The state of Queensland has a small population of approximately 3.7 million spread over a widely decentralised area of around 1.7 million sq km. In this context it is particularly important that more innovative and accessible avenues are made available to its residents (particularly those living in rural and remote areas) to have the opportunity to have their say on matters that are important to them and their communities. In Queensland, people's access to a computer and the Internet has been steadily rising with over 63% of the adult population having access to the Internet or email at home when surveyed in May 2003, making the use of ICTs for democratic engagement a reasonably accessible option for the majority of residents.

The Queensland government is internationally acknowledged as having a particularly active e-democracy agenda and has trialed and evaluated a number of digital democracy initiatives. It is the first and possibly only government to have introduced digital democracy projects within a comprehensive published e-democracy policy framework.

### The 2001 E-Democracy Policy Framework

Queensland's *e-democracy policy framework* was released in 2001 and three specific initiatives—e-petitions, Internet broadcasting of parliamentary proceedings, and online community consultations, were progressively put in place over the next 18 months. Online polling was introduced in mid-2004 with the government making a prior commitment to legislative change to implement the outcome of the first public poll. The policy framework has been revised to take account of new and emerging technologies beyond the Internet. This new framework reaffirms the Queensland government's commitment to using new and emerging ICTs to improve community outcomes and will guide further initiatives currently being developed to integrate digital democracy more fully into wider community engagement practice and government decision-making processes.

The key features of Queensland *e-democracy policy framework*, introduced in 2001, are shown in Table 1.

The policy was informed by developments in the field. Lessons learnt from the international body of knowledge

*Table 1. Key features of Queensland's 2001 e-democracy policy framework*

- A specific definition of e-democracy, centred on Internet use
- An explicit commitment by government to using Internet technology to strengthen representative democracy in Queensland
- Specific acknowledgement that it is the government's responsibility to expand the channels of communication to reach as many citizens as possible
- A clear statement that e-democracy processes will complement existing forms of consultation
- A commitment to addressing key issues of equitable online access, responsiveness, privacy, security and authentication
- A reporting protocol for government's response to citizen input
- Reference to specific standards for addressing privacy and information security
- Links to related government policies, such as the *Queensland Communication and Information Strategic Plan*
- Introduction of the e-democracy initiatives on a trial basis to be evaluated after two years
- A commitment to continuing to explore e-democracy and the opportunities provided by new technologies.

at the time the policy was developed included the importance of addressing key policy issues such as equitable online access, responsiveness, privacy, security, and authentication.

## Review of the 2001 Policy Framework

The policy was reviewed in late 2003. That review process included (1) a gap analysis against developments in the field based on international research and practice literature review; (2) assessment of the policy document against generic good practice policy features such as effectiveness (i.e., whether likely to work in principle, based on factors such as logical cause and effect links and realistic outcomes), feasibility (i.e., whether likely to work in practice, based on operational and administrative viability and legal robustness criteria), strategic focus, stakeholder acceptability (e.g., equity considerations, cost-effectiveness, political sustainability), form (i.e., clearly articulated, internally consistent), development process (eg stakeholder input, evidence informed), and provision for review and evaluation; and (3) a review of implementation issues and preliminary outcomes based on consultation with government stakeholders.

The policy review identified a number of critical features for effective policy in this area. Key issues are summarised in Table 2.

Several specific issues considered particularly important in good policy making for e-democracy are described in more detail as follows.

As with policy in any area, it is critical that desired outcomes are made explicit and that there are logical and credible links between actions taken under the policy and these desired outcomes. This is perhaps one of the most challenging aspects of e-democracy policy-making, given the stage of development of e-democracy policy and practice internationally.

As an example, Table 3 sets out outcomes, objectives, and intervention logic derived from the review of the Queensland policy framework. The policy outcomes and e-democracy policy objectives relate to the overall e-democracy policy framework. The intervention logic (or cause and effect rationale) linking objectives and key elements of the outcome are described, which provides the basis for particular actions or initiatives to be introduced under the policy (such as online consultation, e-petitions, and provision of capacity-building tools and resources online). Objectives for some of the individual initiatives introduced under the Queensland policy framework are also set out.

