac{N_c(RI_u)}{N_c(RI_t)}\right],$$

$$E_3 = \frac{\sum_{t_s}^{t_f} r_3}{t_f - t_s}$$

There are several *time-rates of events* in the whole system that need to be balanced as well as their fluctua-

tion minimized for the benefit of good coordination. These are defined as follows:

$$r_4 = \frac{\text{TaskCompletionRate}}{\text{TaskArrivalRate}}, \quad E_4 = \frac{\sum_{t_s}^{t_f} r_4}{t_f - t_s}, \quad r_5 = 1 - \text{var}(r_4),$$

$$E_5 = \frac{\sum_{t_s}^{t_f} r_5}{t_f - t_s}, \quad r_6 = \frac{\text{ArrivalRateOfUsedResourceInstances}}{\text{RateOfTaskCompletion}},$$

$$E_6 = \frac{\sum_{t_s}^{t_f} r_6}{t_f - t_s}, \quad r_7 = 1 - \text{var}(r_6), \qquad E_7 = \frac{\sum_{t_s}^{t_f} r_7}{t_f - t_s}$$

Note that we can find out the relevance and the extent of importance of the above measures through experimentation. It is true that from the point of view of the whole system, the Es have different levels of importance. We propose as an overall measure of the QMC as follows:

$$QMC = a1.E1 + ... + a7.E7$$

with the constraint that

$$a1 + \ldots + a7 = 1$$

The values of ai, =1,...7 will have to be found by system optimization.

Finally, the third agent environment for our empirical study is of the *Market* type and its environment is called the M-System. It may be active when, e.g., Agents compete for Resources. The following diagram sheds light on this type of structure.

In this area, we have implemented different models of a deregulated electricity market. The models vary in the types of interaction between buyers and sellers, the mechanisms used to transact deals in the market, and in the role of the central agent. Extensive experiments were conducted on the models to determine the type of market structure best suited for trading. The criteria of evaluation were based on resource consumption, number of deals completed, demand satisfied, supply used, excess-over-need bought, and prices paid. The conclusions should be applicable to other deregulated consumer markets of "perishable" commodities with strong time dependence. We have implemented different models of a deregulated electricity market. The models vary in the types of interaction between buyers and sellers, the mechanisms used to transact deals in the market, and in the role of the central agent. Extensive experiments were then conducted on the models to determine the type of market structure best suited for trading. The criteria of evaluation were based on resource consumption, number of deals completed, demand satisfied, supply used, excess-over-need bought, and prices paid. The conclusions should be applicable to other deregulated consumer markets of "perishable" commodities with strong time dependence. A detailed discussion of this type of MAS would be beyond the scope of such short contribution.

*Figure 3. Schematic representation of the m-system*

## CLOSING WORDS

Finally, a short justification of why the present contribution may be relevant to the analysis of e-government. Computer-based multi-agent systems attempt to describe, simulate, study and optimize many important aspects of human as well as artificial societies. Coordination is one of the primary requirements in any society. The present article aims at the analysis and optimization of coordination. It thus provides a theoretical basis as well as heuristic tools to understand the functioning of the societal setting. It is worth stressing that coordination is one of the core functions of any public organization as they need to manage their governance, development and service processes in an increasingly complex environment. When applied to the basic processes of e-government, multi-agent systems give operational tools to analyze and develop the coordination of computer-assisted governance networks and systems.

## KEY TERMS

**Agent:** A software unit that is capable to transform its environment to achieve some goal. They can be cooperative, centrally managed or self-interested.

**Coordination:** The process of managing dependencies and constraints between activities.

**Coordination Theory:** The set of axioms, constructs and analytical techniques used to create a model of dependency management in multi-agent systems.

**Distributed Artificial Intelligence:** At times identified with multi-agent systems, although some researchers consider it a more encompassing area of research.

**Environment of the Agents:** Can be completely or partially accessible by them, deterministic or nondeterministic, static or dynamic, and discrete or continuous.

**Multi-Agent Systems:** Consist of autonomous, cooperative, possibly specialized intelligent individual agents, capable of making independent decisions and which cooperate toward some common goals. They can represent a software engineering paradigm with interacting components, a human society, or any complex, nondeterministic complex entity.

## ENDNOTE

[1] In this context, *analysis* and *design* go beyond the ambits of software engineering and distributed systems research because agent intelligence, coordination and conflict resolution methods must be taken into account in addition to system structure, component interfaces, and synchronization considerations.

# Back–Office Integration for Online Services between Organizations

**Herbert Kubicek**
*University of Bremen, Germany*

**Jeremy Millard**
*Danish Technology Institute (DTI), Denmark*

**Hilmar Westholm**
*Institute for Information Management GmbH, Germany*

## INTRODUCTION

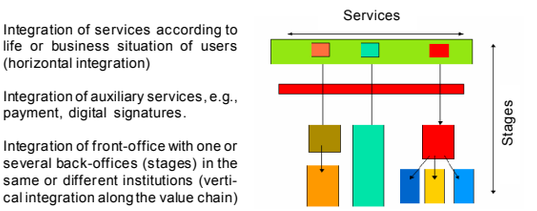
The issue of back-office integration has gained increasing importance within the political e-government debate and e-government research, after the original optimistic expectations for quick gains or digital wonders could not be realized. The term *back office* is defined from the position of a customer or client and distinguishes tasks and processes in relation to a front office, which may be a real office or, in the context of e-government, an additional Web interface for the online delivery of governmental services. Surveys of the European Commission show that by now almost all governmental agencies have their Web sites, offer information about their services in these virtual front-offices and can be contacted by e-mail (CEC, 2004, 2005). Many forms can be downloaded and often filled in online and sent electronically. But only in a few cases, permits and certificates are delivered electronically in return. Incoming electronic forms quite often go to an electronic in-basket and public servants print them or enter data, by copy and paste, in the regular IT systems for the respective service, the so-called legacy system.

From the point of view of the customers (citizens or business), this state of online offers is a lack of fulfillment and service quality; to the administration it means additional cost without savings on other costs by the online tools. The reason for these shortcomings is the missing integration of the Web front ends with the existing legacy systems (i.e., the lack of back-office integration).

Within the recent e-government reviews and analyses, this diagnosis is explained by models of development stages. According to most of these models, the development of e-government systems (and similarly e-commerce systems) follows four stages, but differently defined. With regard to the functions offered online on the governmental Web sites, consulting companies such as Arthur Anderson or the Gartner Group distinguish information, communication and transaction as stages which are developed one after the other, followed by "transformation" as a fourth stage, where the organization (process and/or structure) of the governmental units is changed in order to fully exploit the potential for increase of service quality and/or cost reduction. The OECD report on E-Government (OECD, 2003) introduces a slightly different stage model, distinguishing (1) information, (2) interactive information, (3) transaction, and (4) data sharing, and pointing to the interorganizational dimension of back-office integration. In an early stage model Layne and Lee (2001) distinguish (1) catalogue, (2) transaction, (3) vertical integration, and (4) horizontal integration predicting progress towards higher levels of integration between different levels and branches of government. In order to provide full online service delivery via the virtual front-office, it is in many cases not sufficient to integrate the front-office with only one back office, but also with back offices of other agencies or to exchange information between two or more back offices of different agencies. Full exploitation of the potential of the Internet therefore in many cases affords interorganizational integration which in turn requires interoperability between the systems involved and perhaps transformation of the network of the agencies concerned.

While there is high agreement about the importance of interorganizational integration, the subject is still not well researched, the different options and their benefits and risks not well analyzed. According to Scholl, back-office integration so far has remained grossly understudied (Scholl, 2005b, p. 7), "which is not surprising given the limited experience with online services at this stage" (OECD, 2003, p. 73). There is research on electronic data interchange between private enterprises and interorganizational information systems in the business sector for more than 20 years (Cash, 1985; Eom, 2005; Kubicek, 1993; Porter & Millar, 1985 ), but only a few

*Figure 1. Dimension of integration in e-government*



contributions deal with interorganizational information systems in government. In some respect, research on collaboration and information sharing between governments (Dawes, 2003) is relevant, but adopts a slightly different focus. Unfortunately, insights from the business sector cannot be generally transferred to the public sector because interorganizational relations in particular are quite different. Private enterprises necessarily exchange information with many suppliers and many customers under the pressure of market competition, while governmental units on all levels most frequently have their geographical or subject-related jurisdiction in a form of monopoly. Therefore traditionally there was not much need for data exchange with many other agencies. Scholl, in addition, points to the fact that the public sector is subject to a system of deliberate checks and balances with a strong demand for a division of power which also sets limits to open flows of information and interoperability of systems (Scholl, 2005a). The silo type of organization within government is manifested in incompatible IT systems and closed proprietary networks. The Internet has brought technical interoperability and the private service sector has raised expectations with regard to customer orientation of public services. Therefore, the need for progress in this direction is stressed on all political levels.

Within the European Union, the Ministerial Conference on E-Government in 2001 already asked for support of back-office integration and the Commission ordered a qualitative benchmarking of good practice cases in back-office integration, which was carried out by the authors of this article in 2003. The approach adopted in the study as well as some of the findings can contribute to a more differentiated understanding of the new and multi-faceted issue of back-office integration in and between governmental agencies. In this article, four types of back-office integration are presented which have been employed in a comparative good practice analysis in the European Community in 2003 (Millard, Iversen, Kubicek, Westholm, & Cimander, 2004). Three organizational models will be identified which serve as alternative options in order to achieve a higher degree of back-office integration by reorganizing back-offices. While two of these are derived from established organization theory (centralization and standardization), the third model "clearinghouses" has gained increasing importance in practice but rather neglected in the literature on interorganizational information systems and back-office integration.

## BACKGROUND

Starting from the assumption that a higher degree of back-office integration yields greater benefits for the agencies involved as well as for their customers, it is necessary to distinguish and measure different degrees. For the European Benchmarking Study, four types of back-office integration have been distinguished, each differentiated by different degrees of digitization or automation. This typology starts from the more basic differentiation between three dimensions of integration a back-office can achieve (see Figure 1).

A back office may be defined as an organizational unit using an ICT application to provide a governmental service to customers or other back offices by receiving, processing and distributing information in electronic form. When two or more back offices are involved in order to produce the respective service, they may belong to the same or different government agencies. In contrast to a back-office, a government agency is a formal organization with a formal purpose and a separate legal standing and a ruling body at the top of the hierarchy (e.g., a city government, a regional board or a ministry). An agency usually includes several back offices as departments or other kind of subunits devoted to different services. If two or more back offices of one agency are involved, we speak of intraorganizational integration; when they belong to different agencies, we speak of interorganizational integration.

The term *integration* relates to the organizational and technical flow of information and the related workflows or processes within and between the respective back offices. Back-office reorganization or transformation according to the terminology of the stages models happens

when these processes and/or the structure of back-offices are changed in order to improve these workflows.

With regard to the online delivery of governmental services, at least three dimensions of integration can be distinguished, depending on what kind of processes are to be integrated. Similar to the stages model of Layne and Lee (2001) and the classification of interorganizational information systems in the business sector by Hong (2005), we distinguish between horizontal and vertical integration.

Vertical integration refers to the linkage of processes between back offices, which contribute to different stages of the production and delivery of a governmental service. They perform different tasks in a supply chain and are in sequential interdependency from each other. While Hong defines horizontal integration for the business sector as the linkage of a group of homogeneous organizations contributing identical inputs towards the augmented output (2005), in the context of e-government horizontal integration occurs in two forms with different dimensions of homogeneity. The first one is also named one-stop government and represented by integrated portals, offering a number of services, produced by different back-offices but addressing the same group of customers. Most prominent is the integration of different services according to life events (cf. Hagen & Kubicek, 2000). The second form of horizontal integration concerns the exchange of information between agencies performing the same tasks in different geographical districts.

A third dimension of integration which is not mentioned in the literature so far but which in practice is a necessary condition for a complete online delivery concerns the integration of auxiliary services. Horizontal and vertical integration refer to governmental services which are related to the primary task of the agencies and primary concerns of the customer, e.g., getting a permit. In order to achieve this primary goal, additional processes have to be fulfilled; in particular paying required fees and/or using digital signatures to sign an application. These auxiliary processes usually involve third party agencies such as credit card organizations and trust centers. Only if these processes are integrated with the primary process(es), a complete online delivery of a governmental service is possible.

Based on these three dimensions, four types of back-office integration can be defined which distinguish different degrees of back-office integration. By combining the horizontal and the vertical dimension, referring to the integration of services respectively stages, there are four types:

- **Type A: One Service, One Stage:** The service offered in the front-office is produced by one back office only.
- **Type B: Multiservice, One Stage:** Two or more services are integrated according to citizens' life events or business needs.
- **Type C: One Service, Multistage:** A service to a customer requires contributions of two or more back-offices on different stages of the supply chain.
- **Type D: Multiservice, Multistage:** Two or more services addressing the same customers require the contributions of two or more back offices each. Customers can receive these services by entering identical data for different services only once.

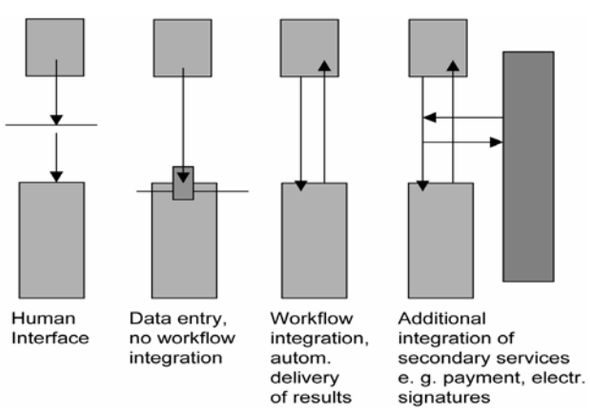
Rather these four types represent different degrees of complexity. However, we are not sure whether they represent four degrees on a ranking scale and whether the assumption by Layne and Lee (2001) is valid for all areas and different situations that horizontal integration is more complex and sophisticated than vertical integration. Not every government service is suited for integration with other services and not every service requires the contributions of two or more back offices. The four types therefore describe different contexts for achieving different kinds of integration.

In each of these four contexts, different degrees of integration can be established. In the Study, they are called degrees of digitization, referring to a continuous digital processing and exchange between the back-offices involved, on the highest level without any change of media and any human intervention. One may also speak of different degrees of automation.

At least four degrees of digitization or automation can be distinguished (see Figure 2):

1. **Human Interface:** The interaction between the customer and the BO-system is only partially mediated by a human agent, e.g. by an employee who

*Figure 2. Different degrees of digitization*



reads e-mail or PDF-forms from the user, checks the data, then keys them into the BO system, and also checks the output generated by the system before having it sent electronically or on paper to the customer.

2. **Automatic Input but Human Interface in Output Response:** The customer can enter his data directly into the BO system, but the generated output still has to be checked and dispatched by an employee.
3. **Full Automation:** The interaction between the user and the BO system is fully digitized and the only need for human intervention is in exceptional circumstances.
4. The highest level of digitization is reached when in addition auxiliary services, such as electronic payment or authentication of digital signature are also integrated without any human intervention.

## ORGANIZATIONAL MODELS

In the above mentioned study on back-office reorganization, 29 good practice cases within the former 15 member states as well as Norway and Iceland were identified representing the most advanced degrees of back-office integration for the 20 reference services used by the European Commission for the comparative benchmarking of advanced back-office integration in e-government. They include services to citizens and business such as certificates and permits and paying taxes and social contributions. The selection of these cases was conducted by e-government experts in each country following the same selection criteria based on the four types and the four degrees as defined above. At the time of this survey, none of the experts could find a Type D case with a degree of digitization higher than two. As such a survey cannot guarantee validity of the comparisons and as progress may have occurred in the meantime, we will not report on the distribution of cases according to countries and services (cf. the full report by Kubicek, Millard, & Westholm, 2003, for methodology; Millard et al., 2004, for findings and extensive case descriptions).

Of more general and lasting importance is the classification of the organizational models which were applied in these cases in order to achieve and maintain a rather high degree of integration. This issue is of particular relevance as the e-government research literature does not provide empirically based typologies or taxonomies of different organizational models or options for achieving back-office integration. These are case studies of integration in particular areas of government for information sharing (Bekkers, 2005; Dawes, 2003; Homburg, 1999, Homburg & Bekkers, 2002). And, as mentioned above, the classifications and typologies developed for the private sector and e-commerce do not fit the particular situation of and between governmental agencies. Meanwhile there are interoperability frameworks and programs by national governments. They differentiate between technical, semantic and organizational interoperability, for example. While the options for technical interoperability in terms of standards are well described and the methodology for achieving semantic interoperability is available, also in this context there is no established knowledge of how to achieve organizational interoperability although this is of great interest to all parties involved (Kubicek & Cimander, 2006).

We started classifying the 29 cases using a typology of coordination mechanisms in organization theory in particular distinguishing between centralization of tasks and the standardization of procedures. If certain tasks in an organization such as purchasing, IT management or personnel development are to be coordinated, they either can be centralized in one unit and be put under control of one leader, or a set of rules for procedures is defined to which the decentralist units have to adhere (cf. March & Simon, 1958). Similar is the development in interorganizational information systems: The organizations involved either establish a common central system with input/output interfaces to their own systems or they define or adopt a set of technical standards and interfaces and agree on corresponding work processes.

### Option 1: Centralization of Back Offices

If cooperation and data exchange between different offices is not working satisfactory and problems in service quality or cost increases raise public concern, what comes to the mind of political leaders first is centralization, that is, putting them under one organizational command or at least to centralize some of their functions, in particular data storage and retrieval. Such concentration can provide strong rationalization benefits which focus expertise, reduce errors and time delays, and are able to exploit economies of scale.

As a general rule, the centralization of the back-office and/or of data sources can make sense for services or aspects of services which are standardized across a large geographic area, normally a nation or federal state. For example, some years ago Austria centralized the numerous local systems for citizens' registration. Other examples in the good practice case selection are the income tax solutions in Finland and Spain and the student grants in the Netherlands. Where a service or an aspect of a service is dependent upon local needs or democracy, or where physical delivery is a necessary component of service delivery, it may make sense to decentralize the

front-office at the same time. An example for this option is the reorganization of car registration in Italy with two central registers and the car dealers as new decentralized registration offices (Millard et al., 2004).

## Option 2: Standardization of Interorganizational Workflow

In some cases there may be legal or political barriers to centralization. At least from a technical point of view, the standardization of workflows and interfaces is an equivalent to the centralization of systems and data sources. In particular the specific mechanisms of checks and balances in the governmental sector and concerns for the citizen's privacy as well as different political affiliations are barriers to centralization in many cases, and standardization seems to offer an increase of technical efficiency while maintaining the political status quo. But the standardization of workflows and technical interfaces requires much more coordinated planning within and between the back-offices involved. The basic work processes within each back office may stay unchanged, but the workflows, that is, the detailed steps almost always have to be adapted. A necessary condition is in any case agreement on data exchange formats at the syntactic and semantic level, for example, EDIFACT or XML and concrete message types. In order to establish interorganizational workflows with minimal human intervention, this has to be embedded in an agreement on gateway workflows which define how input is handled by the receiving next-stage back office, whether receipts or confirmations are sent back and so forth. In order to allow for control over the whole chain, additional workflows have to be set up for tracking and tracing of requests and so forth. For this purpose, systems for identifying customers, applications etc. have to be adapted or a new common system across the different back offices has to be established.

A good example for this model is the reorganization of child allowances in Ireland. Besides the hospital where a child is born at least three different agencies are usually involved: The birth of the child has to be certified by the registrar, based on the birth certificate the child has to be registered in the citizen register, and only then allowance may be applied for by the parents. While in many countries parents have to go to one agency, apply for the respective document and take it to the next agency, in Ireland an interorganizational workflow has been established between the hospitals, the local registrar's office, and the (central) General Register Office. For the electronic data interchange, a naked object architecture running on Compaq's OpenVMS platform had to be agreed upon and a new personal public service number as identifier during the whole process had to be introduced (Millard et al., 2004).

## Option 3: Joint Clearinghouses

The most interesting finding of the survey and the analysis of the 29 good practice cases is that the option of standardization between agencies without any kind of centralization was only found in two cases, while in most other cases standardization of workflows and interfaces was supported by some functions performed by a clearinghouse. Whereas in the case of centralization a central database is created and usually some decision making is centralized as well, in the clearinghouse model each participating agencies keeps its decentralist databases and full decision making authority, but uses supporting services offered by a clearinghouse. These include in particular routing and directory service repacking of data transmissions, adaptation of exchange formats and different versions of standards and so forth.

Clearinghouses represent a certain type of new electronic intermediaries which were discussed in the literature on e-commerce in the mid-nineties (cf. Sarkar, Butler, & Steinfield, 1995).

A relevant example of this organizational model is business social contributions by employers in Belgium. In this case, an autonomous public office called the Crossroads Bank for Social Security (CBSS) was established in 1991, not as a centralized database, but in order to manage registers about the location and type/format of the data it needs, and for whom and for which purpose these data can be accessed. The objective of the CBSS clearing house is therefore to identify and route data, regardless of its format. It is thus a highly intelligent data exchange mechanism rather than a large centralized database in its own right.

The users in this case are different employers, each of whom may have different data systems and formats, and each of which needs to communicate with a variety of different social security institutions, which again use different data systems, on behalf of each of their individual employees regarding social insurance, holidays, illness, accidents, family allowances, and so forth.

# FUTURE TRENDS

The three organizational models distinguished in this article are functionally equivalent. Cultural and political factors have influenced the choice in each case. Also services largely differ in their supply chain structure and are not equally suited for horizontal integration according to life events either. And there may be other factors

explaining why a certain option has been chosen in a certain situation. In organization theory in the late 1960s and early 1970s, the contingency approach was developed in order to explain different organizational structures of industrial companies by context factors such as size, technology, environment or tradition (Lawrence & Lorsch, 1967; Pugh, Hickson, Hinings, & Turner, 1969). In a similar way it should be possible to identify contextual variables or contingency factors explaining the choice of the organizational model of back-office integration. In addition, meaningful hypotheses have to be developed why in a certain situation a certain model fits better than other ones.

As the models provide for coordination, and coordination is to deal with interdependencies, a working hypothesis could relate the choice of the model to the kind of interdependency which has to be managed. Emery (1969) distinguished these types of interdependencies:

- Sequential interdependencies arise when a process depends on the output of another process;
- Pooled interdependencies arise when two or more processes depend on the same pool of resources, in our case in particular data;
- Reciprocal interdependencies exist when each process depends on the output of the other one.

We may assume that the standardization of interorganizational workflows fits to manage sequential interdependencies while centralization and clearing houses are more appropriate to deal with pooled interdependencies. Both are functionally equivalent but differ with regard to power distribution. Therefore where there is a strong ruling body, centralization will be chosen while under a more even power distribution a clearinghouse might emerge as a joint venture. This simple assignment could be tested by empirical comparative research and then probably be differentiated by introducing additional contingency factors.

Additional factors and contingencies may be extracted from other case studies of interorganizational cooperation in the government sector. Homburg and Bekkers (2002) as well as Scholl (2005a) emphasize the importance of cultural factors. From the analysis of the 29 good practice cases the importance of a history and tradition of cooperation can be concluded. Large-scale technical integration mostly occurred where there was already some established cooperation which then was extended and made more efficient by technical integration. Technology seems to be a facilitator or supporter but not the main driver.

As was already stressed in the Introduction, back-office integration in e-government is not only a new field of research, but also a relatively new development in administrative practice, but will attain much more attention. While the research reported here concentrated on back-office integration for governmental services for citizens and business, this could be compared with developments in the area of public security and related services where progress seems to be greater, but deeper knowledge is also harder to get and to publish.

## CONCLUSION

Citizens and business as customers of (e-)governmental services demand better public service quality regarding easier and ubiquitous access. Government agencies are under pressure to save costs and increase efficiency. To reach these objectives, integration of the web front-ends with the existing legacy systems as well as the integration and reorganization among different back offices is a necessity.

On the basis of analysis of 29 cases of good back office integration, in this article we distinguish three functionally equivalent organizational models: Centralization of back-offices, standardization of interorganizational workflow, and joint clearinghouses. Mainly cultural and political factors have influenced the choice in each case. The option of standardization between agencies without any kind of centralization was only found twice while in most other cases standardization of workflows and interfaces was supported by some functions performed by a clearinghouse. For future research, we suggest to adopt the contingency approach from organization theory identifying context factors such as size, organization, environment, tradition, or others to explain, why a certain option has been chosen in a certain situation.

## KEY TERMS

**Back Office:** The term *back office* is defined from the position of a customer or client and distinguishes tasks and processes in relation to a front office, which may be a real office or, in the context of e-government, an additional web interface for the online delivery of governmen-

tal services. In some cases such a service is produced by one unit or back-office, in other cases several back offices of the same service supplier agency or of different agencies, at the same government level or at different levels may be involved.

**Integration:** With regard to e-government, at least three dimensions can be distinguished relating to what has to be put together with what else and for which purposes: Integration of services according to life or business situation of users (*horizontal integration*); integration of auxiliary services, for example, authentication, payment; integration of front-offices with one or several back-offices (stages) in the same or different agencies (*vertical integration* along the value chain).

**Interoperability:** Interoperability between systems is defined as "The ability of two or more systems or components to exchange information and to use the information that has been exchanged" (IEEE Standard Computer Dictionary). Within the context of e-government there are slightly different definitions, for example, strengthening the aspect by which this interlinking of systems, information and ways of working will occur: within or between administrations, nationally or across federations of states, or with the business sector.

**One Stop Government:** OSG covers the integration of a couple of services which usually are requested in combination due to a certain life situation or for other reasons and which make use of the same data. In order to increase benefits or convenience for the customer by having him to enter his data only once, as well as to reduce the cost of processing data, the integration of two or more services, using the same data, is promising.

**Organizational Interoperability:** OI is concerned with defining business goals, modelling business processes and bringing about the collaboration of administrations that wish to exchange information but that may have a different internal organization and structure for their operations. Therefore, OI also deals with the interorganizational coordination of workflows.

**Reorganization of Back Offices:** The term refers to changes in workflows or changes in the structure of one or more agencies involved, that is, the distribution of authority, functions and of tasks, which occur when making services available online. Reorganization is important because the greatest benefits of e-government do not come from replicating paper based processes directly in a computer system, but rather from using the potential of the technology to reengineer the process and to check whether each step is still necessary, whether steps might be merged or abandoned at all, and so forth.

**Semantic Interoperability:** SI is concerned with ensuring that the precise meaning of exchanged information is understandable by any other application not initially developed for this purpose. Semantic interoperability enables systems to combine received information with other information resources and to process it in a meaningful manner. It refers to meta-data, ontologies and similar issues.

**Technical Interoperability:** TI covers the technical issues of linking up computer systems and services via (tele)communication networks. This includes key aspects such as open interfaces between different transmission systems, interconnection services, data integration and middleware, data presentation and exchange, accessibility and security services.

# Bavarian Secondary Modern Schools

**Christopher Oberle**
*Bayerisches Realschulnetz, Germany*

## INTRODUCTION

Since the late 1990s, commercial use of the Internet has increased. Many schools have started to use this new technology for presentations and have been sponsored by several initiatives like "Schulen ans Netz."

The eight ministerial service centres (Ministerialbeauftragte, MB) for the Bavarian secondary modern schools started to think about the use of the Internet, too. To get the best profit out of the Internet it was decided to combine the existing homepages of the *MB*s together on one platform for the Realschulen. The Bavarian Realschulen have a long tradition on IT as a subject, so a team of 24 teachers with special knowledge in creating websites and open source technologies (php, MySQL) was formed in 1999 to work out a concept for the Internet platform. In September 2000 the Bayerisches Realschulnetz (*BRN*) (www.realschule.bayer.de) went online for the first time. During the following 5 years, the project has developed into a one-stop-shop for all parties concerning the Bavarian Realschule.

## BACKGROUND

### School Development—A New Challenge to Improve Education

Thinking about the use of ICT at schools, the first thing that comes to one's mind is e-learning. E-government doesn't seem to be relevant for work at schools. But situations at schools have changed during the last seven to ten years and there are new challenges to deal with.

In 1999, Bavarian Ministry of Education started a project called "school-development with the aim to give all school types new challenges and to guarantee the highest standard of educational quality.

School development comprises three branches: organisational development, personnel development and educational development (Bayerisches Staatsministerium für Unterricht und Kultus, 2004).

Organisational development means to open schools to the public in two ways: to win over local institutions, enterprises and educational institutions in the neighbourhood to use their resources and to enlist parents and pupils for cooperation.

Gaining public interest in schools and involving and engaging parents and the community into the learning process blurs the boundaries between school, home and community (Brooks & Brady, 2004). Students will get a feeling for what is meant by the term *lifelong learning*.

Educational development means new forms of instruction by using new media and ICT, training students in social and methodical skills and teamwork.

To be successful, teachers have to be able to use the new skills (e.g., the use of ICT in class) and to act as coaches in the classroom instead of being traditional teachers.

To support the school development an unfiltered flow of information is necessary. Every member of the school community has to get the information he needs for his work. This means providing information about the different types of schools, their school policies, their curricula and the possibilities of further training (e.g., continuative schooling, vocational training). Parents and pupils need a solid database to make the right choice for their school type. Information about relevant laws and decrees and their actual changes belonging to the type of school and information for teachers about further training offers and educational material have to be available, too.

School development causes big efforts for everyone, especially for teachers and principals who need additional time to realize the project. However, administrative work increases and therefore a simplification of administrative work will save money and time for educational objects. Change management at schools at all levels is necessary to achieve this aim.

Taking the two points—open information for everybody and an organisational changing—together the result is e-government at schools.

Paul Timmers (2004), head of Unit eGovernment at the Directorate General Information Society at the European Commission, defined e-government as the "use of ICT together with organisational change and the acquisition of new skills in public administrations, in order to improve public services and democratic processes".

Giving free information to everyone, raising the possibility for all participants at school to transact and interact with others and to participate in decisions will strengthen democratic processes at schools. Especially parents and pupils can influence their school's development and hence their schooling. In the end the public can

carry out the most important role of democracy: the control of governmental duties which means in this case the quality of education.

## CHANGING THE WAY OF LEARNING

To reach high quality in education it is not enough to change the schools' organisation and to give parents and pupils the right to participate in their school's development. Besides it is necessary, to change the way of learning. Learning is an active process, so it is not the teacher who can teach someone something. Learning is the pupils' responsibility and teachers should act more as coaches who help them to organise their learning. Therefore it must be kept in mind that learning is something very individual. Everyone learns in different ways and at a different speed and has different kinds of interests. The consequence is that learning has to be personalised and individualised, which means it has to be tailored to "meet the needs of each student, taking account of learning styles and learning preferences allowing students to pursue their studies with a range of resources tailored to their individual needs and interests" (Selinger, 2004, p. 8). This sounds like isolated work, but in fact it is not because pupils can decide how long they want to work on a subject.

Knowledge is actually constructed in collaborations among learners (Brown & Duguid, 2002). The usual places for learning are the schools, but if the individual learning should be respected, a possibility to abolish the restriction to one place is needed (schools will not be obsolete in the future but there will be different places where learning will take place). ICT provides the tools to tailor learning and to bring together all participants in learning even away from school.

It is a precondition to have an appropriate ICT equipment at the schools, an affordable broadband connection for everyone and useful e-content to use the advantages of e-learning.

Because teachers tend to teach as they were taught, a constant training and retraining of teachers is necessary to achieve progress or change in classroom (English, 2004).

## BRN: SERVICE AND INFORMATION PROVIDED FOR THE REALSCHULEN

To meet these challenges and to support the Bavarian secondary modern schools the Bayerisches Realschulnetz went online in 2000. The three main targets the project stands for are reduction of administrative work at all levels, support of the teachers' work and more transparency of the Realschulen to the public. The following objectives of the BRN were set out to reach these targets:

1. Availability of general information for parents, pupils and partners and obtainability of basic information about every *Realschule* in Bavaria (headmaster, number of pupils, classes, contact details)
2. Availability of information for everyone interested, including all laws and decrees relevant to the Realschule
3. Quick posting of official publications
4. Presentation of offers for further education (regional and supraregional)
5. Provision of teaching and advisory materials
6. Simplification of administrative work
7. Strict focus of the BRN on its customers' needs

Customer orientation became the main principle of the team's work. Several portals have been designed for the different target groups (pupils, parents, teachers, principals, students, probationary teachers) where specific information is offered.

To achieve a barrier free flow of information, a database-driven news system, the MB-Nachrichten, was created. News and information can be provided in real time by the board of control without any restriction of accessibility. The MB-Nachrichten replaced a newsletter which was sent periodically every 4 to 6 weeks. To get the best benefit of the system, each piece of new information can be forwarded by mail, dates can be transferred into an electronic scheduler and the news can carry several addendums (documents, forms, URLs) which can be followed up electronically to reduce changes in format.

The implementation of the MB-Nachrichten has had a bearing on back office processes on the level of MBs and principals. One result was the unification of the communication channels, which lead to savings in terms of costs and time in the school administration. With MB-Nachrichten BRN established a backbone for an IT-based knowledge management at schools.

To take advantage of synergy effects in order to help teachers to save time in their preparation for lessons a database with teaching and educational material was installed. Teachers can search for and spread their own teaching material to the benefit of all. New concepts for teaching can be exchanged for the benefit of educational development.

A database with all regional and links to all supraregional further training offers as well as an extended job service complete the administrative service for schools. Especially the support of Ministry of Education with the open transfer procedure via BRN enables princi-

pals to see all staff movements at their school planned by the Ministry of Education. This gives them the chance to start planning for the next school year much earlier and to avoid mistakes.

To assist parents and pupils on their search for a *Realschule* in their region, the *BRN* provides topical basic data from each *Realschule* in Bavaria. They get information about compulsory and optional subjects, final examinations and the possibilities of collaboration in the boards of the school (e.g., parents' association, pupils' association).

The most important laws and decrees concerning the *Realschule* (e.g., Bavarian Education Law, regularities for the *Realschulen*), the curricula and the decrees concerning the training of teachers can be seen online, with most of them providing the possibility to search for keywords. So everyone who is interested can get valuable information.

A guest book service for individual requests completes the offer of the BRN.

The effect of all these arrangements was transparency at the *Realschule* and a flattening of the strong hierarchical structures of secondary modern school at least in the flow of information.

## E-LEARNING IN PUBLIC-PRIVATE PARTNERSHIP

The e-learning sector of *BRN* is just under development. Together with Audi, a Bavarian car manufacturer, the *Realschulen* started to bring up e-learning modules for mathematics in 2003.

Audi has had a long e-learning tradition and the necessary software, teachers can provide their pedagogical experience. Based on the basic knowledge which is stated in the Bavarian curriculum for the *Realschulen* for each grade and subject, modules are worked out.

The first module will handle with measurements: length, time, mass, and money. All modules will be built up in a similar way: The first part is an introduction into the topic. It provides all basic information one needs to deal with it. In the second part problems are packed into a context and the pupils play a role to solve different problems. This means they have to collect different kinds of information, put them together and work out several intermediate steps towards the solution. In each step they get a feedback about their solution and help if needed. Pupils can choose whether they start the module at the very beginning or step into a specific problem at the training area.

The modules can be used at home to deepen the subject matter or to fill a gap in the basic knowledge. They can be used in school, too, to give students a stimulation to do mathematics in addition to the classical school book or to do self studies during stand-in classes.

Ending up this project, the whole basic knowledge of mathematics at Realschulen from Grade 5 to 10 will be available as e-learning modules. It will give advantage to students who get prepared for an examination. Teachers can save time at class because the responsibility of repetition of basic knowledge can be delegated to the students.

## FUTURE TRENDS

The value of e-learning is evidenced by studies such as Cox and Abott (2004). There are many initiatives all over the world to enforce the use of ICT in schools, mostly in context with e-learning. Some initiatives use ICT to stay in contact with parents (Edwards, 2004; English, 2004).

What is missed until now is a study about the potential of e-government at schools to support administrative work and to save costs and time for educational work. BRN is a precursor in this sector.

Finally the success of all ICT initiatives depends on the willingness of policy makers to invest money into an appropriate ICT equipment of school and pupils and into useful content.

## CONCLUSION

Implementing BRN has not always been an easy challenge. Many applications were unthinkable in 2000 when the BRN was started. To see parents and pupils as customers is one aspect of school development. On the other hand, every party of secondary modern school is responsible for the success of the whole organisation and therefore needs information and support. There are still prejudices towards it by higher functionaries in the Ministry of Education but they are decreasing by time. The diversification raised the acceptance of the users and especially teachers and principals cannot imagine working without BRN.

What are the lessons learned by realising the project?

The key of success is customer orientation. A project is worth nothing until it is accepted by the customer himself. So customer relation management is important for successful e-government.

Spreading the work to a team, in the case of BRN a team of teachers spread over whole Bavaria, helps to use synergy effects and raises the acceptance. It is not necessary to go online with applications which are hundred per cent perfect. It is better to start at about 70% and to develop them by taking into account the feedback of the users.

Taking a private public partnership to raise the e-learning project produce synergy effects. School and economy get a new view of each other and can learn and benefit from each other. Involved teachers look upon the experiences on this project as an enrichment for their work at school.

## KEY TERMS

**E-Learning:** Use of ICT, multimedia and Internet to improve quality of education. E-learning enables for a personalized lifelong learning. E-learning stimulates remote exchange. It reduces the disparity between individuals or groups caused by social differences.

**Lifelong Learning:** Purposeful learning to get an improvement in knowledge, skills and competences. It is not concentrated on education and vocational training but comprises all aspects of changes humans are faced during their lives.

**Ministerialbeauftragter (MB):** A unique institution at Bavarian Realschulen and grammar schools. The *MB*s are the ministerial service centre for their type of school in each Bavarian administrative district. Each *MB* is responsible for 35 to 70 Realschulen. He provides information, organises further trainings and gives advice to the principles. *MB*s act by order of the Ministry of Education.

**One-Stop Shop:** Internet-based platform which accommodates the demands of different groups to one and the same topic.

**Personalized and Individualized Learning:** Student-centred learning respecting individual learning styles and preferences, which is appropriate to student's abilities and level of knowledge and which meets their needs and interests.

**Realschule:** The Realschule (secondary modern school) comprises Grades 5 to 10. It provides an education for young people who are interested in questions of theory, but at the same time have practical inclinations and abilities. General education is provided as well as preparing pupils for vocational training, and it is established between Hauptschule und Gymnasium.

**Synergy Effects:** Synergy effects are generated by a collaboration of human beings with a view to interact and aid one another.

# Benchmarking Electronic Democracy

**Francesco Amoretti**
*University of Salerno, Italy*

## INTRODUCTION

*Electronic democracy refers to the use of information technology (IT) to expedite or transform the idea and practice of democracy.* (Street, 2001, p. 4397)

From the beginning, a common assumption in many discussions of e-democracy is that ICTs have the power to augur in a new political order. There are of course different ideas about what constitutes as an e-democracy, but it appears to be taken for granted that ICTs have this constructive power regardless of the conditions and environment in which they are used (Barber, 1984).

Whilst the most significant experiences in the field of ICTs have been generated by bottom-up processes rooted in civil society, a great deal of e-democracy projects are characterised by the political action of national and supranational institutions. The enormous resources spent on e-democracy initiatives and the institutional structure of democratic societies that place pressure on politicians and decision makers to justify their decisions in relation to those they represent both generate a need for public evaluation tools and shared instruments of analysis. Moreover, as information technology tends to create spaces of interaction that are easily accessible and interconnected on a global scale, the need for standardised empirical definitions and indicators is attracting more and more attention (Gibson, Ward, & Rommele, 2004; Trechsel, Kies, Mendez, & Schmitter, 2004).

Benchmarking, in this context, is a method of analysis that comprises the identification of significant factors that influence the perceived quality of an interactive virtual space and that facilitates a constant process of comparative monitoring and evaluation of experiences. Many institutions and research centres are currently committed to this task, deducing empirical frameworks of analysis from theoretical reflections about computer-mediated communication (CMC) and democracy, whilst simultaneously seeking to improve theories regarding electronic democracy—and democracy *tout court*—by the observation and comparison of diverse projects. The output of this kind of research is often a set of best practices, intended to export successful approaches from one country to another.

## CONCEPTUAL BACKGROUND

The theoretical foundations upon which benchmarking and standardisation depend may be related to the "institutional isomorphism" (Di Maggio & Powell, 1991) that establishes a pattern of analogies between the working of different organisations. This perspective is founded on the idea that technological innovations in different environments all work toward a similar organisational form (La Porte, de Jong, & Demchak, 2002; Zittel & Bush Hall, 2002). From the perspective of values, the strategic choices of key actors and existing institutional forms prior to the advent of ICTs are of little significance (Yang, 2003). This idea has much in common with the technological determinism which contends that the powerful and ubiquitous nature of communication technology and the speed by which it is being implemented may overwhelm the differences between political and institutional contexts and structures. It can be argued, moreover, that a deep conceptual link exists between institutional isomorphism and theories of globalisation. Ideologies of globalisation in actual fact continue to identify the impediments to development with factors internal to nations, emphasising on the other hand the advantages of integration and interdependence in global markets. Thus, institutional isomorphism and benchmarking practices are strictly linked to the possibility—and desirability—of a global organisational harmonisation that should function as a driver of mutual understanding and shared knowledge. These concepts echo the debate which in the social sciences has taken hold since the 1960s, concerning the concept of modernisation, and render extremely pertinent the differences between two kinds of strategic processes often ambiguously included under the same umbrella: electronic democracy and electronic government (Chadwick & May, 2003). While the latter is conceived as a process of public administration rationalisation in bureaucratic structures that are similar in Western countries, e-democracy relates to the transparency of political processes, to participation in public life and to the quality of opinion formation, all factors deeply influenced by socio-economic variables and the political culture in specific contexts. This is the main reason why benchmarking finds its privileged field of implementation in the analysis of

public service delivery, while on the side of democratic quality of life this approach still encounters difficulties and obstacles to its development. Thus, in analysing e-democracy benchmarking we should take into account both the emergence of a new branch of benchmarking, more adapted to the public sector and deliberative networks, and the whole set of theoretical problems posed by the measurement of democracy, by its culturally and ideologically characterised tools, by its assumptions about progress toward (more) democratic government.

## BENCHMARKING: A TECHNICAL OR POLITICAL TOOL?

Benchmarking is an evolving concept that has developed since the 1940s toward more articulated forms. Watson (1993) argues that this practice has evolved through five generations: reverse engineering, competitive benchmarking, process benchmarking, strategic benchmarking, and global benchmarking. This development follows the shifts from a focus on products to one based on processes, from a competitive scenario to an interactive and cooperative one. Most recent studies have, however, discussed two further steps in this evolutionary process. The first, termed "competence benchmarking" or "bench learning," is founded on the idea that organisational change is for the most part based upon individual behaviour and group learning. The second step in the contemporary development of benchmarking is the so-called "network benchmarking," which extends the idea of learning by cooperation beyond the individual and group levels (Kyrö, 2003). New forms of benchmarking, and new fields of application (small firms, public and semipublic sectors, etc.) introduce a wider horizon for benchmarking practices, allowing its adoption even in more articulated and complex areas of policy. One of the areas in which benchmarking is assuming a prominent role in evaluation practices is that of public projects of electronic democracy. In this field, institutional action is benchmarked on the basis of its efforts to enhance democratic life through the use of information and communication technologies. In particular the process of democratic development can occur in three ways: (1) increasing the transparency of the political process, (2) enhancing the direct involvement and participation of citizens, and (3) improving the quality of opinion formation by opening up new spaces of information and deliberation. This conceptual pattern is the outcome of collaboration and research carried out between the European University Institute and the University of Geneva, conducted on the basis of empirical findings concerning the assessment of the impact of new communication tools on the state of democracy in Europe (Trechsel et al., 2004): "the main goal was to design an instrument that not only counted features and assessed quality but also included an evaluation of interactivity. Indeed, it is precisely the latter feature—the increased scope for deliberative and participatory interactivity offered by ICTs—that has been one of the principal concerns of the literature on e-democracy" (p. 11). The quantitative indicators relating to electronic democracy are construed on the basis of the presence of parliament or political party Web sites, with close attention given to communication systems and not merely limited to the distribution of information, but dedicated to citizen participation. The properties of the sites examined are as follows: (1) information provision, (2) bilateral interactivity, (3) multilateral interactivity, and (4) user friendliness. A similar approach is at the root of contributions presented in Brussels at an international seminar on electronic democracy (Riley, 2004), in which the fundamental assumption of the role of national parliaments is the fulcrum of projects of network involvement of citizens:

*There was a consensus that the goals of e-Democracy will not be met by any one particular strata/stratum of society though many thought that the process of e-Democracy should be guided and driven by legislatures as, in the tradition of representative democracy, these bodies are the drivers of democracy.* (p. 3)

In these examples we find a form of benchmarking that is still product oriented, that is limited to the counting of characteristics related to access, usability, and interactivity. Benchmarking electronic democracy is, in other cases, construed on the basis of indicators that measure the participation of citizens in decision-making processes and greater emphasis is placed on experiences in the sectors of e-consultation and e-voting. Examples are provided by the corpus of studies focused on deliberative democracy and online forums. In their general view of the factors that could affect online deliberation, Janssen and Kies (2004) elaborate a "typology based on three general categories that correspond to three avenues in which research could advance in order to get a better understanding of online deliberation: (1) the communicative structure of the discussion space, (2) the "major"/"minor" distinction, and (3) political culture and ideology" (Janssen & Kies, 2004). Relying on the work of Lincoln Dahlberg (2001), whose list of criteria of the idealised public sphere represents, in essence, an operationalisation of Habermasian concepts, the authors find a set of indicators useful for evaluating online forums with deliberative goals. Even more complex is the methodological approach used in a report commissioned recently

by the United Nations (UN) (Cliff, 2004) preliminary to the *United Nations World Public Sector Report*. In echoing the position expressed in the *UN General Assembly Millennium Declaration* (2000), according to which electronic democracy is a "participatory, inclusive, deliberative process of decision-making," "this research takes a comprehensive look at the democratic outcomes that can be sought by government, civil society, and others in order to deepen and enhance participatory democracy online. With a particular focus on e-government and democracy, the vision for online-enhanced participatory democracy, or "e-democracy," relies on an incremental model of development that involves the many democratic sectors and their institutions across society" (p. 2).

Included among the assessment criteria for democratic living are the following: (1) trust and accountability, (2) legitimacy and understanding, (3) citizen satisfaction and service, (4) reach and suitable access, (5) effective representation and policy making, (6) participation through input and consultation, and (7) engagement and deliberation. The factors taken into consideration show how a wider definition of electronic democracy is discussed, pointing out that "the path toward information-age democracy is a deliberative one" (p. 4), particularly because it aims to stimulate direct and mass participation.

A twofold meaning emerges, therefore, of the concept of e-democracy. The first places the use of new technology by formal institutions at the centre of attention, constructing its particular indices on the basis of renewed communicating strategies by political parties, parliaments, and governments. The second, by contrast, emphasises the role of citizens, since greater involvement in public life or greater satisfaction with administrative services are considered evidence for an advanced phase in the realisation of electronic democracy (Coleman, 2005). The two concepts are not incompatible; on the contrary, they suggest the elaboration of more sophisticated evaluation methodologies.

## TOWARD AN ANALYTIC RECOMPOSITION

The benchmarking of electronic democracy brings with it an inherent difficulty: if any type of assessment cannot be detached from a correct definition of the object under examination, then the ambiguity of the concept of democracy (and, by consequence, of electronic democracy) threatens to increase the uncertainty of assessment procedures (Berg-Schlosser, 2004). It has been said of the term "democracy" that it constitutes an indefinite concept, despite its clearly laudatory significance (Sartori, 1987). E-democracy merely adds to the theoretical issues which are still open concerning democracy per se in terms of a still insufficient understanding of the political consequences of benchmarking (Townley, 2005).

Even in a problematic context of basic definitions, it is still useful to outline a conceptual pattern that tempers at least some of the limits recognised previously in the methodology of official reports. In particular, the well-known theoretical framework elaborated roughly 50 years ago by Joseph Schumpeter (1952) is still extremely useful. His definition of democracy in structural terms is based on three elements: (1) pluralist competition between individuals and parties for all government positions; (2) fair citizen participation in the choice of individuals and parties through free elections, held periodically in accordance with established rules; and (3) the possession of political and civil rights, and in particular freedom of expression and of assembly as fundamental conditions for guaranteeing competition and participation.

Despite the limits of many analyses of the subject, the issue of the quality of democracy and its measurement must be carried out by considering each of these factors (Altnam & Perez-Linan, 2001). Above all, it is necessary to reflect on the fact that in Schumpeter's contribution the characteristics of the working of public bureaucracies is not mentioned explicitly, whilst this is a key element in many reports on electronic democracy. In fact, while significant experiences have been accumulated in the field of deliberative democracy, public administration reform still remains the main focus of this kind of analysis.

The objectives of bureaucratic efficiency, equal rights, the accountability of public agencies, and administrative transparency concur undoubtedly in accomplishing democracy, but they should be accomplished prior to Schumpeter's threefold division. It is difficult to imagine the participation of citizens and competition amongst individuals in the absence of good practice in public administration, fundamental for guaranteeing rights in a liberal state, to which reference is made in the third point of Schumpeter's scheme.

On the contrary, it has been affirmed that the restructuring of the public administration is not a presupposition, but is the threshold for introducing or improving democracy (Chadwick, 2003). There are many reasons why in the literature on benchmarking there is a tendency to reduce the concept of electronic democracy to that of administrative democracy. The scarce theoretical understanding of the distinction between the concept of electronic democracy and electronic government and the overestimation of the latter as the starting point for a wider democratic project certainly weighs heavily. However, the ideological presuppositions and political objectives of benchmarking democracy are even more rel-

evant. In the great faith that is demonstrated in the technological factor and the top-down approach of most innovation, there are signs of a logic of development approach once more (West, 2004). In the past, this has been employed by Western countries to interpret and pilot processes of modernisation in those countries which had just come out of colonisation. The same approach has been recovered on a global scale today, to the extent that ICTs are considered as a panacea for the evils of established democracies (for which the definition "deficit of quality" is used) and as an instrument of action in countries of recent democratisation or in the process of democratisation (World Bank, 2002).

## CONCLUSION

No scientific instrument gives us direct, unmediated access to the phenomenon to be measured. Methods of analysis reflect values, cultural propensities, and ideological positions that must be illustrated. When used to improve public organisations, starting from the establishment of new public management, the notion of benchmarking has theoretical foundations rooted in the past, echoing positions that already emerged in the social sciences during the 1960s with reference to the concept of modernisation. Institutional isomorphism, identifying the "one best way," acceptance of the principle of exportability, the guiding role rediscovered by the more advanced countries which have taken upon themselves the task of tracing the path toward democracy, all of these factors are in harmony with dominant positions in relation to development about half a century ago. Possessing a prescriptive nucleus that is very easily identifiable, addressed to action and policy planning, "the perception was that in one way or another, albeit with disjunctures or frictions and with transitory tensions produced by the unequal advance of different dimensions of development, new nations … would move gradually toward societies characterized by welfare, equity, order, democracy, and autonomy" (Filgueira, 2001, p. 3585). A model was thus identified, a model on the scale of Western social systems and the necessity of transplanting this model to countries judged to be lower on the development scale was considered imperative, following procedures of logic taken from the practice of identifying benchmarks and transferring them to different environments (Rupert, 2000).

The analysis of the literature has shown great diversity in approaches to electronic democracy and its benchmarking practices. Some treat the reinforcement of formal representative institutions as the fulcrum of their analysis, with a view to improving communication between those who govern and those who are governed and giving particular attention to the dimension of vertical accountability (Waller, Livesey, & Edin, 2001, p. 5). Others, following a democratic conception of a deliberative kind, highlight, by contrast, the potential of new media to improve communication amongst citizens, beyond the intermediation of political institutions (Riley, 2004). A third approach considers the improvement of public administrations as the principal indicator for measuring the quality of democracy. The concept of electronic democracy and that of electronic government, albeit distinct in conceptual terms, are perceived to be closely entwined. Indeed, the accomplishment of the former often does not constitute an objective in itself but an indirect effect of administrative restructuring (Waller, Livesey, & Edin, 2001).

The benchmarking of electronic democracy should arguably be founded on a method of analysis that takes into account the multidimensional character of the concept of democracy (Bass, 2005). Contributions have recently been produced that move toward a methodology that can recognise differences in quality (as, for example, that of good governance in the public arena and in quality of life (Bovard & Loffler, 2003). The idea that there is just one path of political development in this field is misleading and overlooks this multidimensional characteristic. What is needed, by contrast, is a form of benchmarking that is less conditioned by such ideological connotations. It is also important to enrich this concept by making reference to carefully contextualised models of best practice.

## KEY TERMS

**Administrative Democracy:** A concept which associates improvements in democracy with progress in public administration, particularly with regard to public involvement in administrative agencies.

**Benchmarking:** A detailed analysis of an electronic reporting programme to determine whether it can be used in whole or in part in another state or agency.

**Best Practices:** Methodologies that provide beneficial results. Some best practices are general in nature and can be applied to almost every industry; other best practices are industry specific.

**Deliberative Democracy:** A term used to refer to any system of political decisions based on some trade-off between consensual decision-making and representative democracy. In contrast to the traditional economics-based rational choice theory of democracy, deliberative democracy theorists argue that legitimate law making can only arise from public debate by the citizenry.

**E-Consultation:** This offers a choice of online public policy topics for discussion with real-time and archived access to audios and videos of public meetings. The government encourages citizens to participate in discussions.

**E-Governance:** This implies the use of ICT channels to change the way citizens and businesses interact with government to enable: (a) citizen involvement in decision making, (b) increased access to information, (c) more transparency, (d) civil society strengthening.

**E-Vote:** E-voting is the possibility to practice political rights with the help of ICT (e.g., using a computer or mobile phone). This includes ballots and signing initiatives and referendums. E-voting in a narrower sense also includes simple ballots on Web sites.

**Institutional Isomorphism:** This is a pattern of analogies between the working of different organisations.

**Policy Learning:** This is a process underlying any changes in the political behaviour of an agency, its portfolio of policy vectors (institutions, programmes, funding schemes, regulatory frameworks, etc.), objectives and management of these, their constitution, and the relative weight of vectors in the portfolio.

**Political Accountability:** This is the principle that governmental decision makers in a democracy ought to be answerable to the people for their actions. The concept implies more than merely the tacit consent of the governed. It implies both a mechanism for the active monitoring of public officials and the means for enforcing public expectations.

**Political Development:** A concept in political science used to describe the processes of nation building and state building. It is closely associated with the concepts of modernisation and economic development, and is now applied to processes of political change throughout the Third World. The idea of political development implies that societies can consciously direct the course of their own nation building rather than submit to the blind forces of social and political evolution or revolution.

# Best Practice in E-Government

B

## INTRODUCTION

The pressure of modernization does not stop at national boundaries—in this respect it is universal and secular. In some regions of the world the pressure of change is particularly extreme (e.g., in Eastern Europe) where the transformation of the administration from a state socialist to a democratic institution is taking place under the enormous time pressure of complying with the new national and international standards and catching up with the global economy. Another example of a country in transformation that is extremely interested in studying best practices is China where a more efficient public administration is required to support the newly installed market economy whereas e-democracy is no issue at the moment.

In view of this starting point for the universal pressure of change and reform, the responsible decision-makers are often eager to model the direction and implementation of their reforms on the best local communities. The high level of interest in the results of various benchmarking studies among local community representatives stems from this pressure and a great uncertainty about the future of public administration.

Actors and experts throughout the world agree that learning from and transfer of good practices internationally can contribute to the goal of global co-operation in e-government, which is a priority of the World Summit on the Information Society. In its Action Plan, the participants of the World Summit defined as an important action to "support international cooperation initiatives in the field of e-government, in order to enhance transparency, accountability and efficiency at all levels of government" (WSIS, 2003).

In its "Communication" of September 26, 2003 on "The Role of E-government for Europe's Future" (European Commission, 2003) the Commission of the European Communities stresses the huge benefit of initiating an exchange of good practice.

*Best practices encompass technological, organizational, legal, and training elements, they require long-term commitment of all key actors involved, and they illustrate tangible benefits and results. Exchange of experience and replication of best practices can bring cost-savings in moving to broad take-up. It also prepares for future interoperability and interworking between administrations.* (p. 21)

The following discussion aims to introduce a theoretical approach which avoids the limitations of the dominant transfer theories of the "one best way" (Bartlett & Ghoshal, 1989; Ohmae, 1990; Womack, Jonas, & Roos, 1990) on the one hand and "path dependence" (Arthur, 1994; Freyssenet, Maier, Shimizu, & Volpato, 1998; Leipold, 1996; Pierson, 1998) on the other hand, and which creates a perspective for practical action in e-government. Whereas the one best way theory regards the adoption of superior concepts as the royal route to overcoming existing inadequacies, the theory of path dependence sees hardly any possibility to adopt solutions from other national environments—it considers that the bonds of the decisions of the past and inherited structures are too strong.

Therefore, a clear understanding of the opportunities and limits of best practice orientation and adoption gives a clear orientation of what way to go in increasing organizational performance. The basic question is if it is advisable and feasible to adopt practices of a well-performing authority by a less-performing authority in the public administration.

Before presenting empirical material on the question of what a good practice in e-government consists of it is feasible to discuss on a theoretical level principle problems with the concept of best practice.

## BACKGROUND

In the current discussion about the best way for public authorities to develop to modernize administration with the help of e-government, familiar thought patterns from discussions about the prospects of the industrial society in the 1980s or the forms of New Public Management in the 1990s are apparent.

There is often an impression that there can be a generally valid concept of modernization with goals that are defined by a best practice model, and that this model is the final goal of the development of the public administration from a Weber-type administration–characterized by increased effectiveness due to distribution of

competence, a highly formal division of labor, a strict hierarchical structure, impartiality, specific control mechanisms or the lifelong staff remuneration principle—to a flexible organization similar to an economic enterprise with customer orientation, holistic forms of work, performance-oriented remuneration and career patterns and shallow hierarchies.

According to the convergence theory[1], an increasingly trans-national development model for the public sector can be expected in the distant future. Then, the public authorities would be under enormous pressure to act, but at the same time without any clear idea of what action is appropriate, so decision-makers would look to the best practice models and imitate their solutions, thus gaining respite in their complex decision-making situation. Best practice models would then form the reference point for their own decisions on the shape of e-government.

From a theoretical point of view, there are several questions about such a convergence theory. First of all, the fundamental question of when a solution is considered a best practice must be addressed. Obviously, a high degree of abstraction is needed to award existing solutions the epithet of the one best way. The abstraction must transcend the distinctly national specific differences in culture, tradition, state structure, language, attitudes, economic structure, etc. The significance of all of these factors for the structure of society and the state has been discussed in the theories of the national innovation system (Dosi, D'Andrea, & Zysman, 1989) and new institutional economics (Soskice, 1994).

Moreover, best practice is a moving target. Possible solutions which are emulated by a latecomer may already be out of date. Best practices certainly evolve over time, as was impressively shown in the analysis of the development of the governance structures of the U.S. economy (Hollingsworth & Streeck, 1994).

This leads to questions which are very relevant to practical applications. If a solution has been identified as a best practice, can it be copied? What role is played by path dependency (i.e., conditioning by the structure that has grown historically)? Classifying solutions as best practice thus often has an ahistorical component, and this can make them devoid of life and soul in face of the historical development of structures and solutions. And the two concepts, modernization and best practice, are isolated from the different political, economic and cultural structures in which they are firmly embedded.

On the other hand, the concept of path dependency restricts learning to the inner potential of an organization. In that perspective, learning takes place if actors consider the inner potential of a choice, an institution as being limited. That leads to severe problems of operationalization of the concept of the path both in a diachronic and a synchronic perspective. Who determines what time frame to be considered to define the path that sets limits? Authors give different answers. In the transformation debate form socialist to market economy the proposals what has to be regarded as a path determining period differ from stressing the pre-socialist phase (Janos, 1984) to the most recent socialist experience (Crawford & Lijphart, 1997).

And in the synchronic perspective the discourse is not easier. How is it possible to identify those institutions that are decisive to define the path for the further development of an institution?

## EMPIRICAL EVIDENCE ON BEST PRACTICE IN E-GOVERNMENT

Benchmarking studies are published all over the place. Web sites are assessed (Capgemini 2002, 2003, 2004), the e-readiness of countries is examined (Booz, Allen, & Hamilton, 2002) or the availability of services is analyzed (KEeLAN, 2004[2]; West, 2001).

But there exists also another type of analysis that focuses on organizational issues (Millard et al., 2004), on special applications such as e-participation (Malkia, Anttiroiko, & Savolainen, 2004).

To check if a best-practice-model can be derived, six studies are presented that deal with the configuration of success factors of e-government on the local level.

### Local E-Government in a Management Perspective

The project of the British research group from the organizations Socitm and I&DeA on the state of development and the development paths for local e-government in an international perspective regards the phenomenon of the "virtual town hall" especially from a management perspective (Socitm & I&DeA, 2002). The main focus is on the question of what has been achieved internationally and what remains to be done. Research teams from the participating 14 countries contribute best-practices examples or typical cases. The study by the country teams and the evaluation by the British team of authors were oriented towards an analysis concept which expresses a comprehensive conceptual approach (cf. Table 1).

Such an approach based on the complexity of e-government projects is necessary to grasp the respective phenomenon with its specific characteristics, and the only possibility to adopt the consistent maxim for action:

*For the majority, life on the local e-government train will be rather chaotic; identifying opportunities and*

*Table 1. Local government now "Template" (Source: Socitm & I&DeA, 2002, p. 180)*

| Vision | Leadership | Management | Infrastructure |
|---|---|---|---|
| Clear Goals | Fast decisions | Projects | Funding |
| Shared Values | Strategic planning | Risks | Technology |
| Commitment to change | Open to experimentation | Contracts | Security |
| Consultation | Communication | Services | Skills |
| Collaboration | ICT governance | Information | Learning |

*following them through where they occur, and remaining in step with the rhythm and life-blood of the local communities and their politicians.* (p. 36)

This is an appropriate maxim for action instead of analyzing the state of development of e-government to determine where more and better online services are offered.

## Profiles of Best Practice in Local E-Government

The second study mentioned here is the analysis of 50 cases of e-government in seven countries (Drüke, 2005) according to ten success factors for local e-government. This set of success factors covers the following aspects: vision and strategy, organization, applications, cost/benefit, technology, competence and qualification, acceptance and marketing, cooperation, sustainable resources, and legality.

The municipalities of the leading group of countries[3] (i.e., Finland, the United Kingdom, and the USA) have considerable agreement especially in the success factor "Guiding principles and strategy" and, to a lesser extent, in the success factor "Organization, project, and change management."

- The project is based on comprehensive guiding principles
- It is integrated into a comprehensive strategy
- It is controlled and steered with professional project and change management, *ex-ante*, *in-progress* and *post-mortem* evaluations and modern cost-benefit assessments

The central figures are the mayors as the political representatives and the city managers, who manage the public administration in a similar way to the chairman of the Board of Directors in private enterprise.

Another common element is the great importance given to "co-operation and partnerships," which is especially strong in Finland and the United Kingdom. Long-standing experience with co-operation and competence in coordination management has existed for many years because there is a tradition of openness to private business. Countries such as France and Japan have much ground to make up in this area.

Almost unanimously obstacles and hindrances have been specified. The items that, regardless of the country, were mostly named are:

- Lack of financial resources due to budgetary constraints
- Gaps in the set of qualification required to work with new technologies and work systems
- Staff resistance to change
- Management resistance to new role pattern
- Traditional stovepipe approach resulting in a lack of departmental collaboration
- Lack of regulation especially to assure security and privacy
- Uncertainty about the return on investment

As a result of this evidence a universal best-practice-core can be identified characterized by a high performance with regard to the factors political leadership, project organization, cost/benefit-assessment, co-operation and e-skilling. The first group is made up of the Anglo-Saxon countries (i.e., the United Kingdom and the USA) which treat the "city as an enterprise" more than other countries and regard e-government as a further instrument to mobilize the forces of the market. This is especially reflected in the priority given to customer orientation and the demands made on the effectiveness and efficiency of local community activities. The differences between the countries in the study are particularly large in the success factors

The importance that is being laid to the factors that determine the best practice: "Guiding principles and

strategy," "Organization, project, and change management," "Competence, motivation and qualifications," and "Co-operation and partnerships" and "sustainable provision of resources" characterizes the approach towards modernization of the public sector in the Anglo-Saxon countries[4] and, to a lesser extent, Finland.

## E-Government Good Practice Framework

The e-government good practice framework (GPF) which is being worked out on behalf of the EC, DG Information Society and Media[5], has three clearly defined targets:

- Define a description template and assessment criteria for good practice cases in e-government
- Collect examples of well-defined e-government cases
- Make the examples available for those involved in e-government by means of an intelligent knowledge database

The task, then, is to offer expert know-how on general or special e-government features and providing easy access to existing communities or expertise centers and to support the sustainable transfer of good practices and learning experiences in an easy and helpful way.

At present 364 members are registered in the GPF, the Web site contains 96 cases. Per day at about 10,000 hits are counted (average for August 2005).

## Best eEurope Practices (Beep)

The project having started in February 2001, officially ended on July 31, 2003 but work is continuing (homepage last updated August 5, 2004).

Beep is an accompanying measure in the European Commission financed Information Society Technologies Programme, which has developed a unique and comprehensive database of good practice. The project collects, analyses and refines good practices (best practices) in a variety of socio-economic area, by collecting case studies (almost 300) and coding them to a wide variety of indicators. In that endeavor Beep collaborates with a large number of organizations, at international, national and regional levels.

The commitment of existing partners will ensure that the beep knowledge system will continue to be updated, upgraded, and, where relevant and where opportunities allows, extended, for at least two further years with or without commission funding.

The beep knowledge system contains detailed case reports with advanced search facilities on the use of ICT to promote, among other things, especially e-government. All in all, 32 of the 316 cases are relevant to e-government in the Information Society. The final project report was published in September 2003[6].

## Research Report "Reorganisation of Government Back-Offices for Better Electronic Public Services: European Good Practices"

The report[7] presents and analyses the detailed results of one of the first studies at European level to systematically research how public agencies are using ICT to reorganize, ant the impact this has upon how electronic public services are experienced by citizens and business—in other words, on the changing relationship between the front and back office. The study is sponsored by the European Commission as a "benchmarking" exercise to support the eEurope and Lisbon Strategy processes.

It attempts to fill the yawning gap left to date by most attention being focused on documenting the roll-out of electronic public services, but very little focused upon how government, its various agencies and (back) offices, is, or should be, adapting and reorganizing to meet the challenges and opportunities presented by ICT.

This study attempts to fill this gap by drawing upon a large scale survey across the EU Members States (plus Iceland, Norway and the European Commission itself) based upon eEurope's common list of 20 basic public services, culminating in 29 in-depth case studies.

## eEurope Awards

The eEurope Awards are organized by the European Institute of Public Administration with the support of the Information Society Technologies Programme of the European Commission for the years 2003-2005[8]. The eEurope Awards recognize innovative initiatives in the areas of e-government and eHealth within Europe.

The four eEurope Awards distributed in the years 2003-2005 are intended to be a driving force in identifying and promoting excellence and creativity in the public sector with a view to supporting the mutual recognition and adoption of best practices. The eEurope Awards aim to highlight and disseminate efforts made by European national, regional, and local administrations in using information society technologies (IST) in order to increase efficiency and performance and to improve the quality and accessibility of public services.

The goal is to promote best practice among the Member States of the enlarged EU, the candidate countries as well as the EFTA countries. The best applications are selected for exhibition at a high-level conference on the topic. The most outstanding applications presented at the

conference are awarded with the prestigious eEurope Awards Trophy.

## TRANSFERABILITY OF BEST PRACTICE

If such a universal best practice can be identified the question is if this best practice can be transferred to other public authorities or, vice versa, be adopted by the less-performing authorities.

The result of our discussion of the two dominant theoretical concepts on the issue of change of institutions was that the improvement of an authority's performance in e-government is not the result of the free choice of rationally acting individuals but depends on structures, choices of the past and attitudes of the institutions' members. It makes sense to distinguish between objective and subjective factors that determine the transferability of good or best practice and, vice versa, the ability of an institution such as a public authority to adopt best practice.

The most important objective factors are:

- *IT infrastructure, Internet penetration* in the population and the world of work, general computer literacy, the existing legal framework, qualification structures, and traditions (cf. also Booz, Allen, & Hamilton, 2002): these factors describe the state of e-readiness (i.e., the general level of implementation of the information society in a country as a basis for e-government)
- *Degree and structure of institutional compatibility.* (Administrative structure, distribution of competence in the administrative structure between central and decentralized levels, remuneration and career patterns) (Scherrer, 2001; Soskice, 1994). The transfer of good practice between countries is comparatively easy if they are similar in their fundamental institutional structure, like the Anglo-Saxon countries on the one hand or countries with a federal constitution and similar administrative traditions such as Germany, Japan, and Poland on the other hand. But if the good practice examples are very closely linked to the basic institutional and cultural structure of one country, they are difficult to transfer to other countries. Conversely, if the institutional structure in the countries is very rigid, it will be difficult to apply the good practice examples. A striking example of this is the narrow limitation within which career patterns, payment, recruitment and staff deployment can be transferred from the United Kingdom or the USA to Germany, with its very specific public service employment laws. Thus, a country cannot leave its own modernization path at will and freely choose to adopt a different model
- *Size, composition, structures, level of regulations and active participants in major markets (software industry, telecommunications, employment market*) (Porter, 1990). The necessary active participant structure for local e-government on the supply and demand side will not develop in closed markets. For example, there will be a lack of creative software companies to implement the large number of specialist departmental procedures for online services
- The *overall strategy* in relation to administrative modernization and e-government. The criteria here are the coherence of the strategy in the top leadership of the federal state and the local communities, and also the degree to which the process is coordinated with administrative modernization (Eifert, 2005)

The yardstick for all of these factors is how closely or loosely they are connected with the special national characteristics and how coherently they fit together. Consequently, they form a system from which individual blocks cannot be removed and changed in isolation. They form a national innovation system (Dosi et al., 1989). "The strength of every successful production system lies precisely in its integration into conventions which work coherently in their interaction [...]: these elements cannot be mixed and joined à la carte." (Storper & Salais, 1997, p. 172)

A relevant factor explaining the differences in the approach to and the realization of local e-government is the specific administrative structure. The sample comprehends diverse countries such as the unitary states the United Kingdom, France, and Japan on one side and federal countries such as Germany, Finland, The Netherlands, and the USA.

To some extent, the differences are very noticeable at the local level, and they can be either beneficial or detrimental. This in turn points to the different structural, institutional, and cultural characteristics especially in the state constitution, labor legislation, vocational training and administrative traditions (Hollingsworth et al., 1994, Naschold, Oppen, & Wegener, 1997) that hinder other countries to easily adopt this managerialistic approach to public authorities. Two extremes for the significance that the administrative structure and/or the national strategy towards local e-government play are given to illustrate the role of national differences.

One extreme is Japan. No significant differences were identified in the characteristics of local e-government. One striking element is the strong central control of local e-government projects by the central government.

*The local e-government initiatives in Japan follow the e-Japan Strategies. Under the powerful navigation and abundant financial support extended by the national government, the pioneering local governments serve as the "model" to proceed with the pilot project, which are expected to be followed by other local governments. Accordingly, the majority of the local governments which are not yet developing the remarkable local e-government initiatives to date may be in the process to accept the policies and measures suggested by the national government, duplicating the preceding cases.* (Fujita et al. in Drüke, 2005, p. 197)

Japan offers a special reason to delay local e-government initiatives: the impending reform of local authorities, which involves merging municipalities.

*The municipalities with the perspective for the potential merger in the near future are taking the wait-and-see approach as they concern that the system should be restructured upon the merger, if it happens, even if they make the major e-investment at this stage.* (Fujita et al. in Drüke, 2005, p. 201)

The other extreme, The Netherlands, illustrate the consequences of a distinct localism in the state organization fort he implementation of local e-government.

*The problems of Dutch e-government development begin with the questions of policy, steering and central coordination. The Ministry of the Interior and Kingdom Relations seems to be made for this part, but operates within the constitutional make-up of [T]he Netherlands in which the Dutch governmental culture, which acknowledges the autonomy of the different layers and sectors of government (ministries), plays an important role. In practice this results in little room for centralized policy making. In [T]he Netherlands it is felt that e-government development requires voluntary participation and consensus among the different participants, making it a typically Dutch syrupy process, the famous "*Poldermodel*."* (Leenes & Svensson in Drüke, 2005, p. 151)

The result of this voluntarism is the lack of coordination and, thereby, a constant re-inventing the wheel by some progressive municipalities.

*Many municipalities are developing online services for what are basically very similar products. This seems not only inefficient, but given the limited resources most municipalities have their disposal, it is also a slow and cumbersome process. When municipalities realize the amount of effort needed to do a proper job, they may even throw in the towel, and wait for better times.* (p. 153)

The problem here is that the state in The Netherlands cannot correct market failure (see Porter, 1990) that is related to a lack of company presence on the market or to information uncertainty for the market actors. The state himself is shivering in terms of responsibility and competence and therefore more of a problem than part of the problem solution.

In addition to the objective factors, so-called subjective factors play a major role in deciding whether there is a successful transfer and adoption of best practices in e-government if the analysis of the objective factors indicates that this is desirable. The subjective factors thus describe the action-based factors.

The major subjective factors are:

- *Attitudes towards the state and state actions, willingness to reform and receptiveness to new ideas* in the population and the civil service. With a high level of risk avoidance among decision-makers and in the population, an ambitious project such as the introduction of e-government will fail
- *The state of procedural competence,* that is, the implicit and sub-conscious rules of social and political life, which are different from the formally fixed rules of a society in the form of laws and statutes (Scherrer, 2001). These tacit rules may play a significant role in causing sub-optimal solutions and concepts to be followed even though other solutions have been shown to be superior. The resistance to reforms which is frequently encountered and the stubborn persistence of established patterns are often associated with a strong influence of a deep-rooted procedural competence
- *Transfer and adoption capabilities* in areas such as management, motivation and leadership ability and practical skills such as language competence, networking, inter-cultural competence (Bartlett & Ghoshal, 1989). This factor decides whether this process can, in fact, be initiated and carried out, even if the people involved assent to the necessity of adopting good practices and the opportunities involved in the transfer. Elements involved include the ability to analyze the starting position in the adopting country and the target country, the selection of partners, setting up relationships of co-operation and practical supervision of the processes in the participating countries. It is very important to take the above subjective factors into account in this process

Elements of new institutional economics (especially in compiling the objective framework conditions for transfer) and path-dependent approaches such as "attitudes" and "implicit rules" obviously play a major role in this theoretical approach. The practical benefits can be seen in a model procedure used to determine the transfer potential.

There is another decisive aspect to avoid misunderstandings in the process of transferring and adopting solutions. This process will not be purely functional and technical in nature.

On the one hand, there are internal power constellations on both sides which have a decisive effect on the question of which countries are involved in which processes, what their interests will be and what the results will look like. Internal political interests and power constellations even affect the question of which country an "adopting" country is willing to receive solutions from. In the words of Scherrer (2001): "Existing power positions influence the possibilities for discourse and interpretation in relation to a foreign model" (p. 13) (i.e., the question of which country with which institutional structure should be considered as a model for the solution of the problems in the receiving country).

In this connection, the role of elites is rightly pointed out. They play an important role in interpreting the situation within their own country, and they also play a significant role in contacts between countries, partly because of their professional internationalism and partly because of their educational advantage which gives them greater access to information and greater credibility in interpreting this information.

On the other hand, power constellations also affect the relationship between the country transferring the solutions and the country adopting the solutions.

*The weaker country will be more willing to learn than the stronger country. This is not only because the apparent success of the stronger country makes it more attractive. The stronger country, or its major active participants, can also mobilize greater resources and incentives to promote the adoption of their institutions.* (p. 14)

The instruments of power naturally include money, for example in the award of subsidies for the penetration of foreign e-government settings by a country's own experts, then influence, for example in the allocation of roles in international committees, which can be increasingly significant in e-government due to the growth in international co-operation, and finally preferential treatment in the formation of coalitions in international negotiations (e.g., on questions such as standardization, interoperability, and international e-government services).

## FUTURE TRENDS

The pressure to improve the quality and performance of public administration is secular, global, and irrevocable. That holds true for the developed countries as well as for the countries in transformation. The interest in studying good practices holds unbroken. Conferences, books, and journals provide broad space for discussions, analysis, and illustrations of good practices respectively what is regarded as good or best practice. What is prevailing is a tendency to learn good practice as there are that means without taking into consideration the institutional, cultural, political, and societal background that a practice is embedded in. A "paste-and-copy"-approach towards good practice is dominant.

## CONCLUSION

To lead a best practice discussion is very practical and very reasonable. Decision-makers are eager to improve the performance of their institution to better cope with the increasing complexity of their surrounding. In times of severe criticism of the performance of public authorities, the pressure for change is increasing. Before this background, it is more than understandable that those individuals that have the responsibility to handle with public money look for solutions for their problem. For reasons that have been discussed here the adoption of a best practice-model in e-government cannot be the royal route. Institutions are too complex, too diverse, and too embedded in their surrounding and their history to be changed according to a one-size-fits-all-model from teaching books on institutional performance.

The analysis of some empirical research on good practices in e-government (Drüke, 2005; Socitm/I&DeA, 2002) made clear that there exists a set of factors that are indispensable for a public authority to be a good performer. Taken from the studies on local e-government the characteristics of a best practice in e-government are: the clear and practical commitment from the political leaders, strong and professional project organization, a cost/benefit assessment, co-operation, and e-skilling.

These factors build up a universal best-practice core insofar they are not deeply linked to the institutional structure of a nation. It is comparatively easy to adopt them to the institutional setting of a nation.

The decisive question, therefore, is not to understand what it takes to be a better performing public authority but to have a clear understanding of the fostering and hindering conditions in a change process. Any change program will affect interest constellations and power distribution that are hard to modify. The challenge is to set up a change

process that integrates the interests of major stakeholders, of the employees' and satisfies the customers of public administration rather than to look for recipes coming from best practice books.

## KEY TERMS

**Best-Practice-Model:** The assumption that there can be a generally valid concept of modernization with goals that are defined by a best practice model. This model would be an increasingly trans-national development model for the public sector

**Managerialism:** The concept to regard public authorities as enterprise-like institutions. In fact, this notion neglects the structural differences between private companies and public entities that go along with the public law, with the separation between state and society and with the role of the state as the sovereign.

**One Best Way:** The one best way theory regards the adoption of superior concepts as the royal route to overcoming existing inadequacies. Public authorities are bound to adopt this way or to continue to be less-performing.

**Path Dependence:** The theory of path dependence sees hardly any possibility to adopt solutions from other national environments—it considers that the bonds of the decisions of the past and inherited structures are too strong. So, this concept restricts learning to the inner potential of an organization. In that perspective learning takes place if actors consider the inner potential of a choice, an institution as being limited

**Political Commitment:** The concept that change processes have to be backed and led by the highest authority in an institution. For public administration it is even more important as the whole of the role of state, the concept of public administration as such is at stake.

**Success Factor:** An element or a factor that determines the success of a change management process. In the field of e-government success factors are those factors that must be regarded when setting up e-government on local, regional, or national level.

**Virtual Town Hall:** The local online public administration as an additional "existence" next to the real town hall. The notion expresses the development state of a local public authority where the services that can and should be offered online have been implemented. In addition, the notion hints at the comprehensive character of modernization in the sense of a deep going restructuring of the way public administration works.

## ENDNOTES

[1] See the discussion about the supremacy of the "Model USA" (cf. Block, 1991) or the discussion

about to copy "The Japanese production system" (cf. Womack et al., 1990) and in public administration the need to follow "The model local community of Christchurch" (cf. Pröhl, 1997)

[2] The project KEeLAN (Key Elements for Electronic Local Authorities' Networks) also examines the Web services of a number of cities and local communities for their quality, their range for the users and the integration of online services. The aim of the KEeLAN project is to establish suitable methods and principles for forward-looking action in local community and regional administrations. To this end, 700 local empirical studies were then used to develop "road maps" with recommendations for local community action and strategy.

[3] Obviously, there are other well-performing countries such as Canada, Sweden, or Estonia.

[4] This result is quite known: It is relevant to note in this regard that NPM-type reforms succeeded best in countries with broadly congruent cultures and institutional frameworks propitious for the task, but also with affinity to those of the country of origin (e.g., Anglo-Saxon countries)" (UN, 2001, p. 59)

## INTRODUCTION

Competitive pressures and improvements in information technology constantly force organisations to re-evaluate their business strategies (Porter, 2001; Venkatraman, 1994). Although public-sector organisations may not operate in a competitive environment, changes in management philosophies are causing public-sector organisations to think and act more like private-sector organisations (Gulledge & Sommers, 2002). Electronic government is one means by which governments can offer more effective and efficient services (Layne & Lee, 2001).

This article investigates the evolution of e-government in Ireland. A case study is presented detailing how the Irish government's e-government strategy was devised and implemented. The success of this implementation yields valuable insights into the identification and management of critical concerns during the evolvement and attainment of business-process redesign in e-government. Cumulatively, these lessons provide a road map for the successful attainment of citizen-centric e-government.

## ELECTRONIC GOVERNMENT

Electronic government consists of using technology, particularly the Internet, as a means to deliver services to citizens, businesses, and other entities (Tambouris, 2001; Watson & Mundy, 2001). E-government has the potential to transform not only the way in which most public services are delivered, but also the fundamental relationship between government and citizen (Burn & Robbins, 2001; Watson & Mundy). Operational benefits of e-government include continuous availability of service, a reduction in response time, and a reduction in error rate (Al-Kibisi, de Boer, Mourshed, & Rea, 2001). These factors contribute to an increase in the efficiency of government (Coulthard & Castleman, 2001; Dearstyne, 2001; Lagroue, 2002).

Through the use of information systems, organisations are challenged to redesign their processes in order to achieve the benefits of increased efficiency, cost reductions, and better customer service (Glassey, 2001; Warkentin, Gefen, Pavlou, & Rose, 2002). Governments can also use technology to improve core business processes (Coulthard & Castleman, 2001; McAdam & Donaghy, 1999).

### Business-Process Redesign

Organisations are required to produce at a low cost, with high quality, and with fast and flexible responsiveness to customer needs (Venkatraman, 1994). This puts pressure on organisations to redesign the way in which they conduct their business and build information systems to support new processes (Venkatraman). Out of such pressures was born the idea of business-process reengineering (BPR; Davenport & Short, 1990; Hammer, 1990). The key aspect of BPR is the fundamental and radical redesign of business processes to achieve dramatic improvements (Hammer & Champy, 1993). The lessons learnt from the BPR era served to inform management that less radical, more holistic, and more incremental changes to business processes were required (Guha & Grover, 1997).

Venkatraman (1994) identified five levels of IT-enabled business transformation. The central thesis of Venkatraman's work is that only marginal benefits will accrue from superimposing IT on existing organisational conditions. This is illustrated by the first two levels of Venkatraman's model (Figure 1). These levels, according to Venkatraman, are evolutionary as they require only minimal changes to business processes.

*Figure 1. Alternative Approaches to BPR (Venkatraman 1994)*

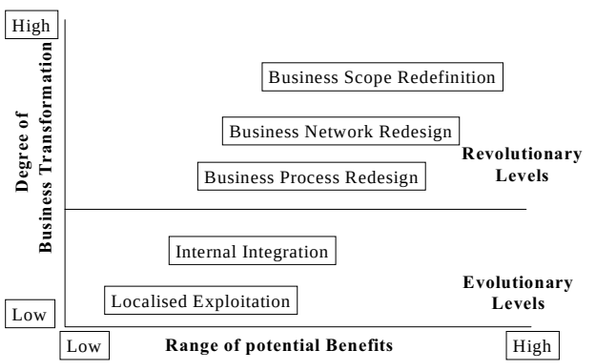

*Figure 2. Structure of government in Ireland*

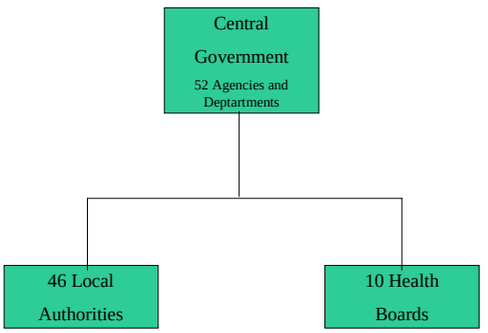


The top-three levels are revolutionary as these levels require radical change to existing business processes. An organisation could redesign its processes and then go on to redesign its network, stretching beyond the organisation, and ultimately redefine the scope of the organisation.

The organisation moving up the framework is seeking efficiency. Initially, this begins with localised exploitation and then moves up to internal integration. As the organisation moves up each level, the range of potential benefits increases. However, each higher stage requires a greater degree of organisational change. Eventually, in order to achieve more dramatic results, it will need to move up to the first revolutionary level and engage in business-process reengineering.

## RESEARCH METHODOLOGY

This research is exploratory in nature and seeks to investigate the extent to which business-process redesign was instrumental in the movement to e-government in Ireland. The Venkatraman (1994) model of IT-enabled change was adopted as a framework for the research.

Five in-depth interviews were conducted with three government agencies involved in the e-government project. An in-depth interview was conducted with one senior civil servant from the Department of An Taoiseach (prime minister), the governmental department providing strategic leadership to e-government initiatives in Ireland. Two in-depth interviews were conducted with members of REACH, the executive body created specifically to implement the e-government strategy. In addition, further interviews were conducted with two senior members of the Local Government Computer Supply Board (LGCSB), a public-sector company providing IS services to local government.

These interviews were conducted on-site in April 2002. All interviews were semistructured and lasted approximately 2 hours. The interviews conducted with all participants were supplemented by access to internal documentation. Records were kept of the content of all interviews. Further clarifications and updates were obtained by e-mail and telephone contact.

## E-GOVERNMENT IN IRELAND

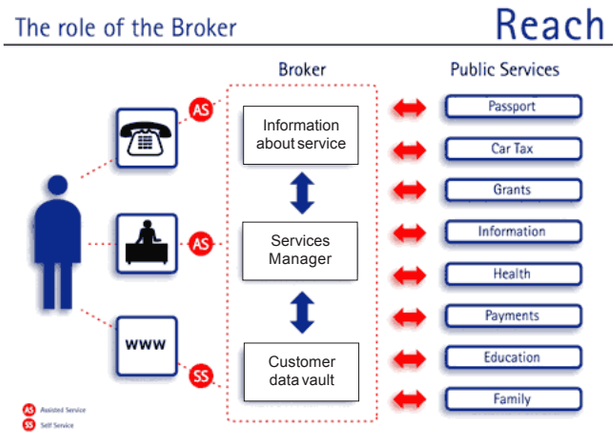
Government in Ireland is conducted at two tiers: the national and local levels as depicted in Figure 2. Central government consists of 17 government departments and 35 agencies, while local government consists of local authorities, with 46 currently in operation, who are responsible for the provision of a variety of government services at a local level, and 10 health boards who are responsible for administering health services.

### IS Support for Government

IS support at both the central and local level is provided through a combination of in-house expertise, outsourcing to the private sector, and LGCSB. LGCSB is a public-sector company whose objective is to provide local authorities with IS systems and expertise on an individual basis.

In response to local-authority requests, LGCSB developed electronic forms (e-forms) for use on local-authority Web sites. These forms were Web versions of the traditional paper-based form. Users could register with their local authority, but there was no online system in place either to process the form electronically or to authenticate

*Figure 3. The public-service broker (REACH)*



the individual. These initial e-forms served only to promote the accessibility of public service forms through an electronic medium.

## Road Map for E-Government

In January 1999, the Irish government released its first action plan on the information society. The plan outlined a three-strand approach to the online delivery of public services: information services, interactive services, and integrated services. Government departments were required to implement Web sites, and the OASIS (Online Access to Services Information and Support) and BASIS (Business Access to State Information and Support) projects were initiated. These Web sites were to be designed to meet the entire informational needs of a client regardless of the source of the information.

Toward the end of 2000, the REACH agency was officially established, its name reflecting the concept of government reaching out to its customers. REACH is an executive body with the responsibility of coordinating the central agencies responsible for implementing the e-government strategy and providing management of the overall e-government initiative.

Initially, REACH was composed of 11 civil servants drawn from a variety of departments and established as an independent unit within the Department of Social and Family Affairs. The concept of a portal-based public-service broker (PSB) was adopted by REACH as the central mechanism for delivering the e-government agenda.

The framework for the PSB, as depicted in Figure 3, consists of three features: integration, multiple access channels, and data security. First, the PSB will provide a single point of access to all services of both central and local government. The revolutionary aspect of the PSB is that service is to be provided from the customer's perspective. That is, the customer interacts with the broker and not the actual service provider. Second, the PSB will make services available through many access channels; these include online self-service, telephone contact centres, and one-stop shops. Finally, the PSB will provide a customer data vault that will store data relevant to their interaction with the government. This data will be used to facilitate online transactions, provide personalization of the user interface, and provide various other aids in form completion.

## Implementing E-Government

In November 2000, the OASIS (http://www.oasis.gov.ie) and BASIS (http://www.basis.ie) Web sites were launched. These Web sites provide detailed information on government services to citizens and businesses, respectively. With a focus on customer requirements, these sites broke the long-standing tradition of distributing government information along functional lines.

During 2001, REACH, in partnership with LGCSB, developed an interim-level PSB. LGCSB was identified as a technical partner for two reasons. First, LGCSB had gained significant expertise through the implementation of e-forms, and second, local authorities had a tried and trusted relationship established with LGCSB.

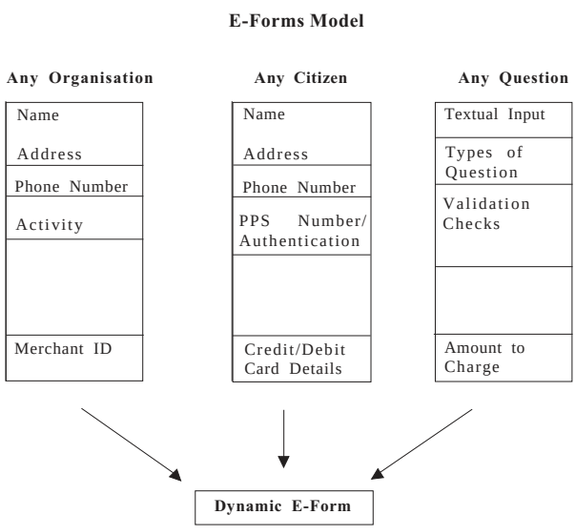
This interim service became known as Reachservices and was officially launched in April 2002.

Also in April 2002, the second government action plan entitled *New Connections* was published. The main objectives of the e-government strategy were outlined as a radical improvement in quality of service to customers, major improvements in administrative efficiencies, and enhanced control of publicly funded services. The government also made a commitment to have all public services capable of electronic delivery available through a single point of contact by 2005. By 2006, the PSB progressed through a procurement process and has been outsourced to a private-sector firm where it is currently under construction.

## Meeting the Challenge of Delivery

The main challenge in the development of Reachservices was to have every local authority's paper-based forms available online for electronic download and submission. Each of the 46 local authorities had at least 133 forms that they required to be individually customisable. This resulted in a total requirement of more than 6,000 forms, excluding health boards. To meet this require-

*Figure 4. Representation of form-builder application (LGCSB)*



ment, LGCSB developed a centrally administered system that would allow each local authority access an electronic form builder.

The form-builder tool has a graphical user interface and is based on the idea that a generic form can accommodate any organisation for any citizen and cover any question (Figure 4). The form builder is based on three basic entities: the organisation, the individual, and the question. It enables the local authority to create its customised form that is then uploaded onto the Reachservices site.

## Process Redesign

The implementation of Reachservices necessitated changes to traditional processes. These changes occurred in three areas: the publication and distribution of forms, citizen identification and data security, and the completion and submission of forms by citizens.

Central to the progression of the online service provision achieved by REACH was the redevelopment of e-forms into the form-builder tool accessible to the local authority through the portal Reachservices. The local authorities are allocated a user name and password, allowing them access to the form builder. Each local-authority administrator can then select which e-forms are to be made available for the authority and can customise those forms online. From a template form, the administrator creates the questions, defines what type of response the user will give, and can add whatever validation checks or mandatory fields that are required.

Another significant advance achieved by Reachservices is citizen identification. Before using the system, the individual must register with Reachservices. Part of this registration is an authentication process that is managed by the Department of Social and Family Affairs. The individual may then access the Reachservices site using their Personal Public Service (Social Security) number and password. This is an essential feature of the process as it provides the authority with proof of the individual's identity and enables features like intelligent form filling. Personal data is then stored in a data vault. All authorities have access to the data vault; however, the citizen retains the right to determine which authorities have access to their individual information. Thus, the system complies with current data protection and privacy legislation as the individual citizen decides what information, beyond the statutory minimum, is shared with whom.

With respect to form completion by the citizen, intelligent form filling allows certain fields to be populated automatically based on the information stored on each citizen. It also allows for certain questions to be deactivated when they are not necessary. The user is also provided with the capability to save a partially completed form for completion at a later date. When the user submits the form, it is automatically routed to the relevant authority in XML (Extensible Markup Language) format. At present, the front-end interface is fully automated while the back-end system still relies on human interaction.

## FINDINGS

The e-government strategy was devised and ratified by the highest possible level of central government. REACH identified and exploited the technological expertise of LGCSB and successfully procured a partnership with the Department of Social and Family Affairs in order to provide an authentication service. The effective management and coordination of otherwise autonomous stakeholders, combined with the right technical infrastructure, provided the ingredients for the provision of a successful public e-service.

Process changes occurred within local authorities and health boards with respect to form publication and distribution, and in the acceptance of electronic submissions. Responsibility for citizen identification was shifted from the service provider to the Department of Social and Family Affairs. This also facilitated the introduction of a single repository for citizen data.

The immediate impact to citizens can be judged in terms of ease of access, ease of use, and efficiency.

*Table 1. E-government initiative compared to Venkatraman framework*

| Venkatraman Stage | E-Government Initiative |
|---|---|
| Localised Exploitation | Development of local authority web sites with PDF forms. |
| Internal Integration | Launch of OASIS and BASIS web portals, availability of e-Forms on local authority sites and the establishment of REACH |
| Business Process Redesign | Partial process redesign though the use of Reachservices form builder application, citizen identification and online access |
| Business Network Redesign | Establishment of interim Public Service Broker Reachservices. |
| Business Scope Re-definition | Strategic thrust from agency centric to citizen centric services |

Providing a multitude of forms from individual authorities in one location gives citizens ease of access resulting in time savings. The completion of a form is greatly simplified through intelligent form filling. The Reachservices Web site went live in mid-April 2002 and was launched without the use of advertising in order to prevent an initial surge of activity. Nonetheless, the initial uptake rate was approximately 500 to 600 registrations per month during its first few months of operation, and the total number of registered users currently stands at 1,500. This volume of traffic was regarded as successful due to the subdued launch and the fact that the site only offered a fraction of the functionality ultimately intended.

Reachservices has had a 100% uptake rate by local authorities, albeit some authorities are implementing at different levels. There has also been a very high take-up rate amongst the health boards, although not 100%. The case also highlights a more subtle yet profound observation. The Reachservices infrastructure and the future PSB are to be developed around the existing government structures. In other words, due to political considerations, a full and complete process redesign will never be possible as the existing authorities must remain in place. Thus, a complete understanding of the intricate and sometimes bureaucratic processes that combine to form citizen services is necessary so that it is possible to identify the process or elements of processes that can be redesigned, automated, or left unchanged.

However, this interim portal highlights the transformation stages that need to be managed in order to deliver any level of e-government. Table 1 compares the e-government achievements in this case with the Venkatraman (1994) framework.

The development of local-authority Web sites represents the occurrence of localised exploitation that is the implementation of IT within a business typically at a functional level requiring little process change. However, the subsequent move to restructure information from a user perspective through the OASIS and BASIS Web portals represents internal integration as this is characterised by a systematic attempt to leverage IT capabilities. The establishment of REACH also illustrates the commitment of senior government officials to the attainment of an integrated and coordinated approach to e-government.

Participation in the Reachservices portal required local authorities to make significant changes to specific elements of their service delivery process: the publication, distribution, and electronic acceptance of forms, and the storage of citizen information. Participation also introduced a new process of citizen identification in which the local authority was a passive participant. Finally, participation also enabled electronic access to services, although this required almost no process change as the actual service itself was still conducted in a traditional manner with the citizen receiving electronic or physical notification of service completion.

Government by its nature is a collection of businesses (agencies and departments), and the development of the Reachservices platform represents the attainment of business-network redesign as the platform radically impacts the nature of the exchange among multiple participants through new IT capabilities. Individual authorities that traditionally operated independently began to participate in a centralised mechanism. The Reachservices platform instigated the move toward electronic information sharing that was capable of supporting seamless interconnectivity, process linkage, and knowledge management.

Finally, business-scope redefinition was manifested by the strategic shift in government policy toward citizen-centric services that are enabled by a public-service broker. Thus, the government was redefining its business role from authoritative redistributor to service provider.

## CONCLUSION AND FUTURE TRENDS

This case provides valuable insights into how citizen-centred e-government can be attained and highlights the

central importance of managing processes and process change in the implementation of e-government. The Reachservices business network connects local and central systems through the use of a centralised database that maintains the authenticated data of the individual citizen. However, Reachservices does not provide sufficient functionally to facilitate the provision of a comprehensive set of services, and thus, while serving as a successful example of a move to e-government, it falls far short of a true citizen-centric e-government platform.

While the case provides strong evidence that the infrastructure for the PSB will be developed, there is a marked absence of focus on the core process. Almost the entire effort of the REACH agency has been on the provision of the technical infrastructure. While REACH has proven that the local authorities are willing to participate in such a network, it has not proven that these authorities are willing or capable of implementing more radical process change.

Business-process redesign has been limited and as such, this case provides evidence of the existence of the gap identified by Venkatraman (1994) between the evolutionary and revolutionary means of business transformation. The model of business transformation proposed by Venkatraman represents very well the process as it actually occurred in this case. In order to move from an evolutionary to revolutionary business transformation, a requirement to abandon existing systems in favour of new systems has been identified. The ability to identify and scope these new systems was in large part facilitated by the learning that occurred while developing the initial e-government initiatives: the evolutionary stages. In addition, the establishment of a specific government entity, REACH, whose sole purpose is to oversee and implement the e-government strategy, has contributed greatly to the success achieved to date.

REACH was in a position to both identify and manage the critical success factors involved in delivering e-government. First, the most appropriate model and technical infrastructure were identified and implemented by outsourcing to leverage expertise that already existed. This use of existing expertise proved highly successful in terms of developing a robust infrastructure within a limited time frame. Second, critical concerns of local authorities were managed by using familiar actors. Third, the interactions necessary between otherwise independent agencies was successfully coordinated to ensure the delivery of a quality service. Fourth, the maintenance of a customer focus by providing quality service through a single portal in which the citizen has control over his or her personal data contributed to a successful uptake of the system.

The case illustrates that e-government initiatives that fit within the evolutionary classification can be achieved in a timely and successful manner. The case also illustrates that more revolutionary initiatives are achievable, but that the development of these initiatives beyond basic services requires sophisticated business-network and business-process redesign.

Thus, an important area for further research is to investigate the unique nature of processes within the public sector so that IS platforms can be developed that accommodate less efficient processes rather than platforms that require unobtainable process redesign.

## KEY TERMS

**Business Process Redesign:** IT-enabled business transformation, or the fundamental and radical redesign of business processes to achieve dramatic improvements.

**Citizen-Centred E-Government:** The development of a client-based approach focusing less on traditional bureaucracies and more on customer attitudes, with the objective of providing services to citizens based on their needs and being accessible from a single point of contact.

**Digital Divide:** The digital divide is defined by the "gap between individuals, households, businesses and geographic areas at different socio-economic levels with regard both to their opportunities to access information and communication technologies (ICTs) and to their use of the Internet for a wide variety of activities" (OECD, 2001).

**E-Government:** Electronic government consists of using technology, particularly the Internet, as a means to deliver services to citizens, businesses, and other entities.

**Electronic Service Delivery:** The provision of services with the assistance of telecommunications and telecommunications-based tools. A range of access methods are available to service users, for example, the Internet, phone, and walk-in counters.

**Integrated Services:** Integration is required on two levels. First, the services that are presented to citizens should be offered in a citizen-centric manner whereby the orientation of information is focused on the customer and not on the service. Second, the underlying processes require functional integration, where services in one department will support or trigger the provision of service in another area.

**Portal:** The provision of integrated services, combining personalisation features, via the Internet. The portal would act as the single point of contact for the delivery of citizen-centric services.

## INTRODUCTION

Public administration is undergoing a radical transformation. Citizens, rather than administrative documents, will be the primary and active subjects of the process of service supply. A new attitude toward administrative service is emerging. Citizens interact with public administration through new channels such as *unified administrative counters*, *multifunction administrative counters*, *citizen liaisons offices*, and *Internet*. Furthermore, having in mind the goals of shortening the distance between citizens to public administration and improving efficiency and efficacy of public bodies, the use of *call* and *contact centres* is quickly spreading out. It is worth to recall the recent case of *Allô Service Public*, the unified call centre of the French public administration, which on its first day of activation has been contacted by more than 100,000 people, more than any optimistic expectation.

For a public administration, a *call centre* represents a simple way for interacting with citizens. Call centres provide many advantages such as improved efficiency, increased hours of operation, and reduced costs. The main advantage for citizens is that call centres can provide the information they need, as fast as possible and reducing waiting time.

Call centres and contact centres are based on an innovative use of the phone channel, on one side, and on multi-channel strategies of access to service and information, on the other side. The combination of these two aspects allows public administration to develop and activate new modes of managing interaction with citizens. A phone-based information service is often the first channel chosen by citizens that want to get in touch with a public body. Call centres, on the other hands, have a relevant role for implementing the link between *front-office* and *back-office* services.

## BACKGROUND

The call centre concept evolves through four main phases (Bagnara, 2000; Kowarsky, 1998).

### Phase 0

In the sixties, a call centre was a complaints office equipped with a toll free number. As the aim of call centres was to reply to standard complaints, human operators had a limited base of knowledge and basic communication skills. The first service of this kind was activated by Ford, as a consequence of a sentence pronounced by an American judge in 1968, in a lawsuit initiated by a consumer association.

### Phase 1

Around the mid-eighties, call centres adopted ACD (Automatic Call Distributor) technology. An ACD is a system to receive a large number of phone calls, especially optimized to equally distribute them to the available operators. At this time, human operators had a still limited, but now specialized, base of knowledge. In 1981, General Electric activated the so called "GE Answer Centre" with the aim of facilitating customers that need, or simply desire, to get in touch with the company. This centre quickly became a benchmark for all the other American companies with a large number of customers. Between 1984 and 1989, while many call centres were opened in U.S., General Electric activated 52 different call centres for its primary business divisions. The success of this new way of providing services to customers was so large that, in the eighties, more than 4 million job positions were created in the newly activated US call centres.

## Phase 2

In the nineties, call centres adopted the emerging Information and communication technologies, thus providing a service that fulfills the three major consumer's requirements: easy access, closeness, personal information. Under this perspective, the development of call centres is considered a basic opportunity to know and address customer's needs, rather than being an additional cost. The main business goal was to differentiate and increase the value of the company offers with respect to competitors. In this phase, human operators have high level communication skills.

## Phase 3

At the beginning of the new century, call centres are considered as places where new value is created both for a company and its customers. The technology used by call centres evolve, in order to provide a personalized service based on the phone and the newly available communication channels. Physical front desks, surface mail, fax, electronic mail, WAP (wireless application protocol) based interface, are channels simultaneously used to grant access to the call centre. Combining these channels with automatic and interactive phone answer systems, Web applications, and the like, the call centre becomes a sophisticated reference point. In this context, human operators play the role of specialized consultants.

# PUBLIC ADMINISTRATION AND CALL CENTRE

In the public sector, call centres have followed a more recent evolutionary path. The citizen liaisons office, a front desk entirely dedicated to communication activities, has been introduced at least ten years ago and has been used as the basis for the first public call centres. Starting from this kind of unidirectional channel (information are simply given upon a specific request), public administration has moved into a phase characterized by more interactive services to citizens.

The change of attitude towards this form of communication channels is due to two main factors: the commitment of public administrations to facilitate the interaction with citizens and private enterprises, the needs of citizens to obtain services with the same quality levels of those provided by the private sector, where call centres are already widespread. Furthermore, public administration is more and more interested in knowing citizen's needs as a concrete base for providing services that address real and concrete expectations (Call Centres in the Scottish Public Sector, 2001).

The goals of a public administration call centre are the following:

- To facilitate contacts between citizens/enterprises and public administration (removing physical queue lines, freedom to choose the preferred mode for getting in touch with public administration, chance to receive desired information in time frames different from the traditional ones) (Controller and auditor general, 2002)
- To improve quality level of relationships with citizens/enterprises by means of timely and trusted answers
- To standardize quality levels and contents of given answers, by means of trained, qualified, and motivated personnel and the fulfillment of high and predefined service levels (Baird, 2004)
- To gather and process information coming from citizens/enterprises, in order to improve and simplify internal procedures and organization
- To constantly enrich the amount of knowledge and competencies available in the public bodies, through sharing and spreading of given answers, best practices in the management of relationships between citizens and enterprises
- To improve and promote the external image of public bodies

In the actual scenario, the number of public bodies involved in innovative experiences based on advanced communication modes that integrate different channels such as phone, physical front desk, fax, electronic mail, Web, SMS messages is rapidly increasing. *Information quality* is the common factor of these initiatives. Information, in fact, is exchanged, processed, exploited in the transactions between citizens and public administration and among different public bodies (Bagnara, Donati, & Schael, 2002).

The other relevant issues are *usability* and *accessibility* of the services to citizens and *universal access right*. In some cases, these issues are handled by *Web call centres*. The feeling of loneliness and uneasiness induced by the use of Internet (or by automatic answering systems, as well) is reduced, or at least mitigated, by virtual front desks implemented with the current technology (Controller and auditor general, 2002).

# FROM WEB TO CONTACT CENTRE IN PUBLIC ADMINISTRATION

The Web call centre is a solution that allows Internet navigators to get in touch, through a vocal connection,

with a call centre operator and to get some support for navigation. Therefore, the Web call centre is the natural evolution of call centre services. Interaction with users becomes more dynamic, thus shortening the sense of distance from the public bodies that provides the service.

Users of a Web call centre visit a site and communicate with human operators by call-back, VOIP (Voice over IP), or chat. The Internet user can interact with a human operator in the following ways:

- **Click-to-Chat:** Through a button the user that is navigating inside the site can immediately activate a chat session with an operator.
- **Click-to-Call-Back:** The user reserves an automatic call-back from an operator, either in real-time or at a given day and time.
- **Click-to-Talk:** By using VOIP, the user can talk with an operator.
- **Collaborative Browsing:** This mode is normally integrated with click-to-chat or click-to-talk; the operator literally "drives" the user through the site, acting as if he or she were physically inside the user's computer.

The use of a Web call centre gives advantages both to the public administration and to its citizens/users. Administrations benefit from immediate contact with its users, elapsed time for handling requests is significantly reduced, management costs are cut down, and number of contacts can increase. Citizens can increase the level of knowledge of the administration, phone costs can be avoided since citizens are already connected to Internet, and a direct interaction with public administration is naturally developed (VoiceCom News, 2002).

For example, in the UK, call and contact centres are an increasingly important interface in the management of government relationships with the citizen and business. Often there are many call centres for each department. Actually call and contact centres are playing a pivotal role in meeting the government's target of complete electronic delivery of public services by 2005.

In the following, we present some example of international Web call centre.

- National Contact Centre of the Federal Consumer Information Centre, a single point of contact for people with questions about federal agencies, programs, and services, http://www.info.gov
- Rural Transaction Centre in Australia provides by e-mail or telephone both commercial and governmental services to people living in rural zones, http://www.dotrs.gov.au/rtc/index.htm
- MAXI of the State of Victoria allows citizens to execute online transactions and payments via Internet, by telephone, or through a network of public kiosks, http://www.maxi.com.au
- Service Tasmania provides a flexible access to the widest range of Web resources, primarily information and services from the state government, but also from the federal and the local governments, http://www.servicetasmania.tas.gov.au/
- Europe Direct is a service to help people to find answers to questions about the European Union. The call centre, free of charge for every member state, provides direct response to general enquiries and, in case of detailed questions, can forward the user to the best source of information and advice, http://europa.eu.int/europedirect/index_en.htm
- Allô, service public in France is a service of administrative information by telephone. A single telephone number makes it possible to obtain a response or an orientation with any administrative request for information. http://www.service-public.fr/accueil/renseignement_3939_oct2004.html
- SuperAbile, an Italian call centre that provides information on disabilities, http://www.superabile.it
- CallDtc (literally Call the District) of Canavese technological district is a remote consultancy service whose use is restricted to the employees of the local bodies on the specific subject of local government, http://www.canavese.to.it/pa/calldtc/default.asp
- Pubblicamente is a service to help people to find answer inquiries about local public administrations, http://www.pubblicamente.it

## PUBLIC ADMINISTRATION AND CONTACT CENTRES

A contact centre provides the customer support service not only through phone calls, but also by means of other communication channels such as fax or electronic mail to interact with users in a more and more direct and personalized way. Current implementations of contact centres are both integrating CRM systems and adding new functionalities for managing non voice interactions. These enhancements aim at shortening the distance between the contact centre and its users, in order to understand their needs and to facilitate their access to the available information.

The contact centre is a tool for:

- Activating relationships and processes towards the citizen/user, through a single and optimized contact point

- Integrating the organization and the information system
- Improving the quality levels of the contact centre, the provided services, and the managed knowledge base
- Coordinating net-learning and continuous training activities both for public administrations and citizens/enterprises

The contact centre aims at integrating specific professional skills available in the public administration with the purpose of addressing the specific needs of its users. Addressing these needs with specialist and precise competences is the main goal of a contact centre. Designing a contact centre corresponds, therefore, to the creation of an integration point for many different actors, where economical, social, territorial resources and citizens/enterprises meet the available services (Zetti, 2003).

## FUTURE TRENDS

Multi-channels communication gives all users, with different skills and socio-technological conditions, an equal opportunity to have access services provided by public administration. On the other hands, the administration can reach all its potential users in an efficient and effective way. For this reason, there is a trend to activate contact centres in public administrations to contrast the risk of creating a digital divide among citizens. The opportunities given by technological advancement would result in another vehicle of exclusion for a large part of the population.

Videoconference and video give a further opportunity to improve and expand the quality and the scope of public services. The goal of a *video Web call centre* is to virtually recreate the same level of confidence and friendliness that is peculiar to the direct physical contact, with the opportunity to extend this kind of contact to a larger set of users with much more reduced costs. This technology enables the user to talk with a human operator, sitting in front of a home computer, as if the operator were just in front of the screen. This channel is a strong approximation to the physical front desk interaction. The wide upcoming adoption of interactive TV and broadband Internet connections will make this communication mode more and more popular.

Up to now, the main difficulty that public bodies are encountering is the process of merging contact centres into the so called *service strategy*. Realizing a contact centre is a task that starts from the re-design and redefinition of the set and the nature of services provided to citizens/users.

## CONCLUSION

The adoption of a model of call or contact centre depends upon both the service strategies that an administration decides to actuate and the goals that it wants to pursue. These are the elements that allow the administration to make a weighted choice between a first level contact centre that provides a service of informative assistance and a contact centre of first and second level, where the first level provides information and forward the request of further details to the second level that provides more specialist information.

The choice of the reference model for the call centre is of paramount importance and depends upon some requirements that the administration has on the service management: how to plan the phases of the project for realizing the centre, what amount of financial resources are available. Besides the strategic choices there are other variables: organization (how to locate the contact centre inside the organization); competences, skills, and training of the required personnel; technological solutions and criteria for choosing the more appropriate one; monitoring of the service quality levels. This is also needed to avoid that the administration transforms the service design into a mere technical issue.

Generally speaking, the call centre and its development are one of the most significant tools for the evolution of e-government. From one side the call centre can decrease the needs of information, which rely on citizens. From the other side, it allows the administration to monitor citizen's needs, thus giving more effective and useful information. This triggers the request of innovation that can be obtained by investing in knowledge, innovative technology, training, professional culture, and development of the human factor. It is this last element the main resources, coupled with a new way of management and government (FITLOG, 2000).