The development of explicit principles to underpin an overarching e-democracy policy framework also provides particular challenges for policy makers. Ideally, these are developed with wider government policy considerations and strategic directions in mind and are aligned with policy in related areas to provide a coordinated and consistent approach that increases the likelihood of e-democracy initiatives being taken up and integrated into practice across the whole of government.

*Table 2. Issues for effective e-democracy policy*

- **Privacy and Security:** E-democracy initiatives provide, and are seen to provide, a safe and secure channel for engagement
- **Inclusiveness:** Promotes access for "hard-to-reach" groups; facilitates accessibility for specific needs groups such as people with a disability; accommodates social and cultural diversity and differing levels of ICT skills and technical capacity
- **Outcome Focus and Rationale:** Clarity of outcome to be achieved and policy benefits are made explicit
- **Principle-Based:** Underlying principles guiding e-democracy processes and developments are articulated--policy is not simply a description of existing or proposed activities
- **Role Statement:** Explicitly articulating government's role and commitment
- **Responsiveness and Feedback:** Acknowledging, considering, and reporting on input provided through e-democracy initiatives
- **Coordination and Integration**: Online processes are integrated with off-line activities to provide a coordinated engagement response; integrating e-democracy outputs with mainstream decision-making processes
- **Flexibility:** Responsive to the rapid changes in the field; open to innovation and uptake of new developments
- **Capacity Building:** Facilitating readiness of government and community users to take maximum advantage of the opportunities provided by ICT-enabled engagement processed
- **Review:** Stated commitment to learning from experience and knowledge sharing; ongoing review mechanisms built in from the start

*Table 3. Outcomes, objectives, and intervention logic example*

- **E-Democracy Policy Outcome:** Inclusive, informed and productive public involvement in decision-making through the use of ICTs
- **E-Democracy Policy Objectives:**
  - Provide safe, secure, and efficient ways for people to interact with Queensland government, Parliament, and each other on public policy issues that are less limited by accessibility constraints such as place, time, cost, and existing networks than traditional avenues
  - Increase knowledge and understanding about democratic processes and public policy issues in the community, which can in turn promote better policy choices, decisions, and outcomes
  - Build capacity and active participation of those involved in democratic engagement, including individuals or communities contributing to public policy making as well as public officials and elected representatives engaging with the community on these matters
  - Demonstrate government's responsiveness to public input and transparency of decision-making
- **Alignment of Outcomes and Objectives:** The "cause and effect" rationale linking the objectives and key elements of the desired outcome
- ***Inclusive* Public Involvement:**
  - Providing ICT-based opportunities for engagement promotes input from sectors of the community that may not engage through the more traditional avenues
  - ICT-based engagement processes need to be perceived as safe and secure to overcome known public concerns in interacting with governments electronically
  - ICT-based engagement avenues are more likely to be taken up if they provide, and are perceived as providing, an efficient process for engagement
- ***Informed* Public Involvement:**
  - Informed involvement is facilitated by providing convenient access to government held information
  - Informed involvement requires an understanding of democratic processes and how to input effectively into government decision-making processes
- ***Productive* Public Involvement:**
  - Providing tools and support that builds individual skills and community capacity to engage effectively with government produces more productive engagement outcomes
  - A critical factor in determining both the level of public engagement and the quality of information exchange is a demonstrated commitment by government to consider the issues raised and provide feedback on how public input has been used
- **Objectives for Individual Initiatives under the Policy:**
  - E-Petitions:
    - To provide an additional avenue for the public to raise issues directly with Queensland Parliament that is safe, secure, efficient, and readily accessible
    - To provide a central location where the public can learn about and support petitions of which they may otherwise have been unaware
    - To deliver greater transparency and responsiveness around e-petitioning
  - Online consultation:
    - To provide an additional avenue for the public to engage in the Queensland government's decision-making processes that is safe, secure, efficient and readily accessible
    - To open up the Queensland government's decision-making process to those who may not be reached through traditional consultation methods
    - To increase the transparency of consultation processes through the publication of consultation responses and the commitment to publish a Government response after the consultation activity has closed
    - To provide a central location where the public can learn about consultation opportunities of which they may otherwise have been unaware
- **Internet Broadcasting of Parliamentary Proceedings:**
  - To enhance public access to parliament and parliamentarians, particularly by those Queenslanders restricted in their capacity to access then physical environs of Parliament in Brisbane
  - To provide an avenue for the public to learn about parliamentary processes and issues

## Lessons Learned and the Development of the Revised 2004 Policy Framework

The conclusions of the 2003 policy review were that the 2001 policy framework had provided an appropriate and robust framework for introducing e-democracy on a time-limited trial basis in Queensland and that many of its elements still provided a sound basis for current practice, but that some aspects could be enhanced given strategic developments in the field since its introduction. Specifically, the review concluded that the framework could be enhanced if extending the policy from a trial to a permanent basis by expanding the definition of e-democracy

*Table 4. Key features of Queensland's 2004 e-democracy policy framework*

- A definition of e-democracy referring to the range of ICTs, including the Internet, interactive digital television and mobile communication systems
- An explicit commitment by government to using new and emerging ICTs to improve community outcomes and articulating government's role in building the capacity of individuals and communities to engage in democratic processes
- An explicit e-democracy outcome statement of "inclusive, informed and productive public involvement in decision-making through the use of information and communication technologies" and four specific objectives relating to (1) providing safe, secure, efficient and effective avenues, (2) increasing knowledge and understanding, (3) building capacity and active participation, and (4) government responsiveness
- A set of nine underlying policy principles (see Table 5)
- New e-democracy directions for Queensland outlining immediate priorities
- A statement of e-democracy policy benefits
- Situating e-democracy within wider Queensland government policy
- Continuing commitment to addressing key e-democracy considerations, such as privacy and security, equitable online access, and using e-democracy to complement not replace traditional forms of engaging with government
- Explicit reference to ongoing review and evaluation

beyond Internet application to include other ICTs, articulating government's capacity building role in this area, documenting explicit statements of desired outcomes, introducing a more generic focus built around strategic policy intentions and supporting principles rather than designated initiatives, and updating the links to related government policy.

A revised policy framework was launched in 2004 based on the lessons learned from two-years experience with e-democracy policy in Queensland, taking into account the outcomes of the policy review and addressing all of the issues for effective e-democracy policy listed in Table 2. An evaluation framework was also developed at this time (presented in a separate chapter) for evaluating both the overarching policy framework and individual e-democracy initiatives operating under the policy.

Key features of the 2004 policy framework are set out in Table 4 and the policy can be viewed in full on the Queensland government's *Get Involved* Web site at: http://www.getinvolved.qld.gov.au/share_your_knowledge/resources/documents/pdf/edemocracy_pf.pdf

In Queensland, e-democracy is strategically positioned within a wider community engagement context. Community engagement refers to the many ways in which governments connect with citizens and communities in the development and implementation of policies, programs, and services. The Queensland government has adopted an integrated, multi level approach to community engagement that includes innovation and reforms in Parliament, executive government and across public sector agencies. The e-democracy initiatives support engagement at all these levels. Table 5 sets out the policy principles underpinning e-democracy given this wider context. They are based on a merging of e-democracy considerations with existing whole-of-government policy principles for community engagement.

The Queensland experience reinforces the position that effective policy can be made that guides and coordinates the development of e-democracy activities and that sets strategic directions for the future.

## FUTURE TRENDS

At both a national and international level, the experimentation with e-democracy by governments is largely in its infancy, with the development and delivery of electronic services and transactions taking priority. There are a growing number of examples of innovative e-democracy projects being introduced by many different countries. Widely cited examples over recent years include the Hansard Society's online consultations for the UK Parliament (Coleman & Gøtze, n.d.; Parliament and Constitution Centre, 2003), Sweden's Democracy Square and other local government initiatives (Gøtze, 2001, Swedish Association of Local Authorities and Swedish of County Councils and Regions & Department of Democracy and Self-government, n.d.), e-petitioning in Scotland (Macintosh, 2003), online consultation by the Canadian Environment Assessments Agency (Poland, 2001), and the Minnesota e-democracy project (e-democracy, n.d.). However, they appear to be implemented as isolated initiatives that are not grounded in explicit statements of policy. As noted in one report "e-democratic experi-

*Table 5. Policy principles underlying Queensland's e-democracy policy framework*