## KEY TERMS

**ACD (Automatic Call Distributor):** The specialized telephone system used in incoming call centres. It is a programmable device that automatically answers to calls, queues calls, distributes calls to agents, plays delay announcements to callers, and provides real-time and historical reports on these activities.

**Automatic Call Back:** A feature of a telephone system that allows a caller to hang up and instruct the system to call back as soon as a busy station or trunk is free.

**Call Centre:** An umbrella term that generally refers to reservations centres, help desks, information lines, or customer service centres, regardless of how they are organized or what types of transactions they handle. The term is being challenged by many, because calls are just one type of transaction and the word centre does not accurately depict the many multi-site environments.

**Co-Sourcing:** Supplying services in-house and with an outside company/vendor to handle some or all of a company's inbound and/or outbound telephone calls or contacts.

**Communication Server (CS):** Also CTI Server, PcPabx, Un-Pabx, CT Server, Contact Server. An integration technological platform that manages several communication resources. Also called ALL-IN-ONE when the CS incorporates functions of telephone commutation.

**Contact Centre:** The term contact centre is sometimes used in place of the term call centre. This reflects the fact that these centres often handle customer contacts from e-mail and the World Wide Web as well as phone calls.

**CRM (Customer Relationship Management):** The strategy of identifying customer needs, improving customer interactions, and customizing contacts, sales approaches, and automation to provide optimum service to each type of customer to maximize the bottom line benefits to the organization.

**CTI (Computer Telephony Integration):** This refers to systems that enable a computer to act as a call centre, accepting incoming calls, and routing them to the appropriate device or person. CTI systems have become quite sophisticated, handling all sorts of corporate communications, such as phone calls, faxes, and Internet messaging.

**Inbound:** Describes a call centre in which the agents wait for outside calls to come in to them rather than make calls out. Inbound call centres perform many varied tasks, such as sales, customer support, and help desk.

**Outbound:** Describes a call centre in which the agents make outgoing calls rather than wait for incoming calls. Outbound call centres perform many tasks, such as telesales, follow-up support, and opinion surveys, to name a few.

**Web Call Centre:** A call centre integrated to a Web site. It offers services on Internet.

# Citizen Consultations via Government Web Sites

## INTRODUCTION

Cynicism toward government is largely a function of trust and social capital (Berman 1997; Putnam 2000). The relationship between government and its citizens has been strained. First, some citizens cynically feel as though government officials abuse their powers in the interest of self-aggrandizement; second, citizens often feel disconnected from government; third, government service delivery is frequently portrayed as inadequate. Administrative strategies to reverse these perceptions typically emphasize the benefits of government and improved service delivery. Some go further, offering individuals a means of influencing public policy and government decision-making, as opposed to traditional structures and cultures of policymaking that minimize citizen input. The Internet is a potentially powerful means for citizen consultation, and may help cultivate a governmental landscape in which information is more accessible, people feel more connected to government, and citizens are better able to participate in political and decision-making processes. This article examines the Internet as a consultative medium, whereby emphasis is placed on government efforts to use Web-based applications as a means of promoting meaningful citizen participation.

## DIGITAL DEMOCRACY: A THEORETICAL EXAMINATION

According to John Stuart Mill (1991), the ideal public sphere is one where debate and differences of opinion flourish. Integrating diverse groups into the public discourse helps to engender and sustain societal stability. Mill advocated tolerance for alternative views points, even those that are thought to be socially deviant, thus minimizing the likelihood of social tyranny and preserving individual autonomy. Mill envisioned a public sphere in which the masses assemble in civic spaces and engage in a pluralistic discourse, helping to prevent ignorance and prejudices from unduly influencing the policy-making process.

Public realm theorists such as Habermas (1989) emphasize the importance of social mechanisms that allow private individuals to pass judgment on public acts. Habermas provides a historical description of European social institutions throughout the 17th and 18th centuries, namely the English coffee houses, German literary societies and the salons of France. These institutions brought together generic intellectuals and created forums for debate regarding the state of society. According to Habermas (1984), the ideal public arena fosters inclusive and voluntary citizen participation within the context of influencing how government power is wielded. Today, the notion of digital democracy has been championed by some as a means of realizing Mill and Habermas' conceptions of the ideal pubic sphere. The notion of digital democracy encompasses the use of information and communications technologies (ICTs) in the practice of democracy.

In the context of a democratic system, citizens have a measure of influence over the policies impacting their lives. The relationship between government and citizens is foremost within a democratic system. In a digital democracy, emphasis is placed on the processes and structures that define the relationships between government and citizens, between elected officials and appointees, and between the legislative and the executive branches of government. According to Hacker and van Dijk (2000, p. 1), digital democracy refers to "a collection of attempts to practice democracy without the limits of time, space and other physical conditions, using ICTs or computer-mediated communication instead as an addition, not a replacement for, traditional 'analogue' political practices." Nugent (2001, p. 223) refers to digital democracy as "processes carried out online—communicating with fellow citizens and elected representatives about politics." Digital democracy may be defined as all practices to improve democratic values using ICTs.

Kakabadse, Kakabadse, and Kouzmin (2003) maintains that ICTs and digital applications may alter the

dynamic of representative democracy by affording citizens a direct means of influencing the public policymaking process. This may include virtual town hall meetings, online consultation portals, and other Internet-based applications where citizens can debate policy and convey their views. Given the rapid development of ICTs, citizens can participate more freely and consult on public policies (Holzer, Melitski, Rho, & Schwester, 2004).

O'Looney (2002) compares the interaction between citizens and government within the context of traditional and digital democracy. According to O'Looney, while communications are filtered through representatives and the media in a traditional democracy, direct communications among citizens, public managers, and technical staff are now possible in a digital democracy. Communications with citizens involve a one-message-fits-all approach in a traditional democracy. Within a digital democracy, official communications may be personalized based on an individual's interests and needs, and citizens can potentially track and influence decision-making at every step in the policy making process, ranging from agenda setting to a final vote. Further, government openness and transparency are central components to digital democracy. The integration of Internet-based applications that allow citizens to obtain information and consult on specific policies may prove ideal in terms of fostering an increased sense of public engagement. This, in turn, may help to reduce citizen cynicism and restore a healthier level of trust in government.

## INTERNET-BASED CONSULTATIONS: NOTEWORTHY EXAMPLES

Governments throughout the world are increasingly using the Internet as a means of engaging citizens (Holzer & Kim 2004). Internet applications have the potential to reconnect citizens and decision-makers, publicizing views presented by consultative parties, and providing greater opportunities for citizens to influence public policy. In the context of this discussion, Internet-based consultations are broadly defined as applications that allow individuals to convey their opinions regarding specific policy considerations. Internet-based consultative mediums need not be deliberative or dialogical in nature, even though this would be more ideal.

Jankowski and van Os (2002) examined Internet-based political discourse in the City of Hoogeveen (Netherlands). Established in 1996, *Hoogeveen Digital City* serves as the formal Web site for the municipality, and is considered one of the more advanced community networks in the context of engaging citizens in digital-based politically oriented discussions. Hoogeveen experimented with three specific Internet-based discussions: (1) the digital consultation hour, (2) digital debate, and (3) digital discussion platform. The digital consultation hour is a bimonthly discussion of community issues. It is a synchronous, real-time exchange between Hoogeveen elected officials and citizens, and it is facilitated through a question and answer format. The digital debate was a real-time event used during the 2002 municipal elections wherein citizens were able to deliberate policy issues and pose questions to candidates and party representatives. Finally, the digital discussion platform is an online public space that allows citizens registered within the network to discuss predetermined community issues.

The *Virginia Regulatory Town Hall* is a public space that affords citizens a means of becoming actively involved in the rulemaking process, as they are able to convey their opinions and concerns via an electronic comment form (which resembles a Microsoft word document). As of October 2004, forty proposed regulatory changes were open for comment. The Town Hall further provides citizens with information regarding proposed regulations and changes, agency background discussions, economic impact analyses of proposed regulations, and agency guidance documents, all of which are designed to help citizens interpret agency regulations, and better ensure knowledgeable citizen participation in the rulemaking process. The public may access regulations by subject, title, cabinet secretariat, agency, and board. Moreover, the Town Hall provides citizens with information on meetings and public hearings, which includes:

- Meeting title
- Host agency and its Web site
- Date and location of the meeting
- Purpose of the meeting
- Agenda and minutes
- Information on handicapped accessibility and deaf interpreters
- Meeting contact information, including name, address, phone number, and e-mail.

Information regarding regulatory actions and meetings is disseminated via email to those having registered with the Town Hall.

Similar to the Virginia Regulatory Town Hall, *Regulations.gov* allows citizens to submit electronic comments regarding proposed federal regulatory changes. Since its development, Regulations.gov has averaged approximately 6,000 hits daily (Miller, 2003) and has established itself as a key component of the digital rule-making initiative by improving quality and access to the government regulation writing process. According to Neil Eisner,

former assistant general counsel for the Department of Transportation, Regulations.gov will likely open the rulemaking process to individuals outside of the nation's capital and the special interest lobby, serving as an egalitarian means of influencing public policy (Skrzycki, 2003a).

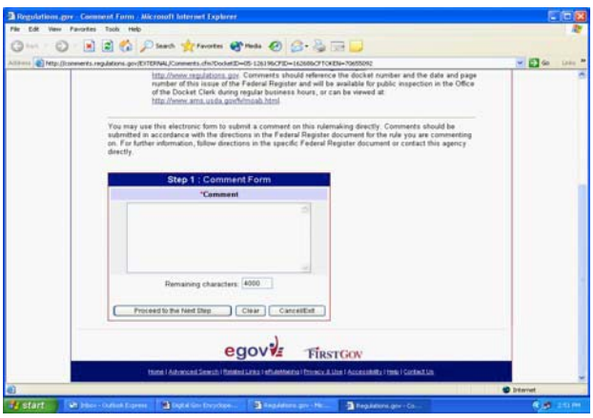
Regulations.gov is the first of a three-module e-rulemaking initiative. Module Two calls for the integration of an online federal docket management system, whereby individuals will be able to access all publicly available regulatory material, including federal register notices and rules, supporting analyses, and public comments regarding proposed regulatory changes. Module three is envisioned as a tool for regulation writers, including applications such as virtual meeting spaces for those writers and analyses of public comments (Morales, 2003).

Through Regulations.gov, citizens can identify regulations open for comment by topic, key word search, or Federal agency. For example, selecting "Internal Revenue Service" from the agency menu allows individuals to view proposed IRS regulatory changes (in either HTML or PDF format) that are open for public comment. Information appearing in the descriptions of a regulation open for comment include:

1. Title
2. Subject category
3. Text and PDF files linked to the description and full text of a regulation
4. **Proposed Rule or Rule:** Proposed rule indicates notices of proposed rulemaking, advance notices of proposed rulemaking, and extensions of comment periods. Rule indicates final rules with request for comment, interim final rules, direct final rules, and reconsiderations of final rules
5. **Docket ID:** Allows agencies to easily track regulatory actions open for public comment
6. **Code of Federal Regulations (CFR) citation:** Corresponds to the section of the CFR that an agency is amending or proposing to amend
7. **Published:** Refers to the date on which the rule or proposed rule was published in the federal register
8. **Comments Due:** Refers to the closing date of a consultation period
9. **How to Comment:** Guides citizens through the comment process

The *How to Comment* section guides citizens through the consultative process. Specifically, when an individual clicks on *How to Comment*, they are directed to a Web page through which they may submit an electronic comment (see Figure 1). According to Oscar Morales, director of the e-rulemaking initiative for the Environmental Protection Agency.

*Figure 1. Regulations.gov comment form*



The primary goal of this initiative (Regulations.gov) is that we are trying to make it more likely that the public will participate. Right now, if you are a small business owner out in the mid-west and you want to participate in the rule making process … that is to say you want to find out which agencies regulate you and/or which rules affect you right now … you could, with a little bit of effort, do that. You would have to know the agency, you would have to know whether they had an open rule, you would have to have a (personal computer), of course, and you could do it (through Regulations.gov). More than likely, however, (the small business owner) would have sent in their $15 to the public interest firm in Washington D.C. or their $50,000 to their law firms here on retainer and (they) would be the ones who would conduct their business by way of participation in the regulatory or rulemaking process, make the comments at the appropriate time, and they would be the one's who do it. What this initiative is trying to do to is enable those citizens, if they so choose, to participate (Morales, 2003).

Nevertheless, skeptics note that online applications such as Regulations.gov and the Virginia Regulatory Town Hall may emerge as another conduit for the political elite. For example, the National Association of Manufacturers has reportedly provided its membership with an electronic template for commenting on proposed federal regulations. Gary Bass, executive director of OMB Watch, (an advocacy group that promotes government accountability and citizen participation), believes that businesses and special interests are likely to benefit in the short-term because of their access to technology (Skrzycki, 2003b).

The United Kingdom recently revamped its Internet-based applications, having launched *Directgov*, a government portal site that provides access to 2,500 govern-

ment Web sites. According to Andrew Pinder, former e-envoy to the prime minister, Directgov simplifies contact between government and the citizenry. Directgov evolved from UK Online, which was a nationwide effort to connect all government departments to the Internet by 2005. Directgov has a citizen participation component in that it provides an external link to a "consultations index," which allows citizens to play a role in public policy consultations. Through the index, users are able to browse or search proposed government policies and register their opinions. As of October 2004, there were 223 policies open for public comment through the consultations index.

There is some criticism of Directgov, as it has yet to integrate electronic services provided by local governments, and about percent of citizen-government contact occurs at the local level. According to Nigel Hannam, head of e-services of Surrey county, "given the number of citizen transactions that are processed by local authorities compared with central government, it's crucial that local authority information is fully integrated (into Directgov)" (Olsen, 2004).

## FUTURE TRENDS

Ideally, Internet-based applications offer ignored groups a greater voice, thereby narrowing the participatory gap in public policymaking. Having been applied in a number of cities throughout the United States and Europe, Internet-based applications allow more citizens to participate in the policy discourse. They have the potential to reconnect citizens and decision-makers, providing greater opportunities for citizens to influence public policy (Malina 1999; Tsagarousianou, Tambini, & Bryan 1998). Moreover, Internet-based applications may overcome what Irvin and Stansbury (2004, p. 62) refer to as "non-ideal conditions for citizen participation," such as geographically dispersed populations that make face-to-face meetings inherently difficult.

The Internet as a consultative medium presents specific challenges, most notably the *digital divide*. This divide draws a distinction between those with Internet access and Internet-related skills and those without such capacities. It weakens the Internet as a mainstream and inclusive consultative medium to the extent that it disproportionately impacts lower socio-economic individuals who have historically played an insignificant role within the public policy process (Norris, 2001). A parallel criticism is that Internet-based applications are skewed towards technical experts fluent in the jargon of public policy, which will alienate average citizens. While experts largely influence public policy dialogues, this may be more pronounced through digital and Internet-based conduits. In addition, the Internet as a communications medium favors individuals with strong writing skills, and these individuals tend to have greater access to financial resources and education.

Another issue to be considered is whether policymakers should give Internet consultations the same consideration they give other policy feedback mechanisms, such as traditional town hall meetings or pubic hearings. Furthermore, public policy makers need to consider if Internet consultations should serve as alternatives to traditional mechanisms for engaging citizens in the pubic policy process, or if they should replace traditional methods. In other words, should the Internet supplement, complement, or be essentially the same as off-line public hearings? Oscar Morales, director of the e-rulemaking initiative for the Environmental Protection Agency, envisions online consultations as supplementary to existing mediums. Morales believes that "most of the rulemaking process is paper-to-paper deliberations. You'll probably always have some face-to-face interactions" (Morales, 2003).

The future development of Internet-based consultations should encompass the integration of more dynamic applications. Regulations.gov, the Virginia Regulatory Town Hall and Directgov's consultations index are static applications. That is, such mediums do not facilitate a real-time, synchronous exchange between citizens and government representatives. More dynamic consultative mediums, similar to *Hoogeveen Digital City*, would help to further bridge the gap among citizens, policymakers, and elected officials. However, unless carefully moderated, real-time synchronous consultations could become chaotic. Unmediated consultations may even become abusive and unfocused (i.e. Internet flaming), and therefore elected officials and other decision-makers with whom citizens wish to interact may be reluctant to participate.

## CONCLUSION

The notion of digital consultation is a reality, as governments are using the Internet to facilitate open dialogue between citizens and government. By and large, Web-based applications show great potential for democratic renewal, especially with regard to reconnecting citizens to government, which may help to overcome participatory apathy and cynicism toward government. The process reduces travel costs for participants in the public policy process, as they need not travel to one location to participate in traditional public meetings. Cases at the national level and the international level demonstrate that, when given the opportunity, citizens will use the Internet to share their ideas and suggest comments or recommenda-

tions on public policy in a virtual, as opposed to a physical, space.

Government should work to identify, study, and implement mechanisms that allow citizens to participate in the public policy process. Regulations.gov and the Virginia Regulatory Town Hall have both provided citizens with opportunities to engage meaningfully in the rule-making process. Portal sites for citizen consultation have opened virtual public spaces for citizens and/or interest groups to deliberate specific rules. By following these model, governments at state and local levels can generate multiple interactions between citizens and governments for deliberation across a range of social issues. More often than not, however, the public sector fails to aggressively market new services and innovations. Marketing Internet-based consultations is a prerequisite for success. Marketing strategies should include the dissemination of materials underscoring not only the availability of Internet consultations, but also the potential benefits of citizen participation. The cases presented in this article demonstrate that government can engage citizens through technology. Internet-based applications are viable and complementary means of participating in the policymaking process. In spite of the public sector's progress, a slow response by citizens could weaken the viability of Internet consultations as a necessary adjunct to existing participatory mechanisms.

## KEY TERMS

**Digital Democracy:** Encompasses the use of ICTs in the practice of democracy, whereby emphasis is placed on the processes and structures that define the relationships between government and citizens, between elected officials and appointed civil servants, and between the legislative and the executive branches of government.

**Digital Divide:** Refers to segments of the population lacking Internet access or Internet-related skills.

**Digital Voting:** The use of the Internet or computer-based systems in the process of voting. Internet voting is simply a type of digital voting whereby an electronic ballot is transmitted to election administrators via the Internet.

**E-Rulemaking:** The integration of Internet-based applications and other ICTs as part of the formal regulations writing and comment process. *Regulations.gov* and The *Virginia Regulatory Town Hall* are examples of e-rulemaking applications.

**ICTs:** Information and communications technologies that facilitate citizen participation in government. ICTs may include networked computer systems and Internet-based applications, such as policy or consultation forums, bulletin boards, etc.

**Internet-Based Consultations:** Internet applications that afford citizens a means of providing input regarding specific government polices.

**Portal Site:** A Web site serving as gateway to other related Web sites. The United Kingdom's *Directgov* is an example of portal site, as it provides access to government information, services, and citizen consultations.

# Citizen Participation and Digital Town Hall Meeting

C

**Donald P. Moynihan**
*University of Wisconsin-Madison, USA*

## INTRODUCTION: THE PROMISE OF PARTICIPATION

If part of the promise of digital government is to enable citizens and businesses to enjoy greater convenience in their interaction with government, another goal is to revitalize democracy itself. A decline in civic engagement between citizens has been noted in society (Putnam, 1993) while citizen distrust of political institutions is on the rise (King & Stivers, 1998). Both trends do not augur well for democracy. Democratic theorists and public administration scholars have argued that one way to reverse these trends is to foster greater citizen participation in public decisions.

Why is participation so important that B. Guy Peters (1996) points to it as one of the four main alternatives for the future of governance? Participation is justified as a normative right, a contributor to better public decisions, and an enabler of higher social capital. One broad rationale underlying greater participation the rise of postmodern values among citizens, characterized by both a distrust of formal institutions such as government and political parties, and a desire for more participatory democracies (Inglehart, 1997). Societal changes, particularly increased education, lead to a greater demand for involvement and access to information (Thomas, 1995). Access to information is facilitated by new technologies. Citizens therefore enjoy both the will and the means to break the monopoly and centralized control on public information enjoyed by the government (Cleveland, 1985).

Participation is also justified in terms of benefits to individual citizens and society more broadly. Any form of citizenship beyond simple legal status requires active citizen involvement in public matters and the community (Cooper, 1984). Participation serves to establish the worth of individual citizens, allowing them to feel a sense of ownership and take an active part in controlling their surroundings and developing their capacity to act as citizens. The process of public deliberation also benefits society by creating democratic legitimacy and a deliberative political culture (Habermas, 1996).

One basic barrier to enhanced citizen participation is the nature of bureaucracy itself. Barber (1986) has argued that government has become a form of "representative bureaucracy" that undermines individual responsibility for beliefs, values, and actions, and is incompatible with freedom since it delegates and alienates political will. The values of bureaucracy are based on expertise and qualifications, conflicting with democratic values that underpin the idea of participation. Citizens are defined as non-expert outsiders who may have to be listened to, but are likely to have little actual impact on decisions. This is reflected in the failings of traditional modes of citizen participation.

Subject to particular ire is the town hall meeting/public hearing mode of participation. King, Fetley, and Susel (1998, p. 323) say: "The most ineffective technique is the public hearing. Public hearings do not work." Such meetings can be poorly attended and dominated by elite, non-representative groups (Fox & Miller, 1996). Hearings are often timed late in the decision process, used to convince citizens of pre-made decisions rather than gain their input, and provide no opportunity for an iterative dialogue. They have also been critiqued for fostering self-interested claims rather than concern with the general welfare of the citizenry and deemed unsuitable to foster choices between policy tradeoffs. Citizens attending public hearings tend to have little background information on issues, often leading to poorly informed opinions about policy and the working of government (Ebdon, 2002).

Can the problems of the traditional town hall meeting be solved through a more digital approach? Yes and no. As this article will show, digital town hall meetings, if well organized, can enable a large and diverse group of citizens to engage in an intelligent iterative dialogue with each other and with elected officials. However, whether this input ends up shaping governmental decisions still rests largely in the hands of public officials.

## BACKGROUND: THE DIGITAL TOWN HALL MEETING IN PRACTICE

Efforts have been made to reinvent the town hall meeting using technology since the 1970s. In 1976, public officials in Reading, Pennsylvania began to televise public forums

and invited members of the public to offer comment or question via telephone (Becker, 1993). This approach can now be extended to allow public responses via the internet. One drawback of this model is that citizens are not physically present at such meetings.

The non-profit organization AmericaSpeaks is a strong proponent of the possibilities of digital town hall meetings that allow a high number of citizens to meet in the same physical space and engage in meaningful discourse. A digital town hall meeting uses technology to foster more meaningful interaction between citizens and public officials. During 1998-1999, AmericaSpeaks engaged thousands of Americans on the future of Social Security through a variety of interactive mechanisms, including five town meetings. It helped Hamilton County, Ohio to develop a comprehensive master plan based on town hall meeting with 1,300 citizens. In this article, I focus on two high-profile uses of digital town hall meetings, one of which is tied to the budget process in Washington D.C., while the other deals with highly symbolic city planning effort in New York City. By focusing on these two cases I develop an in-depth narrative that explains how the process worked and the relative the influence of technology-driven participation in each case. Readers wishing to learn more about AmericaSpeaks can visit: http://www.americaspeaks.org/.

In 1999, the mayor of Washington D.C., Anthony Williams, established a series of "citizen summits" to incorporate citizen involvement in the city government's strategic planning and budget process (Moynihan, 2002). The Office of Neighborhood Action was created to organize citizen participation that would link to district strategic planning. The Office initiated the goal-setting process prior to the citizen summit, facilitating two cabinet retreats that generated broad goals. Following the retreats, cross-agency task forces led by the Mayor's Office developed more detailed strategic plans around these broad goals. The Office of Neighborhood Action summarized the draft strategic plan into a four-page tabloid version to present to citizens both before and at the citizen summit. This was intended to inform the citizens to the basic issues in order to improve the nature of the dialogue that occurred.

The summit itself lasted over seven hours and included the development of district and neighborhood vision statements, discussion of citywide priorities and the draft strategic plan, and identification of action items to be carried out in each neighborhood. Efforts were made to ensure that all elements of D.C.'s diverse citizenry were reached—the summit was open to all comers, and summit literature and translations of the proceedings were available in Spanish, Vietnamese, Korean, and Chinese. Demographic surveys of the summit found it to be racially representative of the district's population.

The 3,000 people who attended the summit were divided into tables of 10; trained facilitators sat with each group to promote meaningful dialogue. The digital aspect of the meeting was reflected in two different kinds of technologies: networked laptop computers and wireless polling keypads. The computers recorded the messages developed at each table. As respondents sought to develop a consensus in addressing the issues raised and decide what messages would be entered into the computer, each group engaged in a discussion. The computers allowed the mayor to receive and respond to the messages during the forum. The polling keypads also allowed the mayor to ask citizens to vote on any question during any point of the summit, providing instantaneous results on large screens at the front of the room. Citizens prioritized citywide goals, which were ranked according to level of support. The data collected through the keypads was cross-referenced with demographic data based on a participant survey.

The input from the meeting served to shape the format and allocation of resources in the district's budget. The next budget request to the City Council saw each department identify strategic issues which were raised at the summit and codified in the strategic plan, subsequently requesting resources to pursue these goals. The meeting also pushed for suggestions of how to solve problems at the more local level, encouraging residents from different wards to register their opinion on neighborhood issues. The summit became the first step for more localized district/citizen planning efforts through a series of Strategic Neighborhood Action Plans. In addition, the head of each department had a performance contract and a public performance scorecard—a single-page list of the key performance targets and measurement of success or failure in achieving those targets–that incorporated goals raised at the summit of relevance to the department.

Following the summit, the revised strategic plan was presented to citizens at a similar forum on January 29, 2000, where 1,500 citizens (60% of whom had participated in the first summit) had the opportunity to hold the mayor accountable for the revisions made and offer final messages before the plan was completed. The final version of the strategic plan bore the clear imprint of the meetings. The front section of each issue-driven chapter identified specific priorities raised at the citizen summit and related strategic goals, action items, and performance targets.

Another digital town hall meeting occurred in New York City in the aftermath of 9/11 (Moynihan, 2004). Authorities sought a way to incorporate public input into the planning process for rebuilding the site of the World Trade Center. AmericaSpeaks was hired to run two meetings—one for the Civic Alliance, a nonprofit coalition of civic, labor, business and environmental groups, and

*Table 1. Reinvigorating the town hall meeting*

| *Critiques of traditional town hall meeting* | *Lessons of digital town hall meeting* |
|---|---|
| Slow, expensive and time-consuming to listen to large numbers of citizens | Digital meetings require careful organization and resources, but can facilitate input of thousands in a single meeting |
| Not representative of citizenry; dominated by middle and upper class | Undertake extensive outreach; track aspects of representativeness through poll of participants |
| Participants driven by self-interest rather than community problems; unable to make tradeoffs; provide mixed messages to government | Structure presentation of questions to force consideration of wider issues and tradeoffs between different policies; generate discussion and seek clarity through polling of ordered preferences |
| Dialogue is not iterative; citizens voice grievances in disconnected way | Can create iterative dialogue through facilitation of small-group discussion, ordering of questions and responses to follow-up questions on polling keypads |
| Participation primarily symbolic to provide sense of legitimacy to decision process | Level of influence depends on willingness of public officials to listen; however, direct involvement of officials, media coverage of events and clarity of citizen preferences can put pressure on government |

academic institutions, and the other for the Lower Manhattan Development Corporation, a specially created public body charged with planning the redevelopment of lower Manhattan. The events became know as Listening to the City. The first meeting in February 2002 featured over 500 citizens, while the second, in July featured over 5,000.

The impact of the second meeting was striking. The audience was presented with six designs for replacing the World Trade Center. All were criticized as being mediocre efforts, resulting in a dense and uninspiring thicket of buildings that added little to the city skyline. Cheers went up as low polling results for each design were projected on large screens at the meeting. There was consensus between participants that a spectacular and symbolic design was required to reinvigorate the New York skyline. While disagreement may have existed on what this design might look like, participants made it clear that it was not contained in the six designs presented. They made it so clear, in fact, that at the end of the meeting representatives of the Lower Manhattan Development Corporation, and the World Trade Center owner, the Port Authority, promised to offer new designs based on an international worldwide competition. The meeting was covered by local, national, and even international media. A New York Times editorial page (2002) concluded that "public opposition saved the city from the ordinary."

While in some respects Listening to the City was a success, participants did not have the degree of influence on the final design that they wanted. After the next rounds of designs were invited, the finalists were publicly displayed, and the public was invited to offer comment, but another high-profile digital town hall meeting was not organized. Public officials and especially Governor George Pataki felt pressure to choose a design quickly. Even after a specially-created committee selected the Studio Daniel Libeskind design, this too was subject to a redesign by David Childs, the architect of leaseholder Larry Silverstein. A key change demanded by Silverstein was more commercial space, which was one of the problems that the participants of Listening to the City had identified with original designs. The resulting design, which became known as the Freedom Tower, incorporated portions of the Liebeskind design, including a towering spire, but in most other respects reflected the preferences of Childs. In July of 2005, the Freedom Tower was redesigned once more. The New York Police Department had argued that the base of the building needed to be further from the street and feature stronger fortification due to concerns about possible truck bombs. The resulting design by Childs essentially abandoned the key motifs of the Libeskind design, with the exception of the symbolic 1,776 foot height.

Listening to the City represented the maximum moment of public influence in the process, rejecting a constrained choice of mediocre designs. But in terms of selecting the final design, the public was excluded. Even if we accept Libeskind's claim that his original design had the imprimatur of public approval by virtue of emerging from a new selection process necessitated by the Listening to the City meeting, this design was increasingly relegated to the preferences of Silverstein and Childs. The two rounds of redesigning the Freedom Tower occurred behind closed doors and were presented to the public as a fait accompli.

## FUTURE TRENDS

What lessons do the cases offer about the future of digital town hall meetings? Perhaps the best way to consider these lessons is to reexamine the criticisms of the traditional town hall meeting and see how the digital town hall approach served to overcome these problems. Table 1 presents this comparison, and while it is clear that the digital town hall meeting does not ensure perfect participation, it does offer an improved option for governments intent on taking citizen input seriously.

Perhaps the most obvious lesson is that technology can reinvigorate the traditional town hall meeting. The experience of the citizen summits in Washington D.C., and to a lesser extent Listening to the City, suggest it is possible to bring together a representative group of thousands and use technology to allow them to have an interactive dialogue with public officials. Trained facilitators played a key role, encouraging members of the small groups to contribute during the day-long experience. The use of specific topics, computer feedback, and polling summarized the results of these conversations into concise points.

In both cases, the need for the legitimacy offered by visible and meaningful public participation made public officials willing to try the digital town hall. Mayor Anthony Williams was seeking to change Washington D.C.'s image of corruption and incompetence. In New York, public officials faced an unsolicited outpouring of public opinion and design suggestions that reflected the citizens' sense of loss and emotional connection to this decision. To have ignored the public completely was unthinkable.

There are differences between the cases also. The citizen summits were more representative of different demographic groups than the Listening to the City meetings, especially in terms of race and income. Habermas (1989) has argued for the importance of including all affected by a decision and disregarding social status of the participants when organizing citizen feedback. This suggests the importance of active and targeted outreach in ensuring a representative sample of the citizenry. More broadly, the cases point to the need for careful organization to facilitate citizen input with digital town hall meetings.

More importantly, the citizen summits had greater influence on decisions than Listening to the City. In Washington D.C., the mayor used the digital town hall meetings multiple times, first to craft a strategic plan, and then to seek public approval of this plan. In the case of the Listening to the City, public involvement was limited to early stages of the decision process, due to perceived time pressures and worries of another rejected design. Perhaps the differences are also explained somewhat by the nature of the decision at hand in both cases. Strategic plans are essentially statements of broad policy goals, something that the citizenry is fundamentally qualified to comment on (Hellström, 1997). Officials may have been less willing to trust qualifications of the public with architectural choices of design. In addition, the role of Silverstein meant that private actors had a much greater degree of control over the decision outcome in New York.

This difference between the cases reflects that despite the benefits of the digital town hall there is no guarantee that the input of these meetings will have a direct influence on decision outcomes. A key criteria for assessing participation is whether it has any meaningful impact on decisions. As with any type of citizen input, the influence of digital town halls depends on the willingness of public officials to take this information into account (Moynihan, 2002).

## CONCLUSION

What can we conclude about digital town hall meetings? An optimistic perspective assumes that as the concept becomes better known, as technology declines in cost, we can expect to see this form of participation increase. The digital town hall meeting requires greater resources and effort on the part of government than alternative technological routes to participation (e.g., online discussion groups or polling). But it also has the virtues of the traditional town hall model—citizens coming together to share their views in person, voicing their concerns, and interacting with each other and the officials that represent them. In this respect, it is an innovation that seeks to use technology not to replace a traditional practice of democracy, but to make it more effective.

A more pessimistic perspective regards the technological sophistication of the meetings as irrelevant, offering symbolic value but little else. From this perspective, public officials will schedule and listen to such feedback when it suits them. The pessimistic view understates the real value that technology can bring to managing the logistics of town hall meetings, but it does point to a critical issue. Ultimately, the success of these meetings depends on governmental willingness to use and listen to the results of digital town hall meetings.

For researchers, three obvious questions emerge: what explains the adoption of these innovations? If they become common and move beyond the novelty stage, will they still manage to incorporate enthusiastic citizen involvement? Finally, how do the results of these forums ultimately shape public decisions, if at all?

## KEY TERMS

**Digital Town Hall Meeting:** A town hall meeting that uses digital technology to foster more meaningful interaction between citizens and public officials.

**Facilitators:** In digital town hall meetings, trained facilitators help citizens create meaningful and coherent feedback.

**Participation:** Ways in which citizens can provide direct feedback to government. Participation advocates argue for such involvement beyond the simple act of voting, and suggest that technology can facilitate participation.

**Performance Scorecard:** A performance scorecard is a short summary of key performance targets and measurement of success or failure in achieving those targets. Scorecards can be created by governments or third parties to track whether citizen goals are being met.

**Polling Keypads:** In digital town hall meetings, wireless polling keypads can be used to facilitate rapid, large-scale and iterative interaction between citizens and public officials. Individuals respond to questions by selecting from a range of alternatives using the keypads.

**Strategic Plans:** Strategic plans identify the mission, values and goals of a government, agency or program. Because they involve statements of values rather than matters of technical expertise, they are an appropriate venue for participation.

**Traditional Town Hall Meeting:** A public hearing where citizens present their views to public officials. Criticized as being non-representative and failing to produce meaningful dialogue.

# Citizen Relationship Management

**Alexander Schellong**
*Harvard University, USA*

**J. W. Goethe- University**
*Frankfurt am Main, Germany*

## INTRODUCTION

Citizen relationship management (CiRM) refers to a cluster of management practices, channel, and IT solutions that seek to use private sector customer relationship management (CRM) in the public sector. Goals can be improving citizen orientation, better accountability, and changing the citizen government relationship. I begin with an overview of citizen orientation in government and the emergence of CiRM. The following section starts with a look at the underlying principles, goals, and components of customer relationship management. Accordingly, there is an in depth discussion and definition of citizen relationship management. Aspects such as the citizen government relationship, technology, public participation, and organizational changes are addressed. Finally, future trends and conclusions are drawn.

## BACKGROUND

It is one of the central interests of government to improve the relationship with its constituents. Public administration (PA) is often ignored in the discussion of the citizen government relationship although it plays a vital role in how the government exerts its role within society. Administrative practices and capabilities are often subsumed within the general discussions of government and governmental obligations to citizens. In fact, with a few exceptions, philosophical foundations of the administrative component of government are seldom discussed at all (Rohr, 1986; Waldo, 1984). On average, citizens have more contacts with public servants than their elected representatives throughout their life. They experience policies and the structure of the state through their interactions with the public administration, the latter being for instance law enforcement or public service agencies. Local public administrations are a strong factor for trust building in the discussed relationship.

The intense competition in the private sector and parallel service sector growth has fostered research and focus on customer management related topics (Bretthauer, 2004; Laing, 2003). Furthermore, private sector customer service orientation had an influence on expectations towards public sector services.

Improving public services can be tracked back to the beginning of the 20th century. Throughout the late 1970s and since the emergence of neo-economic new public management (NPM) and its components like total quality management (TQM) (Berman & West, 1995), a customer-driven government has been on the agenda for public servants and researchers (OECD, 2003; Osborne & Gaebler, 1992). This is due to the fact that customer demands are perceived as an agent for organizational change (Lowenthal, 1994). Today, NPM has become a normative model, especially how we think about the role of public administrators, public services, and their goals (Denhart & Denhart, 2003). In fact, as shown by Schedler (2003) or Hood and Peters (2004), there is no common way or understanding of NPM. Despite components like TQM, which is a set of management and control activities based on statistics, leadership of top management and involvement of all departments and levels of employees aimed at quality assurance and citizen orientation, NPM tended to have a one-sided, internal focus on issues such as economic controlling (Traunmüller & Lenk, 2002). This might also relate to NPM's missing theoretical foundation (Frederickson & Smith, 2003; Lynn, 1998).

Customer approaches to government service increased in the 1990s (Albrecht, 1993; Gore, 1993; Kißler, Bogumil, Greifenstein, & Wiechmann, 1997; Swiss, 1992. Especially true with the managerial/consumerist notion of deconstructing citizens as a consumers raised concerns among researchers (Barnes & Prior, 1995; Hood, 1995). A major objection is that the citizen government relationship is redefined as a passive commercial transaction, rather than an interactive political engagement. It strengthens the idea of elitist politics and reduces a complex relationship to a simplistic voluntary one (Box, 1999). Furthermore, it supports short term politics undermining long term political goals (Swiss, 1992).

The emergence of electronic government (e-government) in the late 1990s added new momentum to the NPM oriented reforms and research on public services improve-

ment through online applications (Abramson & Morin, 2003; Ashford, Rowley, & Slack, 2002; Caldow, 1999; Cook, 2000; Fountain, 2001a; Gisler & Spahni, 2001). I define e-government as the use of information technology to support government operations, engage citizens, and provide government services (Dawes, 2002). ICT neutralises time, spatial, and hierarchical limits of the public administration and public services.

Concurrent with these developments, first publications on public sector customer relationship management appeared (Accenture, 2003; Bleyer & Saliterer, 2004; Hewson Group, 2002; Freeland, 2002; Janssen & Wagenaar, 2002; Kavanagh, 2001; Richter, Cornford, & McLoughlin, 2005; Sharpe, 2000; Souder, 2001; Trostmann, 2002). At this point, it is neither possible to identify a clear research stream on CRM in the public sector, an adapted model or theoretical framework nor to identify the broad existence of public managers responsible for CRM. Other terms used are constituent relationship management or citizen relationship management. This article employs the term citizen relationship management.

## CUSTOMER RELATIONSHIP MANAGEMENT

Customer relationship management can be defined as a holistic management approach, enabled by technology with a broad customer focus, to start, maintain and optimize relationships and to make customers more loyal/ profitable. CRM requires a customer centric business philosophy and culture to support effective marketing, sales and service processes. This is an aggregation of existing perspectives on CRM (Payne & Frow, 2004). For a detailed overview of definitions and research streams see: (Zablah, Bellenger, & Johnston, 2004). Some authors emphasize a single technology solution, others a series of customer-oriented technology solutions and the final group stresses the holistic approach.

CRM's main goal is to optimize the customer lifetime value (CLV) within the customer lifecycle (Homburg & Bruhn, 2005). Customers are long term assets and thus major factors for competitive advantage (Peppers & Rogers, 2004). Further advantages are supposed to be a reduction of marketing costs, strengthening customer loyalty and satisfaction, reduced price sensitivity, new opportunities for up- and cross-selling and erect exit barriers (Janssen & Wagenaar, 2002).

CRM builds on principles of relationship marketing (Berry, 1983). Unlike transaction marketing which focused on a one time transaction (selling process), relationship marketing is about attracting, maintaining and enhancing customer relationships. Other influences come from TQM, business process reengineering (BPR) (McAdam & Donaghy, 1999), and knowledge management (KM) (Alavi & Leidner, 2001; Grover & Davenport, 2001; Nonaka, 1994. Note that TQM and BPR are already included in NPM. Several trends like ICT developments, rigid global competition, and growing knowledge in marketing research (i.e., one-to-one marketing (Peppers & Rogers, 1993), permission marketing (Godin, 1999)) had an impact on the evolution of CRM.

Besides its strategic/organisational component, customer relationship management can be divided into three parts: collaborative CRM, operative CRM, and analytical CRM. Collaborative CRM is focused on channel management. Channel options are:

- Shop/outlets/counter
- Internet
- Telephony (call center)
- Mobile
- Sales force

Collaborative CRM involves decisions about appropriate/ economic channel combinations, keeping single customer view and offering a consistent customer experience across channels. Particularly, electronic channels are very attractive as their self-service potential offers the chance to reduce costs (Kracklauer, 2003).

Processes in the back and front offices are integrated through operational CRM. Software applications can be enterprise resource planning (ERP), sales automation (SA), computer-aided selling (CAS) or knowledge management systems.

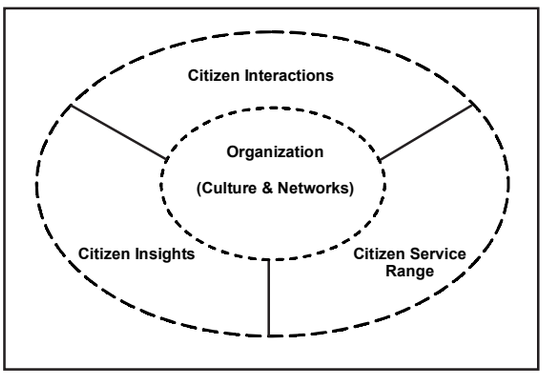
Organization and interpretation of customer data through data mining or OLAP and creation of a 360 degree view on customers are within the area of analytical CRM. Data warehousing, database management and data mining systems are an important part of the technological component of CRM.

Basic principles of CRM are personalization (products, information, services), integration (planning processes, business process reengineering, product development, collaboration), interaction (channels, long-term communication, surveys), and selection/ segmentation (identify the top 20% of customers who make 80% of the profit (pareto rule), termination of unprofitable customers). Moreover, quality/performance measurements, change management, and a strategy/measures promoting customer oriented culture are vital to any CRM concept or project.

Figure 1 summarizes these principles and visualizes the importance of the holistic approach of a CRM/CiRM. Thus, CiRM is about:

- Organization (change)
  - Culture

*Figure 1. The CiRM framework*



- Processes
- Structure
- Responsibilities
- Networked governance
- Cross-boundary collaboration

- Interactions
  - Channels
  - Participation
- Service range
  - Offering
- Insights
  - Analysis
  - Segmentation
  - Personalization
  - Performance measurement

## CITIZEN RELATIONSHIP MANAGEMENT (CIRM)

While identifying and retaining the most profitable or most costly citizens in a commercial sense would contravene against basic principles of social justice, delivering high quality citizen oriented public services is a government policy.

Citizen relationship management (CiRM) can be defined as a strategy enabled by technology with a broad citizen focus, to maintain and optimize relationships and encourage participation. This represents a working definition because CiRM is an emerging research area. CiRM is not a theory but rather a management concept. However, it is possible to build a theory on its impact which has yet to be done.

The main goal of CiRM is to create and optimize the relationship with citizens by embedding their opinions throughout public administration instead within a certain processes/ agency, certain hierarchy level or elected officials. Citizens are a valuable asset in service planning and provision (i.e., cost reductions). A responsive, accessible and citizen focused public administration that creates opportunities for participation can build a close citizen relationship strengthening democracy and legitimating its role.

Though, understanding and application of CiRM by PA practitioners is currently different than the academic discussion or business claims. Reviewing projects in the U.S. and UK, CiRM is mostly applied in conjunction with call centers (311) or citizen service centers (citizen interactions, citizen service range) with a focus on it's technological component at the local level. Technological collaboration across agencies and jurisdictional boundaries occurs, however change and collaboration on the organizational level or other aspects of CiRM is in its early stages.

Miami/Dade County is one of the first cases of a multi-jurisdictional collaboration and a multi-channel, closed loop environment with access to information and services of over 30 municipalities and their agencies in its final level of development. To achieve this, the county takes a gradual approach by bringing in new partners one at a time to cope with any inherent challenges and risks.

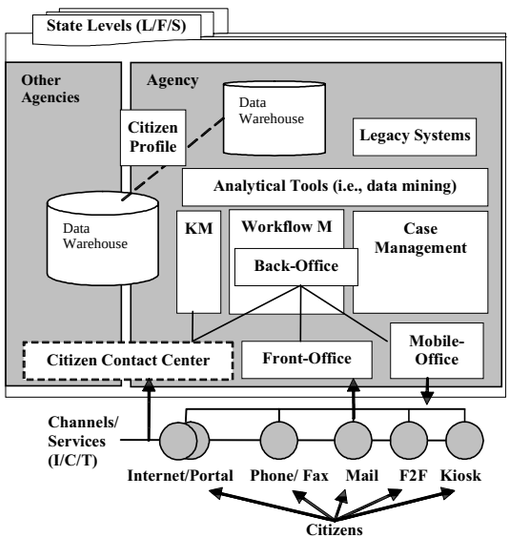
## Citizen Government Relationship

Before addressing CRM a deeper understanding of the citizen government relationship is needed. It can be reached through an analysis of the reciprocal factors and circumstances of both actors. In fact, psychology of the citizen as a customer/consumer of public services (demand side) as well as public service operations from citizen perspective is not very well researched (Reddick, 2005). To learn more about citizens, public administrations use surveys, focus groups and to a lesser extent citizen counsels. Unfortunately, most of (80%) of this kind of market research serves mainly to reinforce existing conclusions which is also the case for private businesses (Deshpande, 2001).

A major difference exists between customer business and citizen government relationships that offer interesting CiRM scenarios. Citizens in most countries are loyal to their government and public administration (Fountain, 2001b), something that would be a dream for any business. Citizens consider obligations to other, present and even future citizens. They have the moral and legal right (and obligation) to build or to participate in the institutions that provide public services. This is not the case for consumers.

Finally, some questions remain unanswered. Could CiRM help improving public participation? What do citizens think about their roles and segmentation? Are satisfied citizens more active or passive participants?

*Figure 2. CiRM technology framework*



## Contributions of a CiRM Technology Framework

A CiRM technology framework (Figure 2) enables public managers to respond in an accurate and appropriate manner to citizens' inquiries. Public servants have access to citizen profiles and knowledge base while they are in contact with constituents regardless of the channel or state level (local, county, federal state, federal). Currently most relevant channels for information (I), communication (C), and transaction (T) type services are counter/ one-stop service centers, inbound telephone, Web self-service, automated email response and kiosks.

Administrators can build new and real-time databases for future orientation. By cross-referencing citizen surveys with service usage and other related data from multiple organizations they can offer more personalized information, services and identify emerging problems (O'Looney, 2002), process or policy improvements. Since this would be an iterative process it fosters innovation.

## Citizen Data

According to a study by Accenture, a consulting company, two thirds of government agencies are not using citizen data they are collecting (Accenture, 2001). Citizen data can be grouped into profile data (i.e., name, address, age, or education), service data (i.e., complaints, suggestions, or questions), contact data (i.e., contact person at agency, date of contact) and service data (i.e., type of service, usage time, costs). Research by Schellong and Mans (2004) revealed that citizens would even allow a personal profile to be saved and shared across public authorities. Those are: name, address, date of birth, education, and the current employment status. Personal history of utilized public services (25%) and personal income (12%) are barely accepted for citizen data profiles. Nevertheless, citizens have more trust in government than in private sector internet services. Information sharing is absolutely necessary to realize the desired benefits of such systems. However, local authority data silos, laws, regulations and culture pose difficult obstacles to overcome (Bannister, 2001).

## Citizen Participation

CiRM attempts to integrate citizens into PA. Citizen participation is two-fold. First, it means self-service/ co-production. The more automated and standardized (by heavy use of ICT), services can be organized, the more money can be saved by PA and the more work is done by citizens. Organized well, it can raise satisfaction levels as experience from other sectors (i.e., banking) shows. However, design flaws will generate dissatisfied customers using other channels. Efficiency gains can be neutralized if the streamlining potential of ICT in conjunction with self-services is mainly used to reduce the work force in the PA. A case manager that has to work on comparative more cases can be equal or less citizen oriented (in terms of response time, case handling) than before.

The second form of participation is citizen feedback/ complaints on service provision (main focus), policies and any form of political issue (sub focus). Citizens reactions are good indicators of policy outcomes (Vigoda, 2002). Analytical CiRM might be able to provide the technical tools to analyze them. Unfortunately, research on citizen participation draws pessimistic conclusions on the willingness of citizens for continuous engagement (Roberts, 2004; Vries, 2000. In addition, many public administrators believe that greater citizen participation increases inefficiency, delays, and red tape (King, Feltey, & Susel, 1998).

## Organizational Changes

Beyond a change of the external relationships the internal relationships change. Agencies, departments, and public managers have to collaborate closely. Consolidations and changes of processes can be necessary measures. Individuals and organizational units need to treat each other like customers to be consistent with the intended cultural change of CRM and seamless service environment. Additionally, CiRM systems can give clerks low in

the hierarchy more accountability as the rules they are to follow can be embedded within the software and not the decision maker (Fountain, 2001a). As claimed by Janowitz and Delany (1957) CiRM systems in combination with other applications might finally connect the substantive knowledge (i.e., clients, face-to-face contacts) of lower level employees with the functional knowledge (i.e., strategy, communication, management) of upper-level administrators or policy makers and avoid their isolation and at the same time give them clear information.

However, a knowledge-centric system and organization requires a front-line worker who has a broad understanding of goals, strategies, stakeholders, and how their work fits in this context. A term being used is system-level bureaucrat (Reddick, 2005). How these people capable of executing such a new role can be attracted to public administration and how upper-level administrator will react to sharing the power of "knowing" has yet to be determined. Furthermore, transparencies through reorganization and ICT will cause political battles over such issues like ownership of data (Fountain, 2001a).

## Private sector CRM lessons

Technology facilitates improving citizen orientation or satisfaction, yet it is not required. The same conclusion is true for the private sector CRM (Rigby, Reichheld, & Schefter, 2002). Improving office hours, accelerating service processes through redesign, training employee friendliness are just some "offline" examples that have and had a positive impact on citizen satisfaction/citizen orientation (Bogumil, 1997). CRM does not mean that the PA starts offering new services demanded by the citizens and identified through data base analysis or market research. In the medium term, it rather supports tailoring existing services to citizens needs.

Recent empirical studies suggest that CRM technology only has a moderate to weak impact on overall success of companies' relationship building efforts (Reinartz, Krafft, & Hoyer, 2003). Reported failure rates of private sector CRM solutions can be up to 70% (Verhoef & Langerak, 2003). Interestingly similar success rates (20-30%) are reported from public sector TQM projects (Bennington & Cummane, 1997; Kelemen, 2000).

The organizational challenges inherent in any CRM initiative and the diversity of people involved pose another threat (Agarwal, Harding, & Schumacher, 2004). A large number of internal and external stakeholders creates accountability problems and makes behavioural/organizational change difficult. Many projects fail because of the lack of coordination between strategy and processes. Not establishing clear business goals before launching a CRM effort is one of the most common and important source of these problems (Ebner, Hu, Levitt, & McCrory, 2002). Public Administrations need a broad understanding of all processes and the demand side (here citizens). Continuous Leadership and communication by elected officials and executive administrators is a key to success even when there is strong opposition caused by the inherent changes over a longer period of time.

The 311/CiRM initiative in New York City is such a case. The 22 Mio USD project was planned and implemented during a budget crisis, fire stations were closed down and more than 20 administrative call centres were consolidated, but the success, especially from the citizen side, was so overwhelming that neither the media nor other political actors opposed.

Costs are as critical to companies as they are to cities, counties or federal states with tight budgets. It takes up to 36 months until a CRM strategy/system is implemented—a rather long time lag in the political sphere. Costs in the private sector usually run from 60 to 130 Mio. USD (Rigby, Reichheld, & Schefter, 2002), (Ebner, Hu, Levitt, & McCrory, 2002). Costs for a public 311 call-centres for cities like Miami, New York City or Chicago are around 15-25 Mio USD. Therefore, sunk costs have to be considered before a CRM solution chosen. Switching between systems and solutions is merely impossible and not economically justifiable towards taxpayers. Furthermore, a rise in quality of service and information transparency can lead to an increase in its use, raising costs by enlarging facilities or staff.

CRM systems rely heavily on databases and establishing connections to legacy systems (Foss, Stone, & Woodcock, 2003). To be efficient, information systems need to exchange data horizontally and vertically on all state and agency levels. Front and back-offices have to be integrated to offer a "closed loop" environment. A certain level of standardization is required. There needs to be more research on how far (state levels, standardization) and where (authorities, services, type of data) this is feasible. The idea runs contrary to the general understanding of federalism and call for subsidiarity particularly at the local level. Virtually, institutional boundaries would be removed. This conclusion is also true for e-government. However, the chances of creating more, rather than cutting red tape are high if we consider a paper by Peled (2000).

A government connected at all state levels (a term being used is joined up government (National Audit Office, 1999; Pollitt, 2003) and data bases with citizen profiles is on the one hand much more efficient and implies major improvements but raises a vast array of questions from a democratic viewpoint. These include questions on controlling data access and how to protect it and again on the effect of the role of the citizen within the state. At its very core, such a scenario also underpins the collectivist

*Table 1. Major differences between private and the public sector CRM environment*

| Private Sector CRM | Public Sector CRM |
|---|---|
| Competition (some) | Monopoly |
| Market orientation | Jurisdiction |
| Million relationships | Billion relationships |
| Homogeneous product range / controllable quantity | Huge number of heterogeneous products (services) / uncontrollable due to political decision making |
| Personalization | "One size fits all" |
| Segmentation (Pareto rule 20-80) | Segmentation possible/no termination of unprofitable citizens |
| Processes flexible | Processes static |
| Budget/sunk costs | Budget/sunk costs |
| Legacy systems (IT) | Legacy systems (IT) |
| | Poor service image |
| Organization culture | Organization culture |
| | Human resources (lack of knowledge, salaries not competing with private sector) |
| Laws | Laws |
| | Federalism |
| | Political influence (planning cycle) |
| Profit orientation/maximising the shareholder value | Democratic understanding |

concept of citizenship, which places primary needs on the broader needs of society and social justice rather than the narrow needs of individuals. Another are of concern is that if citizens and their demands are better understood politicians might misuses this as a source of power. Table 1 summarizes major differences between in the private and the public sector and the constraints on the use of CRM.

## FUTURE TRENDS

Citizen Relationship Management offers new opportunities for local government (borough, city, county) in the next years. Cases like New York City or Miami/Dade County are first indications where developments are heading. In general, there is not enough data available. Besides various operative aspects like channels, data analysis or technologies research needs to focus on inter-organizational arrangements and the use of information in decision making. Does CiRM and e-government lead to a new form of government and governance or are they just enhancing the status quo?

## CONCLUSION

I argued that former attempts of improving citizen orientation in the public sector have partly failed. E-government and CiRM share many objectives, tools, implications and to a certain extent the role of ICT. Indeed, CiRM adds a clear customer strategy to e-government. As demanded by Marshall (1990) CiRM and its bidirectional channel character can enhance citizenship in the administrative process. So far e-government falls short of providing researchers and professionals with a concept on creating a citizen oriented organization and public services. This is where CRM fills the gap. Implicitly or explicitly, ICT can not be the main driver of internal change processes. However, the use of ICT combined with external pressures (constituents) has change potential but may also fail due to the same reasons NPM did not meet its expectations: the logic of bureaucratic politics and multiple stakeholders within the government sphere. Instead of theoretic disquisitions on a brave new CiRM or e-government world we need more empirical evidence on many aspects of public administrations and public services to approach the obstacles in an appropriate way. The most pressing issue is the structural change of the state which is inevitable if we want to truly benefit from CiRM, ICT and other concepts. In this regard, many questions concerning understanding, ownership, control, use, responsibility, collaboration, laws, processes, and costs have to be answered by research.

## KEY TERMS

**311:** The number was approved by the U.S. Federal Communications Commission in 1997. It is a single point of contact call centre for all non-emergency public services.

**Citizen Relationship Management (CiRM):** A strategy or management approach enabled by technology with a broad citizen focus to maintain, optimize relationships and encourage citizen participation.

**Customer Lifetime Value (CLV):** Model to measure the customer value over time. Present net value and expected future value minus costs associated with a customer.

**Customer Relationship Management (CRM):** A holistic management approach enabled by technology with a broad customer focus to start, maintain, optimize relationships and make customers more loyal/profitable. CRM requires a customer centric business philosophy and culture to support effective marketing, sales. and service processes.

**Enterprise Resource Planning (ERP):** Software solution to assist organization with all aspects of operational planning

**Online Analytical Processing (OLAP):** Approach and tool to analyze complex queries of multidimensional databases. It belongs to the broader family of business information tools which include data mining or relational reporting.

**Total Quality Management (TQM):** A set of management and control activities based on statistics, leadership of top management and involvement of all departments and levels of employees aimed at quality assurance and citizen orientation.

# The Civic within the Democratic Project in the Digital Era

## INTRODUCTION

In 1819, Benjamin Constant gave a speech at the Athenee Royal in Paris on how conceptions of liberty changed from the time of the Athenian polis to 1819. After a period of revolutionary upheaval in the United States and France, observed that in the ancient world citizens defined liberty in terms of their positive participation in the affairs of government, while in the modern world, citizens define liberty in terms of the freedom to secure the desires of their private lives. Constant (1988, p. 325) argued that "in the kind of liberty of which we are capable, the more the exercise of political rights leaves us time for our private interests, the more precious will liberty be to us." The additional point that can be inferred from Constant (1988) is that democracy is an unfinished and on-going project that needs constant and continuous attention (Habermas, 1996). Others challenge Constant's (1988) positive outlook and argue that the legitimacy of modern governments is in critical decline, citing falling public confidence and flagging interest in the democratic process (indices which include the low percentage of the electorate that votes; mistrust of politicians; cynicism about the political process and public scandals).

Certainly one modern day determinant that will influence the shape and identity of democracy is the regeneration of information and communication technologies (ICT). The information era is based on the pivotal role of ICT, which now pervades all sectors of society—the public sector as well as the commercial and voluntary sectors (van Dijk, 2001). ICT-based applications provide a new way for citizens to participate in the democratic process through improved

- **Interactivity:** Two-way communication/debate between citizen and government
- **Speed of Communication:** Offering the possibility for politicians to rapidly obtain impressions of citizen's opinions
- **Reach of Scope:** Providing links from politicians to groups with which they were not previously in contact

On the positive side, ICT enthusiasts foresaw the Internet creating a public space free of interference, both from government control and commercialism. They proposed that new "information highways" facilitated by ICT will open alternate pathways to democratic participation, namely electronic democracy comparable with Jefferson's (1984) vision of 1834, involving a network of highways which would open new lines of communication between the American States cementing their union by "new and indestructible ties." The Jeffersonian vision is captured by today's "amplification theory" of technology, holding that ICT enables citizen participation, inducing qualitative changes in society (Agre, 2002). However, ICT also poses threat, a new form of control. Electronic surveillance of the work place is particularly effective because it is *reflexive*—"management" monitors workers as well as itself (Whitaker, 1999, p. 40). At the societal level, it creates and re-creates new structures and new futures. These newly emerging structures, although variously named as "Virtual Feudalism" (Mowshowitz, 1997); "Post-National State" (Whitaker, 1999); "New Serfdom"; "IT-Harems" (Korac-Kakabadse, Korac-Kakabadse, & Kouzmin, 2000) or "New Shoguns," all depict increasingly invisible, all-seeing, all powerful control mechanisms, first envisaged by Bentham's 1 Eighteenth-Century (1787/1995) "Panopticon," depicting citizens loss of freedom. The Panopticon vision of totalitarian, electronic control, is a compelling metaphor because it represents the architecture of modern power (Whitaker, 1999, p. 28). In the

*Table 1. Fundamentals of the Democratic project (Compiled from Kakabadse et al., 2003)*

| Components | Role/Function |
|---|---|
| Democratic Principles or Values | Underlying principles or values which define democracy--such as liberty or rights (*liberté*), equality (*égalité*), communality or brotherhood (*fraternité*), and other socio-economic values. |
| Democratic Processes | Political and governing processes which uphold and support democratic principles--such as free elections, voting, referenda, and participation. |
| Democratic Organs | Mechanisms that support the implementation of democratic processes—legislative, executive, and judiciary. |

information age, the global political economy (globalizing markets) and its major tenants—corporate business and its representatives and lobby groups, exert unprecedented power on sovereign states to introduce "business-friendly policies" which, in turn, lead to (Korac-Kakabadse et al, 2000; Mowshowitz, 1997):

- A retreat of the State (via privatization, outsourcing, and the hollowing out of public functions) and an increase delivery of public services by private parties which exercise authority in their own name rather than in the name of the law which transcends their own power
- A blurring of lines between public and private sectors
- Growing disparities between wealth and poverty and between and within regions and communities (e.g., fortress and affluent suburbia versus desolated quarters)
- A growth of private security and "private justice"

These increasingly business-friendly policies lead to corporate control over impoverished, sovereign governments and the transformation of "citizens" into "customers." The process of being rendered a "client," diminishes the value of citizen rights and equity, as clients with higher disposable incomes can afford to procure higher levels of rights and opportunities. A growing literature highlights that

ICT-mediated democratic relationships are not challenging the fundamental ordering of democratic processes but, rather, traditional bureaucracies are being replaced by "infocracies" as explained by technology "reinforcement" or "enactment" theory emphasising how ICT further reinforces existing power and social control structures (Agre, 2002; Fountain, 2001; Korac-Kakabadse, 2000). New ICT reproduces and strengthens institutionalised socio-structural mechanisms, "even when such enactments lead to seemingly irrational and ostensibly sub-optimal use of technology" (Fountain, 2001, p. 5).

## BACKGROUND

### Models of Democracy

General public opinion is the both the cause and the effect (i.e., the vehicle and the organ) of legislative omnipotence or the power to govern. The opinions of average citizens take on a public significance which is of real consequence in a State in which the idea of popular sovereignty is operative. In discussion about democratic models of governance, Kakabadse et al. (2003) distinguish between *democratic principles*, *democratic processes,* and *democratic organs* (see Table 1), arguing that in order to uphold democratic principles there is a need to re-invent the democratic process.

Appropriate for the ICT age, Kakabadse et al. (2003) identify four distinctive models of Electronic Democracy (see Table 2).

However, while the first three models of electronic democracy are increasingly being implemented in various forms in a variety of countries, they have been adapted to the existing models of democracy (see Table 3). In contrast, the fourth form of democracy, Civil Society, is an inspired form, which resembles Athenian participatory democracy mediated by electronic means**,** namely ICT mediated deliberative democracy.

### Media Control

Habermas (1996) posited that the "public sphere" can politically function only if citizens accommodate or generalise their interests together so that "state power is

*Table 2. Models of electronic democracy (Compiled from Kakabadse et al., 2003)*

| Model | Example | Characteristics |
|---|---|---|
| Electronic Democracy (political communication in the public sphere facilitated by ICT) | Electronic Bureaucracy | Electronic delivery of government services which support the existing model of government to government (G2G), government to citizens (G2C), and government to business (G2B). |
| | Information Management | Electronic means which enable citizens to register their views on particular issues (electronic registers, e-mails). |
| | Populist | Electronically-supported inter-activity as a policy process (town halls; forums and referenda) and includes advocacy, lobbying, and public consultation. |
| | Civil Society | Transformation of political culture to participatory democracy or inter-active democracy. |

*Table 3. Models of democracy (Compiled from Finer (1999); Kakabadse et al., 2003)*

| Model | Example | Characteristics |
|---|---|---|
| Athenian Participatory Democracy | Athens in 5th Century BC | • All free male citizens, over 30, directly participate in the decision-making process and the passage of law<br>• Citizen initiative<br>• Only a genuine majority of the population can make a law which really maximizes the democratic nature of rule<br>• Separation and division of powers between four organs (*Ekklesia* or Legislative, *Boulé* or Executive, *Magistracies* or Administration and *Dikasteries* or Courts)<br>• No political parties |
| *Respublica* | Roman Republic | • Membership to governing bodies depends on a property qualification—an oligarchy of aristocratic families<br>• No political parties but groups of leading political figures and their followers (*Optimates, Populares*)<br>• Constitutional democracy with mixed separation of powers<br>• Supernumerary organ—the *Senatus Consultum* (consultative)<br>• Organ of two assemblies—*Comitia Centuriate* and *Comitia Triubta*<br>• "Anti-organ" of two assembles—*Tribunals* and *Coniclium Plebus* |
| Direct Democracy (government by the people) | Switzerland (since 16th Century) | • Federal states where Cantons (provinces) have more responsibilities than the Confederation<br>• Legislating by *Plebiscite* (initiation by high level of state body), *Referendum* (permanent constitutional institution that can be initiated from top or bottom: administrative, executive or parliament) and<br>• *Popular initiative* or *counter-project* (initiated by civil society)<br>o Host of ordinary policy questions are routinely put to the electorate for their opinion<br>o For a Referendum to be accepted, it must obtain the majority of elector's votes<br>o For an initiative to be adopted, it must obtain a majority of the electorate and of the Cantons (double majority)<br>• Citizen can use petition to any authority |

*Table 3. Models of democracy (Compiled from Finer (1999); Kakabadse et al., 2003) (cont.)*

| | | |
|---|---|---|
| Representative Democracy (government by elected political elites based on indirect rule by the majority of the electorate) | UK (Westminster Parliamentary System) | • Serving in law (or crown in parliament)—unwritten constitutional issues (no formal Bill of Rights)<br>• Bi-cameral system of houses (House of Lords and House of Representatives)<br>• Division of power between Legislature and Executive but separation of powers from the Judicial organs of government<br>• Tight party discipline controls on how elected 'representatives' vote in the Commons<br>• The Prime Minister can wield power with the acquiescence of his/her Cabinet<br>• "Majoritarian democracy" (two big, cohesive parties compete for power: Conservatives and New Labour)<br>• "Actual" representation (elected representatives have a trustee relationship with their constituency)<br>• Elections based on principle of "first past the post" ( the winner takes all)<br>• Referendum can be used to explore public attitudes |
| | USA (Presidential or Congressional System) | • Constitutional system with a written Bill of Rights<br>• Bi-cameral system of chambers (Senate and House of Representatives)<br>• Formal separation of legislative power between Legislative, Executive and Judicial organs of government<br>• The President, as head of the Executive, has full and actual power in decision-making processes to the point of being an "Imperial Presidency"<br>• "Majoritarian democracy" (two big, "coalition" parties compete for power: Republicans and Democrats)<br>• "Virtual" representation (elected representatives have a binding relationship with their constituency)<br>• Elections based on "proportional voting" principle and "district system" (the winner takes all)<br>• Referendum can be used to decide policy issues (e.g., California) |
| | All other democratic societies | • Multitude combinations and variations of the above two models contextually re-defined (Netherlands' consensus model: a multi-party system with proportional representation) |

transformed into a fluid medium of society's self-organisation" (p. 231). Within such a context, the media plays an important role by providing independently informed views on public issues for citizens to debate through "reasoned argument" accommodating a variance of opinion.

However, ownership influences over the information being communicated through the media is an institutional and economic phenomenon. Information authenticity is dependent on those interests who create, present, store and/or retrieve information (i.e., their subjective interpretation). Although, subjectivity is not problematic within a pluralist democracy, the concentrated ownership of communication channels, in the form of oligopoly and/or monopoly control is deemed problematic (Habermas, 1996; Held, 1989). The role of the media (television, magazines, newspapers, and internet) in the modern democracy has been seriously questioned as it now appears to operate in favour of the "commercial good" rather than the "common good." Media control is contrary to democratic principles where the true art of democratic persuasion requires debate and interaction. Some authors have argued that manipulation that creates attitudes and beliefs, chosen in advance by vested interest elites, is carried out at two levels–"grassroots and treetops" (Carey, 1997). The power of rent-seeking, organized interests induces one, two, or all three organs of government to infringe both on citizen rights and public welfare (Held, 1989; Kakabadse & Kakabadse, 2001; Mosher, 1980). Whether the media is technically classified as "public" or "private" is immaterial as how resources in the media are controlled and how that control is determined, is the critical consideration.

In contrast to the aspiration of expanding knowledge and freedom, democratic culture and eroding monopolies of knowledge, ICT creates "several traditions of control: the press, the common carrier and the broadcast media" (Kapor, 1993, p. 174). Neuman (1991) and others (Kakabadse et al., 2003) argue that "in the industrialized nations of the Twentieth-Century, the democratic polity cannot function as such without the institutional struc-

ture of independent mass media" (p. 133). Thus, there is a need to legislate for the "free communicative" organ to ensure democratic processes take place–free elections, transparency and informed citizen participation (Andersen, 1995). If a sum comparable to the U.S. 2004 Presidential election of U.S. $1.6 billion had been spent on improving democratic structures, electronic voting and voters list, the role and influence of "soft and big" money which undermines the political scene, would be minimised.

## FUTURE TRENDS

Opportunity for Participative (and Interactive) Democracy

Although the percentage of citizens voting in general and local elections in the USA, Canada, and UK has declined, in the UK for example, there has been a growth in other forms of popular voting. Citizens, in greater numbers, vote in radio polls, Internet surveys, and television shows. They vote on serious programmes such as Question Time, Restoration, and the Big Red, as well as on light entertainment programs such as Big Brother (Coleman, 2003). They vote by phone calls, text messages, e-mails, and Internet Web sites. Although such voting does not precipitate social change, it does indicate an undercurrent of public will to participate in deciding things as a collective body when it is perceived that the issues are presented clearly and with alternatives spelt out. As Burke (1949) poignantly observed, "in free countries, there is often found more real public wisdom and sagacity in shops and "manufactories" than in the cabinets of princes in countries where no one dares to have an opinion until it comes to them" (p. 106).

For example, a study over ten years, based on VOX survey following Swiss federal elections (June 1981 to June 1991) and designed to measure the decision-making capacity of Swiss citizens, reveals a fair degree of awareness of the four types of basic knowledge deemed necessary for voting (Walter, quoted in Popa, 1998). Swiss citizens scored highly on Knowledge of Project (81.5%), Result of the Vote (79.5%), Content of the Voted project (78.6%) and Watchword on Voting (68.5%) (Walter, quoted in Popa, 1998, p. 143).

Thus, in order to exercise citizen discretion, individuals need a diversity of information rather than carefully-crafted and continuously-repeated messages through a variety of communicative channels. Citizens need a diversity of message content irrespective of the means of communication rather than the same message content delivered in a variety of ways—a technique now used by many ruling parties of democratic, and other, forms of governments. In order to ensure for democratic prosperity, constitutionalising the new organ of the democratic project, namely information, addresses the shortage of free space in which the public sphere is positioned. Whether citizen will to participate is harnessed or not, is open to choice. Dewey (1927) observed that systems of public opinion formation are essential to the organization of power and the "smoothest road to control over political conduct is by control of opinion" (p. 182). Dewey (1927) argued that "only when we start from a community as a fact, grasp the fact in thought so as to clarify and enhance its constituent elements, can we reach an idea of democracy which is not utopian" (p. 149).

## CONCLUSION

Whether the so-called "Jeffersonian Vision" which has inspired contemporary politicians to extol the reputed democratic potential of the communications revolution, and expressed as a belief in the power of public opinion, prevails or whether Bentham's (1787/1995) vision of the "Panopticon" prevails, is open to choice. Jefferson (1984) proclaimed "I know of no safe depository of the ultimate power of the society but the people themselves, and if we think them not enlightened enough to exercise their control with a wholesome discretion, the remedy is not to take it from them, but to inform their discretion" (p. 493)—emphasising the importance of the diversity of information. To ensure the future of democracy, whether electronically mediated or not, it is strongly argued in this paper that a fourth organ of the democratic process—"communicative action" (Habermas, 1996) is created, guaranteeing a plurality of communication channels thereby distinctly diminishing ICT control in the hands of the few.

There is no telling what the interactions of a newly-enabled, global, public (even if electronically controlled) participation in a variety of linguistic and cultural traditions, will create in time. However, it is clear that the understanding of citizenship in a world of nation-states is undergoing transformation which, in turn, will transform the world of nation-states, for better or worst. The clock is ticking! Concentrated ownership of media and other resources within global contexts, the ongoing construction of new, global institutional structures and the decreased will to finance a public utility for the re-generation of democratic values and processes which will ensure independence, openness and freedom for citizen participation, is rapidly moving towards institutionalized ICT and media regimes.

How might, and how should democratic principles such as rights and freedoms of "new speech" (the many ways of sharing multi-dimensional worlds of sight, sound

and touch over invisible and ubiquitous "terabyt" highways) be applied in the era of the information superhighway needs to be examined (Agre, 2002). As Winner (1987) observes, "political ergonomics" will need to be reinvented in order to design new arrangements for democratic praxis and effective governance in the forthcoming digital age. E-democracy is yet to resolve the explicit tension between the Jeffersonian "civic" impulse and Bentham's Panopticon imperative underlying the digital Democratic Project. The design of new arrangements for democratic praxis and effective governance in the forthcoming digital age remains a challenge.

Current use of ICT promulgated as e-government exposes the structural obsolescence of our current bureaucracy. The possible creation of a "virtual state," (Fountain, 2001) may lead to further centralisation of control or provide citizens with the opportunity for self-determination. The struggles over privacy, accessibility, and equity pose will likely determine the extent to which governments "will be recast in the information age and whether citizens will emerge as winners or losers" (Fountain, 2001, p. 203). Hence, there is a need for the re-articulation of democracy and its institutions in order to address the challenges of a digital era.

## KEY TERMS

**Benthamanian Vision or "Panopticon":** Based on reinforcement theory, Bentham's Panopticon perspective provides a conceptual platform which emphasises that ICT provides mechanisms for reinforcing existing power structures and social controls.

**Communicative Action:** The "Chicago school" notion of communication highlights a process in which people create a culture supportive of rational-critical debate and collective decision-making conscious of alternative courses of action which facilitate self correction.

**Democracy:** Democracy is a form of social order involving citizens in a process of participative decision-making with the intention of generating a free and enriching civic base.

**Electronic Democracy:** Electronically-mediated political activities that are embedded in larger social processes, where ICT itself is only one element of an ecology of communication media and social life.

**ICT Mediated Deliberative Democracy:** Aims to increase the quality of democratic judgment through widespread citizen participation facilitated by ICT in multiple public spheres, both within and between the institutions of state, economy and civil society.

**ICT Role:** The role and effect of ICT requires understanding the social processes that surround it as well how the interaction between technology, organisation, and individual is experienced.

**ICT-Mediated Communication:** Structured a-synchronous communication supported via computer-mediated messaging systems that use multi-media processing and communication tools to provide high-speed information exchange (e.g., electronic mail; web-based tale-conferencing; Group-Ware, "public net-work").

**Media Control:** The concentration of media ownership is considered to pose a threat to democracy as communications technology can be used to manipulate the beliefs of people instead of "informing their discretion." Powerful individual owners of large conglomerates influence media output significantly, promoting their interests by "manufactured consent."

**"Jeffersonian Vision":** In terms of functional amplification theory, Thomas Jefferson's vision concerning the power of public opinion and democratic deliberation, the foundations for popular sovereignty, can be realised through ICT facilitating self-governing communities over a vast territory.

**Re-Vitalising Democracy:** On the basis that "the cure for the ills of democracy is more democracy's…may also indicate the need of returning to the idea itself, of clarifying and deepening our apprehension of it, and of employing our sense of its meaning to criticise and re-make its political manifestations" (Dewey, 1927, p. 144).

## ENDNOTE

[1] According to Bentham (1995), the Panopticon ("all-seeing") was designed as a round-the-clock surveillance machine that ensured that no prisoner could ever see the "inspector" who would conduct surveillance from a privileged central location within a radial configuration. The prisoner would never know when he was under surveillance, creating mental uncertainty that in itself would prove to be a crucial instrument of discipline as one is totally seen, without ever seeing those who observe.

# Civil Servants' Resistance toward E-Government Development

**Mila Gascó**
*International Institute on Governance of Catalonia, Spain*

## INTRODUCTION

As the new UNPAN E-Government Readiness Report (2004) stated, during the last years, governments worldwide have made rapid progress in embracing information and communication technologies for electronic government. All over, several projects have been carried out in order to offer more and better information to citizens and to improve public service delivery. Nevertheless, not all of them have been successful. Several factors have restrained governments at all levels from implementing thriving e-government initiatives.

Research has shown that workers' resistance to change is one of the major obstacles that organizations face when trying to implement innovation change processes. The public sector is not an exception. Due to its intrinsic characteristics, the introduction of information technology and, particularly, of electronic government programs requires paying special attention to the potential crisis situation to which these initiatives could lead. The intention of this article is to make clear how public servants experience and react to those changes that result from the adoption of information and communication technologies (ICTs) within the public administration; that is, to analyze the people dimension of change.

## BACKGROUND

More and more, governments and public administrations are getting used to the new tools brought about by the new information era. The Internet and a growing array of information and communication technologies have modified widely the possibilities for organizing the government and the state. In particular, digital government projects have become a powerful way to contribute to public administration reform and modernization processes that have been taking place in many countries during the last two decades.

Indeed, electronic government has the potential to cut transaction costs all the way to zero in some cases (Fountain, 2001) and, therefore, to obtain efficiency gains, to become more transparent, to reduce corruption, and to enhance public service delivery. In short, it may lead to a more citizen-oriented government that offers an improved range of services and that, in return, increases the level of satisfaction among the population as well as the acceptance of the public sector (Bertelsmann Foundation, 2002).

It has been argued that, despite all its latent benefits, electronic government initiatives failure (total or partial) is far more prevalent than success. From analysis of both theoretical and real-world examples, Heeks and Bhatnagar (1999) concluded that the root causes of this situation are seen to lie in what they called conception-reality gaps; that is, those gaps that exist between the way in which digital government projects are conceived and the realities into which they are introduced.

In a sense, electronic government initiatives are not different from any other government actions, which means that they also are subject to unintended consequences that fundamentally are due to the adoption of imitation strategies on the one hand and to the introduction of change processes into a particular type of institution—the bureaucratic one—on the other hand. These two variables represent two conception-reality gaps. Thus, when the conceptual model does not take into consideration both the environment and the organization implementation context, electronic government programs tend to fail.

As Heeks and Bhatnagar (1999) put it, all information technology projects operate within a change context that has two main components. The first refers to the wider environment outside of the organization. It is characterized by the presence of other institutions, a specific level of development of new technologies, a particular state of the economy and the markets, several political pressures, or a variety of cultures and other social systems. That is why electronic government projects developed within the framework of a particular geographic context have to cope with the challenges of that specific country, region, or city. Imitation strategies that generally have been indifferent to economic, social, and political systems usually have been unsuccessful. For example, "a patient information system was developed in the US to support improved health resource management. When similar reforms based around IS were introduced in the UK, they ran into

difficulties. British nurses found it hard to use the new information system because of the U.S.-inspired assumptions it made about the planning and costing of patient care" (Heeks & Bhatnagar, 1999, p. 69).

Even greater can be the problems of transfer from more advanced countries to developing ones, such as the failure of several public administration reform processes in Latin America or other regions of the world already have shown. The World Bank and other international institutions support has depended on the attention paid by the beneficiary countries to those IT policies considered as the correct ones by the lending organizations. This coercive isomorphism has been accompanied by a mimetic isomorphism, which implies that the political and economic elites who have been trained in the United States or in Great Britain have considered these countries' electronic government initiatives as examples to follow. As a consequence, important attributes, such as an inadequate technological infrastructure, an unstable political environment, a limited local skills base, an important restriction on money, or a wide acceptance of patronage practices, have not been taken into consideration when designing digital government solutions. This lack of knowledge frequently has led to partial or total project failure.

The second component that Heeks and Bhatnagar (1999) cited is the organization within which the technology is located. This has an organizational culture, a political dimension, a set of overt or covert management strategies related to change, and both formal and informal structures. Specifically, the public organization is a bureaucratic one. Therefore, electronic government initiatives are necessarily conditioned by the obstacles and problems to which this type of structure gives rise, such as referring all political decisions to the law, stressing a culture of legality, emphasizing senior public managers' control over extremely predictable and rational processes, impeding adaptation to new times as a result of its slow nature, and avoiding quality-oriented structures (Gascó, 2005).

This assertion explains why private sector information technology practices that have proved to be successful often fail when they are transferred to public administration. Failure is not only a consequence of the broadly studied and analyzed dissimilarities that exist between the private and the public sectors, such as pursuing different objectives, being accountable to different stakeholders, or having different types of customers (Allison, 1983), but is a consequence of the prevailing public administration culture. In sum, "government is not a business. Forcing governments into private sector thinking usually causes more problems than it solves" (Osborne & Gaebler, 1992, p. 20).

## PUBLIC OFFICIALS' RESPONSES TO INNOVATION: RESILIENCE TO CHANGE

C

The difficulties that arise from the implementation of imitative electronic government strategies within the bureaucratic public organizations give rise to feelings of fear, anxiety, and uncertainty among their employees, which minimizes the likelihood of project accomplishment. Although, generally speaking, resistance to change has been widely accepted as a natural reaction, it is cited, however, as one of the major obstacles that the public sector faces when trying to implement any sort of change (Kearns, 2004). Just as any other government program, digital government initiatives can lead to failure due to the public servants' negative responses and attitudes about the changes being implemented.

Private companies also may be affected by resistance to innovation projects. Nevertheless, the two conception-reality gaps mentioned in the previous section in relation to the introduction of electronic government programs aggravate the public sector employees' resistances to change in comparison to the opposition experienced by the private arena staff. Although it is important to notice that imitation policies usually do not bring about the necessary commitment from the upper and middle public managers (they are often perceived as imposed strategies), reluctance to electronic government projects is mainly the result of the public sector bureaucracy's attributes. Thus, its job definition and tasks precision, its routines and procedures uniformity, its hierarchical structure, its isolated departments, its organization continuity, its risk aversion, and its reliability are some of the bureaucratic structure characteristics that give rise to a close system based on certainty and exact prevision, a system that is perceived by its members as a stable and secure one (Gascó, 2003, 2005).

Given this environment, the introduction of electronic government actions may result either in resistance to change due to a lack of clear evidence about its positive impact (Heeks & Davis, 1999) or technology enactment in ways that reproduce, preserve, or even strengthen the ongoing social relationships and performance programs (Fountain, 2001, 2002). Since the use of information technology generally leads to uncertain and unexpected organizational changes, the most common reaction to innovation projects is distrust. Kearns (2004) maintained that organizational change usually is related to information technology and can take many forms. According to her, technology may provoke changes in service delivery, business processes, people's roles and responsibilities, or structures and facilities.

Some of the more important resistance-to-change issues brought about by the implementation of digital government projects are as follows:

1. **Loss of Jobs:** Wirszycz (1997) noted that there is continuing evidence of a fear among employees that the introduction of computers will lead to a loss of jobs. Because technological change is implemented recurrently to automate internal processes, it often is regarded as a senior management pretext to downsize or to cut back on overtime hours. Along with the added stress from being asked to master the technology, this fear is a significant force hindering the move toward improved public service delivery. Many other authors have supported this statement; among them are the Working Group on E-Government in the Developing World (2002) and Fountain and Osorio-Urzua (2001). Public servants' unfamiliarity with technology accentuates this perception, because they may feel that their skills and expertise will become redundant and that they will not be capable of developing the new abilities and behaviors that the new electronic government initiatives may require. Particularly in Spanish or Latin American contexts, where stability has resulted in life jobs and, therefore, in aging workers not used to transformation processes, this view has become a remarkable obstacle that hinders change.
2. **Resistance to Cooperate:** Most of the electronic government initiatives that are being implemented require a stout collaboration among different departments within the public administration. This is so, because these kinds of programs are transverse and affect the functioning of several areas (Danish Technological Institute & Institut für Informationsmanagement Bremen, 2004). Nevertheless, in the bureaucratic public sector, departments operate as Taifas kingdoms,[1] which means that they are reluctant to share information and to work together, and that they view other units as competitors for resources and control. The existence of several subcultures within the public sector (scientists, politicians, and bureaucrats) reinforces this behavior. Each of them tends to "(a) require different data, information, and knowledge to do its work; (b) have different abilities and propensities to collect and acquire its own data; (c) gather data about the world in different categories, using different metrics that have specific and not always easily translated meanings; and (d) have different requirements for and uses of the outputs of its information. … As a result, each subculture sees itself with different roles in, contributions to, and purposes for its value chain; these differences can lead to challenges in coordinated and productive information sharing" (Drake, Steckler, & Koch, 2004, p. 68).
3. **Lack of Clear Leadership:** The previous situation results in another effect. To keep everybody content, several people are assigned to a project group that actually leads to a situation in which there is certain confusion about who really is in control of the electronic government initiative. The need of a leader is important from an operational point of view. As stated by the UNPAN (2003), "the chief executive officer of the public sector must be committed to e-government, lead and build broad support for it, and be eager to learn. This generates the all-important positive signals that the civil service needs to receive from its top leadership" (p. 9). However, political and senior management's strong commitments may not always be easy to attain. Two facts lead to this conclusion. On one hand, electronic government strategies still are considered new within public administration (education or health policies have been implemented for decades; it is obviously not the same with digital government programs). On the other hand, the vast majority of electronic government projects has not yet achieved their objectives and, therefore, has not clearly been evidence for all their proclaimed benefits.[2] As a consequence, skepticism has been a widespread attitude among public sector top managers who, in response, have chosen to be cautious when acclaiming ICT projects.
4. **Reform Fatigue:** The public sector has had more than its fair share of reform projects fail. This past experience also has shaped the perceived value of benefits and, therefore, has promoted a behavior against change (Gascó, 2005). In Bourn's (2002) words, "the history of government information technology has led to a poor IT culture for many government organizations, arising from a previous bad experiences with IT projects or procurement. … Previous experience of ICT projects that ran over budget, brought few costs savings or even failed to work altogether can lead to reluctance to invest in web-based technologies. … Alternatively, the organizational response to previous bad experience with IT can be a 'hands-off' approach by all staff outside the IT department, because they do not want their careers tainted through association with any more disasters" (pp. 3-4). Thus, past heritage conditions new projects of change.
5. **Deficient Telecommunications Infrastructure:** As explained in the preceding section, magnificent digital government projects that have succeeded somewhere else are undertaken in context with different premises. Too often, the available IT in-

frastructure is not taken into consideration when designing digital solutions. Under these circumstances, which usually give rise to important delays and unpredicted difficulties, even the most committed employee may develop a feeling of frustration and, therefore, of resistance to change. Other concerns can be found when reviewing electronic government literature, such as fear of extra work (i.e., during the earlier stages of a project, legacy technology may need to run in parallel with the new system) or inappropriate use of outside consultants and contractors (due to the public sector inexperience with IT, digital government projects too often are introduced and managed by third-party teams and contractors and consultants). Nevertheless, the intention of this section has been to highlight those matters that have been addressed more commonly.

## FUTURE TRENDS

Electronic government projects are underway almost everywhere in the world. More and more, governments are exploring the possibilities that information and communication technologies offer in order to build a better-quality democracy and to deeply change public administrations. But in order for these to be successful, civil servants' engagements are needed unquestionably. That is why the future design of digital government plans must include specific actions in order to obtain public employees' commitments.

Much has been said about how to overcome those feelings and perceptions that result in reluctance to change when electronic government or other types of programs that involve the use of information and communication technologies within the public sector are implemented. Gascó (2005), for example, stated that, in fact, the classic organization theory recommendations about how to deal with change in private companies also are suitable in the public context. Thus, education and communication strategies, support, negotiation, and participation must accompany the technological innovation transformations, considering that long-time bureaucratic behaviors cannot be eradicated with isolated short-run courses of action. Yet, despite the validity of these general and broad proposals, change management in public organizations must take place in specific ways.

First, there is a need for proper and complete information about the project to be undertaken. Communication is an essential motivational exercise aimed at gaining support and understanding of the workforce. That is why the communication plan has to take into consideration the following elements:

1. Both written and verbal communications of the facts have to take place before the initiative actually starts.
2. The extent to which communication is successful depends on the communication skills of the participants and the degree of common grounding in the lexicon shared by them. The effective transaction of knowledge and ideas may be hampered by fundamental differences in professional subculture grammars (Drake et al., 2004; Vann, 2004).
3. The language of external consultants, often hired as agents of IT change, is fundamentally opposed to the language of public agencies and departments (Vann, 2004).
4. Electronic government leaders might find that their listening abilities are more important than their abilities to communicate their own perspectives on the change to employees (Piderit, 2000). Dialogue and conversation should take place more frequently than top-down information display. In addition, innovation should be marketed. However, overselling the benefits of IT projects may not be effective in securing employee support, if employees already accept that the new programs will have some positive outcomes but feel that a different perspective is required (Piderit, 2000).
5. Public servants' responses to change may evolve over time. Paying attention to this evolution implies constantly reviewing the message that is communicated.

Second, training ought to take place. But education strategies must focus on two aspects. On the one hand, instruction has to be concerned both with keeping skills up and with sending cultural messages throughout the organization. As a consequence, computer literacy cannot become the only goal to pursue. On the other hand, people who are going to be sent to training should get involved in real projects. Public administration managers too often have abused learning and have adopted it as the only solution to overcome resistance to change.

Finally, planning for change is an imperative, as it may allow one to gain control over the uncertainties inherent in the change process as well as to ensure backout strategies and rollback abilities in the event of serious unforeseen problems (Kearns, 2004). The certain and secure public sector context should allow for these types of arrangements.

## CONCLUSION

The need for efficacy and efficiency has given rise to multiple attempts to reform and to modernize the public sector. During the last years, a new tool—information and communication technologies—has become available to do so. Its adoption within the public context often has resulted in the design of digital government initiatives. Nevertheless, many of these new programs have failed totally or partially. The existence of conception-reality gaps, which refers to the disparities that exist between the way the projects are conceived and the public sector realities in which they are introduced, has been said to explain these breakdowns. Particular emphasis has been placed on the bureaucratic attributes of public organizations and on the ensuing resistance of change to which they may lead.

This article has endeavored to claim that reluctance to change is a common and natural phenomenon when introducing information and communication technologies into the public sector. For that very reason, the biggest challenge to creating electronic government or even just installing a new IT system is not the technology but the cultural changes that must be made to accommodate it.

## KEY TERMS

**Change Management:** The process, tools, and techniques used to manage people effectively and the associated human resource issues that surface when implementing change.

**Conception-Reality Gap:** A gap that exists between the way in which reform is conceived and the public sector realities into which it is introduced.

**Electronic Government Initiatives:** Those actions based on information and communication technologies (particularly, the Internet) carried out in order to increase public sector efficiency, to improve citizen-oriented public services, and to provide a more transparent performance network.

**Organizational Change:** The design and implementation in a deliberate way of a structure innovation, policy, new goal, or operational transformation.

**Partial Electronic Government Failure:** Electronic government projects that are implemented but have something wrong with them (e.g., unattained goals or undesirable outcomes).

**People Dimension of Change:** How employees experience and react to change processes.

**Resistance (or Resilience) to Change:** A restraining force moving in the direction of maintaining the status quo.

**Total Electronic Government Failure:** Electronic government projects that are never implemented or that are implemented but soon abandoned.

## ENDNOTES

1 The Taifas kingdoms were small Spanish realms that resulted from the disintegration of the Caliphate of Cordoba in 1031. This expression is generally used to illustrate the independent functioning of departments or areas that are close together geographically but do not have any relationships among them.

2 Because of the bureaucratic nature of public sector organizations, initiatives and goals undertaken within this context take a long period of time to achieve. One of the features that particularly boosts process slowness and results delay is overregulation, that is, the need to fulfill too many laws and procedures in order to implement a project of change.

# Community Networks

## INTRODUCTION

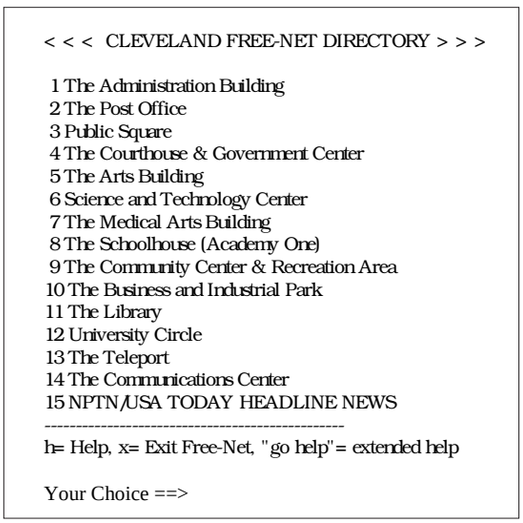
Since the emergence of community networks in the 1980s, several authors have put forth a number of different definitions of the concept. The definitions included below emphasize certain key elements of community networks and comprise a representative sample of views regarding this phenomenon. The Association for Community Networking (AFCN), for instance, defines community networks as "projects that bring local people together to discuss their community's issues and opportunities, learn about Internet technology, and decide upon and create services to address these community needs and opportunities" (AFCN, n.d.). Furthermore, according to the AFCN, there is a "special focus on including those who are traditionally left out of community decision making in general, and technology decision making in particular (e.g., low-income, minorities, senior citizens)." Broadly speaking, community networks are designed, created, and implemented with the purpose of "improving communities—in the social, political and economic realms" (O'Neil, 2002). Indeed, "networks are sometimes defined as communities themselves." A common theme among the various definitions is the belief that networks should create a little self-contained part of cyberspace. Thus, a community network could be construed "as a mini-Internet, only open to members of the community" (Vazquez, 2003). Another important aspect of community networking is the capacity of the Internet and e-mail to aid in community development, in that they "provide access to a new mode of social interaction, one that virtualizes community development processes" (Graham, 1996). Ultimately, community networks and the relationships that develop among the participants make up what has been called an "electronic greenbelt to reinforce and add value to the community" (Cisler, 1993).Schuler (1996) defines community networks as "community-based computer networks … intended to help revitalize, strengthen and expand existing people-based community networks (p. 25). Based on the previous definitions, we postulate our own definition of community networks as organizations that help to strengthen real communities through the creation of virtual communities, not as a substitute for but as a complement to real communities. Typically these community networks are created to address specific local needs involving expansion of Web access to underserved segments of the community but often end up embracing the enhancement of other forms of social, political and economic access as well. Furthermore, as we discuss in some of the sections below, governments can have an important role in sponsoring community networks but, in general, these networks are the offshoots of community activists-volunteers serving in a nonofficial capacity. This allows them to take positions contrary to those of the government(s) serving the jurisdictions that the community networks are in.

## BACKGROUND: BRIEF HISTORY OF COMMUNITY NETWORKING

The following brief history of community networks focuses on a very small number of exemplary cases. A complete chronology and exhaustive list of community networks is beyond the scope of the present work. Furthermore, the focus of this history is limited to community networks within the U.S. The authors recognize the increasing importance of community networks elsewhere, however. Nevertheless, the scope of this article necessarily limits our focus to the U.S. It may, in fact, be the case that community networks outside the U.S. are more vibrant and represent a true growth area for community nets. Community networking originated before the advent of personal computers in the late 1970s. Early community networks had something of a 1960s countercultural quality about them at the beginning with the very first community network system, Community Memory in Berkeley, California, which was started in the early 1970s and featured a preponderance of content regarding local rock bands, particularly the Grateful Dead (Schuler, 1996).

With the growing popularity of personal computers in the early 1980s, community networks started to emerge around the U.S. In 1986, the first free-net (see Figure 1) was created. The Cleveland Free-Net in Cleveland, Ohio, be-

*Figure 1.*



gan as a bulletin board for medical information, "St. Silicon's Hospital and Information Dispensary," and sponsored by Case-Western Reserve University. Users could log-on and leave medical- or health-related questions on the bulletin board, which would be answered within 24 hours by a physician. The project was expanded with funding provided by AT&T and the University Hospitals of Cleveland and the state of Ohio. The information was organized in "town buildings," which could be "visited" by the user:

At the height of its popularity in the early 1990s, the Cleveland Free-Net had over 40,000 registered users (Schuler, 1995).

The Santa Monica Public Electronic Network (PEN) was started in 1989, and in contrast to the two networks mentioned previously, was one of the first to be sponsored by a municipal government. PEN was designed to pursue a number of participatory democratic objectives including:

- Providing easy electronic access to public information
- Providing an alternative means of communication from residents to convey their needs, preferences and intentions to local government
- Facilitating the delivery of local public services to residents
- Serving as a public forum for the expression of opinions on a wide range of issues and concerns of residents to enhance their sense of community
- Providing community members with the means to learn about computer and communications technology

One observer of the experiment notes that its goal from the beginning was to empower the residents of Santa Monica (McKeown, 1991). A key reason for this sense of empowerment was the availability of public computer terminals in libraries and other public places, which allowed even the most disadvantaged community members to participate in the network. Another important aspect of PEN was an attempt to use the nature of online communications to level the playing field of civic engagement; without visible social cues, in theory everyone can participate without the detrimental effects of prejudice. However, this absence of a social context can enable negative behaviors as well. For example, the practice of "flaming"—or exchanging insults online—was alive and well on PEN, even though its creators required participants to use their real names online in order to make it the setting less conducive to abusive behavior.

The Blacksburg Electronic Village (BEV), which still exists (as does the Santa Monica PEN, although it has apparently become part of the Santa Monica city government's Web site), is the result of a unique experiment involving Virginia Tech, Bell Atlantic Southwest and the Town of Blacksburg, Virginia. BEV was created in 1993, to serve as a "virtual community," or as an online location where all the different types of activities (e.g., political activism, social organizing and commercial endeavors) that occur in a physical community can occur via computer network. Unlike the other community networks discussed, the creators of the Blacksburg Electronic Village from the start envisioned that their "wired city" concept would have considerable e-commerce potential. Thus, local businesses lent their support to the installation of a network connection for every home, classroom and business in the city. So that, in addition to the standard provision of information about local events, issues and concerns, the network also provides local businesses with an electronic means to deliver new products and information about services to the residents. According to the BEV Web site, "in 1998, the BEV turned over its residential Ethernet operations to the private sector, again creating new jobs and new business opportunities in the region. By late 1997, there were at least 24 new high tech businesses in the Blacksburg area providing a wide range of Internet services, consulting, hardware, and programming services. … Today, the BEV group works closely with the Town of Blacksburg, local civic groups, businesses, and individual citizens to ensure that these new communications tools are used to support the every day human activities of Blacksburg."

## Community Networks Today

By the mid-1990s, it was already clear to several observers that the community networking movement was in trouble (Beamish, 1996; Schuler, 1996). In little over a decade, civic networks grew from a mere handful to several hundred, with an estimated 400,000 registered users (Schuler, 1996). At the peak of their popularity, however, community networks fell victim to their "vague, simplistic and unrealistically utopian" goals (Beamish, 1996) or their "utilitarianism," lack of community support and understanding, as well as excessive focus on the technology undermined their success (Schuler, 1996). Successful community networks meanwhile were integrated into the life of their community, provided local content and focused on local needs, made linkages with local institutions including government and schools, and installed processed that helped guarantee their long-term sustainability (Rosenbaum & Gregson, 1998).

A typology to classify community networks has been developed (Beamish, 1995). Free-nets are "community-based," rely heavily on volunteers, and provide a rich source of local information and discussion. Earlier free-nets offered free Internet service to community members in addition to an Internet portal, which could also be used to access links elsewhere in the world (e.g., the Cleveland Free-Net). Today, free-nets are still community-based and volunteer-managed but they are less likely to provide free Internet access to community members. Municipal government-sponsored community networks are similar to free-nets except they are operated by local governments instead of volunteers and emphasize access to government records and some services. Nonprofits for nonprofits are community networks that are created and managed by nonprofits to assist other nonprofits with access to the Internet and to form virtual communities based on a commonality of interest. Finally, the wired city is a futuristic model of a community in which every household, government agency, school and a high-speed computer network interconnects business. Needless to say, this is the most rare type of community network since it requires considerable expense to establish.

## FUTURE TRENDS: COMMUNITY NETWORKS AND DEMOCRACY

An early proponent of computer networks as a vehicle to spur democratic change begins an essay with this provocative passage: "The Internet will save democracy. Or so the early 1990s technohype led many to believe. With each new communication medium comes a wide-eyed view about its potential. I'd like to suggest that just as television saved democracy, so will the Internet" (Clift, 1998). As this extract shows, the wildly optimistic belief in the impending advent of electronic democracy is less viable today than it was even a decade ago. As far back as 1985, an influential observer predicted, "very large numbers of people empowered by knowledge … assert the right or feel the obligation to make policy" (Cleveland, 1985). In the 2004 Democratic Party presidential primaries, the Howard Dean campaign made national headlines with its adroit use of the World Wide Web to attract millions of contributors and activists. By focusing so much attention, however, on the Web's capacity to fuel political fundraising, the mainstream media missed a more important point: The WWW represents a new medium for engaging citizens in civic matters on a vaster scale than any other in history. The Internet, with its many-to-many, decentralized, and non-hierarchical flow of information, is in marked contrast to mass broadcasting with its one-to-many flow of information. Moreover, radio and television broadcasting requires large capital outlays, which inevitably leads to centralization of information and power. Mass broadcasting still shapes much of the political discourse in current society, presenting us with a top-down communication channel that equates political power with control of television and radio networks. For example, one of the first things the Bush administration did after occupying Iraq was to establish new American-run radio and television stations as a means of exerting control over the messages received by the Iraqi people.

E-democracy or democracy via the World Wide Web has two key components: (1) e-government, or the use of the Internet by governments to provide information and to provide delivery of public services or goods and (2) Net-Actvism, or the use of the Internet to encourage civic engagement and participation in local governance. E-government is an idea that emerged during the 1990s, as many governments started to adopt many e-business and e-commerce techniques from the private sector. Facilitating citizen access to and participation in government has always been a large part of technology's appeal to activists (Northrup, Kramer, Dunkle, & King, 1990). The ability of citizens to initiate direct contact with government is dramatically enhanced by the Internet. However, this aspect of communication and information technologies tends to be overlooked by governments, which far more frequently view the Internet as a means to improve the efficiency of government operations, rather than as a means to improve government-citizen relations, which is actually of more tangible benefit to citizens (Northrup et al., 1990).

Using community networks to stimulate public discussion of issues and to encourage civic engagement lags far behind a service-based approach to the Web. It

is far more typical for governments to take a "services first, democracy later approach" (Clift, 1998). Although governments generally do a good job of disseminating public information by the Internet, the U.S. Bureau of the Census is an excellent example, one gets the impression that the chief attraction of information and communication technologies for governments is the effect they will have on service delivery. Political and social activists believe that governments are capable of doing much more in the area of strengthening our political institutions via the Web. For instance, municipal Web pages are underutilized as a means to promote civic engagement (Hale, Musso, & Weare, 1999).

## CONCLUSION

Community networks are designed to promote the political empowerment and economic revitalization of local communities, particularly through the enhancement of civic participation. Typically, this means that community networks emphasize improved access to the Web and information technology more generally for marginalized members of communities (e.g., social and economic minorities). The peak of community networking in the U.S. occurred from the mid-1980s to the early 1990s; during that time hundreds of new community networks were formed that served hundreds of thousands of people. Since the mid-1990s, however, the number of community networks has declined for a number of reasons including over-ambitious goals and lack of support. Local governments can help revive community networks as part of their commitment to increasing their presence on the Web. However, government seems less interested in encouraging civic engagement than in achieving efficiencies by streamlining public service delivery.

## KEY TERMS

**Association for Community Networking (AFCN):** An international organization providing resources, shared learning, and experienced guidance to help communities and organizations use information and communications technologies effectively.

**Civic Engagement:** Involving citizens in community building either through NetActivism or non-Web based means.

**Community Networks:** Computer networks (i.e., mini-internets) designed for the purpose of bringing people together to discuss and address a variety of local issues.

**Electronic Democracy (E-Democracy):** The concept that democratic goals can be furthered and democratic institutions strengthened via the World Wide Web and more generally computer technology.

**Electronic Government (E-Government):** Government delivering public services via the World Wide Web, less frequently government use of the Web to facilitate political participation

**Free-Net:** A community network that provided free Internet access to all residents; depends heavily on local volunteers for its administration.

**Net-Activism:** Facilitation of civic and political participation through the Web.

**Virtual Community:** Communities that exist primarily or entirely on a computer network (e.g., computer chat rooms with regular denizens).

# Community-Based Information Networking in Developing Countries

C

**Hakikur Rahman**
*SDNP Bangladesh, Bangladesh*

## INTRODUCTION

The information era refers to a period in this globalized world when economies, social dimensions, and demography are largely dominated and driven by information, in contrast to the previously industrial development driven society. *Information society*, *information network*, and *digital divide* are terms inducted in very recent days. The key element in this periphery, is the information, and it is the easy and free flow of information to the demand routes. Because of the information-based nature of the modern economy, the globalization of the telecommunication industry, and the interdependent global environment, the value of the global network grows and more users are interlinked.

The information society is driven by information, similar to the industrial society. This society is produced by a reliance on information as the most significant factor in the terms of production. Hence, it relies on the information economy to produce products, services, employment, wealth, and lifestyle on which the community depends. Ultimately the whole community of a country can be benefited by optimum utilization of information to be flown into each territory of the society. Given the right incubation, a community based information network molded by information can accelerate the pace of development.

Rapid advancements and convergence of information and communications technologies (ICTs) have a deep and far-ranging impact on economic, social, and political life. The increase in the speed of and variations in communication flows is catalyzing an unprecedented growth in the exchange of ideas, goods, and services. Government, organizations and businesses that ignore this development and lag behind in adaptation risk themselves becoming uncompetitive, marginalized and out of the game (ABDI, 2002).

Efforts have been given to accommodate propositions on fabricating nationwide information networks through utilization of the existing information backbones especially in developing countries, and a centrally driven content repository may eventually be established.

## BACKGROUND

Rapid human development programmes depend on the formation of a robust civil society. Community members develop their capacity by integrating information and knowledge into the various development activities. Such capacity empowers people to solve intelligently the problems that exist in their community and eventually transform them into valuable assets of the society.

E-society or networked society encompasses the role of the Internet and other ICT services in everyday life, particularly related to interactions in the household, personal needs, and entertainment. It also encompasses the needs of individuals and the wider community in work, social relationships, leisure, and activities in other arenas that assist the society to be online. This interest is not only limited to the passive consumption of ICTs in these settings, but also takes into account the design, redesign, production, and governance of the multiplicity of old and emerging communication innovations that are reshaping the media habits and practices across all sectors of society.

When community information centres are supposed to act as a crucial tool for human development, community users are urged to cultivate and adopt a critical attitude towards the usage of information. Justifying the source of information they may evaluate, analyze, and adapt information and knowledge for their own perspective, economic, political, and social conditions. This process of justification of the content and source of content forms the basis for changing and transforming the community.

The UN General Assembly stipulated through a resolution, that "to marshal the global consensus and commitment required to promote the urgently needed access of all countries to information, knowledge, and communication technologies for development so as to reap the full benefits of the information and communication technologies revolution, and to address the whole range of relevant issues related to the information society, through the development of a common vision and understanding of the information society and the adoption of a declaration and plan of action for implementation by Governments, international institutions and all sectors of civil society" (UN General Assembly Resolution, 2001).

It is believed that rural community people everywhere are born intelligent enough to sustain in diversified situations (Edgemont Resource Team Report, 2004; OTA Report, 1996; Saga, 2005). Their ability and capacity in tackling difficult circumstances and finding solutions to the struggle of everyday life have been recognized. It is also believed that the intelligence of rural people is often underestimated and emaciated. Limited access to information and knowledge prevents the full use and potential growth of intelligence in rural communities. The structures (systems and services) supporting the information flow to rural areas and deprived urban areas are not always in healthy condition. Those responsible for putting resources toward such infrastructures have not considered it important to invest in and to set up information and knowledge networks. The time has come to involve the rural community people in identifying their own information needs for their community development.

While expanded infrastructure may ensure physical access to the global communications network, there are other non-physical barriers to access that also contribute to the digital divide. The right to access and use information is one that may be blocked only too easily, for example, by pricing, patents, or censorship policies. On the other hand, high-tech equipment may be necessary but it is useless unless people have the literacy, education, computer-training, and capacity-building required first to operate the equipment, and then make full use of the knowledge or information they access. Furthermore, developing countries' high levels of foreign indebtedness inhibits their capacity to contribute to the generation of knowledge, for example, through national investment in research (Accuosto & Johnson, 2004).

To overcome these issues, a common comprehensive consensus among the developing countries needs to be set up at the country level, integrating policies, implementation plans, usage patterns, and behavioral changes for the marginal communities by adopting the benefits of information and content for their own uplift.

Both the global communications network and the Internet exhibit network externalities—their value to any single user increases as they are expanded and as more users join. The higher the number of telephone users, the greater the number of interactions that become possible. On the Internet, each new user may be a potential supplier or consumer of goods and services, and can expand the global market (UNDP, 2002). Theoretically any number of users can simultaneously interact in cyberspace. By ratcheting up the necessary physical infrastructure- adding servers, increasing telephone lines, building additional satellite capacity—new users can simply piggyback on the existing system: it is almost infinitely expandable (Spar, 1999).

In July 2000, the G8 countries adopted the Charter on Global Information Society at their summit meeting in Okinawa, Japan. This reflected the G8's recognition that information technology is one of the most potent forces shaping the 21st century. The charter discussed the creation of a global information society (ADB, 2003).

To become critical users of information and knowledge, a community would like to analyze both the knowledge that comes from outside the community, and its own inherited knowledge. The community would also like to study the cultural and social aspects of gender, race, tribe, class, and poverty. However, these studies need to be adjusted and formulated so that transforming information into knowledge can create real value-added services at the grass root level.

## STRATEGIES TO ESTABLISH INFORMATION NETWORKING

A rise in per capita income cannot be the sign of digital literacy, but a well established vision at the central level with a dedicated workforce and commitment at the implementation stages would lead to a sustainable society towards achievement of development. Under no circumstances should governments try to over-regulate the growing ICT sectors, at least for the next ten or fifteen years.

The main challenges can be pinpointed as:

- integration and interoperability of technologies
- tackling the speed of technology obsolescence
- shortage of knowledge based manpower
- data and information security and privacy
- mobilization of funds

To face the challenges, the author suggests that a three-tiered effort may be initiated at the national level. It is scheme, evolution, and empowerment.

### Scheme

A concrete strategic plan needs to be initiated at the national level incorporating possibilities of dynamic adjustments in each stage of development and action, resulting in optimum resource utilization and maximum benefit out of it. The new strategy requires an indigenous method, an open coordination concept, and a realistic measure by:

1. Identifying and defining common objectives; and
2. Simulating the quality and relevance of capacity enhancement programmes, to

- Build human resources capacity development to improve knowledge and skills, promote ICT-literacy and lifelong learning of citizens through e-learning and awareness programs, and prevent brain drain;
- Develop ICT applications and information content to support uplift of sustainable development related activities, promoting poverty reduction and better governance;
- Integrate ICT applications to improve the flow and use of information and knowledge for effective usage at the marginal levels;
- Promote strategic alliances and partnerships with existing ICT initiatives at national and local levels, and establish principles of effective partnership of mutual understandings, develop new job markets, and create stable jobs; and
- Establish a center of excellence (promoting lifelong learning, mass information dissemination, improved communication, and knowledge networking) at potential level with dynamic interaction and make it self-sustainable.

## Evolution

Then, an evolution phase may start with:

- **Improved Infrastructure:** Developing countries should emphasize physical infrastructure, human capital, and government policies to enhance and amplify the effects of investments in ICT;
- **Increased Investment:** Developing countries have not invested enough in ICT for productivity increases. They should invest more in ICT by attracting private sector investments, participate in the new economy and seek to achieve e-development;
- **Extended Telecommunications Infrastructure:** In developing countries, telephone lines per 100 people average 2.6, compared with 66.4 in the United States. Computer ownership is 4.4 per thousand people in developing countries compared to 511 per thousand in the United States. These gaps should be lessened;
- **Uplift in Basic Education:** Literacy is fundamental for a society to have the capacity for mass participation in the digital technology;
- **Increased Government Patronization:** National governments have a responsibility to promote the use of ICT and financing for ICT "mainstreaming" to address development goals. Government should reduce taxes, tariffs, remove other barriers on computer imports, encourage competition in telecommunications, itself become a sophisticated user of ICT, and promote mass usage of Internet; and
- **Easy Access to Internet:** Governments must enact legislation to ensure easier access, and wider use of Internet among a larger portion of the general communities.

## Empowerment

Finally, empowerment should focus on:

- **Empowerment of Society:** To capture the ability of ICT to overcome conventional barriers faced by marginalized communities, and to be demand driven;
- **Empowerment of Local Government:** Creation of a national information infrastructure and extension of the network to the local government level for the utilization in better governance and transparency;
- **Empowerment of Business:** Focusing e-commerce at the marginal community level, SMEs need to be empowered with better logistic support, including necessary laws; and
- **Empowerment of Knowledge Network:** Utilizing the information backbone as the catalytic agent, actors, and agencies involved in sustainable development are needed to be networked to form a common platform of knowledge interchange, promoting local content, community participation, and ownership.

In order to optimize scarce financial resources, appropriate cost-effective technological options should be utilized, while avoiding duplication of infrastructure. Additionally, synergies between different sectors and networks can be exploited to this end, with particular attention to the energy and transport sectors, given their close links with the telecommunications sector (Accuosto & Johnson, 2004).

Information kiosks would be a key part of the information infrastructure in rural areas. Despite skeptics who want hard statistics on improvements in poverty levels and other measures of ICT impact, this initiative reflects the confidence that has been observed, and the positive changes that can come from timely and relevant information and communication services (Colle, 2004).

Implementation of a successful community information centre in a locality with potential contribution to the society depends on multi-dimensional aspects and much more complicated issues which can be learned only during the implementation and operation period. One community centre is may be very much more diversified

than another community centre, though they may be located in the same district town. One may focus on local content, while the other may concentrate on the most yielded agriculture product to serve the purpose of the community.

The driving force in setting up a community information centre is the realization that the community has limited access to the information that allows them to make decisions, and to take action to direct and control their own future. However, what is not realized, quite often, is that starting an information resource centre is easier than ensuring that the resource centre survives. To survive, it must become a sustainable entity and an integral force in the struggle for development of the community.

## INITIATIVES ON INFORMATION NETWORKING

A few success initiatives have been described below that are acting as catalysts in several countries towards the establishment of information networking.

A South African-based company has made an investment in a low-cost, four-in-one personal computer that could lower the cost of offering information communication technology in learning institutions. Each system has a built-in telephone handset, 14-inch monitor, built-in speaker, keyboard and touchpad, 56K modem, three Universal Serial Bus (USB) ports, Intel processor, and Ethernet facility (Ramani & Adeyemi, 2004).

Dr. Reddy of Carnegie Mellon University is working on his project, called the PCtvt, a USD250 wireless networked personal computer intended for the four billion people around the world who live on less than USD2000 a year (Markoff, 2004). The MIT Media Lan has launched a new research initiative to develop a $100 laptop, and this received high media coverage in the World Economic Forum at Davos, Switzerland in January 2005, as well as in WSIS Tunisia in December 2005 (MIT Media Lab, 2005).

President Wade has presented the concept of digital economy in his speech in June 2002, at a UN occasion and it can be treated as a conceptual case. The Senegalise president had proposed the establishment of a "World Fund for Information and Communication Technologies" to "help Africa reduce the digital divide that separates it from the rest of the world." He also highlighted the importance that was being given to the development of the new ICT in the framework of the New Partnership for African Development (NEPAD) as an engine for development (http://www.afrol.com/News2002/afr018_nepad_wade.htm). President Wade considers the new technologies one of NEPAD's eight priority sectors (http://www.idrc.ca/en/ev-51491-201-1-DO_TOPIC.html).

In a communiqué issued on the occasion of the Ministerial Round Table on "Towards Knowledge Societies" UNESCO supports the Senegalese concept, and states "We urge the international community to help the developing countries to build their capacity so that they can achieve self-reliance as soon as possible. To achieve this objective, we need to pay particular attention to the identification of possible mechanisms for the funding of this effort, including the setting up of a digital solidarity fund (DSF) to augment national resources (UNESCO, 2003).

The World Bank has been running an Information for Development Program (infoDev) since September 1995, the original aim of which was "to promote innovative projects on the use of ICTs for economic and social development, with a special emphasis on the needs of the poor in developing countries" (infoDev, 2004). However, the 2004-2005 strategy aims to "strengthen the linkages between pilot projects, evidence, analysis, and action in harnessing ICTs for development" (infoDev, 2004).

The mission 2007 is designed as an offering of the S&T and academic community, civil society organizations, private and public sector industry, financial institutions, international partners, and the mass media to the nation on the occasion of the 60$^{th}$ anniversary of India's Independence on August 15, 2007. With this mission, an independent rural India with broadband connectivity for every village at low and affordable costs, and with integrated and diversified technological applications that are relevant to their day-to-day lives, bringing them prosperity and happiness is envisioned (MSSR Foundation, 2004).

The e-Sri Lanka initiative utilizes ICT to develop the economy of Sri Lanka, reduce poverty, and improve the quality of life of the common people through a government and private sector partnership approach (e-Sri Lanka, 2005). Similarly, the Sarvodaya Telecenter program in Sri Lanka provides special emphasis to the Village Information Centers (VICs) to reach out to the rural poor communities, in order to establish sustainable low cost ICT models and empower rural masses (ICTA, 2005; Kapadia, 2005).

To uplift socio-economic development, the government should undertake broad-based action plans. Inclusion of the following article in the ICT Policy of Bangladesh, is a positive step in this aspect:

*3.2.11 Socio-economic development can be accelerated if more people can have access to information. Teledensity is important in this respect and it will be increased to broaden the coverage, which will improve the socio-economic condition of the people through ICT-related activities in line with experience of developed countries.* (ICT Policy, 2002)

## FUTURE TRENDS

There is a great hope that e-development within the new economy will provide a shortcut to prosperity by allowing developing countries to bypass certain traditional phases of development in the conventional, long-lasting and belt tightening process of structural change from agrarian to industrial and, ultimately, to knowledge-based service economies (Clarke, 2003).

Effective networking among development partners will create a level-playing platform of communication and knowledge sharing to promote capacity building and society enhancement activities, especially at the grass roots. Further extended research by focusing specific objectives and implementing methodologies of the existing success cases could be the current demand of the community.

All these imply efforts in strengthening cooperation on education, training, and human resource development policies. Detailed programme and action plans on the future objectives of education and training systems need to be prepared to face the challenges. The policies need to be implemented using the "open coordination concept" among all the partner organizations.

## CONCLUSION

A major barrier to the development of e-governance in developing countries is the lack of information infrastructure. In a few countries in Asia, the phone and Internet penetration may be higher, but still the ratio is low when compared to developed countries. Furthermore, disregarding the limited commercial usage in these regions, affordable ICT usage at the marginal community level is yet to be achieved.

ICT regulation is complicated by the fact that electronic transactions usually involve several third parties and cross numerous territorial jurisdictions. The newness of the subject and its lack of proceedings mean that the interpretation of regulation is inevitably open, and subject to debate (ADBI, 2002).

Public policy in developing countries is important in setting development strategies. Globalization has limited the influence of governments over economic activities within their own countries. But governments still have an important role in defining and establishment an enabling environment for development (Clarke, 2003). As the business of modern government gets more complex and knowledge-intensive, the potential for cost and service benefits associated with streamlining Knowledge Management becomes intense. A more knowledge-intensive approach to governance will redefine how the public sector relates internality among its own agencies and its own employees (Smith, 2004).

It is evident from the discussion so far that ICTs in poor communities can be much more than a means of delivering useful pieces of information such as accessing market prices or health information via the Internet. However, this kind of information access is important, and has been developing in the ictPR (ICT for Poverty Reduction) initiatives. More than simply accessing information, many of the initiatives have been creating, circulating and/or archiving indigenous knowledge (UNESCO, 2004). In the case of ensuring universal access to ICT infrastructure it is only too clear that expansion of communications networks to isolated rural areas or the most marginalized and poorest communities holds little prospect of profitable returns for investors (Accuosto & Johnson, 2004).

Spare bandwidth on low-earth-orbiting satellite may be allocated at a subsidized rate to developing countries, especially to be utilized for community telecenter purposes. Accumulating a majority of the above mentioned networks may form nationwide information backbones with little initiative and effort, providing opportunities to form advanced information and research networks in each country.

## KEY TERMS

**Community Information Centre:** Place in a community where formal organized services and informal neighborhood and support services are available to assist with immediate and basic needs of the community via information based activities.

**Community Telecenter:** It provides the community members the ability to utilize ICTs in a publicly shared manner. Telecenters sometimes provide the only connectivity available to many community members, and their services may be offered with or without a fee. Community refers to a set of people with some shared element, and particularly comprises a group of people living in the same area.

**Communication Network:** A form of telecommunications network that connects entities to disseminate messages from one part of the network to another over multiple links.

**Developing Country:** These are countries that have not achieved a significant degree of industrialization relative to their populations, and have low standard of living.

**E-Government:** A form of government which uses information and communication technologies (ICTs) for improving the activities of public sector organizations.

**E-Society:** A society that deal particularly with the relationship between public agencies and other institutions—other public agencies, private sector companies, non-profit and community organizations through electronic means.

**ICT:** ICT can be termed as the set of activities that facilitate, by electronic means, the processing, transmission, and display of information. It is at the convergence of a tripod of three specialized domains, namely information technology, data and information, and socioeconomic issues.

**Information Society:** In this type of society the information accounts for a significant part of the added value of most goods and services, and information intensive actions become distinctive of the households and the people.

**Networked Society:** A society in which communities participate more directly in an interconnected mode, information devices are culturally accepted and widely incorporated into the daily life.

**Networking:** Networking concerns connecting people of similar interests for the purpose of uncovering opportunities, identifying local demands, and learning of best practices. Alternately, networking incorporates two or more devices (or people) communicating to each other and sharing resources.

# A Conceptual Framework for Considering the Value of E–Government

**Ed Downey**
*State University of New York, College at Brockport, USA*

## INTRODUCTION

E-government implementation requires public administrators to respond to stakeholder value. While there are many concepts of value in the field of public administration, an integrated framework that public administrators can use to consider the value of e-government to stakeholders is lacking.

The new public management suggests that public administrators can best produce value by becoming entrepreneurial and more responsive to stakeholder needs (Barzelay, 1998; Denhardt & Denhardt, 2000; Frederickson, 1980; Goodsell, 1993; Kettl, 1993; Kettl & Milward, 1996; Moe, 1994; Osborne & Gaebler, 1992; Osborne & Plastrik, 1997; Stillman, 1995). Certainly e-government applications hold the promise of strengthening the relationship between public administrators and stakeholders in ways that better respond to needs and thus provide more value to stakeholders and to society in general. Current e-government classification methodologies tend to focus more on the stages of development of e-government applications (Layne & Lee, 2001; Moon, 2002; UN & ASPA, 2001; West, 2004) than on the different kinds of value that can result from meeting stakeholder needs.

There is an emerging emphasis on stakeholder needs and value in the e-government literature rather than on classification methodologies that focus on stages of development (Grant & Chau, 2005; Reffat, 2005; Savoie, 2004; Schware & Deane, 2003; Tan, Pan, & Lim, 2005; Welch, Hinnant, & Moon, 2005). This article responds to these ideas by focusing on stakeholder value to develop a conceptual framework that public administrators can apply to e-government. Such a framework will provide insight into: whether or not an e-government application is worthwhile; and if worthwhile, what political management strategies might be employed to support it. The framework will also facilitate the comparison of e-government alternatives.

## BACKGROUND

This section looks at the new public management debate and how it has focused attention on both market and politically derived stakeholder value. Current methodologies used to classify e-government are then reviewed with the conclusion that they focus more on development than on value. At the end of this section is a discussion of the emerging emphasis in the e-government literature on stakeholder value and its relationship to a new framework of e-government value.

## THE NEW PUBLIC MANAGEMENT DEBATE

The new public management represents a change in our views of governance. From the point of view of its proponents it is a shift away from a reliance on bureaucratic rules and rule making, impersonal systems of control, and managerial professionalism. The new public management emphasizes the implementation of business practices that make government institutions more sensitive to stakeholder needs (Osborne & Gaebler, 1992). As a consequence, government must reinvent itself in ways that are more entrepreneurial, responsive, and consumer oriented (Frederickson, 1980; Goodsell, 1993; Kettl, 1993; Kettl & Milward, 1996; Moe, 1994; Osborne & Gaebler, 1992; Osborne & Plastrik, 1997; Stillman, 1995). Perhaps the approach is best summed up by Denhardt et al. (2000) as public administrators who serve rather than steer society: "the primary role of the public servant is to help citizens articulate and meet their shared interests rather than to attempt to control or steer society." The assumption that underlies this reinvention is that the approach will make government more valuable to society.

Far from being accepted dogma in the field of Public Administration the new public management has caused some lively debate. For example, regarding the implementation of more business practices in government, Terry Moe (1995) is concerned about profound differences between the public and private sectors. These differences are rooted in the contrasting nature of authority upon which the two are based. The authority of the private firm emerges from voluntary, self-interested exchanges, while in public firms authority is not voluntary and often contrary to self-interest.

Oliver Williamson (1995) who has based his work on the idea that institutional structures in the market are the result of attempts to economize on transaction costs none-the-less finds Moe's arguments "compelling." Williamson agrees that Moe's idea that farsighted politicians realize that they will not always be in office and therefore build inefficiencies into public bureaucracies to frustrate the efforts of successors to reshape an agency creates a fundamental difference in public and private bureaucracies.

One of the more lively debates regarding the appropriateness of the new public management took place between Terry (1998) and Frant (1999). Terry is very much concerned about what he believes to be the undemocratic nature of the new public management and that the:

*... public entrepreneur's penchant for rule breaking and for manipulating public authority for private gain has been, and continues to be, a threat to democratic governance. The danger is intensified by the emergence of public entrepreneurs of the neo-managerialist persuasion.* (1998, p. 197)

Frant argues that Terry misunderstands the new public management:

*Neo-managerialism as presented by Terry, then, is a strikingly bizarre ideology, for its two main pillars, the managerialist pillar and the economics pillar, stand in direct contradiction to each other. The former says managers must be freed from constraints, the latter says that they require extensive policing and cannot be trusted.* (1999, p. 268)

Whether or not one agrees with the new public management, it has served the purpose of forcing a reconsideration of the role of public administration and highlighted the relationship between public administrators and stakeholders. In the debate some have cast the public administrator as an entrepreneur and consequently introduced market derived concepts of value (Frant, 1999; Osborne & Gaebler, 1992; Williamson, 1995). It has also invigorated those who see the public administrator as an integral part of the political process and consequently introduced politically derived concepts of value (Denhardt et al., 2000; Moe, 1995; Terry, 1998). In some instances the debate shows sharp contrasts of views as in the case with Terry (1998) and Frant (1999). But it also shows some attempts at accommodation as suggested by Oliver Williamson's (1995) comments on Moe's (1995) work. The real value here has been the raising of issues surrounding two very important concepts of values as they relate to public administration, those that are market derived and those that are politically derived.

These two concepts of value should be applied to e-government initiatives, but this does not seem to be the case. Rather, current classification methodologies are more focused on the staged development from simple to more sophisticated e-government applications.

## E-GOVERNMENT CLASSIFICATION METHODOLOGIES

A great deal has been done to understand e-government from a developmental perspective. The purpose of the classification methodologies has been to provide ways to determine how advanced e-government is in various jurisdictions.

The current state of classification methodologies for e-government applications are typified by West's (2004) approach. West suggests four stages of e-government transformation: (1) the billboard stage; (2) the partial-service-delivery stage; (3) the portal stage, with fully executable and integrated service delivery; and (4) interactive democracy with public out-reach and accountability enhancing features.

Moon (2002) suggests five stages of development "which reflect the degree of technical sophistication and interaction with users: (1) simple information dissemination (one-way communication); (2) two-way communication (request and response); (3) service and financial transactions; (4) integration (horizontal and vertical integration); and (5) political participation."

A joint study done by the United Nations and the American Society for Public Administration also employed five stages of e-government development to UN member states (UN & ASPA 2001, p. 2):

- **Emerging:** An official government online presence is established.
- **Enhanced:** Government sites increase; information becomes more dynamic.
- **Interactive:** Users can download forms, e-mail officials and interact through the Web.
- **Transactional:** Users can actually pay for services and other transactions online.
- **Seamless:** Full integration across administrative boundaries.

Finally, Layne and Lee (2001) look at the stages of e-government development from the perspective of two variables: technological and organizational complexity; and integration. This yields four stages: catalogue, transaction, vertical integration, and horizontal integration each of which have increasing amounts of complexity and integration.

While these approaches have contributed to the understanding of e-government they are based on an assumption that reaching the final stage is an important goal of e-government initiatives. While there is some disagreement as to what the final stage is, the vision seems to be an interface that is highly integrated in ways that maximize user convenience. Ho (2002) describes the vision as a one-stop service center and believes that:

*The emergence of the World Wide Web further facilitates the growth of a one-stop service center model because a government Web site can itself serve as a convenient and cost-effective platform for centralized service provision.*

While more integrated or more developed e-government applications probably indicate more sophistication this does not necessarily translate into more value. Rather than, or in addition to focusing on stages of development, e-government initiatives might benefit from paying direct attention to the concepts of value highlighted by the new public management debate. Evaluating e-government initiatives in terms of the market derived and politically derived value provided has at least two advantages. First, it is consistent with the concerns currently being discussed in the field of public administration (i.e., the new public management debate). Secondly, it is consistent with the concerns of public managers who must justify new e-government initiatives in terms of the value they add.

## EMPHASIS ON MARKET DERIVED AND POLITICALLY DERIVED STAKEHOLDER VALUE

There is concern for stakeholders in the e-government literature (Schware et al., 2003; Tan et al., 2005) and the effects they have on governance and policymaking (Savoie, 2004). E-government initiatives cannot succeed without taking into account, the three critical aspects of stakeholder management: (1) identification of stakeholders; (2) recognition of differing interests among stakeholders; and (3) how an organization caters to and furthers these interests. (Tan et al., 2005) Determining stakeholder values and building those preferences into e-government initiatives is not the same as moving through various stages of e-government development.

In a study of the deployment of e-government in developing countries Schware et al. (2003) used five categories of value to describe e-government examples in India, Estonia, the Philippines, Mexico, and Chile:

- **Direct Citizen Value:** Citizens gain value from increased access and reduced delays, improved service delivery, and less interaction with intermediaries.
- **Social Value:** Improved trust in government. Increased sharing of information. Monitoring of regulatory compliance, greater visibility.
- **Government Operational Value:** Improvement in current performance and in preparation for future requirements: on-time, completion rate, redundancy, network congestion flexibility.
- **Strategic/Political Value:** Organization perceived as moving toward fulfilling its mission: improved public image, legislative guidelines met.
- **Government Financial Value:** Benefits that impact organizational and other federal government budgets: reduced cost and steps per transaction, decreased cost of materials, reduced cost of error correction.

Welch et al.'s (2005) study showed general satisfaction among U.S. citizens with the implementation of e-government. The study also showed a relationship between use of e-government and citizen trust in government. However:

*Individuals with government Web site experience find that government is not fulfilling their expectations about interactivity and in some cases service provision. Results indicate not only that there are direct negative effects on e-government and Web site satisfaction but that there may also be indirect negative effects on citizen trust in government.* (Welch et al., 2005)

This research demonstrates some empirical evidence for the existence and effect of stakeholder responses to e-government based on their values.

In designing a generic framework for e-government Grant et al. (2005) developed what they termed strategic focus areas (SFAs): service delivery; citizen empowerment; market enhancement and development; and exposure and outreach. Each of the SFAs are further defined in terms of key functional applications such as e-participation and e-democracy under citizen empowerment. This represents a more sophisticated view of e-government that goes beyond the classification methodologies that focus on staged development.

This recent research is more consistent with the new public management debate which considers market and politically derived value. For example, Grant et al's (2005) service delivery SFA provides market derived value since it reduces the costs of government imposed ex-

*Figure 1. Categories of e-government value*

| E-Government Value Category | Brief Description of Value |
|---|---|
| Passive-Market Enhancing | Designed to reduce the cost of government imposed exchanges on citizens and perhaps make it more efficient to identify and charge costs to beneficiaries of government programs |
| Active-Market Enhancing | Designed to adjust aggregate demand in the market of a jurisdiction by taking new initiatives made possible by e-government |
| Passive-Politically Derived | Designed to increase efficiencies in existing government operations and are not directly concerned with broader policy matters |
| Active-Politically Derived | Designed to actively search out and test value definitions and are directly concerned with broader policy matters in ways made possible by e-government |

changes on citizens. The citizen empowerment SFA provides politically derived value as it improves constituent relationships management and also searches out and tests value definitions among citizens. (Grant et al., 2005)

Not only does the recent literature focus on value to stakeholders but it also suggests sub-categories for both market and politically derived value. Some of the categories of stakeholder value indicate that e-government initiatives can accomplish pre-existing objectives more efficiently. For example, direct citizen value (Schware et al., 2003), and service delivery (Grant et al., 2005) are designed to reduce the cost of government exchanges to citizens. The presumption is that these exchanges are the same ones that took place prior to the implementation of e-government and therefore can be said to be a more efficient way of doing the same thing. The term passive is chosen to describe this since no fundamental change in the nature of the exchange due to the introduction of e-government takes place. Since direct citizen value (Schware et al., 2003), and service delivery (Grant et al., 2005) for the most part provide market derived value to stakeholders (i.e., economic benefit) by accomplishing pre-existing exchanges at less cost the value is categorized as passive-market enhancing.

The term active is used where the nature of the exchange is fundamentally changed by the introduction of e-government. The active designation implies new initiatives and change that could not take place without e-government. For this reason market enhancement and development (Grant et al., 2005) is categorized as active-market enhancing since it envisions new collaborations and partnerships as well as global business development that become possible only with the introduction of e-government. passive-politically derived value includes Government financial value (Schware et al., 2003) and in part citizen empowerment (Grant et al., 2005) in so far as it improves constituent relationships management (a political process which has not fundamentally changed but become more efficient with the introduction of e-government). Finally, active-politically derived value includes social value (Schware et al., 2003) and citizen empowerment (Grant et al., 2005) in so far as they search out and test value definitions among citizens. Savoie (2004) indicates that the organizational boundaries within government as they affect policy making fundamentally change with the arrival of e-government initiatives related to social value (Schware et al., 2003) and the value testing and search aspects of citizen empowerment (Grant, 2005). As with market derived value the determination as to whether politically derived value is categorized as passive or active is related to the extent to which there is a fundamental change in the nature of the transaction due to the introduction of e-government.

## FUTURE TRENDS

Future e-government classification methodologies will be oriented more toward stakeholder value with less emphasis on the staged development classifications used in the past. In this section a conceptual framework for considering the value of e-government is presented. First the categories of value, both market and politically derived, are reviewed. Secondly, there is a discussion of how public administrators can use the categories to manage stakeholder support in ways that create an enabling environment for e-government.

## CATEGORIES OF E-GOVERNMENT VALUE

The preceding discussion on stakeholder value in the field of public administration is by no means exhaustive. Many important ideas regarding public value have been

ignored. For example, there is no consideration of public choice theory or some of the fascinating work done in the judicial system (Komesar, 1994). However, the beginnings of a framework with four value categories have been developed and briefly discussed in a way that will help practitioners to better understand the value of e-government alternatives. The categories are summarized in Figure 1 (Downey, 2004).

While the four value categories are helpful to public administrators they require a more refined understanding of their utility in order to form a useful framework of e-government value. The categories suggest management strategies for the implementation of e-government which are discussed in the next section.

## CATEGORIES OF E-GOVERNMENT VALUE AND POLITICAL MANAGEMENT

Having defined the four categories of e-government value it is now appropriate to briefly discuss how they might effect the creation of an enabling environment for e-government implementation. The four categories of value have five characteristics, which are general rules that describe how they can be used by public administrators. The four categories together with their five characteristics form the conceptual framework for considering the value of e-government.

Just as Tan et al. (2005) advocates for understanding stakeholders and their values, Moore advocates that public managers accomplish this by engaging in the political process even though, "the political environment surrounding their operations is a dangerous place." (1995, p. 132) This engagement is loosely defined as political management. Despite the dangers, engagement in the political process helps to define and produce public value, making political management essential to the creation of an enabling environment for the public management action required to implement e-government. The degree and form of political management required to create an enabling environment for e-government applications is largely dependent on the categories of value described in Figure 1.

The five characteristics of the categories of e-government value briefly discussed below explain their relationship to the political management strategies necessary to create an enabling environment for e-government alternatives. The first characteristic is that the categories are not mutually exclusive. A particular e-government application will likely provide value in more than one category and, in many instances, in all the categories. Secondly, in those cases where value is provided in more than one category, the value provided is unlikely to be distributed equally across the categories. An application is likely to provide most of the value in one or perhaps two categories and much less value in the remaining categories. Thirdly, the challenges of political management are different for each category and greater for the two politically derived than for the two market enhancing categories where value is more readily understood and accepted. Generally e-government applications that decrease transaction costs or stimulate aggregate demand will be more widely understood and accepted than those that are designed to decrease government agency operating costs or search for and implement politically defined value. Fourthly, within each category value can be affected by the technical and aesthetic qualities that determine an e-government Web sites functionality. In this regard the Center for Public Policy at Brown University does an annual survey that rates municipal, state, and federal government sites based on various aspects of their functionality. (West, 2004a) Fifthly, the total value produced may not be the sum of the values produced by the four categories. It is possible and indeed likely that an e-government application will produce some form of value that does not fit conveniently into one of the four categories.

## CONCLUSION

When faced with complexity it is natural to use what we know to attempt some categorization as a way of reducing confusion and perhaps improving our understanding. The e-government value categories: passive-market enhancing, active-market enhancing, passive-politically derived, and active-politically derived combined with their five characteristics do this more or less imperfectly. The main purpose in developing the framework is to assist public administrators to think about value so that they can:

- Determine whether or not an e-government application is valuable enough to be worth doing
- If worth doing, determine how public managers engage in political management strategies that create an enabling environment
- And finally, determine the operational feasibility of alternatives in conjunction with value and the ability to create an enabling environment

The framework of e-government value suggests research in two broad areas. First and foremost the framework must be rigorously tested. Improving the definitions by a controlled and documented process that asks observers to apply them to real e-government Web sites is

a beginning. Secondly, the fact that the categories may not account for the sum of value produced by e-government applications points to a potentially dangerous flaw in the framework. It could be that, despite the thought that has gone into them, the categories are simply inappropriate or, worse yet, misleading. An alternative is that some residual, uncategorized value will exist no matter how carefully the categories are devised. Insight into this should result from the application of the categories by public administrators.

With the framework presented here the value of e-government applications can be considered in a holistic way that provides public administrators with an understanding that will help them to create an enabling environment for e-government. This will result in better e-government solutions by providing higher levels of value to stakeholders.

## KEY TERMS

**Active-Market Enhancing Value:** E-government value from market adjustments in aggregate demand.

**Active-Politically Derived Value:** E-government value from actively searching out and testing value definitions.

**Enabling Environment:** An environment that allows for and encourages the creation, maintenance, and implementation of e-government alternatives.

**Passive-Market Enhancing Value:** E-government value that results from the reduction of the cost of government imposed exchanges on citizens and making it more efficient to identify and charge costs to beneficiaries of government programs.

**Passive-Politically Derived Value:** E-government value from increased efficiencies in government operations that are not necessarily concerned with broader policy matters.

**Political Management:** Active engagement of public administrators in the political process that surrounds their operations.

**Stakeholder:** A person or group who has a vested interest in government action or in-action.

# Concern-Wide Information Management with the Dutch Police

*Vrije Universiteit Amsterdam, The Netherlands*

## INTRODUCTION

In The Netherlands, police ICT has always mirrored the organization of the police system. Until 1993, the Netherlands had 144 local police forces at its disposal, which were supplemented by a national police force. Since 1994, when the 1993 Police Act was enacted, the Netherlands has had 26 police forces. Twenty-five of those are regional forces, and one provides a few specialist police services on a national scale. Although the number of forces has declined steeply since 1994, a heavy stress is still put on regional autonomy, as the 1993 Police Act knows no provisions for cooperation among forces.

Until 1993, police informatization was primarily a local matter, but after the 1993 Police Act was enacted, it became a regional affair. The Police Act, therefore, did not put an end to the existing situation characterized by so-called *islands of automation*. The Dutch police still use many different information systems that often are incompatible, which seriously hampers the information exchange among forces.

Because of the sharp focus on regional autonomy and the lack of legal or other incentives to encourage cooperation, it is remarkable that the police have been striving toward the creation of a uniform and concern-wide information management in recent years.

In this article, we argue that with this effort, a federative common pool resource (CPR) is called into being that can be seen as a form of administrative innovation in which horizontal intergovernmental cooperation through self-regulation is the central point. Such horizontal cooperation is of huge importance to the Dutch police system, as it is highly decentralized and as central steering, which often has failed in the past, would come with high transaction costs. A CPR can be defined as a shared facility that supplies goods or services to those participating in it. Characteristic for a CPR is either that it diminishes from use and/or that its creation and preservation depend on the participants' collective actions.

The federative characteristics of the developments we describe are best interpreted by using Davenport's (1992, 1997) typology of types of information management. In this typology, five different models are distinguished: anarchy, feudalism, federalism, monarchy, and technocratic utopianism. Davenport's (1992, 1997) main message is that in practice, many organizations struggle with a shift from feudalism toward federalism, the model that he deems superior to all others, as it enables us to create a common information system without the use of central steering, which is so difficult to many organizations, including the Dutch police. Feudalism, the current situation with the Dutch police, is highly unwanted, as it comes down to organizations not sharing information, which seriously obstructs many activities.

Currently, the Dutch police are undergoing a transformation of the kind Davenport (1992, 1997) describes. Not long ago, its information management displayed strong feudal traits, but under pressure from central government over the past few years, the 26 Dutch police forces collectively have pursued the realization of a uniform concern-wide information management with, in Davenport's (1992, 1997) terms, federal characteristics.

Closely associated with these developments is the rise of a new institutional paradigm that differs strongly from the one currently existing in the Dutch police field and that already is influencing the (legal) base of the Dutch police system.

## THEORETICAL BACKGROUND: THE FEDERATIVE CPR

In November 2004, the council of those mayors that play the most important role in the Dutch police system (the so-called police administrators) drew up a plan for the innovation of the police's information management in the years 2005 through 2008. This plan and its predecessor (Regieraad ICT Politie, 2001) calls for the creation of a

uniform concern-wide information management for the entire police field. Uniformization, in this respect, amounts to "the gradual improvement of the information management, leading to a concern-wide dissemination of all police information and to the integral accessibility of such information. It means the end of 'islands of automation' in the police field" (Regieraad ICT Politie, 2004, p. 42).

The effort to bring about uniform concern-wide information management can be viewed as an attempt to create a CPR, as such an information management can only come into being if every police region participates. If some regions refuse to cooperate, the others will not have access to all the information necessary in order to fulfill their tasks. In this case, whether it will be brought about depends on whether a solution can be found for a specific type of collective action problem that is often called *assurance game* or *coordination game* (Ostrom, 1990). In an assurance game, shared provisions only will come into existence if all potential participants coordinate their actions and cooperate. Now, the creation of a CPR is often impeded by a collective action paradox—a dilemma between individual and collective rationality. As it happens, the creation of a collective facility is in the interest of the collective but does not necessarily serve the private interests of all individual participants. Nonetheless, that the Dutch police field appears to succeed in bringing about a uniform concern-wide information management is the result of the peculiar way in which it managed to solve the collective action paradox.

Davenport (1997) defines information management with federal characteristics as a form of cooperation in which "rational negotiation between central and dispersed groups" is central (p. 69). According to this author, "federalism treats politics including the politics of information as a necessary and legitimate activity by which people with different interests work out among themselves a collective definition of purpose and the means to achieve it" (Davenport, 1997, p. 69). The fact that in federalism binding decisions are brought about through self-regulation after negotiations open to all concerned parties is essential.

## A UNIFORM CONCERN-WIDE INFORMATION MANAGEMENT AS A FEDERATIVE CPR

Until recently, the Dutch police system did not account for any financial or legal incentives in order to encourage cooperation among police forces. The council of police administrators, to provide but an example of this lack of incentive, wasn't even mentioned in the Police Act of 1993 and, therefore, did not enjoy legal status (Wagenaar & Soeparman, 2003). Autonomy of the individual police forces prevails in the 1993 Police Act. Naturally, such a lack of incentives for cooperation has had an effect on the domain of information management, which, therefore, could be characterized as feudal. Feudal information management, according to Davenport (1997), is the situation in which fragmentation prevails over the making of connections "when business units … control their information environments like lords in so many separate castles" (p. 72), a lack of cooperation that seriously obstructs the exchange of information often so important to police work. Not surprisingly, therefore, the Dutch minister of the Interior still could write in 1999 that "the police's information management still lagged behind to that found in most other sectors" and "that broad consensus existed over the fact that the arrears in the field of ICT the Dutch police had run into were truly worrying" (Tweede Kamer, 1999-2000, p. 1).

The solution that was found for the problem was of a highly federal character. Two private law cooperations, of which all police forces are members, bring about ICT facilities for all the police forces together—a CPR. One of the cooperations is called Concern Information Management Police (CIP); the other is called ICT Service Cooperation Police, Justice and Security (ISC). Although the cooperations work together, they have separate responsibilities.

CIP handles the demand-side of police ICT. It develops the information architecture and the logical and functional requirements of information systems and draws up long-term policy plans. On behalf of its members, CIP also acts as principal for the development of new applications. The standardization of data and data interchange is an important part of its range of duties, as well. The members of CIP are the police administrators (Veranderorganisatie, 2001; Concern Informatiemanagement Politie, 2004).

The other cooperation, ISC, acts as supplier of police ICT. The police forces, the CIP, and other parties involved are its customers. ISC is responsible for the technical design, actual realization, testing, implementation, exploitation, maintenance, and project management of police ICT. It also has a consultancy function and advises about standards, support, and training of end users, research, and the best way to facilitate innovation. As is the case with CIP, it is the police administrators who represent the police forces in ISC (Veranderorganisatie, 2001; ICT Service Coöperatie Politie Justitie en Veiligheid, 2004).

ISC's sphere of action is wider than that of CIP, however, as ISC caters to more than just the police. The idea behind this wider sphere of action is that police information and communication systems are a link in a much longer chain that also includes the police's partners in the areas of, for instance, criminal justice, security, and immigration. More parties than just the police, therefore,

share a common physical ICT infrastructure. Together, the two cooperations bring about change and innovation of police information management and its connection to the police's partners.

The federative nature of the CPR, in this case, is expressed mainly in the fact that the general meetings of both cooperations know binding decision making. In these meetings, the 26 police administrators all participate to decide on the cooperations' yearly policy plans and budgets. Decision making is characterized by majority rule and by the fact that it is legally binding. Negotiations between the police forces and the cooperations always precede it (Bestek, 2005-2008).

As members of the two cooperations, the police forces transfer part of their individual powers of decision to the collective, thus establishing a self-regulative structure for the bringing about of a joint information management. It is this decision-making mechanism that enables the solution of the collective action problem peculiar to CPRs, especially the so-called provision problems that "concern the effects of various ways of assigning responsibility for building, restoring, or maintaining the resource system over time" (Ostrom, 1990, p. 47). A number of provision problems is caused by a self-fulfilling prophecy: as soon as the potential members of a CPR recognize it as a CPR and, therefore, realize beforehand how unlikely it is that it will come about, their willingness to partake melts into thin air, thus preventing the CPR from materializing before an attempt to create it even has begun. Such mechanisms mean that one actor, by refusing to partake, can prevent the entire CPR from coming into being. If all actors are aware of this, chances are high that they will not even try to bring about the CPR (Kollock, 1999). Yet, if one succeeds in calling a joint decision-making structure into being, which has the authority to enforce majority decisions, changes that the necessary CPR will materialize increase immensely, as this will make it easier to make collective rationality dominate individual rationality (Ostrom, 1990).

The Dutch police actually have succeeded in doing this. The CPR we describe indeed has come into being without making use of hierarchy. In the initial phase of its development, it was rather the shadow of hierarchy, to borrow a term from Scharpf (1997) that has been decisive. By making clear that it could intervene if the police did not succeed in establishing a joint information management, the home office acted as a catalyst in the process, which led to its coming into being (Wagenaar & Soeparman, 2005). Naturally, contingent factors like good personal relations among key actors also played a part in this process.

## THE FEDERATIVE CPR AS A FORM OF ADMINISTRATIVE INNOVATION

It is the ability to self-regulate that is characteristic of the joint information management that is being brought about through the two cooperations. To borrow from Van Duivenboden (2004), it is, a prime example of horizontal intergovernmental cooperation—cooperation between public bodies on the same level of government. Although a legal base for such cooperation was lacking, the police forces voluntarily handed over part of their powers of decision to the cooperations as organs of the federative CPR in which they partake. In so doing, they called a more-encompassing entity into being that has the means to bring about concern-wide dissemination and integral accessibility of all police information (Bestek, 2005-2008).

Thus, the domain of information management is an important seed-bed for possible further administrative innovation in the police field, as a new form of cooperation has been called into being there, combining strongly horizontal self-regulation with an orientation on the Dutch police system as a whole. It also acts as a means by which to make decisions binding by (private) law, a facility the Dutch Police Act (public law) until recently did not provide for. Only recently (2004) has the Police Act been changed to make forms of cooperation among police forces possible. CIP and ISC success has been an important reason for the amendment. The amendment, in turn, creates the possibility to create public law successors for the two cooperations, thus firmly embedding them in public service. In addition, it is sometimes said that the two cooperations might be forerunners of similar structures in other domains of the Dutch police system.

## FUTURE TRENDS: FIRST STEPS TOWARD A NEW INSTITUTIONAL PARADIGM FOR THE POLICE SYSTEM?

The police system, with its long-lasting relations among key actors and its shared view on how it should be organized, can be regarded as a particular policy community with its own paradigm (Hall, 1993). One could say that such policy communities are the outcome of an autocatalytic process in which the interplay of actors and structure constantly confirms and strengthens itself in long-lasting relatively stable relations. Associated with such a policy community is a paradigm specific for

its context, a lasting combination of formal and informal rules and norms, values, conventions, power relations, and visions of reality shared to a high degree by its members.

The Dutch police system's existing institutional paradigm is determined by a number of intertwined topics: the separation of authority and administrative management, the separation between a judicial and an administrative police function (maintenance of public order vs. criminal investigation), and the neither local nor national character of the Dutch police (Wagenaar & Soeparman, 2003). Discussions on the design of the Dutch police system, therefore, either are vertically (centralization vs. decentralization) or functionally (maintenance of public order vs. criminal investigation) oriented, and are concerned with structure (size and number of police forces). In practice, this results in a police system that is functionally and territorially oriented in its organization and administered via a classic functional hierarchical model. The police forces form autonomous isles, and the connections among them have not been institutionalized.

The federative CPR in the police system, both the two cooperations and the coming into being of a uniform concern-wide information management, could be associated with a new paradigm because of its horizontal character . This would be a Hammerian paradigm of organizations sharing information, products, and services through a joint information infrastructure, which would be standardized and homogenized in every aspect. According to such a paradigm, organizations substitute an orientation on functions for a process orientation and act as links in a chain directed at the creation of added value (Hammer, 2001). In such a paradigm, the police would be regarded as an interdependent link in, for instance, the criminal justice system and would work territorially, deconcentrated but according to a single uniform criminal investigation process, and would be supported by a uniform concern-wide information management. Similar images can be conjured up for other police work processes; for instance, in the field of crisis and contingency management in relation to the activities of other emergency services.

With the possibility to create forms of cooperation, the Police Act, since 2004, has provided for elements of the new paradigm to e to come to the surface in a police system that is still heavily under the old paradigm's sway.

## CONCLUSION

Is the CPR described in this article and the administrative innovation to which it leads, by means of its horizontal character, sufficient conditions for success? Will it guarantee the actual coming into being of shared services in the police system's information management supporting its effectiveness? Obviously, the answer to these questions must be negative. The actual coming into being of joint information management is subject to a number of basic factors; for instance, the logic of grand projects (always too expensive, too late, etc.), the capacity for implementation of the various police forces, and a police culture in which sharing of information always has been disapproved of. Therefore, it will take many years for the police's concern-wide information management to be an enabler for the police system's effectiveness. Yet, that does not alter the fact that the innovations sketched previously have removed an important barrier to change. Such change easily could spill over to police activities other than information sharing; for instance, the joint purchase of materials. It also could provide an example to the many other decentralized services that are confronted with problems similar to those of the police. Examples are the (Dutch) health sector or the realm of (small) municipalities, the first being highly fragmented in nature and in need to devise ways to exchange patient information among general practitioners, hospitals, and insurance companies, and the second being highly fragmented by construction and in need of devising all kinds of cost-effective services to citizens but hampered by limited economies of scale.

## KEY TERMS

C

**Administrative Innovation:** Forms of innovation that focus on the introduction of new forms of governance (steering, policy implementation processes).

**Collective Action Problem:** A dilemma between individual and collective rationality in which rational individual action can lead to a strictly pareto-inferior outcome; that is, an outcome that is strictly less preferred by all individuals collectively than at least one other outcome.

**Common Pool Resource (CPR):** A shared facility that supplies goods or services to those participating in it, which diminishes from use and whose creation and preservation depend on the participants' collective actions.

**Federative Common Pool Resource:** A CPR in which all of the participants have agreed to govern collectively the allocation of goods or services through prior negotiation, thus ensuring their continuing supply to all participants.

**Information Management:** The administration of information, its uses, and transmission, and the application of techniques to create, modify, or improve information-handling systems.

# Configurable Reference Process Models for Public Administration

## INTRODUCTION

For the last couple of years public administrations increasingly face a modernization and performance gap which they try to close by reorganizing their processes. Reference models can provide added value in improving those processes and procedures. Their main characteristics, the storage for domain knowledge and their universal validity, create a high potential for reuse and therefore allow for the exploitation of synergies and the reduction of unnecessary tasks and redundancies. In order to reduce the amount of resources for adapting reference models to regional specifics the application of configurable reference models is especially useful and proposed in this article.

## BACKGROUND

During the last years public administrations have started to focus on their processes (Falck, 2002, p. 137; Lenk, 1997), and with the increasing diffusion of electronic government (Becker, Algermissen, Delfmann, Falk, & Niehaves, 2004a) a rising number of reorganization projects have been started to close the modernization and performance gap (Budäus & Schwiering, 1999, p. 145). Information models have proven to be an adequate solution to cope with the complexity of these reorganization projects. In order to reduce the modeling expenses on the one hand side and to allow for a reuse of existing "best-practice" or "common-practice" models on the other side the application of reference information models has been discussed in the domain of public administrations more thoroughly (Lenk, 2002).

This is especially true for the European public domain. Therefore, this article focuses on the given EU context and takes Germany as an example. In Germany—especially on a local level—the potential for a transfer of reference solutions is very high because a quite regulated legal framework creates a high level of task similarities and structural analogies between the 14.000 different municipalities.

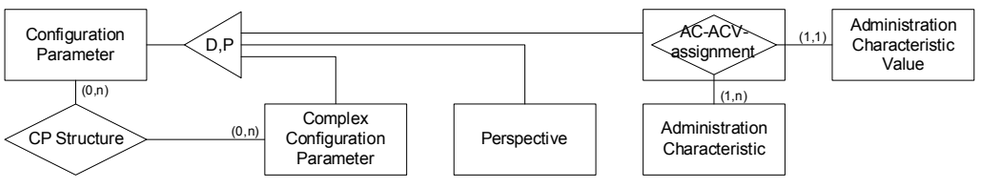
Existing contributions of the literature mainly formulate universal reference frameworks which do not take into account different process variants that are specific to certain administrations (Lenk, 2002). But there are certain variations in public administrations that are caused by the federal system which implies having different laws and regulations on a state, regional and local level. The application of reference models for public administrations therefore requires an adaptation to regional and local specifics.

First, this causes an additional customization effort for an administration using a reference model. Second a general increase of maintenance effort can be expected for all users of the reference models when changes in laws and regulations make a revision necessary.

A good idea to reduce the efforts mentioned is to consider regional specifics during the construction phase of reference models. This approach leads to an increased customization effort for the creator of the reference model.

However, the additional effort can be partly compensated through effects of scale, which are created through the applicability of different model variants for a large number of public administrations. In this context an additional requirement is a non-redundant integration of variants in the reference model as the public domain is faced by continuously changing laws and regulations.

*Figure 1. Configuration parameters*



Regular adjustments in redundant models create a non acceptable effort, especially when adjustments consider a lot of different models as it is the case in the domain of public administrations.

If reference models integrate different variants free of redundancies adjustments are only necessary once. The relevant variants for a specific administration should be easily derivable from the existing reference model by automatic methods. One example could be to select a certain state and hence deliver the process variants including specific state regulations. The main goal of this contribution is to apply an existing approach for a redundancy free management of variants in reference process models to the domain of public administrations. Hence we follow the demand for cheap but high-quality information models.

## CONFIGURATIVE REFERENCE MODELING AS A FOUNDATION FOR THE MANAGEMENT OF VARIANTS

In order to integrate variants into reference models as well as to generate these variants automatically based on adaptation criteria, the concept of configurative reference modeling is considered as an adequate approach (Becker, Delfmann, Dreiling, Knackstedt, & Kuropka, 2004b). Configurable reference models contain rules that specify which model elements and model sections are relevant for which application context. Non-relevant model sections are hidden. On this basis, model variants can be generated by performing configuration mechanisms that are dependent on specific criteria (configuration parameters) (Becker et al., 2004b). Configuration parameters can be specialized in administration characteristics and their values (AC/ACV), perspectives as well as complex configuration parameters that are both based on perspectives and AC/ACV. This interrelation is illustrated in Figure 1 as Entity-Relationship Model (ERM, cf. Chen, 1976).

An administration characteristic can be represented by the affiliation of a certain administration to a federal state or by the number of inhabitants. Perspectives consider that different user groups are characterized by different requirements according to the conceptual and representational format of the used models (Darke & Shanks, 1996; Rosemann, 1998; Rosemann, Schwegmann, & Delfmann, 2005).

In order to reduce the modeling complexity both for reference model developers and reference model users, it is reasonable to provide configuration mechanisms with different impacts on the models. Therefore, configuration mechanisms that operate on models and those that operate on the modeling language are distinguished (Becker et al., 2004b):

- **Model Type Selection:** Model types represent result types of special modeling languages. The relevance of model types is dependent on the actual perspective. For example, different user groups prefer different modeling languages in order to model the same circumstance. The configuration mechanism of model type selection provides the perspective-specific selection of model types and hiding of those that are not relevant for the actual perspective.
- **Element Type Selection:** This mechanism admits the building model type variants. Model type variants differ in the number of valid element types and thus in their expressive power. Users from different perspectives naturally prefer model types with a different expressive power (e.g., due to their different skills).
- **Element Selection:** Element selection allows the assignment of single models, model sections or model elements to configuration parameters. For example, for cities with different inhabitant numbers, different branches of administrational processes are relevant. Non-relevant branches can be faded out by applying element selection.

- **Synonym Management:** This mechanism considers different naming conventions that are valid in different administrations. For example, it is synonymously spoken of "invoice" and "bill" in different administration departments, whereas these denotations have the same meaning. With synonym management, these denotations can be exchanged dependent on the actual configuration parameter value.
- **Presentation Variation:** The assignment of different symbols to model element types and the assignment of different topological adjustments of model types are achieved by presentation variation. For example, users groups differ in their preferences concerning the reading order of process models.

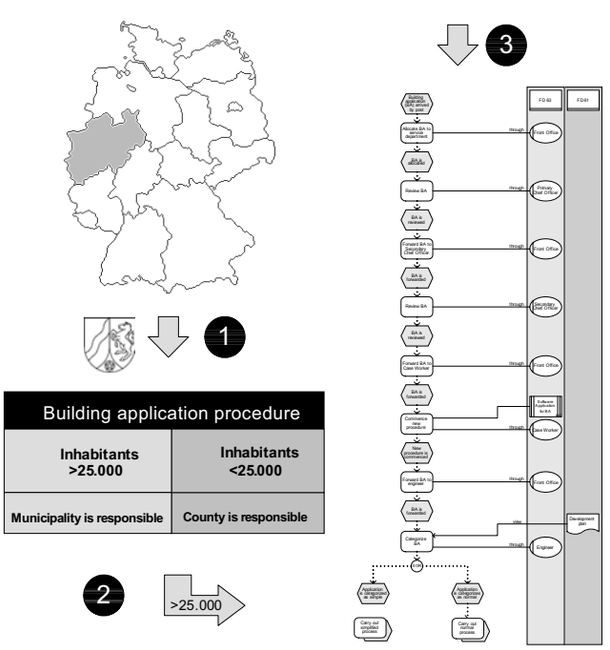
## CONFIGURATIVE REFERENCE MODELING OF THE BUILDING APPLICATION PROCESS

As an application example for the configurative reference modeling in public administrations we show the building application procedure. As the building law lies in state responsibility the first step of configuration is to select the state for which the reference model has to be created (see Figure 2). In the example the German state North Rhine Westphalia has been selected. In each state the procedures are different according to the inhabitants of a certain county or city.

In North Rhine Westphalia only municipalities with more than 25,000 people have their own building application authorities. The authorities for smaller municipalities are concentrated on the county level. As a result, the second step of configuration is the adaptation of the reference model according to the amount of inhabitants. In the example, a municipality with more than 25,000 people has been selected. For both configuration steps the proposed element selection is suitable.

The third step is the selection of the model users' perspective. By selecting different perspectives and the use of configuration mechanisms different aspects of the total model can be varied. One example is the possibility to use the concept of element type selection to hide certain resource types which are annotated in the overall model but irrelevant for a certain perspective. The IT department for example is mainly interested in the annotated resource type information system while the organization department is mainly interested in the annotated organizational units.

*Figure 2. Configuration of a reference model for the building application procedure*



## FUTURE TRENDS AND CONCLUSION

Structural analogies can be identified between different administrational processes within a public administration and, in a higher grade, between similar processes of different administrations. In the course of an expansive process oriented modernization of public administrations, reference process models can serve as a repository of domain knowledge in order to handle the complexity of eGovernment projects and to accelerate their realization. However, up to now, only few attempts have been done in generalizing the knowledge gained in administrational reorganization projects and in documenting it in concrete reference models. Hence, further efforts have to be enacted in order to develop generalization criteria for information models as well as to formulate reference models for public administrations. Furthermore, in the construction of configurable reference models, configuration mechanisms have to be developed that are easy to use. Primarily, administration staff, who are not necessarily skilled in modeling methods, have to be enabled to perform configurations themselves. Thus, the applicability of configurative reference modeling implies the development of an according modeling tool that implements the proposed concepts.

## KEY TERMS

**Administration Characteristics:** Describe differences between public administrations that determine different information models as relevant for different administrations.

**Configurable Reference Models:** Contain rules that specify how the model has to be adapted to specific application contexts.

**Configuration Mechanisms:** Transform configurable reference models in context specific reference models. Model sections or model elements that are not relevant for a certain application context are hidden.

**Configuration Parameters:** Comprise perspectives and administration characteristics and are used as input parameters for configuration mechanisms.

**E-Government:** Entails the simplification and implementation of information, communication and transaction processes, in order to achieve, by means of information and communication technology, an administrative service, within and between authorities and, likewise, between authorities and private individuals or companies.

**Perspectives:** Represent requirements of different user groups according to the conceptual and representational design of information models.

**Reference Models:** Information models that are reusable for different, even though similar application contexts. In terms of their reuse, they have to be adapted to the actual application context.

## INTRODUCTION

The terms *electronic government* (*e-government*) and *digital government* are used to refer to the utilization of the Internet and other information and communication technologies (ICT) effectively in public sectors. In e-government development activities, the concern is often in building new means to support and strengthen democracy (e.g., Watson, Alselsen, Evjemo, & Aarsæther, 1999). In other cases, the main concern may be in supporting the work of people in public sectors (e.g., Mustajärvi, 2003), or in building new kinds of services for citizens (e.g., Lyytikäinen, Tiitinen, & Salminen, 2000). Common to most development activities is the need to have the content of public sector information repositories available on information networks, including the Internet, extranets, and intranets of particular organizations.

The content production practices have a major effect to what extent digital content is accessible and how well the content supports e-government goals. In planning new kinds of e-government solutions, it is important to understand the different alternatives for producing information assets and the consequences of the solutions. In the digital era, the actors on public sector have to update continuingly their content production strategies and practices for effective ICT utilization.

In this article, we will introduce three strategies for content production and discuss the practices related to the strategies. We will also evaluate the benefits and challenges of each of the strategies. We will demonstrate the strategies and practices by examples from the Finnish legislative environment. Data about the case environment has been collected during long-term collaboration of researchers at the University of Jyväskylä with the Finnish Parliament and ministries (Salminen, 2003).

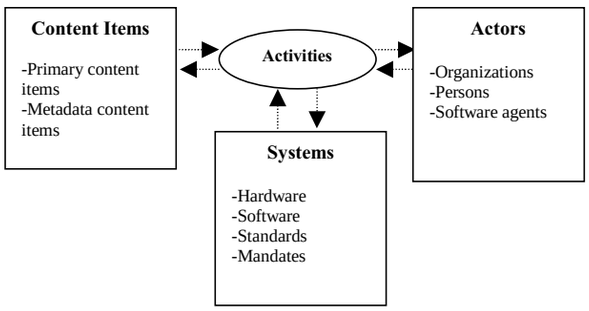
## BACKGROUND

Documents have traditionally been important in public sectors to record rules, applications, decisions, and decision histories. A great deal of the content of digital information repositories is stored either as documents or as metadata related to documents. Information technology has provided powerful tools for authoring and distributing documents in digital form and new document genres have evolved. The Internet has facilitated new kinds of communication both within the public sector and with citizens outside. Digital information repositories are expanding rapidly and more systematic rules and practices concerning content production and organization of the content are needed.

Our analysis of the content production strategies will be based on the content management model depicted in Figure 1 (Salminen, 2003). The model shows two types of entities in a content management environment and information flow between them. The information flow is depicted in the figure by the arrows. All information flows are related to activities depicted by the oval.

An *activity* is a set of actions performed by one or more actors in a process. In the public sector, the process can be, for example, legislative or budgetary process. The

*Figure 1. Information flow in a content management environment*



entities depicted by rectangles in the figure represent information resources. There can be three kinds of resources corresponding to their different roles in the activities: actors, content items, and systems. An *actor* is an organization or a person, in the contemporary and future network environments also software agents can perform as actors. In the budgetary process, for example, Ministry of Finance is one of the organizational actors and Minister of Finance is one of the human actors. *Systems* consist of the hardware, software, standards, and mandates used to support the performance of activities. Mandates can be, for example, regulations and legislation governing the content management of the domain. *Content items* are documents and other addressable units of stored data intended as information pertaining to the activities of the domain. Content items may be clustered in *collections* and *metadata* associated with the collections. Metadata provides information about the content items of a collection and about their production, storage, and use environments. If metadata is accessible in the activities of the environment as content items of their own, then it is possible to talk about two kinds of content items in the environment: *primary content items* and *metadata content items*.

In the analysis of the next section, we will consider the Finnish legislative environment as a case of a public sector content management environment. The legislative process is an example of a complex interorganizational process participated by many organizations, among them the government, ministries, the parliament, and the president of the Republic. Hundreds of people in these organizations participate in the work and content production. The time for developing a new law may take from a couple of months to several years. Dozens of different document types are produced within the legislative work, annually thousands of documents and tens of thousands of original pages. In the parliament alone, about 40,000 original pages are published per year. Information about the legislative activities and results of the activities are available on the public Web pages of the ministries and the parliament. The Otakantaa.fi service provides some opportunities for citizens to discuss and express their opinions related to the legislative activities. ICT is utilized in all organizations involved, and in the communication of people participating in the process. A number of intranet systems, extranet systems, and various software applications are used during the process. Advanced content production and document management strategies are important in the environment to facilitate effective work processes and building flexible e-government services.

## CONTENT PRODUCTION STRATEGIES

We have identified three different content production strategies: traditional, structured, and holistic. Table 1 shows the system basis for the strategies. In the *traditional strategy*, word processors, file systems, and database systems create the technological basis of content production. Word processors are used to produce text documents and file systems to store them. In the *structured strategy*, not only the database content but also the document content is in structured form. The Standard Generalized Markup Language (SGML) (Goldfarb, 1990), its more streamlined subset Extensible Markup Language (XML) (Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004), and the SGML application HTML (HyperText Markup Language) create the basis for the management of structured documents. The *holistic strategy* is based on the use of XML and Semantic Web technologies (http://www.w3.org/2001/sw/). The goal in this strategy is to enable the creation of rich metadata and flexible cooperation of computers and people. In the following, we will discuss more of the strategies. At the end, we will evaluate the benefits and problems of each of the strategies.

### Traditional Content Production

The traditional content production is characterized by a clear distinction of document content and database con-

*Table 1. The system basis of the three content production strategies*

| | |
|---|---|
| Traditional | Word processors, file systems, database systems |
| Structured | SGML, XML and HTML as document standards |
| Holistic | XML technologies and Semantic Web technologies |

tent. Document content is produced by people using word processors, database content by software applications. Documents are used as units of communication between people. The reuse of parts of a document in other documents requires either retyping of the text or using copy-paste capabilities of the document authoring tool. In each software application, its own kind of metadata is created, in its own format, and similar kind of metadata may be created for the same document in different phases of the document life cycle. Metadata about documents is mostly created by the human actors. In using a word processor, the author can embed metadata to the document by giving values to some predefined properties, like author, subject, and keywords. Information about the external representation (layout) of the document is embedded in the document. If the document has to be stored as an official record, then external metadata about the document is created in a diary system or some other kind of records management system. The same data is often typed several times since the systems do not communicate with each other. In an interorganizational process, partly the same metadata is created for one document in several organizations.

As an example, let us consider some content production activities during the lifecycle of a Government Bill in the Finnish legislative process. A civil servant of a ministry prepares the bill by Microsoft Word. Same type of external metadata concerning the legislative process and related documents is produced into four separate systems: the governmental project register, the case management system, a document management system, and a diary system of a ministry. Before the bill is printed for the government plenary session, an assistant edits it using style properties of the Microsoft Word. After the president's decision to send the bill to the parliament for discussion the bill is published by a printing house both in paper format and in PDF format on the Internet (http://www.finlex.fi). The secretary of government sessions completes metadata about the case into the case management system and sends the Bill as a word processor file and as a paper document to phe Parliament. The parliament publishes the bill on the Internet (http://www.eduskunta.fi).

## Structured Content Production

In a structured content production environment, documents are stored as *structured documents* where the structure definitions, document instances, and layout specifications can be handled as separate content items. The use of open standards like SGML and XML facilitates the manipulation and use of documents by different software applications. Automated creation of new content items is possible. Since the layout of documents can be defined by separate style sheets, the same content can be distributed in different forms, for example, for different media.

HTML as an SGML application is in use in many environments where the structured content production is not applied otherwise. HTML documents are created either as static documents, for example, by using an HTML editor, or dynamically at the time of the HTML page access. Parts of the content on the page can be accessed from databases. Metadata about an HTML document can be embedded in the document and processed and manipulated by HTML aware editors.

HTML has been widely adopted for Web publishing since the specification of the language has been available without costs and HTML browsers are available for all having a connection to the Internet. The use of SGML/XML for other purposes than Web publishing usually requires the development of the particular SGML/XML based language for the purpose. Thus an essential activity in the structured content production is the development of document standards. The adoption of the new standard may require major changes in the content production practices and tools. Therefore the standardization process has to include, together with the development of standards for documents, redesign of work practices and tools used in document production (Salminen, Lyytikäinen, & Tiitinen, 2000).

SGML/XML content may be produced by human actors or automatically by a software system, for example, in the ways presented in Table 2.

*Table 2. A List of ways for SGML/XML content production*

| |
|---|
| • Using a syntax-directed editor which validates the content in respect to the structure definition<br>• Transforming the content of a word processor file automatically to a structured document using the structure information attached to styles<br>• Creating the structured content from database content by the export capabilities of the database system<br>• Using word processors or Web browsers with XML support<br>• Creating the content into an XML database, either by a human actor or by a software application |

Structured content offers possibilities for gathering and reusing metadata about content items (semi)automatically by transformations on the grounds of standardized content structures inside and between organizations (Bayerl, Lüngen, Goecke, Witt, & Naber, 2003). If XML is used as the format also for metadata content items, there is a possibility to use the same systems for the production of primary content and metadata content.

SGML based structured content production is in use, for example, in the Norwegian Parliament and ministries (Sundholm, 1997), the Supreme Court of Canada (Poulin, Lavoie, & Huard, 1997), the Tasmanian government (Arnold-Moore, Clemes, & Tadd, 2000), and also in the preparation of the Budget of the European Union (Catteau, 1997). XML has been considered as a basis for document production, for example, in Estonia (Heero, Puus, & Willemson, 2002) and United States Congress (Carmel, 2002). The Finnish parliament has adopted the structured content production strategy for the parliamentary documents. The document standardization was activated in 1994 and by the end of 2002, the SGML implementation covered all parliamentary legislative documentation (Salminen, Lyytikäinen, Tiitinen, & Mustajärvi, 2001). In the Parliament, the proposal of law text included in Government Bill is converted into SGML format. The structure is reused in the creation of the Special Committee Report and parliament's reply. The tool for structured production of parliamentary documents is FrameMaker+SGML providing document type specific applications with several layout definitions. Documents are stored both in SGML and PDF format into the text database, and are available on the Internet. HTML document is created dynamically from SGML. For the Parliament's answer to the government also Word document is created from SGML. Structural metadata is used, for example, for the extraction of index terms from the documents and to support information retrieval.

## Holistic Content Production

The emphasis of the holistic content production strategy is in systematic metadata solutions to cover the important information resources of the environment. The metadata is intended to support information management in the activities of the environment and effective cooperation of computers and people. Primary content items can be produced either by the traditional or structured content production practices. In the strategy, XML and Semantic Web technologies are important means to support interoperability of various software systems. The Semantic Web technologies provide XML-based languages to describe metadata. Special concern in the Semantic Web solutions is in the utilization of the semantic metadata (Berners-Lee, Hendler, Lassila, 2001).

The core standards used in this strategy include, in addition to XML, the resource description framework (RDF) (Klyne & Carroll, 2004) and the Web Ontology Language (OWL) (McGuinness & van Harmelen, 2004). RDF provides a model and an XML-based language for representing metadata related to Internet resources, whereas OWL can be used for defining formal vocabularies to facilitate interoperability of software applications.

According to this strategy, metadata is produced as automatically as possible. Recent prototype systems prove that authoring of informative, structured content, and automatic or semi-automatic creation of metadata is possible in some extent within a single software system (e.g., Brun, Dymetman, Fanchon, Lhomme, & Pogodalla, 2003). Descriptive metadata still needs to be created manually, for example, by using metadata forms integrated in document authoring systems.

Public sector standardization activities started in many countries strongly support the holistic approach. Examples of the activities are the Austrian eGov project (Wimmer, 2002), the Danish Infostructurebase (http://isb.oio.dk/info/) and the e-GIF service in the Great Britain (http://www.govtalk.gov.uk/). Such standardization activities have also been initiated within the Finnish public sector. A special research and development project called RASKE2 (http://www.it.jyu.fi/raske) has been initiated to investigate the metadata requirements of the legislative environment. Currently the legislative process as a whole lacks standardized metadata schema and metadata repository. Metadata is fragmented between 13 ministries, the Parliament, and some other organizational actors involved. For example, keywords of the legislative case are created separately in the Government and the Parliament during the process. Due to this fragmentation and lack of established practices the utilization of metadata in the content production is currently very limited (Lehtinen, Salminen, & Nurmeksela, 2005). The most important metadata lacking today and needed to facilitate the holistic approach is the resource identifier.

## Evaluation

The strategy of traditional content production is simple for producers of software applications and systems analysts, because they need not to consider inter-communicational aspects of systems. For content producers this strategy is familiar but often requires retyping of the same data into various systems.

Structured content production entails well known advantages like rich information retrieval capabilities,

information reuse, multichannel publishing and long-term accessibility of information stored in documents. As a disadvantage this strategy requires demanding standardization process and changes in the traditional work practices.

The holistic content production produces standardized metadata about all important information resources in the content management environment. The metadata supports system integration, information retrieval, and collaboration of people in work processes. Standardized metadata offers a basis for applying Semantic Web technologies and utilizing the metadata solutions developed for related domains. As a disadvantage, this strategy also requires extensive standardization. The standardization of the semantic metadata may be particularly difficult. Legal information is an example domain where finding agreements about concepts and their relationships is extremely challenging. Another challenge lies in immature state of technology and applications. Although XML is currently quite widely accepted and used, there are not so many tools that enable the utilization of higher level languages in Semantic Web (like RDF and OWL).

## FUTURE TRENDS

Current e-government activities for metadata standardization are leading towards holistic content production and new kinds of e-government services. The services will require effective interaction between the software applications. The World Wide Web Consortium is currently developing solutions for Web services in order to provide standard means for the interoperation of applications independent of their implementation platform (http://www.w3.org/2002/ws/Activity). Adding semantic metadata to the descriptions of Web services aids identifying the service that is suitable for the desired needs. By the support of Web services different applications can participate in producing the content for governmental purposes. As an example consider the early phases of producing law initiatives or government bills. The user could give a task to a system to contact the Web services provided by each ministry and the Parliament to browse all initiatives—or other documents and information—related to the issue he or she is currently working with. This way the possibility of unintentional parallel work in law preparation could be reduced. Simultaneously to the browsing of ministerial services, the system could also contact the international news services and search for the news items related to the law initiative. Due to the international characteristics, Web services providing translation between languages could also be utilized.

## CONCLUSION

The article described three strategies for content production in e-government environment: traditional, structured, and holistic. Each of the strategies has its own strengths and weaknesses which should be taken into consideration when planning new practices. The choice of a content production strategy effects on the extent the produced digital content is accessible and how well the content can be used to support e-government goals.

Currently, most of the content production in public sector can be characterized as traditional. In many environments the structured production concerns only HTML documents. The holistic approach is however at the moment a common tendency supported by development activities in many countries.

## KEY TERMS

**Content Items:** Documents and other addressable units of stored data intended as information pertaining to the activities of a domain.

**Extensible Markup Language (XML):** A markup language for representing information as structured documents. A streamlined subset of the earlier language called SGML (Standard Generalized Markup Language). XML was developed particularly for the purposes of information management on the Internet and to facilitate easier implementation than SGML.

**Metadata:** Data about data. In the context of content production provides information about the content items of a collection and about their production, storage and use environments.

**OWL Web Ontology Language:** Used to represent the meaning of terms in vocabularies and the relationships between those terms. This representation of terms and their interrelationships is called an ontology. Intended to be used when the information contained in documents needs to be processed by applications, as opposed to situations where the content only needs to be presented to humans.

**Resource Description Framework (RDF):** A general model for the metadata describing Web resources (or resources in general). The concrete syntax of RDF is given by XML.

**Semantic Web:** An extension of the current Web where information resources are attached with metadata

to support both people and computers to work in co-operation. The metadata is intended to give well-defined meaning to resources and to support automated reasoning about meaning and trustworthiness of resources.

**Structured Document:** Has explicitly indicated structure consisting of named parts so that software applications can identify, retrieve, and process those parts. The structure can be defined by a structure definition for a class of documents. XML is a language for representing and defining structured documents.

# Continuity of Operations Planning and E-Government

C

**R. Eric Petersen**
*Congressional Research Service, USA*

**Jeffrey W. Seifert**
*Congressional Research Service, USA*

## INTRODUCTION

Continuity of operations (COOP) planning, sometimes referred to as disaster recovery planning, business continuity planning, or business resumption planning, is a segment of contingency planning that refers to the internal effort of an organization, such as a branch of government, department, agency, or office, to assure that the capability exists to continue essential operations in response to a comprehensive array of potential operational interruptions. In government, COOP planning is critical because much of the response to an incident might include the maintenance of civil authority and infrastructure repair, among other potential recovery activities. All such efforts presume the existence of an ongoing, functional government to mobilize, fund, support, and oversee recovery efforts. In an emergency, government is likely to need to ensure the ability to communicate with internal and external constituencies. This function is becoming associated with electronic government. For example, many people in the United States and elsewhere, when searching for information and guidance following the September 11, 2001 attacks, turned to government agency Web sites. Beyond such extraordinary examples, the growing public expectations of e-government has put additional pressure on the need to reconstitute systems quickly after an interruption to minimize any disruptions and financial costs associated with a major infrastructure failure.

Government COOP planning may be regarded as a "good business practice," and part of the fundamental mission of agencies as responsible and reliable public institutions. Comprehensive contingency plans, perhaps once viewed, at the least, as optional and, at the most, as a prudent measure, are now seen as an integral part of developing and maintaining an agency's capacity to carry out its essential functions. Continuity planning professionals assert that the perception of a changing threat environment and the potential for no-notice emergencies, including localized acts of nature, accidents, technological emergencies, and military or terrorist attack-related incidents, have increased the need for COOP capabilities and plans that enable agencies to continue their essential functions across a broad range of potential emergencies. COOP planning can be viewed as a continuation of basic emergency preparedness planning, including evacuation planning, and serves as a bridge between that planning and efforts to maintain continuity of government in the event of a significant disruption to government activity or institutions. In the aftermath of an incident, initial efforts typically focus on safeguarding personnel and securing the incident scene. Subsequently, attention focuses on reestablishing critical agency operations according to a COOP plan. Because the number and types of potential interruptions are essentially infinite, effective COOP planning must provide, in advance of an incident, a variety of means to assure contingent operations.

In the context of e-government, the heavy reliance upon information technology to carry out mission critical tasks and provide other citizen services highlights the need to ensure these assets are robust, protected, backed up, and resilient to interruption. COOP is not a new idea. While contingency planning has gained considerable attention in recent years due to heightened security concerns and increased dependence on information technology, modern government continuity planning has been practiced, in one form or another, for several decades. What may now be emerging is a recognition that all organizational assets, in the case of government, this would include leaders, civil servants, and information infrastructures, must be incorporated into organization-wide contingency planning.

## EVOLUTION OF GOVERNMENT CONTINGENCY PLANNING

Government contingency planning grows out of two major streams. One stream, COOP planning, focuses generally on the preservation of staff, facilities, technology systems, and data. The other stream, sometimes identified

as continuity of government (COG), typically focuses on preserving government leadership and high-level officials. Depending on the scope of an operational interruption, COOP and COG plans could be initiated independently or in concert with one another. The failure of the network supporting a regional or national e-government program could be a COOP event. The failure of such a system as a result of war or terror attack on government facilities could also be a COG event if critical national functions are interrupted, or leaders are the target of the incursion. Due to the wide variety of potential operational interruptions, it is all but impossible to make a firm delineation between COOP and COG activities used to support e-government programs that could be generalized across all nations. As a consequence of security concerns, current government contingency plans, whether they are those that focus on localized or low level operational interruptions, or those that threaten the safety and welfare of state leaders, are not public information, and are not widely available within government. The history of government contingency planning strongly suggests, however, that it is reasonable to assume that contingency planning for government leaders, their staffs, and the facilities that support government operations are closely interrelated.

Leadership preservation is the more longstanding contingency practice. For example, Tanfield (1991) found that, before World War II, there was a confidential plan for the evacuation of the United Kingdom's Parliament from Westminster to a secret location (later revealed as Stratford-Upon-Avon) prior to the commencement of hostilities, although this plan was never used. During the war, Parliament was forced to convene outside of its traditional setting after the chambers of the House of Commons were destroyed during an air raid. For the remainder of the war years there was a ban on disclosing the location of Parliament. Similarly, the governments of The Netherlands and France continued to operate from abroad while their nations were occupied.

In the United States, Cold War efforts to preserve leaders and institutions of government focused on preserving the continuity of government in the event of a nuclear conflict with the former Soviet Union. Federal contingency planning focused on preserving the line of presidential succession, by safeguarding officials who would succeed the president. Also, Cold War era plans reportedly included locating and evacuating the officials in the line of succession, along with the other senior leaders of cabinet departments, as well as members of the U.S. Congress and justices of the Supreme Court. In the event of an imminent nuclear attack, the plans called for the relocation of these individuals to secure, alternative operational facilities outside of Washington, DC (Blair, Pike & Schwartz, 1998; Gup, 1992a, b; Zuckerman, 1984).

As leadership-focused plans evolved, it was recognized by emergency planners that it could be necessary to support the country's senior leadership, or to carry out critical functions in the aftermath of an attack, regardless of the need to evacuate and relocate government officials. Consequently, COOP planning became a unifying element that integrated support functions in situations where the lack of such basic support components as personnel, alternative operational facilities, information technology assets, or records posed the potential threat of serious disruption to operations and the ability of the government to provide services and carry out its duties.

In the period following the end of the Cold War, and reinforced by experiences surrounding the September 11, 2001 attacks in the United States, the March 11, 2003 train bombings in Spain, the July 7, 2005 attacks on the London Underground, and attacks on diplomatic and commercial facilities around the world in the past ten years, contingency planning has evolved. Once considered as remote possibilities, the permanent loss of a facility, or the impairment of staff due to radiological or biological contamination, while still unlikely, are now taken more seriously. Recently, for example Cracknell and Elliott (2005) reported that the United Kingdom Parliament, which has not been denied the ability to use its primary facilities since 1681, exercised its plan to relocate Members of Parliament from the Palace of Westminster to another facility approximately 50 miles away from central London. Nevertheless, contingency planners have recognized that contingency plans based on Cold War era assumptions that included a period of warning before an attack, are inadequate protection in a threat environment characterized by potential sudden, localized terrorist attacks by non-state actors that could include the use of weapons of mass destruction (Bhambhani, 2001; Milbank, 2001; Pressley & Hsu, 2003). Accordingly, attention to contingency planning has extended to and incorporated planning to protect vital information technology (IT) assets.

As with the stream of planning that focuses on preserving leaders and staff, government (COG) IT disaster recovery planning has evolved with advances in technology, equipment, and information resources over the past 25 years. At various times, disaster recovery planning preparations have been incorporated into infrastructure and software upgrades deployed in response to emerging events, such as Year 2000 (Y2K) planning, the successive waves of computer virus and worm incursions, and physical attacks on people, buildings, and infrastructures.

While much of the current attention to COOP planning focuses on responding to potential attacks, operational interruptions that are more likely to occur and could necessitate the activation of a COOP plan include routine building renovation or maintenance; mechanical failure of heating or other building systems; fire; and inclement

*Table 1. Potential interruptions and consequences*

**Potential Interruptions**

- **Natural Disasters**: Storm, flood, earthquake, tsunami, hurricane, cyclone.
- **System or Equipment Interruption**: IT, telecommunications, or power infrastructure failure, labor action.
- **Accidents**: Fire, gas leak, construction damage, motor vehicle accident, industrial accident.
- **Malicious Damage**: Security breach, sabotage, theft, vandalism cyber attack, media leak.
- **Military or Paramilitary Attack**: War, terrorism.

**Potential Consequences**

- Loss or destruction of vital records or information
- Loss of critical resources including power, water, office facilities, security systems, and supplies
- Loss of critical support functions including payroll, finance, administration, and internal communications
- Loss of key personnel
- Loss of capacity to provide public services

weather or other acts of nature. Other events that might interrupt government activity include industrial action, failure of information technology (IT), telecommunications, power or other critical infrastructure due to malfunction or cyber attack. Table 1 summarizes the potential incidents that could cause COOP plans to be implemented

Because it attempts to incorporate all facets of organizational operation, COOP planning is multidisciplinary in nature. Professionals in emergency management, information technology, physical security, human resources, facility management, and other specialties could contribute to COOP planning, or lead recovery efforts during an incident. While attention has been growing over time, this multifaceted undertaking can often be a very challenging and frustrating process as planners try to coordinate disparate parts of their organizations while trying to strike a balance between how much they *cannot* afford to be unprepared and how much they can afford to spend on resources they may never use. Further complicating matters has been the tendency for organizations to "stovepipe" the different protections relevant to information technology disaster recovery planning. To the extent that COOP planning is carried out by the practitioners of a particular specialty, there is a risk that the resources of that specialty will be preserved while other vital organizational elements could be overlooked. For example, information security has often been handled independently from physical security. In the e-government environment, the heavy reliance on technology systems could produce a plan that is IT-centric, perhaps at the expense of personnel safety. Such an approach is not unique to public sector contingency planning. In the private sector, contingency planners from backgrounds in human resources and staffing are occasionally at odds with specialists in facilities management or information technology regarding which organizational resources ought to receive priority in contingency planning (Blythe, 2003; Canavan, 2004; Seese, 2004), while others argue for a more integrated approach that preserves capacity across the breadth of an organization (Corcoran, 2003). Accordingly, the compartmentalization of an organization's units and processes that Schulz (2001) suggests can contribute to a fractured planning process, leaving a private sector organization vulnerable, likely could apply to e-government assets in the public sector.

## COOP PLANNING AND E-GOVERNMENT

The heavy reliance upon information technology to carry out mission critical tasks and provide other citizen services highlights the need to ensure these assets are protected, backed up, and resilient to any interruption. Moreover, the growth of the use of e-government applications to conduct government-to-citizen interactions, as well as government-to-business and government-to-government transactions, has put additional pressure on the need to reconstitute systems quickly to minimize any disruptions and financial costs associated with a major infrastructure failure (Musich, 2002). To reduce these costs, some public agencies have chosen to develop redundancy of computer or network system components, including hardware, software, and telecommunications links. These resources have been installed and

*Table 2. COOP plan elements and e-government*

In general, viable, robust COOP plans establish the capacity to:

- identify an agency's essential functions and operations that must be supported during, and in the aftermath of an operational interruption;
- reduce loss of life;
- execute, as required, successful succession to office in the event a disruption renders agency leadership unable, unavailable, or incapable of assuming and performing their authorities and responsibilities of office;
- protect essential resources necessary to the operations of an agency. This could include facilities, equipment, vital records, or other assets;
- achieve a timely and orderly recovery from an emergency and reconstitution of normal operations that allows resumption of essential functions for both internal and external clients; and
- ensure and validate COOP readiness through a dynamic, integrated test, training, and exercise program to support the implementation of COOP plans.

are ready to use as a backup in the event primary resources fail. A related aspect of redundancy is the ability to replace or reconstruct hardware and software quickly and easily when necessary to prevent extended periods of downtime. In addition to redundancy, e-government COOP planning entails the establishment of comprehensive data storage plans that include fully and regularly tested backup sites. A comprehensive backup system would likely need to capture more than just an organization's data files. In addition to backing up data, public sector organizations also need to backup the data catalogs, directories, and software applications used with the data. Following the 2001 attacks on New York, organizations that saved only their raw data had to spend a significant amount of time recreating their applications, organizing the data, and reestablishing user permissions to access the data (Garvey, 2001). Taken together, these issues demonstrate the importance of ensuring the reliability and continuity of information technology systems, as part of overall governmental approach to providing reliable e-government as well as assuring domestic security.

At the same time, it should be recognized that e-government programs may not receive the highest priority in contingency planning. Because COOP planning strives to assure the provision of basic services under any circumstance, the elements described in Table 2 that comprise the entirety of COOP planning, may have only a peripheral relationship to e-government contingency planning. For example, while a timely and orderly recovery and resumption of normal operations is the goal of every COOP plan, an e-government presence (Seifert & Petersen, 2002) might not necessarily be designated as an *essential function*, which is generally defined as a service or program that must be available with little or no interruption. Similarly, it is doubtful that e-government managers would be tasked with preventing loss of life or participating in succession planning beyond their organizational unit. Consequently, e-government COOP planning may focus primarily on the maintenance and protection of facilities and electronic records, as well as the resumption of e-government services when higher priority government functions, such as executive leadership, has been reconstituted or civil order reestablished.

## COOP, E-GOVERNMENT, AND THE FUTURE

Future issues related to COOP planning for virtual and bricks and mortar government center around contingency budgeting, issue urgency, and preparedness.

In public agencies the budgetary environment is typically characterized by limited resources. A potential consequence of the acquisition of technology, infrastructure, and supplies to be held in reserve for use in an emergency is the likelihood that such an allocation might reduce resources available for routine operations. To the extent that COOP facilities and infrastructure are integrated into daily agency operations, this matter might be less salient. On the other hand, COOP activities are not always directly addressed in the agency budgeting processes. For example, in the United States, as a consequence of the multidisciplinary nature of COOP planning, federal executive branch agency expenditures for COOP activities are sometimes spread across several departmental or agency accounts, and data are not readily available to demonstrate agency COOP funding levels. Consequently, there is a possibility that budgetary deci-

sions for COOP planning might not cover minimally necessary resources.

As the memory of dramatic disruptions recede from memory, the urgency associated with administrative operations like COOP planning may decline relative to other issues on agency planners' agendas. It is widely held that the success of contingency planning is dependent on regularly updated plans that match current organizational missions and priorities. A further requirement is that an organization's preparedness must be evaluated through regular drills, simulations, or other testing. A reduction in the attention and resources dedicated to COOP planning could have the effect of compromising the utility of such planning. This could result in the loss or compromise of critical agency resources during an operational interruption, and could cause the loss of life of agency personnel or citizens, or the prolonged unavailability of government services and resources through e-government programs.

## KEY TERMS

**Alternate Database/Records Access:** The safekeeping of vital resources, facilities, and records, and the ability to access such resources in the event that the COOP plan is put into effect.

**Alternate Facilities:** An alternate work site that provides the capability to perform minimum essential department or office functions until normal operations can be resumed.

**Continuity of Government (COG):** Measures taken by a government to continue to perform required functions during and after a severe emergency. COG is a coordinated effort which typically focuses on the protection of elected or appointed national leaders of government in the event of a catastrophic emergency.

**Continuity of Operations (COOP):** An internal effort within individual components of an organization, such as a branch of government, department, agency, or office, to assure that the capability exists to continue essential

operations in response to a comprehensive array of potential operational interruptions.

**Cyber Attack:** An incursion on a range of information technology facilities, which can range from simply penetrating a system and examining it for the challenge, thrill, or interest, to entering a system for revenge, to steal information, cause embarrassment, extort money, cause deliberate localized harm to computers, or damage to a much larger infrastructure, such as telecommunications facilities.

**Essential Functions:** Those functions, stated or implied, that, during an operational interruption, are required to provide essential functions, maintain the safety and well being of the government assets, or citizens.

**Primary Facility:** The site of normal, day-to-day operations; the location where an employee usually goes to work.

**Relocation Site:** The site where all or designated employees will report for work if required to move from the primary facility.

**Stove Pipe:** An organizational model in which departments, managers, and employees have a narrow and rigid set of responsibilities defined by professional or functional norms.

**Training and Exercise:** This activity includes: (1) efforts to educate/advise designated staff on COOP responsibilities, and on the existing plans; and (2) tests to demonstrate the viability and interoperability of all plans supporting COOP requirement.

**Vital Records and Systems:** Records necessary to maintain the continuity of operations during an emergency, to recover full operations following an emergency, and to protect the legal rights and interests of citizens and the government.

## INTRODUCTION

A big challenge for governments from all over the world is to improve the service provisioning to their clients, citizens, and businesses. This is partly motivated by the aim to reduce the administrative burdens for citizens and businesses (e.g., Dutch Government, 2003, 2004), but also demanded by its clients, who expect the public sector to increase its attention on customer service just as businesses have done as a result of the rise of Internet technologies (Donnelly, Wisniewski, Dalrymple, & Curry, 1995; McIvor, McHugh, & Cadden, 2002).

Due to the fragmented nature of governments (Wimmer, 2002), the activities that make up the service-delivery processes of many governmental services are often performed by different governmental agencies (Castellano, Pastore, Arcieri, & Summo, 2004; Contenti, Termini, Mecella, & Baldoni, 2003; Gortmaker & Janssen, 2004). Managing these service-delivery processes that span multiple agencies requires adequate coordination between the different subprocesses and different agencies.

The trend of moving toward electronic service delivery makes the need of coordinating cross-agency service-delivery processes even more apparent, as citizens and business expect fast responses and customer-centric service provisioning. A complication is that information systems are also largely fragmented, which gives rise to a whole new range of coordination issues that need to be solved.

A promising technology that offers many advantages to the problem of automating cross-agency processes is Web service orchestration (Gortmaker, Janssen, & Wagenaar, 2004). However, there is a lack of experience reports, literature, and case studies concerning the potential of Web service orchestration (van Hillegersberg, Boeke, & van den Heuvel, 2004). Moreover, orchestration should be viewed on at least two different levels: on a technical, and an organizational level (Gortmaker & Janssen, 2004). On a technical level, Web-service orchestration makes use of the potential of Web-service technology to orchestrate different Web services into one overall service-delivery process. On an organizational level, orchestration can be viewed as performing process orchestrator roles aimed at managing the interdependencies between various subprocesses performed by multiple agencies.

This article investigates research issues concerning the application of Web-service orchestration technology and process orchestrator roles for coordinating cross-agency business processes. These research issues need to be resolved in order to be able to use process orchestrators in an efficient and effective way to coordinate governmental cross-agency service-delivery processes. First, we present the background of both Web-service orchestration and process orchestrators. Thereafter, we investigate a case study and use this case study to demonstrate the research issues that should be addressed for automating cross-agency processes using Web-service orchestration and process orchestrators. Finally, further trends are presented and conclusions are drawn.

## BACKGROUND

### Web-Service Orchestration

Web-service orchestration is based upon the notion of a service-oriented architecture (SOA). Due to its loosely coupled nature, SOA seems very suitable for orchestrating service-delivery processes that run across relatively autonomous agencies (Stojanovic & Dahanayake, 2005). In a SOA, application functionality is not provided by one large monolithic application, but is provided by relatively

small-grained services that are offered by different independent providers. These services can be invoked by service requesters who found the service in a service directory. A SOA makes it possible to quickly assemble new compound services out of existing subservices.

Although various middleware technologies can be used to achieve SOA, Web-service standards satisfy the universal interoperability needs better (Pasley, 2005). Web services are an important technology for realizing a SOA. Web services enable the provisioning of functionality, both on application and business level, by means of a standardized interface in a way that they is easily invoked via Internet protocols. Web services are modular, accessible, well described, implementation independent, and interoperable (Fremantle, Weerawarana, & Khalaf, 2002). Using Web services, existing legacy applications can be reused by encapsulating them using a Web-service interface.

Web-service orchestration coordinates different Web services using an executable business process. As such it builds upon Web-service technology and the concept of a SOA. Wohed, Van der Aalst, Dumas, and Hofstede (2003) define an executable business process as "[specifying] the execution order between a number of constituent activities, the partners involved, the messages exchanged between these partners, and the fault and exception handling mechanisms" (p. 202). In Web-service orchestration, these activities are typically performed by Web services that are invoked from a process by means of their standardized Web-service interface.

The standard language for orchestration is the Business Process Execution Language for Web Services, BPEL4WS, or BPEL for short. A process that is specified in BPEL consists of two types of activities: basic activities, such as receive, reply, wait, and structured activities as switch, while, and sequence. The structured activities determine the structure, or the sequencing of the process, and the basic activities determine what happens in the process, for example, the invocation of a Web service, receiving a message from a Web service, and so forth.

## Process Orchestrator

The process orchestrator aims at coordinating the different subprocesses making up an overall service-delivery process. The process orchestrator is responsible for maintaining an overview about the entire service-delivery process. For this reason, it is obvious to appoint the process orchestrator role to a governmental organization or department, in this way freeing the customers from doing all the coordination themselves.

Although many process orchestrators will make use of information technologies and communication technologies, it should be noted that most process-orchestrator roles are technology independent. A process orchestrator can be compared with other types of intermediaries including information brokers and supply chain managers (e.g., Janssen, 2004). Governmental service-delivery processes that involve other governmental agencies can be viewed as the governmental supply chain.

Tasks that are typically performed by a process orchestrator are the splitting up of a request into several requests for multiple agencies, coordination of various subactivities, guarding lead times of service-delivery processes, facilitating information sharing among agencies, and ensuring accountability of the process, for example, by means of providing, and updating details about the status of the process.

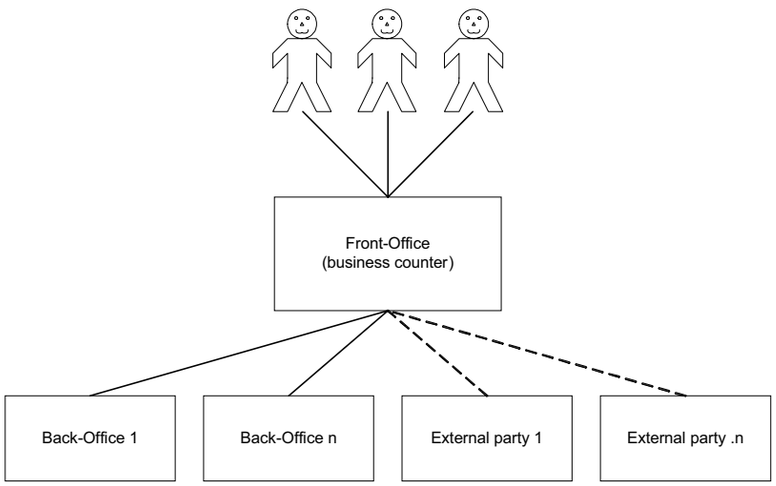
Another major task is providing transaction capabilities. Transaction capabilities are needed when multiple related services are requested in parallel. The use of transactions must ensure that requested services are finalized, or "committed," only when all other services have successfully been delivered. When someone wants to open a new business, he or she needs several permits, such as an environmental permit and a building permit. These permits all require a certain fee to be paid. As there is no use of having an environmental permit for something that cannot be built, these permits should be delivered on an "all or nothing" basis.

A process orchestrator that coordinates cross-agency service-delivery processes can also be viewed as fulfilling certain intermediary roles. Much is written about intermediaries and especially about electronic intermediaries (Bailey & Bakos, 1997; Janssen & Sol, 2000). Bailey and Bakos (1997) make a classification of electronic intermediary roles based on 13 case studies. These roles are (1) information aggregating, (2) being a trusted agent, (3) facilitating the market, and (4) matching buyers and sellers. Although these roles are derived from case studies in the e-commerce domain we also found them useful to analyze the roles performed by a process orchestrator. In the next section, we will investigate these four roles for a case study at a business counter and derive research issues.

# PROCESS ORCHESTRATORS IN PRACTICE

In this section we present a case study of a cross-agency service-delivery process to evaluate the application of BPEL4WS and derive research issues. The business counter is a one-stop shop for different kinds of businesses at a medium-sized municipality in the Netherlands. Throughout the country, this business counter is viewed

*Figure 1. The business counter as process orchestrator*



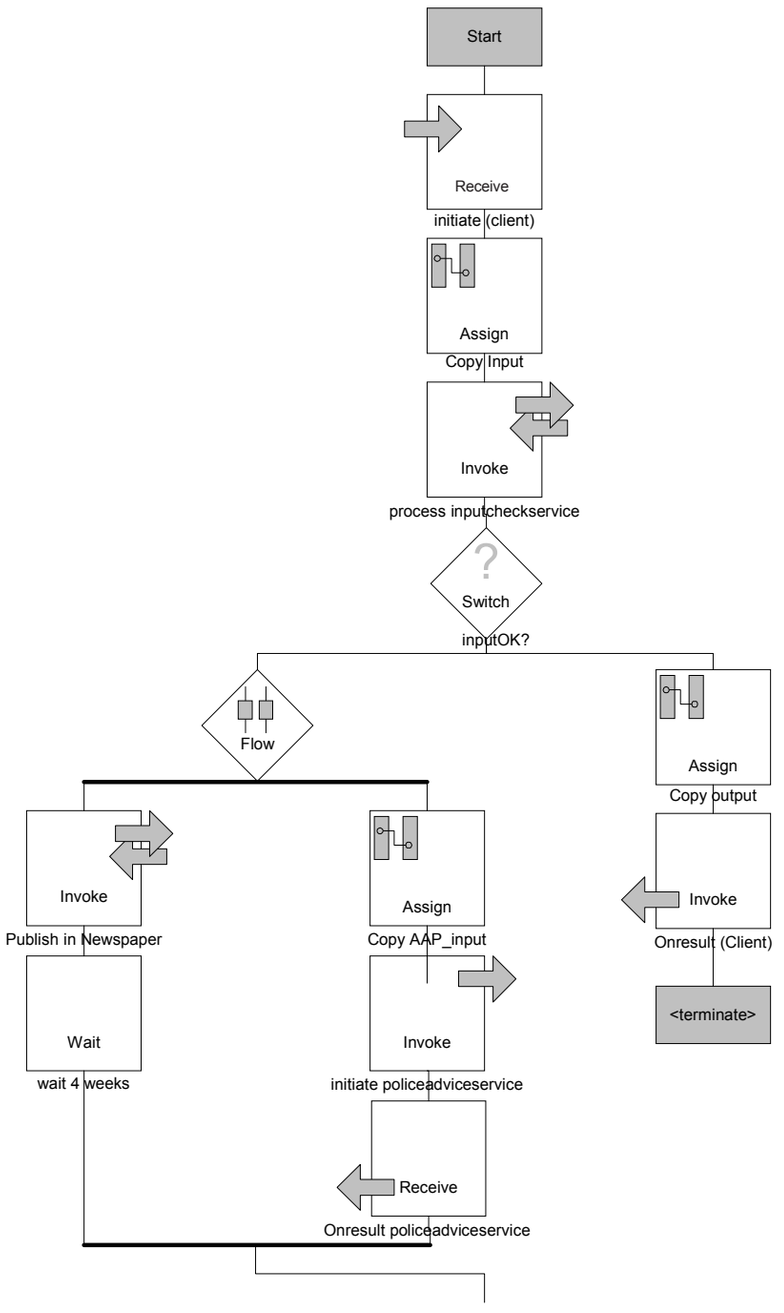
as a best practice due to its organizational arrangement. The business counter coordinates several cross-agency service-delivery processes targeted at local businesses, thereby fitting our definition of the process orchestrator.

An example of a cross-agency service-delivery process that is coordinated by the process orchestrator is the liquor-licensing process. This process involves various governmental and external agencies, such as the building department, the fire department, the police, the justice department, and the chamber of commerce. Figure 2 shows a graphical representation of part of the liquor-licensing process written in the BPEL4WS notation. The process is initiated after an applicant fills in an online application form. First, a Web service to check whether the form is correctly filled in is invoked. When not all fields are correctly filled in, an error message is prompted back to the applicant. When the application is complete, two simultaneous subprocesses are started: the application is published in the municipal newspaper, and a Web service at the police is invoked to obtain information about the criminal record of the applicant.

The business counter performs a number of process-orchestrator roles. Based on the intermediary roles proposed by Bailey and Bakos (1997), we analyzed the roles performed by a process orchestrator.

- **Information Aggregating:** The business counter aggregates information about the services offered by the different agencies. An example in the liquor-licensing process is the aggregation of information from the various agencies, such as constraints on the license from different agencies. This role will become more and more important, as from 2007, governmental agencies in the Netherlands will have to mandatory reuse information about citizens and businesses that is already available somewhere else in the government. Information aggregating can also be viewed from another perspective. Maintaining an overall file of a customer that is available to the relevant officials could also be a great help in increasing the effectiveness of service-delivery processes.
- **Being a Trusted Agent:** The business counter acts as an account manager for the individual businesses, this way being a trusted agent, performing actions on behalf of the businesses. A business should be able to rely on this agent in performing tracking functions and tracing functions, providing accurate status information, and in adequately guarding lead times of the service-delivery processes.
- **Facilitating the Market:** The role of facilitating the cross-agency service-delivery processes is not very obvious at the business counter. In the domain of electronic intermediaries, intermediaries provided facilitating functions such as payment services to its customers. Facilitating functions for governmental service-delivery processes, for example, an authentication service, are provided by agencies other than the business counter.
- **Matching Buyers and Sellers:** concerns the matching of the demands of businesses to the different (sub)services provided by the different governmental agencies. Matching "buyers and sellers" for governmental service-delivery processes be-

*Figure 2. Graphical view of (part of) a liquor-licensing process in BPEL4WS*



comes increasingly difficult, when the services that are needed become less generic and more complex. At the business counter, this matching is done during an initial meeting with the account manager, where the business states its needs and the account manager advises the business about what services are available to fulfill these needs. In the future, matching available services with the demand could even take the form of reverse matching, where the business counter proactively approaches a business telling it that it suspects that the business may also need another permit.

Although the roles do not match completely and other roles might be possible, these roles provide a suitable basis for investigating process orchestrator roles. The case study demonstrates that Web-service orchestration technology using BPEL is a feasible technology that enables the coordination of cross-agency service-delivery processes. Web-service orchestration technology, however, does not solve all problems that arise when automating cross-agency business processes and process orchestrator roles are necessary targeting a number of research issues that will be described in the following section.

## RESEARCH ISSUES

Apart from the further specification and validation of process orchestrator roles, several research issues concerned with automating cross-agency business processes using orchestration were identified using the case study. As the main task of a process orchestrator is to coordinate cross-agency business processes, we limit the issues to those directly related to coordination.

- **Information Sharing:** As can be seen from the analysis of the information aggregating role at the business counter, information sharing between different agencies becomes increasingly important. Different agencies that are involved in a service-delivery process should all have access to the customer data that are relevant to them. Data sharing and integration requires having ontologies describing the semantics (e.g., Linthicum, 2003). These ontologies should be shared and accepted by all autonomous governmental agencies. Web-service orchestration can invoke semantic Web services to make use of semantic technologies. Research should be conducted in how information can be shared between multiple agencies, involved in an orchestrated process, in a way that data is always up to date, that privacy concerns are dealt with (e.g., Ali Eldin & Wagenaar, 2004), and that data are available for enforcement and policy-making purposes.
- **Accountability:** An important requirement for the whole public sector (e.g., Bovens, 2004; Gortmaker, Janssen, & Wagenaar, 2005). Accountability always involves an actor with the duty to render an account and another actor with the power to judge or impose sanctions (White & Hollingsworth, 1999). This can easily be seen from the analysis of the role of being a trusted agent. If the process orchestrator cannot explain the actions or decisions done in the process, it will not be a trusted agent of the client, and the client will most probably resort to contacting the individual agencies himself. Ensuring accountability for governmental service-delivery processes that run across different organizations is especially difficult, as it has to cope with different autonomous agencies that are involved in the process (Ling, 2002). The decision not to grant a liquor license should be transparent and accounted for. Research should be conducted into how governments can ensure accountability of processes that are orchestrated by process orchestrators.
- **Balancing the Needs of the Customers and Agencies:** Balancing the needs of businesses and the supply of services that can be orchestrated by the process orchestrator is difficult. In our case study humans perform the intake with customers. Matching the involved subservices to a simple requested service, such as a request for a liquor license is relatively easy, but highly complex and specific services, such as the governmental services that are needed for moving an existing petrol station to a new location, requires knowledge management. Research should be done on how process orchestrators can use knowledge-based systems to translate customer demand into the services that are supplied by single governmental agencies, and how these can be orchestrated into one overall service-delivery process.

## FUTURE TRENDS

The automation of processes was traditionally the field of workflow management (WfM). In WfM, business processes consist mostly of human-performed activities without using functionality offered by information systems. Nowadays, a shift from WfM toward business process management (BPM) is occurring, where on top of the design, configuration, and enactment of business processes, a module to analyze these processes is also present (Van der Aalst, Hofstede, & Weske, 2003). The paradigms of Web-service technology and BPM merge slowly (Zhao & Cheng, 2005), as a result that BPM systems will become capable of invoking Web services, and Web-service orchestration servers will start offering workflow functionality. It is expected that BPEL implementations will offer more and more advanced workflow capabilities.

We also observe that the enterprise application integration (EAI) market is converging with the workflow/BPM market. This will make the integration and orchestration of business process feasible using standard technol-

ogy. Standardization will especially enable the reuse of complete business processes.

From an organizational point of view, we expect that process orchestrator to become more common in public administration. Moreover, a trend seems to be that process orchestrators will become responsible for the complete end-to-end process and will adopt more roles over time.

## CONCLUSION

Web-service orchestration technology can be used as a technology for improving cross-agency service-delivery processes. As Web-service orchestration technology is rapidly maturing, attention shifts to organizational issues focusing on managing the interdependencies between processes. Consequently, process orchestration should not be mistakenly viewed as synonymous with Web-service orchestration technology.

Coordination of cross-agency processes can be done in a peer-to-peer manner or from the viewpoint of a complete, end-to-end process. Our case study confirmed the premise of this study that a clear allocation of process orchestrator roles taking into account the complete end-to-end process is of crucial importance for the efficient and effective management of cross-agency processes.

Three viable research directions were identified to improve our understanding of process orchestrators. Research should be done in (1) how information can be shared between multiple agencies that are involved in an orchestrated process; (2) how governments can ensure accountability of processes that are orchestrated by process orchestrators; and (3) how process orchestrators can translate customer demand into the services that are supplied by different governmental agencies.

## KEY TERMS

**Business Process:** A business process is a sequence of tasks, initiated by an event and aimed at providing products or services.

**Coordination of Tasks:** Coordination is the management of dependencies between tasks.

**Process Orchestrator:** A process orchestrator is a role that orchestrates (sub)processes that are performed by different organizations into one overall business process.

**Service-Oriented Architecture (SOA):** A service-oriented architecture is an architectural style, according to which application functionality is not provided by one large monolithic application, but is provided by services that can be combined to get the required functionality.

**Web-Service Choreography:** Web-service choreography defines the sequence and conditions of public message exchanges between multiple Web services.

**Web-Service Orchestration:** Web-service orchestration is the process of invoking internal and external Web services from a predefined process flow that is executed by an orchestration engine.

**Web Services:** Web services is a technology that enables the provisioning of functionality, on an application level or on a business level, by means of a standardized interface in a way that they are easily invoked via Internet protocols.

## INTRODUCTION

Public healthcare is facing huge future challenges in order to deal with rising costs, growing demands of customers, information flow, demographic changes, and aging population. The healthcare service sector can be seen as an information intensive area during an era of innovation and information technology (cf. Bellamy & Taylor, 1998). According to McLaughlin, Rosen, Skinner, and Webster (1999), it is common to assume that technological interventions are almost inevitable and it is humans' duty, at least to some extent, to follow the suggested development. In the organizational level of public healthcare, high expectations about the technology and its new possibilities are introduced. Additionally, the customers can seek support and advice for their healthcare needs from thousands online connections at any time of a day (e.g., Silber, 2003). The European Commission (2004) states how "eHealth offers European citizens important opportunities for improved access to better health systems" (p. 22). This trend has implications to human beings and governments.

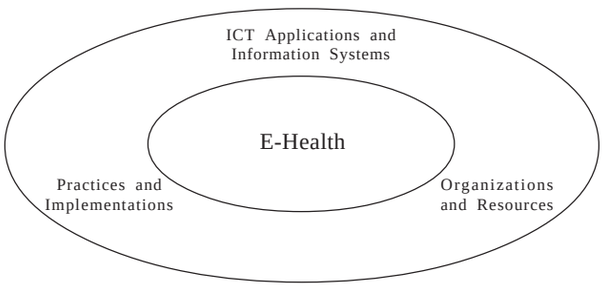
The electronic health services produced by the information and communication technology (ICT) belong to the era of e-government. The e-government can be seen as an electronic exchange of information and services between different actors (cf. Mälkiä, Anttiroiko, & Savolainen, 2004; Oliver & Sanders, 2004). The development of information society throughout the last decades has brought up possibilities to adapt, modify, and reorganize healthcare practices and services (e.g., Gallivan, 2001; Turner, Fraser, Muir Grau, & Toth, 2002). The ICT has been used as a tool to reorganize best organizational practices, information management, and government. The ICT has also given a possibility to produce tailored healthcare services and to gain improvements in cost-effectiveness, access, safety, and quality of public healthcare services (Bates et al., 2001; Whitten et al., 2002).

In the future, the healthcare organizations in public sectors will confront many challenges by means of the ICT implementation. This situation is considered here both as the function of healthcare organizations and as the supply of knowledge intensive public health services. The current viewpoint presumes a paradigm that is structured on the basis of specific conceptualization. The purpose of this article is to conceptualize the complex topic of e-health from the governmental viewpoint and to clarify the best organizational practices. Special notation is also given for human resources, information management and the ICT implementation. Finally, some future trends are shortly discussed.

## BACKGROUND

Experts define e-health differently and the term has some overlapping conceptual views. The term "e-health" is derived from the term "electronic commerce" (i.e., e-commerce), which was introduced in the mid-1990s to reflect the growing commercial use of the Internet. The e-health (cf. Eysenbach, 2001; European Commission, 2004; Silber, 2003), when recognized as a governmental issue, refers to the use of ICT applications or information systems to improve or enable health and healthcare services. Now it also refers to the main organizational and resource based factors before, during, and after an introduction of ICT. Finally, the term refers to best practices and implementations produced or needed to confront and manage with the ICT-based healthcare. The e-health concerns customers, patients, professionals, but additionally the whole primary healthcare, home care, and organizations like hospitals. It engages the terms like telemedicine, telematics, telehealth, medical and health informatics, interactive health communication, and so forth. To conclude, the e-health as a governmental concept give good reason for to describe the abovementioned combination by the means of three conceptual dimensions.

*Figure 1. E-health concept according to the core governmental dimensions*



## CONCEPTUAL DIMENSIONS OF THE E-HEALTH PARADIGM: THE GOVERNMENTAL PERSPECTIVE

In the first dimension, the e-health connection can be found by referring to ICT applications and information systems in healthcare and in supporting functions (cf. McGinnis, 1997; Turban, McLean, & Wetherbe, 1999). In many cases, this has included telemedicine and health informatics as patients have been informed, examined and treated over distance by using appropriate applications (e.g., Hailey, Roine, & Ohinmaa, 2002). The e-health is seen now through issues like information system, standardization, and system quality (e.g., digital referrals, data security, access, and privacy, etc.). Also, the usability or user-friendly orientation should be placed under a close scrutiny. Hence, the applications and systems require understanding about technology and its effect on organizational structures, processes, and actors.

Secondly, it is considered that by e-health it is possible to renew and to produce more effective healthcare practices and implementations. Now the e-health is studied typically in conjunction with key processes like the management of ICT applications and information (Plsek & Wilson, 2001; Tachakra, El Habashy, & Dawood, 2001; Walker & Whetton, 2002) and by the means of best practices or ICT implementations in healthcare (e.g., Paré & Elam, 1999). The introduction of technology may support or change operational practices in organizations. The operational aspect engages also electronic healthcare services as the e-health services are multileveled. Services represent, for example, the possibility of consumers to interact online, the possibilities for institution-to-institution data transmissions, and the possibilities for peer-to-peer communication of consumers. However, the overall question is about the best practices and implementations in order to successfully complete the e-health in service sector.

As third dimension, the organization and its various resources (e.g., economical and humanistic) have been under intensive study. For example, Parente and Dunbar (2001) found that hospitals with integrated information systems have higher total and operating financial margins than those without these systems. Whitten et al. (2002) did a systematic review and found no good evidence that telemedicine is cost-effective. Additionally, the e-health can be seen in terms of human resources. This is the case, for example, with the acceptance of ICT-based organizational solutions (Mathieson, Peacock, & Chin, 2001) and with the professional human resources (e.g., Syväjärvi, Stenvall, Harisalo, & Jurvansuu, 2005). The interest has also been in health services and in policy to provide a diverse range of services (e.g., Silber, 2003; Turner et al., 2002). Both customers and professionals can be seen as key actors, because they use applications and participate in electronic service interaction (e.g., Hailey et al., 2002).

Hence, the e-health from governmental perspective can be defined as health service and information delivered through different technologies. Applications of the ICT and information systems support health, healthcare, and health services. In case of current governmental perspective, the dimension of ICT applications and information systems concentrates mainly on technological system, standardization, and usability issues. The ICT applications can be seen as architectures to understand and plan information system components in the form of an organizational infrastructure. The most crucial questions are the standardization of information systems and their usability in organizational environment.

It seems worldwide that open technical standards to provide e-health are lacking. McGinnis (1997) studied health informatics and stated the critical importance of data exchange standards for communication between healthcare providers. The usability instead is traditionally defined (cf. Isomäki, 2002) by attributes like learnability, efficiency, memorability, errors and satisfaction. However, without neglecting the human factors like learning, sensation, and perception, memory, problem solving, and so forth. An optimal system should be easy to learn, it should be efficient to use, the system should be easy to remember, the error rate with the system should be low, and the system should be pleasant to use. Corresponding arguments of usability and human-centered design are also offered by ISO quality standards.

Second governmental dimension of e-health was about practices and implementations. E-health as practices and implementations emphasizes the need to combine knowledge and the use of ICT in various ways. In this article, the management as an organizational process has the viewpoint of ICT-based e-health. McLaughlin et al. (1999)

claimed that in hospitals it is needed a wider perspective than social, since managers and users need to have a commitment to longtime innovative process. Clark (1995) suggested that leaders have the main responsibility for development work, because the problem with technological changes was frequently that people and technology didn't meet or people didn't participate.

The management has also direct link to best practices in organization and its health service production. Martin (2000) claimed that the quality of public services and cost-effectiveness depend on management. Smith (2004) studied how to inspire and motive professional service teams and indicated the importance of discussion and collective responsibility. The e-health can be seen as a part of knowledge intensive public services in a knowledge intensive society. The previous conceptualization invoked to describe the current e-health practices and implementations more generally as seminal goals for public healthcare organizations. However, it should be reminded that information technology does not necessarily lead so radical organizational changes as expected (Bellamy & Taylor, 1998; Nicholson, 2003).

The third governmental dimension of e-health involved organizations and resources. The governments try to manage with the increasing costs of public administration. Simultaneously the need to improve the cost-effectiveness of public healthcare has become apparent. One way to resolve the dilemma has been the use of electronic health services. However, the results have been controversial. Whitten et al. (2002) made a massive evaluation and they included 24 of 612 identified articles presenting cost-benefit information. About 30% of those 24 tried to solve the economic function of telemedicine without a clear outcome.

However, in public organizations the ICT has had often a transformative role. The e-health is understood and projected as being able to reshape the way healthcare services are delivered. The demands set by stakeholders are obvious. Governments want accountability to ensure that the funds are used effectively. Healthcare providers want a better quality of work life through the ICT tools. Patients and customers want access to the high quality healthcare service. One response has been the virtual life of organizations (cf. Nicholson, 2003). The virtual life in current context can be defined as a group of people or organizations that interact through interdependent task guided by common good purpose. In addition, the actors have learned to interact across space, time and inter-professional or organizational boundaries by using the ICT-based e-health solutions (Syväjärvi et al., 2005).

## ORGANIZATIONS AND E-HEALTH: IMPLEMENTATION AND HUMAN RESOURCES AS CRUCIAL FACTORS

Numerous organizational e-health projects with various goals are ongoing worldwide under public administration. For example, the European Commission launched an Action Plan for a European eHealth area in 2004. The aim is to support EU member states to materialize the benefits available from e-health, and to respond to the growing need for coordinated activities of e-health (European Commission, 2004). These kinds of activities denote a coherent agenda for the implementation of e-health. Hence, the e-health implementation may cause changes in organizational design and such changes typically require new organizational structures, processes, and personnel arrangements. From governmental perspective, the e-health either allows or forces an organization to rearrange especially its human resources. The focus is thus to analyze the relationship between e-health implementation and HR-centered organizational practice. Human resources are considered as a key area of e-health implementation.

Human resources have indeed an essential function both in knowledge intensive healthcare practices and in knowledge innovative services. The implementation of e-health has indeed organizational effects as it should concurrently support the patient mobility, facilitate the citizen-centered healthcare, but particularly to provide healthcare professionals new tools to sustain or improve the quality of public healthcare service. The implementation should allow greater flexibility, for example in case of inter-professional and organizational practices, to enhance information and knowledge exchange between humans. It is given here a synopsis of e-health implementation that contains previous governmental dimensions.

Many nations worldwide are known as countries with high technology. The extensive use of ICT and the adoption of various technological solutions represent everyday practice. In these knowledge intensive nations, the public policy has been largely based on the assumption that society will develop and succeed by focusing on ICT. For example in many European countries the information technology has been harnessed to promote social welfare. The ICT has been used for strengthening and developing the welfare society. The public service organizations and citizens thus have confronted the wave of e-government (e.g., Mälkiä et al., 2004; Oliver & Sanders, 2004). At the same time research has concentrated on the possibilities, quality, and costs of technology. However, what the implemented information technology means to public health service sector,

public organizations, and especially to organizational human resources has usually received less attention. Under the issues of e-government and public services, there are several approaches to the human-centered e-health implementation.