- **Inclusiveness:** Using ICTs to broaden community involvement in government decision-making processes, including with hard-to-reach groups
- **Reaching Out:** Using ICTs to improve access to information and assist knowledge sharing and deliberation, so as to deepen input to government decision-making
- **Mutual Respect:** Applying consistent standards of respect for listening and responding to the views, concerns and experiences of Queenslanders whether they communicate with government using ICTs or more traditional forms of communication
- **Integrity:** Making effective use of ICTs to improve access to information that promotes informed deliberation and transparent decision-making
- **Affirming Diversity:** Using ICTs to promote and incorporate diverse opinions and perspectives into government decision-making
- **Adding Value:** Using ICTs effectively and efficiently to build partnerships and work productively together
- **Security and Privacy:** Ensuring privacy protection, information security, and identity authentication are addressed so that Queenslanders feel confident in participating online
- **Expanding Channels:** Using ICTs to complement traditional forms of community engagement
- **Innovation:** Research and ongoing review to identify new opportunities, build an evidence base of what works, and share knowledge to enhance good e-democracy practice

ments have mushroomed around the world far in advance of any thoughtful theoretical analysis" (Kane & Patapan, n.d.).

This appears to be changing, with an emerging focus on establishing a formal policy base to guide e-democracy practice in various countries, for example, the UK government's consultation paper *In the Service of Democracy* described earlier.

## CONCLUSION

An important aspect of the development of a body of knowledge guiding research and practice in e-democracy is articulating the policy underlying the introduction of individual e-democracy projects. From a conceptual point of view, we need to know more about why e-democracy is deemed to be an appropriate response given the particular policy context operating in the particular place and time. From a practical point of view, understanding the policy purpose better targets implementation options and practice directions. From a research and evaluation point of view, we need to know what is intended to be achieved in order to determine if what has been done is effective so that improvements can be made. The Queensland case study provides an example of a policy framework for e-democracy initiatives.

## KEY TERMS

**E-Democracy:** The use of information and communication technologies (ICTs) in democratic processes.

**Electronic Petitions:** ICT-enabled lodging of public petitions with Parliaments.

**Electronic Voting:** An ICT-enabled process for determining the public's collective intent.

**ICTs (Information and Communication Technologies):** The class of technologies that allows the processing, storage and communication of digital information, including networked and portable computer systems, advanced mobile telephone systems and services, interactive digital television, and similar applications.

**Online Consultation:** Use of the internet to facilitate a process of discussion between those proposing a course of action and those likely to be affected by those actions.

**Public Policy:** Authoritative statements of general applicability establishing intent or planned action by governmental entities.

**Public Participation:** The involvement of citizens in governmental decision-making processes and activities.

**Webcast:** The delivery of live or delayed sound or video broadcasts using Web technologies.

**Web-Based Discussion Forums:** Use of Web technologies to provide a space where people can exchange views on a particular area of interest.

# E-Development in Bangladesh

**Mohammed Jabed Sarwar**
*Multi Media University, Malaysia*

## INTRODUCTION

Numerous factors, like political stability, physical infrastructure, basic healthcare, and so forth influence the extent and speed of social and economic development. There is no suggestion that ICT can eliminate the need for these or offer a panacea for all development problems. But detail analyses of experience around the world reveal ample evidence that, if used in the right way and for the right purposes, ICT can have a dramatic impact on achieving specific socio-economic development goals, as well as, play a key role in broader national development strategies. The real benefits lie not in the provision of technology rather in its application to create powerful socio-economic networks by drastically improving communication and the exchange of information (Vulkan, 1999).

Recent developments in the fields of communications and information technology are indeed revolutionary in nature. Information and knowledge are expanding in quantity and accessibility. In many fields, future decision-makers will be presented with unprecedented new tools for development. In such fields as agriculture, health, education, human resources and environmental management, or transport and business development, the consequences could be really quite revolutionary. Communications and information technology have enormous potential, especially for developing countries, and in furthering sustainable development (Hamelink, 1997).