Firstly, from the point of how the employees' attitudes and approval affect the success of implementation (Mathieson et al., 2001). This kind of approach has produced theoretical models to explain how implementation depends on reasoned action of humans and the technology acceptance. Considering a more professional view, for example, the doctors who have received training in technology and understand technological concepts are more likely to grasp the positive impact of technology in healthcare (Paré & Elam, 1999). Burge, Creps, and Wright (2001) assumed that doctors are key persons to adopt technology in healthcare organizations, however, the doctors are not enthusiastically accepting the technology if it does not help everyday work. Tachakra et al. (2001) suggest that telemedicine includes the ability to rearrange the distribution of work; especially concerning the tasks of doctors and nurses. The ICT-based e-health seems not to be a question of single profession as it reflects over entire professional work society.

Secondly, the ICT has been studied by the innovative theories. Again models have been presented how a technological innovation is adopted in an organization through various phases. Gallivan (2001) developed a frame of references how to merge a technical innovation into the organizational operation. Thus, there are themes like management support, high resources, organization culture, own responsibility of learning, broad work roles, work security, and individual characteristics, which either increase or decrease the innovative implementation. These studies argue that the success of information technology in organizations more generally reflects the systems of innovations' advance in organizations. Finally, as technology is implemented to organization more clear and exact strategies accompanied with leading spokesmen are required (Walker & Whetton, 2002).

Thirdly, the setup "e-health vs. implementation" stimulates the leadership and management dimensions. Clark (1995) suggests that the use of ICT is an organizational issue that needs efforts in the direction of change. The leaders have thus a responsibility to create and sustain participation, but also trust (cf. Harisalo & Stenvall, 2004). In good accordance, Plsek and Wilson (2001) found complexity in leadership and management of healthcare organizations. They assumed that leaders should found ways to make the change more attractive and meaningful for workers. This is done by securing the open information flow of good practices. The earlier observation about the complexity of knowledge intensive health services denotes the importance of information management. The information management refers to interdisciplinary procedures designed to provide and improve the appropriate information systems and resources by planning, organizing, executing, and evaluating necessary management operations. Thus, the human resource perspective both involves multi-professional diversity practices and presupposes the proper activities of human resource management (Syväjärvi et al., 2005).

Fourthly, the human resource centered ICT implementation considers the development of information systems according to usability factors, organizational practice, and the humanization of computerized information systems (Cummings & Worley, 2001; Isomäki, 2002). The usability of information systems is included in this framework. The information system development (ISD) can be introduced by different phases. It is stressed that the ISD tasks must be completed with knowledge concerning users and contextual analyses. Isomäki (2002) found that only a few information system designers have potential to contribute to the humanization of information systems. Cummings and Worley (2001) considered organizational change as a function of implementation process. They indicated how implementation causes organizational change and this can be controlled throughout singular phases like by information or system contracting and gathering, familiarizing, planning and accomplishing, evaluating and stabilizing. The humanization and e-health-based information system development can be seen as a part of organizational development (OD). Organization development in public health service sector applies this kind of knowledge and practice in order to help organizations to achieve effectiveness and social quality of work life.

The fifth and final aspect to comprise human resource and e-health implementation consists of the cognitive human capacity and service administration. The human capacity indicates the multilevel competencies of professionals. The service administration indicates both the service knowledge and management, which are approached in a customer-centered way. The e-health services are a challenge for both individuals and collective work society. Hence, individual, collective, and organizational competencies (e.g., Hamel & Prahalad, 1994; McLagan, 1997) are clearly required in different phases of the implementation. These competencies represent the foundation of service knowledge, which denotes the ability to arrange and manage both professionally and organizationally with the electronic public services. In present context this entirety (i.e., professional and organizational practices), the e-health implementation and customer relationships can be supported by appropriate and flexible service management. The public service management can comprise, for example, the dimensions of project management, human resource management, network management and

customer relationship management. The concept of service management can be also seen as one value creator for service innovations or improvements, and with modifications, as a suitable management approach for organizations from various sectors (cf. Boyne, Martin, & Walker, 2004; Fitzsimmons & Fitzsimmons, 2004; Martin, 2000).

## FUTURE TRENDS

In the near future organizations will once again face a dynamic and turbulent environment. That requires flexible and fast response ability from the healthcare organizations and public services. The ongoing era of e-government has enabled organizations to acquire such structures and processes that support new or additional ways of interaction between electronic service providers and customers. Hence, the future trends of e-health indicate implications for health service users, service suppliers and entire society. The purpose of this section is to discuss shortly some essential future trends of e-health. The future possibilities and needs of e-health are introduced according to present literature and reflected alongside the three main dimensions described in current conceptualization. Thus, the final section is based on future prospects and e-health's relationship to e-government.

The present view indicated that the public healt care services will be going through major electronic turnarounds. The e-health revolution accompanied with the future possibilities are far away from straightforward. Many different issues have to be considered in order to make successful ICT-based transitions in public services. In case of organizations and resources there is going to be a further increase in information intensity of the e-health. Public institutions and human actors are stressed and challenged over again with more sophisticated, and hopefully with more user-friendly and appropriate information technology. There will be a need for competent health professional as continuous cognitive pressure is evident. A clear e-health challenge for public healthcare organizations seems to be how to manage with differences in processes, with strong professional culture of healthcare personnel, with cognitive pressure set by ICT, and with hierarchical or traditional structures.

These prospects as seen as future trends of e-health indicate cooperation, but also knowledge and information integration both in organizational and professional level. For example, healthcare professional will probably have fast and unhindered access to the latest knowledge and to the other relevant information needed in clinical practice. It is also assumed that the number of virtual organizations and new innovative services will be increased. The organizational and resource-based future of e-health has to be affected more by customers and patients. The e-health services are targeted as support for the customers (i.e., for those who daily cope with individual health). Thus, as the impact of ICT on healthcare professionals is extensive, similarly the e-health should be harmonized to the specific needs of the users. For example, citizens will increasingly have an opportunity to access their own health data and to contact directly to health professional (e.g., online booking, e-prescribing, home-care monitoring, health information bank, etc.). It is expected that the customer-centered approach will be even more vital as a resource for the future development of e-health. In knowledge intensive society, more demanding customers can be recognized.

In the future, the applications appear to be even more plentiful for consultations with other organizations, professionals, and patients. Portable and mobile tools will be increasingly adopted in healthcare settings together with many web-based gateways or portals. For example, the question can be about the new innovative e-health systems for retrieval, feedback, participation, clinical data management, and in general about the electronic health recording systems (EHR). There will be quite many views about the needs of e-health-based information systems and probably only a few will get it right. The challenge will be the standardization of ICT applications and information systems. Also the users themselves should be equal partners in development teams. As indicated before, people will probably found themselves in the era of virtual life. This indicates the increasing use of collaboration-support information systems.

Finally, the e-health future has implication in the dimension of practices and implementations. The ICT can be seen as a powerful change agent for the whole healthcare sector and it is important to recognize the importance of non-ICT factors in e-health. In this sense, alongside the system implementation it seems to be significant to concentrate on workplace practices and implementations. The best practices and implementations will be valued even more in the complex future of e-health. The e-health interventions based on ICT re-engineering, human-centered information systems, human resource and change management, and practical work innovations will play crucial roles for wellness in workplaces.

It seems that practical work tools or models that support decision making, management, preparation and processes will have an enormous importance. Public healthcare organizations will continue to invest huge amounts of resources into the latest ICT. It seems that new investments on organizational practices and implementations should support both professionals and customers. For example, one challenge is to combine multi-professional practices and service security for the customers benefit. During the continuing era of e-government, the e-

health concept will be even more inevitable and natural part of the public healthcare service.

## CONCLUSION

The current governmental perspective of e-health has focused into three core dimensions. Current conceptualization has indeed some overlapping areas, but it is important that the approach to e-health is not done only by means of ICT factors or some single science. Hence, the e-health should follow the multi-scientific paradigm as the concept itself has been adopted by the experts of medicine, health science, applied information technology, social science, information and communication science, and by governmental and management science.

It was found how rich the topic of e-health is. The e-health was studied through the ICT implementation and human resources in the knowledge intensive healthcare service organizations. Hence, the implementation of e-health was recognized as a function of various practices and human resources together with future organizational possibilities in public service sector. Alongside the implementation procedures, the human resource was found to be fundamental. Thus, professional, inter-professional and customer perspectives were critical factors. Current perspectives go under the e-government. It combines the perspectives of governmental and management science, social science, health science, and applied information technology. The future trends of e-health thus involve various combined implications to customers and professionals, to service and system suppliers, and to organizations.

## KEY TERMS

**E-Government:** An electronic exchange of information and services between different actors. Usually refers to local or state government activities that take place by digital processes and various networks.

**E-Health:** Health services and information delivered through different technologies in order to improve or enable health, healthcare and services with variable contents and transactions (cf. Eysenbach, 2001).

**E-Health Usability:** The design and technical features that allow electronic healthcare applications and information systems to be suitable for intentional use in a user friendly way.

**Health Informatics:** Knowledge, skills, and tools to support the delivery of healthcare information and services (cf. Silber, 2003).

**Health Information System:** An ICT-based routine constructed for the purposes of delivering health and medical care. Information system can be seen as physical process that supports an organization by providing information to achieve goals.

**Information Management:** Interdisciplinary procedures designed to provide and improve appropriate information systems and resources. Refer to planning, organizing, executing, and evaluating the necessary management operations.

**Standardization of E-Health:** The method to reduce or eliminate inconsistency, potential added costs and quality problems in applications and information systems of the electronic healthcare.

## INTRODUCTION

Regarded from a historical perspective, the appearance of corruption is not a new phenomenon at all. It can be traced back to the ancient civilizations of China, Egypt, Greece, India, Israel, and Rome, which all provide evidence of widespread illegality and corruption. In spite of its long history, corruption increasingly became a political issue in the 1990s: corruption scandals contributed substantially to the resignation of governments in Ecuador, Brazil, India, and Italy and unsettled well-established ruling parties in Japan and Mexico (Lash, 2004; Sen, 1999).

According to Sen (1999), "the prevalence of corruption is rightly regarded as one of the major stumbling blocks in the path to successful economic progress, for example in many Asian and African countries" (p. 275). Dudley (2000) estimates that 30% of the money spent annually for international development loans are diverted from productive pursuits because of corruption. Additionally, countries perceived as being corrupt suffer from lower (private) capital inflows, as foreign investors are deterred by corruption and its associated phenomena, which include bureaucratic red tape, mismanagement and the lack of secure property rights (Transparency International (TI), 2004). Overall, the cost of corruption represents 5% of the volume of total global output or more than 1.5 trillion dollars a year according to "rough, but conservative" World Bank estimates (United Nations, 2003c). Table 1 aims to illustrate the scale of political corruption by presenting estimates of the funds allegedly embezzled by 10 notorious (but not necessarily the most corrupt) leaders of the last 20 years.

## BACKGROUND

Taking into consideration the historical record as well as the increasing public awareness of corruption, it seems to

*Table 1. The scale of the problem (Hodess, 2004, p. 13)*

| *Head of government* | | *Estimates of funds allegedly embezzled* | *GDP per capita (2001)* |
|---|---|---|---|
| Mohamed Suharto | President of Indonesia, 1967-98 | USD 15 to 35 billion | USD 695 |
| Ferdinand Marcos | President of Philippines, 1972-86 | USD 5 to 10 billion | USD 912 |
| Mobutu Sese Seko | President of Zaire, 1965-97 | USD 5 billion | USD 99 |
| Sani Abacha | President of Nigeria, 1993-98 | USD 2 to 5 billion | USD 319 |
| Slobodan Milosevic | President of Serbia/Yugoslavia, 1989-2000 | USD 1 billion | n/a |
| Jean-Claude Duvalier | President of Haiti, 1971-86 | USD 300 to 800 million | USD 460 |
| Alberto Fujimori | President of Peru, 1990-2000 | USD 600 million | USD 2,051 |
| Pavlo Lazarenko | Prime Minister of Ukraine, 1996-97 | USD 114 to 200 million | USD 766 |
| Arnoldo Alemán | President of Nicaragua, 1997-2002 | USD 100 million | USD 490 |
| Joseph Estrada | President of Phillipines, 1998-2001 | USD 78 to 80 million | USD 912 |
| (...) | | | |

be worthwhile to take a closer look at its underlying concept. Literally, the notion of corruption may be employed in several ways; It may refer (1) to the impairment of integrity, virtue, or moral principle in the sense of depravity, (2) to decomposition and decay, (3) to the inducement to wrong by improper or unlawful means, or (4) to the departure from the original or from what is pure or correct (Merriam-Webster Online Dictionary, n.d.). Thus, the term "corruption" is first and foremost marked by its normative nature referring to the departure from some ideal state of purity or rightness (Bukovansky, 2002). Applied in a political context, corruption therefore implicitly incorporates an underlying notion of the original or natural state of government run altruistically by politicians and civil servants in pursuit of the public good.

Hence, political corruption arises whenever civil servants or politicians depart from the "pure" state of politics by violating established rules for personal profit and thus causing damage to the public good (Sen, 1999). In its most common term, corruption in the public sector is therefore defined as the abuse of entrusted power by public officials as well as politicians for private gain (Lash, 2004; Hodess, 2004, Lambsdorff, 2001). As this article discusses the contribution of e-government to the promotion of transparency and combating the misuse of public power, the term "corruption" is deployed in the following in compliance with the common understanding of its political occurrence.

Regarding the phenomenon of corruption from a systematic perspective, incentives for corrupt behaviour arise whenever a politician or a public official is vested with the discretionary power to allocate government services, on which he or she usually has a monopoly, to the private sector. Hence, Klitgaard (1997) regards corruption being equal to monopoly power plus discretion minus accountability (in short: C = M + D – A). Based on this equation, the fight against corruption involves the improvement of both, the political as well as the public administrative system, towards reduced (or at least regulated) monopoly power, clarified official discretion, and enhanced accountability.

In this regard, transparency may serve as a catalyst for better systems, since it reduces discretionary power and promotes a government's (and its administration's) accountability. The promotion of transparency, therefore, is a key element in preventing and also fighting corruption, financial irresponsibility, and underhand dealings (Seifert & Bonham, 2003; Sen, 1999; United Nations (UN), 2003a). According to the "United Nations Convention against Corruption" (UN, 2003b), transparency has to be developed based on an all-encompassing approach: Member states are urged to determine transparency as the guiding principle for the recruitment, hiring, retention, promotion and retirement of civil servants and other non-elected public officials as well as for the funding of candidatures for elected public office and the funding of political parties in general. Systems of public procurement and the management of public finances have to be based on transparency and accountability. Overall, each state should "enhance transparency in its public administration, including with regard to its organisation, functioning, and decision-making processes, where appropriate" (UN, 2003b, p. 7).

## E-GOVERNMENT vs. CORRUPTION

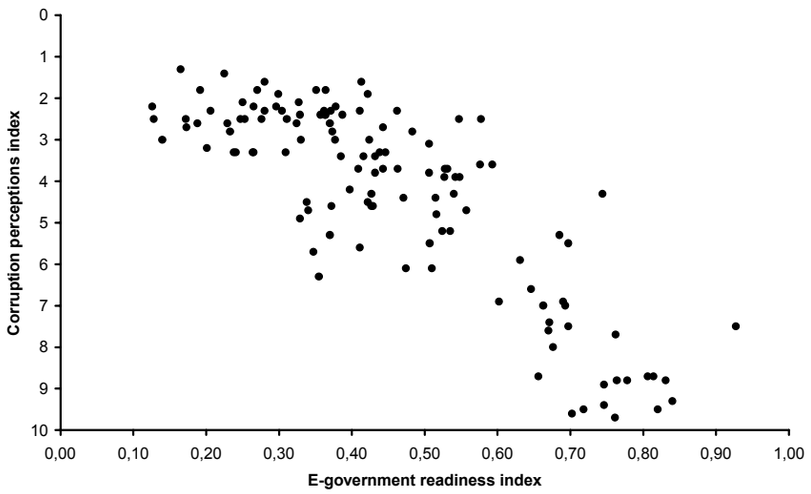
### Evidence (?)

Apart from the ordinary range of e-government's benefits, which has been discussed extensively in literature, increasing focus has been given lately on e-government as a tool to fight corruption (Bhatnagar, 2003). Regarded from a conceptual point of view, the application of information and communication technology (ICT) in public administrations can potentially reduce corruption by enforcing rules, diminishing the discretion of public officials and increasing transparency and social control (Scacco, 2003; UN, 2001; Wescott, 2003).

Figure 1 provides some evidence for the suggested interrelationship between the state of e-government development and corruption: It shows a strong positive relationship (with a correlation coefficient of 0.828) between the e-government readiness index (0=no e-government readiness, 1=sophisticated e-government readiness) and the corruption perceptions index (0=very corrupt, 10=highly clean) for the 123 nations covered by both rankings.

The e-government readiness index, which was collected and published within the framework of the UN global e-government report in 2003, assesses the capacity of the public sector of UN member states to use ICT for encapsulating in public services and deploying to the public high quality information and effective communication tools in a quantitative way. It is a composite index comprising the Web measure index (measuring the generic aptitude of governments to employ e-government as a tool to inform, interact, transact and network based on a five stage-framework distinguishing between emerging, enhanced, interactive, transactional, and networked presence), the telecommunication infrastructure index (the composite weighted average of (PCs, internet users, telephone lines, online population, mobile phones, and televisions)/1,000 persons) and the human development index (a composite of the adult literacy rate and the combined primary, secondary and tertiary gross enrolment ratio with two thirds of the weight given to the first

*Figure 1. Corruption and e-government readiness 2003 (Lambsdorff, 2004 [for corruption perceptions index]; UN, 2003a [for e-government readiness index])*



*Note: Due to the inverse nature of the corruption perceptions index the values on the y-axis are presented in reverse order. A higher scoring in the corruption perceptions framework indicates a lower level of corruption and vice versa.*

indicator and one third to the latter) with one third of the weight allocated to each parameter (UN, 2003a).

Transparency International's corruption perceptions index has been published annually since 1995 and "aggregates the perceptions of well-informed people with regard to the extent of corruption, defined as the misuse of public power for private benefit" (Lambsdorff, 2004a, p. 282). In the 2003 measurement, 133 nations are included. Methodologically, the corruption perceptions index is a composite index based on 17 data sources from 13 different institutions (World Economic Forum, Institute of Management Development, Economist Intelligence Unit, Information International, World Markets Research Centre, Gallup International, Freedom House's Nations in Transit, PricewaterhouseCoopers, Political and Economic Risk Consultancy, World Business Environment Survey of the World Bank, Columbia University, Business Environment and Enterprise Performance Survey of the EBRD, and the World Bank, and a multilateral development bank). All sources provide a ranking of nations and measure the overall level of corruption; after having been standardised, the corruption perceptions index is derived from these data sources (Lambsdorff, 2003).

Having outlined the underlying concept of the corruption perceptions index it should be stressed again, that the index provides a snapshot of the views of decision makers. Thus, one main criticism made of the corruption perceptions index is that it (as any other perceptions index in general) does not replicate the actual situation in a country (Zoido & Chavis, 2004). On the other hand, Lambsdorff (2003) argues that the perceptions gathered are a helpful contribution to the understanding of real levels of corruption. Biased perceptions, which cause a wrong picture of the real phenomenon, can be ruled out because of evidence given that "residents tend to have a consistent ethical standard with regard to the assessment of corruption, while expatriates do not tend to impose an inappropriate standard or to lack cultural insights" (Lambsdorff, 2003, p. 6).

Having presented statistical evidence for the suggested interrelationship between the state of e-government development and the degree of corruption, it seems to be worthwhile to scrutinize whether this relationship is as straightforward as it might appear at first sight. For illustration purposes, a third variable–namely the annual gross domestic product, which is expected to correlate with both corruption as well as e-government–is integrated into the examination of mutual correlations.

First, a high degree of corruption is referred to as a characteristic of developing countries in economic literature (Krugman & Obstfeld, 2000). In fact, correlating the annual per-capita gross domestic product (GDP) (purchasing power parity USD) and the corruption perceptions index shows an even stronger positive relationship between the two indicators than between e-government development and corruption: Using the sample of

123 nations outlined above, the correlation coefficient between the 2002 GDP per capita in real terms (Source: UN, 2004) and the corruption perceptions index (Source: Lambsdorff, 2004a) reaches the value of 0.903. (In the case of Luxemburg's GDP per capita—and in accordance with the United Nations' calculation of the human development index—a value of $40,000 was deployed instead of the published value of $61,190, as the GPD per capita of Luxembourg tends to be overestimated due to the large share of cross-border workers in total employment.)

Several factors featuring different cause-and-effect assumptions underlie this strong positive relationship: First, governmental and administrative systems that promote corruption are suggested to harm economic development as well as prosperity. Second, corruption itself appears to have a net negative economic efficiency and growth. Third, less developed and hence poor nations lack the funds to fight corruption effectively and, finally, poverty itself generates a greater willingness to break existing rules and regulations. As the suggested effects of these factors demonstrate, it is not acceptable to presume any kind of (single) causality between GDP per capita and corruption (Krugman & Obstfeld, 2000; Lambsdorff, 1999, 2005).

Second, the state of e-government development is highly correlated to GDP per capita (Lanvin, 2003; Schware & Deane, 2003) too, resulting in a correlation coefficient of 0.867 for the 123 nations covered, which is again higher than the one generated by correlating corruption and e-government development. (As outlined above, Luxembourg's per-capita GDP was again set at $40,000).

As is true for the correlation between GDP and corruption, the factors underlying the relationship between GDP and e-government development also appear to have effects working in different directions: On the one hand, countries with greater wealth are able to allocate more resources to the development of e-government. According to West's (2004) findings GDP per capita is "the most significant predictor of online services" (p.21). On the other, the United Nations (2003a) regard e-government as a facilitator for socio-economic development, as the proper use of information technology "offers an immense potential to bridge inter- and intra-state socio-economic disparities, reduce poverty and further the goals of development worldwide" (p. 182).

Summing up, the state of economic development (measured by GDP per capita) could be identified as a parameter related to both the extent of corruption as well as e-government readiness. However, no causalities can be derived from these relationships, and it seems likely that other parameters such as democratic culture or civil liberties show effects on the development of e-government and corruption in one direction or another. Widening the originally illustrated relationship between the e-government readiness index and the corruption perceptions index by bringing in a new variable, namely GPD per capita, should therefore demonstrate that increased sophistication of e-governments need not lead to reduced corruption and vice versa.

## Structural Requirements

Having rejected the assumption of a mono-causal relationship between e-government and corruption (i.e., the notion that the implementation of e-government leads to reduced corruption automatically), the question has to be raised, whether—and if so, under which circumstances—the introduction and extension of e-government can contribute to combating corruption.

In a meta-survey on empirical investigations on the consequences and causes of corruption, Lambsdorff (2005) concluded "that corruption clearly goes along with a low GDP, inequality of income, inflation, increased crime, policy distortions, and lack of competition. The direction of causality for these indicators, however, is controversial. Corruption may cause these variables but is at the same time likely to be the consequence as well" (p. 26).

Yet, Lambsdorff (2005) could identify strong evidence that corruption reduces a nation's attractiveness to investors and hence reduces capital accumulation as well as capital inflows and productivity of capital. Moreover, distorted government expenditure and reduced quality of a wide variety of government services could be identified as further consequences of corruption supported by equally strong evidence.

As far as the causes of corruption were concerned, "press freedom and the (de facto) independence of the judiciary and prosecutors appeared to be important elements in reducing corruption. Increased corruption also resulted from complicated regulation of market entry and tariffs" (Lambsdorff, 2005, p. 26). Abundance of natural resources, distance to trading centres and cultural dimensions (in particular the mentality of accepting hierarchies) were found to lead to increased corruption too. However, the latter three factors were not suggested to provide any direction of reform.

Taking into consideration these causes of corruption from a governmental point of view, four indicators favouring the absence of corruption can be derived: law and order, bureaucratic quality, government stability and civil liberties (Lambsdorff, 2004b). Consequently, if trying to judge the contribution of e-government to fighting corruption, it has to be analyzed, which of these four indicators can be addressed by integrating ICT into governance and respective administrative processes.

As documented widely in academic and non-academic literature, e-government incorporates the potential to raise the quality of bureaucratic processes as well as of the relationships between administrations and citizens or administrations and businesses (e.g., Rohleder & Jupp, 2004; United Nations, 2003a). In this context, it appears important to keep in mind that complete automation does not represent a necessary precondition to nurture these potential benefits: In Chile, for instance, procurement announcements are published on a Web site, whereas the core bidding process remains a manual one. Nevertheless, Chile has succeeded in accumulating savings due to expanded supplier choice and enhanced transparency in supplier selection and has hence managed to improve government effectiveness in this certain area (Bathnagar, 2004).

As far as law and order and civil liberties are concerned, these two factors can theoretically be classified as pushing factors to the establishment and development of e-government systems (Moon, Welsh, & Wong, 2005). Thus, these governance indicators do not represent a consequence of national e-government efforts. Instead, the prerequisite nature of a sound legal system based on accepted institutions and a high level of civil liberties to e-government development can be demonstrated by presuming the absence of these values: Without the rule of law applied in public governance, administrative operations are prone to arbitrary actions which cannot be integrated into any ICT-supported system. The absence of freedom of speech, democracy and other civil liberties is regarded as another major stumbling block to e-government: As long as authoritarian or even dictatorial regimes regard their individual citizens as mere subjects, the development e-government applications is likely to be suppressed, as e-government involves citizen participation as well servicing individuals according to their needs (United Nations, 2003a).

Stability of government is also suggested to have an impact on e-government, albeit a weak one. Regarded as a precondition to e-government, the implementation of the latter is expected to result in less friction under a stable government. On the other hand, increased bureaucratic quality due to e-government could be considered as a factor promoting government stability.

Summing up, e-government applications show the potential to increase bureaucratic quality and thus favour the absence of corruption, whereas law and order as well as civil liberties represent prerequisites to their development. Consequently, if endeavouring to implement e-government initiatives in order to enhance transparency and fight corruption effectively, the latter two conditions have to be restored as e-government can only address the bureaucratic factor directly.

## Intentional Design

Having identified structural requirements for realizing the corruption-fighting potential of e-government, the question has to raised, how e-government application should be designed on a micro level in order to enhance governmental transparency. According to Bhatnagar (2003), the decline of corruption opportunities has often been an incidental benefit rather than an explicit intention of e-government initiatives so far. In order to reduce the amount of corruption effectively by the use of e-government applications "some features that lead to greater transparency and accountability need to be consciously built into the design" (Bhatnagar, 2003, p. 25). These features, again, should be geared towards the following three objectives from a conceptual point of view:

First, e-government applications must increase access to information: E-government can only lead to enhanced transparency, if the overall national legislation supports free access to information on the one hand whilst respecting privacy and security issues on the other. In order to reduce discretion by ensuring that relevant information can be retrieved by as many citizens as possible, applications have to be designed in accordance with existing ICT infrastructure and—where appropriate–resort to multiple information channels (e.g., in countries with low internet and high TV penetration, public TV stations could provide information on new legislation via teletext services). In case of inadequate infrastructure the implementation of e-government initiatives has to incorporate the establishment of communication channels as well (see Box 1 for the setup of professionally operated internet kiosks in India). Also, e-government services should be promoted effectively in order to increase their utilization and consequently enhance governmental transparency (Bhatnagar, 2003; United Nations, 2003a).

Second, e-government services must ensure that underlying rules are transparent and applied consistently in specific decisions: The development of an online service delivery system involves the standardisation of administrative rules and procedures in order to enable computer coding. Publishing rules, regulations and requirements for government services online again enhances transparency and reduces the opportunity for arbitrary action available to civil servants when servicing citizens on a case-by-case basis (Bhatnagar, 2003; Center for Democracy and Technology (CDT), 2002). Furthermore, if citizens are offered relevant legislation and online tools, such as, for instance, tax calculators (e.g., withholding calculator, US Internal Revenue Service or individual non-business calculator, Australian Taxation Office) or immigration application tests (e.g., skilled worker self-assess-

ment, Citizenship and Immigration Canada), they can anticipate the presumable outcome and no longer have to take the outcome of the administrative process for granted without any means to re-check. So, e-government services based on transparent rules show the potential to encourage citizens to "question unreasonable procedures and their arbitrary application" (Bhatnagar, 2003, p. 30).

Third, e-government applications must build the ability to trace back decisions and actions to individual civil servants: As outlined above standardized administrative procedures work as a first means to reduce arbitrary action of civil servants. However, by building track-and-trace mechanisms into electronic services the chance of exposure of corrupt practices is enhanced. The fear of consequent embarrassment may therefore serve as a barrier to corruption for the individual civil servant. Moreover, the ability to track the status of their applications emboldens citizens to take specific counteractions in case of excessive delays (CDT, 2002; United Nations, 2003a).

According to Bhatnagar (2003) corruption can be reduced significantly if all three objectives are borne in mind when designing e-government applications. Conversely, ignoring some of these features may lead to ineffective e-government in terms of combating corrupt behaviour: A government Web site focusing solely on the provision of electronic access to information does not ensure enhanced accountability and transparency with regard to service delivery processes. A successful example of the use of e-government as a means to fight corruption, in which all the features outlined above have been integrated, is presented in Box 1.

## FUTURE TRENDS

After having diffused globally in a haphazard manner with not much regard given to costs as well as realized benefits, e-government currently seems to be maturing (Bannister, 2004; Moon et al., 2005). Governments are becoming increasingly reluctant to invest public funding into the development of e-government systems without a detailed estimation of the expected benefits of these initiatives. Consequently, researchers as well as IT consultants are eager to develop more sophisticated models and frameworks of e-government development, taking into consideration not only the amount of online services but also structural and social prerequisites, as well as effects and benefits (e.g., Kunstelj & Vintar, 2004; Moon et al., 2005; Rohleder & Jupp, 2004; United Nations, 2003a).

Referring to application of e-government systems as a means to fighting corruption and enhancing transparency, benefit has rather been incidental so far (Bhatnagar, 2003). Along with the tendency to develop and implement e-government systems based on multi-faceted frameworks, one might well expect that the design of e-governments will be customized in mutual relationship with structural prerequisites in order to perform certain functions.

However, future research is still needed on the relationship between corruption and transparency on the one hand and e-government systems on the other, as the latter can only be a part of the solution resting upon other governmental and societal systems at work. The current presentation and (sometimes superficial) analysis of success stories demonstrating the anti-corruption potential

*Box 1. Computerisation of land records, Karnataka, India (Bhatnagar, 2003, p. 26)*

> The Bhoomi ("land") project of online delivery of land records in Karnataka, one of India's 26 states, demonstrates the benefits of making government records more open so as to enable citizens to challenge arbitrary bureaucratic action. It also illustrates how automation can be used to remove discretion from civil servants.
>
> The department of revenue in Karnataka has computerised 20 million records of land ownership for 6.7 million farmers in the state. Under the manual, paper-based system, 9,000 village accountants maintained land records. Farmers had to seek out the village accountant to obtain a copy of their "Record of Rights, Tenancy and Crops" (RTC)–a document essential for obtaining bank loans. Village accountants were not easily accessible. The time taken to provide RTCs ranged from three to 30 days, depending upon the importance of the record to the farmer and, therefore, the size of the bribe. A typical bribe could range from INR 100 to 2,000 (USD 2 to 40).
>
> All "mutation requests"—requests to alter land records upon sale or inheritance of a piece of land—had to be filed with the village accountant, who was required to issue notices to the interested parties and post the information at the village office. Often neither of these actions was carried out and no record maintained. If no objections were forthcoming within a 30-day period, an update of the land records was to be carried out by a revenue inspector, a practice that could take up to two years.
>
> The Bhoomi initiative reduced the discretion of public officials by introducing provisions for recording mutation requests online. Farmers can now access the database and obtain a printed copy of the RTC online at 180 computerised kiosks for a fee of INR 15 (less than USD 1). A farmer can check the status of his application on a touch screen provided on a pilot basis in three of the computerised kiosks. Operators of the computerised system are made accountable for their decisions and actions by the use of a system that authenticates every log-in through a thumbprint. In the next phase of the project, all the databases will be uploaded to a central, Web-enabled database. RTCs will then be available online at Internet kiosks, which are planned for rural areas. (…)

of e-government (e.g., Bhatnagar, 2003; Scacco, 2003) do represent an anxious first step. In spite of this, the very implementation and functioning of e-government systems cannot be regarded as being isolated from consequences and causes of corruption (Lambsdorff, 2005). In order to provide a concise framework from which steps to be taken can be derived, future research should focus upon the development of a contingent, multidimensional approach including e-government as one means to reduce corruption under certain preconditions.

## CONCLUSION

Even though it is frequently assumed that the use of e-government applications reduces opportunities for corrupt behaviour, reality seems to be more complex: According to Bhatnagar (2003) "e-government offers a partial solution to the multifaceted problem of corruption" (p. 30) in a way that it may lead to reduced discretion and arbitrary action on the one hand and increased transparency and accountability on the other. However, features combating corruption have to be consciously build into the design of e-government applications on a micro level. On a macro level, such e-government initiatives have to be part of broader political and public sector reforms striving for the establishment or consolidation of law and order as well as civil fundamental freedoms (i.e., freedom of opinion, freedom of press, freedom of assembly, freedom of association, freedom of religion…) in order to enable public control of all fragments of the public as well as political sphere.

Relating to the micro level of e-government applications and its essential features to be integrated in order to combat corruption effectively, the United Nations' global e-government survey (UN, 2003a) found that 90% of its member states with official Web presence provide texts of laws and policies on their Web sites. However, only 36% offer substantive service information, which appears to be a prerequisite to transparent rules. In the case of track-and- trace mechanisms, merely 19% of the countries with official Web sites provide online transactions and have thus established the basic infrastructure necessary for the implementation of such mechanisms.

Whether e-government will be used as a tool to create transparency and hence fight corruption on a large scale is finally a question of political will. However, if politicians commit themselves to do so, future e-government applications will feature transparent rules and track-and-trace mechanisms on the one hand and will be embedded in broader political and public sector reforms on the other in order to maximise its corruption-combating potential.

Overall, it seems important to emphasise again that e-government should not be seen as a solution combating corruption in itself, but as a means to initiate and support broader public sector reforms (Bhatnagar & Deane, 2004; Scacco, 2003; Wescott, 2003). It must be kept in mind that "technology is an important facilitator, but it cannot produce results on its own" (Scacco, 2003, p. 29).

## KEY TERMS

**Accountability:** The responsibility to someone or for some action. Used in a political context, it refers to the trait of being answerable to the electorate for political or administrative actions and represents an important factor in securing good governance. In contrast to transparency, it enables feedback after an action.

**Correlation Coefficient:** A measure indicating the degree of linear dependence between two random variables. It can vary from -1 (perfect negative correlation) through 0 (no correlation) to +1 (perfect positive correlation).

**Corruption:** The violation of established rules for personal profit. Corruption is most commonly deployed in a public sector context, in which it refers to the misuse of entrusted power by politicians and public officials for private gain.

**Gross Domestic Product:** The total value of all goods and services produced within a territory during a specified period (usually per year). GDP differs from gross national product in excluding inter-country income transfers, in effect attributing to a territory the product generated within it rather than the incomes received in it. When comparing GDPs internationally two methods can be used: the current exchange rate method (GDP calculated by exchange rates prevailing on international currency markets) or the purchasing power parity method (GDP calculated by purchasing power parity of each currency relative to a selected standard).

**Purchasing Power Parity:** A method used to calculate exchange rates between the currencies of different countries. Purchasing power parity exchange rates calculate the relative value of currencies based on what those currencies will buy in their nation of origin.

**Track-and-Trace Mechanism(s):** They were first developed and applied by private postal and parcel services and enabled clients to track and trace their shipments all over the world. Applied in an e-government context, track-and-trace mechanisms enable the individual to check the processing status of his or her enquiry as well as the actions set by officials throughout the process.

**Transparency:** In physical sciences, a physical object is said to be transparent if one can see through it (at least partially). In social sciences, transparency refers to the opposite of privacy; an action or social phenomenon is said to be transparent if all the information about it is freely available. It enables feedback before or during an action.

# Courts on the Web in Russia

**Alexei Trochev**
*Queen's University, Canada*

## INTRODUCTION

When the Internet reached Russia in the mid-1990s, Russian judicial chiefs actively embraced the idea of having a solid presence of national judiciary on the Web. To judges, having court Web sites would improve public awareness about Russian courts and relieve overloaded court clerks from answering mundane questions about the location of courthouses, hours of work, schedule of hearings, court forms, and so on. However, the chronic underfinancing of Russian courts in the 1990s and the decentralized nature of the Russian judiciary made the creation and the maintenance of the lower courts' Web sites much more sporadic.

Improving public awareness about Russian courts is a priority for Russian judges, who increasingly issue impartial decisions yet at the same time face growing public skepticism about judicial performance (Solomon, 2003, 2004; Trochev, 2006). As the growing number of studies of the information and communication technologies (ICT) in courthouses around the world show, computerized courts can both speed up the administration of justice and strengthen public trust in the judicial system (Bueno, Ribeiro, & Hoeschl, 2003; Dalal, 2005; Fabri & Contini, 2001; Fabri & Langbroek, 2000; Fabri, Jean, Langbroek, & Pauliat, 2005; Langbroek & Fabri, 2004; Oskamp, Lodder, & Apistola, 2004; Valentini, 2003; Malik, 2002). Indeed, as the recent research demonstrates, those who know something about the courts: either about court procedures or about court-ordered public policies, tend to trust the judiciary and to comply with court decisions (Baird, 2001; Gibson, Caldeira., & Baird, 1998; Kritzer & Voelker, 1998; Tyler & Mitchell, 1994; Tyler, Boeckmann, Smith, & Huo, 1997).

This article focuses on the Web sites of Russian courts as the virtual gateways in the world of judicial administration (Trochev, 2002) and discusses challenges of adapting Russian court Web sites to the needs of various users of judicial system: judges themselves, law-enforcement agencies, actual litigants, general public and scholars (Toharia, 2003).

## BACKGROUND: INFORMATION AND COMMUNICATION TECHNOLOGIES IN RUSSIAN COURTS

Following the collapse of the USSR in 1991, Russia's constitution-makers pursued a major program of judicial reform, as they understood that strong and independent courts would help to achieve larger policy goals (Solomon & Foglesong, 2000). In theory, Russia's rulers needed a respected rule of law system and effective courts to attract significant investment for the Russian economy and carry out further reforms on such crucial matters as land ownership (Trochev & Solomon, 2005). With the accession the Council of Europe and acceptance of the binding jurisdiction of the European Court of Human Rights (ECHR) in 1998, Russia has also been facing an additional challenge of administering justice in a timely and fair manner in order to avoid violation of the Article 6 of the European Convention on Human Rights. Since the early 1990s, Russian judges insisted that meeting these challenges and improving the efficiency of their courts in the context of exploding rates of litigation would be impossible without computers and information and communication technologies (ICT) in every courthouse. As Solomon and Foglesong (2000) report, by early 1998, the Russian Supreme Court had plans for a comprehensive publication of its judgments (p. 105), while the Russian Constitutional Court and the Higher Arbitrazh Court had their Web sites up and running even before that. However, the Russian government took this idea seriously only in 2001, when the first ECHR judgments against Russia severely criticized the country's inefficient and slow administration of justice. If in 2001, there were 10,000 computers in all Russian courts, by early 2005, their number grew to 40,000. Starting in 2004, the Russian judiciary annually receives additional 500 million rubles (17 mln U.S. dollars) to buy computers, servers, and modems, to create and maintain electronic data interchange (EDI), network management, court intranets/extranets, videoconferencing, and court Web sites. As a result of this massive funding, by the end of 2005, Russia's 118 commercial (arbitrazh) courts be-

came ready for the integration into a country-wide intercourt network that will serve as a basis for the electronic paperless resolution of commercial disputes. International financial aid and technical assistance has also played an important role in digitizing the Russian judiciary. In fact, Russian government officials encouraged judges to apply for grants from foreign NGOs (Trochev & Solomon, 2005). However, domestic funding and the willingness of court chairs to use information technologies remain crucial determinants of getting Russian courts ready to meet the challenges of the 21st century.

## Russian Constitutional Courts on the Web

Russian Constitutional Court (RCC) has its own Web site, www.ksrf.ru, containing all decisions on the merits of the case and some rulings dismissing the case. Some rulings are published only on the Web site of the Court and are enforceable. In addition to the jurisprudence of the RCC, this Web site contains the schedule of the upcoming hearings, statistical data about the work of the Court, speeches by the chief justice, biographies of justices and historical essay about the Court. Unfortunately, this Web site no longer posts summaries of several RCC decisions translated into in English, French, and German. All RCC Justices and some Court clerks have an access to the Internet. This is in addition to the RCC intranet with an easy access to all judgments of the Court as well as several legal databases. This intranet was made available through German funding in the mid-1990s.

Three out of fifteen regional constitutional/charter courts also have presence on the Internet (Trochev, 2004). Karelia Constitutional Court, www.gov.karelia.ru/Law/index.html, has a regularly updated Web site with decisions, by-laws of the Court and short biographies of Justices. For the text of dissenting opinions, you need to search at the Web site of "Karelia," the official newspaper of this region, www.gov.karelia.ru/gov/Karelia/search.html. Sverdlovsk Oblast Charter Court, ustavsud.ur.ru/1.htm, has similar detailed information on Justices and their work. This court has also several publications by the Justices as well as data on the implementation of the Court's decisions in 2000. St. Petersburg Charter Court, ustavsud.spb.ru/content.asp?cnt=114, is also present on the Web thanks to the efforts of the St. Petersburg State University law school students. This Web site contains fewer court decisions and only few lines on the judges' background. But it has the texts of journal and newspaper articles about the Court's work.

## Russian Ordinary Courts on the Web

Unlike federal and regional constitutional courts, Russia's ordinary courts form a hierarchy with the Russian Supreme Court (RSC) at its apex. The Web page of the RSC, www.supcourt.ru, has information about the Court's work and its history, a collection of judgments, and a schedule of its hearings. In addition, the RSC Web site contains data about the work of the Russian judicial self-government bodies: the Council of Russian Judges, the Congress of Judges, and the Higher Judicial Qualification Collegium, the main body in charge of screening judicial nominees and disciplining judges. Here, one could also find the electronic copy of the monthly RSC Bulletin, an official publication of the Court, which frequently contains important guidelines for lower courts.

Lower ordinary courts are the courts that most Russians are familiar with. There are about 2,500 municipal/rural courts, 87 regional courts and 146 military courts. The Web page of the St. Petersburg courts, www.cdept.spb.ru, lists the contact information for all ordinary courts in Russia. The Web site of the Russian Judicial Department, www.cdep.ru, has up-to-date statistics about their workload. While by early 2004, every regional court had an access to the World Wide Web, the RSC Web site contained links only to a dozen of regional courts including two military courts. This delayed production of the court Web sites reflects the decentralized nature of the Russian judiciary: many regional court chairs have very few incentives to promote their courts on the Web and prefer to spend resources on other priorities of judicial administration. This is why the majority of the regional courts' Web sites simply list addresses, working hours and contact information of these courts and the Justices of the Peace.

Websites of other courts have more usable information for judges, mass media, and the public. Court Web sites in Yaroslavl, oblsud.yar.ru and cdyar.yaroslavl.ru, and in Saratov, www.usdsaratov.ru, regions, target primarily local judges. They publish summaries of cases, numerous interviews with local judges and reports about the judicial reform in the regions. The Web site of Cheliabinsk Regional Court, www.ural-chel.ru/gubern/obl_sud/index.htm, which is famous for its televised cassation criminal trials contains materials on the ICT to support judicial administration. Briansk Regional Court's Web site, www.debryansk.ru/~suddepbr, is also devoted to this issue as well as to the work of the justices of the peace. The Web site of Omsk Regional Court, www.oblsud.omsk.ru, has statistics on the cases heard in 2001 and early 2002, monthly schedule of civil and criminal

cases, and review of publications about the Court in local media. Judges in Khabarovsk Region regularly contribute to the monthly "Justice" newspaper and quarterly Bulletin on Judicial Practice, both of which appear at the regional court Website, www.usd.khv.ru. Kaluga ordinary courts, www.suddep.kaluga.ru, publish downloadable templates of complaints, claims, and civil actions of various categories to assist potential litigants in filing their lawsuits. Municipal courts in oil-rich regions already have functioning Web sites. Usinsk City Court in Komi Region, www.usinsk.com/sud, and Muravlenko City Court in Iamal-Nenets Region, gorsud.muravlenko.com, provide claim forms and contact information for judges, the Bar, the procuracy and the court bailiffs on their Web sites. Noiabrsk City Court in Iamal-Nenets Region, posts weekly updated schedule of hearings and hosts interactive "Frequently Asked Questions" section on its Web site, ngcourt.nojabrsk.ru.

Finally, there is a small minority of Russian courts that follow the example of the Russian Supreme Court and publish their judgments on the Internet. For example, Karelia Regional Court, versud.karelia.ru, and Amur Regional Court, www.oblsud.tsl.ru, have published a selection of their judgments on the Internet. Most valuable and regularly updated Website, www.scourt.vens.ru, is hosted by Ul'ianovsk Regional Court which has a wealth of information on this court's jurisprudence, judicial reform, etc. It even has the minutes of the meeting of the regional conference of Judges. Sverdlovsk Regional Court, www.femida.e-burg.ru, also publishes its judgments on the Web and even has lively interactive "questions & answers" section, where Internet users can receive brief answers from regional judges.

Military courts in Moscow and St. Petersburg have also been particularly active in creating and updating their presence on the Web. Moscow District Military Court, www.movs.ru, has a selection of its judgments issued in 2002. Leningrad District Military Court, www.dk.ru/voensud/INDEXX.HTM, has a database of its decisions issued in 1999 to mid-2001 and a short essay on the history of military courts. The Web sites of St. Petersburg Garrison Military Court, gvs.spb.ru, and Pushkin Garrison Military Court, pgvs.spb.ru, have their judgments, claim forms and even addresses and telephone numbers of local jails and prisons, where the accused or convicted soldiers and officers are likely to be held. Pskov Garrison Military Court, www.psc.ru/voensud, also posts certain decisions issued in 2000 and templates for filing complaints.

Among city courts, Moscow District court in the city of Tver' offers the most informative and up-to-date homepage, www.mossud.tver.ru, with all court decisions since 2000 and templates of complaints, claims and civil actions of various categories. This is the only local court that publishes its own decisions thanks to the generous funding by the Open Society Institute.

## Russian Arbitrazh Courts on the Web

The arbitrazh courts, established in 1991 to hear disputes among firms and between firms and the government, exist at the trial level in 87 regions, 20 appellate circuits of three to five regions (introduced in 2003), 10 cassation circuits of eight to ten regions (added in 1995), and the Higher Arbitrazh Court. The Higher Arbitrazh Court maintains a Web site, www.arbitr.ru, with extensive database of its decisions, the contact information, including e-mail addresses, of all lower arbitrazh courts, archive of publications about them and statistical data on the work of these courts in 1992-2004. Similar to the limited Web presence of ordinary courts, although all arbitrazh courts have Internet access, only few of them have Web sites online. Some courts, like North Ossetiia Arbitrazh Court, as.alanianet.ru, publish only a selection of their judgments and fail to update their Web sites on a regular basis. Omsk Arbitrazh Court, www.omskarbitr.ru, posts a daily schedule of its casework and texts of decisions issued in October-November 2001 and April-May 2002. One judge of this court has his own Web site, chucha.omskarbitr.ru, with several publications and court decisions. The Web site of Primor Arbitrazh Court, primarbitr.ru, has numerous reviews about the Court's jurisprudence, together with an interactive "questions & answers" section, where Internet users can receive brief answers from regional judges. Northwestern Circuit Arbitrazh Court in St. Petersburg, www.fas.spb.ru, has a wealth of data on the work of this court including helpful information for the litigants. This court posts its own quarterly journal "Arbitration Disputes" on the Web at www.kadis.net/asp/asp_view.php3, which you can read after registering free of charge. Moscow City Arbitrazh Court, www.msk.arbitr.ru, boasts a database of about 4,000 decisions issued in 1991-2005, statistical data on the Court's work since 1998, contact information and claim forms. East Siberian Circuit Arbitrazh Court in Irkutsk, fasvso.ru, in addition to various useful court-related information, publishes its quarterly journal "Justice in Eastern Siberia" on the Internet, www.pravosib.ru, featuring arbitrazh court judgments, case comments and interviews with Siberian judges.

# FUTURE TRENDS

In addition to ICTs, the use of Internet among Russian courts is likely to continue if only to ease the burden of

an overloaded judiciary and to improve its reputation at home and abroad. Both tasks are daunting in light of Russia's vast landmass, frequently changing legislation, and widespread public perception of the judicial dependence and corruption. Given the level of current funding, all Russian judges and court clerks will have computers and access to the World Wide Web in the next decade. More and more court Web sites will contain court judgments, particularly in the light of the recent guidelines on court Web sites issued by the Russian Supreme Court and the Higher Arbitrazh Court. Given that, as of mid-2005, each appellate court in Russia has a full-time press-attaché, court Web pages are likely to present interviews with judges and court officials about their achievements and challenges. Judges in post-authoritarian societies must advertise their work: if judges fail to inform the citizens, nobody else will. Greater interaction with journalists as well as with the public via Internet is bound to make the Russian court more user-friendly and more up-to-date. Fortunately, many recent judicial appointments in Russia indicate that the newly appointed court chairs are willing to use ICT, including Internet, in their courts. Finally, greater integration of Russia into the global market place through its imminent accession to the World Trade Organization may provide an impetus for the Russian judiciary to have English-language versions of their Web sites. Indeed, the experiences of post-communist countries (Latvia, Lithuania, and Estonia), which recently joined the European Union, show that deeper international integration contributes to more English-language content of court Web sites.

## CONCLUSION

If designed and maintained properly, court Web sites could greatly improve the administration of justice and the image of judiciary in the eyes of the public. On the one hand, publishing court decisions on the Web is an attractive way to tell the public about the work of the high courts. Electronic dissemination of court decisions to the mass media improves the interaction between the judiciary and the press. Having a court Web site also signals judges from abroad that the Russian judiciary is well equipped to navigate the information super-highway. On the other hand, easy access to judicial decisions on court Web sites places a great responsibility on judges to deliver sound and persuasive verdicts (preferably with the summaries to be easily understood by ordinary citizens). Also, court Web pages must contain up-to-date and accurate information on the site for viewers to use while preventing unauthorized users from accessing confidential data. Finally, court Web sites must enhance the accessibility of the judiciary and cater to the needs of actual and potential litigants. Some Russian judges have already realized this. The Web sites of military courts post claim forms so that soldiers can simply print them out, fill in the blanks, and file a lawsuits. City courts post on the Web contact information of local lawyers and human rights non-governmental organizations, law enforcement agencies and court bailiffs, to whom local residents could turn for help. Other courts answer questions posted on their Web sites by concerned citizens. Sharing these Web-based innovations with other courts would be the next step in the right direction. Moreover, learning from the experiences of foreign (British, Finnish, Canadian, and some state courts in the USA) would be very important for Russian court Webmasters. Still, more research is needed to determine the needs of the users of these court Web sites so that the growing presence of the Russian judiciary on the WWW actually improves the public reputation of the third branch of Russian government.

## KEY TERMS

**Council of Europe:** An international organization founded in 1949, currently consists of 46 member states, which accept the principle of the rule of law and guarantee basic human rights and freedoms to their citizens.

**Electronic Data Interchange:** The computer-to-computer interchange of strictly formatted messages that represent documents, like court conviction records, court orders and judgments, claim forms and legal acts.

**European Court of Human Rights:** A judicial branch of the Council of Europe, which was created in 1959 to hear human rights complaints from Council of Europe member states, and to issue decisions binding on the member states.

**Extranet:** A system for communication among two or more computers, used a group of select users, like judges and court clerks across the country (and excluding everyone else).

**Information and Communications Technologies (ICTs):** Technologies from computing, electronics, and telecommunications to process and distribute information in digital and other forms, like radio, television, phones, computer and network hardware and software, satellite systems, and so on.

**Intranet:** A system for communication among two or more computers, used internally in an organization.

**Network Management:** maintenance of two or more computer systems linked together by telephone lines, cables, or radio waves.

**Russian Judicial System:** Consists of the federal and regional constitutional courts; the ordinary courts including military courts and justice of the peace courts, in charge of civil, administrative, and criminal cases; and commercial (arbitrazh) courts.

# Current Approaches to Federal E-Government in the United States

## INTRODUCTION

The U.S. government is making strides to provide electronic access to government agencies and services. A variety of issues are involved when implementing e-government programs such as electronic tax filing, access to drug information, and so forth. Financial, technical, personnel, and legal issues are common. Privacy issues in the creation of e-government are also of interest to both the e-government implementer and citizen. There are a variety of issues in planning and implementing projects of the scope and magnitude of e-government. Issues such as user requirements, organizational change, government regulations, and politics, as well as descriptions of planning and implementation frameworks, are important. Experience in developed countries shows that it is not difficult for people to imagine a situation where all interaction can be done 24 hours each day, 7 days each week.

Many countries, including the United States, France, Australia, Greece, Canada, Singapore, and Italy have been offering government services online (West, 2004). According to Sharma and Gupta (2003), Canada, Singapore, and the United States are categorized as "innovative leaders" (p. 34) whose continued leadership in the creation of e-government and more mature online services sets them apart from other countries. Canada leads the way in e-government innovation while Singapore, the United States, Australia, Denmark, the United Kingdom, Finland, Germany, and Ireland are countries in the top-10 list. Several Asian countries such as China, Hong Kong, India, Japan, Philippines, Indonesia, Thailand, Bangladesh, and Burma have initiated the concept of e-government as well (Dodgson, 2001).

An article in *Federal Computer Week* (Perera, 2004) reported findings of a recent poll indicating that 77% of Internet users (or some 97 million people) in the United States have gone online for government information. E-government is rapidly becoming a key priority of the government of the United States.

## OVERVIEW OF E-GOVERNMENT

E-government refers to the delivery of national or local government information and services via the Internet or other digital means (Galindo, 2004; Sharma & Gupta, 2003). E-government is the process of transacting governmental business with the public through the use of automated systems and the Internet network. Another way to look at e-government is to see it as an online government service. The purpose of e-government is to provide an e-portal: "a one-stop Internet gateway" (p. 35) to major government services by the streamlining, simplification, and integration of services of various government agencies (Sharma & Gupta, 2003).

One of the key potential benefits of e-government is the enhancement of citizens' access to government information and services, as well as increased citizen participation in the democratic process (e.g., e-voting). Government's customers are increasingly more demanding, and a survey of federal chief information officers found 86% believing that e-government improved service delivery and 63% feeling it reduced costs (McNeil, Tolbert, Mossberger, & Dotterweich, 2003).

The most widely used application of e-government is the publication of information for citizens on the Internet. One challenge to achieving more robust usage is to create an interactive, real-time government service vs. the present static environment. A few governments have Web enabled their transactional systems to allow their constituents to conduct business over the Internet (West, 2004). However, the majority of these systems is limited to a single agency and is not fully integrated with all the governmental structures. The National Science Foundation (NSF) has attempted to address the challenge of helping government agencies adopt concepts derived from basic research and adapt them to the practical problems of government work (Marchionini, Samet, & Brandt, 2003). The NSF Digital Government Program strongly supports research into the development of e-government.

Fountain (2001) states that IT changes the capacity and control features of traditional bureaucracies. Power can be redistributed as well as functional responsibilities within and across federal agencies. This change can affect how the public sector ultimately functions.

## HISTORY OF E-GOVERNMENT

A June 2000 initiative from President Clinton created an integrated online service system that placed federal-government online resources on a single Web site (http://www.firstgov.gov). This administration promoted the idea of "reinventing government"to improve government efficiency and citizen participation (Osborne & Gaebler, 1992, p. 60). This initiative attempted to build one-stop access with $500 billion in U.S. government funding, with $300 billion going to grants and $200 billion to procurement opportunities. Following this federal initiative, many local governments adopted IT for various aspects of local governance.

The E-Government Act was signed by President Bush in December 2002. The purpose of this bill was to increase public access to governmental information. This law requires the federal government to use Internet-based information technology to enhance citizen access to government information. The new Office of Electronic Government within the Office of Management and Budget (OMB) was created in response to the act to encourage the government to make its Web sites more user friendly (GAO, 2004; Tillman, 2003). This office will focus on capital planning and investment control for IT, information security, information privacy, and the access to and preservation of government information (OECD, 2003). The e-government office oversees the development of an integrated Internet-based information system for each federal agency while establishing government-wide policies to support IT standards. Interagency committees are also set up and periodic reports with recommendations are recorded (GAO).

The E-Government Act created two programs: (a) the Federal Information Technology Workforce and (b) the Federal Information Security Incident Center (Tillman, 2003). The former program's initiative requires the Office of Personnel Management (OPM) to assess the government's IT personnel needs. The OMB manages the Federal Information Security Incident Center, which maintains a list of information security incidents and informs the agencies of potential security threats and vulnerabilities.

E-government activities are financed by an e-government fund. The General Service Administration (GSA) manages the fund, which will support OMB-approved e-government projects. Executive Order 13011 created the Chief Information Council in 1996 to develop recommendations on federal information-management policies. Individual federal agencies must develop a set of e-government performance measures dependant on their customer-service record, productivity, and use of innovative technology. Each agency also needs to provide the public with consolidated access to government information and services through an integrated Internet-based portal (OECD, 2003).

The E-Government Act also requires the government to be more accountable. The bill requires every regulatory agency to establish a Web site to collect and post public comments on every rule it considers. The Food and Drug Administration (FDA) has a Web site that establishes public comment periods and considers public opinions before a law is promulgated (Center for Food Safety and Applied Nutrition, 2003). The public now has access to a database of the voting records of Congressional members and the independent analysis of bills from the Congressional Research Service (Tillman, 2003).

Information security is also an important goal of this new legislation (Miller, 2002). National security and law enforcement groups coordinate the management of threats to federal IT with private-sector organizations. Each agency is accountable in preventing unauthorized access to their information systems. Independent auditing is also part of the process.

E-government services used most frequently are filing personal income-tax returns, applying for a state fishing or hunting license, renewing professional licenses, submitting employment information, registering a complaint against a business or a professional licensee, renewing a driver's license, and requesting a government loan. E-learning also provides training opportunities for federal agencies (Welber, 2001). A strategy developed by Health and Human Services (HHS) personnel and IBM uses a portal on the Internet outside the HHS firewall that allows employees access to it at anytime, anywhere.

## ISSUES IN PLANNING

Implementing an e-government framework is a challenging task. Unless careful preparations are made, e-government is not likely to succeed. According to Sharma and Gupta (2003), there are several key recommendations for the planning stage. Creating e-governance awareness is essential at the initial stage. A massive campaign should be conducted to raise the awareness of e-government services and try to build commitment for e-governance. Workshops, programs, seminars, conferences, Web-based documentation, or individual meetings are part of this

campaign, as well as obtaining awareness and commitment from senior officials.

E-governance requires a variety of legislative changes that include the recognition of electronic documents in courts of law, electronic signatures, electronic archiving, data matching, the freedom of information, data protection, computer crime, and intellectual property-rights legislation. Regulatory changes are required for a range of activities that include procurement to service delivery (Thompson, 2003). All changes would form part of a broader change to support generic e-economy and e-nation initiatives.

The e-government framework can be implemented successfully if personnel are available who could assume the role of developers as well as end users. It is vital to establish an effective critical mass of manpower, knowledge, and skills sufficient to support an e-governance strategy. Technical knowledge could be obtained through education at universities, training programs, and special workshops.

Strong technology infrastructures are also an important consideration in the planning process. Effective telecommunication infrastructures facilitate the delivery of e-government services. Countries that have telecommunications infrastructure controlled by government may need deregulation to establish a viable communication infrastructure and competition to decrease prices. The costs of obtaining Internet access (including the hardware) are often too high for many countries.

The goal of e-democracy is to deploy information technology to increase the effectiveness and efficiency of democracy. Another study led by Watson and Mundy (2001) presents a three-phase, dual-pronged strategy for implementing e-democracy: initiation, infusion, and customization. The initiation stage creates the infrastructure (software firms, methodologies, and consulting skills) to acquaint governments and citizens with the e-government concept, and to consolidate the numerous online government services. Large-scale adoption leads to the infusion phase. Customization is used when citizens do not accept the one-size-fits-all solution. Initial studies of property-tax payment show that Web-enabled payment decreases processing costs from more than $5 to $0.22 per transaction. The potential savings of e-democracy could be as much as $110 billion. This framework for implementing e-democracy has been used as a basis by other researchers.

Researchers from the Netherlands present another framework required to implement local e-government planning (Vriens & Achterbergh, 2004). The authors recommend a three-stage framework. Stage 1 generates an e-government applications portfolio. A list of Web-enabled IT applications is created. In stage 2, the required changes to the technological, organizational, and human-resources infrastructures to implement the e-government initiatives are identified. Stage 3 defines the infrastructural- or application-specific projects for e-government implementation. Cost estimates are made, and projects are categorized in several planning scenarios to accommodate political priorities.

Sharma and Gupta (2003) suggest four layers to implement e-government. The first layer is the technical infrastructure in the form of local area networks, Internet connectivity, intranets, servers, and so forth. The second layer represents the office automation or digitization and the integration of government data relating to various services. The third layer creates an official Web portal of government services in the form of an e-government portal. Layer 4 is where the government concerns itself with how the citizen receives the services. The framework for e-government also requires a legal and regulatory infrastructure. The support infrastructure includes an integrated network for banks and financial institutions to serve as an automatic clearing house, and a legal and regulatory framework. This will support payments online and protect privacy.

## EXAMPLES OF SUCCESSFUL IMPLEMENTATION

Change is difficult, especially with the bureaucracy embedded in the government. The Federal Highway Administration (FHWA) adopted a five-step project-management plan in their implementation of e-government. The existence of the FHWA, a division of the U.S. Department of Transportation, is to make the nation's roads safer. It is essential that the agency work with the state and local highway divisions around the country. Until the FHWA turned to the Internet, there was no single easily accessible, central clearinghouse for the wide range of technical resources that highway officials required (Battey, 2001). In 1998, the FHWA undertook the creation of an electronic community of practice for transportation experts and professionals to exchange information and best practices. The knowledge center allows collaboration and the sharing of information between the FHWA and highway officials throughout the country. The FHWA wanted to ensure that the site was not static because interactive collaboration was essential. The knowledge center was tasked with not only converting government documents into PDF (portable document format) and operating a bulletin board, but operating as a real-time collaboration vehicle. FHWA teamed with consultant American Management Systems to develop a program to transform the agency's culture into an electronically accessible transportation community.

According to Battey, they developed a five-step program for e-government implementation.

1. Get senior-level buy-in and focus on people.
2. Obtain necessary funds.
3. Identify strategic partners.
4. Emphasize technical considerations.
5. Plan for efficient transitions.

The Internal Revenue Service's (IRS's) customer-facing Web site, http://www.irs.gov, is a key e-government initiative. The IRS currently collects over $2 trillion in gross revenue, comprising 95% of the federal government's revenue (BEA, 2003). While electronic filing has been increasing rapidly, 77% of returns are still filed on paper. Reaching the Congressionally mandated goal of 80% electronically filed returns by 2007 will place enormous demands on the IRS Web site. This interactive Web site will have to accurately and securely conduct millions of transactions per day. To effectively handle yearly increases in electronic filing, the IRS had to significantly upgrade the site.

The major problem with the IRS' old Web site was that information was difficult to find. The Treasury wanted a new and improved site that would arrange content in ways that make it significantly easier to access and use. The Web site modernization project initially called for a secure, easy-to-navigate design that would make it simpler to find information and tax forms, and allow taxpayers to file online. The proposed plan also needed to provide increased access to persons with disabilities. For the second phase of the project, the IRS' goals included decreasing the number of tax-related forms that an employer must file, providing timely and accurate tax information to employers, increasing the availability of electronic tax filing, and modeling simplified federal and state tax employment laws. The IRS focused on increasing customer access and service on their Web site. The IRS Web site currently receives an average of 80 million hits daily, and it has more than half a million pages, including access to hundreds of forms. The Web site enables the IRS to comply with the Government Paperwork Elimination Act and provide three-click access to information. The projected savings for the IRS and the Social Security Administration is $16 million in one year for staff, printing, and mailing costs. This solution also reduces the costs to states for processing wage and tax data by 5.6% (BEA, 2003).

The FDA issued a 2002 rule that requires certain labeling submitted for review with new drug applications (NDAs), certain biological license applications (BLAs), abbreviated new drug applications (ANDAs), and supplements and annual reports to be submitted to the agency in electronic format (Center for Food Safety and Applied Nutrition, 2004). This rule is the first FDA regulation to require the submission of information by electronic means. It is FDA's first regulation issued under the President's e-government initiative. Each year, the FDA receives more than 1,000 proposed labeling changes for NDAs and BLAs, and more than 2,600 proposed original and supplemental labeling changes for ANDAs.

In response to the e-government directive from the President's Management Agenda, the Department of Labor (DOL) initiated an e-government strategy to improve DOL's service delivery to its customers through the integration of four primary components. The first, organizational capability, incorporates the policies, plans, people, and management processes that are required to support the e-government strategy. This assessment identified existing workforce capabilities in terms of workload and competencies, determined future workforce requirements in the context of e-governmental requirements, and devised strategies to eliminate gaps, both current and future, between workforce capabilities and workforce requirements. The second, customer relationship management (CRM), includes the methodologies, technologies, and capabilities that help DOL identify customers, evaluate their needs, and determine how to meet and continuously improve customer service. The third, enterprise architecture (EA), is the explicit description and documentation of the current and desired relationships among business and management processes and IT. And the last, security and privacy, develops and implements security policies and procedures to address threats and vulnerabilities as well as risk mitigation and management.

## FACTORS THAT CONTRIBUTE TO THE SUCCESS OR DIFFICULTY OF IMPLEMENTATION

E-governments still face a certain amount of distrust from their citizens. Many are wary because of privacy and security concerns. It is a challenge for the governments to address this issue. There are various schemes used such as public-key infrastructure (PKI) systems to protect electronic interaction both internally and externally, but trust for these will evolve slowly. A PKI is a sophisticated encryption system using digital signatures that assures electronic information is protected while being entered, during transit, and when stored in a computer (Forno & Feinbloom, 2001). As the number of Internet transactions with government increases, so does the risk of data being stolen or misused.

It is also essential that agencies publicize the existence of government-service portals. The public needs to be educated about the existence of online services and information. A constant challenge is how to pay for e-

government infrastructure. For example, the typical American state spends 1% to 2% on information technology. This makes it challenging for rapid progress in online services. Alternative financial models exist, but they are based on commercial advertising and user fees, posing risks in commercialization or reliance on user fees (West, 2004).

## CONCLUSION

The E-Government Act of 2002 requires the federal government to use Internet-based information technology to enhance citizen access to government information. The United States is not the only country to encourage the e-government principle. Project planning is vital to the successful implementation of this initiative. There are a variety of theories available to establish a strong implementation plan and strategy. The common elements include a technical infrastructure for Internet connectivity, office digitization and the integration of government data relating to various services, the creation of an official Web portal of government services in the form of an e-government portal, and a user-access layer where the citizen can access the various services. The implementation of e-government varies across different countries as well as types of government (local, state, federal). There are a variety of challenges to the successful implementation and use of e-government principles, which include technical, personnel, and legal issues. Developing countries have the challenge of providing the infrastructure and funds for network, application, security, data, and content tools, and hardware and software system to support e-government. Planning the transformation to e-government is the single most important issue facing most governments today. Constant technological changes affect people's reception and perception of the new way of conducting business with their government.

## NOTE

The views expressed in this paper are solely those of the authors and not of any federal government agency.

## KEY TERMS

**Digitization:** Process of converting a physical item (e.g., paper, sound recording, picture, video) into a digital format.

**E-Government Infrastructure:** Environment where government conducts business electronically with citizens, businesses, other government agencies, and its own employees.

**E-Government Strategy:** Action plan to achieve the government's goals and objectives, which can then be observed and measured, as well as to identify and prioritize key initiatives.

**Electronic Filing:** Filing a document with a government agency by transmitting it in electronic format.

**Public-Key Infrastructure (PKI):** Encryption system that uses a public and private cryptographic key pin that is obtained and shared through a trusted authority that allows users of unsecured public networks such as the Internet to securely and privately exchange data.

# Cyber Attacks

**Neil C. Rowe**
*U.S. Naval Postgraduate School, USA*

## INTRODUCTION

Information systems (computers and networks) are increasingly the targets of attacks ranging from vandalism to serious crimes (Richardson, 2003). Since government systems are valuable resources for a society, it is important to protect them from such attacks. Unfortunately, however, government systems can be especially vulnerable (Lucasik, Goodman, & Longhurst, 2003). This is in part because government is distributed over many locations, and therefore, it is hard to protect all of its information systems well. Second, many government systems must be accessible to a wide range of people (even if through a government intermediary), unlike the specialized systems used in other settings, and users will include a few fools and criminals. Third, governments often use popular business software, and the more popular that software is, the more attacks are known against it. Finally, there are many people with antipathy or grudges against governments for one reason or another, and they may seek revenge by attacking a government's information system and data. With the global Internet, attackers need not be in the same country as the government they attack.

Therefore, it is important to become familiar with the kinds of possible attackers, attacks, and countermeasures that governments could encounter on their computer systems and computer networks (Boswoth & Kabay, 2002; Schwartau, 2001).

## BACKGROUND

Government information systems see several kinds of attackers (The Honeynet Project, 2004):

- Disgruntled citizens who might attack computer systems in revenge. No government can please all of its citizens, and since government procedures can be irritating, there are plenty of motives. However, the disgruntled usually confine themselves to giving false data or to doing simple vandalism such as changing government Web pages.
- Disgruntled government employees and government contractors who may attempt to sabotage or to embarrass government systems. Since they are insiders, they can do considerable damage. Thus, it is important not to give any employee too much power.
- Hackers, or amateur attackers who enjoy breaking into computer systems (Chirillo, 2002). Contrary to media coverage, most do little damage.
- Political opponents who might try to attack computer systems, but this will be rare, since most digital governments should be politically neutral.
- Spies who try to obtain secrets (Shulsky & Schmitt, 2002). All governments have secrets on their computers, and there are many kinds of spies. This involves exploration and may entail setting up electronic backdoors for easier access.
- Criminals who can exploit computer systems, for example, to steal money and services or tools to get them credit card numbers (Boni & Kovacich, 1999; Loader & Thomas, 2000). Computer crime is increasing every year.
- Cyber terrorists, or terrorists who attack information systems (Verton, 2003). There has been little evidence of them so far, but they could create considerable damage with minimal effort.
- Military information-warfare specialists who develop ways to attack the information systems of other countries during war (Denning, 1999). They are well trained, not easily discouraged, and use methods that are difficult to detect. Most computers and networks can be subverted quickly by such determined adversaries.

## TYPES OF ATTACKS

The field of information security analyzes attacks on information systems and develops countermeasures (Schneier, 2000; McClure, Scambray, & Kurtz, 2001). Some classic attacks include the following:

- Defacement and modification of Web pages to criticize their owners or to make political points, as by Chinese hackers in 2000 to Japanese government sites to protest a meeting about Japanese actions in 1937.
- Overwhelming a system by sending it too much data or making too many requests. This is called a denial-

of-service (DOS) attack, because it impedes legitimate users who are sharing the same resource. The U.S. White House (president) Web site was attacked this way on May 3, 2001.

- Spam or useless e-mail that wastes mail resources, often combined with phishing, or computerized scams to steal passwords and other private information by fooling a user into volunteering it. These are increasing problems on government computer systems (U.S. Government Accounting Office, 2005).
- Guessing passwords and encryption keys for secrets. This is possible when passwords and keys are short or consist of English words. Then an attacker can impersonate someone on the information system and access his or her files. For example, someone got the password of a U.S. Air Force employee in August 2005 and viewed personnel records of 33,000 people.
- Exploiting flaws in software to circumvent access controls. Unlike most products, software rarely comes with a guarantee that it works correctly. There are plenty of bugs in commercial software (including operating systems), some of which can be exploited by attackers. Many of the dangerous ones involve privilege escalation, or finding loopholes to gain system-administrator privileges. For instance, testers hired by the State of Maryland in the United States in 2003 showed that they could break in to the state's voting machines and modify the votes, even remotely, due to flaws in the software.
- Buffer overflows, the most common type of software flaw, which allow privilege escalation by failing to check for too large of input. While good programmers do not make this error, software (including the Windows operating system) written in the programming languages C and C++ must check this explicitly, and some programmers forget this.
- Inserting Trojan horses, or innocent-looking programs that secretly either damage software or benefit the attacker in some way. To insert them, an attacker can: (a) send them attached to an e-mail message that encourages the reader to run it; (b) encourage a user to download them from a Web site; and (c) induce a user to insert a storage device that contains them into his or her computer. The Taiwan government alleged in 2003 that China was distributing Trojan horses specifically designed to break in to their government systems.
- Computer viruses and worms inserted onto computer systems via Trojan horses or by breaking in. These programs reproduce themselves automatically, wasting resources and causing collateral damage. For instance, some U.S. Customs computer systems were shut down by a virus for five hours on August 18, 2005, creating backups for arriving international flights.
- Spyware is a Trojan horse that tracks what users do on a computer and reports this information surreptitiously to a collection site. Current instances mostly just report what Internet sites a user visits, but spyware could be used for more serious spying, too.
- Directly modifying the operating system of a computer by replacing key parts of it with the attacker's programs (from a rootkit). This gives an attacker complete control over a computer system.
- Eavesdropping on traffic on a computer network. A smart attacker might pick up passwords, keys, and other insufficiently concealed secrets, particularly on local-area networks.
- Eavesdropping on computer systems and networks electronically via inadvertent electromagnetic radiation. Older cell phones are easy targets, and much electronic hardware provides radiation that can be picked up with antennas (Smulders, 1990). The U.S. embassy in Moscow long was a target of Soviet electronic eavesdropping.
- Social engineering (Mitnick, 2002), or manipulation of people to trick them into revealing secrets, passwords, and keys that are necessary to break into computer systems. Some classic methods are (a) calling an employee and claiming an emergency that requires their password and (b) doing favors for an employee and then suggesting reciprocation.
- Physical theft of a computer or its storage media. A stolen computer can give up its secrets rather easily.
- Physical damage to a computer or its storage media as a form of vandalism.

## COUNTERMEASURES AGAINST CYBER ATTACKS

Defenders of an information system can use a variety of countermeasures, depending on the kind of attack and their resources.

### Education

Employees of an organization must be aware of the kinds of attacks that can occur and what they should do about them. This includes learning proper operating procedures, the key attack targets (like passwords), and the classic attack methods. Some studies have shown education to be more effective than any other countermeasure for protecting information systems, since knowledge of information-systems security is not a requirement for most jobs.

## Legal Responses

Laws prohibit all the attacks we have mentioned, but do not do much to prevent them. In the United States, laws prohibit eavesdropping on communications and damage to computers, which covers most of the attacks we have mentioned, and many other countries have similar laws. But most attackers do not worry about getting caught, since it is hard to track them down, and laws are hard to apply. Laws, however, can be effective against repeat offenders within a given legal jurisdiction, like spies selling secrets.

## Patches

It is important to fix flaws or bugs in software as soon as they are discovered, since attacks typically are launched within days of the discovery of major flaws. Manufacturers provide patches, security updates, or service packs to fix flaws; they are in the form of modified software that a user must go to on a Web site to download. The Web site www.cert.org, among others, keeps a current listing of known flaws in important commercial software and their patches. Software that has been sold for a significant period of time generally requires fewer future patches, because programmers have had more time to find and fix its flaws, so buying just-released software products is not a good idea.

## Backups

Since many attacks destroy data or programs, making copies (backups) of digital information is essential to recovery from attack. Backups need to be done for any critical information and need to be stored some distance from the systems they track so no common disaster (e.g., fire, flood, earthquake) affecting both locations is likely. Optical-disk storage is preferable for backups, because it cannot be damaged as easily as magnetic media can be. A backup can be an entire duplicate computer system, when it is important to maintain continuous operation.

## Access Controls

Automated access controls are important for cyberspace (Pfleeger & Pfleeger, 2002). Access controls for computers generally are managed by passwords that must be supplied to log on and to use resources. Controls can be set for individuals or for groups of people, and they can apply separately to reading, writing, or execution of resources or to the ability to extend those privileges to other users. Access controls for networks are enforced by firewalls, dedicated computers on a local-area network that restrict traffic to and from the network according to simple rules on such features as origin and communications protocol. Unfortunately, access controls are vulnerable to many attacks already mentioned and generally will not protect against attacks by insiders like staff.

## Encryption

Encryption hides data in some form that cannot easily be read; the user then supplies a character-string key to decode it when he or she needs it (Pfleeger & Pfleeger, 2002). Any attempts to modify encrypted data will result in undecipherability, so the user can tell if encrypted messages or programs have been modified (or repeated, if a time is included in the message). Strong and virtually unbreakable methods of encryption have been developed recently with public-key cryptography. Software for it is available for free download from a number of Web sites. Encryption methods also can be used for authentication or to provide digital signatures on documents to prove who wrote them and when. Encryption has been touted as a solution to many security problems, but it is overrated. If an attacker gains system-administrator privileges, he or she may be able to get keys or to disable encryption methods without the user's knowledge.

## Intrusion Detection and Computer Forensics

Logging records the events on a computer system or network. This can generate enormous amounts of data, so intrusion-detection systems (IDSs) (Proctor, 2001) can be set up to check and record just the events that might indicate an attack and alert system administrators when matters become serious. IDSs can be located on individual computers (host-based) or on networks (network-based). They are important defensive tools against a broad range of known attacks including Trojan horses. Most look for signatures or bit patterns of known attacks, but a few look for anomalies or statistically suspicious behavior and, thus, can detect some new kinds of attacks. IDSs are useful but are not perfect, since attackers try hard to disguise their attacks. Other signature checking is provided by stand-alone virus and worm checkers like Norton AntiVirus, which examine files on a computer system.

For new or complex attacks, computer forensics is needed (Prosise & Mandia, 2001) as methods for inspecting computer storage after an attack to determine how the attack was accomplished and what damage it did. Forensics includes a wide variety of techniques and requires an intelligent investigator to use considerable judgment. Thus, it requires time and only can be done after the attacker is gone.

### Honeypots

Honeypots and honeynets (networks of honeypots) provide richer log information about cyber attacks (The Honeynet Project, 2004; Spitzner, 2003). These are systems with no legitimate purpose other than to receive attackers, so everyone using them other than their system administrator is inherently suspicious. Honeypots need not explicitly invite attackers—once they are on the Internet, attackers can find them with automated tools. However, they can be dangerous if attackers use them as springboards to attack other sites. For this reason, reverse firewalls of various kinds must keep the attack from spreading. But an attacker may infer the existence of the honeypot from the restrictions of the reverse firewall, so a honeypot cannot remain effective forever.

### Intrusion Prevention Systems

Most of the methods discussed so far just react to attacks. The alternative is an active network defense, which in its simpler forms is called an intrusion-prevention system. This includes simple things like turning off the Internet connection or logging out a user when they become sufficiently suspicious, as judged by an intrusion-detection system. It also can include forms of limiting damage such as denying the user certain resources, downgrading the user's priority, or delaying the user.

### Backtracing

Backtracing is a form of active network defense that tries to find where an external attack is coming from in order to stop it more easily. Unfortunately, most Internet protocols do not make it easy to backtrace, since a key idea of the Internet is to make only local decisions about routing traffic. Backtracing is also virtually impossible with serious attackers, who take care to come in via a long sequence of sites through many countries and jurisdictions. It is difficult to get the cooperation of all of those jurisdictions, and the attacker will be long gone by the time anyone succeeds in tracing him or her. One hope for backtracing is that when you suspect who is responsible for attacks, you will be able to get a court order to monitor the machines the suspect uses in order to collect evidence. Another idea is to install modified networking software in Internet routers that would collect details of messages. Assuming this does not violate privacy laws, such modified software could be mandated for all government computers. But it is easy for attackers to go through at least a few sites outside the government, thereby terminating backtracing there.

### Counterattacking

A more irresponsible form of active network defense is trying to counterattack whatever machine is attacking you. This became available in a product from Symbiot Security in 2004 and undoubtedly has been done elsewhere. Again, this won't work against insiders. Since most serious attacks use intermediate machines to attack yours, such a response often only will hurt a site or a computer that is an innocent bystander. Even if it works and if you do hurt the attacker, attacks easily could escalate with resultant collateral damage.

### Deception

Deliberate deception also has been proposed for active network defense (Rowe & Rothstein, 2004). Systems could lie, cheat, and mislead attackers to prevent them from achieving their goals. Deception is particularly useful for time-critical, military-style attacks such as those by cyber terrorists or information-warfare experts, when just delaying an attack a while could buy time to find a more permanent defense. Deception has been used in honeypots (Cohen, 1999) to keep the attacker interested. Fake files can be put on a honeypot to make it look more like a normal machine, and fake sites can be programmed to respond like real network nodes. Deception is equally useful against insider and outsider attacks.

## FUTURE TRENDS

The lack of powerful general countermeasures means that attacks on computer systems and networks will continue to increase in the future. A shift in attackers from amateurs to professionals will continue as basic countermeasures become more effective at deterring amateurs. Among the countermeasures currently available, education, legal responses, backups, access controls, and honeypots will remain important in the future. But patches, encryption, intrusion detection, computer forensics, honeypots, simple active network defense, backtracing, and deception will increase in importance as technical details of their implementation are worked out. Despite their weaknesses, countermeasures do help to protect systems, since they have raised the necessary level of sophistication required by an attacker to succeed.

## CONCLUSION

Attacks on the software and data of computer systems and networks are increasing. Digital government is more

vulnerable to these attacks than other information systems because of its accessibility and the number of motivated attackers. While threats can be exaggerated (Ranum, 2004), it is essential that government systems anticipate threats and plan to respond to them, since relatively modest attacks could bring government to a halt for hours or days. Some of the countermeasures to protect systems involve purchase of software and hardware, some require institution of policies, and some involve new actions to be taken. No single countermeasure will suffice, but a wide range of countermeasures must be employed in a coordinated information-security strategy.

## KEY TERMS

**Computer Forensics:** Methods for analyzing what has happened after a computer has been broken into or attacked.

**Cyber Terrorism:** Terrorism applied to computer systems and networks, typically those related to critical infrastructure of a country or organization.

**Cyberwar:** Warfare applied to computer systems and networks.

**Denial of Service:** An attack on a computer system in which the system is so overwhelmed by useless processing that it cannot adequately serve legitimate users.

**Encryption:** The conversion of data to a form in which it cannot be read without supplying a key or decoding string.

**Firewall:** A computer that protects a local-area computer network by scanning for suspicious data or activity in its incoming or outgoing traffic.

**Hacker:** An amateur who breaks into computer systems primarily for the fun of it.

**Honeypot:** A computer system designed to encourage attacks in order to enable the study of attack methods.

**Information Security (Infosec):** Methods for protecting computer systems and networks from attack.

**Information Warfare:** Attacks on computer systems, networks, and data as a tactic of warfare.

**Privilege Escalation:** Surreptitiously obtaining system-administrator privileges on a computer system.

**Social Engineering:** Systematic manipulation of people for personal gain; a term particularly used for attacks on computer systems through manipulation of their users.

**Spyware:** A Trojan horse that relays information about user activities on a computer.

**Trojan Horse:** A computer program hidden within another and designed to change a computer system in some way in order to benefit an attacker.

**Virus:** A Trojan horse that reproduces itself repeatedly on a computer system, damaging the system.

**Worm:** An autonomous program designed to reproduce itself repeatedly on a computer system and thereby waste resources.

# Data Mining and Homeland Security

**Jeffrey W. Seifert**
*Congressional Research Service, USA*

## INTRODUCTION

A significant amount of attention appears to be focusing on how to better collect, analyze, and disseminate information. In doing so, technology is commonly and increasingly looked upon as both a tool, and, in some cases, a substitute, for human resources. One such technology that is playing a prominent role in homeland security initiatives is data mining. Similar to the concept of homeland security, while data mining is widely mentioned in a growing number of bills, laws, reports, and other policy documents, an agreed upon definition or conceptualization of data mining appears to be generally lacking within the policy community (Relyea, 2002). While data mining initiatives are usually purported to provide insightful, carefully constructed analysis, at various times data mining itself is alternatively described as a technology, a process, and/or a productivity tool. In other words, data mining, or factual data analysis, or predictive analytics, as it also is sometimes referred to, means different things to different people.

Regardless of which definition one prefers, a common theme is the ability to collect and combine, virtually if not physically, multiple data sources, for the purposes of analyzing the actions of individuals. In other words, there is an implicit belief in the power of information, suggesting a continuing trend in the growth of "dataveillance," or the monitoring and collection of the data trails left by a person's activities (Clarke, 1988). More importantly, it is clear that there are high expectations for data mining, or factual data analysis, being an effective tool.

Data mining is not a new technology but its use is growing significantly in both the private and public sectors. Industries such as banking, insurance, medicine, and retailing commonly use data mining to reduce costs, enhance research, and increase sales. In the public sector, data mining applications initially were used as a means to detect fraud and waste, but have grown to also be used for purposes such as measuring and improving program performance. While not completely without controversy, these types of data mining applications have gained greater acceptance. However, some national defense/homeland security data mining applications represent a significant expansion in the quantity and scope of data to be analyzed. Moreover, due to their security-related nature, the details of these initiatives (e.g., data sources, analytical techniques, access and retention practices, etc.) are usually less transparent.

## BACKGROUND

### What is Data Mining?

Data mining involves the use of sophisticated data analysis tools to discover previously unknown, valid patterns and relationships in large data sets (Adriaans & Zantinge, 1996). These tools can include statistical models, mathematical algorithms, and machine learning methods (algorithms that improve their performance automatically through experience, such as neural networks or decision trees). Consequently, data mining consists of more than collecting and managing data, it also includes analysis and prediction.

Data mining can be performed on data represented in quantitative, textual, or multimedia forms. Data mining applications can use a variety of parameters to examine the data. They include association (patterns where one event is connected to another event, such as purchasing a pen and purchasing paper), sequence or path analysis (patterns where one event leads to another event, such as the birth of a child and purchasing diapers), classification (identification of new patterns, such as coincidences between duct tape purchases and plastic sheeting purchases), clustering (finding and visually documenting groups of previously unknown facts, such as geographic location and brand preferences), and forecasting (discovering patterns from which one can make reasonable predictions regarding future activities, such as the prediction that people who join an athletic club may take exercise classes) (Han & Kamber, 2001; Taipale, 2003; Two Crows Corporation, 1999).

As an application, compared to other data analysis applications, such as structured queries (used in many commercial databases) or statistical analysis software, data mining represents a *difference of kind rather than degree*. Many simpler analytical tools utilize a verification-based approach, where the user develops a hypothesis and then tests the data to prove or disprove the hypothesis. For example, a user might hypothesize that a

customer who buys a hammer, will also buy a box of nails. The effectiveness of this approach can be limited by the creativity of the user to develop various hypotheses, as well as the structure of the software being used. In contrast, data mining utilizes a discovery approach, in which algorithms can be used to examine several multidimensional data relationships simultaneously, identifying those that are unique or frequently represented. For example, a hardware store may compare their customers' tool purchases with home ownership, type of automobile driven, age, occupation, income, and/or distance between residence and the store. As a result of its complex capabilities, two precursors are important for a successful data mining exercise; a clear formulation of the problem to be solved, and access to the relevant data (Makulowich, 1999).

Reflecting this conceptualization of data mining, some observers consider data mining to be just one step in a larger process known as knowledge discovery in databases (KDD). Other steps in the KDD process, in progressive order, include data cleaning, data integration, data selection, data transformation, *data mining*, pattern evaluation, and knowledge presentation (Han & Kamber, 2001).

A number of advances in technology and business processes have contributed to a growing interest in data mining in both the public and private sectors. Some of these changes include the growth of computer networks, which can be used to connect databases; the development of enhanced search-related techniques, such as neural networks and advanced algorithms; the spread of the client/server computing model, allowing users to access centralized data resources from the desktop; and an increased ability to combine data from disparate sources into a single searchable source (Adriaans & Zantinge, 1996).

In addition to these improved data management tools, the increased availability of information, and the decreasing costs of storing it, have also played a role. Over the past several years, there has been a rapid increase in the volume of information collected and stored, with some observers suggesting that the quantity of the world's data approximately doubles every year (Adriaans & Zantinge, 1996). At the same time, the costs of data storage have decreased significantly from dollars per megabyte to pennies per megabyte. Similarly, computing power has continued to double every 18-24 months, while the relative cost of computing power has continued to decrease.

Data mining has become increasingly common in both the public and private sectors. Organizations use data mining as a tool to survey customer information, reduce fraud and waste, and assist in medical research. However, the proliferation of data mining has raised some implementation and oversight issues as well. These include concerns about the quality of the data being analyzed, the interoperability of the databases and software between agencies, and potential infringements on privacy. Also, there are some concerns that the limitations of data mining are being overlooked as agencies work to capitalize on new means to collect data.

## Limitations of Data Mining

While data mining products can be very powerful tools, they are not self-sufficient applications. To be successful, data mining requires skilled technical and analytical specialists who can structure the analysis and interpret the output that is created. Consequently, the limitations of data mining are primarily data or personnel-related, rather than technology-related (Klosgen & Zytkow, 2002; Martinez-Solano, Giblin, & Walshe, 2005).

Although data mining can help reveal patterns and relationships, it does not tell the user the value or significance of these patterns. These types of determinations must be made by the user. Similarly, the validity of the patterns discovered is dependent on how they compare to real-world circumstances. For example, to assess the validity of a data mining application designed to identify potential terrorist suspects in a large pool of individuals, the user may test the model using data that includes information about known terrorists. However, while possibly re-affirming a particular profile, it does not necessarily mean that the application will identify a suspect whose behavior significantly deviates from the original model.

Another limitation of data mining is that, while it can identify connections between behaviors and/or variables, it does not necessarily identify a causal relationship. For example, an application may identify that a pattern of behavior, such as the propensity to purchase airline tickets just shortly before the flight is scheduled to depart, is related to characteristics such as income, level of education, and Internet use. However, that does not necessarily indicate that the ticket-purchasing behavior is caused by one or more of these variables. In fact, the individual's behavior could be affected by some additional variable(s), such as occupation (the need to make trips on short notice), family status (a sick relative needing care), or a hobby (taking advantage of last minute discounts to visit new destinations) (Two Crows Corporation, 1999).

## Data Mining Challenges

As data mining initiatives continue to evolve, there are several issues for the policy community to consider related to implementation and oversight. These issues include, but are not limited to, data quality, interoperability,

mission creep, and privacy. As with other aspects of data mining, while technological capabilities are important, other factors also influence the success of a project's outcome (Zeanah, 2004).

## Data Quality

Data quality is a multifaceted issue that represents one of the biggest challenges for data mining. Data quality refers to the accuracy and completeness of the data. The structure and consistency of the data being analyzed can also affect data quality. The presence of duplicate records, the lack of data standards, the timeliness of updates, and human error can significantly impact the effectiveness of the more complex data mining techniques, which are sensitive to subtle differences that may exist in the data. To improve data quality, it is sometimes necessary to "clean" the data, which can involve the removal of duplicate records, normalizing the values used to represent information in the database (e.g., ensuring that "no" is represented as a 0 throughout the database, and not sometimes as a 0, sometimes as an N, etc.), accounting for missing data points, removing unneeded data fields, identifying anomalous data points (e.g., an individual whose age is shown as 142 years), and standardizing data formats (e.g., changing dates so they all include MM/DD/YYYY) (Hernandez & Stolfo, 1998).

## Interoperability

Related to data quality is the issue of the interoperability of different databases and data mining software. Interoperability refers to the ability of a computer system and/or data to work with other systems or data using common standards or processes. Interoperability is a critical part of larger efforts to improve interagency collaboration and information sharing through e-government and homeland security initiatives. For data mining, interoperability of databases and software is important to enable the search and analysis of multiple databases simultaneously, and to help ensure the compatibility of data mining activities of different agencies. Data mining projects that are trying to take advantage of existing legacy databases, or that are initiating first-time collaborative efforts with other agencies or levels of government (e.g., police departments in different states), may experience interoperability problems. Similarly, as agencies move forward with the creation of new databases and information sharing efforts, they will need to address interoperability issues during their planning stages to better ensure the effectiveness of their data mining projects (Wang & Oppenheim, 2003).

## Mission Creep

Mission creep is one of the leading risks of data mining cited by civil libertarians, and represents how control over one's information can be a tenuous proposition (Markle Foundation, 2003). Mission creep refers to the use of data for purposes other than that for which the data was originally collected. This can occur regardless of whether the data was provided voluntarily by the individual or was collected through other means.

Efforts to fight terrorism can, at times, take on an acute sense of urgency. This urgency can create pressure on both data holders and officials who access the data. To leave an available resource unused may appear to some as being negligent. Data holders may feel obligated to make any information available that could be used to prevent a future attack or track a known terrorist. Similarly, government officials responsible for ensuring the safety of others may be pressured to use and/or combine existing databases to identify potential threats. Unlike physical searches, or the detention of individuals, accessing information for purposes other than originally intended may appear to be a victimless or harmless exercise. However, such information use can lead to unintended outcomes and produce misleading results.

One of the primary reasons for misleading results is inaccurate data. All data collection efforts suffer accuracy concerns to some degree. Ensuring the accuracy of information can require costly protocols that may not be cost effective if the data is not of inherently high economic value. In well-managed data mining projects, the original data collecting organization is likely to be aware of the data's limitations and account for these limitations accordingly. However, such awareness may not be communicated or heeded when data is used for other purposes. For example, the accuracy of information collected through a shopper's club card may suffer for a variety of reasons, including the lack of identity authentication when a card is issued, cashiers using their own cards for customers who do not have one, and/or customers who use multiple cards (Technology and Privacy Advisory Committee (TAPAC), 2004). For the purposes of marketing to consumers, the impact of these inaccuracies is negligible to the individual. If a government agency were to use that information to target individuals based on food purchases associated with particular religious observances though, an outcome based on inaccurate information could be, at the least, a waste of resources by the government agency, and an unpleasant experience for the misidentified individual. As the March 2004 Technology and Privacy Advisory Committee (TAPAC) report observes, the potential wide reuse of data suggests that concerns about mission creep can

extend beyond privacy to the protection of civil rights in the event that information is used for "targeting an individual solely on the basis of religion or expression, or using information in a way that would violate the (U.S.) constitutional guarantee against self-incrimination" (2004, p. 39).

## Privacy

As additional information sharing and data mining initiatives have been announced, increased attention has focused on the implications for privacy. Concerns about privacy focus both on actual projects proposed, as well as concerns about the potential for data mining applications to be expanded beyond their original purposes (mission creep). For example, some experts suggest that anti-terrorism data mining applications might also be useful for combating other types of crime as well (Clark, 2003). So far, there has been little consensus about how data mining should be carried out, with several competing points of view being debated. Some observers contend that tradeoffs may need to be made regarding privacy to ensure security. Other observers suggest that existing laws and regulations regarding privacy protections are adequate, and that these initiatives do not pose any threats to privacy. Still other observers argue that not enough is known about how data mining projects will be carried out, and that greater oversight is needed. There is also some disagreement over how privacy concerns should be addressed. Some observers suggest that technical solutions are adequate. In contrast, some privacy advocates argue in favor of creating clearer policies and exercising stronger oversight. As data mining efforts move forward, a variety of questions are raised, including, the degree to which government agencies should use and mix commercial data with government data, whether data sources are being used for purposes other than those for which they were originally designed, and the possible application of privacy laws to these initiatives (DeRosa, 2004).

# FUTURE TRENDS

Data mining is used for a variety of purposes in both the private and public sectors. Industries, such as banking, insurance, medicine, and retailing, commonly use data mining to reduce costs, enhance research, and increase sales. For example, the insurance and banking industries use data mining applications to detect fraud and assist in risk assessment (e.g., credit scoring). Using customer data collected over several years, companies can develop models that predict whether a customer is a good credit risk, or whether an accident claim may be fraudulent and should be investigated more closely (Fawcett & Provost, 2002). The medical community sometimes uses data mining to help predict the effectiveness of a procedure or medicine. Pharmaceutical firms use data mining of chemical compounds and genetic material to help guide research on new treatments for diseases. Retailers can use information collected through affinity programs (e.g., shoppers' club cards, frequent flyer points, contests) to assess the effectiveness of product selection and placement decisions, coupon offers, and which products are often purchased together. Companies, such as telephone service providers and music clubs, can use data mining to create a "churn analysis," to assess which customers are likely to remain as subscribers and which ones are likely to switch to a competitor (Dillon, 1998; Two Crows Corporation, 1999).

In the public sector, data mining applications were initially used as a means to detect fraud and waste, but they have grown also to be used for purposes such as measuring and improving program performance, analyzing scientific and research information, managing human resources, detecting criminal activities or patterns, and analyzing intelligence information. In a recent survey of U.S. government departments and agencies, 199 data mining initiatives being conducted by 52 agencies were identified. For example, the Government Accountability Office (formerly the General Accounting Office) has used data mining to identify prohibited purchases made through government purchasing programs or with government credit cards. The U.S. Mint uses data mining to reduce false positives and improve information security for its network monitoring activities. The Justice Department has been able to use data mining to assess crime patterns and adjust resource allotments accordingly. Similarly, the Department of Veterans Affairs has used data mining to help predict demographic changes in the constituency it serves so that it can better estimate its budgetary needs (General Accounting Office (GAO), 2003, 2004). It has been reported that data mining has helped the federal government recover millions of dollars in fraudulent Medicare payments. Another example is the Federal Aviation Administration, which uses data mining to review plane crash data to recognize common defects and recommend precautionary measures (Cahlink, 2000).

Most recently, though, data mining has been increasingly cited as an important tool for anti-terrorism efforts. Some observers suggest that data mining should be used as a means to identify terrorist activities, such as money transfers, by identifying unusual patterns of money flows, and communications, by charting and analyzing all of the contacts made by an individual. Likewise, data mining could be used to identify and track individual terrorists themselves, such as through travel and immigration

records. In the United States, three initiatives in particular highlight the role of data mining in homeland security initiatives, as well as some of the policy challenges they face. The initiatives include the now-discontinued Terrorism Information Awareness (TIA) program1 conducted by the Defense Advanced Research Projects Agency (DARPA), the Computer-Assisted Passenger Prescreening System II (CAPPS II) project (now canceled and replaced by Secure Flight), and the Multistate Anti-Terrorism Information Exchange (MATRIX) project being coordinated by the Florida Department of Law Enforcement (FDLE).

## CONCLUSION

While the policy community remains divided on the merits of specific data mining initiatives, there appear to be some signs of acceptance of the growing use of data mining, provided that appropriate protections are in place and enforced. As previously discussed, while technological capabilities are important, there are other implementation and oversight issues that can influence the success of a data mining project's outcome. The challenges of data quality, interoperability, mission creep, and privacy can all serve to undermine or misdirect data mining initiatives. Equally important to an initiative's success or failure is the cultivation of public awareness and support. The sereptious development of a data mining application aimed at the general population breeds mistrust, and is more likely to generate a vociferous backlash than an initiative that involves potential stakeholders. However, that is not to say that there should be complete transparency either. While transparency is a critical feature of democracy, there are legitimate security reasons for not disclosing all of the technical and analytical aspects of a security-related data mining application. A balance must be struck between enabling openness and oversight, and adherence to the appropriate security protocols.

The discussion of data mining presented here provides merely a snapshot in time. As technology evolves, additional information becomes more accessible, and application demands continue to develop, it is likely that there will be a growth in government use data mining. Moreover, data mining will not be the sole province of national governments. Provincial and local governments, both individually and collaboratively, are likely to push ahead with data mining initiatives of their own in a much more diverse regulatory environment. Looking ahead, then, as more pools of data are collected, combined, and analyzed, one can anticipate that the potential privacy, accuracy, and security concerns will multiply. The larger question, though, is whether the potential benefits of this data mining (i.e., improved efficiency, reduced fraud, better-targeted services) will outweigh the potential costs (i.e., increased surveillance, embedded errors, exploitation of new pools of data)?

## KEY TERMS

**Dataveillance:** The systematic use of personal data systems in the investigation or monitoring of the actions or communications of one or more persons.

**Data Cleaning:** Process of fixing incomplete data, resolving inconsistencies, and removing "noisy data" (unwanted data) in a data set.

**Data Mining:** The use of sophisticated data analysis tools to discover previously unknown, valid patterns and relationships in large data sets.

**Data Warehouse:** A central repository of data from across the enterprise that is used for analytical applications, user inquiries, and/or strategic decision making.

**Interoperability:** The ability of different operating and software systems, applications, and services to communicate and exchange data in an accurate, effective, and consistent manner.

**Knowledge Discovery in Databases (KDD):** The most widely recognized definition, as written by Fayyad, Piatetsky-Shapiro, & Smyth (1996)—"the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data."

**Metadata:** Data about data. Data that describes important characteristics of data, such as the information contained, how it was collected, what format it is in, and other details that may be important to using the data.

**Mission Creep:** The use of data for purposes other than that for which the data was originally collected.

**Privacy:** The condition of being secluded from others.

## ENDNOTE

[1] This project was originally identified as the Total Information Awareness project until DARPA publicly renamed it the Terrorism Information Awareness project in May 2003.

# Deconstructing the South African Government's ICT for Development Discourse

D

**Sagren Moodley**
*Human Sciences Research Council, South Africa*

## INTRODUCTION

The post-apartheid South African government has placed ICTs at the centre of the national agenda for social and economic development (Mbeki, 1996, 2002b; Presidential National Commission on the Information Society and Development (PNC on ISAD), 2003a). The question of whether the application of technologies to improve information and communication access can increase the capabilities of disadvantaged and poor people is central to whether the new ICTs (particularly the Internet) will support or undermine real development. Technology appears in the South African government's ICT for development discourse as a politically neutral force with the power to develop, and without which people are classified as *information-poor*. As Wajcman (2002) cogently argues, "governments everywhere legitimate much of their policy in terms of a technological imperative" (p. 348). One effect of this discourse is to render poor people passive and dependent, as objects to be developed, rather than as active agents of development. Failure to address these assumptions may lead social scientists to become complacent in distracting attention away from the very *real* global economic, social, and cultural inequalities, to *virtual* inequalities, which merely hide an unwillingness to address the core failings of the development paradigm.

The paper attempts to meet the challenge put forth by Robert Wade (2002):

*The current campaign to promote the uptake of information and communication technologies (ICTs) in developing countries and to get aid donors to redirect their aid budgets needs devil's advocates to challenge what John Stuart Mill once called 'the deep slumber of a decided opinion.' (*p. 443)

## BACKGROUND

The real test of the success of ICTs in development efforts is whether they ultimately contribute to reducing poverty and inequality, thereby improving the lives and livelihoods of the poor. Two important questions emerge from the debate: (1) Who will have access to ICTs and the networks formed? and (2) Who will have control not only of the technology and its application, but of data gathered and processed, and of information exchanged via different modes?

The paper makes the following assumptions: (1) technology is *socially shaped*; and (2) the direction and nature of technological development does not necessarily follow some inevitable trajectory, but rather is a component of a complex, multi-dimensional system of social, cultural, political, and economic change. Further, the paper is premised on the belief that: (1) technology, in and of itself, is neither positive nor negative (Kranzberg, 1985), what Heidegger (1977) refers to as "the ambiguous essence of technology" (p. 33); and (2) the deployment of ICTs is the consequence of human choices which are themselves constrained and shaped by social context. Simply put, ICTs are context-dependent (i.e., they are contingent on uses and applications in particular contexts).

Developing at the end of the 19th century in an era of rapid capitalist industrial expansion and the rise of powerfully intrusive states, Touraine (1988) maintains that the social sciences have been overly preoccupied with positivistic explanation and unduly shaped by an emphasis on order and control. This has left little room for human agency and on the individual actor in social science theories. To regain relevance and validity in the social sciences, Touraine (1988) urges social scientists to become *participant-observers*.

The author has been a participant-observer in numerous government ICT forums (e.g., the Government Information Technology Officers' Council (GITOC), the knowledge and information management (KIM) sub-committee, the Universal Services Agency (U.S.), the Presidential National Commission on the Information Society and Development (PNC on ISAD), the Department of Communication's electronic commerce discussion process and various discussion colloquia on telecommunications, ICT convergence policy, etc). Collectively, these experiences have been a rich source of data gathering for the paper. By operating as a reflexive critic and a participant-observer, the researcher is well positioned to question the highly problematic set of assumptions underpin-

ning the South African government's ICT for development discourse.

## TECHNOLOGICAL DETERMINISM

The benefits of ICTs for the poor are seen as intuitively, self-evident, and universally valid by the South African government. It is clear that government has invested a great deal of faith in the power of ICTs to fast-track development (Matsepe-Casaburri, 2002a, 2003; Zuma, 2002). The optimistic view of government focuses heavily on technology potential rather than on adapting appropriate information systems to meet the real needs of poor communities in different environments. Further, this rose-tinted view of technology fails to adequately deal with the constraints for accessing and applying ICTs by the poor. What is urgently needed is a more integrated framework for understanding both information and ICTs in relation to poverty alleviation and development.

The optimistic view of the South African government needs to be tempered in the light of evidence showing that learning is a critical feature of technological change (Bell & Pavitt, 1993; Giuliani & Bell, 2005; Lall, 1992). Further, the importance of ICTs for addressing the real information needs of the poor has tended to be overstated and there is a danger of the policy debate becoming too strongly focused around the capabilities of emerging technologies.

It would appear as if government is underplaying the constraints that make it difficult for the poor to access, assess, and apply information through ICTs. These include lack of human capabilities (i.e., literacy, English language skills, and technical computer competence); urban/rural inequities; gender inequalities; affordability; and lack of relevant information content. Further, it takes time for people to comprehend the potential benefits of ICT-mediated information, or to be willing to trust information that does not derive from personal networks.

The information needs of poor households, communities, and small-scale enterprises should be understood in advance of proposing ICT-based solutions. Significant "financial opportunity costs" for poverty alleviation strategies are likely to arise, since large amounts of limited resources are being diverted to poorly conceived ICT-related investments that might not have a direct impact on the needs of the poor. There is also the risk that introducing digital information systems may supplant existing systems that may be more appropriate and more cost effective in terms of access and coverage. Moreover, over-emphasis on technological solutions can have the effect of drawing attention away from the underlying causes of poverty such as inadequate health and educational facilities.

As part of an integrated development strategy, ICTs can contribute to socio-economic development, but investments in ICTs alone are not sufficient for development to occur. ICT applications are not sufficient to address problems of rural access without adherence to principles of integrated rural development. Unless there is minimal infrastructure development in transport, education, health and social and cultural facilities, it is unlikely that investments from ICTs alone will enable rural areas to cross the threshold from poverty to growth.

Government has over-enthusiastically embraced the application of ICTs to address the pressing needs of the poor (Fraser-Molekete, 2002; Naidoo, 1998a-c). The major problem is that there is a widespread misunderstanding about how substantial benefits can be derived from ICTs for the poor. Persistent poverty, at both an individual and societal level, has deep and systemic roots. Chronic poverty, limited growth, and inequality are primarily the result of uneven access to material and financial resources.

The material deprivations of the poor are compounded by their lack of access to education, information, and knowledge; their lack of voice in the institutions and societal processes that shape their lives; and their inability to communicate effectively their needs, hopes, and expectations to those who have control over them. These deprivations are mirrored at the societal level by institutions and markets that function poorly, that are often unresponsive to the needs of the disadvantaged and disenfranchised, and that are all too frequently captured or are excessively influenced by economic, social, or cultural elites.

Government's discourse on ICTs for development is couched in the upbeat "we will all benefit from this" language (Mbeki, 1996, p. 1). There are times when it would seem as if government regards ICTs as the technical solution for poverty and underdevelopment (Mbeki, 2002a-b). The technological utopianism of government maintains that the digital world of the new ICTs holds the potential for breakthroughs in resolving the social problems of poverty and inequality in South Africa. The isolation of the poor can be ended and radical new approaches to poverty and social inequality can develop directly through the cyber-world (Ministry of Communications, 2001). The digital space holds potentials for conferring enormous economic benefits on society as a whole and its low-income segment in particular. It is for these reasons that government sees exclusion from the digital world as disastrous for those excluded.

There is a distinctive view in government that technology determines the nature of society (Matsepe-Casaburri,

2002b, 2003). ICTs have become idolised as a force that can "fix" the economy, raise the general standard of living and human well-being in the country, and deliver on poverty alleviation (Zuma, 2002). For government, the transfer of technology to poor communities is seen as unproblematic (Universal Service Agency (U.S.), 2002). It is not realised that such a transfer would depend not merely on technical elements, but on social and cultural factors as well. Technology is seen as neutral, not as an instrument for the creation of cultural and social orders. The understanding of technology, as part of a wider socio-economic system, is particularly important when the technology is adapted within environments very different from those for which it was originally intended (Schumacher, 1973). When technology is transferred from one society to another, it reflects the social values, institutional forms, and culture of the transferring country.

Since the outcomes of ICTs are open-ended, we have no reason to expect the emerging socio-technical system built around ICTs to remedy social inequalities in our society or to relieve the plight of the poor, any more than other major socio-technical changes have had such effects in the recent past. The three previous "communication revolutions," for example, have had significant impacts on society but failed to deliver the optimistic predictions first hoped for. The railway was believed to spark the *dictatorship of the proletariat*, the telegraph to engender world peace and the television to revolutionise education. It is highly unlikely then that ICT alone will end global poverty. In the long-term widespread adaptations to the new technological system will likely take place, just as broad social adaptations have been made to other socio-technological shifts (e.g., railways, automobiles, and electricity). But these adaptations are unlikely to remedy the fundamental, structurally based inequality between the poor and the well-to-do. Structural inequalities can be solved only by attacking them within the larger historical, cultural, and socio-economic matrix that generated them.

It would appear that the South African government is driven by a deterministic perspective on social development: technological innovations have a direct impact on social processes (PNC on ISAD, 2003a-b). This can be detected at all levels of discussion, both descriptive and predictive. There is no space for reflection on the myriad of complex ways in which technology and society are dialectically linked. The fact that technologies almost always have unintended and unplanned consequences is ignored. As much in its development as in its application and use, technology is intrinsically shaped by its economic, political and social environment (Williams & Edge, 1996).

There is a widespread approach in government that seems blinded by the "newness" and novelty of digital ICTs, and which, by emphasising the "revolutionary" character of the Internet and related technologies, tends to become (either deliberately or by negligence) ahistoric. To conceptualise technology and technological change outside of any social, economic, political, or cultural context can have several consequences. The first is that the approach becomes one of technological determinism, in which the technology is seen to act as an autonomous agent that has a direct effect on other social systems. Following MacKenzie (1984) and Winner (1993), Edge (1995) defines technological determinism as:

> *a belief…which holds that technical change is a prime cause of social change, and that technical innovations are themselves "*uncaused"*—in the sense that they arise only from the working out of an intrinsic, disembodied, impersonal 'logic', and not from any "social" influence.* (p. 4, emphasis in original)

Such accounts ignore the social shaping of technology and the fact that technologies and social life are interconnected (Groper, 1996; Schmidt, 2001). These approaches disregard the political, social, and cultural processes that necessarily accompany the development of any technological innovation, not least in the form of values, judgements and interests in operation that help structure Internet access and use (MacKenzie & Wajcman, 1999). Technological development comes to be seen as autonomous and self-generating. Technologies, however, are always situated within circuits of human action which provide their context and shape their direction.

## THE "SOCIAL SHAPING OF TECHNOLOGY" APPROACH

Edge (1995) critiques traditional approaches to the social analysis of technical change, emphasising the extent to which such approaches "imply a *technological determinism*, use a simplified *linear model* of the innovation process, tend to treat the technology as a 'black box,' and are preoccupied with the 'social impacts' of a largely predetermined technical 'trajectory'" (p. 14, emphasis in original). At a lecture entitled *The Question Concerning Technology*, delivered in 1955 in Germany, Martin Heidegger (1977) made the following prescient remark:

> *[W]e are delivered to [technology] in the worst possible way when we regard it as something neutral; for this conception of it, to which today we particularly like to do homage, makes us utterly blind to the essence of technology.* (p. 4)

That said, we should not replace technological determinism with social determinism. The view we subscribe to is that the "social" and the "technological" cannot be separated. New technology is as much a social product as the shape of society is a technological product. There is a constant interplay between "technology" and "society" (Loader, 1998; Lyon, 1988, p. viii).

The technical attributes of the new ICTs increasingly dominate explanations of contemporary change and development. There is a discernible tendency to understand or conceptualise these technologies in terms of technical properties and to construct the relation to the sociological world as one of applications and impacts. The challenge for social scientists is not so much to deny the weight of technology, but rather to develop analytic categories that allow us to capture the complex interweaving of technology and society.

It would appear that the "social shaping of technology" approach is beginning to take root in the social sciences (Klein & Kleinman, 2002; Kling, 2000; Pinch & Bijker, 1987; Rip, 1995; Sassen, 2002; Werle, 1998; Woolgar, 1991).

Following Heeks (2002), a reconceptualised "social shaping of technology" approach to ICTs is one which is:

- Centred on information rather than technology
- Integral to its environment
- Integrated with development objectives
- Indigenised

Such an approach potentially has the power to:

- Restore the agency of those rendered passive in the ICT for development arena
- Reorient technology to socially embedded, local uses
- Break down the binary of developed/underdeveloped, recognising poor people's knowledge and experience, and so opening up the possibility that "we" can learn from and with "them"

It cannot be assumed that the ICT-based information system will be beneficial or harmful without understanding the local social dynamics and how the technology will be used. This is especially the case since communities are complex and dynamic. ICT will be best used where it is embedded in existing social relations, and where it serves to extend the capacity of people to perform tasks they would wish to do, *even in the absence of ICT*. Moreover, from the literature on technology transfer (Archibugi & Michie, 1997; Archibugi & Pietrobelli, 2003), the role of local adaptive assimilation and learning is seen as key to successful implementation of technology in new settings. Learning, however, will not come about simply by local control of the technology. A level of technical competence and an understanding of the technology's potential are also required before local learning can take-off.

## CONCLUSION

The post-apartheid South African government has embraced the ideology that ICT represents modernisation; and it is seen as a key technology for alleviating poverty. The theoretical heritage of this perspective is linked to the modernisation school, which assumes that social change is unidirectional, progressive, and moves society from industrial (or pre-industrial in the case of least developed countries) to post-industrial with modern ICT as the engine. In much of government technicist rhetoric we find an implicit belief in an unproblematic causal progression from ICT innovations to social change (Fraser-Moleketi, 2002). Technological complexities, complex social processes, and independent human agency are not seriously considered.

It seems that the South African government is attracted to the neutral, instrumental view of technology, which is why it builds an increasingly central role for it in its vision of an "information society." Government has taken the technological configuration of the new ICTs as a "given" or prefigured system that needs to become more widely diffused to citizens. Hence, government rhetoric forecloses an assessment of the need for greater variety in the deployment of ICT configurations. The challenge, however, is to reorient this technology to socially embedded and locally-led development that affirms and makes use of the information, knowledge, and experience that poor people have.

There is clear evidence of technological determinism, which is steeped in a modernisation discourse arranged around political rhetoric and informed by a discursive power which rests on the universalisation of a particular, interpreted, theorised, and valorised regional (i.e., Western) experience. The imposition of policy legitimacy in terms of linking formalised systems of ideas with a recognised interpretation of a dominant Western experience formed within relations of power is set down in a hegemonic tradition (*pace* Gramsci, 1971) and widely accepted as proven and universally applicable.

By and large what emerges from a reading of government's ICT policy documents is a very optimistic view of the benefits to be harnessed from ICTs for poverty alleviation in South Africa.[1] This is surprising, given the recency of ICT developments and the paucity of solid empirical investigation of trends and impacts to date. Very little attention is paid to the costs, risks, and constraints that ICT diffusion is likely to entail. The fact that the poor face multiple barriers both to ICT utilisation and to ben-

efiting from that utilisation, since they have little to spend on communication; live in areas where the Internet is costly and complex to provide; have low rates of education and speak languages that are not very well represented on the World Wide Web, tends to be played down in policy debates. At best, this selective reading of ICTs for development oversimplifies a complex reality; at worst it is likely to result in wasted resources, poorly thought-out projects, and unrealistic expectations.

ICT for development programmes have a better chance of success if the poor are seen as autonomous agents of action and if they define a social process of change in terms of the growing role of independent autonomous action on the part of dominated groups. Such an exercise will, of necessity, entail a *self-analysis* that requires the active participation of social actors engaged in a collective struggle concerning political and social issues. It is imperative that we move away from the "heroic scenarios" and "intoxicating visions" (Bellamy & Taylor, 1998, p. 170) characterising much of government's discourse on ICTs for development, and attempt to re-conceptualise the complex and multi-layered relationship between ICT, poverty, and development.

Contrary to the South African government, the key to integrating ICTs in the fight against poverty, then, is not to begin with ICTs, nor to posit them as an essential need. Rather it is to determine the impediments to poverty alleviation and to reducing inequality in society and, thereafter, to ascertain the information, communication and knowledge components of these impediments. In the light of this, the task is to: (1) assess, on the basis of global experience, how ICTs, broadly deployed and properly adapted, could help address these impediments; and (2) to develop and implement a strategy for encouraging and supporting the deployment of ICTs, in support of, and subordinate to, a national poverty-reduction strategy.

Government needs to move away from analytical perspectives that are techno-centric and determinist, that focus on historical discontinuity (i.e., the "information revolution"), and that make unwarranted claims about the future impact of ICTs on the lives of the poor. Much more useful is the "social shaping of technology" approach, which puts the dynamic interaction between social forces and technological innovation into the forefront. This approach calls for proactive policy-making, since it stresses the imperative that *the technological solutions must be shaped to match the vision of a preferred future*. ICTs will not by themselves change existing institutional settings. The use of ICTs within the conventional social and institutional framework not only hampers these technologies full potential, but may also cause many frustrating social problems.

## KEY TERMS

**Dictatorship of the Proletariat:** In Marxist theory the dictatorship of the proletariat refers to the ideal of proletarian supremacy following the overthrow of capitalism and preceding the classless state.

**Discourses:** The public or outward expression of (usually) unstated or implied ideological positions. Discourses connote values and these values are often assumed to reflect general endorsement. It is characteristic of discourses that they occur as self-evident truths or facts and therefore act to occlude oppositional or resistant discourses.

**Information and Communication Technologies (ICTs):** Reflects the technological convergence between digital computing, telecommunications, and broadcasting. Whereas computers were largely focused on the processing of information, ICTs undertake *both* processing and communication of information.

**Information Revolution:** Underscores a notion of historical discontinuity. The emphasis on historical discontinuity runs the danger of underestimating the continuities involved in the process, as much in the technological innovations as such as in their adaptation in the economic, social, and political contexts. Further, the term "information revolution" tends to imply that the technological discontinuity goes hand in hand with a revolutionary discontinuity in social and political relations. The empirical evidence does not live up to the proclaimed epochal dimensions of change. This then raises the question of what should change, thus opening up a wide field for ideological preferences of all sorts.

**Information Society:** Though as a heuristic device, the term information society has some value in exploring features of the contemporary world, it is far too inexact to be acceptable as a definitive term. In fact, the further one moves from grand national ICT plans and from futuristic forecasts of conditions prevailing within the information society, and the nearer one gets to actual social analysis in which technology is not perceived as a quasi-autonomous force acting upon society, the more questionable the concept of an information society appears.

**Social Shaping of Technology:** Technical change is no longer seen as autonomous or external to society, but as influenced and shaped by its societal context. Technology is inflected by the values, cultures, power systems, and institutional orders within which it is embedded. Thus, the social shaping of technology approach serves as a needed corrective to technological determinism.

**Technological Convergence:** ICTs are based on a long list of technological innovations and evolutions that took place earlier. Effectively, ICTs are characterised by a complex process of technological convergence between microelectronics, telecommunications, computing, and broadcasting. Thus, there is no single historical moment that can be named as its starting point

**Technological Determinism:** The notion that technological development is autonomous of society; it shapes society, but is not reciprocally influenced. In more extreme varieties of technological determinism, the technology is seen as the most significant determinant of the nature of a society. The reality, of course, is that technologies do not, in practice, follow some predetermined course of development. Also, although technologies clearly have impacts, the nature of these is not built into the technology itself, but varies from one culture to another, depending on a broad range of social, political, and economic factors.

## ENDNOTE

[1] Government sees an array of positive developments emerging from the information society, with increased productivity and better quality employment, decentralised and increased access to politi-

cal decision-making and potential for e-government and e-commerce to improve the lives of the poor (Centre for Public Service Innovation [CPSI], Department of Public Service and Administration [DPSA] & The State Information Technology Agency [SITA], 2003).

# Design of Government Information for Access by Wireless Mobile Technology

**Mohamed Ally**
*Athabasca University, Canada*

## INTRODUCTION

As the world becomes mobile, the ability to access information on demand will give individuals a competitive advantage and make them more productive on the job and in their daily lives (Satyanarayanan, 1996). In the past, government information was presented by government employees who verbally communicated with citizens in order to meet their information needs. As print technology improved, government information was, and still is in many countries, communicated to citizens using paper as the medium of delivery. Because of the cost of printing and mailing printed documents and the difficulty of updating information in a timely manner, governments are moving to electronic delivery of information using the Web. Currently, governments provide digital service to their citizens using the Web for access by desktop or notebook computers; however, citizens of many countries are using mobile devices such as cell phones, tablet PCs, personal digital assistants, Web pads, and palmtop computers to access information from a variety of sources in order to conduct their everyday business and to communicate with each other. Also, wearable mobile devices are being used by some workers for remote computing and information access in order to allow multitasking on the job. It is predicted that there will be more mobile devices than desktop computers in the world in the near future (Schneiderman, 2002). The creation of digital government will allow the delivery of government information and services online through the Internet or other digital means using computing and mobile devices (LaVigne, 2002). Also, there will be more government-to-citizen and government-to-business interactions. Digital government will allow citizens, businesses, and the government to use electronic devices in order to communicate, to disseminate and gather information, to facilitate payments, and to carry out permitting in an online environment (Wyld, 2004). Digital government will allow citizens to access information anytime and anywhere using mobile and computing devices (Seifert & Relyea, 2004).

## BACKGROUND

According to O'Grady and O'Hare (2004), mobile computing will become the major computer usage model of the future. This will be possible since the digital divide is decreasing due to wireless access, increasing use of mobile devices, decreasing cost of Internet connections and computer technology, and transparent access of computer systems. Governments need to take advantage of technology-literate citizens and design and make available information for citizens to access government information digitally from anywhere and at anytime. This is important, since citizens expect the same level of service that is being given by businesses that are providing services and information anywhere and anytime (Dawes, Bloniarz, Connelly, Kelly, & Pardo, 1999). Users need just-in-time information for the job and in the community. The use of wireless mobile devices will facilitate access of government information from anywhere and at anytime. Also, computing is becoming ubiquitous, where citizens will work from anywhere and access government information from many networks using wireless mobile devices (Huber, 2004; Perry, O'Hara, Sellen, Brown, & Harper, 2001).

Before the use of mobile devices to access government information and design of information for mobile access are discussed, it is important to examine the information processing required when citizens access digital government information. Citizens acquire government information at many levels. At the lowest level, citizens may want to be aware of what is happening in government, so they will read the information in order to be informed. For example, some citizens may want to know the changes made to tax regulations. At the next level, citizens and businesses may want to access government to apply the information to complete everyday tasks. For example, some occupations require that businesses and citizens follow approved safety procedures when completing tasks. This requires comprehension and application of the information. At the highest level, citizens and businesses may want to critically analyze, synthesize, and evaluate

government information for research purposes. To achieve this, citizens will have to access government information from many sources through ubiquitous computing using mobile devices.

## USE OF MOBILE DEVICES TO ACCESS DIGITAL GOVERNMENT INFORMATION

There are many benefits to the use of mobile devices to access digital government information. According to a recent report by the European Commission (2004), digital government can provide better quality public service, reduce waiting time for information and service, lower administrative costs for businesses, and allow higher productivity for the public. Using mobile devices will allow citizens to access government information from anywhere and at anytime. With the use of wireless mobile technology, users do not have to be connected physically to networks in order to access information, and the mobile devices are small enough to be portable, which allows users to take the devices to any location to send and retrieve information. For example, a worker in the field who requires specific government regulations while completing a task can use a mobile device to access the information just in time. If government regulations in a field change, the government can update the digital information to allow individuals and businesses to access the current information immediately. In addition, a worker in the field can use a mobile device to contact a government employee remotely and to request specific information for immediate use.

Mobile devices have many benefits for accessing government information; however, there are some limitations of mobile devices of which designers of government digital information must be aware when designing information for delivery on mobile devices. Some of the limitations of mobile devices in delivering government information include the small screen size for output of the information and the small input devices for accessing the information (Ahonen, Joyce, Leino, & Turunen, 2003). Designers of information must be aware of these limitations when designing government digital information for access by mobile devices and must design for ease of use. Rather than scrolling for more information on the screen, users of mobile devices must be able to go directly to the information and move back and forth with ease. Information should be targeted to the users' requests when they need it and should be presented efficiently to maximize the display of the information on the mobile device screen. The interface of the mobile device must be appropriate for individual users and the software system should be able to customize the interface based on individual user's characteristics.

## Designing Government Digital Information for Mobile Devices

As the evolution of delivery medium of information changes, so does the strategy for processing the information. According to Grudin (2004), prior to writing and print, most information access and interaction were done by listening, memorizing, and speaking. With the print medium, information acquisition strategies were reading, analyzing, and writing. As government information becomes digital, acquisition strategies include searching, synthesizing, and constructing. Designers of government information for mobile devices must design for the new information acquisition and interaction strategies.

Most government information tends to be text-based, which takes longer for users to process and interpret. This is because past government information was designed for printing on paper for delivery to citizens. Designers of digital government information must use the capability of the computer to present information visually as well as textually in order to facilitate efficient processing and acquisition of the information. According to Paivio's (1986) theory of dual coding, information storage and retention is enhanced when information is represented both in verbal and visual forms. Presenting material in both textual and visual forms will involve more processing, which will result in better storage and integration of information in memory (Mayer, Fennell, Farmer, & Campbell, 2004).

In addition, because of the limited display capacity of mobile devices, government information must be designed for display using rich media such as audio, video, pictures, and graphics. Tabbers, Martens, and van Merrienboer (2004) found that for Web-based multimedia information, students who received visual cues to pictures scored higher on an information retention test compared to students who did not receive the cues for the pictures. According to cognitive psychology, information acquisition is an internal process, and the amount retained depends on the processing capacity of the user, the amount of effort expended while reading the information, the quality of the processing, and the user's existing knowledge structure (Ausubel, 1974). These have implications for how government information is designed for mobile devices. Designers must include strategies that allow the user to activate existing cognitive structure in order to conduct quality processing of the information. Mayer, Dow, and Mayer (2003) found that when a pedagogical agent was present on the screen as information was narrated to students, students who were able to ask

questions and receive feedback interactively performed better on a problem-solving transfer test compared to students who only received on-screen text with no narration. It appears that narration by an intelligent agent encouraged deep processing, which resulted in better information acquisition and higher-level information processing. This suggests that government should use audio to present government information to citizens.

## Guidelines for Designing Government Digital Information for Mobile Devices

### Chunk Information for Efficient Processing

Designers of government materials for mobile devices must use information presentation strategies to enable users to access and process the information efficiently because of the limited display capacity of mobile devices and the limited processing capacity of human working memory. Information should be organized or chunked in the form of information objects of appropriate and meaningful size to facilitate storage and processing in working memory (Ally, 2004).

### Adapt the Interface to the User

To compensate for the small screen size of the display of the mobile device, the interface of the mobile device must be designed properly (Ally, 2004). Mobile access to government information requires interface designs for multi-mobile device access and intelligent agents to adapt the interface to the user (Nylander, Bylund, & Boman, 2004). The interface can be graphical and should present limited information on the screen in order to prevent information overload in short-term memory. Users must be able to jump to related information without too much effort. The interface must allow the user to access the information with minimal effort and to move back to previous information with ease. For interaction sessions that are information-intense, the system must adjust the interface in order to prevent information overload. Some ways to prevent information overload include presenting less information on one screen or organizing the information in the form of graphical outlines to give the overall structure of the information and then presenting the details by linking to other screens with the details. The interface also must use good navigational strategies to allow users to move back and forth between information displays. Navigation also can be automatic, based on the intelligence gathered on the user's current position in the information and the information needs of the user.

### Design for Minimum Input to Retrieve and Access Information

Because of the small size of the input device on mobile devices, information access must be designed to require minimum input from users. Input can use pointing or voice input to minimize typing and writing. Because mobile devices allow access of information from anywhere at anytime, the device must have input and output options in order to prevent distractions when using the mobile devices. For example, if someone is using a mobile device in a remote location, it may be difficult to type on a keyboard or to use a pointing device when accessing government information. The mobile technology must allow the user to input data using voice input or touch screen.

### Target Government Information to the User

One of the variables that designers tend to ignore when they develop information for mobile devices is the user of the devices. Different users have different styles and characteristics, and some users may be more visual, while others may be verbal (Mayer & Massa, 2003). A graphic outline of the information can be presented before the details are presented in order to cater to users who prefer to get the big picture before they go to the details of the information. Government information must be designed with the user in mind to facilitate efficient access and processing.

Government systems must be smart and should have built-in intelligence in order to customize and target the information for individual citizens. Information must be personalized by selecting and aggregating information according to the user profile (Huber, 2004). Intelligent software systems can be built to develop an initial profile of the user based on current and previous interaction with the government information database and then present materials that will benefit the specific user, based on the user profile. As the intelligent agent interacts with the user, it learns about the user and adapts the format of the information, interface, and navigation pattern according to the user's style and needs.

### Use Visual Outline to Show the Structure of the Information

A visual outline can be used to show the main ideas in the information and the relationship between the ideas rather than to present information in a textual format. High-level visual outline can be used to represent information spatially so that users can see the main ideas and their

relationships (Novak, Gowin, & Johanse, 1983). Tusack (2004) suggests the use of site maps as the starting point of interaction to which users can link back in order to continue with the information.

## TRENDS IN USING MOBILE DEVICES FOR ACCESSING GOVERNMENT INFORMATION

The use of mobile devices with wireless technology allows access of government information from anywhere and at anytime and will dramatically alter the way that work is conducted (Gorlenko & Merrick, 2003). For example, mobile devices can make use of global positioning and satellite systems to send and receive government information digitally. There will be exponential growth in the use of mobile devices to access government information, since the cost of the devices will be lower than desktop computers and a user can access information from anywhere and at anytime. Also, the use of wireless mobile devices by businesses and organizations will be more economical, since it does not require the building of the infrastructure to wire buildings for employees and customers. The challenge for designers of government information for mobile devices is how to standardize the design for use by different types of mobile devices. Government information systems need to have agents to deliver the right information to the user. A profile agent can be used to learn about the user and then to interact with a presentation agent in order to customize and format the information to meet the user needs (O'Grady & O'Hare, 2004).

## CONCLUSION

Government information was designed for delivery on paper medium. Governments need to rethink and redesign information for delivery on mobile devices. Future development of information for mobile devices should concentrate on the user to drive the development and delivery (Gorlenko & Merrick, 2003). Mobile devices can be used to deliver government information to users, but the materials must be designed properly to compensate for the small screen of the devices and the limited processing and storage capacity of users working memory. Design principles for government information on mobile devices are the same as design principles for other applications such as education and training. The only difference is that government information tends to be one way, and there is less interaction with the information, since the purpose of most government information is to inform citizens. More research should be conducted on how to improve security and privacy of government information on mobile devices. Also, the type of information presented on mobile devices must match the needs and the styles of the users. Government information systems must use the power of computer technology in order to develop intelligent agents to customize the information for users and to provide context-sensitive information. According to Rist and Brandmeier (2002), more research is needed on how to flexibly translate government information from one medium into another format and how to decide which media combinations are most appropriate, considering a mobile user's style, current task, and situation. Finally, governments need to shift from print and desktop delivery of information to delivery on mobile devices in order to make the transition to becoming mobile government (m-government).

## KEY TERMS

**Concept Map:** A graphic outline that shows the main concepts in the information and the relationship between the concepts.

**E-Government:** The delivery of government information and services using electronic technologies.

**Information Object:** Digital information stored in chunks in a digital repository and tagged for retrieval to meet users' information needs.

**Intelligent Agent:** A computer application software that is proactive and capable of flexible autonomous action in order to meet its design objectives set out by the designer.

**Interface:** The components of the computer program that allow the user to interact with the information.

**Mobile Device:** A device that can be used to access information from anywhere and at anytime. The device consists of an input mechanism, processing capability, a storage medium, and a display mechanism.

**Pervasive Computing:** Use of computer devices to access information from interconnected networks using wireless technology.

**Ubiquitous Computing:** Computing technology that is invisible to the user because of wireless connectivity and transparent user interface.

**User:** An individual who interacts with a computer system to access information.

**Wearable Computing Devices:** Devices that are attached to the human body so that the hands are free to complete other tasks.

# Development and Use of the World Wide Web by U.S. Local Governments

**Carmine Scavo**
*East Carolina University, USA*

## INTRODUCTION

San Carlos, California (www.cityofsancarlos.org) claims to have developed one of the earliest local government Web sites in the world, posted on May 10, 1994 (San Carlos, 2006). From this early effort, United States (U.S.) cities moved rapidly onto the Web. Norris and Moon (2002), for example, report that some 4.4% of U.S. cities in a 2000 survey by the International City Management Association (ICMA) reported developing Web sites before 1995; 27.1% reported developing their Web sites in the 1995-'96 time period, and 68.5% reported their Web site developed after 1997. San Carlos' original Web site comprised one page; its current Web site now contains some 8,000 pages and uses some of the Web's most modern technology available, such as really simple syndication (RSS) and Flash Paper.[1] This article uses the example of San Carlos' Web site, along with two surveys of local government Web sites in the U.S., to illustrate the experience that U.S. local governments have had in developing and using Web sites in the pursuit of bettering governance. The article examines four local government Web applications—bulletin boards, promotions, service delivery and citizen input—and assesses their use by U.S. local governments. The article then addresses current issues of outsourcing Web site design and maintenance, and future issues of privacy, security, the digital divide and the possible effects of increased local government Web sites on U.S. civil society.

## BACKGROUND

Some idea of the expanse and number of city Web sites can be obtained by consulting one of several search engines to locate local government Web sites. One such engine, containing links to some 10,235 Web sites, is State and Local Government (www.statelocalgov.net). This site provides not only links to local government Web sites in the U.S. but also to national organizations that represent state and local governments (e.g., U.S. Council of Mayors) and a functional area listing of service Web sites for state and local government (economic development, tourism, etc.). Another such engine is Official City Sites (www.officialcitysites.org), which not only lists local governments (towns, cities, counties, etc.) in the U.S. but also in Australia, Canada, France, Germany, Japan, The Netherlands, New Zealand and the United Kingdom. The Official City Sites Web page is particularly attractive, with clickable stylized maps of the individual countries leading to individual maps or lists of sub-units within that country (states, provinces, etc.) and then to the local Web sites within those sub-units.[2]

## LOCAL GOVERNMENT WEB APPLICATIONS

In previous work (Scavo & Shi, 1999; Scavo, 2003), we identified four types of Web applications that local governments tended to use: bulletin board applications; promotion application; service delivery applications; and citizen input applications. Bulletin board applications involve the use of a Web site to provide information about the services, personnel, programs and so forth provided by a government agency. Promotion applications have to do with the provision of information about the area—population characteristics; climate data; tourist attractions; and so forth. Service delivery applications are much more interactive than the previous two; involving the use of the Web to do such things as apply for licenses, pay taxes and make appointments. Last, citizen input applications allow citizens to communicate directly with government officials and personnel and also with each other (Scavo, 2005).

The four applications demonstrate an increasing level of Web application sophistication—the base is bulletin board usage. Posting basic information on government was the original function of local government Web sites—at first, some of this information was simply posted; later, much of the information became clickable, meaning that clicking on the name of the mayor, for example, would open a dialog box that would allow the user to send an e-mail to or chat with the mayor. Promotion applications are only somewhat more sophisticated than bulletin board applications. With these latter applications, information is posted, as with bulletin boards, but the information has a somewhat different focus and audience. Service deliv-

ery and feedback applications are more sophisticated than the previous two, with feedback being even more specialized than service delivery. Both of these applications require more technically sophisticated Web sites which, in turn, require more highly trained Web site designers and maintenance people, faster servers and, most likely, a greater financial investment by the local government in Web site design and operation. Scavo and Shi (1999) found empirical support for this hierarchy of applications and concluded that it seemed likely that local governments would introduce themselves to the Web by developing bulletin boards and promotion applications and then move into service delivery and feedback applications.

Scavo (2003) found that while U.S. local governments had generally improved their Web sites across the four utilizations from 1998 through 2002, there was a great deal of random movement within this increase. The mean score for all local governments on the overall Web feature scale increased dramatically between 1998 and 2002, as did the scores (some much less dramatically) for the sub-scales for the four utilizations, indicating improvement. However, the across-time correlations for the four sub-scales were low, varying between 0.00 and +.25, indicating a great deal of random variation among the Web sites. And, five local governments that had Web sites (one county and four municipalities) in 1998 did not have them in 2002, indicating some retrenchment.

The four applications are of varying interest to constituencies inside the city or those outside the city; promotion utilizations being the most interesting to external constituents (who may be considering relocating to the given area and want to investigate weather, schools, transportation facilities, etc.), and service delivery applications are of the greatest interest to internal constituents, who have the largest stake in the services local government provides (see Table 1).

San Carlos' Web site demonstrates good use of the four utilizations described above. Sections of the city's main Web page address the bulletin board utilization (headlines, agendas and minutes, city newsletters, municipal code, news releases, job announcements, etc.), promotion (business guide, restaurant guide, schools, transportation, etc.), service delivery (garbage and recycling, guide to utility services, service requests and compliments, parcel and zoning information, permits by fax, etc.) and citizen input (forms on the Web, report traffic complaints, comment on development proposals, etc.). Users can click on any of the items and are directed to relevant Web pages for further information or contact.

In 2004, Brown University's Center for Public Policy surveyed federal, state and local government Web sites around the U.S. to examine the features that the Web sites provided. Some 1,873 Web sites in the 70 largest cities[3] in the U.S. were assessed for the types of features they offered to the user. The Brown study found that the most common types of services provided by these city Web sites were the renewal of library books and the payment of utility bills and parking tickets. Barriers to the increased use of Web sites to provide services were shown to be the inability to use credit cards and digital signatures on Web financial transactions. Only 14% of the Web sites allowed credit card use, while 6% allowed the use of digital signatures (West, 2004). These numbers, however, were a marked increase from those in the 2003 version of this survey.

## CURRENT ISSUES IN LOCAL GOVERNMENT WEB SITE DESIGN AND MANAGEMENT

The evolution in Web site design by local government across the four applications described above was a phenomenon of the 1990s that may not have survived the transition to the new century. In the early 1990s, Web site design was often something that local government IT professionals learned on the job; few if any academic programs existed that taught such skills. Even as late as 1998, some city Web sites were designed as university class projects. By the early 2000s, much of this tentative introduction to the Web had been abandoned and even cities' initial forays into Web site use were quite sophisticated. Part of the reason for this is the changing nature of local government Web site administration and management. In 1998, national or regional Web-hosting companies did not administer a single one of the Web sites surveyed; by 2002, those same-type companies administered some 8% of the Web sites. As city Web sites became more sophisticated (and more expensive to design and maintain) and it became increasingly more difficult to recruit and retain IT professionals, an increased number of cities began contracting out the design and mainte-

*Table 1. City Web utilizations by type of constituency*

| **External** | | Primarily | | |

nance of their Web sites to national or regional companies who specialize in such activities. A 2001 ICMA survey found that 80% of U.S. city managers queried reported outsourcing Web site hosting, while 64% reported outsourcing Web site design and/or Web site operations and management (Norris, Fletcher & Holden, 2001). Web hosting companies, such as ProjectA (www.projecta.com), NIC (www.nicusa.com), the Alpha Group (http://alphais.com) and egovt.net—now part of cboss (www.cboss government.com), have all aggressively moved into local government Web management and design. Scavo (2003) found, however, that outsourcing of Web design and maintenance was much more popular for small cities in the U.S. than it was for larger ones. As of 2002, local governments that maintained their own Web sites showed a mean population somewhat more than 300,000; those that used local organizations showed a mean population of slightly less than 150,000; and those that contracted out Web design and maintenance showed a mean population of just more than 40,000.

Early criticisms of outsourcing of Web site design and management stressed the need to retain the expertise in Web-related matters that might be lost if the services passed out of the hands of local government into those of contractors. In partial response to this, professional associations like ICMA have developed low-cost or free Web design software (e.g., GovOffice) that can be easily adapted to a variety of city Web design uses (www.govoffice.com). Additionally, various organizations that support local governments in the U.S. have sought to reduce the costs of building internal Web expertise by publishing online manuals and offering other free or low-cost resources on Web site design and management. Some of these relevant organizations and their Web sites are The Center for Technology in Government (www.ctg.albany.edu), Government Technology (www.govtech.net) and Public Technology Inc. (http://pti.nw.dc.us).

## FUTURE ISSUES IN LOCAL GOVERNMENT WEB SITE DESIGN AND MANAGEMENT

In recent years, one of the major issues surrounding Web usage has been the so-called digital divide—the difference in Internet and Web usage between relatively advantaged and disadvantaged groups in the population. While early differences in Internet and Web access usage between men and women, minorities and the majority, wealthy and poor, and even urban and rural dwellers have either narrowed greatly or largely disappeared, newer gaps persist. Several of the more pernicious problems that U.S. local government Web sites have yet to address are meeting the needs of users who are disabled, those who speak languages other than English and those with lowered literacy. The Brown study, for example, found that the cities they surveyed were not particularly successful in addressing these needs. Only some 21% of the Web sites surveyed passed the "Bobby" test (http://bobby.watchfire.com)[4], a widely used test of the accessibility of Web sites to the disabled, while only 17% of the Web sites provided some accommodation for non-English speakers.[5] And the mean grade level at which the Web sites were aimed was approximately 11.1, with some 71% of the Web sites aimed at the 12$^{th}$-grade level at a time when the typical American is reading at the 8$^{th}$-grade level (West, 2004). For all of these, however, there was a large degree of inter-city variation. Cities with the most accessible sites for the disabled were Cincinnati (95% of sites meeting the Bobby test) and San Diego (94%); those with the most accessible sites for non-English speakers were Houston (93%) and Kansas City (92%); while those with the most accessible sites for those with lowered literacy rates were Salt Lake City (mean grade level of 8.5) and Grand Rapids, Michigan (8.6).

Security and privacy are also issues that U.S. local government Web sites have shown varying degrees of success in addressing. For users to develop similar levels of trust in using the advanced features of service provision and feedback in local government Web sites as they have in the analogous features of business Web sites, local governments need to provide similar levels of security. Many users who would not give a second thought to ordering books online from Amazon.com hesitate when it comes to paying their local taxes online. Perhaps some of the reason for this has to do with the earlier evolution of e-business to e-government, but some of it may have to do with the lowered level of trust in U.S. government in general as opposed to business (Holzer, Meltiski, Rho, & Schwester, 2004). It is still odd, however, that users would, for example, input their credit card information into an e-business Web site with far more trust than they would input their voter information into an e-government Web site, when it would be far more troublesome to the user for the credit card information to be misused than it would be for the voter information to be misused.

Web site security has two different meanings—the first, discussed above, is the confidentiality of the information provided by the user to the Web site. The second, however, is the potential dangers in the information actually posted on the Web site. In the wake of the September 11, 2001 (9/11) terrorist attacks in the U.S., this second aspect of Web site security became a much greater issue in the U.S. than it had before. One immediate consequence of these attacks was a re-evaluation by many local governments about the openness of their

Web sites, especially the provision of large amounts of information to potential terrorists. Earlier efforts—commonly known as community right-to-know laws—required U.S. local governments to publicly list potentially harmful chemicals (these lists moved from paper listings to Web-based listings over time). These requirements were relaxed since, in some places, such information was thought to be too useful to potential terrorists. For many years, government Web sites were touted as ways to inexpensively increase the amount of information the public could access; in response to 9/11, even such openness advocates as Steve Aftergood, the director of the Federation of American Scientists' Project on Government Secrecy, rethought the organization's stand on how much information should be made available to the public. In late 2001, Aftergood said in an interview, "I have had to come to terms with the fact that government secrecy is not the worst thing in the world … There are worse things" (Toner, 2001, p. B4).

The managers of U.S. local government Web sites have also become much more cognizant of the sensitivities of user privacy. As more Web sites are being used to gather information on users, many U.S. cities have responded with elaborate privacy statements addressing the use of their Web sites. Several are indicative—Austin, Texas, for example, contains a 650-word policy statement that describes the types of information the site gathers on users (time of day of contact, day of week of contact, URL of site consulted before the city Web site, etc.), how that information is used (it will not be sold for commercial purposes but may be surrendered to law enforcement agencies requesting the information), the nature of the site's security routines, and that the site uses cookies. Austin's nearby neighbor, San Antonio, Texas, states in its privacy policy that it does not gather any personal information about users, except in the most general fashion—number of hits, for example. Other U.S. city sites take positions between these two, for example, certifying that they do not use cookies but that Web sites linked to the city Web site may indeed use cookies. Thus, there does not appear to be one standard for cities in terms of the types of information the sites gather about users, but there does appear to be an evolving standard that the user should be informed about what types of information is being gathered, how that information will be used and so on.

One additional future issue needs to be addressed—that of the type of local culture that increased use of Web-provided services may be creating. As more local government services are moved online, physical interactions between citizens and employees become less frequent. A result of this may be a lowered sense of empathy by citizens with local government employees. This tendency brings with it a larger question—can an Internet-based community replace a physical one? Will future citizens, whose predominant interactions with local government are on the Web, understand and appreciate physical problems and issues occurring in the communities in which they live? While there has been much speculation about the effect of Web-based interactions on civil society (Cain, 2001; Levine, 2002), there has been little empirical research on this issue; thus, this is a subject crying out for future research.

## CONCLUSION

This article has examined the development and use of Web sites by U.S. local governments. The article demonstrates that local governments in the U.S. have been and remain very active in the development and use of Web sites to deliver services, promote local government activities, communicate with citizens and so forth. However, while there is a great deal of activity, there could be more—local government use of Web sites has not yet attained the level that U.S. business, for example, makes of the Internet.

Beyond the question of resource availability, a good part of the reason for this lowered level of development in government Web sites in the U.S. has to do with low levels of trust in U.S. government in general. Internet users who trust e-business to maintain the confidentiality of electronic financial information might not trust local e-government to do the same with other forms of electronic information. But the causality may run both ways—U.S. local governments that inspire trust from their citizens may also have an easier time implementing advanced Web functionalities that those citizens will use, while local governments that inspire lower levels of trust would have a more difficult time. Local government Web usage does not arise nor does it function in a vacuum; it is part of local government culture. Where that culture features mutual trust, local government Web sites can develop into very sophisticated instruments of e-government. When the culture features mistrust, that development will be stilted.

## KEY TERMS

**Blog:** A Web log; basically, a diary posted on the Web available for users to access. Blogs can provide first-hand observations of events, reflections on current events and so forth.

**Bobby Test:** An online test of a Web site's accessibility to the disabled. The test reports the site's conformance with either the World Wide Web Consortium's (W3C) Web Content Accessibility Guidelines 1.0 or the U.S. Americans with Disabilities Act Section 508 Guidelines.

**Branding:** A marketing concept in which all pages on a Web site have a consistent, unique visual appearance, thus associating all of them with the agency or institution that sponsors the Web site.

**Cookies:** Short text files generated by a Web server and automatically stored in the user's computer for future access. Cookies store information about how the user has used the Web site in the past so that future use can be more customized. They can also store other personal information about the user; this information is transmitted to a relevant Web site when the user accesses that site.

**Digital Divide:** Differential Internet and Web access and usage by different groups—originally men and women or minorities and the majority; now rural and urban, non-native speakers and native speakers; disabled and non-disabled; and so forth.

**Flash Paper:** A program developed by Macromedia that allows documents to be formatted in a way that they can be easily transmitted to users over the Web.

**Really Simple Syndication (RSS):** A way of retrieving information on the Web where the user subscribes to a Web site or blog and information is delivered automatically to the user's e-mail address in conformance with the information supplied by the user in his or her subscription.

## ENDNOTES

1. A history of the evolution of San Carlos' Web site can be found at http://web.archive.org/web/*/http://www.ci.san-carlos.ca.us/.
2. Official City Sites has recently changed its Web site since it has come under the management of bigdaddydata.com. The new version of the Web site does not function in the same way as the old one, and the information stated in this paragraph may not be able to be retrieved.
3. The Web sites represented executive offices, legislative offices and major service delivery agencies, such as health, human services, police, fire, taxation, and so forth.
4. Oddly, the San Carlos Web site also does not pass the Bobby test. The site showed two Priority One Accessibility errors and six Priority One User Checks. A variety of Priority Two and Three errors also were reported for the Web site.
5. These accommodations ranged from providing text translations into commonly used second languages to routing a user to one of several Web translation services.

# Development Stages of Digital Government

D

**Janet Kaaya**
*University of California, Los Angeles, USA*

## INTRODUCTION

In recent years, a number of authors have reported studies on the emergence and development of digital government or e-government using various criteria (Forlano, 2004; Holliday, 2002; Kaaya, 2004; Layne & Lee, 2001; Netchaeva, 2002; Reddick, 2004; Silcock, 2001; Stowers, 1999, 2004; UN, 2001, 2002, 2004). From such studies, models have been proposed which indicate two to six stages of e-government development. Some of the models place emphasis on the structural features of government agencies in relation to electronic provision of services; others place emphasis on the nature and evolution of government Web sites and corresponding services. Still, a few models consider the evolution of the use of information technology (IT) to facilitate the undertakings of government tasks. However, with the exception of the latter, the consensus emerges from the models that the development of digital government entails an evolutionary process starting with the creation of simple government Web sites for publishing information on the functions of government agencies. These simple Web sites further develop into sophisticated portal designs which correspond with the services provided, along with the levels of transactions with the users. The majority of the countries of the world are implementing e-government strategies and various assessments have categorized countries according to their stages of development based on the existing models. Apart from the brief description of the models, this chapter will also give examples of the levels of development of e-government services in different regions and countries.

## E-GOVERNMENT DEVELOPMENT MODELS

Scholars examining the characteristics of e-government strategies under implementation by government agencies have devised various models of e-government development. For example, Layne and Lee (2001) conceive a four-stage growth model for e-government development using local, state, and federal governments in the United States as points of reference. They refer to the first stage as cataloguing in which the governments develop Web sites for presenting information about their respective functions and services. The second stage, called transaction, allows online transactions with citizens, such as renewing licenses and paying various fines. This stage is also associated with enhancement of online interfaces within the internal structures of governments. Layne and Lee refer the third stage as vertical integration, which they describe as "local, state, federal governments connected for different functions or services of government" (p. 123), and the fourth stage, horizontal integration, as "integration across different functions and services" such as "the business being able to pay its unemployment insurance to one state agency and its state business taxes to another state agency at the same time because systems in both agencies talk to each other or work from the same database" (p. 125). According to this model, each stage is associated with the types of functionalities involved along with the technological and organizational challenges facing government agencies that are implementing e-government strategies.

Silcock (2001) reports six stages that governments go through both in their delivery of services to the citizens electronically and in their own internal communication. These are (1) information publishing and dissemination involving creation of Web sites for posting information on government functions and services, basically a one-way communication; (2) official two-way transaction, such as replacing letter-writing or phone calls with e-mail exchange; (3) multi-purpose portals, whereby a single portal provides links to various government departments, allowing citizens to get the kinds services they need; (4) portal personalization, allowing citizens to incorporate online features as needed; (5) clustering of common services in which portal designs allow citizens to perform transactions with different departments from one point; and, (6) full integration and enterprise transformation of which Silcock says "old walls defining 'silos' of services have been torn down, and technology is integrated still further to bridge the shortened gap between front and back office" (p. 90). Thus, this is an advanced stage of the fifth stage.

In a related model, Netchaeva (2002) provides a description of five stages: the first stage involves the various departments forming online sites that carry information corresponding to departmental functions. In the second stage, the sites develop some degrees of

interactivity such as e-mail exchanges with ordinary citizens, while in the third stage, according to Netchaeva, "users are given the opportunity to take part in forums and opinion polls" (p. 408). The fourth stage involves various degrees of online transactions for provision of government services such as car registration, license renewals, and payment of fines. The fifth stage entails a comprehensive and unified government portal with a range of complex services to the citizens.

Stowers (1999, 2004) offers three stages of e-government services as virtual bulletin board, the Web reaching out, and 24/7 service delivery. Stowers further reports a four-stage model proposed by Sood as presence (i.e., presence of government information), interaction, transaction, and transformation; as well as another four-stage model posited by the New Jersey Center for Governmental Studies as static, interactive, transactional, and transformational (Stowers, 2004). Reddick (2004) provides a two-stage model of e-government growth in connection to municipalities in the United States. According to Reddick, the first stage involves cataloguing of information online and applies to the relationship of government to citizen, while the second stage involves the completion of transactions online and applies primarily to the relationship of government to business. The latter is associated with the cities that have advanced levels of e-government implementation. Heeks (2002), like many other authors, considers the growth of e-government as an evolutionary rather than revolutionary process; but unlike such authors, his discussion implies that the growth of e-government did not start with the creation of government Web sites. Moreover, he views it in terms of two models of technology use: an old model and a new model. In the old model, information technology (IT) is employed for automating the internal tasks of government to process data (and this goes back to the advent of computers in the government structures). In the new model, according to Heeks, information and communication technologies (ICTs) are employed to support the external tasks of government through data processing and communication.

While many scholars advocate e-government growth models that have evolutionary patterns, some of the authors have cautioned about generalizing such patterns. For instance, Yong and Koon (2003) contend that no single development model fits entire e-government implementation, while Accenture (2003) has described a pattern that depicts the maturity of e-government through a series of plateaus, namely, online presence, basic capability, service availability, mature delivery, and service transformation (but looking closely at the model, one can realize that it is evolutionary in nature).

Perhaps the most extensive studies to determine levels of e-government development and associated implementation features of almost all the countries of the world are those of the United Nations' Department of Economic and Social Affairs (DESA), Division for Public Administration and Development Management (Formerly the United Nation's Division for Public Economics and Public Administration, UN-DPEPA). which categorizes the development of e-government into five main stages: emerging, enhanced, interactive, transactional and networked or fully integrated (UN, 2002, 2004). In the first stage (emerging), a country becomes an e-government player by establishing modest Web sites owned by individual government agencies for posting government and contact information. In the second stage (enhanced), the government's Web presence expands to include more Web sites and features such as the links to other agencies, features for searching and e-mail addresses. In the third stage (interactive), more features are incorporated for interacting with the citizens, while the fourth stage (transactional) entails more comprehensive and secure features for various online transactions, including digital signatures and passwords. The fifth and last stage (networked or fully integrated) is envisioned for complete integration of a government's Web resources, for instant access to (or delivery of) all services irrespective of the department.

One can clearly note that most of the above models of e-government development are closely related; they just differ in the level of detail employed to address the research questions of the authors. Based on common features of such models Kaaya (2004) has summarized the various models presented above into four main stages, starting from simple to sophisticated and interactive Web sites (Table 1).

## ASSESSING COUNTRIES ACCORDING TO E-GOVERNMENT DEVELOPMENT

It is worth mentioning that the UN-DESA's model (hereafter referred to as the UN model), with its corresponding benchmarking of nations of the world, has attracted the attention of researchers in this relatively new area of study and has thus emerged as a sort of a standard development model. For instance, Forlano (2004) has discussed the UNDESA's five stages of e-government development and provided an analysis of the e-government services of selected countries that correspond with each stage. The countries presented in Forlano's study include Botswana (emerging stage); Vietnam (enhanced); China, Estonia, India and Malaysia (interactive); and Brazil, Singapore, Mexico and UK (transactional). Likewise, Martin and Byrne (2003), as well as Panagopoulos (2004), have discussed and provided summaries the of the UNDPEPA's findings, while Mutula (2002) has analyzed

*Table 1. Development stages of e-government services*

| Stage | Characteristics |
|---|---|
| Stage 1: Web site creation | • Setting up of Web sites to provide information about structure, functions and services of a government agency information publishing and dissemination<br>• There might be links to related Web sites |
| Stage 2: Initial two-way interaction | • The Web site includes downloadable forms that can be submitted off-line<br>• There can be a two-way interaction between government officials and users via e-mail. |
| Stage 3: Online transactions | • The Web site supports some formal online transactions such as renewing driving licenses and filing tax returns. |
| Stage 4: Comprehensive government portals | • Supports one-stop transactions without the need for dealing directly with different agencies.<br>• Web design sophistications include improved gateway points coupled with security features. |

*Table 2. Categories of e-government capacities and examples of representative countries or regions (UN, 2002)*

| E-government capacity & development stage | Representative countries |
|---|---|
| **High** (Stages 3/4 of Table 1; Stage 4 of UNDPEPA's model) | Most developed countries plus such countries as Singapore, S. Korea, Brazil, Chile, Uruguay |
| **Medium** (Mostly stages 2/3 of Table 1; Stage 3 of UNDPEPA's model) | Several eastern European countries, Egypt and Malaysia |
| **Minimal** (Mostly stage 2 of Table 1; stages 2/3 of UNDPEPA's model) | Some of the former Soviet republics, several Asian countries, Costa Rica, India, South Africa and Nigeria |
| **Deficient** (Mostly stages 1/2 of Table 1; stages 1/2 of UNDPEPA's model) | Most African countries |

them in the context of Africa's Web content, and Kaaya, (2004) assessed the e-government services of the three East African countries using various attributes and established that their levels of development correspond with the second stage of the UN's model.

In 2002, 32 countries were in the emerging stage, 65 countries enhanced, 55 countries interactive, 17 countries transactional, and no country had achieved the fully integrated stage. There has been a gradual progress in the levels of e-government development over time. In 2003, 33 countries provided online transactional services (the fourth stage in the UN model) while the figure for 2004 is 38 countries.

Along with the five stages of e-government development, UN-DESA has developed an index, the E-Government Index, which benchmarks all of the United Nation's member countries according to their progress in implementing e-government services. The UN-DESA uses a number of parameters to calculate the E-Government Index. These include a Web presence measure that indicates the stages of government Web sites, and telecommunication infrastructure measures that define the ICT's capacity of individual countries. The infrastructure indicators include the internet hosts per determined number of people; the percentage of the population that has online access; and the percentage of the population with personal computers, telephone lines, mobile phones, and televisions. The UNDESA also uses a human capital parameter to determine the E-Government Index. This parameter employs the United Nations Development Programme's Human Development Index, the Information Access Index, and Urban/Rural Population Ratio as indicators. From the figures derived from the E-Government Index, countries are categorized into four groups according to their e-government capacities: high e-government capacity, medium e-government capacity, minimal e-government capacity, deficient e-government capacity. Examples are shown in Table 2 (examples randomly selected from each group or region).

According to the UN's 2002 benchmark, the countries with top e-government environments are USA, Australia, New Zealand and Singapore; these were closely followed by Norway, Canada, UK, and The Netherlands. These are classified to have transactional Web presence

*Table 3. E-government indices of top ten and ten other selected countries (UN, 2002)*

| Country | E-Gov't Index | Country | E-Gov't Index |
|---|---|---|---|
| USA | 3.11 | Chile | 2.03 |
| Australia | 2.60 | Nigeria | 1.02 |
| New Zealand | 2.59 | Egypt | 1.73 |
| Singapore | 2.58 | Costa Rica | 1.42 |
| Norway | 2.55 | South Africa | 1.51 |
| Canada | 2.52 | Malaysia | 1.63 |
| UK | 2.52 | Uruguay | 2.03 |
| The Netherlands | 2.51 | Kenya | 0.90 |
| Denmark | 2.47 | Brazil | 2.24 |
| Germany | 2.46 | India | 1.29 |
| **Global average** | 1.62 | | |

*Table 4. E-government readiness indices of top ten and ten other selected (UN, 2004)*

| Country | E-Govt Readiness Index | Country | E-Govt Readiness Index |
|---|---|---|---|
| USA | 0.9132 | Jamaica | 0.4793 |
| Denmark | 0.9047 | Fiji | 0.3912 |
| UK | 0.8852 | Egypt | 0.2653 |
| Sweden | 0.8741 | Germany | 0.7873 |
| Republic of Korea | 0.8575 | Israel | 0.6805 |
| Australia | 0.8377 | New Zealand | 0.7811 |
| Canada | 0.8369 | Japan | 0.7260 |
| Singapore | 0.8340 | Mauritius | 0.5055 |
| Finland | 0.8239 | Chile | 0.6835 |
| Norway | 0.8178 | Kyrgyzstan | 0.4468 |
| **Global average** | **0.4130** | | |

and high e-government capacity. Table 3 shows the top ten e-government-environment countries according to the indexes, and ten other selected countries from different regions (i.e., the regions without representative countries in the top-ten list; this applied to other comparison tables).

Lately, UN-DESA has published the UN Global E-Government Readiness Report which "assesses the 191 Member States of the UN according to a composite index of e-government readiness based on Web site assessment, telecommunication infrastructure and human resource endowment" (UN, 2004, p. 18; The difference between the "e-government index" and the "e-government readiness index" is difficult to determine because the measures used to devise the indices are similar). However, the latter focuses on potential environments for e-government implementation. Over 50,000 features of government Web sites were assessed. Along with the e-readiness index, the report provides values of Web measure and e-participation indices. According to the UN, the distinction between the two indexes is that, "Whereas the Web measure index assesses the availability of information and services online, the e-participation index measures 'how useful' are these services and frequently they appear. In particular, the index attempts to qualify if these tools and materials are conducive to the online deliberative and participatory process between the government and the citizen" (p. 65). Top ten countries according to their e-government readiness index are shown in Table 4, while Table 5 and 6 show top e-participation and Web measure scorers respectively. The indices of ten other selected countries from different regions are shown for comparison.

*Table 5. E-participation index of top ten and ten other selected countries (UN, 2004)*

| Country | E-Particip. Index | Country | E-Particip. Index |
|---|---|---|---|
| U. K. | 1.0000 | Estonia | 0.639 |
| United States | 0.9344 | Colombia | 0.6230 |
| Canada | 0.9016 | Belgium | 0.6066 |
| Singapore | 0.8361 | Philippines | 0.3607 |
| Netherlands | 0.8033 | Turkey | 0.2951 |
| Mexico | 0.7705 | Pakistan | 0.1639 |
| New Zealand | 0.7705 | Mauritius | 0.1475 |
| S. Korea | 0.7705 | China | 0.0820 |
| Denmark | 0.7377 | Jamaica | 0.0492 |
| Australia | 0.6721 | Fiji | 0.0328 |

*Table 6. Web measure index of top ten and ten other selected (UN, 2004)*

| Country | Web measure Index | Country | Web measure Index |
|---|---|---|---|
| United States | 1.000 | Sweden | 0.772 |
| U. K. | 0.973 | New Zealand | 0.741 |
| Singapore | 0.969 | Japan | 0.629 |
| S. Korea | 0.946 | Chile | 0.884 |
| Denmark | 0.934 | Israel | 0.691 |
| Chile | 0.884 | Mauritius | 0.544 |
| Canada | 0.873 | Argentina | 0.643 |
| Australia | 0.830 | Jamaica | 0.409 |
| Finland | 0.807 | India | 0.568 |
| Germany | 0.795 | Estonia | 0.699 |

All the indices and other measures show the United States to be the top e-government—environment country (on only one index, e-participation index—which is derived qualitatively—the United States is second to the United Kingdom). Its e-government portal, Firstgov, is considered to be the most advanced in the world in terms of the technological aspects of e-government development and implementation strategies (Abramson & Means, 2001; CBO, 2002; Fletcher, 2004; Ho, 2002; Stratford & Stratford, 2000, UN 2004) coupled with top policy support strategies (Relyea, 2002; Relyea & Hogue, 2004). The UN reports that the Web site gets about 6 million visitors per month and is a gateway to over 180 million other (federal and state) government Web sites. Further, in terms of the UN's scores of the percentage utilization of stages of e-government, the United States scored 100% for stages 1-3, and 92.7% and 77.8% utilization of stages 4 and 5 respectively (UN, 2004), again making the U.S. the top country in achieving the advanced stages of e-government with an overall average of 94.5%. In other words, there remain only 5.5 percentage points for the U.S. to achieve fully integrated or networked (seamless) stage of e-government development. The U.S. government enacted the E-Government Act in 2002.

The UK government has also been instituting the "UK Online" campaign since 1999 (Bennett & Cirell, 2003; Devargas & Marshall, 2002; Grimshaw, 2003; Gunter, 2004; Ranger, 2002; Silcock, 2001) by challenging its public sector bodies "to modernise and achieve citizen-centred services—to integrate policies and programmes, to 'join-up' service delivery across departments and agencies, to harness the potential of information technology, to value the ideals of public service and get the best out of staff" (Silcock, p. 91). As a result, the UK has made great progress in implementing e-government strategies, and it is second to the U.S. in achieving the advanced stages of e-government development. Its scores in terms of percentage utilization of development stages is 100% (stage 1), 97.7% (stage 2), 94.0% (stage 3), 92.7% (stage 4) and 77.8% (stage 5), with an overall average of 92.0%. Together with the USA and UK, there are 16 countries in the world that are categorized within High Range scores

*Table 7. E-readiness of select countries (McConnell International, 2001)*

| Low E-Readiness | | | High E-Readiness |
|---|---|---|---|
| 1st Tier countries | 2nd Tier countries | 3rd Tier countries | 4th Tier countries |
| Turkmenistan, Turkey, Kazakhstan, Slovakia, Russia, Ecuador, Romania, Kenya, Poland | Bangladesh, Kuwait, Ghana, Ukraine, Czech Republic, Sri Lanka, Slovenia, Bolivia, Columbia, Senegal, Malaysia, Saudi Arabia, Lebanon, Bulgaria, Hungary | South Africa, Nigeria, Morocco, Pakistan, Costa Rica, Panama, Jamaica, Lithuania, Tanzania, Egypt, Philippines, Greece, Latvia, Thailand | India, Indonesia, Venezuela, Vietnam, Jordan, Argentina, Estonia, China, Taiwan, UAE, Peru, Mexico, Chile, Brazil, Korea |

by stages; the percentage utilization of high range category is 67-100%. The other categories are Mid Range (34-66% utilization) with 48 countries, and Low Range (0-33% utilization) which has 114 countries (see UN, 2004, for details). Thirteen member nations of the UN do not have a government Web presence. By region, North America is the most advanced region of e-government development followed by Europe while Africa is the least advanced and other regions are in the middle.

Other studies have assessed various countries to determine their status in their capacity to make use of ICTs for various activities including e-government services. For example, the McConnell International assessed e-readiness of 53 countries—excluding most western nations--defining "e-readiness" as "the capacity to participate in the networked world" (McConnell International, 2001). Accordingly, the main attributes of e-readiness were considered to be connectivity, e-leadership, information security, human capacity, and e-business climate. The study ranked those countries into four tiers from low e-readiness to high e-readiness (Table 7).

With some few exceptions (e.g., India, which appears to have minimal e-government capacity but with high e-readiness), these categories compare well with the UN's benchmarking results (Tables 2-6). Differences might be due to differences in assessment techniques (the UN used Web site and survey data while the McConnell International used a group of workshop participants representing the assessed countries).

## LOOKING FORWARD AND CONCLUSION

The majority of the countries of the world are implementing e-government strategies at different stages of development, ranging from advanced and sophisticated stages in developed countries to simple dissemination of government information in many developing countries. Investigating the development of e-government strategies is a relatively recent addition to the ever growing areas of research, and scholars in this area generally agree that the development of e-government is an evolutionary process. Various assessments of evolving e-government strategies have generated different but related models showing stages of e-government development, ranging from two to six stages. Why should there be different models? In this chapter, it was speculated that different models emanate from the scholars' places of emphasis (such as government structures and corresponding services, the nature of government Web sites, and the use of IT in the government systems irrespective of the existence of the Internet), as well as the research questions these scholars want to address. There are also various measures employed by different researchers to assess the performance of e-government strategies. There is, therefore, a need at this juncture for the scholars in this area to establish common criteria that can be used to determine the stages of e-government development together with the performance and subsequently the impact of e-government strategies. The model and measures developed by the UN's Department of Economic and Social Affairs (UN, 2002, 2004) is a promising start but there is a need for its methodological reports to be more explicit. Abramson and Means (2001, p. 14-15) have also suggested 13 steps to be followed when benchmarking Web-based service delivery as a policy and management tool.

The findings of the various studies (notably, e-government index/e-government readiness index, e-participation index, Web site scores, percentage utilization scores, etc.) have revealed that many countries have made great efforts in reaching out to their citizens through e-government implementation strategies. Only African countries are far behind in all of the measures reported. The findings are a wake up call for those countries that have not reached the advanced stages of e-government to face

the challenges of realizing potential benefits of implementing e-government strategies.

There are also joint efforts for e-government implementation through regional groupings such as the ASEAN countries (Holliday, 2002), but especially the EU countries, that seek to support their members in their endeavors to improve government performance through effective delivery of and access to government services by their citizens. Martin and Byrne (2004) have discussed the various public strategies for achieving the information society in the EU. The international and intergovernmental organizations such as the UN agencies and the World Bank are striving toward similar goals (see also the chapters on regional cases for more joint initiatives).

## KEY TERMS

**E-Government Index:** An indicator of the progress the UN member countries have made in implementing e-government strategies (uses almost the same measures as e-government readiness index).

**E-Government Readiness Index:** A quantitative composite measurement of the capacity and willingness of countries to use e-government for ICT-led development. Along with an assessment of the Web site development patterns in a country, the e-government readiness index incorporates the access characteristics, such as the infrastructure and educational levels, to reflect how a country is using the ICT opportunity for national, economic, social and cultural empowerment of its people (UN, 2004).

**Emerging Presence:** The first stage of e-government development in which a country becomes an e-government player by establishing modest Web sites owned by individual government agencies for posting government and contact information (UN Model).

**Enhanced Presence:** The second stage of e-government development whereby the Web presence in a country expands to include more Web sites and features such as the links to other agencies, features for searching and e-mail addresses (UN Model).

**E-Participation Index:** The e-participation index assesses the quality, relevance, usefulness and the willingness of government Web sites for providing online information and participatory tools and services to the people (UN, 2004).

**E-Readiness:** The capacity to participate in the networked world (McConnell International, 2001).

**Interactive Presence:** The third stage of e-government development whereby more features are incorporated for interacting with the citizens (UN Model).

**Percentage Utilization of Development Stages:** Indicates the extent to which a country makes use of each stage of e-government development.

**Seamless or Fully Integrated/Networked Presence:** The fifth and last stage of e-government development, providing complete integration of government's Web resources for instant access to all services irrespective of the department (UN Model).

**Transactional Presence:** The fourth stage of e-government development incorporating more comprehensive and secure features for various online transactions, including digital signatures and passwords (UN Model).

**Web Measure Index:** A composite index measuring features of government presence online.

# Different Types of Information Warfare

**Aki-Mauri Huhtinen**
*National Defence College, Finland*

## INTRODUCTION

Information warfare (IW) has recently become of increasing importance to the military, the intelligence community, and the business world. The purpose of many actors, like decision makers, military advisers, non-governmental actors, or business people, is to facilitate an understanding of information warfare with reference to both military and civilian life (e.g., Huhtinen & Rantapelkonen, 2002; Kaldor, 2001).

According to James Der Derian (2003), information warfare has become the umbrella concept for understanding cyberwar, hackerwar, netwar, virtual war, and other technological network-centric conflicts. Many of these concepts associate technology and digital equipment and refer to a specific kind of computer technology. But these concepts are also connected to the definition of conventional conflicts and warfare. The question of conflict or warfare is not only physical, but also a psychological issue. For example, the terrorist group would hit the automated teller machine systems (ATM) and steal the money of private people. The damage would be very small technically but the influence of psychological behaviour could have a long effect. The ATM systems work perfectly and safely after the damage has been done but people no longer want to use it because of bad rumours.

Military operation other than war (MOOTW) has a history that goes back at least as far as Sun Tzu, who considered defeating an enemy without violence to be the "acme of skill" in warfare. Asymmetric, non-linear model of war underline the capability of perception and fast influence. The idea of avoiding open linear contact with the enemy and trying to seize the initiative to strike is the revival of the art of war. (Der Derian 2003, p. 453) Information warfare is concept of information society conflicts and threats. Information warfare means the use of information or information technology during a time of crisis or conflict to achieve or promote specific objectives over a specific adversary or adversaries. Cyberwar is an assault on electronic communication networks.

"The POST-COLD WAR paradigm for U.S. forces in combat and in military operations other than war (MOOTW) is increasingly a nonlinear battlespace where brigades and battalions conduct independent operations in assigned sectors. In postcombat and peace-support operations, nonkinetic/nonlethal means are often the main effort. The new paradigm is changing the way the Army plans, coordinates, executes, and conducts information-operations (IO) and IO-effects assessment at brigade and below." (Tulak, Broome, & Bennett, 2005)

The action of information warfare is defined as information operation (IO). Information operation can be divided into offensive IO (e.g., computer network attack, command and control warfare, special information operations), civil affairs, public affairs (media warfare), and defensive IO (e.g., physical security, computer network defense, and counter propaganda) (Huhtinen & Rantapelkonen, 2002). Information superiority means the simultaneous joint operation with all aspects of information operation. For example, the lack of defensive IO aspect can put at risk offensive IO. Without civil affairs of public affairs capabilities there are risks at achieve success in offensive and defensive IO. Media is one of the most important parts of modern warfare.

## BACKGROUND

Information warfare is not a new phenomenon, but it has been there from the beginning of human society. The effectively of information warfare has drastically increased along the emerge of global information and cyber space. The theory of information warfare is based on the laws of physics, interaction of and within societies, principals, means, and tools that enables one to gain information superiority over opponent. Information warfare is waged both during peace and war. The base of information warfare is created with psychological warfare, deception, and operation security. (Huhtinen & Rantapelkonen, 2002)

Information warfare has two main types. The first one is psychological warfare like media war and perception management, which can also be called the "soft" part of information warfare. The second is net warfare like computer or electronic warfare. The goal of information warfare is information superiority and securing the information system from an enemy or target. Cyberwar as a type of information warfare can define the high-technological warfare in cyberspace and mainly with machine-based warfare. One example is satellite reconnaissance.

The information revolution mainly means digital technology is available to more and more common people. There are two main arguments. The first one is that the information revolution has extended economic and political freedom expanding the world's democratic core. The second one is that computer technology is primarily a supporter of conservatism in government. These two contradictory arguments have brought about significant changes in the conduct of warfare, giving the United States, with its lead in information technology, a great advantage in international relations. So-called "roughly stated" information technology can help those who master it to win large wars at long distances with small forces. Rogue states are likely to turn to asymmetric strategies, for instance, weapons of mass destruction, terrorism, and information operation attacks against the United States and its partners.

For example, in March 2003, we had the opportunity to follow the U.S. attack on Iraq in real time online and on television. "The shock and awe" strategy had been taken into use the one example of information operation. According to its creator Harlan Ullman, it was important that the United States take control of the observations made by the states belonging to the Axis of Evil (Iraq, Afghanistan, North Korea), create a fear of these states' vulnerability, and emphasize the superiority and invulnerability of the United States. A good metaphor is a room into which the Iraqis have been locked in while the United States turns the lights on and off according to its desires. The whole idea was achieved by information superiority goal (e.g., Franks 2004)

## INFORMATION SUPERIORITY AND PERCEPTION MANAGEMENT

The authorities, researchers, and intelligence workers are interesting in outer space, human brains, human imagination, and artificial intelligence (AI) (Baudrillard, 2002). Gilles Deleuze wrote how our reality changes towards the TV studio where we can be the audience, the producer, and the movie star at the same time. The world itself changes movies (Deleuze 1995, p. 72). In the book "*Imagewars. Beyond the Mask of Information Warfare,"* we argued that life is full of paradoxes. They are everywhere: in politics, business, science, and war (Huhtinen & Rantapelkonen, 2002, p. vii). Rantapelkonen interpret the concept of war machine according to the thinking of Paul Virilio and James Der Derian. In his article "The War Machine, Dromology and Iraq War II" Rantapelkonen sees that Der Derian's concept of "military-industrial-media-entertainment (MIME)" network is an extension of the concept of "revolution of military affairs" (RMA). This MIME network runs on videogame imagery, twenty-four hour news cycles, multiple nodes of military, corporate, university, and media power. It is like havens a dream-machine and a horror-machine in one (Rantapelkonen, 2005).

Contending that access to lack of information today is just as crucial as possession of petroleum and ammunition. For example, there are closed circles within information, electric current, and the computer. The pump of petroleum needs electric current and without a computer you cannot direct information you need to pumping petroleum. Without electric current you cannot use computers. The cyberthreat posed by "almost invisible computer assailants" to a nation's power grids, transportation networks, financial systems, and telephone exchanges. Media (e.g., TV and Internet) is the one of the most important parts of information warfare. Superpower states military exercises have involved actions that elevate information warfare from a tactical level to a strategic level. Information warfare involves a new kind of battlefield but with the potential for equally as many casualties. Information warfare does not have the same lethally as classical weapons, but it can be neutralize as lethally (Rampton & Stauberg, 2003).

We assume that in democratic countries the media are not easily controllable and cannot easily be used as an instrument of war. Artz emphasizes that global companies own and control the media that creates spectators and consumers rather than informed citizens. Economical, political, and cultural leadership act neither with unlimited power nor simply through manipulation, but rather with widespread consent arising from the "common sense" of everyday life that has been institutionally organized. (Artz, 2005, p. 9) False beliefs about everyday lives are more dangerous to people than terrorists or criminals. Artz argues that the media–government–popular culture model encourages "Western" countries to understand individual actions as they are institutionally and culturally played out in the daily lives of working people as citizens, students, and soldiers. More dramatically, this model posits that our contemporary culture of spectatorship grounds the legitimacy of government actions and "our way of life." (Artz, 2005, p. 10)

The so-called "militainment" of society has a long tradition in cooperation between media and government. Actors and artists have visited troops since World War I. For example, NATO has a special budget for what is called "morale and welfare activities." The aim is to make the audience familiar with the situation of soldiers training and going to battle, to make the viewers get involved in military thinking and behaviour, and to lose distance from weapons and the force of arms. (Thomas & Virchow, 2005, p. 29-32)

According to Jansen, in 2003, for example, the U.S. government spent $600 million on public diplomacy programs intended to enhance its image abroad; it spent an additional $100 million directly targeting the Middle East through the Middle East Partnership Initiative; and it spent $540 million on international broadcasting, Voice of America, Radio and TV Marti, Radio Free Europe/Radio Liberty, Radio Free Asia, Worldnet, Radio Farda, and Radio Sawa. These figures do not include funding for U.S. military and intelligence networks' resources dedicated to information warfare, including psychological operations and "counterinsurgency" campaigns (Jansen, 2005, p. 51).

In the information warfare, war is experienced through television, internet and newspapers as a real time representation that has a new kind of effect on media consumers. In information warfare, those who experience the war are an unspecified extensive audience that is not touched by time- and place-specific war. Every day we have to look at the theater of war, burning cars, destroyed homes, homeless people, and humiliated prisoners, even if we seem to have nothing whatsoever to do with the war. With sovereign power, the media presents pictures of and viewpoints on war without the audience having an opportunity to communicate.

Information warfare works for the private and restricted communication of authority and government. The other aspect of information warfare is the perception management of peoples' "open" communication networks. The mass media is not a neutral, fully autonomous subsystem of society; it is closely linked to both the political and economic systems. It opens a new world but at the same time it makes relatively everything. They shape public opinion and are shaped by external social interests. Mass media is a territory of propaganda warfare; they compete for steering public opinion into certain directions. (Fuchs, 2005, p. 206)

## THE CYBERSPACE AND CYBERWAR

Der Derian describes (Der Derian, 2003, p. 441) how the digital age came to enjoy a natural hegemony over other descriptors of modernity. When we speak the digital age, we speak the same time digital war, information warfare, or cyberwar. Cyberwar means that we focus on the threat and possibilities of space, information technology, and network. According to Derian, although the digital age might stretch in the United States from Silicon Valley to Alley and globally from Bangalore to Singapore, the distinguishing characteristic of the digital age is a spatio-temporal intensivity rather than a geopolitical extensivity. The digital age as a spatio-temporal intensivity means high frequency and density in area while a geopolitical extensivity means an enlargement of areas. The global networking of multimedia has become unstoppable. (Der Derian, 2003, p. 442-445). Multimedia is one form of information. Multimedia is a key source of our worldview, for example how we stand on war and violence. Security is not a fact but feeling. Terrorism is not a new threat but we think about it more and more thanks for media and news. "In times of terror," when everyone is something of a conspirator, everybody will be in a situation where he has to play detective. Der Derian speaks about "global heteropolar matrix," in which different actors are able to produce profound global effects through interconnectivity (Der Derian, 2003, p. 451).

The technologically network-based understanding has become increasingly important to common "Western" people but also to government officials and military decision makers. Of course, the technology and digital network-based culture is obviously the main target of terrorist groups. The western public audience creates its feelings of security through the global media and that is why terrorism has become so important role of western world in the new threat (Baudrillard, 2002; Borradori, 2003).

## THE FUTURE TRENDS

The military leadership is well aware of the value of all kinds of cultural and social activities. For example, computer games are of the most popular leisure activities in many countries, and war games have a significant share of the market. The ego-shooter *Operations*, which 1.2 million copies had been distributed for free, is not only game the U.S. Armed Force uses for recruitment. America's Army is downloadable from the Internet free of charge, but the track the progress a player makes in the career training that he or she has chosen (Thomas, 2005, p. 29-32).

One reason the information warfare expansible situation is that we have a strong technological understanding of warfare and the role of the warrior. Soldiers have increasingly lost their "warrior existence." In "instrumentalizing" war as much as it has, the West has reached a point at which it no longer understands the expressive element. Instead, it tends to dismiss it as "irrational," "evil," "barbaric," or "senseless." The trouble is that we have no way of understanding a totally different understanding of warfare, like terrorism. (Coker, 2002)

The trend that war has become computerized has slowly changed soldiers' physical relationship with their work. To an increasing extent soldiers no longer "physically" work, but sit in front of computers and keep an eye

on the battle with different icons. The enemy is an icon on the screen. Of course, on the ground, the common soldiers use traditional and conventional weapons and conventional vehicles. But there are too new elements like media and high technological command and control systems. The soldiers of the United States have been forced to do police duty in combat gear and they are being killed. In this police duty-system, soldiers' lives and the whole readiness of the armed forces have been placed at great risk (Sennett, 2003).

Information warfare relate to the traditional war can understand also how we use the word of war. The concept of war is also present in language and war is created by texts and pictures in media. Especially, the metaphors of the language of scientific and economic experts are old concepts of military strategy. Audiences have adjusted to the war against terrorism and its phenomena just as the people of earlier generations adjusted to the forms of warfare in their era. The concept of war also presents clear solutions to the social challenges of the culture of each era. The difficulties of diplomatic activity and the aimless problem solving of democracy are increasingly challenged by clear "win or lose" thinking. The alternative to peace is a viscous, endless process in which the quick model to quick thoughts offered by war receives more and more attention in western thinking. Its speed is supported by the information technological infrastructure.

## CONCLUSION

In this study, I try to describe different types or aspects of information warfare. The concept of information war is expanding from the traditional concept of war. Nowadays, there are wars against terrorism, independence wars, liberation and civil wars, justified wars, drug wars, preventive, economic, and oil wars. On the other hand, the Second World War and Cold War are outdated concepts for describing organized violence. As a newcomer in the field of concepts that describe war, terrorism inspires discussion for and against it. In background of all kind of wars there is the idea of network. When the world globalizes more and more and become depended on technology the concept of information warfare is useful to understand future threats and conflicts.

For example, the enemy in the information warfare will be mostly invisible and networked. Machines, computers, and "cyborgs" could play an important role in information warfare. Characteristic to the network is that it is loose and can be broken apart and put together again very quickly. Therefore, it is possible to get involved quickly, too. This way the organizational structure itself feeds a constant chase with no end in sight. Earlier the enemy was defined and static.

It is customary to network combat that power is concentrated without the concentration of power. Because of information systems both sides to a conflict can keep an eye on each other and it is almost impossible to evade electronic detectors. This is how power becomes concentrated without the concentration of power (Sennett, 2003, p. 55-56).

Video surveillance, electronic identity cards, and gated communities are the future that is already here. The information age leaves us to wonder whether we are on the inside or the outside of these new invisible boundaries. How would we know?

## KEY TERMS

All terms were obtained from http://www.wordreference.com/definition/cyberwar

**Asymmetric Strategies:** Characterized by asymmetry in the spatial arrangement or placement of parts or components.

**Cyberwar:** An assault on electronic communication networks.

**Cybernation:** The control of processes by computer.

**Cyberspace:** A computer network consisting of a worldwide network of computer networks that use the TCP/IP network protocols to facilitate data transmission and exchange.

**Information Operation (IO):** Information Operation can be divided into Offensive IO (e.g., computer network attack, command and control warfare, special information operations), civil affairs, public affairs (media warfare) and defensive IO (e.g., physical security, computer network defense, and counter propaganda).

**Information Warfare:** The use of information or information technology during a time of crisis or conflict to achieve or promote specific objectives over a specific adversary or adversaries; "not everyone agrees that information warfare is limited to the realm of traditional warfare."

**Interconnectivity:** Be interwoven or interconnected; "The bones are interconnected via the muscle."

**Military Operation Other Than War (MOOTW):** Has a history that goes back at least as far as Sun Tzu, who considered defeating an enemy without violence to be the "acme of skill" in warfare.

# The Digital Citizen

**Zizi Papacharissi**
*Temple University, USA*

## INTRODUCTION

The objective of this article is to sketch out the profile of the digital citizen. The premise for this article rests upon utopian views that embrace new media technologies as democratizers of postindustrial society (e.g., Bell, 1981; Johnson & Kaye, 1998; Kling, 1996; Negroponte, 1998; Rheingold, 1993) and cautionary criticism that questions the substantial impact new media could have on reviving a dormant public sphere (e.g., Bimber & Davis, 2003; Davis, 1999; Hill & Hughes, 1998; Jankowski & van Selm, 2000; Jones, 1997; Margolis & Resnick, 2000; Scheufele & Nisbet, 2002). Concurrently, declining participation in traditional forms of political involvement and growing public cynicism (e.g., Cappella & Jamieson, 1996, 1997; Fallows, 1996; Patterson, 1993, 1996) position the Internet and related technologies as vehicles through which political activity can be reinvented. Still, conflicting narratives on civic involvement, as articulated by the government, politicians, the media, and the public, create confusion about the place and role of the citizen in a digital age. The digital citizen profile, therefore, is defined by historical and cultural context, divided between expectation and skepticism regarding new media, and presents hope of resurrecting the public sphere and awakening a latent, postmodern political consciousness. This article outlines these conditions, reviews perceptions of the digital citizen, and proposes a digital citizen role model for the future.

## BACKGROUND

Any discussion of political consequence new media is preceded by discussion of the following four predominant and overlapping trends in civic participation, as presented in relevant research: (a) nostalgia for past forms of political engagement, articulated within public sphere rhetoric; (b) the aggregation of public opinion within representative democracy models; (c) the growth of public cynicism and disillusionment toward politics and the mass media; and (d) declining civic participation through formal channels of political involvement.

First, retrospective examinations of public engagement frequently evoke the ideal of the public sphere, as articulated by Habermas (1989), who viewed the public sphere as a domain of our social life in which public opinion could be formed out of rational public debate, leading to public agreement and decision making, thus epitomizing democratic tradition. According to this view, mass media have rendered these forms of democratic involvement in politics extinct. Critics of the Habermasian viewpoint argue that anarchy, individuality, and disagreement, rather than rational accord, lead to true democratic emancipation (Lyotard, 1984). They also find that Habermas's examples of past, romanticized public spheres excluded women and nonpropertied classes and propose a postindustrial model of coexisting public spheres or counterpublics, which form in response to their exclusion from the dominant sphere of debate (Fraser, 1992). These multiple public spheres, not equally powerful, articulate, or privileged, exist and give voice to collective identities and interests. Schudson's (1998) reviews of political activity reveal that the evidence a true ideal public ever existed is sparse, and that public discourse is not the soul of democracy, for it is seldom egalitarian, may be too large and amorphous, is rarely civil, and ultimately offers no magical solution to problems of democracy. Perhaps it is more meaningful to view the public sphere as an impossible ideal worth striving toward, rather than an extinct form of political interaction.

Second, congruent to the demise of the public sphere in modern society is the trend to aggregate public opinion. Several conditions associated with the postindustrial condition, especially mass society, urbanization, and the orientation of mass media have led government, politicians and the mass media to rely on aggregations of public opinion obtained through polls. This trend, which Herbst (1993) refers to as "numbered voices," exchanges the individuality, detail and authenticity of personal opinion on public affairs for a concentration of opinions that fit into predetermined question and answer sets reported in aggregation. The tendency to group and categorize public opinion, therefore, limits the opportunities and the scope of discussion on public affairs, as citizens are not called upon to deliberate, but merely to report agreement or disagreement with certain questions. This phenomenon compromises the depth of the public sphere and restricts civic involvement with public affairs.

Third, a parallel development of growing public cynicism and disillusionment with politics and the mass media

keeps citizens from becoming actively involved with public affairs. Research conducted on the effects of cynicism consistently reveals that cynical language employed by politicians and the media, as well as the tendency to focus on discussing/reported insider goings-on instead of important issues, leads skepticism about the impact political, media, and citizen action could have on improving public affairs (e.g., Cappella & Jamieson, 1996, 1997; Fallows, 1996; Patterson, 1993, 1996). As the prospect of civic participation influencing governance appears grim and as this skepticism is reinforced through negative or cynical coverage in the mass media, growing cynicism spreads in a spiraling manner (Cappella & Jamieson, 1996, 1997).

Fourth, all these trends are reflected in growing reluctance to participate in politics through formal or conventional channels of civic engagement, such as voting, community involvement, and volunteering. Despite the fact that the modern public sphere attempts to not draw distinctions based on gender, class, or race, the democratic model practiced in modern societies leaves little room for citizen involvement. Representative democracy, the prevalent mode of democracy at present, allows citizens to elect officials who deliberate and make decisions for them. Efficacy of governance in a mass society is thus secured, but public deliberation of civic affairs is compromised. Compounding forces place additional restrictions. Carey (1995), for instance, argued that the privatizing forces of capitalism have created a mass commercial culture that has replaced the public sphere. Putnam (1996) attributed the disappearance of civic America to the omnipresent television, suggesting that television occupies all time previously devoted to civic affairs and induces passive outlooks on life. Hart (1994) argued that some media, such as television, "supersaturate viewers with political information," and that as a result, "this tumult creates in viewers a sense of activity rather than genuine civic involvement" (p. 109). In the same vein, in a striking comparison of civic disengagement among over the past 30 years, Delli Carpini (2000) described young Americans as less trusting, less interested in politics or public affairs, less likely to feel a sense of obligation associated with citizenship, less knowledgeable about the substance and processes of politics, less likely to read a newspaper or watch the news, less likely to register to vote, less likely to participate in politics beyond voting, less likely to participate in similarly minded community organizations, and less likely to engage in traditional forms of civic engagement.

Within this context, new media are viewed as vehicles through which these conditions can be amended. For instance, the Internet could serve as a virtual sphere or revive the public sphere, provide a forum through which individual, not numbered, voices can be heard, host political discussion that focuses on issues and not strategy, and encourage deliberative or direct models of democracy. Digital media, including the Internet, set the state for a digital citizen to function, a stage in which several of shortcomings of past modes of civic participation can be overcome.

## THE DIGITAL CITIZEN

As an entity in modern society, the digital citizen is defined and reified through his/her use of digital media. This means that the digital citizen observes, monitors, and becomes involved in civic affairs through digital media and implies that the digital citizen can be both empowered and restricted through use of digital media. The Internet, the primary medium for this type of citizen, as it converges and sustains several operative digital technologies, becomes an asset or a detriment, depending on how it is put to use.

While the Internet and surrounding digital technologies provide a public space for the digital citizen to function, they do not necessarily provide a public sphere. The possibility of information access enabled by emerging media has not been associated with increase in political participation or civic engagement (Bimber, 2001), and has not been identified as a factor in reducing voter cynicism (Kaid, 2002). Moreover, entertainment uses of the Web tend to prevail over more informational ones, and do not generate substantial social capital (Althaus & Tewksbury, 2000; Shah, Kwak, & Holbert, 2001). A new public space is not synonymous with a new public sphere, in that a virtual space simply enhances discussion; a virtual sphere should enhance democracy.

As a virtual public and political space, the Internet is plagued by lack of universal access, discussion that sometimes unites and often divides further, and growing commercialization that threatens to marginalize alternatives uses of digital media. The advantages of the Internet as a public space can be enjoyed only by the select few who have access to it, thus harboring an illusion of an open public sphere (Pavlik, 1994; Williams, 1994; Williams & Pavlik, 1994). While digitally enabled (Abramson, Arterton, & Orren, 1988; Grossman, 1995; Jones, 1997; Rash, 1997), this citizen operates within an online sphere that reproduces the class, gender, and race inequalities of past public sphere incarnations (Hill & Hughes, 1988). Discussion online also bares the potential of connecting citizens or further emphasizing insurmountable differences (e.g., Mitra, 1997a, 1997b; Schmitz, 1997), and can suffer from the same conditions present in traditional media or forms of involvement. Specifically, digital citizens may express opinions online, and do so loudly, but

that does not necessarily result in discussion of greater substance or political impact (Jones, 1997; Poster, 1995; Schement & Curtis, 1997). Finally, the Internet is rapidly becoming more of an online shopping arcade and less of a deliberative space, which influences the orientation of digital political discussion. As a medium constructed within a capitalist context, it bears the architecture to resist commercialization but is also susceptible to it (McChesney, 1995; Newhagen & Rafaeli, 1996), thus unable to "produce political culture when it does not exist in society at large" (McChesney, 1995, p. 13). Not only is the content featured online not innovative enough or distinct from that feature in other mass media, but the sheer volume of information available online fails to capture the attention of the average citizen in the manner traditional mass media do (Bimber & Davis, 2003; Margolis, Resnick, & Tu, 1997; Scheufele & Nisbet, 2002). Moreover, the Internet as a mass medium is susceptible to the same type of control and commercial concerns that normalize the content of traditional media (Davis, 1999; Margolis & Resnick, 1997), thus reinforcing, rather than challenging the existing political culture (Margolis, Resnick, & Tu, 1997).

So, who is the digital citizen? A citizen enabled by technologies that carry both promise and bias, thus compromising the potential of the digital citizen. Moreover, this citizen also functions within a political system not equipped to sustain the direct democracy uses new media encourage. Within the prevalent mode of representative democracies, the free-flowing and robust online deliberation possesses no channel of being directed to governing officials. As Melucci (1994) argued, "the ceaseless flow of messages only acquires meaning through the code that order the flux and allow its meanings to be read" (p. 102). Similar research conducted by Jankowski and van Selm (2000) indicated that online discussions seemed to be dominated by elites and seldom extended to the off-line sphere of interaction.

And how does the digital citizen function within this compromised environment? On the one hand, the digital citizen is summoned by the power structure to enter the sphere of governance in limited ways that mimic traditional forms of civic engagement. Based on research accumulated by the Pew Internet and American Life Project, citizens are increasingly drawn to digital media, and attracted mostly to interest group and nonpartisan Web sites (Cornfield, Rainie, & Horrigan, 2003). Thus, the Internet does still bear some promise on attracting activity that challenges the mainstream flow of political information. Still, politicians and the media are limited in how they engage the digital citizen, in that they employ digital media mostly to conduct political research, enhance two-step flow communication with other media and opinion leaders, invite donations to political causes, and publicize news releases and endorsement (Cornfield, 2004). Digital citizens, on the other hand, express frustration at failing to locate the information they are seeking online, enjoy participating in online polls and circulating political jokes and cartoons, but are not drawn to conventional formats of political content online (such as news releases and endorsements) (Cornfield, Rainie, & Horrigan, 2003). Digital citizens still prefer Web sites of major media outlets or TV for information on public affairs over Internet-based news organizations (Kohut, 2003). These compounding orientations reveal that digital citizens enter virtual space seeking new forms of political involvement and to exert political influence. The prevalent political structure, on the other hand, is not equipped or reluctant to sustain such modes of deliberative, two-way communication.

Uses of digital media by politicians and the media that are one directional and do not sustain feedback channels for the digital public, present less meaningful, and thus less inviting ways for citizens to become politically involved. At the same time, it is substantive involvement that restores faith in the efficacy of civic involvement and challenges growing cynicism (Delli Carpini, 2000), leading to the conclusion that is not the quantity, but rather the quality of online involvement, that could potentially influence civic engagement. Recent research supports this assertion, indicating that it is generally the nature of online deliberation that tends to support medium uses that generate social capital, revive civic engagement, and could contribute to public sphere regeneration. For instance, recent research has shown that Internet users are aware of and expose themselves to a wider variety of arguments, including ones that challenge their own preferred candidates and positions, thus lending support to a public sphere that supports accord and dissention. Specifically, online users who attended or participated in Web deliberative groups possessed greater argument repertoire, a concept defined as "the relevant reasons that one has for one's own opinions and the relevant reasons that others with opposite opinions might have" (Cappella, Price, & Nir, 2002, p. 73). Similarly, additional research documents that, while Internet hard news use has a positive main effect on political activity, this influence is mediated by face-to-face and online political conversations (Hardy & Scheufele, 2005). The effect of the Internet, as an independent factor, is frequently moderated by past and present political habits that the individual sustains (Jennings & Zeitner, 2003), thus revealing a modest and integrative, rather than radical, impact for digital media upon the routines of the digital citizen. Raise awareness and participation, but not necessarily a sense of collective identity, that we could term the digital citizen.

## CONCLUSION

Therefore, the digital citizen is equipped, but not shaped by emerging digital media. Schudson's (1998) model of the monitorial citizen seems to fit the digital landscape well, in that he argues that in modern times, citizens are mischaracterized as inactive or uninformed and should be viewed as existing within and responding to the present historical context. According to Schudson (1998), monitorial citizens "scan (rather than read) the informational environment … so that they may be alerted on a variety of issues … and may be mobilized around those issues in a large variety of ways" (p. 310). Monitorial citizens are "defensive," rather than "proactive," surveying the political scene, looking "inactive, but [poised] for action if action is required" (p. 311). In the same vein, and adapted to the context of the Internet, Bimber's (1998) model of "accelerated pluralism" presents the environment within which the digital citizen functions, in which "the Internet contributes to the on-going fragmentation of the present system of interest-based group politics and a shift toward a more fluid, issue-based group politics with less institutional coherence" (p. 135).

The identity of the digital citizen is fluid and flexible, but also fragmented. Citizens are digitally enabled and digitally connected, but not part of a digital collective or cognizant of an identity that corresponds to a claim to digital citizenship. It is apparent that the digital citizen is no different from the off-line citizen; just technologically equipped. Confusion and redundancy, in terms of how politicians and the media view the digital public, discourage a collective digital consciousness. The digital citizen is hailed to enter the political sphere of interaction in ways that rely on one-way communication. While indeed digital media augment surveillance possibilities for the ordinary citizen, they do not necessarily provide channels through which substantive political action may be generated. Digital media do offer great promise regarding the role the citizen can play in the present political environment, yet this promise is restricted by the predisposition of the political system, which allots the citizen the role of the distant purveyor.

## KEY TERMS

**Citizen:** A person owing loyalty to and gaining sense of identity from belonging to a certain place.

**Civic Engagement:** Activity related to citizens and the affairs of citizens forming a public.

**Cynicism:** A general distrust for the motivation and efficacy of others' actions.

**Digital:** Expressed in numerical form, to be used in the design and application of technology.

**Digital Citizen:** A person deriving identity and loyalty from functioning within a digital space.

**Political Efficacy:** The power to generate an effect of civic substance and consequence.

**Public Opinion:** Publicly expressed judgment concerning the community or the people.

# Digital Divides and Grassroots-Based E-Government in Developing Countries

**Farhad Hossain**
*University of Manchester, UK*

## INTRODUCTION

Once properly managed, e-governance can add tremendous dynamism in reforming public administration and can change the mode of interaction between the state and its citizens. However, concerns regarding digital divides and the challenges of e-governance in the developing states of Africa, Asia, and Latin America are growing. If the factors contributing to digital divides are not carefully identified and properly solved, there is a growing risk that in the coming years digital resources might become the preserve of the "haves," while ignoring the plight of the "have-nots" as they seek access to resources in developing countries. The current Secretary General of the United Nations, Kofi Annan (2000) provided the insight that new information and communications technologies are bringing people together, and bringing decision-makers unprecedented new tools for development. At the same time, however, Mr. Annan added, the gap between information "haves" and "have-nots" is widening, and there is a real danger that the world's poor will be excluded from the emerging knowledge-based global economy.

E-governance in this article could be referred to as the use of digital devices, usually by public authorities, when dealing with their public, private and non-profit stakeholders. E-governance comprises a practice, process, or activities through digital means and could equally be practiced by different stakeholders in managing public affairs. While in contrast "e-government" is defined by Shafritz and Russel (2003) as conducting any aspect of government business operations over the Internet—from providing information by government to paying bills to the government. This article examines and analyzes the current status of emerging electronic and Web-based governance (e-governance) in developing countries. In doing so, the article outlines the market model, participatory state model, flexible government model, and the deregulated government model presented by Professor Guy Peters for reforming governance. In light of the above, the article brings forward the emerging issues of governance, e-governance, and the possibility of shared governance. Emerging e-governance is reshaping the process of administrative reforms in developing countries—which requires fresh academic research and a scholarly contribution.

## THEORETICAL BACKGROUND AND PRACTICAL CONCERNS

### Theoretical Background

In terms of technological efficiency and effectiveness, it seems that e-governance can be applied in developing countries. However, in practice, models of e-governance remain a paradox between myth and reality in most countries struggling to overcome their present-day developmental challenges. The emerging trend of e-governance in global development and the dynamic interplay of power and practices between the local, national, and transnational governmental agencies are real concerns in development management led by information and communication technology (ICT).

Professor Guy Peters (2001) brought valuable theoretical insights in the areas of changing states, governance, and the public sector. His work brings new perspectives into administrative reforms in developing and transitional countries where he presents the contesting scenarios of the following four models of governance. His scholarly work provides an important insight and the scope with which to understand the growing concerns of governance and to analyze e-governance in developing countries. His theoretical arguments are summarized below:

1. **Market Models:** Claim that private-sector methods are almost inherently superior for managing activities, when compared to those of the traditional public sector.
2. **Participatory State Model:** Is completely the ideological antithesis of the market approach and emphasizes the promotion of political, democratic, and collective mechanisms by laying emphasis on public participation.

3. **Flexible Government Model:** Emphasizes the capability of the government to respond effectively to new challenges and survive in the face of change.
4. **Deregulated Government Model:** Is built on the assumption that if some constraints on bureaucratic action were to be eliminated, government could perform its functions more effectively. The work provides directions for future reforms and changes in governance.

Probably the context of e-governance in developing countries is more suitable to the above private-sector led market models for reforming the government. The participatory state model is completely the ideological antithesis of the market approach and emphasizes the promotion of political, democratic, and collective mechanisms by promoting public participation. Due to various concerns with resource scarcity, low rates of literacy, and other disadvantaged human development indicators, e-governance cannot be easily promoted in developing countries. However, e-governance may result in increased attention being paid to the third alternative, the flexible government model—which emphasizes the capability of the government in responding effectively to new challenges and in surviving in the face of change. As a matter of fact, this is what most developing countries are doing with emerging Internet-based operations. And finally, Peters' deregulated government model also suits well the basic principles of e-governance in assuming that if some constraints on bureaucratic action are eliminated, government could perform its functions more effectively. Probably the context of e-governance is opening up a new theoretical horizon for shared governance, which Professor Peters (2001) did not address. However, the practical challenges of establishing e-governance in developing countries are many. The following section may help understanding of the context.

## The Practical Concerns

Initiating grassroots-based e-governance is not easy. Comparable indicators of the "networked world" are even more skewed than those in the "economic world." One may ask the question: how? Singh (2000) presents the scenario: at the turn of the millennium the richest 20% of the world's people accounted for 93.3% of Internet users, while the poorest 20% accounted for 0.2% of Internet users. While the Internet is, in theory, the great leveler, in practice, various divides are becoming accentuated. For example, South Asia, with 23% of the world's people, has less than 1% of Internet users. Though growing, however, on average African countries will not account for more than this percentage—if not less. While only 10% of the people worldwide speak English, almost 80% of all the Web sites are in English. There is a strong correlation between the spread of telephone lines, televisions, fax machines, personal computers, and Internet usage. More importantly, buying capacity has always remained the central question: what percentage of the people living in the developing world can afford new technologies? The fact of the matter is that by the end of the twentieth century more than 80% of the people in the world had never heard a dial tone.

Traditionally, a major obstacle for the effective performance of public bureaucracies in most developing countries is the excessive concentration of decision-making and authority within the central government. Decentralization within the state involves a transfer of authority to perform some service to the public from an individual or an agency in central government to some other individual or agency closer to the public to be served. However, in practice, the challenges to good governance through decentralization are numerous. In most developing countries, there has been a tendency of independent governments to prefer delegating power within the public services rather than through locally elected authorities. Also the capacity of local and regional authorities has remained generally weak. There has been much rhetoric about participation and local autonomy, but central governments have jealously guarded their power (see, e.g., Turner & Hulme, 1997). Similar findings have also been experienced by other researchers (e.g., Khan & Zafarullah, 1991; Seppälä, 2000) in their work on central and local governance. In general, governance has thus remained far from being referred to as "good." Therefore, one could easily judge how enthusiastic the central governments in developing countries would be to initiate effective e-governance, which might start to open up doors to real administrative decentralization.

Naturally, having considered the above scenarios, the establishment of e-governance in the developing world will sound "ambitious"—and a major, daunting task. However, in the era of electronic activities, e-governance is being initiated and certainly will move forward—even in the developing countries. In the meantime, if ICT possibilities are not given to the world's poor, the technological divides will grow even further and provoke legitimate concerns about "inclusiveness" and "exclusiveness" in systems of governance. In addition, the emerging e-governance will create opportunities for the "few" and ignore the plight of the "many." But will it lead scholars to re-think alternative definitions of good governance? It will, especially if the grassroots-based challenges of electronic governance are not taken care of in advance.

## CHALLENGES OF GRASSROOTS-BASED E-GOVERNANCE IN DEVELOPING COUNTRIES: OBSERVATION AND ANALYSIS OF SELECTED KEY ISSUES

Compared with the possibilities, the challenges in promoting e-governance in developing countries are many; they are summarized in this section. The relatively low rate of literacy in developing countries is one of the major challenges that e-governance is facing. Even literacy alone does not guarantee computer literacy, not to speak of fluency in English, which are often needed in order to gain access and use the basics of e-governance. Purchasing power is always connected to the socio-economic status of the individuals—that is, it must be asked if people with an average income can even buy a computer and bear the operational costs related to the computer and Internet services? Even though someone has got all the required skills, the necessary economic basis, and a computer, it still depends on the availability of the basic infrastructural support to actually gain access to the computer and the Internet. This means, for example, electricity, availability of Internet services, even in some cases telephones, and so forth. Purchasing power of the poor should not be difficult to guess. It can also be hard for a growing number of the poor in the present world to justify the use of a computer in their everyday lives as even the basic services (i.e., housing, healthcare, education, etc.) are not secured.

Very few scholars actually disagree with the assumption that the success of e-commerce cannot be equally expected in e-governance. E-led business or governance may produce good results at the micro-level, which may become inappropriate at the macro-level—since e-led operations often in the first place exclude the poor and disadvantaged. At the same time, the failure of the macro-level e-approach may have a direct effect on a large number of populations regionally or nationally. The legitimacy of government-provided information could very much depend on the good will of the party-in-power. As stated earlier in this article, 80% of Web resources are in English—while only a small proportion of people generally with a sound economic background in the developing world are proficient in English. It is important from citizens' perspective to ask: Who provides and maintains the Internet information? Is the information useful? What can citizens do with the information provided?

### Internet and Governance: An Overview

Today Internet-based operations constitute a huge information flow—some of it is useful, some is not, and much of it is simply advertisement. In order to shift governance into the computer-based world of operations, one has to be practical, since governance encompasses all citizens—from every walk of life, no matter who he or she is. The Web resources on e-governance in many countries are full of e-advertisements—like "meet our ministers," "the cabinet," "president's bio," and so forth. Access to classified information vs. non-classified information also creates a dilemma in the state-citizen relation. Classified information for some powerful people and nonclassified information for general citizens does not bring democracy into governance. The concept of "gate-keeping" in the flow of state information will result in e-colonialism. Technology can exclude people, but governance should not. As a matter of fact, the moral foundation of good governance is democracy and the inclusive nature of the state. The performance of governance should be measured not by the selection of technologies the state uses, but by the participation that the state promotes in its operations. This is indeed a matter for the dynamic interplay between ethics and economics.

## FUTURE TRENDS

E-governance can bring the central government closer to people by bypassing unnecessary bureaucratic interference by local authorities or oligarchic regimes. At the same time, local governance operations can be made more transparent by initiating e-governance. Today, people can share a lot of useful information with their governments around the world. Most importantly, citizens are enjoying direct access to useful information by bypassing bureaucrats and conventional and conservative bureaucratic systems. Inter-governmental relations are gradually becoming possible through online governance systems. E-governance is also creating awareness of the merits of the information society, computer literacy, and visual governance. It is also creating new jobs every day. Many citizens are enjoying job facilities by familiarizing themselves with some basics of electronic services. E-governance may make traditional bureaucracies more accountable—and citizens more responsible. A good example is computer-based tax administration. Electronic governance has got the potential for promoting electoral democracy—the recent success of effective election monitoring systems in developing countries is well known. Success stories of e-governance at the micro-level are numerous—and they range from the level of governmental relations to relations between public, private, and third sector organizations, as well as between private citizens. There is every reason to believe that the journey towards e-governance will continue in

the future, and developing countries will also gradually start reaping the benefits of this form of electronic governance. Therefore, strategic policies are needed in order to manage the transitional stages of present-day e-governance.

After considering the practical challenges, it is clear that before reaching any sustainable e-governance policies, most developing countries have to go through a transition and adopt a practice of e-governance at the micro-level before stepping into national or macro-level operations.

## SUITABILITY OF E-GOVERNANCE FOR TRANSNATIONAL AGENCIES, NGOs, AND COMMUNITY-BASED ORGANIZATIONS

One would agree that the concept of e-governance in the developing world did not come through indigenous means. Obviously the impetus really came through foreign aid agencies and local non-governmental organizations (NGOs) and community-based organizations connected to international governmental agencies, that is, the United Nations, the World Bank, OECD donor agencies and other transnational governmental agencies (see, e.g., Ferguson & Gupta, 2002). Certainly different private multinational companies are also involved in producing, manufacturing and supporting computer-based e-technologies in the developing world. It is believed that NGOs and community-based organizations have got a comparative advantage in development management (see, e.g., Anheier, 1990; Anheier & Seibel, 1990; Hulme, 1994; Hossain, 2001; Mälkiä & Hossain, 1998). Their comparative advantage is also applicable in developing e-governance. The restructuring policies of the World Bank and other influential donor institutions (e.g., in OECD countries) led to a planned reduction of the role of the state in developing countries and increased space for development NGOs (Tvedt, 1998).

The thorough and impressive analysis of Helmut Anheier (1990) on the comparative advantage of NGOs in developing countries can be referred to here. In his social, economic, political, and cultural arguments (see also Mälkiä & Hossain, 1998), one could easily understand the presented context of e-governance and the suitability of NGOs in promoting e-governance in developing countries.

The *social argument* comprises the idea that NGOs try to stimulate the participation of the poor and are able to reach those strata of disadvantaged Third World societies that are bypassed by public service delivery systems. This argument attaches greater social equity to private voluntary efforts than to the public sector. Because of shortages of public funds combined with cultural and social access problems, disadvantaged populations are difficult to reach by conventional service systems—a problem that is amplified by elite influences on governmental decision-making. Thus, NGOs are in a better position to reach the poor and the disadvantaged.

The *economic argument* claims that NGOs are able to carry out services more economically than governments. In addition, as they are not seeking to profit from their actions, they usually aim at self-reliance and self-sufficiency. Just as the social argument refers to equity, the economic argument addresses the greater efficiency of NGOs. Their efficiency could be a guarantee of their operational sustainability and credibility to the donors. Greater efficiency among NGOs is largely based on a major cost advantage, which is related to both lower labor costs and incomplete pricing, that is, not making provisions for depreciation, relying on voluntary local inputs, not including transaction costs, and so forth. Moreover, according to this type of argument, failures connected with NGO-led projects (as compared to failures with government-led ones) have much less impact on the economy as a whole, since nearly all NGO-led development projects are designed and implemented at the micro-level. Governments, on the other hand, are often working at the macro-level.

The *political argument* suggests that NGOs are relatively immune to changing political tides, while government policies and agencies are subject to unexpected change. An extension of the political argument refers to the "hidden agenda" and ultimately the political motivation of official development assistance if we consider aid as a political tool in global politics. By using NGOs as local and international operators, the problems with hidden agendas can be better dealt with. Thus, in general, NGOs are believed to be more "honest" and less guided by political considerations.

Finally, the *cultural argument* stipulates that NGOs, embedded in the local culture, are more sensitive to local needs and their articulation. Rather than replacing indigenous social structures with large-scale organizations, NGOs try to nurture local organizations within their own cultural context.

Stakeholders in recent years have experienced a real developmental concern with NGOs and the developing states in Africa, Asia, and Latin America. There are obvious reasons to believe that governments cannot implement sustainable e-governance alone. The market model, participatory state model, flexible government model, and the deregulated government model of governance developed by Professor Guy Peters (2001), which was presented and discussed at the beginning of this article, are also not equally suitable for the individual

governments alone to use in designing their e-governance strategies. Whereas the same models could be beneficial for the government agencies in designing their e-governance strategies while they work in partnership with NGOs and the private sector at local, national and international level. Therefore, involving NGOs and other community-based organizations in e-initiatives would always provide a strategic advantage.

## E-Governance Through Shared Governance?

In recent decades, governance has evolved to the extent that it is no longer in the domain of the public sector alone. Emerging concepts of "transnational governance" and "shared governance" pluralize traditional theories of public administration and give increased roles to a diverse group of stakeholders involved in governance in the developing countries (Ferguson & Gupta, 2002; Hossain, 2002; Nelson, 2000). This very concept of shared governance gives increasing roles to the private and third sector (e.g., civil society, NGOs) in development management (see, e.g., Tvedt, 1998). In this scenario of global governance, the dynamic interplay of power and politics between local, national, and transnational agencies provides contesting dimensions for local governance and administrative decentralization. At the same time this interplay also provides possibilities to these organizations to solve local problems with shared responsibilities. Though transnational agencies often challenge the traditional, legitimate, and naturalized authority of the state over the local and suggest new forms of "grassroots" governance, they can contribute to promoting e-governance together with local NGOs and community-based organizations. Indeed, the dimensions of e-governance mentioned above are reshaping the process of administrative reform in developing countries. Research attempting to empirically cover the context of e-governance and the dynamic interplay of power and politics between local, national, and transnational agencies can provide interesting and useful perspectives.

## CONCLUSION

The developmental challenges of the present world and the division between the rich and the poor also bring about an ethical perspective on the subject. An in-depth and empirical exploration is required to explain the current status, challenges, and the possibilities of people-centered grassroots-based e-governance in developing countries. Further exploratory and thorough research should be carried out on the contemporary factors of digital divides and the practical challenges of e-governance. As Kofi Annan (2000) emphasizes, information technology is not a magic formula that is going to solve all our problems. But it is a powerful force that can and must be harnessed to our global mission of peace and development. This is a matter of both ethics and economics.

Whatever the obstacles to e-governance might be, the local, national, and transnational stakeholders in development management must constantly promote and ensure citizen participation in e-governance by making use of various meaningful channels. In order to make e-governance sustainable, people living at the grassroots level in the developing world should be given the right to share their concerns with the local, national, and international governmental agencies. An individual poor person is an isolated island by himself and herself. Information technology can end that isolation overnight (Yunus, 2005). The poor of the world certainly should be an integral part of the emerging global information society.

## KEY TERMS

**Developing Countries:** Countries with underdeveloped and transitional economies.

**Digital Divides:** Refers to the division between electronic "information have societies or communities" and "information have-not societies or communities" among and within countries of the present world.

**E-Governance:** E-governance could be defined as the practice of using digital devices; usually the public authorities use them when dealing with their public, private and non-profit stakeholders. This comprises a practice, process, or activities through digital means and could equally be practiced by different stakeholders in managing public affairs.

**E-Government:** E-government refers to electronic and Web-based governance – e.g., conducting any aspect of government business operations over the Internet – from providing information by government to paying bills to the government (Shafritz & Russel, 2003).

**Governance:** Governance refers to modes of managing public institutions in terms of "effectiveness" and "legitimacy"; the essence of both may be judged on the basis of participation, the rule of law, transparency, and accountability (Ibrahim, 1997).

**Grassroots:** Local, community-based and citizen-oriented development intervention.

**NGOs:** Non-governmental organizations refers to non-profit oriented and society-based community development organizations.

# Digital Governance and Democratization in the Arab World

## INTRODUCTION

Making the choice to be an Internet society is not a process governed simply by a state's attitudes towards computers and the data that flows between them. Rather, being an Internet society means fostering the wide embrace of perspectives modeled on the technology itself. The basic components of designing an Internet society include a commitment to the free flow of information across and among hierarchies; a belief that it is best not to privilege any single information node; a realization that censorship is difficult if not futile; and a commitment to the idea that communities, companies and individuals have the right to represent themselves within electronic landscapes. All of these information attitudes have spill over effects in the real world. While constructing an Internet society is also about building information infrastructure and teaching people to use new tools, it is the clear spill over effects linked with the technology's design principles that have most developing countries proceeding with caution. For many countries around the world, especially (semi) authoritarian ones, no matter how strong the economic incentives for being an Internet society are, politically and socially, accepting such processes of change without selective state intervention is uncommon. Nowhere are these interventions more apparent than in the puzzling mosaic of Internet led development in the Arab World.

This article entertains a series of questions regarding emerging Internet societies in the Arab World:

1. To what degree is the Internet spreading in the Arab World and what factors are most commonly driving (or inhibiting) these processes of technological change?
2. In what way is the Internet contributing to processes of political change in the region? And how is the authoritarian state intervening to regulate Internet use in an attempt to control the spill over effects of such use?
3. What might be the longer term impacts of emergent Internet cultures in the region?

## BACKGROUND: INTERNET DIFFUSION IN THE ARAB WORLD

While the Internet has been evolving for the past five decades, it's presence as a part of everyday life in the Arab World is relatively new.1 The first connections to the Internet in the region date back to the early 1990s. For example, Tunisia was the first Arab country to link to the Internet (1991). Kuwait established Internet services in 1992 as a part of its reconstruction after the Iraqi invasion. In 1993, Egypt, Turkey, and the UAE established links to the Internet. Jordan linked to the Internet in 1994; while Syria and Saudi Arabia were the slowest states in the region to allow public access to the Internet—with regular access not available until the late 1990s. In Syria for example, even as late as 1997, there were only two places with Internet access—the American Cultural Center and the Syrian Engineers' Association, both located in Damascus. When Bashar Al-Assad, former president of the Syrian Engineers' Association and son of the late Hafiz al-Assad became president of Syria June 10, 2000, Internet access began to be more readily available. Before then, many Syrians were obtaining access via long distance phone calls to Internet service providers (ISP) in Lebanon and Jordan. These same practices of long distance remote access to the Internet (this time via Bahrain) was also common in Saudi Arabia, before the state made access to the Internet available through locally licensed ISPs. Thus when we study the development and meaning of the

*Table 1. Internet users by region 2004 (http://www.nua.com/surveys/how_many_online/index.html)*

| | |
|---|---|
| World Total | 605.60 Million |
| Africa (5 million in South Africa) | 6.31 Million |
| Asia/Pacific | 187.24 Million |
| Europe | 190.91 Million |
| Middle East (2.5 million in Israel) | 5.12 Million |
| Canada and USA | 182.67 Million |
| Latin America | 33.35 Million |

*Table 2. Internet users in the MENA region 2001 (Adapted from NUA How Many On-Line, http://www.nua.com/surveys/how_many_online/index.html)*

| Country | Number of Users | Percent of Population |
|---|---|---|
| Algeria | 180,000 | 0.57% |
| Bahrain | 140,200 | 21.36% |
| Egypt | 600,000 | 0.85% |
| Iran | 420,000 | 0.63% |

| Algeria | 3,000 |

Internet in the Arab World, we are really looking at a short, but rapidly changing history.

The general statistics are not encouraging with regards to information technology (IT) diffusion in the Arab World. The Arab World constitutes 4% of the world's population, yet it contains less than 0.1% of the world's Internet users. Moreover, world production in of Information and Communication Technology (ICT) equals 1.2 trillion dollars, while the Arab World's share of this economy is tiny. According to its population size, the Arab World's share of this global technology production should be 48 billion dollars; while in real terms, production of ICT in the region is only a fraction of this—Egypt: $418 million; Saudi: $642 million; Lebanon: $400 million (2000 estimates). One factor which weakens production in ICT is the underutilization of female knowledge capital in the region. For example, women equal 63% of university students in the Arab World, and yet women constitute only 30% or less of the labor force (Shalhoub, 2003, p. 3).

Internet use disaggregated by country reveals great regional disparities.

Connectivity in the region ranges from high Internet penetration in countries like the United Arab Emirates (nearly 40% of the population is online) to places like Sudan, where only 0.2% of the population are Internet users. One problem with connectivity measures is that a large portion of society in the region goes on line at an Internet café or community access point (such as Publinet centers in Tunisia and Knowledge Stations in Jordan)2. Current measures grossly underestimate the popularity of the Internet in everyday life by failing to capture users not tied to a particular Internet protocol (IP) address or ISP. Perhaps it is not by accident, that there is a strong correlation between the number of Internet cafes within a country and low connectivity figures by conventional measures.

Thus, in Algeria there is an estimated 0.57% Internet penetration, judged by the number of Internet accounts, but a high availability of Internet cafes, an estimated 9.52 cafes per 100,000 inhabitants. Similarly, in Libya, where per capita Internet penetration is estimated to be 0.24%, there are an estimated 13.21 Internet cafes per 100,000 inhabitants. Given the difficulties in determining what percentage of the population has access to the Internet via Internet cafes, it is hard to judge the mass appeal of the Internet. If in places like Algeria and Morocco, there is enough public demand for the Internet to support two or three thousand Internet cafes, then the Internet must be more important than indicated by conventional estimates. The large number of Internet cafes in the MENA region suggests that the Internet may be more of a mass technology than currently documented (Wheeler, 2004a).

## Factors Shaping Internet Diffusion in the Arab World

There are at least nine factors which shape the diffusion and use of the Internet in the Arab World including:

1. Infrastructure
2. State

3. Education
4. Economy
5. Location
6. Gender
7. Age
8. Size
9. Public opinion and culture

Infrastructure determines who has easy access to Internet technologies, as well as the cost of access. For example, it is very common to find a mass base of Internet users in the capital cities of the Arab World, but less common to find active Internet users in rural locales or small villages where infrastructure is weak or non-existent. Recognizing the role that infrastructure plays in expanding Internet access, several countries in the region have invested in building community access points throughout their territory, even reaching places where market demand is low, and infrastructure had to be built from scratch. This is especially the case in Tunisia, Egypt, and Jordan (Hashem, 1999, 2000).

State support for Information Technology use is a vital factor in shaping regional Internet cultures. As evidenced in the case of Egypt, Morocco, Jordan, and Dubai, the willing support of the leadership structure for building and expanding an Internet society makes a huge difference in the cost and ease of access, the presence of Internet training and access in schools, the shape and scope of e-governance programs, and public attitudes towards the technologies.