ICTs have therefore brought about a new hope for the developing world. Many of these countries continue to labor in the agricultural age and their economic development is thus restricted and unable to move on and catch up with the developed world. Most developing nations have also been unable to industrialize their economies leading to greater impoverishment and dependence. In this context, the very prospect of "leapfrogging" the traditional stages and cycles of progress, is seen as revolutionary. Telemedicine, distance education, wireless applications, the use of the Internet for a wide variety of critical information dissemination tasks—hold the promise of overcoming fundamental barriers of infrastructure which have plagued the developing world (Mody, 1999).

## BACKGROUND

In examining the use of ICTs for development between 1995-1997 conducted by the United Nations Commission on Science and Technology for Development (UNCSTD), the Working Group on IT and Development noted that despite the positive impacts experienced in the industrialized countries and certain sectors of many developing countries, evidence showed that there were many people, especially in the least developed countries whose lives had been barely touched by ICTs.

In this context, Mansell and Wehn (1998, p. 6) raise some crucial questions, which should be urgently addressed by the political leaders and citizens of the developing world:

*Are the benefits of the increasingly widespread, albeit uneven, diffusion and application of these technologies outweighing the risks for developing countries? Are the stakeholders in developing countries taking appropriate measures to minimize the risks of social and economic exclusion that could be associated with these revolutionary technologies?*

ICT has changed the course of development in the Asia-Pacific region. It has, however, not progressed at the same pace of change and progress across all countries. Connectivity, infrastructure, human capacity and knowledge creation and exchange, underpinned by cohesive national e-strategies fed into national development plans remain a daunting challenge, with some countries seizing the opportunities for enhanced development provided by ICT, better than others. Efforts are needed to level playing fields and encourage strategic and effective use of ICT to further human development and help eradicate poverty.

## VISION

Bangladesh seeks to build an ICT-driven nation comprised of a knowledge-based society by 2006. To meet this overall vision, the nation must develop a country-wide ICT infrastructure to give all Bangladeshis access to information. This will empower citizens, enhance demo-

cratic values and promote sustainable economic development. The infrastructure will be used for human resources development, governance, e-commerce, banking and public utilities, among other functions. A National ICT Task Force, headed by the Prime Minister, has been formed to help Bangladesh realize its established vision. (The World Bank & Centre for Advanced Studies, 1998).

## NATIONAL POLICIES

The Bangladesh Telegraph and Telephone Board (BTTB) will shift from its role as a service provider to an infrastructure provider for telecommunication service providers and ISPs. The BTTB will work to make use of underutilised resources of other public utility sectors (e.g., gas, railways). Such resources may include land, radio towers, power pylons, cable ducts, etc. Establishing the national Internet access platform must not affect the functioning of the present telephone network. Increased teledensity is essential, and advanced and new technologies must also be introduced in all areas. A national high-speed backbone and high-speed gateway facilities will be established to facilitate the installation of ISPs. Telecommunications facilities will be made available to all parts of society and at an affordable cost, and Internet-access will be provided to educational institutions and libraries. The country will promote the launch of cyber kiosks in all post offices and similar facilities.

To meet growing demands, infrastructure will be expanded immediately in the public and private sectors, and will reach out into rural and under-served areas. Liberalization of telecommunications and little or no customs duties will facilitate the construction of this infrastructure. As cellular mobile phones are increasingly used for functions such as emailing, customs duties on these items should also be lowered.

## CURRENT STATUS OF THE ICT SECTOR IN BANGLADESH

### Overview of the ICT Sector in Bangladesh

ICT infrastructure encompasses the transmission, storage, processing, and display of voice, data and images. This includes devices ranging from cameras and compact disks to mobile phones and computers. Depending on the requirements, a connected ICT infrastructure may be wired, wireless, automated, manual, or a combination of all. At present, connectivity requirements in Bangladesh are still relatively basic, with public access to telephones among the most inadequate in South Asia. The Public Switched Telecommunications Network (PSTN), the backbone of any ICT infrastructure, remains restricted to parts of Dhaka and major towns, with limited penetration in rural areas. The present state of ICT infrastructure does not include even the most basic services and information on an institutional level, and while poor legislation is the cause, the absence of public awareness to the benefits of such services and information has allowed this situation to prevail. The mobile sector is developing rapidly, primarily as a substitute for people who do not have a fixed line. The majority of these users are restricted to voice communication and some peripheral data services, and do not have universal access to the fixed line network (Kayani & Dymond, 1997).

### Regulatory Framework

Although the Ministry of Posts and Telecommunications (MOPT) officially assumed this role in 1995, Bangladesh did not have a regulated Telecom sector until the introduction of the TRC Act in July 2001. The National Telecommunications Policy was passed in 1998, before which The Telegraph Act (1885) and Wireless Act (1933) had been the only governing tools in the sector. However, the BTTB has effectively continued to perform the role of regulator, preventing any significant reforms from taking place in the sector and preventing the growth of the competitive private sector.

### Universal Access

In 1999, Bangladesh numbered among the nations with the lowest teledensity ratings in the Asia Pacific region. At 0.5 %, Bangladesh fares poorly against an average of 8.5% teledensity in Asia Pacific, and 2.8% in South Asia. Although there are no actual measures of access to telephone (as opposed to teledensity) in Bangladesh, a vast majority has little access to affordable and reliable telephony services, and/or access is restricted to basic voice services.

### Fixed Network Development

Within Bangladesh, there are currently only 600,000-fixed line connections, with waiting lists for new lines exceeding several years. As the only major provider of fixed network services at present, the BTTB lacks the necessary resources, incentives and framework for aggressive network expansion. This lack of connectivity has necessarily excluded Bangladesh from the global information revolution and its accompanying benefits.

## Mobile Network Development

The mobile sector in Bangladesh is developing rapidly, with a number of licensed private operators providing service, with funding through private sector equity and debt. Bangladesh's ability to foster growth in this sector sets a precedent for the industry as a whole, but a clearer definition in policy is still required in many critical areas. Currently, the most pressing issue is the lack of universal access (i.e., connectivity to BTTB's fixed line network by mobile phone users) due to a shortage of interconnections to its local and long distance networks. The call traffic of roughly 650,000 mobile users (75% of all mobile users) is, as a result, confined to the four existing mobile networks. The relatively new mobile industry has already overtaken BTTB's market penetration in number of users and continues to grow exponentially; mobile users with universal access increased by only 15% in 2000, while mobile users without such access increased by 359%.

## Convergence

Effectiveness of the proposed policy is overshadowed by the lack of focus on the issue of convergence. The situation would be more complicated soon after the CATV industry diversifies with the Internet and telephony services. A recent study reflects the modest growth of telephony and Internet over CATV networks in the developing economies of Asia. While Bangladesh was not included in this survey, India, Vietnam, Indonesia and Philippines are among the early starters of telephony over CATV, and continue to experience annual growth-rate in the double-digits.

## Internet

Internet usage in Bangladesh has increased rapidly over the last few years. In July 2000, the total bandwidth capacity was estimated at between 100 to 150 mbps, a capacity much below the desired level for an efficient transmission network (TechBangla, 2001). Connection speeds vary between 64 kbps and 2 mbps gateway access. There is a limited scope for digital cable network access for optimal bandwidth and/or broadband services, but only a handful of operators provide these services at present and then only to select areas. Internet access is very limited for reasons such as low teledensity, poor electricity networks, the high cost of computers, and limited knowledge of internet. Public access is limited to a few private telephone centers and cyber cafes, while on a national level, only divisional headquarters and some district towns have access to internet. While there is huge competition among the ISP's, the overall growth of services has been in decline following the deregulation of VSAT by BTTB. Prices have since fallen an average of 140% with average rates now at Tk. 0.45 per minute, and several ISP's are now offering flat monthly rates. Despite a huge reduction in cost, internet services continue to remain unaffordable and inaccessible to the majority of people, including students.

## ICT Education/Training

In the last four years, Bangladesh has experienced a growth of 300% in ICT training institutes, with total investments in training facilities exceeding 2000 million taka. In an effort to address the global boom in ICT education Bangladesh has taken measures to implement computer education at the secondary and higher secondary levels throughout schools in Dhaka. At the 12-university level, all national public universities, particularly the new universities, now have a computer science department and offer degrees in the subject, although with limited scope.