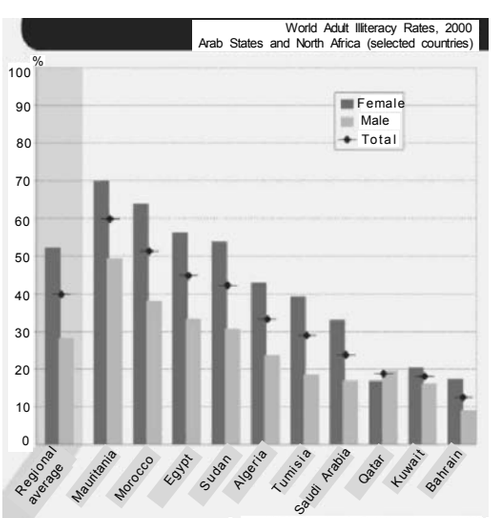
Education levels and the quality of education help to shape regional Internet cultures. In places like Morocco and Egypt, where illiteracy is high, Internet penetration is low. In countries where literacy, fluency in English, and early training in the use of computers and the Internet is high, public demand for and familiarity with the Internet is also high, as is the case in Bahrain.

Those countries that are actively building a knowledge economy and attempting to leverage information technology sectors to stimulate local economic growth tend to have higher Internet awareness and use, and more e-governance capability. We see regional knowledge economies emerging in Lebanon (a recent study found 12.5% growth in the IT sector in Lebanon) (USAID, 2004), Dubai (as evidenced by the Dubai Internet City www.dubaiinternetcity.com), Bahrain (especially in the banking industry), and to some extent Jordan (Nearly 6% of the Jordanian GDP comes from IT related exports) (Ministry of Foreign Affairs, 2004, p. 1). Another economic factor which shapes regional Internet cultures is oil wealth. Most of the countries in the Gulf have higher Internet penetration rates than the rest of the Arab World.

Location matters, both in terms of capital and information resources tending to concentrate in the Gulf region, but also domestically, in terms of proximity to the capital city. The closer one is to a capital city, the higher the likelihood one will find reasonable and regular access to the Internet. For example, in Lebanon, "half the population of Greater Beirut between the ages of 18 and 48 are internet users" whereas Internet penetration rates for the country as a whole are just over 11%. Moreover, "90% of ICT related sales are concentrated in the capital" (Office of the Minister of State for Administrative Reform, 2003, p. 18). The geographic nature of the digital divide can also be felt in terms of number of land lines per location, with only 45,000 phone lines in the Bekaa valley, and 279,000 in Greater Beirut (Office of the Minister of State for Administrative Reform, 2003, p. 18).

Gender also shapes regional Internet cultures. Our most recent data (2001) suggests that 6% or less of Internet users in the Arab World are female (Hafkin & Taggert, 2002, p. 5). Explanations for low female participation in Internet cultures include low literacy rate. In Yemen, for example, 90% of women cannot read or write according to the National Committee for Literacy. According to the UNESCO chart above, 65% of women in Morocco are illiterate, whereas in Egypt, female illiteracy hovers just over 55%. Low representation of women in the work force is also a contributing factor to women's slow adoption of Internet technology. Regionally, women constitute less than 30% of the work force. Even in Lebanon, where female participation in the labor force is the region's highest, women still only constitute 28% of the work force (Prusher, 2000, p. 6). A recent study of women's Internet use in the Arab World illustrates that many Arab women are not Internet users until they are

*Figure 1.*



trained or required to use the technology for work (Wheeler, 2004b). Cultural and religious issues have also been suggested as factors in limiting women's Internet access and use.

Age is also a contributing factor to regional Internet cultures. It is common to find a lack of Internet use regionally among citizens who are 40 and over. A study by DITnet found that a less than 5% of Internet users in the Arab World are aged over 46 (DITnet, 1999, p. 1). Since nearly 60% of the population in the Arab World is youths, under the age of 30, age alone cannot explain slow Internet growth rates (Gerges, 2004, p. 2).

The size of a country, in terms of land mass and size of population also shapes regional Internet cultures. Smaller countries, like Bahrain, Kuwait, and the United Arab Emirates tend to have much more comprehensive information infrastructures and thus higher Internet penetration rates. Countries like Oman, Morocco, and Jordan, with larger land masses, and Egypt, with its huge population (76,117,421 million, July 2004 est.) tend to have less depth and breadth of Internet access points, and fewer people who can afford access.

Public culture and opinion also shapes Internet attitudes and use. In more open information environments, citizens are more accustomed to seeking out alternative sources of information and are attracted to the Internet. In cases like Syria and Tunisia where the state maintains tight control of information environments and regularly arrests and harasses citizens for "illicit" Internet activities, there is a stronger culture of self censorship and Internet abstinence. The opposite might also be true; that is that in strict authoritarian settings, some citizens might be more drawn to the Internet as a source of uncensored information. But the costs for surfing can be high if the government interprets access to banned sites (e.g., as a threat to national security). As explored more completely below, there have been many people in the region arrested for illicit Internet use.

## POLITICAL EFFECTS OF THE INTERNET

The political effects of the Internet in the Arab World include use of e-governance projects to stimulate good governance and political reform, enhanced processes of civic engagement stimulated by the discussion of politics and social issues in on-line forums, and increased powers of the state for surveillance. States in the region regularly filter the Internet (Zittrain & Edelman, 2002), and attempt to maintain tight control over on line environments, often arresting cyber dissidents. Such arrests illustrate that at this stage, the Internet in the Arab World more clearly enhances state power rather than individual human rights. While headlines claim, "Technology fuels democracy in the Middle East" realities on the ground suggest the need for caution (Mitchell, 2005, p. 1). The same technology that empowers individual freedoms of self expression also extends the powers of the state.

One reason for caution regarding the power of the Internet to promote good governance in the region is that many countries in the Arab World are under prepared for harnessing the power of e.governance adoption. While the Arab World scored above the global mean for e-governance readiness in a recent survey, there remain only 4 countries in the region that scored in the "High Capacity for E-Governance" category globally (UNPAN, 2004, p. 2). These include United Arab Emirates, Kuwait, Bahrain and Lebanon. The highest ranking country in the Arab World, the United Arab Emirates, placed 21$^{st}$ globally for e-government capacity. The lowest ranking country of those surveyed in the region was Oman, with a global ranking of 56$^{th}$ place. Countries like Yemen, Syria, Morocco, Sudan, Libya and Algeria were not included in this study. Had they been, the Arab World more likely than not would have been rated above the global mean for e-governance capacity. This survey measured the degree to which countries "were able to facilitate information access for enhanced citizen participation through e-governance." Measurements included indicators of a country's official on-line presence, telecom infrastructure and human development level.

E-governance ratings also indicate the degree to which "a country's leadership recognizes the fact that information has become a social and economic asset" (UNPAN, 2004, p. 1). This level of understanding is clearly evidenced in the state of Jordan. His Majesty King Abdullah II observed in 2002 that "In a networked world, investors have a low switching cost to move from one country to another. Governments that are not business and citizen-centric will not be able to compete. This necessitates a fundamental shift in the way government operates and hence the importance of e-government initiatives" (MOICT, 2002, p. 1).

Examples of the relative state of e-governance capabilities in the Arab World:

1. Saudi Arabia is in the initial stages of developing e-governance, and as of yet, does not have a "true national site or portal," however, four branches of government, the Ministries of Health, Labor, Education, and Foreign Affairs do have a Web presence (www.moh.gov.sa; www.mol.gov.sa; www.moe.gov.sa; and www.mofa.gov.sa) (United Nations, 2004, p. 38).
2. Egypt in 2004 launched an e.government central services portal (www.egypt.gov.eg/english/

*Table 4. (Adapted from UNPAN Global E-Governance Index, 2004)*

| Country | PCs/100 | Int Hosts/ 10000 | Tele lines/100 | Mobile/ 100 | TVs/ 1000 | Human Dev. Index | Urban as % of pop. | E. Gov Index |
|---|---|---|---|---|---|---|---|---|
| UAE | 12.51 | 176.00 | 41.79 | 58.51 | 294.00 | 0.809 | 85.5 | 2.17 |
| Kuwait | 12.13 | 17.55 | 24.40 | 24.86 | 491.00 | 0.818 | 97.4 | 2.12 |
| Bahrain | 13.98 | 0.77 | 24.97 | 30.05 | 419.00 | 0.824 | 91.8 | 2.04 |
| Lebanon | 4.64 | 23.00 | 19.96 | 19.38 | 352.00 | 0.758 | 89.3 | 2.00 |
| Saudi Arabia | 5.74 | 1.73 | 13.72 | 6.37 | 26.00 | 0.754 | 85.1 | 1.86 |
| Turkey | 3.81 | 10.64 | 28.00 | 24.56 | 286.00 | 0.735 | 74.1 | 1.83 |
| Qatar | 13.58 | 37.68 | 26.77 | 19.96 | 808.00 | 0.801 | 92.3 | 1.81 |
| Jordan | 1.39 | 1.36 | 9.29 | 5.38 | 52.00 | 0.714 | 73.6 | 1.75 |
| Egypt | 1.20 | 0.35 | 8.64 | 2.14 | 127.00 | 0.635 | 45.5 | 1.73 |
| Oman | 2.64 | 11.46 | 8.88 | 6.48 | 595.00 | 0.747 | 82.2 | 1.64 |

default.asp). The site offers basic services such as requesting a birth certificate, paying a phone bill and renewing vehicle licenses online (United Nations, 2004, p. 39).

3. In Oman, at the Ministry of Awqaf and Religious Affairs (www.mara.gov.om) one can register for the Hajj online.
4. Jordan recently began using the Internet to distribute the Tawjihi test scores. The Tawjihi exam is a test all matriculating high school students must take. A passing grade on this exam signifies that a student has passed high school and can enter the University. Passing the Tawjihi is also a requirement for joining the army, and other government service professions. In 2004, Jordan signed an enterprise licensing agreement with Microsoft to modernize government e-services. The government of Jordan continues to develop its list of e-government services which it will offer its population in the near future.
5. Dubai has the most developed e-government program in the region. Online in the UAE, one can log on to the Web to access customs clearance services, register for social security, search for a job, obtain a driver's license or passport, register a car, obtain a building permit, check resources at the public library, obtain birth certificates, enroll in higher education, and register for health services.

In spite of these signs of a transition towards more efficient government in the Arab World, in most cases, a complex bureaucracy of sometimes non-transparent transactions are required for many government services. Applying for government assistance, a residency permit, a business license, or registering a child for school can all require multiple visits to multiple ministries and government offices. Moreover, a rich history of privilege and influence known as "*wasta*" or using appeals to personal connections to get something better or faster than others, is also ripe in the region (Cunningham & Sarayrah, 1993). Often, it is those in most need of government services who cannot get them, because they live outside of the capital city, can't afford transportation costs, or don't understand their rights. Regional e-government projects are designed to bring more comprehensive services to more people, better and faster. Whether or not they will succeed remains to be seen.

While the governments in the region are attempting to harness the powers of the Web to create administrative reform, to enhance the investment climate, and to improve the transparency and responsiveness of government, citizens are likewise harnessing the power of the Web to carve out more participatory political climates and freer flows of information among citizens and global civil society (Eickleman & Anderson, 2003; Alterman, 1998). For example, a recent study of the impact of the Internet in Saudi Arabia observes, "Saudis are poised on the edge of a significant new social landscape. Called the Internet, this new frontier includes not only the creation of new forms of private communication, like electronic mail and chat, but also online public discussion areas, which for the first time enable communication between males and females in this gender-segregated society" (Saggaf, 2004, p. 1). Recent studies of the Internet in Kuwait support Saggaf's findings, suggesting that in the conservative Gulf, it is the politics of gender which are most easily transgressed and subverted online (Wheeler, 2001, 2003).

In Jordan and Egypt, for example, where relations between genders are more open, but spaces for talking about politics are more constrained, the Internet's transformative powers are more easily grasped in terms of its ability to enable the sharing of political ideas and opinions. A recent study of Internet café users often yielded evidence with which to support this view. (Wheeler,

*Table 5. Arab state attempts to discourage cyber-dissidence (Adapted from Reporters without Borders, 2004)*

| Country | Arrest | Charge |
|---|---|---|
| Tunisia | Zohair al-Yahyaoui, Journalist | Arrested June 4, 2004 and sentenced to 28 months in prison for "disseminating false news" on the Internet through his Web site TUNISIANE |
| Bahrain | Galal Olwi | Arrested in March 1997 and detained for 18 months. The charge was sending information via the Internet to the Bahraini opposition, "The Bahrain Liberal Movement." |
| Algeria | Ahmed Fattani, Journalist | Arrested on October 13, 2003 for "posting articles online while the paper he edited, Expression, was officially suspended." |
| Egypt | Ashraf Ibrahim and four other members of a "revolutionary socialist movement" which he runs. | Arrested on April 19, 2003, released on March 11, 2004. The group was using the Internet to publicize human rights violations, especially against the Copts. While acquitted, the charges against them were "trying to undermine the state by sending false news to foreign organizations" |
| Syria | Abdel Rahman Shagouri | Arrested on the of February 23, 2003 for emailing a newsletter Lavant News from the banned Web site www.thisissyria.net. He is still being held on charges that he "endangered Syria's reputation and security". |

2004a). For example, one 27-year-old female from Cairo observed,

*I love the Internet. It has made a huge difference in my life. It is a world of its own, and it has its own particular charms including abundant information, the chance to know people from all over the world, having all kinds of discussions from politics to social issues to religious debates ... It is interesting to chat and to make friends. I like talking to foreigners. I am not that keen on the closed Arab mentality. I like people who are themselves in chat ... no masks. In person they have to put on masks.* (Interview, Cairo Internet Café, May, 2004)

Similarly, a 21-year-old female from Cairo observes,

*The net has surely changed my life. I like to read and to get info about different topics and ... I like to also know in detail about news from events in the Arab World, and we discuss them in chat forums. The net is a great invention to get to know new people and exchange opinions.* (Interview, Cairo Internet Café, May, 2004)

This ability to share and develop opinions, to extend social networks, and to grow in one's political consciousness and commitment on world and Arab affairs represents one of the most powerful political effects of the Web. In the Arab World, the Internet is creating better informed citizens with more social capital and expectations for more responsive government.

We must not forget, however, that the Internet is not free from state surveillance. Especially in authoritarian countries, the loss of tight state controls on information environments has placed the state on the defensive. Some of the tactics used by the state to minimize the revolutionary effects of the Internet in the Arab World include using technologies like router-based IP blocking and, more recently, DNS redirection, to attempt to block the Web content they dislike, while still obtaining what they consider the benefits of the Internet (Reporters without

Borders, 2004, p. 10). Granting a monopoly over Internet service provision to one state run company in order to best exercise control over Internet use is another strategy used by Arab states to control and survey Internet data traffic (Tunisia, Oman, UAE, Bahrain Saudi). In this case, control is maintained by creating one pipeline for data transfer … easily monitored; and by keeping prices high so that most people cannot afford access. In addition, traditional methods of encouraging self censorship are also used to reduce the political power of the Internet. These old tactics include efforts by the *mukhabarat* (intelligence officers) to forge charges and prosecute any person who may transgress the unidentified line between that which is permitted and that which is prohibited. Typical charges: defamation, harming the state's reputation, violating public morality. Evidence of these more draconian methods include the recent arrest 27-year-old Bahraini Ali Abdul-Imam, the Webmaster of www.bahrainonline.org, a site that is openly critical of the Ruling al-Thani family and its government. The charges against Abdul-Imam were "stirring hatred against the government and spreading false news that could jeopardize state security. He could face a sentence of up to 20 years in prison (Reuters, 2005, p. 1).

## CONCLUSION: LONGER TERM IMPACTS OF THE INTERNET

The question remains, "where will Internet freedoms and experimentation lead, if at the same time, the powers of the state to police citizen's lives are enhanced by the same technology?" It is clear that as access to the Internet increases in the region, a greater mass of citizens, from a wider set of social, political and economic backgrounds, will be able to experiment with the technology. Those who experiment by sharing opinions and discussing politics, widening their social networks, but refrain from overt challenges and criticisms of the state, will contribute to organic forms of civic engagement as we see emerging in Internet cafes, community access centers, and private homes throughout the region. These forms of experimentation are disorganized and wide spread, and yet touch peoples' lives and political consciousness in fundamental ways. At the same time, the state, which is increasingly aware of the challenges the Internet poses to its control on public information, will continue to crack down on cyber activists who openly challenge the state. As surveillance techniques evolve, and Internet access and use grows, crack downs might also increase, as the state attempts to publicly impose strict boundaries on acceptable vs. unacceptable forms of cyber experimentation. These imprisonments are widely reported in the local media, and discussed via word of mouth. They serve to remind citizens that the government is watching what they do online, reminding them to self censor any questionable behavior … from surfing pornography, to logging on to banned sites, or distributing news without a license. At the same time, the forces of globalization are powerfully at work on Arab states. It is not possible for the knowledge economy to take root, grow and spread opportunity without more open information environments emerging. So, the economic incentive to foster a culture of discursive openness is strong in Arab societies. One cannot but help to think that the evident steps towards a more democratic politics in the region, as evidenced by recent elections in Iraq and Palestine, democratic reforms in Jordan, Bahrain, Qatar, and Egypt, and huge public demonstrations both for and against a Syrian presence in Lebanon, are not somehow enabled by and enabling new communications environments.

## KEY TERMS

**Arab World:** The 22 members of the Arab League including Algeria, Bahrain, Comoros, Djibouti, Egypt, Iraq, Jordan, Kuwait, Lebanon, Libya, Mauritania, Morocco, Oman, Palestine, Qatar, Saudi Arabia, Somalia, Sudan, Syria, Tunisia, United Arab Emirates, and Yemen.

**Authoritarianism:** A political system where the administration of government is centralized. The ruler's personality may play an important role in maintaining the system and advancing the notion and practice of extreme authority as a political virtue. It is characterized by the curtailment of individual freedoms; excessive reliance on

actual and the threat of violence and punishment; virtual unaccountability of government officials; and the aversion of the decision-making process to consultation, persuasion, and the necessity of forging a policy consensus (Hart, 2005).

**Civic Engagement:** "Individual and collective actions designed to identify and address issues of public concern. Civic engagement can take many forms, from individual volunteerism to organizational involvement to electoral participation. It can include efforts to directly address an issue, work with others in a community to solve a problem or interact with the institutions of representative democracy. Civic engagement encompasses a range of activities such as working in a soup kitchen, serving on a neighborhood association, writing a letter to an elected official or voting" (Pew Charitable Trust, 2004).

**E-Government:** The delivery of government service through electronic means.

**Good Governance:** Government that is participatory, consensus oriented, accountable, transparent, responsive, effective and efficient, equitable and inclusive, and follows the rule of law.

**MENA:** Middle East and North Africa.

**Mukhabarat:** (Arabic) Secret police.

**Infrastructure:** The basic facilities and services for the functioning of a community or society, such as transportation and communications systems, water and power systems, and public institutions.

**Wasta:** (Arabic) Intercession or mediation; applying influence. Historically, the head of the family in the Islamic World performed wasta services by obtaining for the supplicant what is assumed to be otherwise unattainable. In the contemporary world, wasta is a common feature of attempts to derive goods and services from the state.

# Digital Government and Democratic Legitimacy

**Peter M. Shane**
*The Ohio State University, USA*

## INTRODUCTION AND CONTEXT

The current flush of worldwide interest in digital government coincides with considerable anxiety, even discontent, with the performance of predigital democratic governments, including democratic governments in what seem to be highly functional societies. Primary causes for this malaise involve an interlocking set of complex phenomena. These include globalization, the marketization or privatization of ever-larger aspects of our social and economic life, challenges to the vitality of national political identities that are supportive of democracy, a pervasive sense that government is increasingly driven by special interests rather than a genuinely public interest, and the alienation of the ordinary citizen from governments that seem increasingly remote and indifferent (Castells, 1997). Although few still tout the Internet and universal interconnection as promising by themselves to cure all political ills, the fact is that hopes for digital government run high across the developed world. This enthusiasm seems linked to a yearning for improvements not just in government efficiency, but also in democratic legitimacy. It is the potential linkage between digital government and democratic legitimacy that this article will explore. My thesis is twofold: first, that digital government has enormous potential for enhancing democratic legitimacy, but second, it can realize that potential only if implemented with democratic principles in mind and if designed to fulfill multiple models of democratic legitimacy.[1]

## BACKGROUND CONCEPTS AND DEBATES

Discussions of this topic necessarily start with two matters of definition. The easier of these to address is the distinction that must be drawn between the phenomenon of digital government and the movement for "digital," "cyber-," or "electronic" democracy. "Digital government" is most widely used to refer to the use of digital information and communications technologies (ICTs) for the delivery of government services, as well for functions of government management and procurement. "Electronic democracy" refers to the design and deployment of digital ICTs to enhance democratic political practice. Although these goals and functions overlap, in ways about to be discussed, the distinction between them is significant. On the digital government side, for example, there exist significant Web applications that enhance government efficiency, but have virtually nothing to do with policy making or public accountability. By contrast, electronic democracy initiatives may well include online campaigns to facilitate grassroots community organizing among the citizenry or interaction among organizations of civil society—activities that do not involve government actors at all.

The second, and much harder issue, is, "What does 'democratic legitimacy' mean?" At the most general level, political "legitimacy" presumably refers to the moral entitlement of any governmental entity to wield political power. Allan Buchanan (2002) has argued that, for a democracy, political legitimacy must rest upon processes that help assure, in public policy making, equal consideration for the interests of all persons subject to the government's putative authority. This approach offers an objective standard by which to assess the legitimacy of democratic rule, but does not take explicit account of the subjective experience of those who live in a putatively democratic regime. Even though democracy is a system of collective self-determination, its legitimacy cannot be entirely divorced from the opportunities democracy provides for the experience of individual self-determination as well. Constitutional theorist Robert Post has written: "[W]e could not plausibly characterize as democratic a society in which 'the people' were given the power to determine the nature of their government, but in which the individuals who made up 'the people' did not experience themselves as free to choose their own political fate" (Post, 1995, p. 7). That is why a full account of democratic legitimacy must embrace a second criterion: the degree to which the system supports the experience of individual citizens as autonomous actors free to participate meaningfully in acts of collective self-determination.

With these criteria in mind, there are three models of democratic legitimation widely known in the postindustrial West. The boundaries between these models are porous; a democratic system can easily incorporate elements of all three. But each of them rests on a different account of how citizens and institutions combine to afford democratic legitimacy. The accounts differ especially in the relative

importance they ascribe to individual citizens versus government officials in arriving at decisions of public policy.

The most familiar model of democratic legitimacy rests on the election of public officials to make and enforce the laws. For virtually all observers, elections are the sine qua non of modern democracy in any sizable community. In the election-centered model,[2] the experience of autonomous citizenship is focused on the selection of candidates and the electoral choice among them. When it comes to actually deciding the content of public policy, elected representatives are centrally important, but individual citizens only indirectly so. The system's claim to legitimacy thus rests on twin pillars. One is the hope that autonomous electoral participation will afford citizens a sufficient experience of self-determination to warrant their allegiance to the outcome. The second is the presumption that the accountability of representatives to the people who elect them will yield the equal consideration for the interests of all persons that provides democratic government with its moral foundation.

An alternative account of democratic legitimacy is typically called "direct" democracy (Cronin, 1999).[3] The practices that actualize the ideal of direct democracy are generally thought to come in two forms: One is "assembly democracy," typified by the town meeting, in which every adult citizen residing within the relevant jurisdiction is entitled to attend the meeting, help shape the agenda, and vote on public measures. More common, for obvious reasons of scale, are practices that, like candidate elections, are dependent on voting: the referendum and the initiative. In any case, direct democracy locates the moral entitlement of democratic government to rule in the capacity of citizens to determine for themselves the content of the laws that constrain their freedom. Because citizens experiencing these mechanisms are more likely than in candidate elections to "experience themselves as free to choose their own political fate," direct democracy has obvious appeal as a model of democratic legitimacy. On the other hand, it is difficult to see, however, how direct democracy promotes the equal consideration of the interests of all persons, which is thus a weakness of this model (Hamilton, 1996-1997).

A third model of democratic legitimacy has come to be called deliberative democracy. Under this model, democratic legitimacy is rooted in the position, as articulated by James Bohman and William Rehg, that "legitimate lawmaking issues from the public deliberation of citizens" (Bohman & Rehg, 1997, p. ix). "Deliberation," in theories of deliberative democracy, is a special form of rational communication operating in formal arenas and under specified norms (which, pursuant to deliberation, may become further specified). Mere political talk, although it may create a richer environment for deliberation, is not deliberation (Noveck, 2005).

According to virtually all theorists of this model, deliberation should ideally meet five criteria. The first is that the relevant deliberations must be open to all, and all who participate must be able to do so free of coercion. Second, each participant must be treated as an equal. Everyone can speak. Everyone has a voice in shaping the agenda. Everyone can raise questions, debate, and vote on outcomes. The third condition is rationality. Everyone who deliberates agrees to advance positions either by appealing to the common interest or by making arguments of a sort that all participants could accept. The fourth is reflexivity. Anyone can raise questions to the group about whether foundational norms are being respected. It is encouraged for speakers to reflect on their own biases. Finally, the reasons for ultimate decision must be public. They must be open to the scrutiny of all, in order that they can again become the subject of yet further deliberation (Cohen, 1997).

Deliberative democracy contributes to the equal consideration aspect of legitimacy in two critical ways. First, while the procedures of election-centered or direct democracy take the individual citizen and his or her preferences as given, it is accepted—even intended—that the processes of deliberative democracy will transform the perspective of the individuals who participate. In the words of Arthur Applbaum (2002), "A usable definition of deliberative democracy refers to processes and institutions that aim at changing motivations, and consequently outcomes, for the better" (p. 24). Thus, although also directly participatory in nature, deliberative democracy rests on ideas of self and identity distinctly different from those associated with initiative and referenda processes. Second, and relatedly, while the deliberative model resembles election-centered models in promising equal regard for the interests of all, such equal regard is achieved not in the accountability of decision makers to the governed, but in the very process of citizen deliberation. That is the fundamental accountability in deliberative democracy does not run from the governor to the governed, but from each citizen to every other. It is the phenomenon of mutual regard among citizens, with consequent impacts on each citizen's sense of self and collective political identity, that is the key instrument under deliberative democracy for assuring the equal consideration of all persons' interests.

There is yet a fourth possible account of democratic legitimacy, which I will call the managerial model. Some theorists argue that democracy ought be judged not by values of process, such as equal consideration, but rather by the substantive results that people care about, such as the promotion of economic prosperity, individual and

collective security, and social justice. The influential work of John Hibbing and Elizabeth Theiss-Morse (2002) even tries to show that citizens, at least of the United States, prefer government to be run more like an efficient business than a deliberative or participatory public sphere, as long as they get positive results. Dan Hunter (2004), expressing a similar notion, has written: "Democracy is an empty concept that describes few, if any, of our genuine political commitments" (p. 142). Our "genuine" commitments are presumably to the substantive goods that democratic government promises to achieve.

For democratic theorists, of course, it may matter quite substantially which of the foregoing approaches to political legitimacy is most persuasive. This is less true, however, for designers of digital government and electronic democracy initiatives. That is because well-designed digital initiatives can advance, often simultaneously, multiple models of legitimacy and, if digital government is truly to contribute to democratic revitalization, it is probably imperative that such an eclectic approach be followed.

## HOW DIGITAL GOVERNMENT INITIATIVES CAN SUPPORT DEMOCRATIC LEGITIMACY

With regard to each of the three better-known models of democratic legitimacy—election-centered, direct, and deliberative—a well-informed citizenry is plainly a critical element. Indeed, even with regard to the last, managerial view of democracy, citizens are likely to value information that confirms the effective performance of government. Because public access to politically significant information is thus critical to every theory of democratic practice, the importance of the Internet on this ground alone can hardly be overstated. Throughout the developed world, virtually every significant information outlet critical to predigital democracy, including broadcast and print media, along with every level of government now uses the Web to make vast quantities of policy-relevant information accessible to the public. Indeed, the very same information made available through the Internet becomes more valuable because it is likely to be stored and "served" to interested viewers for longer periods of time, and is frequently searchable through effective and convenient technology.

Among the most important categories of information is information about government activities that provide opportunities for citizen engagement. Digital government sites make it possible to share public meeting calendars, listing programs and policy-relevant events of interest open to the public. Combining such sites with e-mail notification services enables government units to keep citizens informed and up to date on the activities of agencies, boards, and commissions in which those citizens have expressed an interest.

To the extent democratic life revolves around candidate elections, the Web facilitates a wide array of activities around political campaigning, issue advocacy and debate, and the monitoring of elected officials and the candidates seeking to replace them. While online voting is still rare, digital government Web sites now provide potential voters with much more easily accessible information about polling places and ballots. Online voter registration is potentially an invaluable tool for expanding the qualified electorate. Web sites have multiplied to give information to voters regarding candidates, their positions, their records, and their contributors. Of course, virtually every digital government application with the potential to enhance the candidate election process would have counterparts with regard to those issue elections—initiatives and referenda—that stand at the core of so-called direct democracy. Web sites can enable sponsoring organizations and advocacy groups to organize volunteers and raise funds. If legally authorized, they can facilitate the signature-gathering process. Web sites can help inform voters about the content and implications of proposed ballot measures, as well as sharing the identities of who is advocating or opposing various propositions.

Most of the genuinely distinctive electronic democracy applications, however, are probably those associated with theories of deliberative democracy. For example, ICTs offer significant possibilities for improving those aspects of contemporary government that are already deliberative in nature. Online administrative rule making is the paradigm case. In the United States, new applications such as www.regulation.gov (Noveck, 2005) have made it immeasurably easier for citizens to petition for regulatory initiatives or changes, to review agency proposals and background data, to scrutinize the contributions of other commentators, and to offer additional data and argument (Brandon & Carlitz, 2002). It would be technologically straightforward for policy makers to convene online dialogues that could be designed to move yet further in the direction of full citizen deliberation.

Significant experimentation with online consultation is a global phenomenon (Coleman & Gøtze, n.d.). A few current or recently concluded English-language consultations are illustrative:

- In May 2002, a Joint Committee was established by orders of both Houses of the British Parliament to consider and report on a draft Communications Bill. The Committee commissioned an online forum, under the auspices of the Hansard Society and the

Parliamentary Office of Science and Technology, to assist in gathering a wide range of citizen views on the bill.[4]

- The so-called Environment Group of the Scottish Executive held an on-line consultation from June through October, 2002, under the title, "What Sort of Scotland do we want to live in?" which focused on sustainable development issues facing Scotland. The aim was to equip government ministers with input for a policy document preparatory to the 2002 World Summit in South Africa (Smith and Macintosh, 2001).
- The Information Society Directorate General of the European Commission conducted in 2002 and 2003 an online consultation based on a Commission staff working document concerning barriers to widespread access to new ICT services and applications made possible through "open platforms" in digital television and third generation mobile communications.[5]
- The Canadian Department of Foreign Trade and International Affairs hosts a web site to solicit public comments on Canada's trade policy agenda on an ongoing basis, and to obtain information on specific consultation initiatives launched by the Canadian government. The site includes not only directions for submitting comments relevant to a host of current consultations, but also background information on trade policy and access to results of past consultations.[6]
- The Government of New Zealand launched a web site to solicit and summarize public input regarding a national strategy on "biosecurity," defined as "the protection of New Zealand's economy, environment and people's health from pests and diseases."[7]

It seems clear that all well-designed digital government applications bolster, by definition, the managerial model of democratic legitimacy. These would include Web applications that facilitate efficient access to government services, applications that permit citizens to report problems and concerns directly to government officers and agencies, and applications that permit the tracking of ongoing administrative processes. The latter have been shown to have significant potential for reducing the reality and appearance of government corruption (World Bank, 2000).

It is arguable, however, that even those web sites that are oriented only to the delivery of services actually do more. That is, even if they do not directly foster citizen engagement in public policy making, they have an indirect role to play in strengthening election-centered, direct, and deliberative democratic ideals, as well. At the very least, this is because using ICTs to render government more visibly accessible and accountable to the citizenry potentially increases citizen confidence in the project of collective self-governance. Research on political engagement shows that a major rationale for political apathy is the sense that citizen involvement does no good; individuals cannot accomplish anything meaningful (Muhlberger & Shane, 2001). It is plausible that, as government increases its demonstrated willingness and capacity to address people's real needs, the visible possibility of accomplishing positive results through government will encourage people to become more involved in shaping what government does—thus furthering the more participatory models of democratic legitimacy.

## FUTURE TRENDS AND CONCLUSIONS

If the argument is right that all forms of well-designed digital government can make at least indirect contributions to deepening democratic legitimacy, does it matter to the future of democratic legitimacy whether democratic intentions actually play a significant role in the design of digital government initiatives? The answer is almost certainly, yes (Noveck, 2005). The forces responsible for citizen skepticism and alienation, described at the outset, are simply too strong for us to imagine that the mere use of ICTs to facilitate improved efficiencies in existing managerial practice will be sufficient to produce a significant revitalization of democracy. This seems especially so given the array of forces that make it difficult to advance the cause of participatory democracy (Shane, 2005). To facilitate effective citizen engagement, digital government designers must focus consciously on the potential of the Internet to become a significant vehicle for helping citizens to become well-informed, fully engaged partners in democratic public policy making.

For this reason, an especially exciting area of interdisciplinary research is focusing on how to integrate digital democracy initiatives with more conventional projects in digital government. Researchers are asking what it would take not only to engage citizen attention initially, but also to sustain that attention through online interaction. One can easily imagine government agencies augmenting their traditional face-to-face citizen outreach efforts with online meetings, e-mail services, and bulletin boards that foster the creation of online communities of citizens becoming informed contributors to agency policy making. The creation of online libraries of information for interested citizens could itself become a collaborative task involving both government officials and citizens engaged in deciding what information is needed and how it can best be presented in meaningful and accessible form (Shane, 2004b).

This vision, of course, poses very large questions: How can government attract and sustain citizen participation? How can public policy questions be framed and the stage set for informed and productive online deliberation? What are the practical issues of technology, organization and personnel that will arise for governments seeking to implement electronic democracy projects? How can government help to prepare all citizens to participate effectively in a world of electronic democracy? How can government help to establish and maintain norms of civil online discourse? How can electronic democracy tools and face-to-face civic interaction best be integrated? Partnerships between government and academic researchers designed to shed light on these questions offer perhaps the greatest potential for yielding insights helpful to those government units most intent on implementing digital government in a way that will deepen democratic legitimacy.

## KEY TERMS

**Deliberative Democracy:** A model of democracy in which legitimacy is rooted in public deliberation among citizens as conducted in formal arenas and under specified democratic norms.

**Direct Democracy:** A model of democracy in which citizens participate directly in the formulation or approval of the laws and policies that govern them.

**Election-Centered Democracy:** A model of democracy in which political legitimacy rests on the accountability of elected representatives to the voters who choose them (also frequently called, "representative democracy").

**Electronic Democracy:** The design and deployment of information and communications technologies to strengthen democratic political practice.

**Electronic Rulemaking:** The practice, in the United States, of using the Internet to facilitate the collection and analysis of citizen input with regard to proposed administrative regulations.

**Managerial Democracy:** A model of democracy in which legitimacy rests on an elected government's capacity to provide citizens with security, economic prosperity, and social justice.

**Political Legitimacy:** The moral entitlement of any governmental entity to wield political power.

## ENDNOTES

1 An extended version of this chapter's argument appears in Shane (2004b), from which portions of this chapter are drawn with permission.

2 I prefer the term "election-centered democracy" to the more familiar "representative democracy" because, as I have argued elsewhere, representation is crucial to models of practicable models of "deliberative democracy" as well (Shane, 2004a, p. 80).

3 "Direct democracy" can also be considered a species of "participatory democracy," although I find the latter label potentially confusing, given that both representative and deliberative democracy obviously entail popular participation as well.
A species of "participatory democracy" that differs from each of the models discussed here is "associative democracy" (Perczynski, 1999), a model generally attributed to Paul Hirst (1994). Under Hirst's model and its offshoots, substantial responsibility for the governance of social life would devolve from the state to democratically structured voluntary groups. To the extent such governance could succeed without the exercise of state power, the problem of legitimating state power would necessarily be reduced. But by its very terms, "associative democracy" does not appear to be a distinct model for legitimating whatever exercise of state power would remain, which would still have to be justified by election-centered, deliberative, or direct democracy principles.

## INTRODUCTION

All governments face difficulties in trying to ensure the full participation of every citizen. The further a citizen is located from the centre of power and administration, such as a capital city, the less engaged they are likely to be. This phenomenon can be observed at both a national and an international level. At the global level countries located in close proximity to major world markets are more likely to have well-developed e-government services, than more marginally located countries, particularly those with low population densities. Within individual countries, there is typically a marked variation between rural and urban areas both in terms of access to available infrastructure and uptake by citizens (Parker, 2000). In general, the more remote the location and the smaller the population density, the lower the rate of participation will be. This can be observed in even in the most highly developed, highly populated countries; for example, the Japanese government struggles to provide the often elderly residents of remote islands with government services (Hayashi & Hori, 2002). In a country that is less developed without easy access to major world markets, the effects on rural citizens are intensified.

The small island developing states of the South Pacific are some of the most remotely located nations in the world; their economies are relatively underdeveloped and they have low population densities. By researching the difficulties faced in attempting to implement e-government in some of the most distant corners of the earth, lessons can be learned about the way that information and communication technologies (ICTs) can overcome the barriers of geography. The insights gained from this exercise are relevant worldwide; as many economically developed countries also have pockets of population that are hard to reach.

A counter argument is that some of these differences may be attributable to a country's level of economic development rather than it's actual geographic location. A notable example of a remotely located country that has a highly developed e-government system is New Zealand. Despite having only four million inhabitants, and being placed on the other side of the globe from the major world markets of Europe and the USA, in 2001 New Zealand was nominated by the UN as the country with the third most advanced e-government system in the world (Boyle & Nicholson, 2003). ICTs now make it possible to connect a citizen in even the most far-flung location directly to central government services.

This article investigates the status of e-government in remote locations. Representatives from ten different South Pacific Islands were surveyed to discover what they perceived as the main barriers and opportunities in developing e-government in each of their different countries. The island states of the South Pacific have developed independently and are culturally diverse. However, they all share some common features with regards to adoption of ICTs. In order to appreciate these factors more fully, one country, Samoa, has been used as an example. By comparing Samoa with New Zealand, lessons can be learned about how to utilise ICT to overcome the disadvantages of distance and low population.

E-government is sometimes viewed as a subset of e-commerce. However, it needs to be remembered that there are substantive differences between the private and public sectors. Governments have a duty to make sure that services are available to all citizens, and usually the citizens who are the most needy are those who have the least access to government services (Curthoys & Crabtree, 2003). Often this is because such citizens live in remote rural locations. The public sector is a law-based system, and government includes many processes that are different from processes encountered in private sector settings such as retail or banking, for example: complex decision making; negotiations between stakeholders; policy formulation; and democratic participation (Lenk, 2002). An example is the highly contentious issue of land ownership in the South Pacific; the use of e-government could

*Table 1. UN-ASPA Five stages of e-government (adapted from UN & ASPA, 2001)*

| STAGE | DESCRIPTION | SPECIFIC FEATURES |
|---|---|---|
| **Stage One** | **Emerging Web Presence**<br>Static information on the government is provided | Postal address<br>E-mail address<br>FAQs |
| **Stage Two** | **Enhanced Web Presence**<br>Information is kept up to date, some documents can be downloaded | Updated regularly<br>Search function<br>Newsletters |

potentially help land boards to demonstrate a fair and transparent approach to this issue.

## BACKGROUND

Samoa is an independent island nation in the South Pacific, with a long history of political and economic stability. The country has a land area of approximately 2,938 square kilometres, and a population of approximately 170,000. The Samoan economy is made up of agriculture, fishing, handicraft production, small manufacturing goods, and one automobile-wiring firm. Tourism has recently become a valuable contributor to the Samoan economy, and since 1990 has been the top foreign exchange earner. SMEs are central to Samoa's economic well-being comprising 98% of the Samoan economy.

New Zealand has been able to adopt e-government quickly due to a number of factors:

- It has a relatively simple structure of government compared to many countries
- A small population facilitates the quick spread of new ideas
- The population is well educated
- The country has a history of being an early adopter of innovative ideas (Boyle & Nicholson, 2003)

If Samoa is to learn from the example of New Zealand, any common features shared by both countries need to be identified and considered. Samoa also has some of these characteristics. As a small country, it has a simple governance structure. Though central government does consult with village mayors (Pulenu'u) and presidents of the village women's committees, there is no local government as such. This means that current systems of government are relatively easy to automate. Like New Zealand, Samoa has a low population density, which can be an advantage, in that provided internal communications are adequate, ICT-based strategies can be implemented more rapidly than in a larger country. However, a small population often means that there is a lack of appropriate skills to implement such policies (Comnet-IT, 2002). Samoa has its own University, and the educational level of the population is high for a developing country, with a 96% literacy rate, and two thirds of 15-19 year olds in education (Purcell & Toland, 2004). Despite this, there is still a shortage of the relevant ICT skills. Though a comparison between the two countries is useful, it does need to be remembered that New Zealand is much more economically developed than Samoa, and in terms of factors such as transport and telecommunications infrastructure, the two countries are worlds apart.

Recent research (Curthoys & Crabtree, 2003) has found that many governments have poured resources into developing e-government systems with mixed results. Despite the extensive development of e-government services in the UK, most citizens have continued to interact with government by traditional methods; as of 2002, only 11% of UK citizens had used a government online service. The conclusion that can be drawn from this is that to be successful e-government must be popular with its actual users, the citizens themselves. Governments need to consult with their citizens in order to identify services that citizens are likely to use online. Samoa has taken careful steps to involve rural as well as urban citizens in the development of its new ICT policy. The policy was built up through a bottom-up process of consultation at the village level, representatives of the National ICT Committee visited both rural and urban villages to collect the opinions of a wide range of people.

A number of frameworks have been developed that can be used to track the growth of e-government (Jupp, 2003). The UN/ASPA five-stage model, shown in Table 1, has been selected for this research as it clearly identifies each step of development. At stage one, the e-govern-

*Figure 1. Most frequent method used to contact the Government Department*

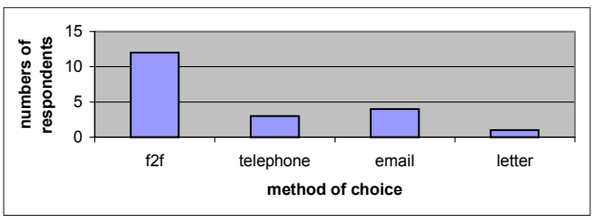

*Figure 2. Estimated percentage of external clients with Internet access*

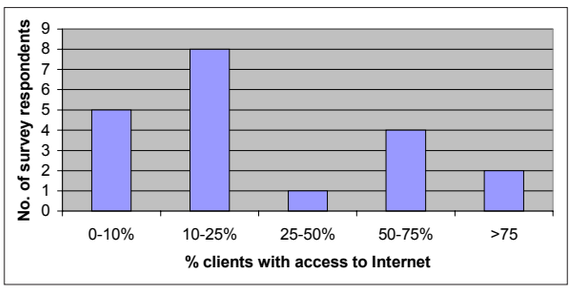

ment presence consists of Web sites that provide fairly static public information. At stage two the Web sites will be regularly updated, some documents will be available for download, and e-mail will be present. Once stage three is reached, the government Web site begins to act as a portal with links to related sites, both government and non-government. At stage four, citizens will be able to complete transactions online, and Web sites will be secure. Stage five occurs when there is an integrated countrywide portal where all services offered by government can be offered through one integrated "one-stop shop" site (Lallana, Pascual & Soriano, 2002).

In the case of Samoa, most government departments now have Web sites (Purcell, 2003). However they are generally still at stage one of the model and are limited to advertising and information sharing only. Like other Pacific countries, government departments in Samoa use the Internet mainly for e-mail. The technology has not yet begun to contribute to efficient and effective procurement, as it does now with governments in developed countries.

## EMPIRICAL STUDY

To find out where South Pacific countries were on the UN-APSA model, and to assess the opportunities for, and barriers to progress, an exploratory study was carried out. This involved surveying attendees at a 2002 conference1 on ICT use in the Pacific region about their use of e-mail and the Internet. In parallel with this, a number of government Web sites from Fiji, Samoa, and Vanuatu were sampled for evidence of features derived from the UN-APSA model.

The attendees at the conference came from 10 different South Pacific countries. Some respondents worked directly for their countries' governments, while others worked for NGOs or telecommunications companies. The instrument used was an anonymous questionnaire, which queried the respondents' use of e-mail within the government, and between government and its external clients. Twenty individual respondents completed the questionnaire, a response rate of 75%. Respondents were asked whether their own organisations had Web pages, and what they used their government's Web pages for. Respondents were also asked to estimate what percentage of their clients had access to e-mail and the Internet. This was to confirm the information already collected about e-readiness, by establishing what access citizens had to ICT either as individuals in their own right, or through NGOs that might lobby on their behalf. In terms of the development of e-government, we sought to investigate communications between governments and organisations such as schools, NGOs, and utility companies. The survey was followed up with an open ended discussion in which focussed on the barriers, threats and opportunities stemming from e-government.

Figure 1 shows that the most common method used to communicate between a government department and an individual citizen is still face-to-face discussion. This was the method that individuals felt most familiar with, and it was seen as the best way to achieve results. The respondents who picked e-mail as their first choice method appreciate the speed and convenience it offers.

Individuals were asked to estimate what percentage of their external clients had access to the Internet. The results are presented as Figure 2. The findings confirm the results of an earlier UNESCO study (Zwimpfer Communications, 2002), with the majority estimating that less than 25% of their clients had access to the Internet. However, the feeling was that this number was increasing, particularly in the urban areas.

Seventy-five percent of the respondents worked for an organisation that had its own Web site. Most were regular users of government Web sites, with only two people reporting that they never used such Web sites. The most frequent uses of government Web sites were for general browsing, looking up contact details, downloading documents and sending e-mails. None of the participants had ever made a payment using a government Web site.

*Table 2. E-government: Barriers, threats, and opportunities*

| BARRIERS | THREATS | OPPORTUNITIES |
|---|---|---|
| Lack of commitment from government/ decision makers (9) | Security issues (3) | Improve transparency (6) |
| Lack of awareness of the benefits (8) | Could foster corruption (3) | Will be cost efficient/ cheaper (5) |
| Poor telecommunications infrastructure (8) | Use of ICT could replace jobs (2) | Will improve access to information for general public (5) |
| Lack of skills and knowledge (4) | Availability of sensitive materials (2) | Pacific people living overseas will have easy access to information (3) |
| High costs of hardware and telecommunications access (4) | Loss of income for telecommunications companies (2) | |
| Lack of regulations and policies (3) | | |
| Monopoly for telecommunication companies (2) | | |

The sampling of selected government Web sites confirmed these findings. Most sites featured documents to download, contact details for government departments, and FAQs (sites answering "frequently asked questions"). The more sophisticated sites also featured up-to-date news feeds, and search facilities. None of the sites sampled had online forms, featured portals, or included any facility for online transactions. Most of the sites were at stage one of the UN-APSA model (emerging Web presence), with a few at stage two (enhanced Web presence).

As a follow-up to the questionnaire, 26 conference participants from 12 different South Pacific countries discussed the barriers, threats, and opportunities to e-government. The main points submitted are summarised in Table 2. The numbers in brackets refer to the number of participants citing that item as a concern.

The major barrier to e-government was felt to be a lack of commitment from the governments of the respective countries. Respondents felt that the governments did not view e-government as an important issue. The poor telecommunications infrastructure, and a lack of awareness of the benefits, are also key barriers. The participants saw the main opportunities being offered by e-government as being improved transparency, better access for the general public, and cost- saving.

In 2005 government, Web sites in Samoa, Fiji, and Vanuatu were revisited to assess what progress had been made since the initial survey was carried out in 2002. In all cases there had been significant developments. In Fiji it is now possible to download application forms for civil service positions, showing that e-government is at Stage Two of the UN/ASPA model and is moving towards Stage Three. The government's Strategic Development Plan 2003-2005 explicitly commits it to developing both internal and external e-government applications. Internally about 3,000 (out of a total of 17,000) civil servants now have access to the Internet, and the objective is to connect 10,000. Externally the government intends to make the Internet available in all 19 public libraries. There are also plans to develop a dynamic Web site for the Immigration Department, which will allow customers to apply, pay for and receive immigration services online (Minges & Gray, 2004). This illustrates that the Fijian government has recognised the value of e-government, the major barrier to expansion of services is the high costs of telecommunications which makes it difficult to connect users located outside the capital city, Suva (Minges & Gray, 2004). In Vanuatu, government Web sites now have a range of features particularly aimed at attracting overseas users: potential tourists are able to book accommodation and tours online; potential investors are able to set up a company online. The ability to submit online forms in these areas means that Vanuatu is now at Stage Three of the UN/ASPA model. Samoa's government sites still contain mainly static information, and have not moved from Stage one of the UN/ASPA model. However the government is committed to developing e-government and a significant development is the introduction of a Mapserver system (Martin, 2005). This will feature geographical information from many government departments, regional and international organisations and will enable more informed planning decisions.

## FUTURE TRENDS

A number of Pacific island countries have a history of political instability, with the result that many citizens distrust their government. E-government is a tool that can be used to help build trust by making interactions between citizens and government more transparent, and reducing the possibilities for corruption. E-government

can help to transform government to be more citizen-centered, and to improve services to citizens. Information technology is a crucial driver of these improved services (The Working Group on E-Government in the Developing World, 2002).

As well as developing a shared vision with their citizens, governments need to develop partnerships with private businesses in order to move forward. For example, a major barrier to the development of online payment in Pacific island countries is the lack of a clearinghouse for the validation of credit cards. The Samoan government is offering incentives to the private sector to develop a central payment clearing system, which could be used by all Pacific island countries.

Poor telecommunications infrastructure is a common barrier among the developing countries. Samoa is no different. The poor condition of the infrastructure is due partly to the condition of the cables being used. Both the underground and aerial cables are old and deteriorated. The national telecommunications provider, Samoatel is working on improving this situation by laying down fibre-optic cable in Apia, the capital. Currently, about 80% of Samoans have access to at least a basic telephone, and Samoatel plan to have achieved 100% connectivity by the end of 2005. New developments in wireless technology open up the possibility of providing access to e-government without the development of costly infrastructure (Caldow, 2003). Telecom Samoa Cellular provides wireless communication in Samoa, and the prepaid mobile telephone is proving to be a popular method of communication (Vaa, 2003).

A key issue in establishing ICT connectivity between small islands is affordability. Travel in these countries is expensive often involving a combination of bus and boat journeys, therefore although sending an e-mail may be relatively expensive, the cost compares very favourably with the cost of a journey to the nearest government office. A long journey can be undertaken to reach the nearest telephone, only to find that the official you want to contact is out of the office.

## CONCLUSION

The findings show that while Web sites and e-mail are quite common in the public sector in the South Pacific, there is little transactive use at present, though this is increasing. The survey indicates that the main opportunity offered by e-government to the South Pacific would be increased transparency. In 2002, the low priority it was given by government was a major barrier. By 2005, governments were beginning to recognise the potential of e-government and were setting up projects to increase e-government services. However poor telecommunications infrastructure still remained a major barrier to progress.

Though it is useful to compare findings against an internationally agreed model, such as the UN-APSA model, what is important is not what stage of the model a country is at, but whether it is delivering services to its citizens in a manner they find satisfactory. Our findings show that online communications between government and NGOs are reasonably developed, and given the collective nature of South Pacific society it may be more effective to develop a model of e-government where an individual citizen's access to government is through an NGO acting as a facilitator, rather than aiming for direct government to citizen access.

Before e-government can be fully developed and implemented, there is an urgent need for such countries to develop a national ICT strategic plan to ensure that any ICT development—including e-government—is aligned to the country's overall national strategic goals. In 2004, the Samoan parliament approved a national ICT strategy. The overall vision is "information and communications technologies for every Samoan" (Samoa Information and Communications Technologies Committee, 2004, p. 2). This strategy built on the guiding principles outlined in the overall plan for the South Pacific region. This was developed by the Ministers of Communication in the countries which are members of the South Pacific Forum (Council of Regional Organisations in the Pacific, 2002). The plan has four guiding principles: up-skill human resources; develop infrastructure; facilitate cooperation between stakeholders and improve policies and regulations. The development of an appropriate telecommunications infrastructure is a particular challenge for small island developing states, due to the low population density, and the vast distances to be covered. The goal is to open up regulatory frameworks to allow competition, and encourage private sector participation in infrastructure development. A key role for the government will be to act as a role model in it's own use of ICT to link up government departments and corporations. This should encourage the private sector and NGOs to expand their use of ICT in interacting with their stakeholders (Samoa Information and Communications Technologies Committee, 2004). National ICT strategic plans can most effectively be developed and implemented by drawing upon partnerships among organisations, and collaboration among people across organisational borders.

Decision makers in South Pacific countries must be made aware of the benefits of e-government. In particular, they should understand that e-government could be a driving force to re-engineer and transform governance, and to better meet the needs of the country's citizens. The example of New Zealand shows how the innovative use of e-government can help to overcome the disadvantages of

remote location. Samoa has taken steps towards overcoming the barrier of lack of government commitment by developing an ICT strategy. The next step is to complete the upgrade of the telecommunications infrastructure so that full advantage can be taken of the benefits offered by e-government.

## KEY TERMS

**FAQs:** Frequently asked questions.

**Joined-Up Government:** Seamlessly linking together different government departments, so that information is shared rather than being held in separate information silos.

**NGO:** Non-government organisation, a private non-profit making body, which operates independently of government. NGOs normally provide various forms of social services or community development.

**One-Stop Shop:** The idea that an individual citizen or business will be able to conduct all their business with government from one access point.

**Portal:** A multifunctional Web site that forms a gateway to a range of services that usually includes Web directories, search capabilities, and links to other Web resources.

**Transactive Use:** The ability to fully complete secure financial transactions online.

**Transparency:** Making the reasoning behind decision making open to all citizens to ensure fair play.

**UN-APSA:** United Nations and the American Political Science Association.

## INTRODUCTION

Recently, digital government is a prevailing concept in public sectors around the world. Regarding digital governments' contributions to the democratic administration or democratic society (Leigh & Atkinson, 2001), a fundamental question has emerged: How can e-government cultivate citizen participation and citizen competence for public affairs? This question stems from a more basic philosophical question on how we set the relationship between the state and the citizen in the information age (Beachboard, McClure, & Wyman, 1997).

The prevailing efficiency-oriented application of e-government has caused side effects and different opinions,[1] because digital government strategies just focus on information providers' interest rather than public interest, and focus more on the managerial side of the digital government than on substantial contribution to increasing citizen participation, citizen competence, responsibility or responsiveness, and transparency or openness (Dunleavy & Margetts, 2000; West & Berman, 2001; Cullen & Houghton, 2000; Relyea, 2002; Beachboard, McClure, & Wyman, 1997).

Digital government strategies mainly focused on providing information or simple transaction functions, and they did not pay much attention to interaction with people via digital government systems (Leigh & Atkinson, 2001). Therefore, it is not surprising that a new way of thinking of digital government is emerging, in terms of increasing democratic values like citizen participation and citizen competence for the democratic administration and democratic society (Relyea, 2002).

Since the White House established the Web in 1993[2], there are three perspectives on digital government strategies in the United States (U.S.): policy environment and operational requirements; chronological procedures; and the four-stage model (Relyea, 2002; Beachboard, McClure, & Wyman, 1997; Leigh & Atkinson, 2001; Layne & Lee, 2001). For example, Leigh and Atkinson (2001) explained the e-government development situation based on chronology. They divided the digital government of the U.S. into three phases: Using the Internet to share information (Phase one; 1993-1998), online transactions, service provision (Phase two; 1998-2001) and integration (2001-?)[3].

In addition, we can see digital government development with the four-stage model. Layne and Lee (2001) analyzed the e-government procedures with four-stage models based on state government in the U.S.: Catalog, transaction, vertical integration and horizontal integration. In the case of catalog, the initial efforts of government Web are focused on establishing an online presence for the government. With transaction as the second stage, digital government initiatives will focus on connecting the internal government system to online interfaces and allowing citizens to transact with government electronically. In the stage of vertical integration, for example, once a citizen filed for a business license at the city government, this information would be transmitted to the state's business licensing system and to the federal government to obtain an employer identification number. The final stage, horizontal integration, is defined as integration across different functions and services. Some scholars suggest there are four usage criterions for digital government strategies: information dissemination, social equality, privacy rights and public interests, with two broad criteria, such as information-content criteria and ease-of-use criteria (Kaylor, Deshazo, & Van Eck, 2001). These criteria have been applied to the assessment case study for the New Zealand government Web site in 1998 (Cullen & Houghton, 2000)

## BACKGROUND FOR DIGITAL GOVERNMENTS

According to the Office of Management and Budget (OMB) memorandum for *E-Government Strategy*, there are three aims in modernizing government: Make it easy for citizens to obtain service and interact with the federal government; improve government efficiency and effectiveness; and improve the government's responsiveness to citizens (OMB, 2002). Digital government offers the potential to deliver public services in a more efficient, more holistic matter, and improve a government's responsiveness to citizens' needs. Old divisions between governments, between tiers of government and even between the public and private sectors become increasingly irrelevant in the digital age.

Smart digital government should focus on the goal of helping citizens solve problems. Most people are not interested in which government agency, or even which tier of government, is responsible. Nor should they be.

Nor are they interested in bureaucratic acronyms and governmental self-promotion. Digital government should deliver services to citizens seamlessly and in a commonsense way, without requiring them to surf around to find the right Web site. Based on these substantial purposes that digital government has and the diverse approaches and the current usage patterns of digital government, we must reconsider how we understand the digital government, and what the substantial goals of digital governments should be. We can approach these basic questions through various theoretical backgrounds for digital government strategies. There are various theoretical models for digital government strategy: four-model by Dunleavy and Margetts (2000), two models by Glassey, and four stages models by Layne and Lee (2001).[4] In this study, I choose the Dunleavy and Margetts' model (2000).

### The "Digital NPM Scenario"

The digital NPM scenario was aimed at producing a dramatic displacement of demand from current physical services into electronic substitutes, with emphasis on substantial cost reductions for standardized public services and major cutbacks in public agencies' personnel numbers. NPM is focused on the disaggregation, competition and incentivization agenda, as well as cost-cutting potential, rather than on potential for enhancing quality of service or opening government to greater citizen accountability. From this approach, we can expect some negative impacts, such as: difficulty in making citizens appropriate recipients of corporate suppliers, strong resistance from small businesses and elderly people, digital divide and strong government mandating that citizens interact with them in particular ways. In other words, other forms of substantial costs have emerged in terms of damaging citizens' competence and levels of political involvement, along with a likely increase in policy complexity, as governments' remaining in-house capabilities for undertaking Web administration and Web-enabling hollow out.

### The "Digital State Paradigm"

This approach represents a different track, where radical Web-enabled change inside government replaces NPM as the dominant public administration paradigm. This approach works strongly against the fragmenting tendencies of NPM, and is much more integrative. In addition, Internet and Web changes are now one of the strongest forces for "joined-up government," for a "holistic" approach to data acquisition and utilization instead of the previously highly compartmentalized and non-communicating data "silos" of fragmented departments and agencies. This approach uses the Web as part of a process of continual organizational learning, making incremental improvements and testing effects on customers, which allows continual and rapid customer feedback; and entailing agency staff trying to get close to customers and use their feedback to reengineer public services. In addition, this approach dramatically enhances citizen competence and reduces policy complexity, and becomes the central operating tool of the whole organization, as well as the critical interface between government and society.

## INTERIM EVALUATION OF THE U.S. DIGITAL GOVERNMENT

Based on usage patterns of people in the U.S. and the theoretical backgrounds for digital government, the current appraisal results of the U.S. digital governments can be concluded. According to the Development Phase model, the U.S. is mainly in phase one and phase two, and in the field of criminal data integration, partly in phase three. According to four-stage models for digital government development, the U.S. is mainly in catalog/transaction with limited activities and vertical integration, in part based on different levels of government, such as criminal data integration. In addition, the U.S. is focused on economy-related activities rather than on broader public policy proposals, such as policy-related information dissemination or citizen participation. According to the United Nations (UN) assessment report on e-government readiness, among 191 nations around the world, the U.S. shows upper levels of ranking of government Web sites and online transaction services, but e-participation, citizen participation and feedback on policies still have a long way to go (see Figure 1).

Based on these appraisals, there is an emerging issue: Interactive communication and service delivery, in particular, require developers to re-think past assumptions and their own training and, on a daily basis, implement new and different ways of using rapidly changing technology (OMB, 2002). The result of this shift is that governments are using technology to present information in old ways and are also moving to develop new ways of presenting information and providing services for citizens. These changes will continue to occur as the public sector gains experience with and learns to exploit its potential. The phenomenon of the government on the Web promises to change how governments interact with their citizens, how the democratic process unfolds (Stowers, 1999; Beachboard, McClure & Wyman, 1997; Layne & Lee, 2001).

For this reason, some scholars suggested that we have to reconcile the incoherent directions of develop-

*Figure 1. The interim evaluation of e-government of the U.S. (UNPAN, 2004)*

ment between NPM initiatives and digital government strategy (Dunleavy & Margetts, 2000).

## BARRIERS TO THE "DIGITAL STATE PARADIGM" IN THE U.S.

The digital state paradigm can be seen as a new approach for current digital government strategies, since the current digital NPM scenario has already pointed out some critical problems (Leigh & Atkinson, 2001; OMB, 2002) and the necessity of "digital state paradigm" has been suggested as a new way of thinking for better digital-government. In this article, I will suggest some barriers to improving the "digital state paradigm" in the U.S.

First, "stovepipe" structures of digital government (Leigh & Atkinson, 2001) "Island of Automation" (OMB, 2002) are prevailing in the U.S. Too many government Web sites still require users to know which agency delivers the service they are seeking (Legal, 2004). Government Web sites only list information provided by the agency. Leigh and Atkinson (2001) also pointed out the limitation of the chief information officer (CIO) at all levels of government, because they have narrow-minded perspectives focusing on their own departments or agency rather than integration or information sharing among organizations.

Second, portals of digital government are focusing on programs and politicians (Leigh & Atkinson, 2001). Although the role of digital government is to help citizens, too often, digital government seems to be a publicity portal for programs and politicians. The worst Web sites give top billing to a photograph of the governor or secretary with the latest press release from the agency highlighted. They then proceed to list their own government programs, often with indecipherable acronyms. Third, portals are unfriendly to the user. Web sites need to be designed with an intuitive interface, making them easy to navigate. Instead, too many are confusing and unfriendly, particularly once the user goes a level or two past the opening page. The different database structures and languages also contribute to more unfriendly portals.

Fourth, search engines of digital government do not work smoothly. When you try to use a search engine, you are more likely to be presented with reports, financial statements and press releases about specific issues than useful text on how to get information you want. In other words, many Web sites are not properly divided into a core database system. Fifth, digital governments are focusing on efficiency rather than on citizen participation. Digital government strategy based on NPM focuses on the managerial aspects of e-government strategy rather than on citizen participation or open governments (Dunleavy & Margetts, 2000). Even though some studies show that there was no closely related correlation between information technology (IT) spending and organizational efficiency in the United Kingdom (UK) and the U.S., a lot of published purposes or goals are still mainly focused on cost reduction and efficiency using digital government strategies.

Sixth, policy usage of digital government is still insufficient (OMB, 2002; UNPAN, 2004). Many government Web sites lack policy usage. Instead, they focus on information-providing from the perspectives of the providers. The government Web sites rarely provide policy usage except when providing budgetary information. Some government Web sites tried to use the Web as the means for policy usage, but still there is much more room for policy usage.

Seventh, there is insufficient time and resources for implementing digital government strategies. To implement digital government strategies, governments need a lot of time and resources, but the replacement of leaders by election on a regular basis and limited resource allocation influenced by economic circumstances make digital government strategies work in reality. Finally, a lack of clear policies and guidelines focused on effectiveness is another barrier for implementing digital government strategies. Although electronic media may seem to provide universal access to information and specifically to government information, without clear policies and guidelines focused on this outcome, the citizen's access to information, and the government's accountability for information provision, may be reduced rather than enhanced.

In addition, there are many barriers to government information—physical, economic, intellectual and technological—that may impede citizens' participation in democratic processes of their own nation and society (OMB, 2005). These barriers might be actively impeded

by government, or they may be allowed to continue simply through lack of action by government. The same barriers can also impede intra-governmental information flows.

## FUTURE TRENDS FOR E-GOVERNMENT IN THE U.S.

First, digital government will increase the importance of e-democracy. Clear goals and purpose for e-democracy will reconcile efficiency and citizen participation (Leigh & Atkinson, 2001). For this purpose, each government's strategic plans, including the OMB memorandum for digital governments, should be revised, giving priority to the policy usage or electronic citizen participation. In particular, bureaucracies should have the more positive perspective on information sharing and open government, because this kind of strategy will, in turn, contribute to improving efficiency and stability of policy implementation. We have to consider that we can use the Web for strategic planning teams, including current public officials, when we are setting goals and purposes. In addition, we have to make a coordinating environment between agencies' line managers and Web master when we establish a government Web.

Second, a one-stop shopping concept will be applied to e-government strategies. Ideally, a citizen should be able to contact one point of government and complete any level of governmental transaction. From the viewpoint of all levels of government, this could eliminate redundancies and inconsistencies in their information bases for citizens (OMB, 2002). For this purpose, governments should establish horizontal integration as well as vertical integration, including private sectors. We may consider that the central CIO, such as e-envoy in the UK, is needed for coordination and giving guidelines to all levels of governments in the U.S.

Third, the importance of up-to-date information and securing digital government usage by the people will be increasing. Accuracy includes timing for appropriate and useful information and correctness of the information provided by e-government. These characteristics are related to confidence in the government, so checking for accuracy and up-to-date information are considered in the digital state paradigm.

Fourth, personalized pages will prevail to make pages convenient and users feel secure. One way corporate Web sites encourage repeat business is by allowing users to personalize their viewing by identifying their particular interests. Government Web sites can use the same technology to make life easier for users. For example, North Carolina's Web site allows users to create a login and password and customize how the page appears by identifying the categories of information they are interested in. OpenGov.com, a Web site of the UK, has used these kinds of Web pages.

Fifth, digital governments will make a greater variety of interactivity—ways to actively increase citizen participation and citizen competence in using digital government strategies (Leigh & Atkinson, 2001; Holzer, Hu, & Song, 2004). There are several patterns for interactivity, such as e-mail addresses; comments; soliciting inputs; complaints; and service requests. In addition, computer conferences or full discussion areas using digital government have to be introduced more broadly and frequently. Recently, an interactive Web-based survey tool developed at the University of Illinois at Chicago was applied to advance a community planning process.

Finally, the processes of e-government implementation will be monitored or evaluated with The E-Government Act of 2002. With this monitoring, e-government strategy as well as implementation will be evaluated by OMB regularly (OMB, 2005).

## CONCLUSION

There are several critiques of the U.S. digital government strategies, because these focus on digital NPM strategies, emphasizing the managerial side for improving efficiency rather than increasing interactivities like public participation or public competences. These criticisms forced the creation of a new alternative for digital government, and the digital state paradigm is being considered as a new alternative for digital government strategy. The digital state paradigm focuses on closing the distance between state and society through interactive ways and participation, open government and making more democratic political procedures in policy-making and implementations. As a way of improving the digital state paradigm, barriers for it should be addressed. However, the new approaches to digital government focusing on the digital state paradigm do not say that we do not need to consider the managerial perspectives of the digital government; rather, both parts are reciprocally supplemented.

## KEY TERMS

**Citizen Competence:** The capacity of the people to understand what happens around them and within the society, as well as the ability to decide some social issues with appropriate information and sound judgment.

**Digital NPM Scenario:** Focusing on the managerial side of digital government strategies as a way of increasing efficiency and productivity of public services.

**Digital State Paradigm:** Focusing on the bridge between state and society via digital government strategies and emphasizing citizen competence and trust through mutual communication between the state and the citizen.

**Four Models of E-Government Evolution:** Explaining e-government evolutions in four stages: Emerging level, enhanced level, interactive level and transactional level. Recently, a seamless level has been added as the fifth evolutional level of e-government.

**One-Stop Shopping:** Providing related Web sites to easily access necessary information and useful service through visiting one portal or Web site.

**Stovepipe Structure:** A structure of the digital government that focuses on each department and only lists information provided by the agency without considering integration or information sharing among organizations.

**Transaction Function:** Carrying out some government services electrically without visiting the public places that provide diverse governmental services to the people. For example, transaction functions include paying taxes using the Internet, renewing driver's licenses via the Internet and issuing some documents without visiting the public offices.

## ENDNOTES

1 One research result claimed that there are two kinds of cost shifting rather than cost saving: E-government strategy needs a huge amount of investment both in government and individuals for preparing this plan, and has caused a serious accessibility problem that we called "digital divide." The other example of cost shifting is from government budget to the individual's time and perseverance. In addition, the author considered the privacy problem, privatization and so forth. For more detail, see Jacobs, J., & Peterson, K. (2001). The technical is political. *Of significance, 3*(1), 25-35.

2 Some scholars claim that the beginning of e-government based on the Web was the establishment of the White House Web site in 1993 and Congress in 1994. For more detail, see Leigh, A., & Atkinson, R. D. (2001). Breaking down bureaucratic barriers. *Progressive Policy Institute's project report*.

3 According to Karen Layne and Jung-woo Lee, they divided digital government development into four stages: catalog, transaction, vertical integration and horizontal integration. For more detail, see Layne, K., & Lee, J-W. (2001). Developing fully functional e-government: Four stage model. *Government information quarterly*, *3*(18), 122-136.

4 For more detail, see Layne, K., & Lee, J.-W. (2001). Developing fully functional e-government: Four stage model. *Government Information Quarterly, 3*(18), 122-136. Also see Glassey, O., *Model and Architecture for a Virtual One-Stop Public Administration*, Switzerland.

# Digital Government Online Education for Public Managers

**Marc Holzer**

## INTRODUCTION

The opportunities that arise from the practice of digital government continue to increase. Public managers responsible for adopting and implementing such new practices will be searching for existing best practices to incorporate into their respective communities. They may choose to rely on their information and communication technology (ICT) departments to develop necessary digital government applications, but an appealing option for public managers is to familiarize themselves with the most recent digital government applications through Web-based courses. Online education eliminates distances, allows for flexible scheduling and can incorporate current best practices of electronic-government on a timely basis.

Public managers play a critical role in the development of digital government initiatives (Halachmi, 2004; Heeks, 1999; Ho, 2002; Melitski, 2003; Weare, Musso & Hale, 1999). Although public managers can refer to numerous individuals within government municipalities, in the case of digital government, the chief administrative officer (CAO) is often the key individual in deciding the direction of government initiatives. By completing Web-based courses, CAOs can assess and strategically plan for effective and efficient digital government in their communities. Melitski (2003) argues that there is a need for public mangers that are "familiar with both IT and the programmatic goals and missions of public organizations" (p. 389). With respect to implementing digital citizen participation in government, Holzer, Melitski, Rho, and Schwester (2004) state, as their primary recommendation, "governments should work harder to identify, study, and implement best practices" (p. 28). The means to study such best practices, however, have generally been scarce, and the literature has been limited to specialized e-government reports and articles. But Web-based courses now offer the means for a CAO or any other public manager to study digital government practices and theories in a more effective and convenient manner.

## BACKGROUND

In order to optimize their city's e-government performance, public managers now have opportunities to educate themselves via a growing number of courses that address digital government in public administration and management programs. Some of these courses are also being offered online; however, Web-based courses that focus on digital government's opportunities and challenges are still rare. Web-based education, which is also termed online education, utilizes the Internet to deliver distance education.

Web-based education involves two types of learning: asynchronous and synchronous. In asynchronous online education, students do not need to interact with the instructor in real time. Students can complete a Web-based course on their own time and schedule. Asynchronous online education currently dominates Web-based education because of the advantage of individual control of time (Kim, 2004). Synchronous online education has an advantage when geographically dispersed students and the instructors interact in real time using communication technologies such as digital audio, digital video, and text-based messaging software (Martinez, 2004). Synchronous education is more popular in academic programs than in training programs (Kim, 2004).

Web-based education results in significant, positive outcomes, so that institutions need to learn "how to leverage the technological resources in curriculum and course design, student access and support" (Mayadas, Bourne, & Moore, 2002, p. 9). Web-based education requires effective tools to create, manage, and deliver content and collaborative activities. For that reason, "the selection of a course management system, which uses

templates designed for Internet-enabled instruction, is important in developing online courses" (Kim, 2004, p. 279).

Web-based education is increasingly utilized by academic institutions as a hybrid teaching approach in order to support face-to-face teaching and learning. Further, the United States government has attempted to develop advanced distributive learning initiatives through online education. However, these Web-based courses are typically limited to students within academic programs, whereas public managers may be seeking in-service courses about government's opportunities and challenges. One approach is certificate or continuing education programs for public managers. For example, the National Center for Public Productivity (NCPP) offers an online *Certificate in Public Performance Measurement,* with five-week modules such as "E-government and Citizen Participation" (NCPP, 2004). This certificate program includes practitioners, academicians and students. Designed as one-credit courses, these modules are built around course readings, case studies and online discussions. The e-government and citizen participation module addresses issues and opportunities of digital government, and provides case studies. The following five subject areas are based on this certificate module, and may serve as a model for similar Web-based courses in other venues.

## DIGITAL GOVERNMENT INITIATIVES

One of the first objectives that any course on digital government should cover is the various definitions, initiatives and forms of practices. E-government, digital democracy and digital divide are just a few of the terms that should be defined at the onset and then further developed throughout the course. This encyclopedia is an ideal reference for such courses as it includes definitions and developmental perspectives on digital government. The following readings can complement the Encyclopedia as they incorporate cases and studies relevant for municipal digital government. Melitski (2004) provides a thorough overview of e-government, including definitions and distinctions used in the public sector. O'Looney (2002) outlines some of the possibilities of a digital government for public managers, while Ho (2002) identifies typical initiatives among local governments. Moon (2002) highlights the status of e-government in relation to its expectations.

## DIGITAL GOVERNMENT CONSIDERATIONS

Following a grasp of the terminology and practices of digital government, organizational capacity and the digital divide should be addressed. The ability to practice e-government is dependent on the organization's capabilities and the community's resources for interacting digitally with government. Chen and Perry (2003) and Melitski (2003) address issues of organizational capacity and outsourcing for e-government. But the capacity to reach the community must be complemented by an understanding of the digital divide. If certain populations within a community lack Internet access or Internet-related skills, then the utilization of e-government services will be limited. The U.S. Department of Commerce (1999) has produced a report that outlines various issues associated with the digital divide: households without computers, access to the Internet, and the method of Internet access. Samuel (2002) looks at strategies to move beyond the divide: effective uses of public access points, facilitating computer purchases, and making Internet access more affordable.

## CITIZEN PARTICIPATION AND DIGITAL DEMOCRACY

An area that often reflects more advanced practices of digital government is citizen participation. Active and equal participation in government by citizens via the Internet is a necessary basis for digital democracy. Kakabadse Kakabadse, and Kouzmin (2003) discuss democratic governance through information technologies. This is part of a larger debate centered on the concept of a digital or electronic democracy. West (2004) looks at the transformation of service delivery via e-government and the resulting attitudes of citizens. The ability to include citizens in government is not limited to service delivery, but can expand to citizen involvement in the decision making process. Holzer et al. (2004) look at the possibilities of digital citizen participation for "restoring trust in government." Online discussion boards, real-time chat rooms, and e-mail exchanges with elected officials are just a few of the means by which citizens can actively engage government, and exemplary cases of digital citizen participation can be found at every level of government.

## DIGITAL GOVERNMENT BEST PRACTICES

Case studies should reflect local, state and/or federal government practices, depending on the course participants. Regular studies survey digital government practices annually with reports highlighting particular areas where governments excel or fail. One such e-government survey at the local level is done annually by the Center for Public

Policy at Brown University. West (2003) reports on the research done by this Center with an analysis of the most populated urban areas within the United States. The Center for Digital Government does an annual study at the state level: Digital States Survey (2003). Holzer and Kim (2004) at the National Center for Public Productivity and Sungkyunkwan University have developed extensive survey instruments (92 measures) to evaluate digital governance throughout the world and will replicate that bi-annually. In addition, individual case studies such as Kim and Lee (2003) look at the success of the Seoul metropolitan government's Open System, as do Holzer and Kim (2002). Other studies of current digital government projects include those done by the Organisation for Economic Co-Operation and Development (OECD, 2003) and United Nations Development Programme E-government Primers (Pascual, 2003). Individual cases also allow for specific comparisons and challenges that public managers may encounter.

## DIGITAL GOVERNMENT AND PUBLIC MANAGERS

The final week of the module allows CAOs the opportunity to design a framework for exemplary digital government practice in their communities. There are no assigned articles or case studies for the week, allowing time for a final project. This project is expected to include the concepts discussed throughout the module. In addition, the best practices studied in Week IV will provide specific examples for public mangers to use in their designs.

## FUTURE TRENDS

The potential for online education of digital government depends on the courses being designed to meet the needs of public managers. The modules used in the *Certificate in Public Performance Measurement* are designed to cover various topics in a short period of time. They include weekly papers, weekly discussion topics, and 2-4 readings a week. The following module is limited to 5 weeks. The following outline provides a general structure of a course in digital government using readings such as those previously suggested.

- **Digital Government Initiatives:** Would you define digital government differently at a local level as compared to national government practices?
- **Digital Government Considerations:** Is the digital divide an issue that CAOs should be held responsible for in communities where digital government is practiced?
- **Citizen Participation and Digital Democracy:** Define in your own words what digital democracy entails and its potential in the next decade.
- **Digital Government Best Practices:** What challenges may survivors face in studying different e-government practices throughout regions?
- **Digital Government for Public Managers:** Beyond those cases discussed in the readings, are you familiar with any digital government practices that are exemplary?

## CONCLUSION

The 5-week module was based on an existing course offered by the National Center for Public Productivity; however, additional courses can and should be developed that address the specific issues that are discussed in this Encyclopedia, focusing on capacity, planning, and development of digital governments. The medium of the Internet offers great opportunities for public managers and scholars to stay current on contemporary practices and issues. Digital government holds a great deal of promise for a truly digital democracy. To reach such expectations those responsible for implementing such practices must become knowledgeable as to the subject. Web-based courses for public managers on digital government can provide insight to current scholarship and best practices throughout the world. Online courses must also meet the needs of public managers, and as the outline above has exemplified, this can be done through short and direct course modules.

## KEY TERMS

**Digital Citizen Participation:** The active participation of citizens in government or organizations with the use of ICTs.

**Digital Democracy:** Government information dissemination to and participation by citizens via ICTs.

**Digital Divide:** Refers to segments of the populations lacking Internet access or Internet related skills.

**Discussion Boards:** Online communication forums among groups/communities categorized by specific topics or questions.

**Chat Rooms:** Online discussions that occur at real-time, unlike discussion boards that occur over longer periods of time.

**ICT:** Information and communication technology, often used in reference to such technologies such as the Internet.

**Web-Based Courses:** Also termed online education, utilizes the Internet to deliver distance education.

# Digital Information Kiosks

**Anna Ya Ni**

## INTRODUCTION

The word "kiosk" is derived from the Turkish word "kösk," meaning an open summerhouse or pavilion. Before the arrival of computer technologies, a kiosk was a small, rugged standalone structure often used as a newsstand or bandstand in public places. As early as the 1870s, kiosks could be found in the streets of Paris for displaying theater and gallery advertisements.

The advancement of information technologies in the 20th century gave information kiosks a new meaning. Instead of being simple post-boards for printed materials, digital information kiosks now provide not only easy and convenient access to information, but also transactional services that traditional kiosks could not perform. As the scope of digital government continues to expand, digital kiosks are becoming an important platform to support a wide range of e-government strategies.

## BACKGROUND

For the past decade, many policymakers and managers have been excited about the potential and promise of "e-government." By putting transactions and public information online, a government can give citizens and businesses more convenient and flexible access to public services and more direct interaction with public officials. This also offers significant cost-saving potential by reducing the need for office personnel and office space.

It is therefore not surprising that many governments have expanded the scope of e-government services tremendously over the past few years, especially in the areas of information provision, online feedback and complaint forms, license applications, and fee payment (Cook, 2000; Ho, 2002; Moon, 2002; West, 2000, 2002). At the same time, inequitable access to the Internet and technological opportunities among different population groups, which is sometimes known as the "digital divide," has become a rising social concern. Past studies have found that minority populations and households with lower income and less education tend to have fewer opportunities to access computers and use Web-based services (Bertot, 2003; Wilhelm, 2000). If traditional access to public information and services is gradually replaced by online platforms, those population groups who have less access to the Internet will be disadvantaged not only in public service usage, but also in their opportunity to voice their opinions and participate in democratic governance.

These are some of the reasons why public officials have expressed an increased interest in kiosk technologies in recent years. Many policymakers realize that, in addition to Web site development, part of their e-government strategy should focus on how the government can provide more equitable access to online information and services, and one of the tools to accomplish this goal is digital information kiosks.

## DIGITAL INFORMATION KIOSKS

A digital information kiosk is a computer-based device that provides an interface medium between users and a service or information provider with features designed to make it suitable for the general public (Sargent & Mclvor, 1996). It is usually composed of a hard outer shell, an internal computer, and a monitor that enables users to make selections using a touch-screen or keyboard (see Figure 1). Since the device is expected to withstand high traffic, long hours, and potential user abuse, it is specifically designed to include some fail-safe and energy-saving features, provide only limited functionality and user access, and contain stronger physical protection of the equipment. Some kiosks also have special visual or audio effects to catch the attention of the public so that certain information or advertisements can be disseminated more effectively. In addition, some kiosks are equipped with Braille instructions or voice enunciation to serve the needs of the disabled.

With the advancement of information technologies, digital information kiosks can now perform functions that traditional kiosks could not do. Traditional kiosks primarily play the role of information dissemination by posting posters or notices on a board for passers-by. The commu-

*Figure 1. A digital kiosk unit deployed by the U.S. Department of Housing and Urban Development*

nication between the information provider and readers is one-way, and the latter only play a passive role in determining what information they receive. Digital kiosks, on the other hand, can go beyond this by offering interactive or transactional services. For examples, many digital kiosks have an interface where a user can make a choice of content by pushing the buttons on a touch-screen or filling out a form using a keyboard. Some kiosks that are equipped with a credit card reader or a cash taker can also support financial transactions, such as buying tickets, paying fees, making deposits or withdrawing money.

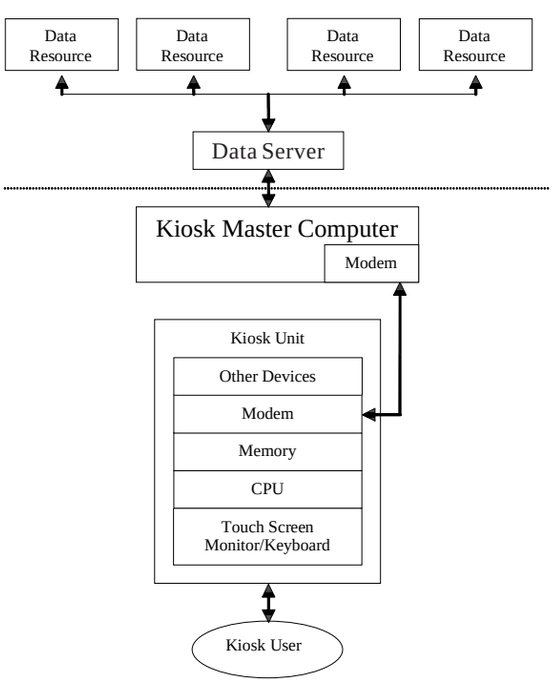
In general, digital kiosks can be grouped into the following three major categories (Morris, Sanders, Gilman, Adelson, & Smith, 1995; Ni & Ho 2005; Tung & Tan, 1998):

- **Information Dissemination and Advertising Kiosks:** These kiosks are primarily used for information display and can be commonly found in trade conferences, showrooms, tourist spots, and visitor centers. Users may request information through a touch-screen monitor, or use voice-activation to navigate through the information menus. Proximity detectors may also be used to automatically start an advertisement module with sound and video when a potential customer is close to the kiosk.
- **Interactive Information Kiosks:** These kiosks allow two-way communication between the provider and users in order to both automate information access and collect information. They can be found in high pedestrian traffic areas, such as airports, stores, malls, and convention centers. Users may input information, such as names, codes, or dates, through a touch-screen or, less frequently, with a keyboard. Hard copy output, such as maps and coupons, can be provided if the kiosk is accompanied by a printer.
- **Transaction Kiosks:** These devices are relatively more advanced because they allow for more complex and secure transactions and information exchange. Kiosks of this type can access and update databases, and require personal identification for transactions. Besides a touch-screen or a simple keyboard, transaction kiosks need additional room and security features to allow them to accept cash or credit or debit cards.

While an advertising kiosk or a data collection kiosk may contain all the information and services internally in its hard drive, it is more common to connect the machine with a computer network. The latter allows instant update of information by content providers, enables more effective monitoring and control, and reduces maintenance burdens and administrative costs. A typical kiosk network contains the following components: one or more servers, an operator workstation, telecommunication equipment, and kiosk computers and related devices (see Figure 2).

Kiosk network technologies have existed for a long time. In the private sector, for examples, financial institutions have deployed automatic teller machines (ATM), an early form of transaction kiosks, for decades. Some retail stores have also used kiosks to provide customer and product information (Rowley & Slack, 2003). In recent years, many airlines have used digital kiosks to let passen-

*Figure 2. Kiosk system data flow (Ni, & Ho, 2005)*



gers do their own check-ins to simplify the process and cut cost (Melnick, 2003).

Hence, the public sector is relatively behind on the technology adoption curve and is trying to catch up. The recent interest in kiosk technologies for public sector applications is motivated by both economic and policy reasons. First, similar to the rationales for private industries, the government wants to adopt the technologies to cut administrative costs and paperwork. Kiosks can be used to substitute for or complement a human information agent. Although a kiosk system still involves maintenance and development costs, a government agency may save a considerable amount of salary, benefit, and insurance costs in the long run because these expenditures have been rising rapidly for the past decade.

Kiosks can also help handle the peak hours demand for services, such as during early mornings, lunch hours, and late afternoons, when many citizens may come to visit the government office to avoid interrupting their normal work schedule. Kiosks can be used to handle some of these citizens' requests for services and reduce the need to hire additional or temporary labor assistance. This not only creates financial savings, but also allows public managers to avoid collective bargaining and other personnel regulations and have greater flexibility in deciding when and where to deploy a service, and when they may terminate it.

In addition to economic reasons, there are also policy reasons why many government agencies are looking into the kiosk technologies. As a result of the reinventing government movement and the wave of new public management, many agencies are emphasizing the need to provide better customer services and more convenient access for the public. Digital kiosks therefore become a natural solution to this goal, as many services, such as license applications and renewals, fee or fine payments, and access to government forms and public information, can be obtained through kiosks without the limitation of office hours and office location (Kitfield, 1994; Maxwell, 2001; Walsh, 2000). In addition, public officials can collect information about citizen preferences almost instantaneously through kiosks. By analyzing what kiosk services citizens browse and use, public officials can use data mining techniques to identify service priorities and tailor service provision that better fits the citizen demand (Hill, 1997).

Furthermore, by placing digital kiosks strategically in disadvantaged neighborhoods, community centers, and schools, a government can use the technologies to address the problems of the "digital divide." Kiosks are especially helpful in addressing the information needs of the disabled and certain minority populations who are less comfortable with the dominant language in a community. By equipping kiosks with multi-language options and voice-activated instructions, a government agency can reach out specifically to these population groups so that they receive equal access to various e-government services.

## FACTORS INFLUENCING THE SUCCESS OR FAILURE OF DIGITAL KIOSK PROJECTS

No matter how great the potential benefits of a kiosk system might be, the ultimate social and economic benefits of the system are determined by how much they are used. The degree of usage depends on seven factors: location, applications, ease of use, aesthetics and ergonomics, structure, and security (Hill, 1997; Morris, et al., 1995; Tung & Tan, 1998) (see Table 1). Kiosks need to be placed in high traffic areas that are safe and convenient

*Table 1. Evaluation metrics for kiosk system*

| Factors | Metrics |
|---|---|
| Location | • High traffic flow<br>• Convenient access |
| Applications | • Matching the type of kiosks<br>• Suitable for the targeted users<br>• Versatile to meet the various needs of targeted users |
| Ease of Use | • Intuitive and consistent interface<br>• Easy application navigation<br>• Simple data entry<br>• Clear and concise instructions<br>• Fast response |
| Aesthetics and Ergonomics | • Unobtrusive to the environment<br>• Comfortable touch screen or keyboard position<br>• Durable interface and cabinet design against environment stress |
| Structure | • Modularized structure for easy replacement of parts |
| Security | • Protected from theft and vandalism<br>• Uncompromising confidentiality of users' information or transactions |

to citizens. They also need to provide services that have high demand but are constrained by the personnel capacity or the physical location of an agency. The design of the kiosk interface should be intuitive, clear, and consistent, and the physical design should be friendly not only to users but also to the maintenance crew. If the kiosks are to perform financial transactions, how to ensure network security and protection of the users and the machines from theft and physical harm are also important.

In addition, how to manage a kiosk system is also critical. Many past kiosk projects failed because the governments failed to budget for the full costs, did not have effective cost control and monitoring of private contractors, overlooked the importance of cost-recovery and marketing strategies, and did not retain sufficient financial and technical capacity to sustain a system in the long run (Ni & Ho, 2005). Therefore, the following are critically important in managing a kiosk project (Hill, 1997; Ni & Ho, 2005):

- Identify the targeted user groups and develop a reasonable estimate of the potential demand for the services
- Develop a clear strategic plan that specifies the rationales and goals of the kiosk system and the deployment phases and strategies
- Develop specific action plans that define who should be responsible for maintaining and financing the services after the system is launched
- Develop a team approach in the design of the system by involving all relevant agencies, vendors, and other internal and external stakeholders
- Develop a full budget that covers not only the initial development costs, but also the maintenance and operating costs over the use life of the system
- Investigate and evaluate thoroughly different kiosk technologies available in the market, including their costs and technological cycles; avoid the newest technologies that may not be fully tested, and at the same time, beware of the problems of using technologies that will be phased out in the near future as they may create a lot of maintenance difficulties
- Develop clear performance goals and monitoring standards for private contractors if they will be used
- Develop a marketing plan to increase the public awareness of the services

## FUTURE TRENDS

In many developed countries, digital information kiosks are commonly found in public places, such as in libraries, museums, airports, and highway rest areas. In the United States, the Department of Housing and Urban Development (HUD) has placed kiosks in many cities across the country to provide information, ranging from how to buy a house to where to find the nearest homeless shelter.[1] In Ontario, Canada, the award winning kiosk project, ServiceOntario by the Ministry of Transportation, allows citizens to renew license plate stickers, search driver, vehicle and carrier records, update address information, pay court fines using VISA or Mastercard, and view and order graphical license plates in convenient locations.[2]

A number of developing countries have also begun to deploy the technologies. In India, for example, information kiosks are placed in rural villages, providing poorly educated villagers—who have reaped few benefits from the country's booming trade in information technologies—with direct access to government officials and records as well as to online services such as banking and medical consultations (Lancaster, 2003).

Some predict that in the future, public kiosk systems will be as common as automated teller machines are today (Maxwell, 2001). The technologies will also be used to provide an even wider range of informational and transaction services. For example, digital kiosks can be used to address the future needs of homeland security. As the kiosk technologies continue to evolve and become more integrated with smart card systems or identification systems, digital kiosks may perform a broad range of security functions, including applications for, or renewal of, essential government documents, such as traveling documents or drivers' licenses. In addition, patrols at airports and at border checkpoints can use digital kiosks to verify the personal identity of legal residents more cost-effectively.

Future kiosk development may also lead to new potential of e-governance. At present, most governments only use kiosks for service provision. However, as the identification functions become more secure and standardized, and as more citizens become comfortable with using computer technologies to interact with their government, information kiosks can be placed in public places so that citizens can use them not only to file complaints or request for services, but also to participate in public policy forums, do electronic voting, and provide other forms of direct input into the policymaking process.

## CONCLUSION

Citizen-friendly and convenient access to public information and services is an important goal for effective governance. This is why many governments today have deployed digital kiosk systems as a platform for service delivery. As the technologies continue to advance and

become more widespread, more citizens may rely on them to interact with the government and get what they need 24 hours a day, seven days a week.

Since the widespread adoption of kiosk technologies in the public sector is still a recent phenomenon, more future research about their use is still needed. For example, how the technologies have impacted the labor-government relationship, whether it has impacted citizens' perception of the effectiveness and customer-orientation of the government, and how the technologies can be used more effectively to advance citizen participation and electronic voting, are some of the questions that future researchers may investigate further.

## KEY TERMS

**Braille:** A system, named after its inventor, of representing letters by raised dots that blind people can read by touch.

**Data Mining:** The process of using analytical techniques to search for meaningful correlations, patterns, trends in a large group of data.

**Digital Divide:** The gap between the information-haves and have-nots, suggested by Lloyd Morrisett. It is marked not only by physical access to computers and connectivity, but also by access to the additional resources that allow people to use technology well.

**E-Government:** A short-form of "electronic government," which refers to governmental effort to enhance access to, and the delivery of, services and public infor-

mation for citizens, business partners, employees, and other governmental entities through information technologies, particularly Web-based Internet applications.

**Information Dissemination Kiosk:** A kiosk system used to display information or to advertise product by providing information about it.

**Interactive Information Kiosk:** A kiosk system used to automate information access or to collect information through interactive communication between users and the provider.

**Kiosk Network: A** series of digital kiosks and other computing devices interconnected by communication paths.

**Proximity Detector:** An electronic sensor which detects the presence of an object within a user-selectable range of the device.

**Touch Screen:** An intuitive computer input device that is operated by touching the virtual push button on the display screen.

**Transaction Kiosk:** A kiosk system used to sell goods and services or to exchange information.

*University of Salerno, Italy*

## INTRODUCTION

Up to 1980, *development*, which had been defined as nationally managed economic growth, was redefined as "successful participation in the world market" (World Bank, 1980, quoted in McMichael, 2004, p.116). On an economic scale, specialization in the world economy as opposed to replication of economic activities within a national framework emerged as a criterion of "development." On a political level, redesigning the state on competence and quality of performance in the discharge of functions was upheld, while on an ideological plane, a neo-liberal and *globalization project* was to the fore.

The quite evident failure of development policies in peripheral countries, on the one hand, has contributed to the debate on the need for reform of governing institutions in the world (de Senarcless, 2004); and, on the other, has pushed them, de-legitimized as they are, in the direction of finding new strategies and solutions. In the 1990s, considering their leading role in government reform, international organizations such as the United Nations Organization (UN), the World Bank, the Organization for Economic Co-operation and Development (OECD) and the World Trade Organization (WTO) classified e-government as a core issue on their agenda.

Innovation through information and communication technologies (ICTs) (social and economic advancement among the peoples of the world has become increasingly tied to technology creation, dissemination and utilization) is at the core of the renewed focus on the role of the state and the institutions in this process. Redefining the state—functions, responsibility, powers—as regards world-market priorities and logics, has become a strategic ground for international organization intervention, and ICTs are a strategic tool to achieve these aims.

## BRINGING THE STATE BACK IN

While during the 1980s, the government reform movement had concentrated on deregulation, in the 1990s, it focused more on the reform of core state functions and the building of state capacity. Even though that during this decade for first-world countries, efficiency and the extensive introduction of information technology (IT) for government were fundamental, and the efforts of developing countries were more on building state capacity, decentralization and fighting corruption, differences were not absolute. Converging reform strategies have been widespread.

In the developing world, the impetus for reform of the state came, more often than not, from the development institutions on which those countries relied. Thus, the reform movement involved the re-creation of the state along lines that would help, not hinder, the newly created market economies. Starting in the 1990s, the institutions for development turned their attention and their funding to governance issues. The World Bank, the International Monetary Fund and the OECD all developed extensive programs offering financial resources to countries interested in developing state capacity.

Rethinking the state's role in development is a prerequisite for the *structural adjustment programs (SAPs*). This is a shift in bank-lending policies from providing assistance for developmental concerns to aid for comprehensive policy reform. The World Bank's premise for the shift was that post-colonial development states were overly bureaucratic and inefficient on the one hand, and unresponsive to citizens on the other. This strategy is a way of rebuilding states, through institution building. In this phase of bank involvement, the states are committed to the redefinition of the government's economic priorities. The state sheds its accountability to its citizens, who lose input from their own government.

The UN—recognizing that the state has a key role in the development process and in making globalization work for all in alleviating poverty and income inequality, advancing human rights and democracy—commissioned a report from the Department of Economic and Social Affairs. The *World Public Sector Report* reviews major trends and issues concerning public administration and governance and is published regularly every 2 years.

Moreover, the UN, under the auspices of its Development Programs section, established a program in Public Administration and Civil Service Management Reform. In recent years, it has coordinated external assistance in promoting a professional civil service, transparency, the use of ICTs and other areas of government reform in more than 90 United Nations Development Program (UNDP) countries.

Their funding policy did not seek to recreate the bureaucracies of the 20th century. Rather, their recommendations were couched in the language of new public

management and in favor of reinventing government movements that were popular in first-world countries. For instance, the World Bank declared in its 1997 *World Development Report*:

*[State capacity] means subjecting state institutions to greater competition to increase their efficiency. It means increasing the performance of state institutions, improving pay and incentives. And it means making the state more responsive to people's needs, bringing government closer to the people through broader participation and decentralization.* (Kamark, 2004, pp.18-19)

One implication of this strategy is an expanding trusteeship role for the multilateral agencies that subordinates national policy to the demands of the global economy. Development is namely about policy reform in which ICTs become one of the main implementing tools for organizational and institutional consolidation (Heeks, 2002). This was the prevalent approach throughout the 1980s and '90s. It reflected the spirit of the time and was summed up in the formula *Washington Consensus* (Williamson, 1993); that is, universal convergence on specific principles seen as a shift from bureaucratic centralization to market logics on the one hand, and the establishing of a new way of framing development issues and policies for development on the other.

The UNDP and the UN Conference/Council for Trade and Development (UNCTAD), however, denounced the ever-wider gap between different countries. The responsibility for shifting the approach and the agenda of the international organizations, however, did not lie with these dissenting "voices," but rather with the total or partial failure of e-government for development projects. These failures come at a high price for the world's poorer countries; that is, those very countries which, according to the prevailing paradigm, should have gained most advantage from e-government policies (Heeks, 2003).

## DIGITAL GOVERNMENT OPPORTUNITIES: MANY VOICES AND ONLY ONE REFORM AGENDA?

In the light of the data on the evident inefficiency of development schemes and programs in action, towards the end of the 1990s, a broad-spectrum rethinking policy on strategies to adopt on the part of the international organizations was implemented. Inevitably, e-government policies were affected, too. In a recent study, the UN declared (2004):

*At present, the disparities in access to ICT-related development for the future are remarkable and are likely to become greater, at the current rate of technological advancement. The challenge for development today is to find ways and means to surmount the inequality in development benefits from new technologies. The new paradigm of development requires a re-visitation of the way countries think about ICT and e-government. It needs innovative approaches to government and the public sector; business and the citizen; and culture and society. In other words, a holistic approach is required which fully exploits the centrality of ICT for the vision of a future knowledge society.* (p. i)

The UN *Global E-Government Readiness Report 2004* emphasizes this necessity to elaborate new strategies.

*The new imperative of development is to employ ICT applications across the board for creation of economic opportunities and human development. It is not a matter of choosing between traditional programs to further health, education or ICT, but choosing* the most effective way *for ICTs to help in the delivery of development goals. If disparities are to be removed in the collective global march towards a knowledge society, free access to information and knowledge must become a way of life for all* (p. ix)

Even the World Bank (1997) and OECD (2001, 2003a, 2003b) have adapted their strategies in the direction of a *state-friendly* approach. In the report *Information and Communication Technologies: A World Bank Group Strategy* (2002a), the necessity is underlined for "a shift in the approach to the sector" given that realizing the new vision involves broadening the Bank's established agenda (p. ix). The new strategic agenda envisages the broadening of the World Bank's action range to cover the entire information infrastructure sector. The G-8 Okinawa charter on the global information society concluded that the World Bank Group has an important role to play in this area: as a catalyst in improving access to ICTs and promoting their use for stimulating economic growth, increasing equality and reducing poverty.

The challenge has been to show that growth, liberalization and globalization are still good for the poorer countries, but in a multi-dimensional understanding of both causes and consequences of poverty in which the bureaucratic machine plays a crucial role.

Most recent developments are moving in the direction of convergence between international organization strategies, as emerges from the joint proposals and schemes for identifying medium-term goals for global development, tools for achieving it and for progressively assessing outcomes. All of them, not least that of the *Development Contract* (Emmerij, 2004), have as their reference point the proclamation of the *Millennium Development Goals* at the

Millennium Summit, organized in 2000 by the UN, and in the presentation of the project *A Better World for All*, promoted jointly by the UN, OCED, IMF and the World Bank.

An important milestone was the *International Conference on e-Government for Development* organized by the government of Italy in Palermo on April 10-11, 2002. The event, part of the Italian Initiative on E-Government for Development, was a multi-million effort that combines advocacy with funding development projects. The conference provided a platform for members of the G8 Digital Opportunity Task Force (DOT Force) and the United Nations Information and Communication Technology Task Force (UN ICT Task Force).

Convergence was reached in the definition of the framework. The conference recognized that:

- E-government initiatives should be measured by the degree to which they contribute to good governance, empowering people, raising human capabilities and increasing people's access to life choices and opportunities.
- E-government initiatives and projects must be put in the context of broad government reform and a transformation process that aims at increased efficiency, effectiveness, transparency and accountability of government operation.
- E-government initiatives must be put in the context of a broad enabling environment, in which leadership, education and connectivity constitute the core ingredients.
- E-government initiatives based on international cooperation must be open to all in their design and implementation, built on existing local strengths and capacities and respectful of local culture and traditions.

At the Fifth Global Forum on Re-Inventing Government (Mexico City, November 3-7, 2003), Guido Bertucci, director of the Division for Public Economics and Public Administration at the UN, after briefly illustrating the principal trends of development that affect the public sector and the state worldwide, had this to say on developing countries:

*Experience suggests that one of the main causes of the crises plaguing developing countries and the inability of some of them to integrate in the world economy is state capacity deficit. Globalization is certainly presenting many opportunities, including foreign direct investment, trade, access to information technology. However, only countries that have in place an effective public administration, solid political and economic institutions, adequate social policies and a committed leadership can ensure that all sectors of society benefit from greater integration into a world economy.*

The problem is not whether to go global, but rather how to globalize.

The are no quick fixes or ready-made solutions to complex development problems, and it is necessary to consider that reform "should not be imposed from outside" and that "deep understanding of local conditions is essential in designing development programs" (pp.6-7).

Essential factors for success are:

- Political will
- Time: Reforms need time to take effect
- Flexibility of financial resources
- Stakeholders' support
- Investment in ICT
- Support of all sectors of society.

In this approach, even though revived, there is a tendency to de-contextualize the social dimensions of development, and thus to favor generic arguments about social engineering (Bebbington, Guggenhaim, Olson, & Woolcock, 2004).

## TOWARD *E-DEPENDENCY*?

This two-fold tendency to explain the underlying causes of failure and to understand how risks can be reduced, on the one hand, and to de-contextualize the social dimensions of development, on the other, emerges in the framework of one of the most important contributions based on exchange of best practices and dissemination of knowledge: *The E-Government Handbook for Developing Countries* of *info*Dev (World Bank, 2002b). In the preface we read that "e-government will be a powerful tool to help all types of economies (developed, developing and in transition) to bring benefits of the emerging global information society to the largest possible part of their respective populations … ." The need to provide an operational tool to help e-government practitioners arises from the awareness that "since resources remain scarce in regard to the immense tasks of socio-economic development and poverty alleviation, it is essential that they be used wisely and with a maximum chance of success." To the future of e-government will be vital understanding of the causes of their successes and failures, and adapting that knowledge to the characteristics of one's socio-economic environment. The *Handbook* presents a roadmap for policymakers considering electronic government as a mechanism for reform. "It is now clear around the globe that the utilization of ICTs has the potential of revolutionizing the way people interact with government and each other" (p. 1). E-government is a process that requires planning, sustained dedication of resources and political will. The message is that, up to now, too many resources have been wasted for the

limited knowledge of the main variables at stake in the implementing of e-government policies.

However, the *Handbook* has its weak points. On the one hand, there is acknowledgement that e-government policies have greater probabilities of success on the basis of a greater knowledge of socio-economic contexts of reference. On the other hand, it is these very contexts that are missing in the presentation on *best practices*. The short descriptions in the grids of model experiences and what can be learned from them are not much more than general observations under the guise of a *vademecum* for aspiring reformers.

While the shift in discourse has been significant, there is a gap between the rhetoric and the implementation of the policy framework. The UNDP reports and other data support a reciprocal relationship between technological achievement and human development, but also that "the digital divide, which recognize the yawning gap in accessibility to the Internet among countries, continues to grow, condemning entire regions of the world to even greater poverty" (Hill & Dhanda, 2003, pp.1021-1022). It would seem, then, that these policies often have not only been inefficient, but also that the new course does not take into due consideration the reasons for such failure; on the contrary, attempts to bridge the digital divide may have the effect of locking developing countries into a new form of dependency on the West. As Wade (2002, pp.443-461), once a World Bank economist, said:

*The technologies and 'regimes' (international standards governing ICTs) are designed by developed country entities for developed country conditions. As the developing countries participate in ICTs, they become more vulnerable to the increasing complexity of the hardware and software and to the quasi-monopolistic power of providers of key ICT services ... Much of the ICT-for-development literature talks about plans, intentions and opportunities provided—and blurs the distinction between these and verified actions on the ground. It talks about benefits and not costs. And it explains cases of failure, when noted, in ways that protect the assumption that ICT investment is a top priority.*

Developing countries are in danger of locking themselves into a new form of e-dependency on the West as they introduce software and hardware systems that they have no capacity to maintain for themselves and that become crucial to the very functioning of their corporate and public sector.

Technical and investment assistance to promote access in liberalized markets is accompanied by definitions of criteria of selectivity and evaluation that maximize the project development impact, and at the same time enhance the role of the organizations that are responsible.

## IN SEARCH OF A NEW PARADIGM

Most recent developments do not suggest a radical shift in policy on the part of the international institutions. In the first phase of the World Summit on the Information Society (WSIS), held in Geneva, December 10-12, 2003, the core issues were put into the framework of the prevailing development paradigm: ICTs have the power to advance human development; in other words, human potential can be through ICTs and access to knowledge. "Development is delivery. This delivery process is geared towards the integration of its recipient into a global marketplace. There is no space for a different conceptualization of development as a process of empowerment that intends 'to enable people to participate in the governance of their own lives'" (Hamelink, 2004, p. 284).

E-dependency issues highlight how the developing countries are disadvantaged in their access to the global economy also by the very standards and rules built into international systems. These standards and rules ensure that as developing countries become more integrated into an international ICT system, Western suppliers benefit disproportionately.

While the international institutions have found agreement on strategic objectives, the many dissenting voices underline how the patterns of globalization and liberalization over the past 2 decades have provoked economic stagnation or decline, and state collapse in some regions of the developing world, such as Africa and Latin America (Putzel, 2005).

Such criticism has damped enthusiasm somewhat, but up to the present time, have not succeeded in altering significantly the predominant approach. It is true to say that the key concepts are now possibilities and opportunities, and technological determinism, therefore, seems to have been replaced by a more realistic approach. However, the pursuit of efficiency and choice for the global consumer-citizen remains a characteristic tendency of institutional policies and ideology.

On the other hand, if it is true to say that the balance of e-government policies has up to now been a negative one, the new opportunities offered by technology innovation should not be discarded: *mobile government* (*m-government)* is the new frontier of institutional and political change.

## KEY TERMS

**Development Contract:** A comprehensive package of national and international policies, long term in nature, and based on a contract – hence, *reciprocal* conditionality – between industrial and developing countries.

**Information for Development Program (*info*Dev):** A multi-donor grant program that supports innovative projects demonstrating the development opportunities offered by ICTs. *info*Dev's mission is to promote the application of these technologies and the sharing of best ICT practices for social and economic development, with a special emphasis on the needs of the poor in developing economies.

**Globalization Project:** An emerging vision of the world and its resources as a globally organized and managed free-trade/free-enterprise economy pursued by largely unaccountable political and economic elite.

**Mobile Government (M-Government):** A subset of e-government. In the case of m-government, those ICTs are limited to mobile and/or wireless technologies, like cellular/mobile phones, laptops and personal digital assistants (PDAs) connected to wireless local area networks (LANs). M-government can help make public information and government services available "anytime, anywhere" to citizens and officials.

**Millennium Development Goals (MDGs):** The MDGs embody the key dimensions of human development – poverty, hunger, education, health – expressed as a set of time-bound targets. They include halving income-poverty and hunger; achieving universal primary education and gender equality; reducing under-five mortality by two-thirds and maternal mortality by three-quarters; reversing the spread of HIV/AIDS; and halving the proportion of people without access to safe water. These targets are to be achieved by 2015, the comparison point being 1990.

**Organization for Economic Cooperation and Development (OECD):** Organization of industrialized countries of Western Europe, North America, Japan, Australasia and Mexico responsible for gathering data and organizing conferences.

**Structural Adjustment Programs (SAPs):** Programs involving comprehensive economic reform as a condition of a loan package from Bretton Woods agencies.

**Technological Transfer:** The transfer of modern technologies to developing regions.

**United Nations Conference on Trade and Development (UNCTAD):** The arm and voice of the third world in matters of international trade, established in 1964.

**United Nations Development Program (UNDP):** Organization of the UN that enters into joints ventures with third-world governments to found training and other development programs.

**Washington Consensus:** A phrase coined by Williamson to refer to 10 policy issues around which the powerful in Washington, DC (the United States government and international financial organizations) could agree.

**World Bank:** Formed in 1944 to channel public funds into large development projects, including infra-structural and energy loans; key debt manager via structural adjustment and governance conditions.

# Digital Knowledge Flow Platforms for Regional Innovation Systems

**Philip Cooke**
*Cardiff University, UK*

## INTRODUCTION

For the first time in history, practically all the information required to navigate the oceans of a globalising knowledge economy are embodied in the Internet. Yet the demand for proximity to sources of economically valuable knowledge has never been greater. The rise of knowledge clusters like Oulu in Finland, Kista in Sweden, Cambridge in UK, and Cambridge, Massachusetts, let alone Silicon Valley, are testimony to the human desire for face-to-face and handshaking business contact. This paradox is widely commented upon by leading economists and business analysts (Chesbrough, 2003; Krugman, 1995; Porter, 1998) who show that the age of the hierarchical, vertically integrated production function embodied in the fabric of the multinational firm has changed significantly. Ushered in to replace it is a system, we have called Globalisation 2 (Cooke, 2005) based on externalised "node and network" forms of interaction. The Internet and other digital means of managing such informational complexity were said to be essential if we would but learn its rubric and adapt practice accordingly. But, rather like "e-learning" and "online learning" as means to do this, much less is heard of their virtues now than hitherto. The reason is that they underplayed and even ignored the important corollary regarding "learning organisations," which is that good knowledge management also requires "developing organisations." By that is meant reconfiguring inherited hierarchies and their associated technologies and incentive systems.

## BACKGROUND: FROM LEARNING ORGANISATIONS TO DIGITAL KNOWLEDGE PLATFORMS

Although "the myopia of learning" has been condemned since at least 1993 (Levinthal & March, 1993), the most penetrating critique of this comes recently from two distinctive sources. The first is Hansen (2002) who showed the failure of organisational learning wrapped up in the language of "knowledge management" to lie in failure to develop the organisation. He showed that under the guise of "knowledge management," large firms had sought to look into the brains of the workforce to transform its implicit or tacit knowledge (Polanyi, 1966) into explicit or codified knowledge and exploit it. These ideas had been floated in Nonaka and Takeuchi's (1995) influential book on the knowledge-creating company. However, Hansen showed that the "knowledge management systems" put in place had produced disappointing results. This was for three reasons. First, the knowledge management system technologies were designed so that knowledge mainly moved upwards to executive level. Second, workers received no feedback or knowledge-sharing opportunities and, crucially, no new incentive structure to reward them for sharing tacit or specific codified knowledge, so they stopped divulging knowledge for obvious reasons. Finally the "silo" structures of large-firm bureaucracy also prevented lateral movement of knowledge and information. Accordingly, only top management in theory benefited from knowledge transfer, but they were first presented with knowledge overload that could not adequately be absorbed organisationally, then they were confronted with a knowledge drought when the workforce stopped engaging.