## The Most Crucial Problem: ICT Leadership

The most crucial problem for Bangladesh is the lack of ICT leadership and strategy, both in government and NGO level, which come from the lack of technical knowledge and expertise of senior citizens who are policy makers and top of the society. All ICT service providers in Bangladesh now are focusing predominantly on the city area, not interested in the village, even though 80% of the population of the country lives in villages. All are reluctant with the prejudice that villages are not a profitable region, even though there is a great prospect and need for "Rural Internet" program such as Grameen Phone (Bayes, 1999).

# POTENTIALS OF ICT IN BANGLADESH

## Prospects in Building the Human Resource

Human Resource is the most important component for ICT industry. Bangladesh has a huge educated, unemployed youth force with the ability to read and write in English. The country can take advantage of its immense manpower to train and prepare programmers and ICT professionals. The role of the ICT sector for the national economy is constantly increasing. It is also likely, that

this sector will play a major role in the government and private sector. Thus, perhaps most importantly, this article highlights the significance of carefully selecting the ICT practices that are used in government and private sector the growing population of ICT.

## Healthcare

The main focus in the use of IT and communication technologies in healthcare will be to deliver new capabilities for hospitals and healthcare providers. IT should be used to develop such capabilities specifically in the areas of electronic medical records, telemedicine, and medical and health education.

Telemedicine System Network shall be introduced throughout the country for cost-effective delivery of healthcare services. The Telemedicine Network will be used for rural patient management, distant medical education, training of health professionals and to develop mass awareness for disease prevention. Development of Bangladesh Health Portal should be given priority for appropriate growth of e-health and telemedicine referral system. International tele-consultation through telemedicine for critical patients will be supported in both private and public sector. All public hospitals and medical research centers shall be linked by computer networks with Bangabandhu Sheikh Mujib Medical University as the central hub in order to make expert services available throughout the country. This network may be gradually extended to the Upzila level.

## Education and Skills

The country seeks to produce a large ICT labor force. ICT education will be promoted at all levels. Universities, Bangladesh Institutes of Technology and both public and private colleges will be strengthened to produce graduates with four-year computer science and computer engineering specializations. The government will designate one of the three proposed science and technology universities as a centre of excellence in ICT and give resources to fulfill this position. Furthermore, the country will establish multimedia institutes to make use of the opportunity offered by the growing multimedia market. Public and private education institutes, including polytechnics, will offer diploma and trade courses in ICT. To enhance and upgrade the skills of existing technology professionals, in-service training programs will also be created. As Bangladesh faces a shortage of qualified instructors to teach aspiring ICT in education professionals, the country is introducing IT-Capacity-Building in the Teachers Training Institutes (TTI), intensive post-graduate diplomas and in-service programs. Virtual ICT teachers will be used to fill the current lack of trained instructors, and CD and Web-based courseware will enable computer-aided instruction. A national certification and accreditation system will also be formed, ensuring standardized, quality ICT education (Madhavan, 1999).

## Access to Information and E-Services

E-governance shall use IT system within the public administration to improve efficiency, reduce the wastage of resources, enhance planning, and raise the quality of services. Government shall implement wide-spread IT systems to provide nation wide coverage and access by any citizen to the government databases and administrative systems, which can be used to extend public services to the remotest corner. Promote and facilitate use of IT in all sectors of the economy for transparency, good governance, and efficiency improvement. ICT can also possible to conceive small business ventures at the national and global level that could economic recovery and create new jobs. The development of the national and global information infrastructures networks and the application of the new telemetric technology could now provide the platform fro a national and global resurrection. I would like to refer to the following example where people are getting benefits to use ICT in developing countries:

1. **Case of Madhya Pradesh State of India:** The government is introducing an experimental intranet computer network for government services and local information. This allows citizens to have faster and more transparent access to government services. For example, farmers can get copies of land titles for 10 cents that previously cost as much as U.S. $100 from corrupt officials. Andhra Pradesh in India has also launched Internet-enabled integrated service centers providing access to different types of government services. (Vasanth & Kumaran, 2001).
2. **Case of Andhra Pradesh Citizen Service Centers:** Andhra Pradesh, a state of India, has launched Internet-enabled Integrated Citizen Service Centers. Access to services including bill payments, issuance of certificates, permits and licenses, public information, and administration procedures are provided.

These are merely some of the examples where ICT has been of great service to the socially disadvantaged group, the poor people in the rural areas. There are success stories like these, but there are also many opportunities unexplored (Madhavan, 1999).