On the basis of this research, Hansen made a number of recommendations that required organisational change that could enable digital knowledge management systems to function optimally on the basis of what we are referring to in this contribution as Digital Knowledge Flow Platforms (DKFP). The first lesson is that knowledge management systems do not function appropriately unless the organisation is itself transformed. The second step, which moves towards a more appropriate knowledge management environment is to reduce organisational hierarchy and remove "silos." Third, knowledge has to be organised so that it has lateral as well as vertical upwards and downwards vectors, allowing for feedback looping. Fourth, the workforce must be incentivised to share knowledge, not merely through improved job-satisfaction but through pecuniary rewards based on the frequency, quality, and impact of knowledge sharing. Finally, appropriate digital systems software is required so that knowledge sharing is made technically simple through interaction with computers and mobile telephony.

A second illustration of how DKFP requires organisational transformation comes from Aalborg Uni-

versity, Denmark where Dirckinck-Holmfeld (2002) showed how e-learning failed when no change was made to the traditional lecture-based pedagogy of traditional learning. This discovery occurred with the introduction of e-learning, Internet-based activity in Aalborg University itself, where it worked. But when it was transferred to other Danish universities it was a failure. The reason was that Aalborg, like Roskilde University was one of Denmark's two new universities dating from the 1970s. In those radical times, they were organised with an interdisciplinary core curriculum centred upon students engaging in team-based project work rather than lecture-based learning. E-learning in a classroom where a video of a lecturer standing at a lectern with text of the lecture scrolling down the side of the lecturer's image proved actually to be a good cure for insomnia. However, interactive, project-based team learning where problem-solving information of relevance to knowledge development by the student team is instantly accessed by Internet is actually efficient, effective, and exciting. However, most universities still mainly use lectures rather than projects to teach, especially the much enlarged classes of the 2000s, hence e-learning has failed to make great inroads. That is not to say that lecturing itself cannot be refreshed by DKFPs, as cases where the lecturer accesses from a console Internet updates to points that are being made verbally show. But this requires levels of expenditure and expertise, never mind possible time inefficiencies if technological discontinuities occur, that make it something of a luxury in most public sector pedagogic contexts[1].

Thus, some important lessons have been learned about learning and knowledge generation itself during the past decade. For example, many business leaders confronted with the preceding account might emphasise the fact that their businesses have successfully run DKFPs for year if not decades. But these are usually information not knowledge management systems. Hence, as long ago as the early 1990s IBM utilised a third party to manage its supply chain for items costing then less than DM 50 per unit. At that time, in Germany for example, the media giant Bertelsmann was IBM's favoured third-party supply chain manager for small items. IBM's strict internal accounting rules meant that, at that time, more valuable items had to be signed off by the head purchasing manager (Cooke & Morgan, 1998). More recently, it has become common in global supply chain management for all predictable items to be managed even by small, specialist third party supply chain management companies. Hewlett Packard in Scotland, for example, and presumably elsewhere was in 2002 contracting this function to such a company that used proprietary IBM Lotus Domino software to replenish consignment stocks as these ran down (OECD, 2004)[2]. But such systems are scarcely knowledge management, they are scarcely even artificial intelligence—another digital dream that turned sour in the 1990s—but simple automatic shelf stacking systems based on codified information. Clearly, the key lesson learned is how different knowledge is from information.

To dwell on this distinction for a moment, let us consider the nature of the difference. Information theory can be traced back at least to the pioneering research at Bell Laboratories of engineer Claude Shannon (1948, p. 379-380) who defined information as messages possessing *meaning* for sender and recipient. This is a "train timetable" theory since Shannon said that communication's "significant aspect is that the actual message is one *selected from a set* of possible messages..." (1948, p. 379 original emphasis). Thus, you choose from a menu of provided information that has meaning for your next action as a relatively passive recipient. Typical of its time this was a linear, inscriptive, traditional engineering metaphor. This approach then fuelled research professing to have identified "information overload" (Miller, 1978) from the exponential growth in messages, subsequently increasingly diffused by "information and communication technology" (ICT) (Lievrouw & Livingstone, 2002; Seely Brown & Duguid, 2000). This rather conflated information and knowledge. To return to the train timetable, it is clearly full of information, but it is as Shannon said, only useful when meaningful. But meaning is not supplied by the information but by the knowledgeable actor. In this case, the knowledge of where she wishes to travel to is what gives the timetable meaning on which action is based. So the distinction is based on interactions between the supply of (codified) *information*, the application of *meaning* derived from tacit (but codifiable) *knowledge* that triggers subsequent *action.*

## DKFP AND REGIONAL INNOVATION SYSTEMS

Hence, we have a glimpse at the cause of a major problem both for firms and other kinds of organisation, including whole economies or regional parts of them that must change to confront new pressures to innovate, be creative, and implement novel strategies. Digital systems react to information not knowledge, especially not tacit knowledge. Transferring tacit knowledge to the outside world in a meaningful way is not a direct but a mediated process. Thus far much of the knowledge management literature has been insufficiently appreciative of these considerations. The innovation literature typically refers to the necessity for implicit knowledge to be made explicit and codified as documentation, manuals or software, for example, in order that the potential productivity of new

knowledge may be realised (Edquist, 1997). Thereafter such knowledge becomes information that may be configured for digital analysis and application as discussed above. However, organisational knowledge is difficult to translate, especially when the organisation is externalised and takes the complex form of an economy or a regional part of it. Hence, knowledge transfer is a much more uncertain, indeed strictly asymmetrical process (Akerlof, 1970; Cooke, 2005). To improve, become more competitive or innovative a firm, organisation, or person may try to learn from the observable information that may be gained from what is perceived to be a superior performer. It might engage in study visits to benchmark "best practice," another activity that has grown enormously in scale in the past decade or so.

But an organisation or person that becomes accustomed to learning from elsewhere in the form of pre-existing (pre-digested) information, cannot cope with novelty[3]. Desultory regional economies and their learning organisations are condemned to a treadmill of absorbing old information. After trying to learn its lessons it may possibly implement them in time to discover that superior intelligence from elsewhere has already set new standards. Learning and innovation are opposites, and innovation, as we have seen, requires organisational change.

This is largely because it is difficult to transform the tacit nature of successful practice into the codified recipe capable of successful emulation. This affects core thinking about knowledge in many fields. That is because tacit knowledge does not transfer simply into codified, because of "epistemic communities" and "cognitive dissonance." Rather it is mediated, but until now there has not been a word or concept to capture that mediation. The third party must be *complicit* with the knowledge of the implicit knowledge-holder for that knowledge to be made reasonably explicit to her interlocutor. In this way, *meaning* may be given to the member of the "other" epistemic community by a process somewhat comparable to that of "triangulation" in social scientific methodology.[4]

A complex organisational change that numerous regions effected in the 1990s and into the 2000s concerns innovation systems, specifically *regional* innovation systems. Although in the EU over one hundred regions have been exposed to regional innovation *strategies* since 1994 (Oughton, Landabaso, & Morgan, 2002), Carlsson (2006) has tracked over two hundred regional innovation systems *studies* between 1987 and 2002, half of them products of empirical research. These show leading and lagging regions improving innovative performance by re-designing their boundary-crossing mechanisms or "bridging social capital" (Putnam, 1999) between research (*exploration* knowledge) and commercialisation (*exploitation* knowledge; March 1991)[5]. Moreover, in Cooke, Heidenreich, and Braczyk, (2004) the evolution of regional innovation systems worldwide in the face of economic downturn and globalisation effects is delineated. These now transcend simplistic knowledge transfer notions like the "Triple Helix" (Etzkowitz & Leydesdorff, 1997) which presents the institutional clash of "epistemic communities" (Haas, 1992) among government, industry and universities as akin to a Holy Trinity. The disequilibriating impulses of the "knowledge economy" have prompted innovative thinking in lagging regions whereby the Holy Trinity is eschewed and even the "holy of holies" the *university* is looked upon askance in the quest for regional *constructed advantage* (Foray & Freeman, 1993). Solutions arising from these new approaches will be presented in the next paragraph.

The point here is that economic governance agencies, like firms and persons, eventually realise the futility of trying to "clone" successful cases by learning and copying information–even if mediated by a complicit third party[6]—and are forced to the ominous deduction that they must, fundamentally, devise their own solution tailored to their own conditions, informed by lessons from elsewhere, but interacting with the endogenous knowledge-base of their own context. This is what is best termed *recombinant* innovation, contrasted with *incremental* organisational innovation that as Lindblom (1977) showed, may lead conservatively in the wrong direction or even round in circles, and *radical* organisational innovation, which as Simon (1955) showed produces "variable overload" and is thus difficult to manage. Recombinant organisational innovation is massively assisted by development of regional innovation systems adapted to contextual specificities as discussed above. And of immense support to well-functioning regional innovation systems is a successful DKFP that circulates and communicates much codified or explicit, complicit, and potentially some fragmentary implicit knowledge across the "epistemic communities" that compose it. For, in a far more complex way than that imagined in the Triple Helix literature (Etzkowitz & Leydesdorff, 1997) regional innovation systems must integrate complexity in the external environment.

## FUTURE TRENDS: DKFP IN PRACTICE AND EXPERIMENTATION

How might internal and external disconnects be moderated? In respect of Scottish Enterprise the question arose of an enhanced Intranet facility, problematic as it had been designed for confidential business interactions among the Scottish global business diaspora. Time would be needed to populate it with requisite information, and commitment from field officers and HQ staff to

keep it updated. Moreover job descriptions would need to specify as a requirement that it should be an everyday responsibility to find out what of relevance was posted upon it. To give weight to the importance of intra-organisational "knowledge of the world" this knowledge management and processing function should be given status through the appointment, presumably at the centre but with network-wide scope, of a senior knowledge manager. TalentScot was the forerunner, having been similarly digitally created to enable Scotland's advanced software research Alba Centre to recruit talent in ICT businesses and research. This model was adapted to that provided by GlobalScot as an Extranet, albeit focused on Scots and Scotophiles abroad. A polling function to access key international knowledge (including tacit perceptual as well as explicit knowledge) flows while maintaining security is in development.

A different model is under development at VINNOVA in Sweden. There, it is internal "organisational knowledge" concerns that have stimulated the creation of an Intranet that could be transformed into an Extranet to regional innovation systems the agency is constructing throughout Sweden. VINNOVA was in 2001 an organisational innovation arising from a former technology transfer agency called NUTEK. The latter was seen politically as having failed Sweden's regional development and to be over-wedded to an engineering culture influenced still by the linear innovation model, itself reflected in over-allocation of technology subsidies in the Stockholm area. VINNOVA's task is to build innovation systems in Sweden's regions. It has begun with cluster building activities in Skåne, Uppsala and west of Stockholm. However the new economic governance agency contains two cultures and administrative "silos" and different parts of the agency did not necessarily know what other parts were doing. Hence, this author's recommendation that VINNOVA should construct a DKFP along lines advocated in Hansen (2002). By late 2004, such an Intranet system had been constructed and populated using a Geographical Information Systems program format. Thus, the system contains locational data on all innovation nodes and networks in Sweden and its regions, with detailed firm data available in layered map-based geographical information. On to these bases are added policy information, types of measures and financing regimes. This database GIS will be accessible by all VINNOVA employees, and if successfully adapted so that knowledge may be added in structured form by any authorised member of the workforce, will act as a policy-based knowledge management system. In time and subject to data protection standards it could, in principle be made accessible to actors external to VINNOVA. So far both systems discussed are only in the experimentation phase.

## CONCLUSION

This contribution has discussed three main things and shown how lessons learned from inadequate conceptualisation of the nature of knowledge have assisted economic governance agencies to advance digitally in their support services to innovation. It was shown first that business made several early efforts to develop "knowledge management systems" that did not work due to no change being made to the organisation in which knowledge management was introduced. The critique of this showed that breaking down of silo mentalities and stimulating feedback within the organisational structure were essential, as indeed was incentivisation of the workforce. Other digital system management, as with supply chain management outsourcing to third parties constituted information management—a far simpler task than knowledge management because it lacks the tacit dimension.

Second, organisations that increasingly deal with external complexity, across epistemic community boundaries, and including many different kinds of third party *complicit* knowledge intermediaries are exemplified well by those that engage in economic governance, particularly that characterised by supporting the design and realisation of regional innovation systems. Experience of managing complex interactions of this kind where exploration, examination, and exploitation knowledge have to be successfully recombined revealed that past traditions of imitative learning were insufficient to aid implementation of modern innovation support strategies. Third, interactive innovation for knowledge creation endogenised to the specific region is now widely seen as a superior albeit challenging methodology. Early results are promising and practical, with Geographical Information Systems (GIS) technology proving to be a highly effective digital means of facilitating global knowledge flows animated by economic governance agencies involved in facilitating regional innovation systems.

## ACKNOWLEDGMENTS

The comments of two anonymous referees are acknowledged for helping sharpen the argument.

## KEY TERMS

**Digital:** A system that uses discrete values rather than a continuous spectrum of values.

**Flow:** Movement of physical or non-physical entities through time and space.

**Innovation:** The processes whereby "exploration" or basic research knowledge has been "examined" in various ways for "exploitation" as a new product, service, process, or organisational form with commercial value.

**Knowledge:** Information enabling meaningful action.

**Learning:** Transferred and absorbed knowledge.

**Platform:** Support framework consisting in multiple elements, actors, and processes assisting fulfilment of shared purposes.

**Region:** This derives from Latin "regere" meaning "to govern." Thus a region is a level of governance, normally as part of a country's administration, between the local or municipal and the "nation state."

**System:** Links between nodes that interact for a purpose. In social systems these interactions are relatively "open"; whereas in, for example, engineering systems (e.g., central heating) they are relatively "closed."

## ENDNOTES

1 Space does not allow a fuller review of improvements to knowledge management systems occurring of late. Technologically-speaking, convergence between computer tools, the Internet and communication software networks has evolved, rather as with, in a different context, mobile telephony (see Cooke, 2002). An anonymous referee also suggests the move towards a notion of "intellectual capital" integrating creativity and reverse engineering tools by digital means is the way to go. However, in social science the reductionism implied in an idea such as "intellectual *capital*" is widely criticised for its inattention to context and cognition. While the industrial economics literature shows how its measurement is heavily influenced by stock market "hype" bordering on fraudulence, as in cases such as Enron, WorldCom, and AOL Time Warner (see, for example, Fusano & Miller, 2002; Klein, 2004). Digital governance cannot risk such ethical quagmires, thus GIS is seen as a more "trustworthy" tool, also possessing geographically attuned technical capabilities perhaps more susceptible to jurisdictional needs than those of profit-maximisation.

2 This was related to this author by the owner of the specific business, during an OECD mission to Scotland in November 2002 to examine the economic governance agency *Scottish Enterprise*'s global knowledge flows strategy response to the rise of the knowledge economy. The published report from OECD is available as OECD (2004).

3 It is often the view of proponents wedded to the "apple pie" virtues presumed to be denoted by "learning" that it is an intrinsically "good thing." This is not disagreed with here. However, an uncritical perspective upon learning is. Thus while such proponents may nowadays accept governance weaknesses associated with "learning from samples of one" or "myopic learning" (e.g., the "clusters craze") there is reluctance to recognise that endogenous "learning" may also not be problem-free. The governance problem here is twofold: first, endogenous learning may not be innovative; second, asymmetric knowledge endowments may be exceptionally difficult to overcome. To paraphrase Akerlof (1970), learning policy "lemons" (which it is arguable is not unusual) is as ineffective and inefficient as, at the individual level, buying successive poor-quality second-hand cars (a "lemon" in U.S. slang) which have non-repetitive basic faults about which the salesperson is knowledgeable but the customer is not. The obvious solution is not to buy second-hand, which is an "organisational innovation" admittedly prompted by a kind of Pavlovian stimulus-response "learning."

4 Triangulation is the process whereby in, say, interviewing, the interviewer, and interviewee interact and some hidden or tacit knowledge comes forth. This must normally be checked with a third party for accuracy and veracity. Hence the knowledge is triangulated with someone complicit with the knowledge field.

5 Elsewhere (Cooke, 2005) this couplet has been shown to be as inadequate as that referring to a facile implicit-explicit knowledge transfer process. This is because, as regional innovation systems research regularly shows, exploration knowledge and exploitation knowledge are also mediated, increasingly so, by *examination* knowledge that tests and trials innovations to assess whether they are dangerous to humans and the environment. The exemplar case is, of course, the pharmaceuticals industry where such examination knowledge is now in 2005 having to be made public since large firms have been caught suppressing it as a consequence of which treatments have had lethal effects on patients.

6 Such as, for example a consultant, another activity that mushroomed in the 1990s. Consultants are well-known for having stock knowledge which they profit from by offering suitably adapted on the surface as basically a "one-size fits all" solution. Hence in economic governance, "clusters" consultants make a good living despite absence of evidence that their advice works.

# Digital Morality and Ethics

**Peter Danielson**
*University of British Columbia, Canada*

## INTRODUCTION

While "digital morality" and "digital ethics" may sound strange, the technologies that drive digital government and democracy operate as well in these less formal areas of social regulation. Information technologies can affect morality and ethics at several levels: facilitating compliance with moral rules, altering the formation of norms and rules, and aiding the ethical assessment of rules. This article sketches an account of ethical decision-making which lets us explore some threats and opportunities of the emerging technologies of digital morality and ethics.

## BACKGROUND

The focus of this article is how new communication technology affects ethical decision-making. Since ethics has a large and controversial literature, we will simplify. First, while disagreement about substantive issues is wide-spread, there is greater agreement about the process of ethical decision-making. Most writers on ethics agree on what counts as ethical agents (i.e., most people, with minor disagreement about young children, some animals, and organizations). Further, there is wide agreement on the kind of decision-making broadly characterized as ethical. We summarize this agreement in terms of ethical decision-making having three components: compliance with moral rules, discovery of moral norms, and critical ethics. Second, while ethics has many dimensions, there is broad agreement in the social sciences that morality and ethics are coordination mechanisms. Agents who can discover the local moral norms and use them to govern their behavior can solve the coordination problems endemic to social life. The ability to critically assess alternative moral rules helps to solve the higher-level coordination problem of moral disagreement.

Although the terms, "morals," and "ethics" are used in a variety of ways, we shall use them to distinguish these two levels, lower and higher, respectively, of coordination and decision-making.

### Rationality and Morality

Moral and ethical agents are a subset of rational agents, whose behavior tracks their values. Rational agents must be able to consider alternative courses of action and their outcomes, rank these outcomes in terms of relevant values, and select the most valued option. Therefore, moral agents inherit the problems of rationality: uncertainty and time constraints, problems of self-control (Rachlin, 2000), framing and other decision biases (Tversky & Kaneman, 1981). On most accounts, moral agents are distinguished from rational agents by a broader set of pro-social or altruistic values and a commitment to following moral rules. These features bring new problems specific to moral decision-making, such as balancing self and others (Schmidtz, 1998) and hypocrisy.

### Social Morality

In addition, moral decision-making has a distinctly social component. Morality depends on moral norms, a subset of social norms that influence individual decisions. Social norms go under the name "conventions" in some literatures; "social equilibria" in others, and refer to existing institutions, rules, traditions, or practices (Binmore, 2004). All involve some coordination: strategic situations where most agents value doing what (most of) the others are doing. In addition, moral norms involve special motivations. Deviant behavior typically invokes both psychological (shame) and social sanctioning (blame).

The social component of moral decision-making can easily go wrong for lack of information, or due to misinformation. In several well-studied cases—college drinking in the US is most thoroughly documented–behavior is in a mistaken equilibrium (Greenberg, Dodd, & David, 1999; Perkins & Berkowitz, 1986). Believing most other students drink heavily, many drink in excess to comply with the norm. Their beliefs are a self-confirming estimation of the group's behavior, which should be amenable to new information.

### Ethics

Ethics aims at critically evaluating morality. Obviously, partisans of two competing norms in a society should not simply appeal to what their own norms require. They need to appeal to "higher" standards: human harm or benefit, rights, progress, national solidarity, tradition, or other ideals. Failures in ethical decision-making combine the problems surveyed for rationality and morality. Ethical

decision-making has an ideal element that links it to other normative ideals, such as deliberative democracy.

## COMPUTER-MEDIATED OPPORTUNITIES AND THREATS

Having resolved the field of ethics (broadly considered) into three components, it becomes clearer how computer-mediated technologies can change, perhaps threaten, and hopefully improve each of them.

### Moral Rationality

Computerization can assist rationality in myriad ways—from calculators through spreadsheets and databases—beyond the scope of this article. We will mention a few examples of aids relevant to the rationality of moral and ethical agents.

Visualization software is a major innovation relevant to normative rationality. These programs allow us to see how our values map onto the world. Examples are maps of political preferences and scorecards ranking firms and mutual funds by "ethical" scorecards. Calculators allow us to evaluate our choices in terms of our values. For example, global warming gas emissions calculators help us decide between our energy intensive options and so achieve personal responsibility, if desired (Danielson, 1993). Simulators allow us to think through values and choices in complex technical and social environments. (Epstein & Axtell, 1996) is the most developed academic example of a simulator designed to increase insight into elementary social science. Of course, computer-mediated communication also can threaten moral rationality. New media can add new distractions and sources of poor quality information, especially until our information filters catch up with the technology. Simulators may imbed biases in ways that are difficult to counter. Violent electronic games that give the thrill of combat, aggressive driving, and street crime shorn of all consequences are prominent examples of morally dubious simulators (McCormick, 2001). Some criticize even the more pro-social SimCity series for the weight of entertainment as contrasted with educational values (Starr, 1994).

Moral decision-making is based on moral rules. Compliance is difficult when the rules are complex, unclear, and various. Research ethics provides a good example of this problem and the promise of digital technology to mitigate it. Human "gene banks" are collections of genetic data (or tissue samples), clinical data, and environmental data. Genomic scientists see great promise in research linking this data across large populations. Unfortunately, the moral rules governing who can access which data vary across jurisdictions and are often unclear (Maschke, 2005). Note that this problem arises in spite of the relatively formal nature of the rules and their institutionalization by ethics review boards. Recent work by bioinformaticians involves applying digital technology to this problem. Wilkinson (2003) suggests that "ethics ontologies" can allow automated "agents" to navigate the rules governing access to various sources of data. This computer-mediated resolution of moral uncertainty yields the direct benefit of allowing researchers to access only the data they morally ought to be permitted to use. Indirectly, it may allow research subjects deciding between granting or withholding consent to a particular use better to understand the consequences of their decisions.

### Moral Norms

As the most social of our three factors, morality is the most subject to change due to the introduction of new computer mediated technologies. We consider three ways.

1. **Knowledge of Norms:** Most obviously, Web technology has made simple polling very easy. For example, a Victoria, Canada, radio news station runs a different public affairs poll every day on its Web site. These polls attract about 275 responses a day. Notice that polls like this are likely to serve as moral convention amplifiers rather than ethical instruments, for several reasons. First, the poll page displays a tally of previous responses, so participants' answers are not independent. Answers are subject to an information cascade effect that reinforces the power of existing norms (Hirshleifer, 1995). Second, participants are self-selected, inviting interested parties to skew the sample. Third, Web surveys collect superficial "top of head" opinions. However, we need not restrict ourselves to simple polls. More sophisticated computerized surveys allow us to support more complex moral decision-making (Danielson, Ahmad, Bornik, Dowlatabadi, & Levy, in press).
   Since moral norms, as social equilibria, are a function of agents' knowledge and expectations, new information can change norms. Recall the example of campus drinking. Were students to realize that most others are not drinking excessively, they may drink less. In this case, more information weakens the force of the norm that supported drinking.
2. **Changing Social Networks:** Computer-mediated communication can change the social basis of norms by facilitating non-spatial social networks. Consider the example of ""apotemnophilia"—an attraction to the idea of being an amputee" leading to

healthy people seeking amputations, publicized by bioethicist Carl Elliott. It is a good example for several reasons. First, the desire is baffling, "Why would anyone want an arm or a leg cut off? Where does this sort of desire come from?" A surgeon who has performed such operations "has said that the request initially struck him as "absolutely, utterly weird" (Elliott, 2003, p. 209). Second, it is a disturbing example, which helps to overcome the prejudice that something as recent and superficial as computer-mediated communication cannot make a real moral difference. Third, the reader is unlikely to have come across this new community, which helps make the point about coordinating out of the public eye. Fourth, apotemnophilia has been made acceptable due to computer-mediated communication. "By all accounts, the Internet has been revolutionary for wannabes. It took me months to track down even a handful of scientific articles on the desire for amputation. It took about ten seconds to find dozens of Web sites devoted to the topic. Every one of the wannabes and devotees I have talked with about the Internet says that it has changed everything for them…Because the desire is so rare, it is unlikely that most wannabes would ever spontaneously meet another wannabe. But the Internet brings [them] together, online if not in person" (Elliott, 2003, p. 217, 219). Another example of the Internet bringing together groups that validate otherwise morally impermissible behavior are Japanese "suicide clubs" (Harding, 2004).

3. **Anonymity:** While communicating anonymously or using a pseudonym in political debate has a long history, computer-mediated communication has greatly increased its importance (Danielson, 1996). Elliott brings this out as he elaborates on his case study, "Many wannabes participate in on-line groups anonymously. So they get both the comfort and satisfaction of being part of a group, and knowing they are not alone in the world, while also avoiding the potential shame of actually having to reveal themselves to anyone else face-to-face" (Elliott, 2003, p. 219).

## Ethics

At the ethical level, we act as legislators, taking various feasible moralities as the laws amongst which we choose (Rawls, 1955). Computer-mediated communication can add this activity in several ways already covered above. We can collect more information about our own moral norms and other groups" norms, which may be feasible alternatives for us. In addition, we can calculate and simulate how these proposed norms might work for us, and even how our own values might change if make some choices.

Turning to distinctly ethical factors, computer-meditation offers new ways to implement the ideals of deliberative democracy. However, the question whether and if so, when, computer-mediation improves deliberation remains open. Scott (1999) summarizes the recent research on face-to-face versus computer-mediated deliberation as "mixed and inconclusive findings." In a welcome development, the leading theorist of deliberative democracy, James Fishkin is actively experimenting with computer mediated variations of traditional face-to-face meetings (Fishkin, 2004). His group identifies the main drawback of online deliberation: "The major liability of the online model concerns the representativeness of the participant pool. Access to technology remains closely dependent on socio-economic standing, and there is no reason to suppose that the "digital divide" will disappear in the ordinary course of events. The digital divide might, therefore, compromise the ability of online researchers to draw representative samples in the absence of special interventions. But interventions—in the form of free access to technology—are possible" (Iyengar, Luskin, & Fishkin, 2004, p. 4).

Straightforward benefits of online deliberation are low cost and flexible access. A third feature is more complex: "the online process offers greatly improved metrics for determining exactly what the participants are doing, what aspects of the experimental treatment they are making use of, which parts of the briefing documents or the answers to questions they are reading. Hence online Deliberative Polling opens up new possibilities for understanding the mediators of the treatment effects (what exactly is causing the opinion changes), and whether there are inequalities in participation in specific aspects of the process" (Iyengar et al., 2004, p. 4). Here the benefit accrues to the researchers; the deliberation is treated as an experiment. While it is important at this early stage to learn more about alternative deliberative processes, there is a tension between experimentation and ethics here, unless we make the deliberators themselves aware of the new information gained on their process. This is not an objection to the experiment but a pointer to the richness of problems that lie ahead. While the natural information constraints of face-to-face deliberation limit this process, we do not yet know how to use the rich resources of computer-mediated communication in a fully open and reflexive way.

Another feature of deliberation is "the phenomenon of *group polarization*. The idea is that after deliberating with one another, people are likely to move toward a more extreme point in the direction to which they were previously inclined, as indicated by the median of their predeliberation judgments. With respect to the Internet,

the implication is that groups of people, especially if they are like-minded, will end up thinking the same thing that they thought before—but in more extreme form" (Sunstein, 2001). The concern here is that the internet facilitates association with the like-minded (Sunstein, 2000).

## FUTURE TRENDS

Digital morality and ethics are new ways of social regulation, charged with controlling power. Therefore, they are subject to the same forces as more familiar political mechanisms. A report on a participatory experiment in local government observes, "… teledemocracy initiatives potentially perturb the power balance. This effect is likely to be most evident in groups where information is held by a few. Frequently, barriers to communication are clearly more social and political than technological. Also, reluctance to adopt might be ascribed to differences in status (a source of influence) among organization members and, in addition, reflect the values of different political parties and structures" (Watson, Akselsen, Evjemo, & Aarsaether, 1999, p. 61).

Second, we should expect these new communication media to be subject to the pressures found in our traditional fora and venues: the press, media, libraries etc. Ithiel Poole opens his groundbreaking book, *Technologies of Freedom*, with this dramatic warning about "the right of people to speak and print freely, unlicensed, uncensored, and uncontrolled. But new technologies of electronic communication may now relegate old and freed media such as pamphlets, platforms, and periodicals to a corner of the public forum. Electronic modes of communication that enjoy lesser rights are moving to center stage. The new communication technologies have not inherited all the legal immunities that were won for the old" (Pool, 1983, p. 1). Generalizing, traditional modes carry norms—not only legal protections but also communities and professionals such as journalists and librarians—and communal memories. New technologies will not automatically pick up these norms, nor maintain continuity with these communities. A search engine like Google may not distinguish content and advertising in the same way as a newspaper, or indeed, at all. Nor, evidently, do even electronic voting machines, as subject to scrutiny as they are, meet the same standards as more traditional voting practices (Larsen, 1999). Therefore, we need to be cautious about what we may lose in our enthusiasm to embrace new technologies of collective self-governance.

Most generally, we should expect unanticipated consequences: digital morality and ethics are new developments. In particular, technological innovations have fostered optimism. Langdon Winner's essay "Mythinformation" reminds us that other technologies such as television were welcomed—indeed hyped—with great social and political expectations (Winner, 1986). Moreover, most digital morality and ethics innovations are small research projects. They may be utopian; their small scale cannot explore the range of unintended consequences that would likely follow general introduction. Until digital morality and ethics are played out by real social and political agents their full set of consequences, many unanticipated, are practically impossible to discover and assess. They remain beyond our rational or ethical planning horizon.

## CONCLUSION

While digital morality and ethics are new topics, they point to real and important developments. Digital technology has the capacity to change our moral and ethical decision-making at several levels, from implementing existing moral rules to forming new social norms and ethically evaluating our norms.

## KEY TERMS

**Anonymous Communication:** Occurs when the author cannot be identified.

**Apotemnophilia:** An attraction to the idea of being an amputee.

**Compliance:** The ability to guide one's behavior by social rules.

**Deliberative Judgments:** Contrasted with the more superficial data gathered by public opinion polls.

**Ethics:** Procedures for evaluating moral norms.

**Morality:** The social norms the support the current social equilibria via coordination, psychological and social sanctions.

**Pseudonymous Communications:** Allows the user to retain a continuing name, or "handle" without revealing their identity. Many bulletin board and multi-player games support pseudonymous interaction.

**Social Coordination:** Strategic situations where each agent values doing what (most of) the others are doing.

**Top of Head Judgments:** Superficial opinions associated with public opinion polls.

# Digital Multimedia

**Neil C. Rowe**
*U.S. Naval Postgraduate School, USA*

## INTRODUCTION

Multimedia data can be important assets of government computer systems. Multimedia data can be documents, statistics, photographs and graphics, presentations, video and audio of events, and software. Examples include maps, video of meetings, slide presentations by consultants and vendors, graphs of budgets, and text of regulations. Video of meetings of legislatures and other government organizations is particularly valuable as it makes government processes more visible to citizens and can encourage trust in government. Multimedia is also particularly valuable in presenting geographical information (Greene, 2001), a concern of all governments. Added multimedia can also be used to more effectively deliver information to people, as with films, animations, sound effects, and motivational materials.

Multimedia information is important for digital government because it is often a more natural communication mode for people than text. It is thus important that government be responsive to the needs and desires of citizens by providing it. Much of the world is illiterate, and the ubiquity of television means even the literate often prefer watching video to reading text. Some citizens have special needs: Blind people need audio, and deaf people need images. Video and audio also convey information beyond text: A video of a legislature meeting contains subtleties not apparent from its transcript. Research has shown that multimedia is especially good at conveying explanatory information about functional relationships in organizations (Lim & Benbasat, 2002). Research has also shown that people learn better from multimedia presentations than from conventional classroom instruction, and the multimedia provides a consistent experience available at any time unlike human instructors (Wright, 1993).

## BACKGROUND

The management of multimedia data entails considerations not encountered with data that is solely text (Vaughan, 2003). The main problem is data volume: A typical report can be stored in 20,000 bytes, but a typical 20-centimeter square image requires 500,000 bytes to represent adequately, an audio clip that is 1 minute long requires around 1,000,000 bytes, and a typical 3-centimeter square video clip that is 1 minute long requires around 50,000,000 bytes. Compression techniques can reduce storage requirements somewhat; however, media that can be compressed significantly tend to be merely decorative and not very useful for digital government. Multimedia size is especially a problem when transferring media between computers, especially with the limited data rates of conventional telephone lines and modems (Rao, Bojkovic, & Milovanovic, 2002). So, since digital government cannot be sure what technology its citizens have, it must be conservative in its use of multimedia.

Distributed database technology (Grosky, 1997) can help manage multimedia data efficiently. However, the human side of multimedia management requires a different set of skills than those of most computer support staff. One needs media specialists familiar with the problems of the technology, including some staff with art training to address the aesthetic issues that arise. Much multimedia management is time consuming, so adequate personnel must be available. Government can also choose to actively encourage the development of a multimedia-supporting infrastructure by its industries (Mohan, Omar, & Aziz, 2002).

## INDEXING AND RETRIEVAL OF MULTIMEDIA

A first issue in using multimedia data is finding it. Citizens often want to retrieve quite specific multimedia objects to meet their needs, and they can do this with a browser or a search engine (Kherfi, Ziou, & Bernardi, 2004). This requires metadata describing the media objects such as size, date, source, format, and descriptive keywords. A browser can provide a hierarchy of media objects that users can navigate. This works best when media objects can be described in just a few words, or are characterized along a single dimension like date or place. Otherwise, a keyword-based search engine is necessary, such as that provided by commercial services like Google but adapted to search only government data. Accommodating a broad range of citizens means keeping extensive synonym lists for keyword lookup so that many possible ways of specifying the same thing will work. In some cases, a graphical

specification may be a good way for the public to specify what they are looking for, such as a visual timeline or geographical display on which they click on the location they want.

Unfortunately, it is difficult to index and search nontext media for its contents. Segmentation by identifying shapes within images can be tried, but it is time consuming and often unreliable. So captions on media objects (text that describes them) are valuable (Rowe, 2005). They can be directly attached to a media object or located near it in a document. Captions directly attached include the name of the media file, descriptive keywords, annotations describing the object like the *alt* string associated with Web media, the text of clickable links on the Web that retrieve the object, text directly embedded in the media like characters drawn on an image, and data in different channels of the media like narration or closed captions for video. Captions indirectly attached include text centered or in a special font above or below the media, titles and section headings of the document containing the media, special linguistic structures like "The photo shows …," and paragraphs above or below the media. Caption text can be indexed for a more precise keyword search than that obtained by just indexing all the words of the enclosing document (Arms, 1999). This is what the media search engines such as the image searchers of Google and AltaVista do, though their success rate at finding images is not as good as their success rate at text search. Media retrieval is, however, an active area of research, and new developments are appearing frequently.

## DELIVERY OF MULTIMEDIA

Multimedia can enhance documents in many ways. It can enliven information, and this is helpful for the often-unexciting information provided by governments. But the primary concern of government must be for media that convey important information of their own. Mostly, this means the delivery of multimedia information from the government to its citizens, though there are also issues in the collection of information by government (Cheng, Chou, Golubchik, Khuller, & Samet, 2001) and communications within government.

Broadcast technology is the traditional method for a government to disseminate media through newspapers, radio, and television. Broadcast is a one-way technology. This is fine for announcements and authoritarian governments, but interactivity is very important to a responsive and effective government. So, the Internet and especially the World Wide Web are increasingly preferred to deliver user-selected information and permit the completion of forms. The Web is well suited for multimedia. It permits the embedding of pointers to multimedia content in documents with much the same ease as text. Web multimedia can range from informal illustrations to media retrieved from structured databases in response to queries entered on dynamic Web pages. Media is particularly helpful for the illiterate as graphical interfaces can enable access to the full power of computers without the necessity of words.

A key issue for digital government is the choice of media formats. Government information systems intended for only internal use can follow very few mandated formats for interoperability. But much multimedia is for the public, and the public uses a diversity of computers, software, and networking services, and accessibility to all citizens is important. So copies of important multimedia in different formats are essential. Web images are currently mostly in JPEG and GIF formats, with some in PNG format. Audio and video are more diverse: Currently popular audio formats are WAV, RAM, MID, and ASX, and currently popular video formats are MPEG, SWF, MOV, FLI, AVI, and MP3. Multimedia can also be software in various formats. Not all these formats are supported by all Web browsers, so it is important for government to provide free viewer software for downloading so citizens can view any of its multimedia. This generally restricts governments to using formats that have free open-source software for reading or viewing them.

Multimedia software of particular interest to government organizations is groupware, supporting collaborative activities of groups. It can be used to run meetings of people at widely scattered locations so participants can see, hear, and read comments by other participants. Groupware requires transmission of video, audio, and graphics between sites (Klockner, Mambrey, Printz, & Schlenkamp, 1997).

## STREAMING MULTIMEDIA

Because of its bulkiness, multimedia is often best stored at a few centralized sites and retrieved from there. That can entail logistical problems since video and audio in particular need to be delivered at a certain minimum speed to be viewable or listenable (Smith, Mohan, & Li, 1999). Video or audio can be fully downloaded in advance of playing, but this entails a time delay and most citizens prefer real-time delivery (streaming). Important applications with streaming are being accomplished including video meetings, video medicine, distance learning, multimedia mail, and interactive television. Streaming is simplified if it is delivered by one-way broadcast, and this works well for standardized content such as training materials. Traditional technology like television can also be effective in

the streaming of government media (Morisse, Cortes, & Luling, 1999) but requires citizens to access it at a particular time. Another alternative is to supply citizens with an optical disk (CD-ROM or DVD) containing the media.

The biggest challenge with streaming is ensuring adequate bandwidth (rate of data transmission). A single MPEG-1 compressed video of standard television-picture quality needs around 2 megabits per second (though videoconferencing and speeches can be adequate with less), and music audio requires 1 megabit per second. Standard (ISDN) telephone lines provide 0.064 megabits per second, inadequate for both. T-1, T-2, and other lines can improve this to theoretically 1.5 megabits per second, but that is still inadequate for video. Digital subscriber lines using cable-television technology can provide higher bandwidths using network technologies such as ATM, but even those can be pressed to produce real-time video. Data-compression techniques can reduce bandwidth somewhat; typical maximum compression ratios range from 2:1 for audio to 20:1 for images and 50:1 for video. Other tricks with noncritical video are to periodically skip frames or decrease the size of the images.

Transmission bandwidth is also bounded by the delivery rate of the media from an archive. Live video may be able to bypass storage and go directly onto the network. But in general, multimedia data must be archived in blocks for efficient memory management, though the blocks can be larger than those typical for text. Magnetic tape and optical disks are less flexible in manipulating blocks than magnetic disks, so the latter is preferable for multimedia. But it does take time for a disk head to go between blocks, so successive blocks can be put on different disks so that a block from one disk can be transmitted while the other block is being readied (striping).

Besides bandwidth limits, networks can also have transmission delays (latency), which affects real-time interactive applications like videoconferencing. Delays can be minimized by good network routing (Ali & Ghafoor, 2000; Gao, Zhang, & Towsley, 2003). Using different paths to relay different parts of multimedia data from source to destination can reduce the effect of any one bottleneck. If data loss is especially important to avoid, redundant data can be sent over the multiple paths. But much video playback can tolerate occasional data loss.

Another transmission issue is the evenness of the arrival of multimedia data at a destination site (burstiness or jitter) since unevenness can cause unacceptable starts and stops in audio or video. This can happen when other network traffic suddenly increases or decreases significantly. Usually, video delays cannot exceed 0.1 seconds and music-audio delays 0.0001 seconds, so this is a key quality-of-service issue. Caching of data in storage buffers at the delivery site reduces the problem, but effective multimedia buffers must be big. Transmission by multiple routes will also help.

Multimedia delivery is still more difficult when the destination device is a small handheld one since these are limited in memory, processor speed, and networking capabilities. Although multimedia is better displayed on conventional computer hardware, many users prefer such small devices to access the Internet while engaged in other activities. Then streaming is necessary and must be done with significant bandwidth and screen-size limits. Managing the display of information on handheld devices is called content repurposing and is an active area of research (Alwan et al, 1996; Singh, 2004).

Other important technical issues in streaming include the following (Jadav & Choudhary, 1995).

- System architectures should be chosen for fast input and output; parallel ports are desirable.
- Star and fully connected network topologies are desirable. That may only be feasible with local networks for many applications.
- Switches should be preferred to routers on network connections since the routers have lower bandwidths and higher delays.
- Experimentation with the packet size for multimedia data may improve performance since the best size is hard to predict.
- Caching of frequently used data can help efficiency since some media objects will be much more popular than others.

Thus, without careful design there can be serious problems in multimedia delivery. These problems can be negotiated between senders and receivers, either beforehand or at the time of transmission. Generally speaking, worst-case or deterministic metrics for quality of service are more important than average-case or statistical ones for real-time multimedia since users have limits in unacceptable speed, delay, or jitter.

## ARCHIVING OF MULTIMEDIA

Governments must archive many important records, and this includes multimedia information. The size of media objects necessitates high storage costs and slow access. While the costs of storage media continue to decrease, now more data is being created in the first place.

A problem for archiving is the diversity of storage devices and media formats. New ones arise continually, so archiving requires either archiving the hardware and software that can read the stored media even when the hardware, software, and formats are no longer being used

for new media, or else periodically recopying the data into new devices and formats (Friedlander, 2002). For instance, the Library of Congress of the United States still has audio stored on wire media, a technology long obsolete. Video may be a particular problem in the future as there are several competing formats today as well as an ongoing shift to high-definition images. Unfortunately, digital media is different from old books in that it can be virtually undecipherable without the right hardware and software to read it. So governments must continually invest to support their media archives.

Another problem for digital government is to decide what to archive (Liu & Hseng, 2004). Legal requirements may specify particular archiving, but governments have a responsibility to anticipate future data needs as well. Copyright issues can actually simplify as media ages and enters the public domain. But when money for archiving is limited, conflicting interests within the public may disagree as to what information to keep, and politics may be needed to resolve this.

## FUTURE TRENDS

The increasing speed of computers and networks and the decreasing cost of digital storage will enable increased use of multimedia in computer systems in the future. This will enable governments to store and offer increasing amounts of multimedia data for their citizens. Media like video of public meetings, census maps, and graphics documenting government practices will become routinely available so that all citizens can access them without needing to be physically present at government facilities. The main challenges are indexing all these media so citizens can find them, and delivering them (particularly video) across a network fast enough to be useful. Speed and cost improvements alone will not solve all the technical problems as other issues discussed above must be addressed, too. It will take a number of years to reach levels of adequate government media service even in technologically advanced countries.

## CONCLUSION

Multimedia is a natural way for people to communicate with computers, more natural than text, and should become an increasingly common mode for people to learn about and participate in their governments. Good planning is necessary, however, because the data sizes of multimedia objects can be significantly larger than those of text data. This means that media delivery can be unacceptably slow or uneven with current technology, and this limits what can be offered to citizens. Nonetheless, the technology to support media access is improving, and governments will be able to exploit this.

## KEY TERMS

**Bandwidth:** Amount of data (measured in bits per second) that can be transmitted across a network.

**Broadcast:** Transmission of some data in one direction only to many recipients.

**Caption:** Text describing a media object.

**Data Compression:** Transforming of data so that they require fewer bits to store.

**Groupware:** Software to support collaborative work between remotely located people.

**Jitter:** Unevenness in the transmission of data, an important problem for streaming video.

**Media Search Engine:** A Web search engine designed to find media (usually images) on the Web.

**Metadata:** Information describing another data object such as its size or caption.

**Multimedia:** Data that include images, audio, video, or software.

**Quality of Service:** The quality of data transmission across a computer network as a composite of several factors.

**Streaming:** Video or audio sent in real time from a source, thereby reducing storage needs.

# The Digitalization of the West European Party Systems

## INTRODUCTION

American politics has been at the forefront of World Wide Web use. In the early 1990s political parties and candidates started to employ Web sites to spread their message. President Bill Clinton's second-term campaign for the 1996 election was the first time the Internet appeared as a pervasive presence in American Politics, and in which all presidential candidates had Web sites (Rash, 1997). After some time, European parties and politicians followed the lead. In this article, we intend to describe the emergence of Web sites of political parties in West European nations. Reaching out to the Web required allocating limited resources. What advantages did parties hope to reap by creating a Web site, and what disadvantages might they have encountered once the sites were in place? Ideally, a comprehensive analysis would include all political parties in every West European nation. Given the complications regarding collection of data from multiple nations, however, we focused on the parties which were represented in parliament. At the same time, not all nations are currently included in this assessment. The data set consists of information provided by country experts that kindly responded to an expert survey, which included categorizing their national parties by party family (ideologically).[1] To facilitate comparative analysis, we have organized the existing data into four chronological lists (tables) and two figures such as the level of Internet penetration in countries, as well as party family, size, and ideological characteristics:

1. "Complete Chronology" provides the data according to party Web site inauguration for all parties and all nations. The calendar year is divided into three-month quadrants. Is there a correlation between the spread of party Web sites in national party systems and the emergence and development of Internet connections within individual countries?
2. "Party Family Chronology" categorizes site emergence regardless of nationality by ideological divisions ranging from "Nationalist/extreme-right" toward the left ending with "Other" (mainly regional parties). Did ideology influence parties' decisions to initiate Web sites?
3. "National Chronology" arranges Web site emergence by individual nation. Did party size (small, medium, or large) influence the Web site creation decision?
4. "National Initiator Chronology" lists only the first political party in each nation to initiate a Web site.

We also include figures that consolidate the data from the lists to portray potential patterns behind party Web emergence.

Our content analysis of the digitalization of Western European parties is limited only to their decisions and motivations for initiating a Web presence. We do not intend to systematically look at other facets of digital activity such as internal uses of Information Communication Technologies (ICTs) by political parties for data management (archiving or membership lists) or communication (newslists).

## BACKGROUND

### Political Parties and the Web: Advantages and Disadvantages

The Internet, and particularly the Web sites, provides a number of advantages to political parties (Abramson, Arterton, & Orren, 1988; Jordan, 1999; King, 2002; Margolis, & Resnick, 2000; Norris, 2000; Selnow, 1998). First and foremost, the Web sites can rapidly provide seekers large amounts of information that can be updated without much difficulty, such as press releases, brochures, electoral programs, or even complete books. Moreover, this information can be presented through varied multimedia forms such as text, image (photographs, video), or sound (spoken word, music). A second advantage is the speed with which information transmission processes are running on the Internet, and the decentral-

ized way in which information can be retrieved. Visitors to a Web site can download abundant information regardless of their geographical distance from the server on which the site is based; in other words, Web sites have a global reach.

Both the demand and supply sides find the speed of the Internet profitable. Parties can update their sites quickly to inform supporters of latest official positions. The political messages can be directed toward a broad public (broadcasting) or oriented toward certain target groups, such as party members, youth, or female voters (narrowcasting). Another advantage is that parties can highlight positions in a "controlled" fashion, without the intermediary roles of selective and interpretive journalists from newspapers, radio, and television—which leads to a new form of political communication ("unmediated politics")—that is neither filtered by, nor dependent upon, the traditional media. In addition, parties can use their sites to attract new members and/or to mobilize campaign workers or money.

Furthermore, the interactive aspects of the Internet allow parties to tailor the issues that are deemed important to followers. If desired, parties can allow site visitors explicit reaction to certain standpoints, propositions, or elements of the electoral campaign. Through this two-way communication, parties can collect sympathizers' opinions and, in principle, confirm, modify, or fine-tune their views where necessary.

In sum, these Web site properties appear to be ideal for the parties, even more so because the costs of installing and maintaining a site are relatively low, certainly in comparison to the costs of advertising in the traditional media. However, not all that glitters is gold; there are also disadvantages with this new medium such as accessibility and security.

The first drawback of the Internet is the flawed, technological security. In the run-up to the British elections in 1997, for example, the Labour Party site was infiltrated and swamped with anti-Labour political slogans and pornographic images. However, security has improved fairly substantially in recent years, though Web sites are still not immune from hackers.

The second one is the "digital divide," which is still relevant. Access to the Internet is restricted in both quantitative and social terms, and this was especially the case at the start of the World Wide Web in 1993 (and continues today). Those who are active in *cyberspace* are certainly not a true reflection of the electorate; in general they are (still) largely male, young, highly educated, and wealthier than the average. Even now a part of the population will not be reached by the new medium (Table 1).[2] Moreover, it may also be assumed that not all netizens will be interested in politics, which means that these advantages for the parties are relative.

Although Web sites certainly have some disadvantages, the advantages for the political parties seem to be much greater. Because parties generally are rather reluctant to provide information regarding the number of visitors to their Web sites, there are strong indications that the use by voters of party Web sites to obtain political information is growing. In the campaign for the parliamentary elections in the Netherlands in 1998, for instance, party sites attracted at most about 100,000 visitors in the five weeks leading up to the elections (Voerman, 2000; Voerman & Boogers, 2005). In the final three weeks of the 2002 and 2003 election campaign, the sites were visited between 1.5 to 2 million times. About 16% of the electorate visited one or more Web sites during the 2002 election campaign and by January 2003 that increased to 17% (Voerman & Boogers, 2005). This relatively high number of voters actively seeking political information reveals that the party sites are beginning to play a more important role in communications between parties and politicians, on the one hand, and the electorate on the other—at least in Dutch politics.[3]

Given the many attractive elements surrounding political party Web sites, it is surprising that so many parties waited so long before starting Web sites. In this article we deal with possible factors which have influenced the moment at which parties adopted Web sites, such as the level of Internet penetration in countries, as well as party family, size, and ideological characteristics. We also expect that parties generally start sites prior to scheduled elections.

*Table 1. Internet users in member states of the European Union and the United States, 1997-2001 (European Commission, 2001, p. 38)*

| | 1997 | 1998 | 1999 | 2000 | 2001 |
|---|---|---|---|---|---|
| European Union | 5.2 | 9.7 | 14.9 | 26.2 | 30.2 |
| Belgium | 4.9 | 7.8 | 13.7 | 22.7 | 27.3 |
| Denmark | 11.4 | 18.9 | 28.2 | 48.4 | 56.2 |
| Germany | 6.1 | 12.8 | 19.4 | 29.6 | 33.2 |
| Greece | 1.9 | 3.3 | 7.1 | 9.5 | 11.8 |
| Spain | 2.8 | 4.4 | 7.2 | 13.9 | 16.4 |
| France | 1.7 | 6.0 | 9.7 | 16.9 | 16.8 |
| Ireland | 4.1 | 8.1 | 11.9 | 27.5 | 27.9 |
| Italy | 2.3 | 5.2 | 8.7 | 23.3 | 24.3 |
| Luxemburg | 7.2 | 11.8 | 17.5 | 27.5 | 33.9 |
| The Netherlands | 6.4 | 10.2 | 19.0 | 45.9 | 57.7 |
| Austria | 8.1 | 7.4 | 10.5 | 37.0 | 51.3 |

| Finland | 19.5 | 25.5 | 32.3 | 44.5 | 56.1 |
| Sweden | 22.6 | 33.5 | 41.4 | 56.4 | 62.6 |
| UK | 7.3 | 13.5 | 21.0 | 33.5 | 41.7 |
| United States | 15.0 | 22.3 | 40.5 | 56.1 | 61.1 |

## POLITICAL PARTY PATTERNS: GEOGRAPHICAL PATTERN, FAMILY, AND SIZE

### Geographical Pattern

Regarding the geographical pattern, we anticipated that there would be a correlation between the spread of party Web sites in national party systems and the emergence and development of Internet connections within individual countries (see Table 1). An examination of Table 2 demonstrates, indeed, a tendency for Northern European political parties to create Web sites earlier than Southern European parties, because in the former countries more people were online, thus providing a target "audience." The first national party system in which a party started a Web site was Norway in May 1993, followed by the Netherlands in January 1994, the United Kingdom in October 1994, Finland in November 1994, and Italy in December 1994 (see Table 3). Whereas there does appear to be a digital divide of 1.5 years between the north and the south, one should be cautious regarding the lag's implications. Although southern parties may have surfaced later, the motivational Web presence factors that led to site initiation appear to be the same geographically. We see that South European nations score weaker statistically in per capita access to the Web, but that did not keep parties from scrambling in the mid-1990s to create an online presence (Cunha, Martin, Newell, & Ramiro, 2003).

*Table 2. Complete chronology*

Perhaps the most important variable is a party's decision to create a Web site looking toward the future rather than the number of netizens existing in a given nation during the early history of the Web. In fact, research by Treschel, Kies, Mendez, and Schmitter (2003) found that public Internet access did not make a difference in the emergence of party Web sites.

## Family Pattern

We assumed that ideology most likely influenced parties' decisions to initiate Web sites. Generally, we expected within the national party systems, parties on the left (social democrat, left-socialist, and communist) to be more open to modernization and, therefore, to the use of new ICT's. We also anticipated that Green/ecological parties would be at the forefront of Web site initiation because of their ideological commitment to participatory forms of democracy and rhetorical emphasis on the importance of ordinary members' and activists' involvement in internal party life. A Web site might, therefore, provide an increased opportunity for Green parties to put into practice grassroots democracy (Ward & Voerman, 2000). On the other hand, we expected parties on the right, Christian-Democrat and especially conservative parties, to lag in Web site formation because of their historical inclinations toward traditionalism. But the data present surprising results.

On the whole, "nationalist/extreme right" parties (Table 4 and Figure 1) presence on the Web began relatively late when compared to other party families. The National Front (France) was the first to initiate a site sometime in 1994/95,[4] much earlier than the remaining parties that appeared from 1996 to 1999 (most by 1998). This is contrary to what might have been expected, namely that these parties were more likely to create a Web presence because they were banned for ideological reasons from traditional media or had to curtail their message. These parties were only successful in parliament from France to the north. One pattern that is clear in terms of site emergence is that most nations have multiple parties (and, therefore, multiple sites) in the "conservative/right-liberal" party family. A substantial number (seven) surfaced sometime in 1994/1995, with the bulk of the 33 parties present by 1998.[5] The Christian-Democrat parties began a Web presence in Austria in 1994, Portugal in February 1995, with most of the remainder on the Web by 1998. There does not appear to be a geographical correlation in this family with emergence scattered over the years.

Left-liberal parties got their start with the Dutch D66 in mid-1995, followed by most of the others by 1997. With the exception of the two Italian parties, most of the seven parties in this family are in northern Europe. There does

not appear to be a geographical correlation in this family with emergence scattered over the years. The Norwegian Senterpartiet (Social-Democrat) holds the record for being the first West European party to place a site online. Its ideological compatriots did not surface until 1.5 years later in the United Kingdom (UK) and the Netherlands, with the bulk having emerged by 1997. The communist onslaught was led by the French Communist Party in 1995 with the four other European parties following in 1996. We question whether there was an outside motivating force leading them to join in the same year, although we do not know the exact start date for France. It is also noteworthy that electorally, communism has now been reduced to a mainly South European phenomenon.The ecologist family appeared mainly between 1994 through the end of 1996. There does not appear to be a geographical correlation in this family with emergence scattered over the years. The Other category, mainly regional parties, initiated a Web presence beginning in mid-1995 and 1999. The bulk of these parties lie in Spain and the UK.

Ideological categorization by "party family" does not appear to be significant because parties on the right and left got involved with the Web fairly early on. What we found, therefore, is that the Christian-Democrat, Left-liberal, extreme socialist, communist, ecologist, or "other" parties do not appear to support a geographical correlation in terms of family because emergence is scattered over the years.

## Size Pattern

The size of parties does appear to have been an important variable in giving small parties (that normally have difficulties accessing the national media) the impetus to get on the Web early on, but not necessarily more so than the larger parties that also made an early presence. The difference was in the forces catapulting the parties onto the Web. For the smaller parties the Web was in theory a leveler in giving them equal access to the netizens and media. For larger parties it was natural to pursue cutting edge technologies hoping for gains in upcoming elections. As we see in Table 5 and Figure 2, parties that received greater than 20% of electoral votes (large parties) began going online in Austria in 1994 and had completed the process by mid-1997 (the size classification is based on Norris, 2000, pp. 152-153). Parties with 3 to 20% of the votes (small parties) were present slightly earlier and those with less than 3% (fringe parties) slightly later. Fringe parties also continued to go online later than the larger parties, probably because they did not have the resources (in terms of money and technical know how) – even though not so much was needed. All in all, it does not seem that the introduction of Web sites has contributed to a "leveling of the playing field" (Norris, 2001, p. 149). But not much more can be said relative to the impact of size and Web presence emergence.

## CONCLUSION

In conclusion, we have found that parties in Northern and Southern Europe, of varied party families and size, were all interested in creating a Web presence — in order to get their message out, or because they did not want to look old-fashioned by not having a Web site. Examining the past has not supported most of the assumptions with which we began. The only substantial statement we can make is that what does seem to play a role in Web presence is upcoming elections. They seem to not only stimulate the initial creation of Web sites but are also key factors in their redesign and currentness. Other parties then appear to quickly imitate the initiators. Ideally, a future study will

also focus on parties not represented in parliament to see if these smaller parties, which generally get left out of the governing system, are using the Web to gain greater exposure.

## KEY TERMS

**Cyberspace:** A metaphor for describing the non-physical terrain created by computer systems and networks. In a cyberspace people can search and exchange information, communicate, contact public authorities, organize political campaigns, etc. without face-to-face connection or meeting in a physical space.

**Internet:** A global network connecting millions of computers.

**Political Party**: An organized group that selects and nominates candidates for elections of representative bodies.

**Party Family:** A group of parties that share the same ideology and belief-systems.

**National Party System:** Refers to all the parties within a national-institutional context.

**Web Presence:** Refers to having an established existence, through a Web site on the World Wide Web.

**Web Site:** A site (or location) on the World Wide Web. Each Web site contains a home page, which is the first document users see when they enter the site.

**World Wide Web (or simply Web or WWW):** A way of accessing information over the medium of the Internet. It is a system of Internet servers that support specially formatted documents (using a markup language called HTML for HyperText Markup Language) and links to other documents, as well as graphics, audio, and video files.

## ENDNOTES

[1] We would like to acknowledge the following individuals for contributing to the data set as nation experts: Peter Filzmaier, Austria; Michel Bruneel and Jean-Marc Galant, Belgium; Karl Löfgren, Denmark and Sweden; Tuomas J. Alaterä and Vilho Harle, Finland; Laurence Monnoyer-Smith, Thierry Vedel, and Bruno Villalba, France; Gerd Strohmeier, Germany; Irene Martín and Korinna Patelis, Greece; Pierpaolo Naccarella and James L. Newell, Italy; Markus M. Bugge and Anders Ekeland, Norway; Luis Ramiro Fernández, Spain; and Steve Ward, United Kingdom. We (Carlos Cunha – Portugal and Gerrit Voerman – Netherlands) provided the data for our own countries.

[2] It was not possible to acquire reliable and comparable data regarding Internet users in the years before 1997.

[3] The primary focus of party Web sites everywhere is to communicate information about party policy, issues and candidates, not to solicit active participation (Ward, Gibson, & Nixon, 2003). This emphasis on information provision seems to tie in well with the wishes of the average visitor, who according to Dutch research is primarily seeking information, and has much less of a need to interact (Boogers and Voerman, 2004). On the other hand, in campaign times parties are increaslingly becoming successful in using their Web sites to mobilize volunteer and financial support.

[4] The experts for this nation were unable to provide the specific date for the Web site initiation.

[5] The experts for these nations were not always able to provide exact start dates for the relevant parties. In the case of Sweden, not even Webmaster interviews could uncover the information because the officials were not aware of the start dates.

# Disabilities and the E-Clusive Workspace

## INTRODUCTION

The use and deployment of information and communication technologies (ICTs) in the public and private sectors has opened an array of options, best practices and implementation approaches for workplace (or workspace) operation. The increasingly widespread adoption of these ICTs, while often an efficient means of delivering services, encouraging communication, and facilitating transactions, still excludes sizeable portions of the population (Baker & Fairchild, 2005; Baker & Ward, 2005). Much of the focus of discussions on ICT adoption has assumed that patchy use of ICTs relates principally to socioeconomic variables. A consequence of these kinds of analyses is the omission, in formulating policies that seek to incorporate ICTs into the workplace, of a key group of people with functional limitations that go beyond relatively remediable conditions (e.g., economic, educational, location)—people with disabilities. Some 15 years after the 1990 implementation of the U.S. Americans with Disabilities Act (ADA), the employment rate of U.S. persons with disabilities is only about 30% (Weathers, 2005). This represents significant and underutilized resource and societal costs for unemployed persons with disabilities ranging from $78 billion to $200 billion annually (U.S. Census Bureau, 2000; Worksupports.com, 2000). A similar situation exists in Europe. Dupré and Karjalainen (2003) report that, according to the preliminary results of the "ad hoc module on employment of disabled people of the Spring 2002 round of the Labor Force Survey", "78% of the severely disabled aged 16-64 are outside of the labor force as compared to 27% for those without" long-standing health problems or disabilities (p. 1).

While policymakers generally recognize that the availability of ICTs allow telework to be a realistic work option and a reasonable workplace accommodation for people with disabilities, focused, comprehensive programs targeted at advancing these applications of ICTs for people with disabilities have yet to be developed. Aside from a few token programs such as the interagency website on teleworking, telework.gov, and a handful of laws "encouraging" telework, requiring reporting to the U.S. Congress or establishing telework coordinators (e.g., Public Law 108-447, § 622 (2004), Public Law 108-199, § 627 (2004) and Public Law 106-346, § 359 (2000)), little real attention seems paid to this work modality.

A possible downside to the e-clusive "virtual workspace" is the potential for the inadvertent marginalization and stigmatization of people with disabilities from the employment community. While using ICTs facilitates may increase accessibility to employment and function as reasonable accommodations for people with disabilities, they may also act to decrease (or at least alter) the kinds of social networks that disabled people have within their occupations. This is an important consideration given that limitation of workplace contact (either in terms of degree or attenuation), can increase the likelihood that people with disabilities will occupy positions of inferior power (they will be more dependent) within the work environment. Such a restriction of power affects the ability to affect positive changes in the workplace. Moreover, as noted by Schur, Shields, Kruse, and Schriner (2002), voting "has been found to be strongly and positively related to … employment and union membership which can represent recruitment and mobilization networks" (p. 169). Thus, the failure to integrate people with disabilities into the workplace can also have a significant impact on their ability to exercise political power and influence. It is within this context that this article identifies some of the principal workplace accessibility issues faced by people with disabilities and discusses the use of teleworking as a reasonable workplace accommodation for people with disabilities.

## BACKGROUND

### People with Disabilities: Employment and the Workplace

Using data from the 2001 and 2004 American Community Surveys (ACS), the Rehabilitation Research and Training Center on Demographics and Statistics at Cornell University (2005) reports that the "employment gap between the

employment rates of working-age people with and without sensory, physical, mental, and/or self-care disabilities increased from 37.3 percentage points in 2001 to 38.9 percentage points in 2004, in the US" (p. 4). Since almost 67% of unemployed persons with disabilities state that they would like to work (NOD/Harris Poll—National Organization on Disability/Harris Poll, 2000), persons with disabilities are a significant "hidden labor pool" (Anderson, Bricout, & West, 2001). With just over 14.5 million unemployed 16 to 64 year old Americans having some sort of disability, the societal cost for unemployed persons with disabilities range from $78 billion to $200 billion annually. These costs include lost productivity, Social Security payments and public funds spent on health care and medical services (Worksupports.com, 2000). The U.S. Equal Employment Opportunity Commission's (EEOC) proclamation that telework may be a potential accommodation for persons with disabilities defined by the ADA opens an additional avenue for the employment of U.S. persons with disabilities (Anderson, et al., 2001). As an alternative work arrangement, telework shifts the workplace from a centralized location to which all workers must physically travel to a geographically remote space, potentially miles away from the boss and work colleagues—a workplace at the employee's home, a satellite location, a hotel room (Fetzner, 2003; Peters, Tijdens & Wetzels, 2004; Stanworth, 1997; Sullivan, 2003). As Bricout (2004) writes, for "workers with disabilities home-based telework offers the possibility of ready access to employment unhampered by consideration of distance, fatigue or interpersonal demands" (p. 147).

Bias and discrimination are often significant barriers to employment for persons with disabilities. Employment is highest among persons with sensory disabilities and lowest among persons with mobility and mental impairments (Schur, 2002). The employment of persons with severe disabilities tends to be less than the employment of persons with less severe disabilities (NOD/Harris Poll—National Organization on Disability/Harris Poll, 2000; Bricout, 2004). Kennedy and Olney found an employment rate of 58% amongst persons with disabilities who had experienced discrimination, and a strong correlation of job discrimination and the severity of (disability-based) work limitation. Employers' perceptions of persons with disabilities may affect, unconsciously or consciously, their hiring decisions. For example, employers may fear an increased number of accidents and absences related to disabilities, even though research suggests that employees with disabilities typically have lower accrued compensation costs—$82 vs. $1,564 for employees without disabilities (Graffam, Smith, Shinkfield, & Polzin, 2002). However, it may also be the case that employers are accommodating employees with those disabilities that least affect productivity, or whose disability (or disabilities) is the easiest and least expensive to accommodate (Blanck, Schur, Kruse, Schwochau, & Song, 2003). A 1999 Job Accommodation Network (JAN) survey on workplace accommodations reported that since 1992, 71% of workplace accommodations have cost $500 or less with 20% of those costing nothing (Wireless RERC, 2003).

Schur (2002) found that employment reduces the social isolation experienced by persons with disabilities, as well as increasing the "overall life satisfaction and … feeling of being useful and needed" (p. 344). However, employed persons with disabilities still perceive themselves as both physically and socially isolated in their workplace. In fact, it is common for persons with disabilities to consider their work location as a "dumping ground" for people who cannot otherwise fit into the mainstream workplace, and feel themselves to be victims of harassment in the workplace (Robert, 2003). Compared to employees without disabilities, employees with disabilities tend to receive lower hourly and annual earnings. Moreover, employed persons with disabilities are less likely to be involved in decision making and making a presentation at work (Schur, 2002). On the plus side, employed persons with disabilities frequently report improved self-esteem, and increased social contact and personal satisfaction (Graffam et al., 2002).

The ADA requires U.S. employers to provide "reasonable accommodations" for persons with disabilities. Commonly occurring reasonable accommodations include employer provision of extra supervisory or co-worker attention (68%), establishment of flexible work hours (51%), and provision of a job coach (46%) (Olson, Cioffi, Yovanoff, & Mank, 2001). According to Loprest and Maag, typical environmental workplace accommodations for persons with disabilities include: parking or public transit stops (19%), elevators (17%), work stations (15%), work hours or job restructuring (12%), handrails or ramps (10.4%), Braille, enlarged print, lighting, audio tape and voice synthesizer, technical device or interpreter (2.5%) (Loprest & Maag, 2001). Eighty-two percent (82%) of employers who made accommodations for persons with disabilities provided a facility-accessibility accommodation (Bruyere, 2000).

## Telework: Not Just "Phoning In"

Telework, as an alternative work arrangement, shifts the workplace from a spatially and geographically centralized place of group activity, to a technologically connected albeit remote space, potentially miles away from managers and work colleagues—a workspace at the employee's home, a satellite location, or even a coffee shop (Fetzner, 2003; Peters, Tijdens & Wetzels, 2004; Stanworth, 1997; Sullivan, 2003). In contrast with the more traditional expression, "telecommuting," telework refers specifically

to the reconceptualization of the structure of the assigned work tasks within the virtual environment, the virtual workspace created by use of appropriate ICTs. Such ICTs, including broadband availability, allow for the implementation of the virtual workspace where teleworkers can engage in collaborative activity with both on-site workers and other teleworkers.

Telework is not as new a concept as one would think. One of, if not the first U.S. teleworker was a bank president in Boston who had a phone line installed between his bank and his home in 1877 (Langhoff, 1996). As a generally recognized phenomena as early as the 1950s, technological improvements led people to envision the use of automated technologies to work from home (Mills, Wong-Ellison, Werner, & Clay, 2001). Simpson, Daws, Pini, and Wood (2003) write that the concept gained additional currency in the 1970s "as a response to the need to reduce energy consumption with the oil crisis" (p. 115). More generally, advances in information technologies—broadband and wireless communications, smart-phones, desktop computers, compact facsimile and printing machines—have enabled telework arrangements that can be, in the most robust implementations, conceptualized as creating "virtual workspaces." For people with disabilities, particularly with certain physical conditions that constrained transportations and ordinary workplace interactions, the untethering of "work" from the proximate physical workplace can allow an employment possibility that might be otherwise costly economically or in terms of simple ease of movement or comfort.

Telework represents an underappreciated opportunity for employers, enabling them to tap into new and generally underutilized labor pools—such as persons with disabilities. The U.S. EEOC has acknowledged this, noting that telework arrangements are potential "reasonable accommodations" for persons with disabilities under the ADA. However, the actual implementation of telework for people with disabilities appears to lag behind the kinds of arrangements that are possible with existent information technologies. Tahmincioglu (2003) estimates that only 7% of the employed persons with disabilities work from home 20 hours or more a week.

In the United States, surveys indicate that around 2.8 million employees telework regularly, and that approximately 17% of Americans teleworked full-time while 30% teleworked at least one day a week (U.S. Department of Labor, 2003). According to a recent survey, teleworkers can save employers approximately 63% of absenteeism costs per teleworker per year and 25% of an employee's annual salary due to retention related to employee satisfaction with telework arrangements or around $10,000 in reduced absenteeism and job retention costs (Telework Coalition, 2003). Benefits that accrue go beyond the purely economic to the perceptual. Some 45% of Teleworkers with a separate office in the home perceive an improved quality of life—work, home, and social—because of the telework arrangement (Gibson, Blackwell, Dominicis, & Demerath, 2002; Khaifa & Davidson, 2000; Raines & Leathers, 2001).

Professed ancillary advantages of telework as an alternative work arrangement include environmental improvements resulting from reduced commutes to the workplace, the dispersion of the workforce in light of natural or human-made disasters, and allowing people living in rural or otherwise geographically remote areas to participate more fully in the workforce (Raghuram, London, & Larsen, 2001; Simpson et al., 2003). Other employer-related benefits of telework arrangements can include improved morale, expected reduced real estate cost, and increased employee loyalty. Teleworkers claim an increase in productivity and a reduction in absenteeism because of telework arrangements. Teleworkers themselves report other advantages of telework such as having a more flexible schedule (Raghuram et al., 2001), reduced work-related expenses—clothes, vehicle fuel—and avoiding commuting to and from the traditional office (Gibson et al., 2002).

Even with all of the professed benefits, telework has its critics. The critics tend to focus on two features of telework: First, the remote aspect of telework—the lack of work support, job structure, technology, social interaction and communication, and second, the potential liabilities of telework—U.S. Occupational Safety and Health Administration (OSHA) regulations, and fair labor laws. Critics also express concerns about the costs associated with setting up teleworkers—for example, equipment and remote communication access, and determining who pays for specific components of the telework ICT infrastructure. Employers are increasingly concerned with the problems of securing proprietary information in remote telework locations, reductions in teamwork due to little face-to-face contact between employee members, and remote management problems such as not being able to directly (face-to-face) monitor employee work. Finally, there are concerns about wider impacts, such as disruptions to family and neighbors, which could result in distractions and decreased productivity (Peters et al., 2004). This is a concern of not only employers but also employees. According to Mills, "the traditional styles of management [monitoring employees] often do not work with telecommuting" (Mills et al., 2001). In telework arrangements, managers must transition to a manager of employee performance or facilitator (Gibson et al., 2002; Illegems & Verbeke, 2004; Mills et al., 2001; Swink, 2001; Telework Coalition, 2003).

The widespread adoption of telework may also be slowed by concerns, fears, or misconceptions of employees. Employees fear, not without some justification, long

work hours, potentially becoming "workaholics" because of the lack of discipline or experience self-managing flow of work. Isolation from the mainstream or from the background flow of office "information" might result in limited career development (Illegems & Verbeke, 2004; Khaifa et al., 2000; Mills et al., 2001). While some organizations regularly offer telework as a partial solution to urban traffic and air quality issues, critics, paradoxically, have suggested that telework arrangements will result in increased urban sprawl, fewer jobs in public services such as transportation due to teleworkers being isolated to neighborhoods (Swink, 2001; Mills et al., 2001).

## Social, Cultural, and Policy Considerations

Aside from the narrowly characterized employment and workplace related variables that affect telework as an employment alternative, there are also social and cultural factors may affect the desirability of telework as a reasonable workplace accommodation for people with disabilities. For example, one concern is that teleworking results in increased social isolation rather than being a "community-friendly" form of work (Kamerade & Burchelle, 2004). Persons with disabilities are more likely to report feelings of social isolation, disconnection from their managers, decreased communication with peers, and isolation from the company culture. Thus, if teleworking results in increased social isolation of those workers whose principal form of work is telework, then using telework to accommodate people with disabilities is likely to exacerbate their isolation rather than enhance their social capital or increase the density of their social ties. Employers also express concern that telework arrangements are not in keeping with the current emphasis on teamwork and the need for rapid change and response (Anderson et al., 2001; Gibson et al., 2002; Igbraria & Guimares, 1999).

A second contributing factor closely related to social interaction is job discrimination. According to various studies, anywhere from 10% to 36% of employed persons with disabilities report having experienced job discrimination (NOD/Harris Poll—National Organization on Disability/Harris Poll, 2000; Kennedy & Olney, 2001). Other sources report that the potential job discrimination is one of the principal concerns of teleworkers, especially from the standpoint of career development and promotions. (Anderson et al., 2001; Khaifa et al., 2000; Mills et al., 2001; Igbraria et al., 1999; Robertson, Maynard, & McDevitt, 2003).

Liability is a third factor that may contribute to persons with disabilities not implementing telework arrangements. Ambiguities in legislative and regulatory terminology leave uncertainties regarding employers' liabilities in telework arrangements. Uncertainties include but are not limited to the U.S. OSHA's mandate that employers provide a safe workplace (Mills et al., 2001) and the U.S. Fair Labor Standards Act of 1938's (FLSA's) requirement that employers "pay all nonexempt employees for all hours worked and time-and-one-half for all overtime regardless of where the work is performed" (Mills et al., 2001). The ADA forces a case-by-case, individual approach regarding litigation (Kreismann & Palmer, 2001; Robertson et al., 2003). An individual legal claim can cost employers anywhere from $50,000 to $150,000 in attorney fees, even if the court dismisses the claim (U.S. Commission on Civil Rights, 2003).

An issue that is perhaps more tied to a different, contextual variable related to infrastructure and issues related to telecommunications and the deployment of broadband technologies is remote access to technology. In order to telework, an employee must have ready and consistent access to the technological infrastructure that enables telework arrangements: the Internet, email, wireless communications devices, facsimile, and voice communication. "Virtual teams cannot exist without technology" (Pratt & Associates, 2000). Only 25% of persons with disabilities own a computer and just 20% have Internet access, compared to 66% and 40% of persons without disabilities respectively (Kaye, 2000).

A final contributing factor closely associated with the telework infrastructure factor is cost (Fairweather, 1999). Some employers pay for the cost to implement telework arrangements for their employees considering an investment; others do not. If employers do not pay for the cost of implementing telework arrangements, a large number of persons with disabilities will more than likely not have the financial resources to do so—around 23% of 16 to 64 year old persons with disabilities have an annual income below the U.S. poverty level, compared to around 10% of persons without disabilities (U.S. Census Bureau, 2000).

## FUTURE TRENDS

If telework and virtual workspaces represent positive developments in employment possibilities, and viable approaches to advancing the inclusive workplace, then what policy responses might be reasonable ones? At present, the U.S. ADA states that employers must make "reasonable accommodation" for persons with disabilities unless such results in undue hardship to the employer (Blanck et al., 2003). In addition, the EEOC and the New Freedom Initiative recognize telework as a potential alternative work arrangement for persons with disabilities (Anderson et al., 2001). One approach could be to promote legislation that provides monetary incentives for unem-

ployed persons with disabilities who participate in telework arrangements. Although such legislation has been introduced in the U.S. House and Senate, to date none has become law.

A different type of strategy would be to expand the development of awareness and education outreach campaigns such as the European Union's "eInclusion and eAccessibility Initiative" (Europe's Information Society, 2006). Such a communication campaign provides an avenue for facilitated discourse between vested stakeholders that will not interfere with each stakeholders' other priorities, keeps telework and the employment of persons with disabilities on the agenda and allows the synergy between the two issues to progress along the timeline of the stakeholders. Funding a communication campaign to supplement existing efforts by the U.S. Small Business Administration could increase the involvement of large corporate enterprises with more resources to invest, and larger potential savings related to telework arrangements, as small business only pays around 44% of the U.S. private payroll (Small Business Administration, 2003). An awareness and education communication campaign also has the potential to directly expose employers to persons with disabilities. Research indicates that persons' without disabilities affective attitudes toward persons with disabilities tend to be more positive with greater exposure to persons with disabilities (Popovich, Sacherbaum, Scherbaum, & Polinko, 2003).

## CONCLUSION

Both national and international efforts are required to encourage the progress of research on the impact of teleworking as a workplace accommodation on both employers and people with disabilities (Baker & Fairchild, 2005; Baker & Ward, 2004; Wireless RERC, 2003). Raising awareness of the advantages and disadvantages of using ICTs to create virtual workspaces will likely encourage research of teleworkers with disabilities and the role of computer mediated virtual workspaces as reasonable accommodations. Moreover, a targeted set of public policies should reflect a renewed emphasis on leveraging information technologies to reduce insidious aspects of the digital divide. Such research is needed to understand better the opportunities and challenges specific to teleworkers with disabilities. The research is also an important part of finding ways to increase the political power of people with disabilities and to provide opportunities for people with disabilities to engage in public sector work (e.g., government). Currently, claims and assumptions regarding teleworkers with disabilities result from overlaying research on teleworking and research on employees with disabilities. Without research specific to teleworkers with disabilities, the assumptions and claims made regarding teleworkers and, more specifically, persons with disabilities, will continue to encourage speculations interfering with telework as a viable reasonable accommodation that can increase the employment of persons with disabilities.

## KEY TERMS

**Americans with Disabilities Act (ADA):** According to the U.S. Department of Justice, Civil Rights Division, Disability Rights Section (2004), the 1990 Americans with Disabilities Act "prohibits discrimination on the basis of disability in employment, state and local government, public accommodations, commercial facilities, transportation, and telecommunications" (p. 1).

**Disability:** As reported by the Disabled People's Association of Singapore (2005), the United Nations Standard Rules on the equalization of opportunities for persons with disabilities says that the "term 'disability' summarizes a great number of different functional limitations occurring in any population in any country in the world. People may be disabled by physical, intellectual or sensory impairment, medical conditions or mental illnesses." Typically such limitations are relativized to "normal human functioning" (World Health Organization) or to major life activities (Americans with Disabilities Act).

**Information and Communication Technologies (ICTS):** ICTs are those technologies (typically electronic) used to store, process and transmit information. Recent examples of ICTs include telephony, satellites and cables, and the Internet. According to the European Commission (2001), "[I]nformation and communications technologies is a term which is currently used to denote a wide range of *services*, *applications*, and *technologies*, using various types of *equipment* and *software*, often running over telecom *networks*."

**Public Policy:** A public policy is a rule, law or guideline established (and typically enforced) by some governmental authority whose goal is to regulate the actions of the people who fall under the jurisdiction of that governmental authority.

**Telecommuting:** While sometimes treated as synonymous with "telework," telecommuting refers to the use of information and communication technologies to communicate with other workers or one or more geographically centralized workplaces to exchange information relevant to work duties and assignments.

**Telework:** Telework is work that occurs outside of the traditional, geographically centralized workplace, in which the worker uses information and communications technologies such as the Internet to complete the work and communicate with the workplace (Bailey, & Kurland, 2002; Bricout, 2004; Fetzner, 2003; Kamerade, et al., 2004; Potter, 2003; Topi, 2004).

**Virtual Workspace:** A virtual workplace is an electronic "space" created by the use of information and communications technologies in which, through the medication of such technologies, workers can perform, interactively and collaboratively, work duties.

# The Dubai E-Government Project

**James Piecowye**
*Zayed University Media Center, UAE*

## INTRODUCTION

Ranked 26th worldwide and second in the Middle East for its e-government initiative, the United Arab Emirates (UAE), and Dubai, in particular, is an excellent example of how e-government might be developed, implemented and advanced as a customer service-based concept (West, 2005).

The e-government project that continues to evolve in Dubai can be credited almost exclusively to the Emirate's leadership as embodied in Sheikh Mohammed Bin Rashid Al Maktoum, Crown Prince of Dubai, his vision and sheer tenacity to make grand ideas a reality.

It is not our intention in this article to suggest that the Dubai e-government project is without challenges and room for improvement. It is our intention, though, to present the Dubai case study as an evolving example of e-government from which to learn.

While the development and implementation of the e-government project is advancing in Dubai at a frenetic pace, the rollout of the concept to the public and the general acceptance and inclusion of the public in the larger governance process is still, to a large extent, a masterful work in progress.

The general global assessment of e-government delivery undertaken by Darrell West (2005) makes it very clear that progress is being witnessed worldwide when it comes to the implementation of e-government ideals. The greatest challenge to e-government, according to West (2005), is at times its very slow pace, its uneven nature and failure to adapt to changing conditions within which it exists. Dubai, in some instances to a lesser degree and others to a greater degree, is experiencing the same problems being experienced globally by those engaged in implementing e-government.

Fortunately, e-government performance in Dubai is improving rapidly, as budget, bureaucracy and institutional forces are pushed towards compliance. But what continues to be fundamentally lacking from Dubai's e-government project is a means of promoting and facilitating authentic e-governance where society as a whole has a means of engaging in meaningful interaction as a participant in the process of governance and not simply the service side of the state.

Dubai is one of seven Emirates that constitute the UAE federation. The country's constitution identifies it as an Arab state, with Islam as its religion and Arabic as its official language. The UAE is a member of the Arab League and the Gulf Cooperation Council (GCC), a regional group that joins the Gulf states of Kuwait, Saudi Arabia, Qatar, Bahrain, UAE and Oman. In general, GCC countries share many political, economic and social characteristics, including high reliance on an imported work force.

In the last decade, Dubai and the UAE have undergone phenomenal change. Fifty years ago, the country had little to no electricity, plumbing or simple infrastructure, such as surfaced roads and bridges. In 1950, there was no hospital and but a single school in Dubai. Dubai was a city comprised of barasti huts (housing made from palm fencing) and clay buildings lining sand streets. As late as the 1970s, according to Timothy Walters (unpublished), the literacy rate of the UAE hovered around 20%, with only a fraction of adults having any formal education.

Today, the landscape of Dubai has been radically transformed. Dubai is experiencing a level of prosperity never before seen. Physically, the city has been morphed from a sleepy regional trading post to the premier economic and tourist hub of the Middle East.

The transformation of Dubai is marked by its rapid installation of a modern infrastructure, the embracing of technology and both the vision and resources to rapidly roll out change to the general population. In 1999, Sheikh Mohammed Bin Rashid Al Maktoum championed the idea of launching a visionary e-government project to set the standard for such endeavours in the Middle East. More recently, in 2005, the idea of a government connecting to at least a large segment of its constituents is quickly becoming a reality.

This article will review why we believe Dubai might be considered an excellent e-government case study in the implementation of e-government as a customer-service concept. This article will also suggest that one of the greatest challenges of any e-government project is to include governance in the equation. This examination is primarily based on a synthesis of government publications available through the e-government portal www.dubai.ae, where examples of the e-government exercise are available, with other accounts of the Dubai e-government project.

## BACKGROUND

According to the UAE Ministry of Economy and Planning, the UAE's population in 2003 was estimated to be 4.041 million (Dubai Development and Investment Authority, 2005). Dubai is the UAE's most populous city, with an estimated population of 1.071 million. Census results from 2000 shows that 80% of Dubai's population is comprised of expatriates. According to official government statistics, UAE nationals constitute 18% of the country's population, followed by other Arabs expatriates at 13%, Asians 63% and Europeans and others 4%. Dubai's population is similar in its diversity to the nation at large (Datadubai.com, 2005; Dubai Development and Investment Authority, 2005).

The diverse expatriate population of Dubai uses language as one tool of cultural expression and interaction. While English is the dominant language in the business and tourism industries, government agencies use both Arabic and English to cater for the Emirate's residents and visitors. In addition, Urdu, Hindi, Farsi, Tagalog, and Russian, along with other languages, are also widely used on a daily basis. Most schools in Dubai offer one or two languages as additional foreign languages for non-native speakers.

International schools in Dubai cater to the myriad of nationalities living in the Emirate. Expatriate children are not admitted to the UAE public schools in the country; therefore, they study in private institutions. Local authorities have licensed K-12 schools offering Lebanese, British, American, French, International Baccalaureate and Indian curricula, to name just a few. American, Canadian and British-styled institutions of higher learning also provide higher studies to nationals and expatriates.

Dubai also plays a role as an international trading site. With an advanced infrastructure that includes world-class ports, airport, roads, free zones, a financial center, banks, insurance sector and retail outlets, to name just a few, Dubai attracts business as well as leisure visitors year round. To promote itself as a trade destination, the Dubai government organizes an annual shopping festival that attracts millions of visitors. In addition, it organizes a summer program of shopping and hotel promotions to revive the local economy during the months when temperatures soar and local residents take their annual leave abroad.

Dubai is one of the Middle East's most successful tourism destinations. According to the World Tourism Organization, Dubai has witnessed steady positive growth as a destination for the past decade, with only a marginal decline during periods of regional wars and instability. In 2002, Dubai achieved 31% growth in tourist arrivals—the world's highest for the year. In 2003, Dubai guests reached 4,980,228, with the majority coming from other Arab countries, Europe, Africa, Russia and the CIS republics and Asia. There is no question that Dubai is a city state in the throngs of rapid development.

## THE IDEA OF E-GOVERNMENT

E-government can be defined as the electronic enablement of services provided or commissioned by the public sector specifically capitalizing upon applications of information and communication technology (ICT) tools to the wide range of service activities undertaken by the state.

The goal of any e-government project is to enhance the effectiveness and efficiency of a government's activities and, in many instances, alter the procedural relationship of the government with the public. This altered government/public relationship typically progresses through several distinct phases, according to Sami Atallah (2001): posting information; two-way communication; exchange of value; integrated service and exchange.

The move towards e-government by many first-world countries is fundamentally altering the government/public relationship on one hand and citizen/business relationship on the other. In the Middle East, change in the government/public and citizen/business relationship is no different.

What is different in the Middle East is the relationship of e-government to e-governance. In many democratic-styled countries, e-government and e-governance projects are being developed concurrently. E-governance might best be understood as the electronic enablement and management of democratic activities, ensuring a degree of fairness, transparency and ultimately participation in the public-policy process of the otherwise disenfranchised (Bovaird, 2005).

E-governence is less about access and more about the style and intent of leadership. E-governence, as Khosrow-Pour (2005) suggests, is about enabling new ways of debating and deciding public policy. E-governance is less an economic investment and more an investment in the populous itself, thereby facilitating a new means of listening and consulting the citizenship.

E-governance, thus, becomes about enabling democratic tendencies and efficient government. The ideals of e-governance are being talked about today across the Middle East in general, but have yet to be adopted in any meaningful way, including in the UAE.

Sami Atallah (2001) suggests that the most striking effect of e-government is seen in the enhancement of the communicative ability of governments. But e-government is not simply the reinvention of the communication structures of governments. E-government is the reinvention of the way the business of governance is conducted. From information delivery, service procurement and delivery,

the manner of conduct of the state is dramatically changing. What is coming about is the imposition of a customer service-centered mentality in the manner in which the state interacts with the population it serves.

The goal of e-government as it is being embraced today worldwide and, in particular, in Dubai, can be summarized as to provide unified quality services (UQS) under the common slogan "the customer first." Unified quality services are being promoted in the context of e-government embracing the use of technology to simplify customer/government transactions and create a better environment for efficient government operations (Dubai eGovernment, 2004).

The process of e-government is much more than simply facilitating UQS. What e-government is facilitating is the complete institutional, cultural change of government internally and as it is perceived by the public itself. What is being advanced is organizational change towards customer relationship management, with the goal being to meet and exceed customer expectations from the start to the end of the transaction (Bovaird, 2005).

## THE DUBAI E-GOVERNMENT EXPERIMENT

The driving force behind e-government in Dubai is Sheikh Mohammed Bin Rashid Al Maktoum. His idea for e-government is embodied in the government's portal, www.dubai.ae, where customers can access a plethora of services being made available to them, in many cases, only electronically.

Sheikh Mohammed has set out two broad objectives for e-government in Dubai:

1. The government of Dubai shall e-enable 90% of its public services by 2007
2. Customers should conduct 50% of e-enabled government transactions through innovative channels by 2007 (Geray, 2004).

The Dubai e-government project is ambitious and premised on the simple idea that anything is possible if the right people are involved. Thus, what is constantly suggested within the Dubai government is that you are either part of the team or not, and those who are not up to the challenge of e-government are free to move on.

By 2007, it is expected that there will be:

1. E-enablement of 90% of public services (including identification of all online and off-line public services in each department and also service prioritization for e-enablement)
2. Implementation of e-service quality guidelines in all departments
3. Implementation of virtual governance by joining administrative boundaries through electronic integration and data sharing
4. Implementation of targeted marketing campaigns
5. Implementation of synergistic e-services to achieve expedited implementation and cost savings to the Dubai government (Geray, 2004).

The key to the success of the Dubai e-government project so far has been the ability of Dubai to re-invent the attitude of public service itself. Nowhere is this reinvention more prevalent than in the Department of Tourism and Commerce Marketing (DTCM). DTCM is a natural success story in Dubai because of the persistence of the Dubai government to continually try to accomplish the impossible and the desire of the Dubai government to see the Emirate become a unique tourist, financial, manufacturing and service destination.

The DTCM activities with e-government focus on connectivity to those who may want to come to Dubai and the eventual ease of their integration into Dubai. From general information to the obtaining of visas to the finding of suitable accommodations, the DTCM e-project embraces the idea of aiding the user first. The department considers its eServices a strategic gateway to the world. DTCM, as of December 2003, had 10 eServices, of which four were transactional and six informational (Dubai eGovernment, June 2004f).

## THE DUBAI DIFFERENCE

What makes Dubai and its e-government initiative different than most other places in the world, according to Sheikha Lubna, CEO of Tejari (the first e-commerce supply chain market in the region), is that contrary to the practices in most parts of the world, where the corporate community and business sectors take the lead and impose their e-initiatives on society. the government sector in Dubai is the real leader in the transition into e-commerce (Dubai eGovernment, August 2004g).

Under the leadership of Sheikh Mohammed Bin Rashid Al Maktoum, the e-government initiative of Dubai has seen amazing advances. According to Sheikh Mohammed, "the e-government concept depends on many factors, two of which are: making essential improvements to the government services provided to the public, and prompting the public sector to deal with its customers as dynamically and easily as the private sector" (Dubai eGovernment, May 2004d, p. 2).

The Dubai e-government initiative has two basic guiding objectives: simplification of government transactions in the emirate, and creation of initiatives to help Dubai assume a leadership position in the IT-driven global economy (Dubai eGovernment, October 2004h).

To operationalize these two objectives, the Dubai e-government project has relied very heavily, but not exclusively, on cultivating a reflexive relationship with the private sector and business community. The Dubai government is very cognizant of the fact that its constituents comprise both individual residents and private industry, and its initiatives serve to satisfy the needs of both. In the case of private industry, the challenge is to get them to buy into the e-government initiatives by making the industry a key component of the goods and services supply train of the state.

According to Sheikh Mohammed Bin Rashid Al Maktoum, the success of any e-government initiative is premised on the symbiotic relationship of economics and social services that can only be realized if state and business interests work as partners.

The rapid movement towards the implementation of e-government and the changed mentality that comes with it has brought its own share of challenges. Dr. Khalid Al Khazraji, Undersecretary at the UAE Ministry of Labor and Social Affairs, considers one of the most significant challenges to the implementation of e-government in Dubai the changing of the attitudes of the employees who must buy into the current government-centered system to a customer-first e-government system. Part of the process of change can take place through re-training. The other, more difficult, aspect of change comes from convincing employees of the benefits of moving towards e-enabled government services (Dubai eGovernment, May 2004d).

Dubai has always been a pioneering state. In April 2000, Sheikh Mohammed Bin Rashid Al Maktoum called for the transition of the Dubai government into the new knowledge age, demanding that the departments of the Dubai government provide their services electronically within no more than 18 months! Between April 2000 and the time of Dubai e-government launch in October 2001, all the infrastructure for the rollout of the e-government project was put into place. After 2 years, Dubai government, through its e-government project, provided more than 600 electronic services. Dubai turned the initiative into a project and the project into an organization (Dubai eGovernment, April 2004c).

What distinguishes Dubai's e-government project from any other world wide is the constant desire to continually innovate. A further example of this innovation was seen in September 2005, when the Dubai government launched the first Arab electronic mobile phone e-government portal. The mobile phone portal was launched with 26 services divided into 10 categories: traffic and roads; health; business; aviation and flights; information about Dubai; information on Islamic issues; Emirates Airline; Real estate; and the Dubai stock market. The project is specifically intended to help enable the prime objective—the greater e-government project of 90% of all government services being available electronically (Dubai eGovernment, October, 2005h).

## DUBAI E-GOVERNMENT IN ACTION

As of August 2004, the Dubai e-government exercise had 1,444 total online services. Of those, 173 were informational, 49 interactive and 1,222 transactional. The completion rate for transactions was 47% (Dubai eGovernment August, 2004g).

As of August 2004, there also were 20 government departments actively participating in the e-government project; this number is larger today, although exact statistics are not available. The Dubai municipality is by far the leading department, with 304 e-government services in total, of which 54 are transactional and 250 are informational. The Dubai Airport Free Zone Authority has 124 e-government services, of which 118 are transactional and 6 are informational. Links to various projects in the Dubai e-government project can be found at www.dubai.ae (Dubai eGovernment, March 2004b).

While Dubai was the first government to move towards e-government in the Middle East in 2001, according to measures of the effectiveness of these services by West (2005), even with its innovative approach, it is not the leader of e-government in the Middle East.

E-government ratings done by West (2005) put the UAE on par with Qatar in 26$^{th}$ place world wide, with an effectiveness rating of 30.1. Bahrain leads the e-government exercise in the Middle East, in 23$^{rd}$ place world wide, with an effectiveness rating of 31.

## FUTURE TRENDS

What is being changed through the Dubai e-government project is the very nature of the state's relationship to its citizens, visitors and businesses. What is being seen is the transformation of residents to customers through the e-government project.

Dubai's e-government project is not, and never has been, intended as a solution to failed government development. No one knows this better than Sheikh Mohammed Bin Rashid Al Maktoum. What makes Dubai's case so interesting is that, for the most part, the state is rebuilding its services as the e-government project itself is being implemented. E-government is being used as a means to

push improvement and enhancement, and not as a stop-gap to brace failed programs and ideas that have become entrenched as part of the system (Atallah, 2001).

But it also needs to be remembered that there is a politico-administrative process at work as e-government is implemented. This politico-administrative process only works when it is understood that residents are not simply customers, but participants in the governmental process (Van Duivenboden, 2005).

For e-government to work, it needs to have a clear strategy that recognizes the commerce aspect of the exercise and simultaneously the governance aspects that are evolving and inextricably linked to effective government.

So far, the UAE, and Dubai in general, is concentrating on the e-government project only. There are hints of more open electronic channels between the Dubai's residents and the decision makers as seen through the Dubai municipality suggestion and complaint service, called "Have your Say." While this service provides a means of tracking the progress of submissions and has a mechanism to reward creative comments, it is a long way from a means of input into the public in the public-policy process of the Emirate (Dubai eGovernment, September 2005a).

## CONCLUSION

There is no question that through the visionary leadership of Dubai and the rapid implementation of ICTs into the communication process of the government e-government has realized success in Dubai.

According to Qassim Sultan Al Banna, the adoption of ICTs and, ultimately, e-government has led to the Dubai government becoming more customer- and quality-centered in its delivery of products and services in an extraordinarily short period of time.

Dubai's e-government project has increased and expanded access to government services by enabling interaction with the Dubai government through a variety of ICTs, from mobile phones to the Internet. In many cases, the adoption of ICTs has actually reduced costs of service delivery by the state by as much as 30%, according to the Dubai government.

But the learning and adoption curve to a completely integrated e-government across society is steep. While the young e-generation is an early adopter, and a significant portion of Dubai's population, there still is much to be done to bring those skeptical of technology on board with the e-government project.

*The 21st century brings with it a new expectation from businesses and individuals who require an environment that is conducive and one in which they can prosper. The Internet revolution is re-shaping the world, and in this New Economy, it is critical for governments to re-invent themselves as it is for business to transform into e-business* (Sheikh Mohammed Bin Rashid Al Maktoum, 2004).

## KEY TERMS

**E-Culture:** The ordinary societal rudiments of interaction and acquisition taken for granted and sometimes ignored in any society, because they are so common, which are now mediated through ICT. Examples include activities such as conversations with friends via instant messaging or the ability to order goods and services through Web portals like Amazon.com.

**E-Generation:** The demographic born between 1995 and 2005 that has only ever known an environment employing ICTs for everything from entertainment to political participation.

**E-Governance:** The enabling of a new means of listening and consulting the citizenship, thereby enabling democratic tendencies and efficient socio-political development.

**E-Government:** The electronic enablement of all services provided or commissioned by the public sector capitalizing upon specific applications of ICT tools to the wide range of societal activities undertaken by the state.

**E-Services:** The exchange of goods and/or activities that in the past involved face-to-face communication but are now facilitated through an electronic, people-free interface.

**Information Communication Technology (ICT):** Devices utilizing microchip technology that enable enhanced information exchange.

**Unified Quality Services (UQS):** The use of technology to simplify customer/government transactions and create a better environment for efficient government operations.

## KEY TERMS

**Americans with Disabilities Act (ADA):** According to the U.S. Department of Justice, Civil Rights Division, Disability Rights Section (2004), the 1990 Americans with Disabilities Act "prohibits discrimination on the basis of disability in employment, state and local government, public accommodations, commercial facilities, transportation, and telecommunications" (p. 1).

**Disability:** As reported by the Disabled People's Association of Singapore (2005), the United Nations Standard Rules on the equalization of opportunities for persons with disabilities says that the "term 'disability' summarizes a great number of different functional limitations occurring in any population in any country in the world. People may be disabled by physical, intellectual or sensory impairment, medical conditions or mental illnesses." Typically such limitations are relativized to "normal human functioning" (World Health Organization) or to major life activities (Americans with Disabilities Act).

**Information and Communication Technologies (ICTS):** ICTs are those technologies (typically electronic) used to store, process and transmit information. Recent examples of ICTs include telephony, satellites and cables, and the Internet. According to the European Commission (2001), "[I]nformation and communications technologies is a term which is currently used to denote a wide range of *services*, *applications*, and *technologies*, using various types of *equipment* and *software*, often running over telecom *networks*."

**Public Policy:** A public policy is a rule, law or guideline established (and typically enforced) by some governmental authority whose goal is to regulate the actions of the people who fall under the jurisdiction of that governmental authority.

**Telecommuting:** While sometimes treated as synonymous with "telework," telecommuting refers to the use of information and communication technologies to communicate with other workers or one or more geographically centralized workplaces to exchange information relevant to work duties and assignments.

**Telework:** Telework is work that occurs outside of the traditional, geographically centralized workplace, in which the worker uses information and communications technologies such as the Internet to complete the work and communicate with the workplace (Bailey, & Kurland, 2002; Bricout, 2004; Fetzner, 2003; Kamerade, et al., 2004; Potter, 2003; Topi, 2004).

**Virtual Workspace:** A virtual workplace is an electronic "space" created by the use of information and communications technologies in which, through the medication of such technologies, workers can perform, interactively and collaboratively, work duties.

**James Piecowye**
*Zayed University Media Center, UAE*

## INTRODUCTION

Ranked 26th worldwide and second in the Middle East for its e-government initiative, the United Arab Emirates (UAE), and Dubai, in particular, is an excellent example of how e-government might be developed, implemented and advanced as a customer service-based concept (West, 2005).

The e-government project that continues to evolve in Dubai can be credited almost exclusively to the Emirate's leadership as embodied in Sheikh Mohammed Bin Rashid Al Maktoum, Crown Prince of Dubai, his vision and sheer tenacity to make grand ideas a reality.

It is not our intention in this article to suggest that the Dubai e-government project is without challenges and room for improvement. It is our intention, though, to present the Dubai case study as an evolving example of e-government from which to learn.

While the development and implementation of the e-government project is advancing in Dubai at a frenetic pace, the rollout of the concept to the public and the general acceptance and inclusion of the public in the larger governance process is still, to a large extent, a masterful work in progress.

The general global assessment of e-government delivery undertaken by Darrell West (2005) makes it very clear that progress is being witnessed worldwide when it comes to the implementation of e-government ideals. The greatest challenge to e-government, according to West (2005), is at times its very slow pace, its uneven nature and failure to adapt to changing conditions within which it exists. Dubai, in some instances to a lesser degree and others to a greater degree, is experiencing the same problems being experienced globally by those engaged in implementing e-government.

Fortunately, e-government performance in Dubai is improving rapidly, as budget, bureaucracy and institutional forces are pushed towards compliance. But what continues to be fundamentally lacking from Dubai's e-government project is a means of promoting and facilitating authentic e-governance where society as a whole has a means of engaging in meaningful interaction as a participant in the process of governance and not simply the service side of the state.

Dubai is one of seven Emirates that constitute the UAE federation. The country's constitution identifies it as an Arab state, with Islam as its religion and Arabic as its official language. The UAE is a member of the Arab League and the Gulf Cooperation Council (GCC), a regional group that joins the Gulf states of Kuwait, Saudi Arabia, Qatar, Bahrain, UAE and Oman. In general, GCC countries share many political, economic and social characteristics, including high reliance on an imported work force.

In the last decade, Dubai and the UAE have undergone phenomenal change. Fifty years ago, the country had little to no electricity, plumbing or simple infrastructure, such as surfaced roads and bridges. In 1950, there was no hospital and but a single school in Dubai. Dubai was a city comprised of barasti huts (housing made from palm fencing) and clay buildings lining sand streets. As late as the 1970s, according to Timothy Walters (unpublished), the literacy rate of the UAE hovered around 20%, with only a fraction of adults having any formal education.

Today, the landscape of Dubai has been radically transformed. Dubai is experiencing a level of prosperity never before seen. Physically, the city has been morphed from a sleepy regional trading post to the premier economic and tourist hub of the Middle East.

The transformation of Dubai is marked by its rapid installation of a modern infrastructure, the embracing of technology and both the vision and resources to rapidly roll out change to the general population. In 1999, Sheikh Mohammed Bin Rashid Al Maktoum championed the idea of launching a visionary e-government project to set the standard for such endeavours in the Middle East. More recently, in 2005, the idea of a government connecting to at least a large segment of its constituents is quickly becoming a reality.

This article will review why we believe Dubai might be considered an excellent e-government case study in the implementation of e-government as a customer-service concept. This article will also suggest that one of the greatest challenges of any e-government project is to include governance in the equation. This examination is primarily based on a synthesis of government publications available through the e-government portal www.dubai.ae, where examples of the e-government exercise are available, with other accounts of the Dubai e-government project.

## BACKGROUND

According to the UAE Ministry of Economy and Planning, the UAE's population in 2003 was estimated to be 4.041 million (Dubai Development and Investment Authority, 2005). Dubai is the UAE's most populous city, with an estimated population of 1.071 million. Census results from 2000 shows that 80% of Dubai's population is comprised of expatriates. According to official government statistics, UAE nationals constitute 18% of the country's population, followed by other Arabs expatriates at 13%, Asians 63% and Europeans and others 4%. Dubai's population is similar in its diversity to the nation at large (Datadubai.com, 2005; Dubai Development and Investment Authority, 2005).

The diverse expatriate population of Dubai uses language as one tool of cultural expression and interaction. While English is the dominant language in the business and tourism industries, government agencies use both Arabic and English to cater for the Emirate's residents and visitors. In addition, Urdu, Hindi, Farsi, Tagalog, and Russian, along with other languages, are also widely used on a daily basis. Most schools in Dubai offer one or two languages as additional foreign languages for non-native speakers.

International schools in Dubai cater to the myriad of nationalities living in the Emirate. Expatriate children are not admitted to the UAE public schools in the country; therefore, they study in private institutions. Local authorities have licensed K-12 schools offering Lebanese, British, American, French, International Baccalaureate and Indian curricula, to name just a few. American, Canadian and British-styled institutions of higher learning also provide higher studies to nationals and expatriates.

Dubai also plays a role as an international trading site. With an advanced infrastructure that includes world-class ports, airport, roads, free zones, a financial center, banks, insurance sector and retail outlets, to name just a few, Dubai attracts business as well as leisure visitors year round. To promote itself as a trade destination, the Dubai government organizes an annual shopping festival that attracts millions of visitors. In addition, it organizes a summer program of shopping and hotel promotions to revive the local economy during the months when temperatures soar and local residents take their annual leave abroad.

Dubai is one of the Middle East's most successful tourism destinations. According to the World Tourism Organization, Dubai has witnessed steady positive growth as a destination for the past decade, with only a marginal decline during periods of regional wars and instability. In 2002, Dubai achieved 31% growth in tourist arrivals—the world's highest for the year. In 2003, Dubai guests reached 4,980,228, with the majority coming from other Arab countries, Europe, Africa, Russia and the CIS republics and Asia. There is no question that Dubai is a city state in the throngs of rapid development.

## THE IDEA OF E-GOVERNMENT

E-government can be defined as the electronic enablement of services provided or commissioned by the public sector specifically capitalizing upon applications of information and communication technology (ICT) tools to the wide range of service activities undertaken by the state.

The goal of any e-government project is to enhance the effectiveness and efficiency of a government's activities and, in many instances, alter the procedural relationship of the government with the public. This altered government/public relationship typically progresses through several distinct phases, according to Sami Atallah (2001): posting information; two-way communication; exchange of value; integrated service and exchange.

The move towards e-government by many first-world countries is fundamentally altering the government/public relationship on one hand and citizen/business relationship on the other. In the Middle East, change in the government/public and citizen/business relationship is no different.

What is different in the Middle East is the relationship of e-government to e-governance. In many democratic-styled countries, e-government and e-governance projects are being developed concurrently. E-governance might best be understood as the electronic enablement and management of democratic activities, ensuring a degree of fairness, transparency and ultimately participation in the public-policy process of the otherwise disenfranchised (Bovaird, 2005).

E-governence is less about access and more about the style and intent of leadership. E-governence, as Khosrow-Pour (2005) suggests, is about enabling new ways of debating and deciding public policy. E-governance is less an economic investment and more an investment in the populous itself, thereby facilitating a new means of listening and consulting the citizenship.

E-governance, thus, becomes about enabling democratic tendencies and efficient government. The ideals of e-governance are being talked about today across the Middle East in general, but have yet to be adopted in any meaningful way, including in the UAE.

Sami Atallah (2001) suggests that the most striking effect of e-government is seen in the enhancement of the communicative ability of governments. But e-government is not simply the reinvention of the communication structures of governments. E-government is the reinvention of the way the business of governance is conducted. From information delivery, service procurement and delivery,

the manner of conduct of the state is dramatically changing. What is coming about is the imposition of a customer service-centered mentality in the manner in which the state interacts with the population it serves.

The goal of e-government as it is being embraced today worldwide and, in particular, in Dubai, can be summarized as to provide unified quality services (UQS) under the common slogan "the customer first." Unified quality services are being promoted in the context of e-government embracing the use of technology to simplify customer/government transactions and create a better environment for efficient government operations (Dubai eGovernment, 2004).

The process of e-government is much more than simply facilitating UQS. What e-government is facilitating is the complete institutional, cultural change of government internally and as it is perceived by the public itself. What is being advanced is organizational change towards customer relationship management, with the goal being to meet and exceed customer expectations from the start to the end of the transaction (Bovaird, 2005).

## THE DUBAI E-GOVERNMENT EXPERIMENT

The driving force behind e-government in Dubai is Sheikh Mohammed Bin Rashid Al Maktoum. His idea for e-government is embodied in the government's portal, www.dubai.ae, where customers can access a plethora of services being made available to them, in many cases, only electronically.

Sheikh Mohammed has set out two broad objectives for e-government in Dubai:

1. The government of Dubai shall e-enable 90% of its public services by 2007
2. Customers should conduct 50% of e-enabled government transactions through innovative channels by 2007 (Geray, 2004).

The Dubai e-government project is ambitious and premised on the simple idea that anything is possible if the right people are involved. Thus, what is constantly suggested within the Dubai government is that you are either part of the team or not, and those who are not up to the challenge of e-government are free to move on.

By 2007, it is expected that there will be:

1. E-enablement of 90% of public services (including identification of all online and off-line public services in each department and also service prioritization for e-enablement)
2. Implementation of e-service quality guidelines in all departments
3. Implementation of virtual governance by joining administrative boundaries through electronic integration and data sharing
4. Implementation of targeted marketing campaigns
5. Implementation of synergistic e-services to achieve expedited implementation and cost savings to the Dubai government (Geray, 2004).

The key to the success of the Dubai e-government project so far has been the ability of Dubai to re-invent the attitude of public service itself. Nowhere is this reinvention more prevalent than in the Department of Tourism and Commerce Marketing (DTCM). DTCM is a natural success story in Dubai because of the persistence of the Dubai government to continually try to accomplish the impossible and the desire of the Dubai government to see the Emirate become a unique tourist, financial, manufacturing and service destination.

The DTCM activities with e-government focus on connectivity to those who may want to come to Dubai and the eventual ease of their integration into Dubai. From general information to the obtaining of visas to the finding of suitable accommodations, the DTCM e-project embraces the idea of aiding the user first. The department considers its eServices a strategic gateway to the world. DTCM, as of December 2003, had 10 eServices, of which four were transactional and six informational (Dubai eGovernment, June 2004f).

## THE DUBAI DIFFERENCE

What makes Dubai and its e-government initiative different than most other places in the world, according to Sheikha Lubna, CEO of Tejari (the first e-commerce supply chain market in the region), is that contrary to the practices in most parts of the world, where the corporate community and business sectors take the lead and impose their e-initiatives on society. the government sector in Dubai is the real leader in the transition into e-commerce (Dubai eGovernment, August 2004g).

Under the leadership of Sheikh Mohammed Bin Rashid Al Maktoum, the e-government initiative of Dubai has seen amazing advances. According to Sheikh Mohammed, "the e-government concept depends on many factors, two of which are: making essential improvements to the government services provided to the public, and prompting the public sector to deal with its customers as dynamically and easily as the private sector" (Dubai eGovernment, May 2004d, p. 2).

The Dubai e-government initiative has two basic guiding objectives: simplification of government transactions in the emirate, and creation of initiatives to help Dubai assume a leadership position in the IT-driven global economy (Dubai eGovernment, October 2004h).

To operationalize these two objectives, the Dubai e-government project has relied very heavily, but not exclusively, on cultivating a reflexive relationship with the private sector and business community. The Dubai government is very cognizant of the fact that its constituents comprise both individual residents and private industry, and its initiatives serve to satisfy the needs of both. In the case of private industry, the challenge is to get them to buy into the e-government initiatives by making the industry a key component of the goods and services supply train of the state.

According to Sheikh Mohammed Bin Rashid Al Maktoum, the success of any e-government initiative is premised on the symbiotic relationship of economics and social services that can only be realized if state and business interests work as partners.

The rapid movement towards the implementation of e-government and the changed mentality that comes with it has brought its own share of challenges. Dr. Khalid Al Khazraji, Undersecretary at the UAE Ministry of Labor and Social Affairs, considers one of the most significant challenges to the implementation of e-government in Dubai the changing of the attitudes of the employees who must buy into the current government-centered system to a customer-first e-government system. Part of the process of change can take place through re-training. The other, more difficult, aspect of change comes from convincing employees of the benefits of moving towards e-enabled government services (Dubai eGovernment, May 2004d).

Dubai has always been a pioneering state. In April 2000, Sheikh Mohammed Bin Rashid Al Maktoum called for the transition of the Dubai government into the new knowledge age, demanding that the departments of the Dubai government provide their services electronically within no more than 18 months! Between April 2000 and the time of Dubai e-government launch in October 2001, all the infrastructure for the rollout of the e-government project was put into place. After 2 years, Dubai government, through its e-government project, provided more than 600 electronic services. Dubai turned the initiative into a project and the project into an organization (Dubai eGovernment, April 2004c).

What distinguishes Dubai's e-government project from any other world wide is the constant desire to continually innovate. A further example of this innovation was seen in September 2005, when the Dubai government launched the first Arab electronic mobile phone e-government portal. The mobile phone portal was launched with 26 services divided into 10 categories: traffic and roads; health; business; aviation and flights; information about Dubai; information on Islamic issues; Emirates Airline; Real estate; and the Dubai stock market. The project is specifically intended to help enable the prime objective—the greater e-government project of 90% of all government services being available electronically (Dubai eGovernment, October, 2005h).

## DUBAI E-GOVERNMENT IN ACTION

As of August 2004, the Dubai e-government exercise had 1,444 total online services. Of those, 173 were informational, 49 interactive and 1,222 transactional. The completion rate for transactions was 47% (Dubai eGovernment August, 2004g).

As of August 2004, there also were 20 government departments actively participating in the e-government project; this number is larger today, although exact statistics are not available. The Dubai municipality is by far the leading department, with 304 e-government services in total, of which 54 are transactional and 250 are informational. The Dubai Airport Free Zone Authority has 124 e-government services, of which 118 are transactional and 6 are informational. Links to various projects in the Dubai e-government project can be found at www.dubai.ae (Dubai eGovernment, March 2004b).

While Dubai was the first government to move towards e-government in the Middle East in 2001, according to measures of the effectiveness of these services by West (2005), even with its innovative approach, it is not the leader of e-government in the Middle East.

E-government ratings done by West (2005) put the UAE on par with Qatar in 26$^{th}$ place world wide, with an effectiveness rating of 30.1. Bahrain leads the e-government exercise in the Middle East, in 23$^{rd}$ place world wide, with an effectiveness rating of 31.

## FUTURE TRENDS

What is being changed through the Dubai e-government project is the very nature of the state's relationship to its citizens, visitors and businesses. What is being seen is the transformation of residents to customers through the e-government project.

Dubai's e-government project is not, and never has been, intended as a solution to failed government development. No one knows this better than Sheikh Mohammed Bin Rashid Al Maktoum. What makes Dubai's case so interesting is that, for the most part, the state is rebuilding its services as the e-government project itself is being implemented. E-government is being used as a means to

push improvement and enhancement, and not as a stop-gap to brace failed programs and ideas that have become entrenched as part of the system (Atallah, 2001).

But it also needs to be remembered that there is a politico-administrative process at work as e-government is implemented. This politico-administrative process only works when it is understood that residents are not simply customers, but participants in the governmental process (Van Duivenboden, 2005).

For e-government to work, it needs to have a clear strategy that recognizes the commerce aspect of the exercise and simultaneously the governance aspects that are evolving and inextricably linked to effective government.

So far, the UAE, and Dubai in general, is concentrating on the e-government project only. There are hints of more open electronic channels between the Dubai's residents and the decision makers as seen through the Dubai municipality suggestion and complaint service, called "Have your Say." While this service provides a means of tracking the progress of submissions and has a mechanism to reward creative comments, it is a long way from a means of input into the public in the public-policy process of the Emirate (Dubai eGovernment, September 2005a).

## CONCLUSION

There is no question that through the visionary leadership of Dubai and the rapid implementation of ICTs into the communication process of the government e-government has realized success in Dubai.

According to Qassim Sultan Al Banna, the adoption of ICTs and, ultimately, e-government has led to the Dubai government becoming more customer- and quality-centered in its delivery of products and services in an extraordinarily short period of time.

Dubai's e-government project has increased and expanded access to government services by enabling interaction with the Dubai government through a variety of ICTs, from mobile phones to the Internet. In many cases, the adoption of ICTs has actually reduced costs of service delivery by the state by as much as 30%, according to the Dubai government.

But the learning and adoption curve to a completely integrated e-government across society is steep. While the young e-generation is an early adopter, and a significant portion of Dubai's population, there still is much to be done to bring those skeptical of technology on board with the e-government project.

*The 21st century brings with it a new expectation from businesses and individuals who require an environment that is conducive and one in which they can prosper. The Internet revolution is re-shaping the world, and in this New Economy, it is critical for governments to re-invent themselves as it is for business to transform into e-business* (Sheikh Mohammed Bin Rashid Al Maktoum, 2004).

## KEY TERMS

**E-Culture:** The ordinary societal rudiments of interaction and acquisition taken for granted and sometimes ignored in any society, because they are so common, which are now mediated through ICT. Examples include activities such as conversations with friends via instant messaging or the ability to order goods and services through Web portals like Amazon.com.

**E-Generation:** The demographic born between 1995 and 2005 that has only ever known an environment employing ICTs for everything from entertainment to political participation.

**E-Governance:** The enabling of a new means of listening and consulting the citizenship, thereby enabling democratic tendencies and efficient socio-political development.

**E-Government:** The electronic enablement of all services provided or commissioned by the public sector capitalizing upon specific applications of ICT tools to the wide range of societal activities undertaken by the state.

**E-Services:** The exchange of goods and/or activities that in the past involved face-to-face communication but are now facilitated through an electronic, people-free interface.

**Information Communication Technology (ICT):** Devices utilizing microchip technology that enable enhanced information exchange.

**Unified Quality Services (UQS):** The use of technology to simplify customer/government transactions and create a better environment for efficient government operations.

# e-ASEAN and Regional Integration in South East Asia

**Xiudian Dai**
*University of Hull, UK*

## INTRODUCTION

As a relatively new feature of the digital revolution in the Association of Southeast Asian Nations (ASEAN), e-ASEAN was initiated by the ASEAN economic ministers in September 1999 and endorsed by ASEAN leaders at their summit in Manila in November the same year, when the e-ASEAN Task Force was also set up (ASEAN Secretariat, 2003). At the Fourth ASEAN Informal Summit in Singapore in November 2000, a Framework Agreement was signed to serve as the legal foundation for the e-ASEAN initiative. To ensure success, the Senior Economic Officials Meeting (SEOM) was tasked to supervise, coordinate, and review the implementation of the e-ASEAN Framework Agreement. As stipulated in the e-ASEAN Framework Agreement, the SEOM reports to the ASEAN Economic Ministers (AEM) and assists the AEM in all matters concerning this Agreement (ASEAN, 2000, Article 13).

While there is no lack of literature discussing trade liberalisation and transborder cooperation in the ASEAN region, the impact of new information and communications technologies (ICTs) on the development of regionalism, and *vice versa*, remains a rather neglected area of study (Dai, 2003). The purpose of this article is to investigate the implications of the e-ASEAN initiative for regional cooperation and integration in South East Asia in the information age. In particular, the key challenges to achieving the objectives of the e-ASEAN initiative will be analysed.

## BACKGROUND

It is widely perceived that new ICTs can significantly advance transnational co-operation and regional integration in both economic and political terms (Bangemann et al. 1994; European Commission, 2000). Transnational flows of communication are synonymous to the decline in the importance of national, geographical, and institutional boundaries (Castells, 1996). The launch of the European Information Society in the early 1990s serves as an example of public policy based on the notion that new ICTs can be a positive factor to regional integration (Dai, 2000; Federal Europe, 1995).

Generally speaking, e-ASEAN is "to develop a broad-based and comprehensive action plan including physical, legal, logistical, social and economic infrastructure needed to promote an ASEAN e-space, as part of an ASEAN positioning and branding strategy" (ASEAN Secretariat, 2003). Internally, the e-ASEAN initiative is to use ICTs "to speed up economic integration of the group" and, externally, to "help them compete better in the global economy" (Ng & Nurbanum, 2002, p. 39).

The promotion of regional economic growth and acceleration of regional peace and stability have been the key objectives of ASEAN since its establishment in 1967. In today's globally competitive world, ASEAN officials argue, "regionalism has to take on a larger meaning and scope than market integration alone" (ASEAN Secretary-General, 2000). It is perceived vital that, in close cooperation, ASEAN members endeavour "to acquire the technological prowess without which the ASEAN nations cannot hope to move forward economically" (ASEAN Secretary-General, 2000). A key question to be asked is whether or not the global communications revolution can be advantageous to regional integration in South East Asia.

## E-ASEAN AND REGIONAL COOPERATION: CRITICAL ISSUES

Intra-regional cooperation among member states is manifested in the aims of e-ASEAN Framework Agreement: (1) co-operation to develop, strengthen and enhance the competitiveness of the ICT sector in ASEAN; (2) co-operation to reduce the digital divide within individual ASEAN member states and amongst ASEAN member states; (3) co-operation between the public and private sectors in realising e-ASEAN; and (4) the liberalisation of trade in ICT products, ICT services and investments to support the e-ASEAN initiative (ASEAN, 2000, Article 1).

In order to achieve their objectives, ASEAN countries are committed to undertaking the following measures through the e-ASEAN initiative (ASEAN, 2000, Article 2):

- Facilitating the establishment of the ASEAN Information Infrastructure
- Facilitating the growth of electronic commerce in ASEAN
- Promoting and facilitating the liberalisation of trade in ICT products, ICT services, and of investments in support of the e-ASEAN initiative
- Promoting and facilitating investments in the production of ICT products and the provision of ICT services
- Developing an e-society in ASEAN and capacity building to reduce the digital divide within individual ASEAN Member States and amongst ASEAN Member States
- Promoting the use of ICT applications in the delivery of government services (e-government)
- Enabling advanced member states to assist the lagging member states to undertake capacity building

The signing of the e-ASEAN Framework Agreement has generated much enthusiasm within the public and private sectors across the ASEAN region. This is in part manifested in the large number of transnational ICT projects established in response to the launch of e-ASEAN involving project partners from different member states. Of a total of 40 ICT projects, 22 are within the field of e-commerce and the rest address the new and specialised market areas such as e-society, Information Infrastructure and e-governance (Dai, 2003). The dominance of e-commerce projects, in terms of the number of projects, serves as an indication that commercial organisations in the private sector are convinced of the potential opportunities to be afforded by e-ASEAN for promoting transnational e-commerce activities.

To make e-ASEAN a success, ASEAN countries would have to address a number of important issues. Among others, the existence of an intra-regional digital divide, national differences in the provision and application of cyberlaws and the competitive relationship between some ASEAN member states are the focal points of public debate.

## Digital Inequality in ASEAN

Access to ICTs in ASEAN remains significantly uneven. Data presented in Table 1 shows a general trend in ASEAN: the region is clearly divided into countries moving along the fast lanes of the information superhighway and those crawling along the slow lanes. Singapore, Malaysia, and Brunei are the three ASEAN countries that are far ahead of the other member states in terms of penetration rate of main telephone lines, mobile phones, PCs (personal computers), and, last but not least, the Internet.

In 2000, when main telephone line and mobile phone penetration rate reached 484 and 684 per 1000 people (or 48.4% and 68.4%) respectively in Singapore, the corresponding rates for Myanmar were 6 and 0 per 1000 people and 8 and 2 for Laos. Commenting on the present situation of the telecommunications industry in Myanmar, the CIA (Central Intelligence Agency) believes the sector "barely meets minimum requirements for local and intercity service for business and government" (CIA, 2005a).

Concerning the Internet sector, the contrast between the advanced and the lagging countries in ASEAN adds another dimension of the intra-regional digital divide: while 30% of Singaporeans and just under 16% of Malaysians were Internet users in 2000, the proportion of Internet

*Table 1. Access to ICTs in ASEAN, 2000 (Source: Based on figures from World Bank [2002], CIA [2005b] and Dai [2003]).*

| Country | Telephone mainlines per 1000 people* | Mobile phones per 1000 people* | PCs per 1000 people* | Internet users (% of population)* | GDP per capita, PPP in US$** |
|---|---|---|---|---|---|
| Brunei | 245 | 289 | 70.1 | 8.82 | 18,600 |
| Cambodia | 2 | 10 | 1.1 | 0.05 | 1,900 |
| Indonesia | 31 | 17 | 9.9 | 0.95 | 3,200 |
| Laos | 8 | 2 | 2.6 | 0.11 | 1,700 |
| Malaysia | 199 | 213 | 103.1 | 15.88 | 9,000 |
| Myanmar | 6 | 0 | 1.1 | 0.01 | 1,800 |
| Philippines | 40 | 84 | 19.3 | 2.65 | 4,600 |
| Singapore | 484 | 684 | 483.1 | 30.00 | 23,700 |
| Thailand | 92 | 50 | 24.3 | 3.79 | 7,400 |
| Vietnam | 32 | 10 | 8.8 | 0.25 | 2,500 |

*Notes: * Adapted from World Bank (2002) and Dai (2003); **All GDP figures are Estimated Purchasing Power Parity (PPP) of 2003, except for Brunei, for which the PPP figure is for 2002.*

*Table 2. Cyberlaws in ASEAN*

| Member State | Cyberlaw |
|---|---|
| Malaysia | • The Communications and Multimedia Act (1998)<br>• The Malaysian Communications and Multimedia Commission Act (1998)<br>• The Digital Signature Act (1997)<br>• The Computer Crimes Act (1997)<br>• The Telemedicine Act (1997) |
| Singapore | • Electronic Transactions Act (1998) |
| Brunei | • Electronic Transactions Order (2000) |
| Thailand | • Electronic Transactions Bill (Draft) |
| Philippines | • Electronic Commerce Act (2000) |

users among the population in the CLMV (Cambodia, Laos, Myanmar, and Vietnam) and Indonesia was below the 1% level.

The intra-regional digital divide in ASEAN does not come as a surprise. Rather, the picture of digital divide between ASEAN countries is in line with the differentiation in GDP per capita. Figures in Table 1 indicate that the three leading countries (Singapore, Brunei, and Malaysia) with higher ICT deployment rates are actually the three countries with much higher GDP per capita. To address the challenges posed by the digital divide, therefore, it is important to bear in mind that uneven access to ICTs is more than often associated with the varying levels of economic development.

## Regional Governance of Cyberspace

One of the key objectives of the e-ASEAN initiative is to promote the harmonisation of cyberlaws across ASEAN. The e-ASEAN Framework Agreement states that "Member States shall adopt electronic commerce regulation and legislative frameworks that create trust and confidence for consumers and facilitate the transformation of businesses towards the development of e-ASEAN" (ASEAN, 2000).

The harmonisation of cyberlaws in ASEAN is faced with fundamental challenges. First, in addition to the digital divide in the sense of uneven access to ICTs, there is a gap in the provision of cyberlaws between different ASEAN countries. While some countries, notably Malaysia, have already become regional as well as world pioneers in enacting cyberlaws, others have hardly made any progress in the same field (see Table 2 for a list of cyberlaws in ASEAN).

The second challenge comes from the fact that social and political systems vary from country to country within the ASEAN region. Judged by their attitude towards the Internet, states in East and South East Asia fall into three different categories including the following (Hachigian, 2002):

- States with severely restrictive policies and rules towards all public use of the Internet (e.g., Myanmar and North Korea)
- States with moderately restrictive rules towards Internet access and contents (e.g., Vietnam, Singapore and China)
- States that actively promote Internet access and allow for online political pluralism, (e.g., Malaysia)

The different socio-political systems currently prevailing in ASEAN constitute a big challenge to the region's plan for harmonising cyberlaws for the simple reason that online contents and behaviours acceptable in one country may not necessarily be acceptable in another.

## National vs. Regional Interests

In ASEAN countries, there is no lack of high profile ICT initiatives. For example, the Singaporean government has embarked upon an information age vision and strategy to "develop Singapore into a vibrant and dynamic global Infocomm Capital with a thriving and prosperous infocomm-savvy e-Society" (Infocomm Development Authority of Singapore, 2000, p. 5). Following closely the development in Singapore, the Malaysian government has developed a comprehensive strategy to fundamentally transform Malaysia from primarily an agricultural economy now into a developed country by the year 2020 and one of the policy measures for achieving this vision is the Multimedia Super Corridor (MSC) initiative. These national initiatives in ASEAN, however, remain largely disconnected and piecemeal efforts at the national, rather than regional, level—there seems to be a lack of any regional coordination.

Together, Singapore and Malaysia are arguably the two most ICT-savvy member states in the ASEAN region. This is reflected in the fact that these two countries

have already put in place well-developed information age policy and strategies as well as cyberlaws, ahead of the other ASEAN countries. Not surprisingly, both Singapore and Malaysia would like to become *the* ICT hub for the South East Asian region. In this respect, Singapore's Intelligent Island initiative and Malaysia's MSC initiative are in direct competition—they compete for attracting external attention and inward investment. It remains to be seen whether this kind of competitive scenario could be changed and turned into genuinely interconnected initiatives. If this happened, ASEAN countries' common endeavour, that is, the e-ASEAN initiative, would be of much more substance.

## FUTURE TRENDS

Given the critical issues faced by e-ASEAN, the overall impact of the initiative is broadly viewed as a positive one. More specifically, this impact is manifested in two ways: internally the initiative works as a positive factor to the process of regional integration among ASEAN members and, externally, it serves as a new mode of governance of the digital revolution at levels beyond the nation state.

Firstly, under the auspices of e-ASEAN, the promotion of Internet usage by individuals, businesses, and government organisations throughout the region has already established an additional platform for cross-border (or borderless) communication and transactions. Although there is an intra-regional digital divide between the member states, the level of Internet access and usage is improving throughout ASEAN. It is not unreasonable to believe that the Internet, as a cost-effective way of social and business communication, will play an even bigger role in promoting regional integration - national borders are still there but cross-border communication and e-commerce is already a reality on the Internet.

Secondly, if the collective effort of ASEAN countries in promoting the harmonisation of national cyberlaws proves successful, it would serve as an interesting example for the governance of ICTs in general and the Internet in particular at a regional or transnational level. To be sure, the simple fact that cyberspace does not have due respect for national and geographical borders is a major challenge for not only ASEAN countries but also the rest of the world in terms of governance.

The growing consensus in the public debate over the need for working towards a transnational or regional level of ICT governance leads to an interesting dimension for future research. The ASEAN Secretariat highlighted two specific issues that governments in the region need to address in order to implement the e-ASEAN initiative: jurisdiction and taxation (ASEAN Secretariat, 2001). Regarding jurisdiction, the harmonisation of cyberlaws through the e-ASEAN initiative cannot by-pass controversial questions such as, among others, which national law to be used in resolving transnational e-commerce disputes and whether court judgement reached in one country could be enforced in another. The issue of e-commerce taxation is equally challenging: whose taxation regime should be used and to which state should taxes be paid when an e-commerce transaction occurred in more than one country and conducted in an "e-space," where there are no clearly defined national borders?

Outside ASEAN, the only comparable model of ICT regulation at a regional level is provided by the European Union (EU), where a regulatory framework for electronic communications has been adopted by member states. It would be worthwhile to undertake further research to compare and contrast the eASEAN model of cyberlaw harmonisation with the European model of communications regulation. A comparative study of this kind could shed light on the issue of whether regional or transnational level governance for ICTs is a desirable and practical solution to the challenges posed by the information age to the nation state at the national level in terms of governance and regulation.

## CONCLUSION

The launch of the e-ASEAN initiative represents one of the most significant attempts at the regional level by a group of nation states to collectively explore the potential benefits that the global communications revolution brings with it. The main objective of the e-ASEAN initiative is to promote regional economic development and regional cooperation by effectively fostering an "e-space" within the region.

While it is not inconceivable that new ICTs in general, and the Internet in particular, could help overcome many traditional barriers, such as national boundaries and geographical distance, that hinder transnational cooperation, the same technologies poses a number of challenges to ASEAN political leaders. Firstly, before the intra-regional digital divide is effectively closed, many individuals and some parts of the ASEAN region will remain excluded from the digital revolution. This begs the question of who and which countries are going to benefit most from the e-ASEAN initiative. Secondly, cyberlaw harmonisation, one of the stated missions of the e-ASEAN initiative, is faced with a reality in which not all member states have passed legislations regarding cyberspace and those states with cyberlaws in place have their distinctive national approaches. It will be a daunting task to achieve a consensus over the governance and regulation

of cyberspace at the regional level in ASEAN. Finally, some member states in ASEAN are torn between pursuing their national ICT agenda and the common e-ASEAN agenda. The fact that both Singapore and Malaysia wish to become a regional ICT hub has added a competitive feature to the emerging "e-space" in ASEAN, which goes against the key word of the e-ASEAN Framework Agreement—'cooperation!'

## KEY TERMS

**ASEAN:** The Association of Southeast Asian Nations (ASEAN), representing a key regional trading block in the world, was established following the signing of the ASEAN Declaration on August 8, 1967 in Bangkok with five founding member states, namely, Indonesia, Malaysia, Philippines, Singapore, and Thailand. Brunei became the sixth member in January 1984. This was followed by the CLMV (Cambodia, Laos, Myanmar, and Vietnam) to join ASEAN in the 1990s. The main objectives of ASEAN include: (i) accelerating regional economic growth, social progress, and cultural development and (ii) promoting regional peace and stability. The 10 member states have a total population of about 500 million, covering a total area of 4.5 million square kilometres.

**Cyberspace:** A virtual or notional environment of electronic communications. The online environment facilitated by the Internet is the most popular type of cyberspace.

**Digital Divide:** Digital divide refers to the disparity in opportunities and abilities for making use of information and communications technologies that exists between different social groups and between different countries in the digital age.

**e-ASEAN:** Originally initiated by the ASEAN economic ministers in September 1999 and endorsed by ASEAN leaders at their summit in Manila in November the same year, e-ASEAN aims to develop an ASEAN "e-space." The e-ASEAN Framework Agreement, signed by the ASEAN member states at the Fourth ASEAN Informal Summit in November 2000 in Singapore, serves as the legal foundation for the e-ASEAN initiative.

**E-Commerce:** E-commerce refers to online electronic transactions involving the sale and purchase of physical goods or digital goods (e.g., software, digital films, and music, value added information in electronic format).

**Information and Communications Technology (ICT):** Information and Communications Technology (ICT), as defined in the e-ASEAN Framework Agreement, refers to "infrastructure, hardware, and software systems, needed to capture, process, and disseminate information to generate information-based products and services" (ASEAN, 2000, Article 1a).

**Multimedia Super Corridor (MSC):** Launched by the former Prime Minister Dr Mahatir in 1997 and remained as his pet project until his retirement, the Multimedia Super Corridor initiative (MSC) includes the creation of an ICT business and technology centre (Cyberjaya) to attract foreign direct investment (FDI); an "intelligent city" as the new federal government administrative centre (Putrajaya); a new international airport (i.e., the Kuala Lumpur International Airport (KLIA) and the Kuala Lumpur City Centre (KLCC)). The four "hot spots" are digitally linked through a fiber optic cable infrastructure offering high speed communications and a new motor way network. The MSC stretches over a designated development area of 50 kilometers long and 15 kilometers wide.

## INTRODUCTION

Market economies rest on a foundation of the private ownership of resources. Certain resources, however, have been managed outside of the market mechanism, even in the United States' decidedly pro-free-market economy. The management of radio frequencies, or spectrum, is a prime example of government control of a valuable resource. Spectrum management is practiced by governments around the globe, and the experience of the U.S. Federal Communications Commission (FCC) provides a valuable illustration of how management of this resource may be improved through the use of electronic resources.

## BACKGROUND

The portion of the electromagnetic spectrum consisting of the frequencies ranging from 3 kilohertz (KHz) to 300 gigahertz (GHz), commonly known as radio frequencies, represents a natural resource that may be exploited through technological means. When considered in the context of other naturally occurring resources, radio frequencies are unique. On a geographic basis, radio frequencies are limited but are uniformly distributed. As long as the strength of the radio signal is controlled, the same amount of radio frequency is available per square mile in the U.S., Uganda, or any other nation. Each nation must live with what is available within its borders; the import and export of radio frequencies is not possible. While the resource is limited, it is continuously renewable—each frequency becomes available again at each new moment in time.

In addition to the geographically limited nature of the resource, various portions of the radio-frequency spectrum have properties that affect their usefulness. As the frequency of a radio wave increases, the wavelength decreases. Smaller wavelengths have a higher likelihood of being deflected by physical objects such as buildings, foliage, or even water droplets in the atmosphere in the form of rain, snow, or fog. Longer wavelengths easily can penetrate objects. These differences in the physical properties of spectrum make certain frequency ranges more useful (and more valuable) than others. The differences in the quality of spectrum place further impetus for management of the resource. By matching the performance needs of a technology with a spectrum range, the resource can be used more effectively. For example, broadcast radio, which may encounter significant environmental barriers associated with mobile receiving units (in automobiles) or stationary receiving units (inside dwellings) benefits from the use of relatively longer wavelengths associated with the AM and FM frequency bands. On the other hand, satellite-to-earth transmission can rely on a fixed ground station antenna that can be oriented skyward to avoid physical barriers such as walls and trees and, thus, can perform well with relatively shorter wavelengths associated with higher frequencies.

Concerns regarding interference between competing users of spectrum have been the prime motivation for strict control of most of radio-frequency resources (Noam, 1998). Analog technologies, which were associated with early radio-frequency applications, suffered functional degradation if they were not guaranteed the exclusive use of a specific radio frequency. Thus, management of radio frequencies by the FCC and other governmental bodies around the globe traditionally are based on an approach that systematically organizes the spectrum resource into logical groupings and then assigns exclusive rights to use the spectrum to certain individuals or organizations.

## U.S. POLICY AND SPECTRUM MANAGEMENT

In order ro facilitate the management of spectrum in the U.S., the entire range of radio frequencies is divided into bands or blocks that are associated with specific applications or technologies, such as broadcast television or cellular telephones. These divisions are known as allocations. Within the allocation of radio frequency, the bands face further subdivision, known as allotments. Allotments are associated with a specific geographic area; for example, a specific frequency to be used as a television channel in a specific metropolitan area or a frequency to be used by cellular telephone companies in a rural area. With these divisions, the spectrum then may be assigned,

or licensed. The grant of a license gives the user the ability to provide the specified service in the geographic area and may impose additional conditions on the use of the radio frequencies, including the type of technology (analog vs. digital) and the strength of the signal.

## Assigning Spectrum in the U.S.

While economists have advocated private property rights for spectrum for years (Coase, 1965), U.S. law prohibits private ownership of spectrum (Shelanski & Huber, 1998). Thus, administrative means were traditionally used to manage the resource (FCC, 1997b). Applications that had the most significant potential to suffer from interference degradation, such as broadcast radio and television, required significant capital investments, which led to relatively little competition for the required spectrum resource. In geographic areas where the economics of the market was substantial enough to lead to higher demand for the resource, comparative hearings were used to determine which of the competing entities would be eligible to receive an exclusive license. In a comparative hearing, the competing interests (typically a broadcast radio or television station) would present their cases before an administrative law judge, who ultimately decide whether the public interest would be better served by one or the other of the competing interests.

## Impact of Cellular Technology

With technological change, significant difficulties emerged with the then-existing approach to spectrum management. While radiotelephones were commercialized in the 1950s, the development of analog cellular telephone technology during the 1970s offered the potential for a much broader dissemination of wireless telephony. By carefully limiting signal strength, a limited amount of spectrum could be reused in multiple adjacent cell sites. While the previous radiotelephone service might enable 40 to 50 simultaneous calls in a metropolitan area, the new cellular technology potentially enabled thousands of simultaneous calls, which generated the possibility of a much larger subscriber base (Rappaport, 2002). The new technology required that spectrum be licensed to companies that essentially would resell use of the radio frequency to the public, which the FCC deemed Commercial Mobile Radio Service (CMRS). Underlying the distribution of spectrum for the initial cellular telephone technology was a policy of duopoly. In each geographic area, only two licenses would be granted, with one offered first to the local telephone company serving the geographic area and the second available to other businesses. The limited availability of licenses combined with the commercial potential of the new service led to high levels of demand for available licenses. As a result, the FCC was confronted with a new problem with the allocation of spectrum resources. Multiple competing interests were interested in the limited number of licenses, with 200 applicants vying for the first 30 licenses made available (FCC, 1997b). Comparative hearings were the only means by which the FCC could settle the issue of which of the limited number of licenses should go to whom. Complicating the comparative hearing process was the similarity of the applicants. As a result, the administrative process was faced with numerous situations that, for all practical purposes, were ties between competing interests. The inefficiency of the comparative hearing process led to significant delays in the distribution of the initial cellular licenses.

Following the problems associated with the distribution of spectrum licenses through comparative hearing, the FCC sought authority for an alternative mechanism—lotteries. Given the prevalence of ties in the qualifications of those seeking licenses, the theory of the FCC lottery scheme was based on random selection from a qualified pool of interested parties. With the winner picked randomly, ties would be broken, and the speed of distribution would be promoted. However, the process of qualifying lottery participants also introduced delays, with the first prequalifications taking about two years. To remedy this situation, the FCC sought further authority from the U.S. Congress to eliminate the need for prequalification. With prequalification eliminated, lottery participants quickly obtained licenses, but now another set of problems emerged. As the public became aware of the value of the resource that was being given away through the lottery process, large numbers of individuals sought to participate in the lotteries. Given the pre-Internet period, the paperwork required by the FCC to participate in a lottery presented a hurdle for those uninitiated in the operations of U.S. federal government agencies. Thus, third-party businesses, which came to be known as license mills, emerged. The license mills would process and submit the necessary paperwork for participation in a lottery. This rent-seeking activity resulted in hundreds of millions of dollars of revenue for the license mills (Hazlett & Michaels, 1993).

While the rent-seeking activity associated with the license mills was socially wasteful, further problems emerged after the licenses were awarded. Licenses were awarded relatively quickly; however, the licenses were not put to immediate use. Rather, a secondary market for licenses emerged, resulting in windfall profits for license holders. Delays once again were introduced into the process of distributing licenses while lottery winners sought the highest bidder for their licenses.

The problems associated with the distribution of spectrum licenses led the FCC to approach Congress again to

revise the method by which licenses could be granted for spectrum, resulting in the establishment of the FCC's electronic auctions.

## AUCTIONS

Auction authority was granted to the FCC as part of the Omnibus Budget Reconciliation Act of 1993. The auction authority that was granted to the FCC was quite limited. The interests of broadcasters and other entities who already utilized spectrum resources without charge were protected by the law. The authority granted to the FCC limited the auction process to spectrum that was to be newly transferred from governmental use to non-governmental use and that also was to be used by the licensee to generate revenues from subscribers for transmitting and receiving signals over the licensed spectrum (47 USC, §309(j)(9) and §309(j)(2)(A)).

The newly available spectrum ultimately was used to enable a variety of new services, including digital cellular services (Personal Communications Services [PCS]), fixed high-speed data services (LMDS), direct broadcast satellite service (DBS), and paging services (FCC, 1997b). The legislation required that the FCC take a flexible approach to determine the best bidding method for the spectrum resource.

*Figure 1. How an FCC auction is initiated (FCC Wireless Bureau Web site)*

**How is an FCC Auction Initiated?**

1. Comment Public Notice
(Approximately four to six months prior to auction)
A public notice is released seeking comment on auction procedures.

2. Procedures Public Notice
(Approximately three to five months prior to auction)
A public notice is released providing potential participants with the procedures, terms, and conditions for the auction event.

3. Seminar
(Approximately 45 days prior to auction)
A free pre-auction seminar is conducted for potential participants in order to introduce them to the auction rules and process. The bidding software is demonstrated.

4. Short-Form (FCC Form 175) Application Filing Deadline
(Approximately 30 days prior to auction)
Form 175 application, which must be filed electronically, collects basic information about the applicant.

5. Filing Status Public Notice
(Approximately one week after the filing deadline)
After the deadline for filing, the FCC reviews all timely filed short-form applications and deems them accepted, incomplete, or rejected. The status of the applications is communicated to the public through the release of this public notice.

6. Upfront Payment Deadline
(Approximately two weeks prior to auction)
Potential bidders must submit a refundable deposit, which is used to purchase the bidding units required to place bids in the auction.

7. Short-Form Application Resubmission Deadline
(Approximately two weeks prior to auction)
Form 175 applications that were deemed incomplete must be refiled by this deadline, which often coincides with the upfront payment deadline.

8. Qualified Bidders Public Notice
(Approximately 10 to 12 days prior to auction)
This public notice lists the bidders qualified to participate in the auction.

9. Qualified Bidders Registration
Immediately following the release of the Qualified Bidders Public Notice, the bidder registration process begins.

10. Mock Auction
(Approximately two to three days prior to auction)
To ensure that bidders understand the auction process, the FCC sponsors a mock auction as a service to the qualified bidders. The mock auction allows bidders to work with the bidding system, become comfortable with the rules and conduct of the auction, and familiarize themselves with the telephonic bidding process.

11. Auction Begins

## Designing an Efficient Auction

Every market transaction is based on information. The price at which an object is bought and sold depends on the information available to the buyer and to the seller. With regard to the newly available spectrum that the FCC was charged with selling, there was a distinct asymmetry of information between the seller (the FCC) and potential buyers (companies interested in providing wireless services). Obviously, the FCC wanted to generate the highest level of revenues possible from the sale of spectrum rights, while the buyers wanted to pay as little as possible. Thus, designing an auction structure that resulted in the highest level of revenues was a priority for the FCC.

Spectrum rights have an interesting economic characteristic. Unlike an object of art or a piece of sports memorabilia, which may have a unique personal value to the purchaser, spectrum rights are likely to provide a similar value to any purchaser. This situation is known in the economics of information as common values (Baye, 2000). For example, suppose that the FCC were to auction five new licenses to provide a new digital wireless service to the Boston, Massachusetts, market area. Because the service is new, *ex ante*, no firm knows the exact value of these licenses. To any firm winning a license, however, it is likely that the profits associated from providing the service will be similar. In formulating a bidding strategy for a license, each bidder estimates the costs and revenues expected if the license were to be won. Once this calculation is completed, the bidder has an estimate of the highest bid that they would possibly be willing to make. While it is likely that the various bidders would come up with similar valuations of the licenses, it is unlikely that the valuations would be identical. There would be some variation in the valuations.

This situation results in a potential risk to any prospective buyer. If common values are present, then the high bidder in any auction is likely to be the party that has experienced a random variation in calculating the expected value of the license on the high side (i.e., the winner likely will pay too much for the object). This outcome has been dubbed the winner's curse. Of course, potential bidders are aware of the winner's curse; thus, rational bidders will follow a bidding strategy that leads them to shave their bid (i.e., to not bid as much as they think the object is actually worth). From the seller's perspective, the winner's curse will lead to lower auction revenues, as buyers will not be willing to bid up to their true valuation of the object. Thus, the FCC was interested in developing an auction format that would mitigate the impact of the winner's curse.

Compounding the FCC's auction design problem was the complexity of the objects to be auctioned. Policy objectives of promoting competition in the provision of wireless services and also promoting small-business participation in the auction process resulted in the creation of numerous market areas. For the PCS auctions, a total of 493 market areas (known as basic trading areas) were used, and multiple licenses were available within each Basic Trading Area. This led to the availability of more than 2,500 licenses for 10-year terms (Bykowsky, Cull, & Ledyard, 2000). Thus, a potential bidder would be very concerned about the complementary and substitute relationships of licenses and would be faced with a complex and risky environment.

## Electronic Simultaneous Multiple-Round Auctions

In order to solve these problems, the FCC developed electronic auctions, which allow users to participate over the Internet or by telephone. All licenses are made available for bidding during the entire auction period, which creates the simultaneous nature of the auctions. The auction is conducted in rounds, each having a set duration. At the end of each round, the bids are posted on a Web site for review by the bidders. This format allows bidders to evaluate the bids placed by other participants.

While the duration of rounds is established by the FCC, the number of rounds are not. Bidding is allowed to continue until all bidder activity ceases. When this occurs, the auction is closed.

The FCC's approach also allows bidders to place combinatorial (package bids) in which the bidder can place bids on groups of licenses. Package bidding is particularly important where complementary relationships between licenses exist. For example, a firm that is planning on offering service on a regional basis might want to purchase licenses in two or three basic trading areas. With the package bidding approach, a firm could place bids on the entire group of licenses in which it was interested. Package bidding will tend to increase auction revenues, since it encourages bidders to reveal their perceptions on the values of groups of licenses.

## Look and Feel of the Auction Web Interface

The auction interface requires qualified bidders to log in, and then it presents menus of information, including public notices associated with the specific auction, pages where bidding histories can be reviewed, and pages where bids can be placed. Several screen shots from the FCC's auction Web interface have been provided in the appendix.

## FCC Auction Structure and the Winner's Curse

Recall that the winner's curse is related to the bidder's lack of information. When formulating their bidding strategies in isolation, bidders will be reluctant to place bids up to their estimate of their true values. While prohibiting collusion, the FCC's auction structure offers an opportunity for bidders to exchange information by viewing all of the bids that are placed in each round. For example, if a potential bidder, when formulating its bidding strategy, calculates a value of $500,000 for a specific license, and after two or three rounds of the auction, the high bids observed are significantly lower than $500,000, then the bidder might want to reevaluate the analysis underlying its bid. Perhaps it made a mistake or overlooked something in the development of its valuation.

## FCC AUCTION OUTCOMES

As of early 2005, the FCC had conducted 55 auctions, which generated about $44 billion in revenues, all of which have not been collected. The results of the auction process have overcome some of the difficulties associated with the granting of spectrum licenses through administrative hearings and through lotteries. Auctions generally have delivered the spectrum into the hands of those who can put it to use quickly (FCC, 1997b), and the auction process has a tiebreaker, as there can be only one winning bidder per license.

## PROBLEMS WITH FCC AUCTIONS

As was discussed earlier, the auction approach utilized by the FCC encourages the sharing of information through the public availability of bidding information. Auction participants, however, are not allowed to exchange information privately, to stake out claims to certain licenses, or otherwise to collude (FCC, 2003). However, auction participants have been found to signal one another regarding their intentions by incorporating desired basic trading area numbers into their bid values (Cramton & Schwartz, 2000), a practice that the FCC now carefully monitors (FCC, 1997a). The biggest problems associated with the FCC's auction process have not been a result of the auction process itself but relate instead to separate policy mandates regarding small business participation in the auction process. Some have pointed to the general inefficiency of these set aside programs (Hazlett & Boliek, 1999), but the ultimate problem that emerged from the small business set-asides resulted in the authority to manage spectrum being partially wrestled from the FCC.

In order to accommodate the more limited financial capability of smaller-scale bidders, the FCC auction rules allowed winning bidders to pay off their winning bids on an installment plan. Following the completion of these so-called entrepreneur block auctions, several winning bidders encountered financial difficulties, and some filed for bankruptcy protection prior to paying off their installments. A pressing question that then needed to be answered was how the licenses of a bankrupt bidder would be disposed. The FCC thought that they should be returned so they could be auctioned off again. However, the jurisdiction of federal bankruptcy courts was now involved, and a process of judicial review that led to the U.S. Supreme Court was undertaken. Ironically, the Supreme Court ruled in favor of the license holders, which allowed the licenses to be treated as an asset of the bankrupt bidders. The result of these bankruptcies has been to reduce collections of auction revenues (CBO, 2002). It also removed the FCC from the process of controlling the distribution of these licenses.

## FUTURE TRENDS

Despite the problems encountered to date, the FCC auction process generally is viewed as a success (Cramton, 1998, Hazlett, 1998), but there are dissenters (Morris, 2004). The structure of the FCC's auctions have been adopted by other nations following problematic outcomes with other formats (Anadalingam, 2001). Some non-U.S. auction formats have been viewed as successful (Crandall, 1998). Licenses for third-generation wireless services have been auctioned throughout Europe (Anderson, 2002). While there is no question that auctions are superior to other methods for generating revenues, whether they promote good spectrum management policy is an issue of concern. Spectrum licenses are founded on the assumption that the services utilizing the spectrum will suffer from interference. New technologies, such as digital spread spectrum, utilize intelligent devices, which are capable of coping better with interference. Some have suggested that the future of spectrum management will not require much management due to these new technologies (Noam, 1998). A major impediment to the advancement of these new technologies may be the existing licensing of spectrum, which leaves little room for the deployment of these new technologies (GAO, 2004). Of course, economists point to the superiority of property rights in spectrum (Hazlett, 2005); thus, it likely will be some time before the dust settles on the long-term need to license spectrum and to use auctions for that purpose.

## CONCLUSION

Auctioning spectrum licenses is a major innovation in the governmental management of natural resources. The complexity of the economic process has been mitigated significantly due to the use of electronic resources. The ability to conduct simultaneous multiple-round auctions would have been limited significantly absent electronic means to process and distribute information in real time. Electronic spectrum auctions, as conducted by the FCC, have provided valuable lessons in the application of electronic technology to achieve policy objectives.

## KEY TERMS

**Allocations of Spectrum:** The categorization and division of spectrum into blocks that are then associated with a specific technology; for example, broadcast television.

**Allotments of Spectrum:** Divisions of spectrum allocations on a geographic basis; for example, broadcast television station 5 in New York City.

**Basic Trading Area:** A geographic region used by the FCC determines service areas for PCS wireless licenses. The entire U.S. and some of its territories are divided into 493 non-overlapping BTAs.

**Combinatorial Bidding:** Allowing auction participants to place bids on groups of licenses.

**Comparative Hearings:** Method used in the U.S. to award spectrum prior to the advent of cellular telephones.

**Hertz:** The number of cycles per second.

**License:** The right to use a specific portion of the radio frequency in a specific area for a set term.

**Radio Frequencies:** The portion of the electromagnetic spectrum ranging from 3 kilohertz (kHz) to 300 gigahertz (300 GHz).

**Simultaneous Multiple-Round Auction:** An auction process in which all licenses are available for bid at the same time.

**Spectrum:** Radio frequencies.

**Winner's Curse:** Tendency in common value auctions for the high bidder that wins due to variation in the formulation of a bid on the high side.

# Ecology of E-Governance

**Sangeeta Sharma**
*University of Rajasthan, India*

## INTRODUCTION

The concept of e-governance in the modern times refocuses on the fundamental role of government as the institution of transformation of society. To understand the intricacies of e- governance it will be pertinent to examine the concept from an ecological perspective. The system of governance in order to meet the challenges must equip itself with the mechanisms of managing the pressures generated from different subsystems. The interrelationship and interdependence of these subsystems explain the operational reality of bureaucratic systems in relation to societal transformation. In last few decades, the history of humankind has seen the enormous growth of technology and its utilization for creating a better global society, by disseminating the knowledge down to common person and transcending the geographical boundaries. The accessibility of knowledge is not confined to any nation. Thus, the whole world has to acquire a bigger vision of coexistence with divergent societal patterns in future, because it is the source of developing shared visions. The present analysis focuses on the normative aspects of e-connectivity, specifically,

1. It proposes a conceptual framework to understand the futuristic operational dynamics of ecology of e-governance;
2. It proposes how the interactions of various components of e-governance, can help in evolving a universal society with ethical axis to create a better world;
3. It suggests that the whole world eventually has to move in the direction of evolving a global society by inculcating universal values of coexistence with divergent ethos. Hence, the need to transform the society cannot be subdued; and
4. It focuses on striving a balance between technological and human aspects by bringing out philosophical core at the centre to evolve global society.

## BACKGROUND

The era of information technology has opened many vistas of understanding human dynamics from different perspectives. The thinkers have shown a great concern to view the repercussions of electronic connectivity on society, culture, polity, and economy. To name a few, for instance, Daniel Bell explores the dimension of knowledge and technology in relation to the emergence of the new class structure of postindustrial society (Bell, 1996). Manuel Castells has discussed the formation of Network Society, which elaborates the economic, social, and cultural changes that are occurring around the world due to computerization (Castells, 1996, 1997, 1998). An interesting aspect related to changing relationship is also examined by Mark Poster, who is keen on constructing correlation of human-machine imbrications due to exposition of communication machines (Poster, 2000). Raising the question of evolving alternative theories, Frank Webster questions the technological determinism by evolving the theories of Information Society looking closely at the different approaches to informational development (Webster, 2002). Maintaining the continuity of the discussion, futuristic social transformations can also be viewed from ecological perspective. This needs identifying various components of e-governance and interplay to shape future society with universal areas of normative structuring.

## ECOLOGICAL PERSPECTIVE OF E-GOVERNANCE

The concept of ecology in governances refers to the understanding of the interrelationship and interdependence of bureaucracy with its environment. To understand its ecology, it would be pertinent to identify various components, substantiated by elaborations regarding how these components interact with each other to deliver the output in to society: (1) technological component focuses on electronic dimension, (2) social component focuses on egalitarian dimension, (3) cultural component focuses on ethical dimension, (4) political component focuses on enactment dimension, (5) psychological component focuses on extensional dimension, (6) service component focuses on empowerment dimension, (7) administrative component focuses on enforcement dimension.

The "E" in the aforementioned dimensions emphasizes the role that can be played by e-connectivity that metamorphoses into respective components.

- **Technological Component:** This relates to educating people who are in the bureaucracy or outside its periphery regarding the use of electronic means to develop better connectivity within and with the system. It requires use of technology (a) in developing the database, (b) in networking to facilitate the communication, and (c) in creating e-knowledge workers to increase the potentiality. This focuses on the "e" of electronic knowledge and its proper utilization.
- **Social Component:** The fundamental duty of any government is to educe a society, based on the principles of equality and justice. A society, which is classless having no distinction between haves and have-nots, where nobody is marginalized from the main stream, and is committed to provide a respectful essence of life to its people without any discrimination of caste or race, must be set up. This is possible only when people are aware of their rights and duties on the one hand, and know about the governmental policies made for them on related issues on the other, hence a vigilant society can be evolved where they can raise their voices by questioning the governmental decisions. This would help in attaining the "e" of egalitarian society with thrust on equality.
- **Cultural Component:** With the advent of the era of knowledge explosion there is a need to reorient some of the value patterns without eroding the fundamental normative structure of any social system. The need to create value patterns conducive for e-governance to operate focusing on work ethos therefore cannot be denied. Thus to work out the ethical framework is the key to move further by discarding obsolete sets of values that come in the way of potential utilization. Thus, "e" of ethical framework has to be the focal point in constructing a morality-based system.
- **Political Component:** The political system is essential aspect of governance. It holds responsibility of rationalizing various operative frameworks by enacting laws. This helps to maintain and sustain the cohesive force that is required by society to integrate its people and abide them to follow a uniform policy to fulfill their targets. This refers to the importance of "e" of enactment of laws to stop society from disintegration.
- **Psychological Component:** Evolving balanced society requires psyche to facilitate formation and inculcation of right type of attitudes in the people. It is prerequisite for efficiency. Apart from this, readiness to connect to people, to listen to their queries, to look for solutions, to improve communicative skills, and so forth, will be necessary elements for behavioral modifications. Hence, personality adjustments must be carried out to cater to the needs of common people. This specifically relates to "e" of extension of self to have constructive collaborative social relationships.
- **Service Component:** The ultimate function of any welfare government is to serve. As a provider of good services to its people, it has to assimilate the basic needs and expectations of common person in to the documentation of policy, which then has to be implemented in the right spirit. This develops a constant pressure on the government to respond to public demands as this leads to the realization of power they can exercise on government to maintain impartiality, integrity and transparency in its functioning. This explains "e" of empowerment of people in any system.
- **Administrative Component:** Administrative component is inevitable because it is through this component that policies are translated into action. How to enforce decisions effectively need to be worked out keeping in view, the modifications and adaptations required. Thus, a responsive system can only be there when system is open to respond to the changes, this explains the "e" of enforcement of carrying out its decisions.

To get an insight into the mechanism of functioning of various components there is a need to identify at least two parameters each, so that variations can be measured and recycled into society.

- Political parameters
  1. Identifying areas for which integrated cyber laws are needed
  2. The contents of laws
- Administrative parameters
  1. Evolving unified machinery connected with networks
  2. Registering and solving people centered problems
- Social parameters
  1. Ensuring people's participation in governmental policies
  2. Enlarging the domains of making choices by people.
- Cultural parameters
  1. Designing universal value systems and
  2. Inculcating the designed values at various levels of operations.
- Psychological parameter
  1. Restructuring the attitudes of individuals and
  2. Readiness to connect to people

- Empowering parameter
  1. Awareness about the rights and duties and
  2. Knowing how to get benefited by these rights
- Technological Parameters
  1. Increasing the potential of every individual as knowledge worker and
  2. Catalyzing the usage of his knowledge for transformations

## PROGNOSTIC REALISM: A FUTURE VISION

The prognostic realism involves identifying attributes of parameters of components from individual society to society in the logical manner that leads to the formation of idealistic global society. The "transformation" as positive notion indicates capacity of a system to resolve inherent conflicts and fight back the situations of crisis. To create such society the world has to work out broader vision of constructive collaborations, because once we have vision, it can be converted in to reality. We therefore must identify various attributes of components.

### The Attributes of Various Parameters of Components

Looking to future reality the quantitative attributes of these parameters will always be putting demands on subsystems to combine in right combination to cater to the needs of continuous change. Assuming development is desirable and planned change, and will remain so in future the following attributes of different components can be identified.

- Political com
  1. Number of cyber laws enacted and amended
  2. Percentage of votes in favor/in opposition
- Administrative com
  1. Number of laws implemented
  2. Number of innovations carried out
- Social com
  1. Number of effective choices made available
  2. Amount of participation mobilized for policy
- Cultural com
  1. Identifying obsolete value patterns
  2. Level of perceptions for newer patterns
- Psychological com
  1. Amount of resistance reduced for implementing policies
  2. Amount of behavioral adjustments made
- Service com
  1. Degree of transparency of policies
  2. Degree of awareness achieved.

Qualitatively this means content with which laws/programme/policies are made. The integrity is an important aspect for facilitating creation of better world through e-governance. In addition, a genuine commitment to get the consequential outcome of developing an ideal society by using various inputs of e-governance to redesign the world over systems into more closely connected system of functioning together is needed.

What lies in future is unknown, but if we can design logically and systematically, perhaps a better future can be created. Thus there is a need to evolve a philosophical core that might help us in understanding what shape might emerge of the society if the entire world is governed by e-governance, which will be a trajectory of today's society for future.

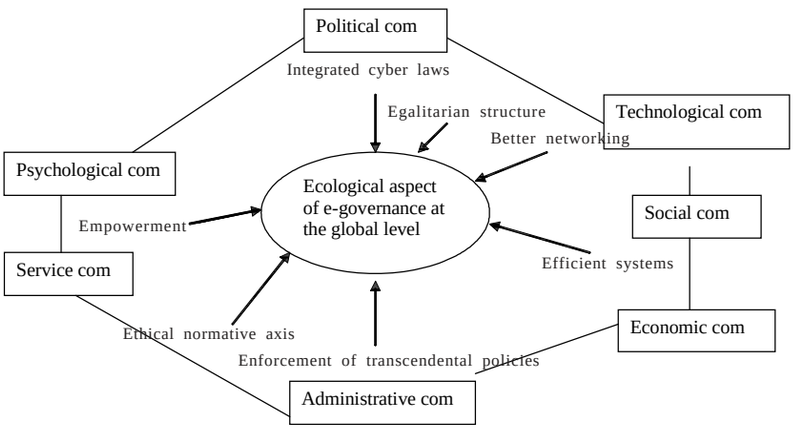
The assumptions would be as follows:

1. If various governments are connected electronically then there is shrinkage of distances hence arises the need of having congregated society.
2. If we move toward a congregated society, then normative axis has to be designed, hence arises the need of inoculating universal values.
3. If universal set of values has to be designed then geographically tightened sets of values have to be defied, hence arises the need of identifying and accumulating divergent sets of value patterns.
4. If we accept the coexistence of divergent values then collaborative identities can be evolved hence arises a need to have a closer look at the types of worldwide societal patterns.
5. If ethical core of future society revolving around virtuous values is to be created then there is a need to examine all other systemic variables that might shape the polity and economy in the direction of evolving a highly contended mega-social structure.
6. If future indicates the formation of mega-social structure, then there is a need to understand ecology of e-governance, thereby focusing on strategically designed components.

This mega-society can be viewed as the resultant outcome of interaction of various components of e-governance, which will require the following parameters to have permutations to see that how interactions of various components must be planned conceptually to visualize the future transformations.

For transforming the future, various polities will have to work in a more coordinated way by resolving issues

*Figure 1. Interplay of various components*



related to discrimination and disparity at various levels through conscious efforts by evolving mechanism of futuristic social engineering, following:

1. A careful exercise on prognosis mentioned
2. The appropriate mixing of quantitative attributes of different parameters
3. A construction of desirable design of future operational reality, focusing on professionalism, idealism, philosophy, and realism.

The key to shaping the future lies in idealizations of what type of system we want to evolve. The human-created structures can never become perfect structures of functioning, but by keeping high ideals, molding can be one alternative to strive for seemingly difficult targets. This relates to highlighting what possible efforts must be taken to convert ideals into reality.

## The Operational Designing

It requires:

1. Defining resultant activity of social transformation
2. Managing input-output inflow of components
3. Managing the environmental forces
4. Evolving knowledge-based global society
5. Achieving the objective of social transformation by assimilating the above-stated functions.

A concrete statement about future vision must be spelled out so that it will help us to visualize those prerequisites for changes without which no transformation can occur. Web connectivity must be used for facilitating peaceful coexistences by mobilizing the population to contribute in generating positive and virtuous environment. To explore the practical possibilities it would be pertinent to understand how does ecology help to manage the input–output inflow of components in achieving the objectives of social transformation. Attributes identified must be carefully internalized to support the formation of ideal global society. This can be understood by looking at the Figure 1 to visualize the interplay of components with probable outcomes.

## Strategic Interventions

The scientific and humanistic explorations will be the two important epicenters of future activities. The challenging task would be to reduce the extraneous effects by controlling the negative impacts. In this regard, e-connectivity can help in perpetuating the stronger and eternal principles of existence that will take us to the evolved state of human existence by providing the better mechanics of managing conflicts at different levels. The value structuring is important for the creation of global society. This can be done by polarizing various sets of values as per the need along the major normative axis.

Three sets of values can be identified:

1. Blokades values which are detrimental for transformation
2. Plasmatic values, modified version of term plasma taken from science which refers to free flow of particles. The analogy here is that in society we also have some sets which can generate positive energy. Thus they must be recycled.
3. Axial values which are fundamental values, conformity to which is essential for any particular society

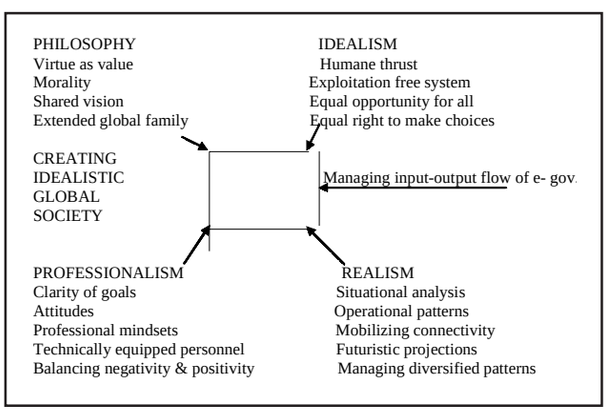
The formation of universal values must be inoculated to evolve global society in the following way:

- Initiating discussion regarding the type of global society we are looking for
- Arriving at the consensus regarding design of values that is needed
- Reshaping the various socio-economic, political, cultural subsystems, keeping in mind their alignment with global society. Keeping in mind the operational design and vision as mentioned above, systems have to be molded to get the desirable transformations. The central focus of the transformation is creating global society that combines philosophy with idealism and professionalism with realism.

The foremost contribution of e-governance in constructing universal society is evolving philosophical core of idealistic nature but conversion into empirical realities is not impossibility. The purity of society will depend upon true empowerments to awaken individuals. Empowered people will create knowledge-based society with complete knowledge of technicality of electronics. These knowledge workers need to follow ethical axis based on universal normative alliance. This fixes the high morality as the basic core of functioning that will help them to enact and enforce policies regarding evolving the egalitarian society. Humanitarian aspect is important outcome of this society, thus extending oneself psychologically to provide fruitful connectivity must be seen as an ultimate activity. This would mean creating a society with (a) philosophical idealism, and (b) professional realism. This is shown in Figure 2.

This clearly explains the future scenario in a conceptual framework. For getting better results, futuristic trends need to be controlled, structured, and recycled in to the society.

*Figure 2. Transformational forces*



## Conversion in to Empirical Realities

The fundamental question searched is, can we convert this philosophy in to empirical reality? To look for an answer, there is a need to identify conditioning factors. These factors are (i) the capacity of institutions to respond to the demands of changing needs, (ii) the preparing institutions of governance at different levels to manage resistances at various levels, (iii) the management of environmental inputs to deliver desired output, and (iv) the commitment to create society based on justice and equality has to be ascertained.

## CONCLUSION

The seeds of future lie in present. The power of mind and beauty of heart must work in consonance toward managing deprivations, depression, dehumanization, and desensatization which are adding to the misery of humankind. The fundamental question is can we rise above our individual ideas and identities? E-governance can be used as the important tool for releasing an individual from the capitivity of his or her parochial outlook and help him or her acquire a vision of coexistence in broader perspective to work toward humanity. Any concept which is devoid of philosophy is meaningless. Some of them may seem to be difficult to achieve, but it helps in maintaining a momentum to guide for future transformations. There lies a fragrant hope only if we allow new philosophies to emerge, then prediction about futuristic trends can be converted into realities. Some efforts are already in row; some need to be explored.

## KEY TERMS

**Components of E-Governance:** Refers to "e" dimensions of various components, such as technological, social, cultural, political, psychological, service, and administrative, of e- governance. Interrelatedness and interdependence of these components will affect the output in the society.

**Idealistic Global Society:** This is idealization about the form of global society. It can be seen as an extended form of mega-structure. The objective is to merge positive traits from the world over patterns then to create a structure around virtuous elements.

**Quantitative Attributes:** In order to understand the variations and to control their impacts, conversion of quality into measurable quantas will be necessary. If planned properly, these can deliver the results. Many more can be identified.

**Value Structuring:** Three sets of values have been identified: (i) blokades values which are detrimental for transformation; (ii) plasmatic values, modified version of term plasma taken from science which refers to free flow of particles. The analogy here is that in society we also have some sets that can generate positive energy. Thus they must be recycled; and (iii) axial values which are fundamental values conformity, to which is essential for any particular society.

# Ecuador's Experience in E-Governance

**Santiago Reyes Mena**
*Informatic and Law Degree at Universidad Compluetense de Madrid, Spain*

## INTRODUCTION

Countries in Latin America, nongovernmental organisms, private corporations, and international organisms are working on a preliminary phase to develop information communication technology (ICT) as well as national strategies to convert current weaknesses into opportunities for an information society (IS).

There are numerous initiatives which have promoted the introduction of IS and demonstrated significant progress and development in several countries. Latin American governments have begun elaborating a regional action plan, based upon the action plan resulting from the first World Summit on the Information Society (WSIS), in Geneva during 2003. They have also participated on the second phase of the WSIS. Currently, these governments are defining an integrated strategy for Latin America, taking inventory of the different activities carried out and monitoring progress. Latin American governments are working to form a unified agreement which allows for social progress and sustained development in the Latin American and Caribbean regions.

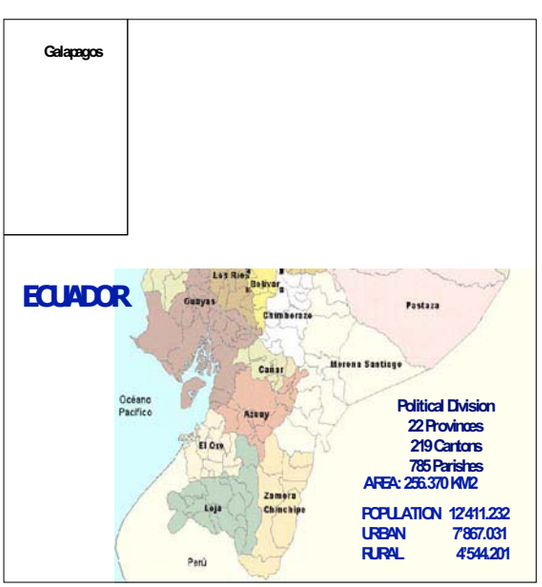
## BACKGROUND: ECUADOR'S GOVERNANCE PROBLEMS

Ecuador has several different levels of government; the central government, sectional governments, and local governments. The central government is characterized by only minimal national planning, a huge social debt, and a large foreign debt. The sectional governments, which are pushing for decentralization and modernization, have a strong commitment to support local governments, due to their practical viewpoint. Democracy only returned to Ecuador in 1978, and has not yet completely consolidated. Thus, democracy is quite fragile in Ecuador.

There are several governance issues which are currently quite evident in Ecuador:

1. **Social:** There is significant social and economic inequality characterized by a high poverty rate, migration, illiteracy, lack of national identity, and limited access to health care and education. Another problem is the issue of Colombians displaced by guerrillas.

*Figure 1.*



| Key Figures | |
|---|---|
| **Fixed Lines Installed** *Fixed teledensity* **– 2Q05** | **1,66** *12.6%* |
| **Mobile Subscribers** *Mobile teledensity 3Q05* ***GSM Subscribers*** | **5.39** *40.8%* *2,6* |
| **Internet Accounts** 2004 | **0,11** |
| **Internet Users 2004** | **0,19** |
| **PC's** - 2004e | **0,16** |
| **Regulatory "agency"** | **SUPERTEL** |

2. **Political:** Presently, there is a governance crisis, characterized by a lack of political leadership, lack of political coordination, corruption on public management, mistrust in political groups, and a mistrust of government in general.
3. **Economic:** There is mismanagement of public funds and a crisis in the banking sector.

## APPROACHES TO E-GOVERNANCE STRATEGY IN ECUADOR

The strategies of e-government in Ecuador must be implemented at each of the different levels of government.

The central government has a national plan designed for IS. A project presented to the Presidency of the Republic of Ecuador, called Government Unity of ICT (http://www.presidencia.gov.ec), proposes policies related to basic standards for transmission, management of digital documents, use of the Internet, digital equipment, and government regulations. In addition, recommendations are being made to government authorities for the elaboration of a national plan and policies related to ICT. The National Telecommunications Board—CONATEL (http://www.conatel.gov.ec)—has designed a proposal called the National Board of Connectivity, as an interinstitutional entity in charge of establishing and developing the National Agenda of Connectivity (http://www.conectividad.gov.ec) with central and sectional government. The Agenda has created programs such as e-government, governmental connectivity, governmental services online, Web pages for governmental institutions, information on government projects, Internet for everybody, e-education, e-health, and e-commerce.

The Presidency of the Republic has designed the governance and financial management systems to implement the project. The system of management for governance—SIGOB (http://www.sigob.gov.ec)—gives information support. The integrated system of financial management—SIGEF (http://www.sigef.gov.ec)—includes government accounting and thus, makes the nation's general budget accessible and transparent for every citizen.

Many government institutions have created their own Web sites, offering institutional information and consulting help such as the Central Bank of Ecuador (http://www.bce.fin.ec). Some institutions have incorporated systems to attend information requests such as the Superintendence of Corporations (http://www.supercias.gov.ec) and the Ecuadorian Social Security Institute (http://www.iess.gov.ec). There are also government organizations which carry out training and equipping programs and in departments such as the Ministry of International Trade, Industry, and Fishing (http://www.micip.gov.ec), the Ministry of Education and Culture (http://www.mec.gov.ec), and the Supreme Electoral Tribunal (http://www.tse.gov.ec). The Supreme Electoral Tribunal Web site allows inquiry about the assigned voting place and electronic voting. The Internal Revenue Services Web site (http://www.sri.gov.ec) includes a security information system, tax return, and tax payment on the Internet, and will soon allow for the managing of electronic invoices. CONTRATANET (http://www.contratanet.gov.ec) contains public contract processes, and is an Internet information system, which is transparent, reliable, accessible, and innovative.

The National Congress (http://www.congreso.gov.ec) has designed a project called Legislative Information System (SIIL). Its objective is to provide legal data on laws presented and resolutions taken. SIIL allows searches for citizenship participation, publishing of legislative acts, Web searches to access legislative information, the establishment of the e-vote, and document digitalization

The judicial branch of government also has a number of ICT projects (http://www.justiciaecuador.gov.ec). One project will set up the configuration of electronic formats of judicial decisions. Another project provides current information on the state of pending lawsuits available to the public and electronic notification.

Sectional Autonomous Government: Provinces and Municipalities, which depend financially on central government, are beginning to develop their own e-government strategies. Provincial Boards have their own informative Web sites. In particular, the Provincial Board of Pichincha (http://www.pichincha.gov.ec) is developing a program that will broaden ICT access for the poor and provide basic education to the rural population in that Province. This program is called "edufuturo" (http://www.edufuturo.com).

The Provincial Board of Guayas (http://www.guayas.gov.ec) community program called "telecentros", and the Provincial Boards Association of Ecuador—CONCOPE (http://www.concope.gov.ec)—have designed an interactive platform to provide information flow between the different Provincial Boards of Ecuador.

Cities such as Quito (http://www.quito.gov.ec) and Guayaquil (http://www.guayaquil.gov.ec) have resources to implement the project and are developing electronic payment platforms, while at the same time fostering direct citizen participation at their Web sites. The Municipality Association of Ecuador—AME (http://www.ame.gov.ec)—has a project which integrates every municipality through a national information ICT Web site. Many municipalities in Ecuador participate on the Andean Web of cities which have connectivity

between other cities and regions (http://www.redandinadeciudades.org). The Board of Parishes (counties) has an acquisition and training strategy for ICT.

Other Provinces and Municipalities are now designing an e-government strategy with the help of CARE. Care has also designed an e-government program called GOBEL. That program improves the efficiency and transparency in management; improves ICT's use and access capacities, software, hardware, and communication; and supports decentralization to improve decision making, expenses, and management control. The program also has designed a strategy due to the government's lack of knowledge about this topic. This strategy allows better negotiations with suppliers, includes a basic informatics infrastructure providing excellent results, and allows expansion possibilities to include other sectional governments.

## CRITICAL ISSUES

Although there are several e-government strategy initiatives, there is no coordinated national strategy. Therefore, technical, economical, and management problems frequently occur as well as management inefficiencies and the duplication of efforts. As a result, there are many independent Web sites providing national coverage using different technologies pertaining to different institutions. Unfortunately the site developers keep the information and advances to themselves which prevents the spread of technology to the rest of the country.

Since there is no national strategy for e-government, the following results are experienced:

- The coordination between central and sectional governments is almost nonexistent.
- Investment in technology is too expensive in Ecuador due to the lack of cooperation between institutions and lack of promotion for investments in technology.
- Training for public managers and citizens on ICT varies according to the type of technology that the institution requires.
- The costs of connectivity are high and access to communications difficult.
- There is a lack of public and government knowledge in regard to terms such as information society and e-government.
- Government distrust and fear is at a high level regarding public use of ICT.
- The digital breach increases progressively.
- Connectivity is limited due to language barriers.

## SOLUTION ALTERNATIVES

Ecuador requires a strengthening of the National Board of Connectivity so that it becomes an independent and highly technical institution. In order to accomplish this, the following steps need to be taken:

1. Cooperation must be developed between central and sectional government with specific national action plans to minimize the needed resources.
2. National Policies must be developed to strengthen the national communication infrastructure.
3. The intranet must be consolidated and citizenship participation promoted to encourage communication and information exchange between the public and government entities. On a national level a more efficient, legitimate, and transparent exchange of information must be implemented.
4. Secure public service platforms must be established with easy broad access to the public.
5. Training and education of ICT should be provided for government managers and the public with materials written in Spanish and other Ecuadorian languages. Education programs should be provided for children, teenagers, the illiterate, and persons with diabilities so the digital breach in Ecuador decreases progressively. As a result, poverty and inequality will be reduced and sustainable development enhanced.
6. Communication strategies must be designed to promote the implementation of ICT allowing universal access to this technology and its benefits. Opportunities to acquire ICT and appropriate fee structures to access ICT must also be created.
7. The hardware and software technological development must be consolidated with incentives for technological innovation, and adequate tax benefits to prevent the exodus of ICT professionals.

## CONCLUSION

The present social and foreign debt keeps Ecuador in the dilemma between attending the social problems which are of great importance in the country vs. investment in ICT to help the country progress technically. Until a proper balance is found Ecuador will continue to regress in the area of information society. Another national strategy which should be implemented is the renegotiation with foreign creditors to allow investment in programs related to e-government.

The success of e-government requires changing the way government presently functions to help the public.

In order to successfully implement e-government in Ecuador the following strategies are required:

1. Innovation between the governed and the government processes,
2. Political leadership for the success on an e-government strategy,
3. Strategic and sustainable investments to use resources effectively, and
4. Solid cooperation between the public and the private sector, nongovernmental organisms, and all international organizations.

It is important that legislation which restrains the use and development of ICT not be passed. Laws implemented should rather be flexible on the regulation of ICT so that its development is unimpeded. There should be constant evaluation and monitoring of the effectiveness of the e-government strategy. The success of e-government depends on the public trust in government institutions and their communications.

## KEY TERMS

**Digital Divide:** Is the distance that separates those who have access to ICT from those who have it in a limited way or from those who do not have it at all; and thus, it increases the distance between each other in knowledge and information access and social and economic development.

**E-Government:** is the use that the nation makes of the ICT, with the purpose of simplifying internal management procedures and save costs, grant transparency to certain political procedures, make public services more efficient and effective, spread information of interest to the community by opening channels for citizen participation and thus, legitimizing the government's actions and decisions.

**Information and Communication Technology (ICT):** The umbrella term that encompasses the entire field of computer—based information processing: computer equipment, applications, and services, telecommunications links and networks, digital databases, and the integrated technical specifications that enable these systems to function interactively.

**Informatics Infrastructure:** The interdependent capacities and standards for digital communication and data processing (both hardware and software) that support the flow of information, much as a highway infrastructure support the flow of vehicles.

**Internet:** The vast network-of-networks that uses open rather than proprietary standards to support computer based communications at an incredibly large and efficient worldwide scale.

**Intranet:** Network of interconnected computers, designed to be used inside the company, university or organization. The difference between the intranet and free access internet is the fact that the intranet is private.

**Society of Information:** Study of social development characterized by the capacity of its members to obtain and share any information, from any place instantly and in the way it prefers.

**Universal Access:** Is the possibility that all the people, without exception could access, if they wish to the ICT. This possibility is considered in relation of the cost of the service, a reasonable distance of the homes, work of study places and the existence of special equipment for the persons with disabilities.

**Web Site:** Set of web pages that can form the whole unit. Even it is possible to have a web with an only page.

# E-Democracy and E-Economy in Africa

**Sirkku K. Hellsten**
*University of Birmingham, UK*

## INTRODUCTION

A new world governance and economy characterised by globalisation has an increasing emphasis on knowledge and knowledge-transfer as the primary driver of economic growth, competitiveness, and participation. The economic, social, and political landscape in which future development will take place has then also changed. All countries, rich and poor, must now reconsider their approach to development to incorporate this new reality. Opportunities exist for poor countries to use information and communication technologies (ICT) to make rapid advances in their economic and political development, but there are also risks that a digital divide might widen the inequality between the "have's" and "have not's" across the world.

This article focuses on the role of ICT and the development of e-democracy and e-economy in Africa. The chapter will discuss the prospects and problems in enhancing e-democracy and e-economy in Africa by examining global and local obstacles to the access and use of ICT in many African countries. It also discusses whether ICT can empower people locally and regionally to participate more actively in politics, public affairs and economics.

## BACKGROUND: ICT OPPORTUNITIES IN AFRICA

In the process of globalisation, democracy and economy are expected to go hand in hand. The spread of democratic political order across the world is closely tied to global economy that is based on free market capitalism. Both trends assume as well as promote free flow of information, global communication, exchange of knowledge, and free movement of production of goods and services as well as wide participation of civil society.

The spread of Internet into Africa, the mushrooming of cyber cafes in African cities and major towns, personal computers and mobile phones have created a virtual global village, in which information and knowledge from most parts of the globe is accessible at the click of the mouse. The ICT access numbers have come up rapidly. As an indicator five years again, only a handful of countries had local Internet access, now it is available in every capital city. In 1996 just in Africa only, about 700.000 people had access to the Internet. However, Tokyo had almost twice as many telephones lines than the whole African continent. During the year 2000, sub-Saharan Africa had already passed the threshold of one telephone per 100 inhabitants. In the same year also all the African countries become connected to the Internet. According to a report by the UN Information and Communication Technologies Task Force (UNICT, 2002) in September 2002, the proportion of Africans with Internet access has risen by 20% between January 2001 and 2002.

Interactive local, national, and global communication and dissemination of information and knowledge is central in building democracy, participation, and economic productivity. This is particularly important in poor countries that face serious global and domestic economic, geographical or political challenges. Domestic challenges can include, for instance, the promotion of sustainable development and the eradication of poverty; the access to and allocation of natural resources; prevention, management, and resolution of conflicts with the reinforcement of peace, security ad stability; the endorsement of popular participation in the development processes, democracy and good governance; as well as the promotion of human rights.

The global challenges, for their part, consist of the promotion of competitiveness in the global markets; the exigencies of the emerging information and knowledge based societies of the 21st century; the continuous scientific and technological changes, and the incessant flows of new ideas, views, experiences, and opinions of development and international cooperation. Access to the global networks of ideas, policies, and practices would enable African across the continent to be at least more aware of what is taking place in the world markets; and to help them to design strategies to improve their competitiveness. (Modiddin, 2002; see also Annan, 2003; UNESCO, 2002.)

Wider entrance to the global village and centres of power and decision-making would enhance Africa's opportunities to acquire the competitiveness needed to be credible producers in those markets. The lack of it will leave Africa marginalised in global political economy. However, access to the global networks and global mar-

kets requires certain capacities, a combination of highly qualified human resources and technical productive capacity which is equally highly specialised and costly (particularly in terms of the initial costs), given African meagre resources and the many competing alternative demands on African development. (Modiddin, 2002) New world economy has emerged over the last decade as two long-run broad and overlapping trends: globalisation and advances in information and communication technology have converged. In this new economy, knowledge has replaced traditional productivity inputs, such as labour and natural resources, as the primary ingredient for economic growth. This has created a landscape to which countries must adapt their economic policies as well as their governance. Through the process of globalisation, capitalism has become the dominant form of economic organisation across the globe resulting in free flows of trade and capital.

Recent advances in ICT have increased the knowledge intensity within the production process and economy is now characterised by "knowledge" as the major factor in production and comparative advance. This has caused structural and qualitative changes in world economy, which need to be recognised and incorporated in global and local development policies. As Matthew Clarke (2003) points out, we need to focus on achieving knowledge-intensive development or *e-development*. Within the new economy, information is unbundled from its physical carrier and economics can be separated from the economic of physical objects. De-materialised markets and the digitisation of production and consumption mean that development policies have to overcome the traditional barriers of natural resources and to maximise an environment for the efficient working of the new economy (Clarke, 2003, p. 6).

## GLOBAL DIGITAL DIVIDE, E-ECONOMY, AND WORLD MARKETS

The new economy will not automatically end poverty, because poor countries lack the current type and amount of investment required to benefit from the new economy. Despite the fact that new telecommunication technology undeniably has advanced rapidly and more and more people around the globe have today direct access to it and to the information it conveys, there are still vast regions in the world which have either no or very limited access to these new means of communication and exchanging information. In fact, these places may have very restricted means for even local, let alone global, connections. Many regions lack even more traditional information channels such as mail, newspapers and books, telephone, television, or radio.

On the other hand, in many parts of the third world, and particularly in Africa, many of those countries, which now have the access to the ICT, have not succeeded in using it internally and internationally to promote local interests. Statistics show that even if the know-how and technology is already there and there are some signs of change, the distribution of the latest telecommunication technology is both globally and locally still very uneven. Of the approximately 816 million people in Africa in 2001, it is estimated that only 1 in 4 have radio (205 m), 1 in 13 have a TV (62m), 1 in 35 have a mobile phone (35m), 1 in 40 have a fixed phone line (20m), and 1 in 130 have a personal computer (5.9m). (UNECA, 2005). When we discuss the increasing numbers of Internet users, we should keep in mind that still it is only 0.2 per cent of Africa's population who actually has the access to Internet and that the lack of infrastructure and affordability has centralised these connections in the bigger cities and business centres. In 2000 there were only about 580 000 estimated regular Internet users in the LDCs, representing less than one per cent of the population and 0.16 per cent of global Internet Users. (See Molosi, 1999; Sarocco, 2002) Also in most African countries each computer with an Internet or e-mail connection usually supports a range of three to five users. This puts current estimates of the total number of African Internet users at around 5-8 million, with about 1.5-2.5 million outside of North and South Africa. This is about 1 user for every 25—400 people, compared to a world average of about one user for every 15 people, and a North American and European average of about one in every two people. (Figures for other developing regions in 2000 were: 1 in 30 for Latin America and the Caribbean, 1 in 250 for South Asia, 1 in 43 for East Asia, 1 in 166 for the Arab States). (The UNDP World Development Report, 2001).

While e-economy is to be promoted with e-democracy and e-development in general, it is important to notice that the obstacles in the access to information and knowledge are the same as the access to global markets in general. The lack of ICT in Africa is at least partly based on global economic inequalities. In most parts of Africa, the very same obstacles that we could overcome with the help of new information technology are the ones that prevent its widespread use in the poor parts of the world. Geographic isolation with no reliable means of transportation, lack of infrastructure together with lack of education and with severe poverty mean that there exists very few people who could use even the traditional communication channels, let alone the new technology. This entails that providers are charging high fees to make up for their investment costs. Because most private companies have to play according to the rules of market rationality, the service

providers are locked in charging excessively high prices in regions where there are less customers and where the connections are more difficult to establish. Therefore, the use of new technology such as the Internet or cellular phones in much of Africa remains limited to a small elite (who consists often largely of foreign business and donor representatives) who can afford the costs. This has kept the demand relatively low, which has meant limited competition and less interest from private investors. Thus, the prices continue to remain unaffordable to the wider public on the crass-root level. Also, when the use of ICT is considered in a global context it should be also kept in mind that many of those who are living in isolated rural areas around the third world have never even read a book leave alone a newspaper. And about half of the world's population has never made a telephone call.

There is a paradox in using ICT for enhancing democracy and economy in Africa: on the one hand, e-economy has been offered as the ideal solution to increase Africa's competitiveness in the world markets, on the other hand, markets themselves play an essential part in the unequal access to ICT across the continent and continents. What makes the situation even more complex is the fact that not only is information technology and its allocation led by the market forces, but information, in itself, has turned into a commodity one has to pay for.

The more valuable information is the more people are willing to pay for it. This once again, results into a market mechanism that makes it certain that the poor have even less chances in obtaining the most wanted and vital information. All in all, the vicious circle is created by the lack of infrastructure, unfavourable regulatory environment, high pricing, and uncompetitive market structure that cannot be broken without decisive intervention with focus on the realisation of human capabilities and social justice rather than the invisible hand of the globalised economy. If the lack of economic capacity competitiveness do not allow African countries a chance to democratically and equally participate in the world markets of ICT, it is hard to believe that ICT in itself can create more equality in global power relations or to provide all inclusive global economic and democratic participation in the near future.

It appears that in a global scale democracy and market economy do not necessary go hand in hand. Closing the knowledge and technology gap between rich and poor nations is not easy, and it appears to be particularly difficult in Africa. African countries appear to be pursuing a moving target, as the high-income industrial countries constantly push the knowledge frontier outward, and make it more and more difficult to reach. Indeed, even greater than the gap in access to knowledge technology is the gap in the capacity to create, disseminate, and exchange knowledge worldwide. Differences in some important measures of knowledge creation can then be far greater between rich and poor countries than the differences in income or economic activity. The information coming from African sources has difficulties in finding its way to the centres of intellectual, political, or economic power. (World Bank 1998/1999).

## E-DEMOCRACY AND LOCAL JUSTICE: PARTICIPATION IN NATIONAL POLITICS

The use of the Internet has grown relatively rapidly in most urban areas in Africa, in much the same pattern of adoption of the mobile phone, which followed shortly after. Thus, more people are better connected and have chances to exchange information. The question is, however, has this empowered African citizenry to participate in national and local policy-making or in the national or regional markets. The proponents of new technology are confident that ICT can play an important role in increasing civic involvement also in poor African countries. Creating and supporting these systems of e-government or e-democracy can help create a more direct relationship between people and their representatives, and empower citizens with knowledge that can help them make informed decisions. Working Internet and telecommunication connections can help citizens in developing countries to find government information, contact elected officials or regional offices, and research government programs; or, they can help in disseminating local information and concerns to the centres of power by setting set up Web sites for local and regional governments that will allow citizens to engage in all of the aforementioned activities.

While many African countries may still lack the economic competitiveness and related political influence, the digital age should then at least have brought more possibilities to local democracy and created changes to revive local economic activities. Since civic involvement and political participation can lead to economic development, this in turn, can lead to a more favourable performance by democratic institutions and more social trust of government by citizens. Across the region ICT could then offer new ways for providing access to essential information and knowledge as well as the potential for widespread knowledge sharing (of indigenous as well as global knowledge) that could have tremendous impact on the promotion of human development, alleviation of poverty and enhancement of economic activities and participation in political decision-making. It could create significant opportunities from governance and economic management. Domestically, citizens could have new ways

of online registration and voting, of communicating with their representatives and articulating their grievances about service deliveries by the bureaucrats.

Since the mobile phones and other telecommunication devices available are still very unevenly distributed and in poor countries it is mostly only the wealthy people who have access to new information technology and telecommunication services, the participation can not be equal either. The gaps are the greatest between urban and rural areas in Africa. There are almost three times as many fixed telephone lines per 100 in the largest city of lower-middle-income countries as in their rural areas, and more than seven times as many lines per 100 people in the largest city of low-income countries as in their rural areas. These gaps are even more significant given the fact that more than 50 percent of the population, and as much as 80 percent in the poorest countries of the world, lives in rural regions. (Hudson, 1997, p. 180-181).

All in all, the theoretical possibilities for promoting e-democracy and e-economy in Africa exist today. There are experiences in the practice of e-democracy and e-government worldwide that Africans could learn from. The revolutions in ICT and globalisation make it technologically feasible, accessible and eventually more affordable, to distribute information and to provide access to mutual dialogue in affairs of governance as well as of business. However, at the moment these opportunities are available only to those who already have had access to education, those who are well enough acquainted with the modern world and modern technology, and who can afford the costs. While these future leaders of African business and politics constitute the critical mass that supports the utilisation of ICT in all sectors of society: business, government, and civil society, they still represent a very small portion of the whole post-independence citizenry of many African countries. (Modidin, 2002, p. 12).

However, the problem is not merely about access to technology but also how can technology be used to enforce such democratic values as transparency, accountability, respect for human rights and equality. How can citizens who are concerned with Africa's endemic dismal socio-economic and political conditions, disappointed with the working of traditional democracy, frustrated with the quality and service deliveries of the public sector, worried about the future of Africa in a rapidly globalising world, and disenchanted with there ailing political leadership in Africa, find a way to successfully use ICT to enhance more open forms of governance? Will the new generations of African leaders welcome and promote the introduction of participatory e-democracy when the technical capacity has been reached?

Besides the questions that revolve around access, maintenance, affordability of e-technology, we need to pay attention to the evaluation of the possible consequences of implementing e-democracy on the structures and values of African societies, economy and politics. While improving the infrastructure and access we need to ask, whether e-Democracy will empower the ordinary people to effectively and meaningfully participate in the decision-making that affects their lives, livelihood and life-styles. Will e-Democracy really enhance the opportunities of the poor the disable and illiterate to be heard more clearly than before? Will it enhance their capabilities and opportunities to call to account those in positions of governance and public service? Will e-democracy make leaders and administrators more responsible, accountable and transparent—or will it strengthen the powers of the elites, the rich, the educated, and the corporate sectors at the expense of the ordinary people, and in particular the poor and marginalised? Could e-participation in fact further weaken what little influence the poor have over their rulers if the human face-to-face relations are eliminated and replaced by the impersonal virtual communication? Will e-democracy strengthen or weaken the African sense of community, cohesion and solidarity? Will it undermine the development of social capital so crucial to African economy as well as to the prevention of violent conflicts, creation of the enabling environment of peace and stability conducive to the promotion of human development? Can e-democracy mend the failure of traditional democracy and its inefficiency in Africa? Can e-economy provide for the alleviation of local poverty? (Modiddin, 2002, p. 13)

## E-SOLUTIONS AND ENVIRONMENTAL ECONOMY

While the access to relevant information has a central role in globalised economy and profitable markets, free market practice, civic education, and democratic ideals do not always go hand in hand. Particularly when technological advancement and information resources itself often does not reach them who would most need it and benefit from it. Instead, free markets tend to enforce the development of information society and lead into marginalisation of groups of people in a manner that prevents all the citizens from realising their capabilities as rational, moral, and political agents in the first place. If the distribution and use of ICT is left to the care of an invisible hand of the capitalist market forces, the result tends to be society fragmented by egoistic pursuits and self-interest and profits rather than a global village of wisdom. (See for example Lyons, 1988)

There is then a vicious circle involved in the idea that technology–or markets, for that matter–could be used to cure economic marginalisation: improved economy is first

needed to get into the technology markets to start with. New technology, for its part, is needed to participate in the new economy and in the global markets. Thus, there appears to be no direct connection between globalised information economy and global justice. Instead, people, particularly in the affluent part of the world, who have access to all the information channels available are not using the information they receive or the knowledge they process out of this information to share their prosperity and abundant resources any more equally—and in order to diminish the global suffering.

The fact that we can now, through satellite connections of television, radio, mobile phones and Internet, get information more easily, faster and more accurately about any natural disasters, famines, victims of war and conflict, sufferers of diseases, or in general about any human agony that happens anywhere in the world, has not radically increased our solidarity or changed our habits of sharing our prosperity with those who are in urgent need and/or live in absolute poverty. The moral problem then remains: if we cannot use the new ICT to take up our global responsibilities in affluent countries, how can we expect this technology to bring about local equality in the form of shared power and other essential resources in the underprivileged countries which have much less resources available, much poorer infrastructure, less efficient and inclusive educational systems and limited civic participation? Instead of providing essential channels of interactive communication to those who need it most, new information technology is still for the most part connecting those who are better off and better connected to start with. Simultaneously in many parts of the world, the worst-offs have become even more disconnected from the centres of influence, power and resources. (Heldman, 1994, p. 264-265)

If the traditional African values of solidarity and communal responsibility were taken seriously in the use and applications of ICT locally, regionally and globally we could promote more sustainable development everywhere. Resources could, for instance, be used to design computers that can be used away from electricity distribution grids. Such technology would enable potential users to bypass the inefficiencies of downstream power grids and could be environmentally friendly. Some positive initiatives have already taken place: for example non-grid dependent PCs have been applied to practice in the Mtabila refugee camp in Tanzania. People have been given access to the Internet as a result of a new source of electricity generation. The camp lies well away from the existing Tanzanian power distribution grid. So power is being generated using methane gas produced by fermented cow dung. There could also be ways to power computers by solar energy, if resources to work on these innovations were made widely available and affordable. (Ford, 2003, p. 53-54, Sarocco, 2002).

## CONCLUSION

The latest ICT that can be used for fast creation, acquisition, storage, dissemination, retrieval, manipulation and transmission of information, could greatly help the marginalised. It could make less affluent countries to benefit from the positive side of globalisation and to help them to promote local and global democracy. It could also provide them changes to more efficiently participate in global economy, that is, to take part in e-development itself. (Humprey, 2004; UNCTAD, 2004). ICT provides powerful means for more direct global and local democracy. However, as the sceptics point out, presently the trends of economic globalisation have not led to either to more equal local and global access to the ICT itself nor to the information it transfers. Instead, the information age has not yet significantly narrowed the gap between the affluent and the poor, connected and disconnected, developed, and less developed.

## KEY TERMS

**E-Commerce:** The buying and selling of goods and services over the Internet.

**E-Democracy:** A neologism and contraction of *electronic democracy*, is the utilisation of electronic communication technologies, such as the Internet, in enhancing democratic processes within a democratic republic or representative democracy. The term is both descriptive and prescriptive. Typically, the kinds of enhancements sought by proponents of e-democracy are framed in terms of making processes more accessible, making citizen participation I public policy decision making more expansive and direct so as to enable broader influence in policy outcomes, increasing transparency and accountability, etc. Sometimes referred to also as *cyberdemocracy, digital democracy,* or *techno-democracy.*

**E-Economy:** The system or range of economic activity through ICT and digital means.

**Global Village:** A term, coned by Marshall McLuhan describing how electronic mass media collapse space and time barriers in human communication, enabling people to interact and live on a global scale. In this sense, the globe has been turned into a village by the electronic mass media and ICT in general.

**ISP:** Internet service providers (ISPs) provide access to the Internet via different communications channels such as traditional telephone lines or high speed fiber optics channel.

# E–Democracy and Local Government – Dashed Expectations

**Peter J. Smith**
*Athabasca University, Canada*

## INTRODUCTION

This article examines the impact of information and communications technologies (ICTs) on electronic democracy at the local government level. It concentrates on measures taken by local governments in the United States, Canada, and the United Kingdom to transform their relationship to citizens by means of e-democracy. The emphasis on democracy is particularly important in an era when governments at all levels are said to be facing a democratic deficit (Hale, Musso, & Weare, 1999; Juillet & Paquet, 2001).

Yet, as this article argues by means of an examination of the available evidence in the United States, Canada, and the United Kingdom, e-democracy has failed to deepen democracy at the local level, this at a time when local government is said to be becoming more important in people's lives (Mälkiä & Savolainen, 2004). The first part of the article briefly summarizes the arguments on behalf of the growing importance of the city as a major locus of economic and political activity. It then discusses how e-democracy relates to e-government in general. Next, it discusses the normative relationship between two models of democracy and ICTs. The article then reviews the evidence to date of e-democracy at the local level of government in the aforementioned countries. Finally, it discusses why e-democracy has not lived up to expectations highlighting the dominance of neo-liberalism.

## BACKGROUND

It has become commonplace to observe that we are living in an era of unprecedented changes affecting all aspects of our lives, societies and the global order. Changes in technology, particularly ICTs, are frequently identified as being pre-eminent (Webster, 2001). The impact of technology is particularly noticeable on globalization. Within an environment in which the borders of the state become increasingly porous and the economy becomes organized on a global basis globalization has become "associated with 'hollowing out' nation states as powers are transferred upwards to international organizations, devolved downwards to more local governments, or dispersed to markets" (Gibbins, 2000, p. 675).

Moreover, no longer is governing confined to the structures and processes of government. Instead governance invites us to consider the "whole range of institutions and relationships involved in the process of governing" (Pierre & Peters, 2000, p. 1). The complexities of governance and the necessity of interacting with a wide range of networked social actors means that without ICTs modern governance would be difficult, if not impossible. Modern governance, then, is closely connected to e-governance, defined by Zussman (2002) as "no more and no less than governance in an electronic environment. It is both governance of that environment and governance within that environment, using electronic tools" (p. 2). Within this networked system of governance and e-governance there is e-government. E-government represents, as Zussman notes, a terrain, the public sector – including its institutions, people and processes that utilize electronic tools in the operations of government and in the provision of services to and engagement with the public. Within e-government there is e-democracy.

## GLOBALIZATION AND THE RISE OF THE CITY

In an age of economic globalization and instantaneous flows of information some argue that the economy and politics are being organized at a global level, disembodied from, if not superior to, place (Castells, 2000; Harvey, 1989). Others, however, disagree arguing there has been an increased emphasis on the local. Saskia Sassen, for example, notes:

*Economic globalization has mostly been represented in terms of the duality national/global where the global gains power and advantages at the expense of the national. ... Introducing cities into an analysis of economic globalization allows us to reconceptualize processes of economic globalization as concrete economic complexes in specific places.* (p. 205)

Moreover, as Beauregard and Bounds (2000) argue, when one combines the rise of "city-regions as the primary economic units in the global economy ... with the lessened identification of peoples with nations and the devolution of state policy to the local level, an urban citizenship begins to make sense" (p. 247). The rise of the city and the existence of a democratic deficit, speak, then, to the potential, if not need, for local governments to use ICTs to create new discursive spaces at the local level, the level of government closest to the people (Delanty, 2000).

This, admittedly, is an optimistic argument. However, before the potential of ICTs to deepen democracy within cities is examined, it is necessary to explore the relationship between e-democracy and e-government along with the relationship of information technologies to models of democracy.

## E-DEMOCRACY AND E-GOVERNMENT: NEW TOOLS FOR GOVERNANCE

As a part of e-government, e-democracy is intended to bring local governments, like all governments closer to the people. That said, e-democracy is nestled within the more general phenomenon of e-government which, in turn, is emblematic of the transformation of the public service in terms of its culture and organization as a consequence of the increasing diffusion of ICTs. (Ho, 2002; Layne & Lee, 2001; Moon, 2002; Norris & Moon, 2005). E-government represents a move away from the traditional bureaucratic paradigm with its emphasis on hierarchy, formality, command and control structures, and inward focus. The e-government paradigm is known for its flexible management, horizontal structures and processes, and for being outward-looking (Ho, 2002). It is thus said to be well suited to an era of networking and governance with its emphasis on users and citizens as empowered partners in governance. (Anttiroiko, 2004)

E-government implicitly rests on enhancing two aspects of the legitimacy of government. On the one hand, e-government is promoted because it can improve government performance and delivery of services, output legitimacy. On the other hand, it is promoted because it can provide additional means by which citizens can become engaged in the process of governing, that is, input legitimacy or e-democracy.

In turn, these two aspects of legitimacy are closely linked to a telos of e-government, linear phases claimed to culminate in more robust political participation. The most elementary of these linear phase models has three stages, those of static information, transactional services, and online communities. (Lenihan & Hanna, 2002) The provision of static information is the stage at which cities, for example, post information about the city. The second stage, transactional services, is interactive between the government and users permitting service and financial transactions. The third stage, e-democracy, our concern here, culminates in active citizen participation, online communities, which could include citizen-to-public official exchanges, or horizontal citizen-to-citizen dialogue.

## MODELS OF DEMOCRACY AND ICTS

While the first two stages are commonly depicted as emphasizing the improvement of government performance, all stages can potentially enhance democracy, not just the third stage. For example, the provision of information is a vital aspect of democracy providing transparency and ensuring government accountability. In fact, for the two main models of democracy considered in this section, pluralist and deliberative democracy, the provision of information is an important, but, albeit, not the only, requisite.

According to the pluralist model of democracy, articulated by Dahl (1967) and Schumpeter (1950), citizens do not participate directly in making decisions. Rather, they exercise influence through competing interest groups whose leaders negotiate and bargain with one another and decide on their behalf. Individually, citizens participate directly and infrequently by means of elections where they judge the performance of government and make rational choices among the representatives of political parties.

Clearly there is a close compatibility between pluralist democracy and ICTs. As Norris (2003) notes "new technologies multiply and fragment the access points for information, communications, and interactions between group representatives and public officials" (p. 5). In this sense, then, ICTs contribute to the pluralization and fragmentation of society and groups who can use these tools to organize and make demands upon government for improved policies and services.

By and large, few analysts of e-democracy view it as a means of promoting pluralist democracy (Barber, 1999; Chadwick & May, 2003; Hale et al., 1999). Rather, they extol the virtues of e-democracy as facilitating deliberative democracy as a remedy to the shortcomings of contemporary democracy, especially, the decline in public trust in political institutions and politicians along with declining voter turnout (Juillet & Paquet, 2001; Kearns, Bend & Stern,2002).

For proponents of deliberative democracy a deeper form of democracy than pluralist democracy is required. According to Yankelovich (1991):

*For democracy to flourish, it is not enough to get out the vote. We need better judgment, and we need to know how cultivate it. ... Good judgment is something that must be worked at all the time and with great skill and effort. It does not exist automatically; it must be created.* (pp. 102-103)

As a consequence, deliberative democracy places a strong emphasis on what Benjamin Barber (1999) describes as "dialogical" communication, direct, horizontal communication between citizens and citizens and between citizens and public officials.

In theory, e-democracy, in the form of more participatory and inclusive governance, has the potential to enhance deliberative democracy. As collaborative devices ICTs can potentially bring dispersed citizens together to form online communities promoting citizen interaction, dialogue, and judgment. ICTs also permit citizens to become producers of knowledge, thus democratizing public information and discourse.

## E-DEMOCRACY AT THE LOCAL LEVEL: A PROGRESS REPORT

With these models in mind the article now examines the progress of e-democracy at the local level in the United States, Canada, and the United Kingdom using extant surveys and reports on the adaptation of local e-democracy in each country. These three countries were selected because of their high state of e-government capacity and the fact that they are seen as strategic leaders in e-government innovation (UN, 2002). Moreover, the population in each country is judged to be Internet savvy.

### The United States

The roots of e-democracy at the local level in the United States go back nearly two decades, prior to the championing of e-government by the Clinton administration. Probably, the most noted of all e-democracy initiatives was the ill-fated Public Electronic Network (PEN) in Santa Monica, California that started in February 1989. Despite being adopted within a municipal political culture and administration supportive of this experiment in deliberative e-democracy, PEN failed to live up to its high promise. The quality of unmoderated discourse was judged to be poor, if not acrimonious at times, dominated by a small and vocal group of citizens with little participation from elected officials. With the arrival of the Internet interest in PEN declined further and the city shifted its priorities "away from discussion and towards the provision of information and electronic public services" (Docter & Dutton, 1998, p. 131).

Since then, there is little indication that deliberative e-democracy at the local level has fared particularly well in the United States. If the provision of online information is a barometer then pluralist democracy has fared better. An early study by Hale et al. (1999) of the municipal Web pages of nearly 300 Californian cities concluded "that municipal use of telecommunications technologies concentrates primarily on *information provision*, not the communication linkages that might promote the quality of democratic discourse" (p. 97). Exemplar sites that supported deliberative democracy were rare.

Later, nationwide studies in the United States come to much the same conclusion. Ho (2002) found that "only a few cities engage in online policy dialogues or partner with community organizations to strengthen citizen participation at the neighborhood level" (p. 8). A subsequent PEW study (2002) of 2000 mayors and city council members of the National League of Cities found that the Internet and e-mail had not deepened democracy to any great extent (p. 16). This is confirmed by a later study of Norris and Moon (2005) who assert that at all levels e-government in the "United States is principally informational—that is, it involves the one-way transmission of information from government to citizen" (p. 64).

### The Canadian Experience

Regrettably, the U.S.'s neighbour to the north, Canada, has fared little better in its evolution towards deliberative e-democracy at the local level. Studies indicate that e-government has failed to deepen democracy at the municipal level in Canada although the increasing provision of information could be seen as encouraging by advocates of pluralist democracy.

A number of studies indicate that most Canadian municipalities are at the informational and transactional stages of e-government with little progress towards deliberative e-democracy. Downey and Berdahl (2001), for example, found that of 152 municipalities in Western Canada only five had any type of citizen forum and only two provided online consultation.

Another study by Lenihan and Hanna (2002) indicated that most Canadian municipalities were at the first stage with others moving to transactional services. Indeed, most municipalities found it a "major challenge" simply ensuring information they posted was up-to-date (Lenihan & Hanna, 2002, p. 8). While this may be a significant contribution to pluralist democracy, Lenihan and Hanna found few municipalities had formed online communities with active citizen engagement. Municipal officials, moreover, expressed concern that the costs of maintaining online discussions would be too high and have dubious results (Lenihan & Hanna, 2002).

The most recent and exhaustive survey on the role of the Internet in municipal life in Canada by Fortin and Sanderson (2003) surveyed 304 municipalities in the province of Quebec focussing on the question of whether the Internet was "really being used to improve local democratic institutions and processes" (p. 5). Their conclusion differs little from other Canadian studies. They found that while virtually all Quebec municipalities have a Web site, progress towards a deeper notion of e-democracy has been slow. They found, for example, only 1% of Quebec municipalities had any public discussion forums related to municipal affairs (p. 1). They conclude that "there appears to be a clear gap or at least a significant lag between the [utopian] visions of some authors and the actual use of the Internet for these [democratic] purposes" (p. 8).

## The UK Experience

While the United Kingdom lagged behind the U.S. by at least five years when it came to pursuing e-government initiatives, the election of the Labour government in 1997 brought with it a concerted effort to modernize government at both the national and local levels (Chadwick & May, 2003; Pratchett & Leach, 2003). Since 1998 the emphasis in the UK clearly has been on moving from providing information to providing services but there has been less emphasis on e-democracy, particularly at the local level.

In a far-reaching study Kearns et al. (2002), attempted to ascertain the state of e-democracy at the local level in the UK, surveying 235 local authorities in England and Wales with follow-up research in a further 120 local authorities. They found "that, with the exceptions of a few islands of good practice, e-democracy is currently in a highly underdeveloped state" in the UK (p. 7). This mirrors the conclusion of Karakaya (2003) whose research indicated that the emphasis of local councils is primarily on offering e-services rather than online citizen involvement.

Illustrative of the very limited use of the Internet for citizen input to policy consultation, and debate was the survey of Kearns et al. (2002). They asked respondents in local councils two questions in this regard. First, did "local authorities use the Internet to invite submission of views from citizens as part of its consultation process," to which 70% responded, "yes" (p. 22). They then asked the following question: "Which of the following internet communication channels does the authority encourage for this purpose?" (p. 22). Overwhelmingly, the answers were either e-mail to a council officer (64%) or an elected member (23%). No more than 7% of local authorities provided for any type of moderated or unmoderated discussion, a reflection of the limited effort to develop e-democratic tools of citizen deliberation (p. 22). Moreover, the number of communications received by local authorities from citizens was very low, the predominant figure being less than 10 per month (p. 23).

From this perspective ICTs have not approximated their reputed potential to facilitate deliberative online democracy at the local level. On the other hand, advocates of pluralist democracy may take comfort from the fact that almost all local authorities are online in the UK and moving to providing online services. Yet, other experiments with online pluralist democracy, such as e-voting, have failed to stimulate higher voter turnout in local elections.

In May, 2003, under the supervision of the UK Electoral Commission, 59 pilot studies were conducted exploring innovative ways to vote in local elections including e-voting. The net effect of the e-voting pilot studies was that voter turnout only slightly increased. On the other hand, in those pilot studies where wards experimented with postal ballots voting turnout increased by about one-third, from 34% to 44%. Subsequent public opinion surveys found that of the two major pilot studies, the public found all-postal voting was quick and easy to use (UK Electoral Commission, 2003, p. 25).

## UNDERSTANDING WHY E-DEMOCRACY HAS NOT LIVED UP TO ITS POTENTIAL

For those who hope that ICTs would enrich the democratic process at the local level, the limited accomplishments of e-democracy must be a disappointment. For example, while the provision of online information is an advance, the record is spotty with the quality and type of online information found on local government Web sites an open question. Those who hoped that e-government would also bring a deeper, more deliberative form of democracy have reason to be dismayed.

There are a number of factors that help explain the marginal record of deliberative e-democracy. One approach has been to examine the way in which use of ICTs has been framed by governments since the 1990s. That is, e-government was developed within the broader ideology of neo-liberalism with its emphasis on the market as a model for governments to efficiently provide information and customer services to consumer-citizens. In particular, local e-government in the U.S., Canada, and the UK was framed and implemented within an ideological climate that de-emphasized the participatory, deliberative aspects of e-democracy (Ho et al., 2002).

Neo-liberalism and globalization have also had other related, negative consequences for local e-democracy. In

many instances superior levels of government have increased their regulatory and administrative oversight of local governments and weakened local governments by, for example, state-enforced municipal amalgamation and restructuring, and by reductions in transfers to municipalities (Ruppert, 2000).

Thus e-government was introduced in a period of declining resources for municipalities. On the one hand, this meant that e-government could be more easily "sold" as a means of bringing greater efficiency and savings to governments. On the other hand, the potential burden of increased transaction costs that could be imposed on public officials by e-democracy and citizen engagement practices in a time of resource scarcity dampened the enthusiasm of local government officials for deliberative e-democracy (Karakaya, 2003; Lenihan & Hanna, 2002). To all this must be added a preference on the part of locally elected officials, government officials and citizens for more orthodox means of interacting, for example, face-to-face meetings. This, then, raises the question of the demand for deeper forms of e-democracy (Karakaya, 2003; Kearns et al., 2002).

## CONCLUSION

No doubt a number of other explanations can be found for the weakness of e-democracy at the local level, for example, privacy related concerns (Norris & Moon, 2005). Certainly the utopian vision that ICTs could, by themselves, invigorate existing local political institutions has not been realized suggesting as Barber (1999) argues "if democracy is to benefit from technology then we must start not with technology but with politics" (p. 588). In effect, by starting with politics we must return to questions of power, difference, and antagonism that characterize all societies.

Viewed from this perspective one can ask if our models of democracy, in particular, deliberative democracy are appropriate models in which to envision the political and democratic uses of ICTs. Deliberative democracy, for example, with its emphasis on disinterested, rational argumentation in politics is claimed to be an impossible ideal. Instead, another model of democracy appears to be emerging, one that is more pluralistic, contentious, and agonistic in nature, but not in the form of pluralism with indirect and infrequent participation by citizens as outlined above (Mouffe, 1999, p. 745).

In an era of governance, political participation is widening beyond state institutions, becoming more direct and confrontational with the Internet instrumental in this regard (Norris, 2002). By focussing on the democratic uses of ICTs within a state-centric local government context, our approach may be too narrow. Local politics need not be equated with official, accepted modes of citizens' interactions with the state (Garber, 1997, p. 35). Those who take a social movement approach argue that, thanks to ICTs, local politics has become closely linked to broader, global forces.

This, it is argued, is particularly true with respect to anti-war and anti-economic globalization movements. Here, ICTs have proven to be useful, democratic tools, permitting local groups to collaborate on a global level, opening up new and contentious forms of political space (Smythe & Smith, 2003).

What this suggests is that research into the democratic uses of ICTs at the local level should take a less state-centric tact, one that does not focus, for example, on the stages of e-government or the meagre steps local governments take towards deepening e-democracy. Rather, there should be greater emphasis on how local citizens, civil society organizations, and social movements, as users, decide for themselves how they are going to use ICTs. Beyond this, greater attention must be paid to how these local citizens and organizations, as political agents, use ICTs to form complex translocal and transnational ties that come together to shape complex, hybrid forms of contested politics in which global politics are localized and localities transnationalized (Smith, 2001).

## KEY TERMS

**Deliberative Democracy:** Refers to the centrality of disinterested reason, rational persuasion, and dialogue in politics. It involves a process by which the common good in a society is derived from "collective deliberation conducted rationally and fairly among free and equal individuals" (Benhabib, 1996, p. 69).

**E-Democracy:** The use of ICTs, in particular, the Internet, to facilitate democratic practices. This ranges from the provision of information by governments to citizen participation and dialogue, that is, interaction among citizens and between citizens and policy-makers.

**E-Governance:** Defined by Zussman (2002) in terms of process as "no more and no less than governance in an electronic environment. It is both governance of that environment and governance within that environment, using electronic tools" (p. 2).

**E-Government:** The use of electronic tools by the public sector in the operations of government and in the provision of information and services to and engagement with the public.

**Globalization:** Defined by Held, Mcrew, Goldblatt, and Perraton (1999) as "a process (or set of processes) which embodies a transformation in the spatial organization of social relations and transactions ... generating transcontinental or interregional flows and networks of activity, interaction, and the exercise of power" (p. 16).

**Governance:** Originally derived from the Greek "to steer" it refers to the way societies or organizations steer themselves. Referred to by Pierre and Peters as "the whole range of institutions and relationships involved in the process of governing" (p. 1). Governance can include a variety of social actors, public and private, which are steering society on a variety of levels, local, national, and global.

**Neo-Liberalism:** An ideology that argues that markets and consumers, not governments and citizens, should be the arbiters of what is best for society. It emphasizes government downsizing, de-regulation, and privatization.

**Pluralist Democracy:** Refers to a model of democracy in which society is divided into numerous groups and power dispersed. According to this model, between elections democracy is maintained by competing and countervailing centres of power in which leaders of interest groups check one another and prevent any one interest group from abusing its power. Individually, citizens participate directly and infrequently by means of elections where, as voters, they judge the performance of government and make rational choices between competing elites, representatives of political parties.

# E-Democracy Policy in Queensland

## INTRODUCTION

The term e-democracy has tended to be used interchangeably in the literature with e-governance or e-government, and these terms have been described as "being in a constant state of definition, redefinition, and evolution" (Riley, 2002). For the purpose of this article, e-democracy is seen as one facet of a wider use of information and communication technologies (ICTs) in the business of government, where the focus is on increasing citizen participation in the public decision-making process rather than using ICTs to deliver government information, programs and services, to make financial transactions electronically, or to enhance government internal administrative practices such as record-keeping.

E-democracy has been variously defined, described in one report as "easier to recognise than define" (Kellner, 2004). New terms have also been coined, such as m-democracy—"m" for mobile, addressing mobile communication technologies separate from electronic processes such as the Internet that are more commonly used for e-democracy (Brucher & Baumberg, 2002). The case study that follows proposes a simple definition: "E-democracy refers to the use of information and communication technologies in democratic processes."

E-democracy covers a wide range of activities that support public participation in democratic processes, including electronic voting, online consultation, Web-based discussion forums, electronic petitions to parliament, using the Internet to Webcast parliamentary debates, and digital polling and surveys. Clift (2002a) lists the leading e-democracy practices as e-mail notification as an active information dissemination tool; online public hearings and consultations; ICT use by members of parliament for electoral engagement; digital recording and availability of public hearing recordings and materials; and ICT-enabled local civic deliberations and global networking.

## BACKGROUND

Historically, e-democracy has emerged in many countries, driven by a number of factors including a need to address declining levels of public trust and confidence in government and increased public expectations for governments to be responsive, accountable and effective. ICTs provide an excellent medium for engagement between citizens and government in terms of capacity to reach to a wide audience, timeliness, accessibility, convenience, and efficiency of information exchange.

E-democracy is a fairly recent phenomenon internationally, and is undergoing rapid developments at both practical and conceptual levels. It is an evolving area and for that reason, there is no comprehensive body of knowledge that agrees on what e-democracy is intended to deliver, or even how it is defined. According to recent reviews and practice discussions (e.g., Riley, 2004), there is no single-agreed approach to how e-democracy will eventually take form. There is certainly no established policy base to guide development and implementation. In fact, some in the field have argued that it is yet too early to have a comprehensive policy about e-democracy, and that governments should introduce e-democracy as an ongoing series of projects or initiatives instead (e.g., Chen et al., 2002). Clift (2002b) notes that while a government e-democracy policy is not necessary to provide useful online democracy services, high level policy direction serves to accelerate and deepen second and third generation applications and a strong e-democracy policy with specific measurable goals is essential to promote long-term progress. Morison (2002), in a Northern Ireland executive briefing paper on e-government, suggests that the introduction of an "e-democracy charter" should be considered.

In a recent overview of e-government and e-democracy, the United Nations Department for Economic and Social Affairs (2003) *World Public Sector Report 2003: E-*

*government at the crossroads* surveyed approximately 190 member countries and found that only 13 (8%) have direct/clear statements or policy encouraging citizen participation. These policies do not necessarily address e-democracy explicitly.

Some countries are currently in the process of establishing formal policy for e-democracy. For example, in June 2002 the UK government published a consultation paper *In the Service of Democracy* (HM Government & Ukonline, 2002) outlining a possible policy on e-democracy and calling for public submissions. A report on the consultation process and its outcomes has been posted (HM Government & Ukonline, 2002), however the government's response is still to be published (E-Government Unit, n.d.).

To date, the state of Queensland in Australia appears to be the only place where e-democracy initiatives have been introduced within a formal policy framework by state government. The case study below describes the policy framework and lessons learnt from a review of that framework after two years of operation.