## Prospects in Improving the Livelihood

### Rural Economy

Rural economy can be substantially improved with the application of ICT. Farmers can have continued specific advice regarding fertilizers, choice of crops and timing of sowing for their individual plots. They can learn about relevant technology. Growers can know the current prices of vegetables; fruits etc. throughout the country and can make their strategy for timing and place for sale of their products.

The size of Bangladesh's economy is very small while the country has a large population. In the past, hardly anybody took notice of the existence of this country; at times it is not even spotted in the world map because it does not feature as a serious market for buying or selling. All these can change now. Bangladesh can become a familiar name in the world market if it takes advantage of the new technologies, particularly Information and Communication Technologies, which is changing the world dramatically. Stage is already set. In the previous decade the world has just seen the tip of these changes. Next decade will unfold scenarios, which will redefine the lives of people around the world (The World Bank, 1999).

Bangladesh is one of the most densely populated countries in the world. Bangladesh has huge population and more than 80% of this population lives in villages. The vase majority of the rural population is not well educated and most of them are farmers. Agriculture, including fisheries and livestock, is the main source of earnings for the majority of the people of Bangladesh. IT systems can be used in these sectors to reap its unutilized potentials thereby improving the socio-economic conditions of the rural people. Proper initiatives should be taken to utilize IT systems in agro-business development, agriculture research, dissemination of agricultural technology to the farmers and preparation and maintenance of agricultural database. They live hand to mouth and without development of this population Bangladesh can't reach good position. Bangladesh's economy mostly depends on agricultures. (Prof Muhammad Yunus, on April 1, 2001), opined Infect the per capita income of the people could be doubled and the number of the people living below the poverty line could be halved by allowing the free access of information and communication technology. On the other hand, the rural people also can benefit from the use of ICT. The farmer can get information about their products and also can get up-to-date information regarding selling price of their products. (Yunus, 1999)

### Tourism

To harness the potential of the tourism industry in Bangladesh, Information Technology can play an important role. Information Technology should be used to promote tourists' attractions in Bangladesh through the Internet. A reliable, comprehensive, online information system to satisfy the needs of the tourists for travel and accommodation to deliver instant and up-to-date information will be developed. The partnership with both the local and foreign agencies relevant to tourism will be strengthened and encouraged to introduce online reservation for travel and accommodation, booking, and ticketing for arts and entertainment events and shopping.

## FUTURE IMPACT OF ICT ON LABOUR MARKETS

Information and communications technologies (ICTs) have dramatically reshaped labor markets around the world. Social inequality within and between countries has increased and young men and women have tended to bear the brunt of this. The number of unskilled, semi-skilled and entry levels jobs in a wide variety of sectors have declined. Large organizations in both the public and private sectors have shed good number of positions. For young people this has resulted in stubbornly high unemployment levels, in most countries these are locked in at rates many times above national unemployment. ICTs have been extremely important in generating two strongly diverging forces for the Bangladeshi workers. They have contributed to the automation of processes making some workers redundant and closing off jobs many young people could have expected to begin their careers; and changed the economics of many sectors reducing the importance of scale, so facilitating an upsurge in employment in small, medium, and micro enterprises (SMMEs). Where young people, with the benefit of a good education and training foundation, could have once expected to have a job for life this is no longer the case. But if that education and training is in ICT-related skills, and if they demonstrate enterprise and resourcefulness there are vast opportunities in Bangladesh (World Bank, 1999).

## FUTURE TRENDS

Bangladesh is still a developing country and has to go a long way to have a good economic position in the world map. As I mentioned earlier, Bangladesh economy depends on agricultures sector. Most of the population,

nearly 80%, lives in villages. Without improvement of the rural economy, healthcare, government sector, human resource, and tourism, Bangladesh cannot go far. This scenario has been changing from the early 1990s. The government of Bangladesh has realized that ICT has good potentials to improve Bangladesh economy. The government of Bangladesh has taken some important initiatives to develop the IT sector. Some noteworthy steps of the government are the following:

- IT has been declared as a thrust sector.
- Quick implementation of the recommendations of Joint Review Commission's (JRC) report (a high powered committee for software export).
- Waiving all taxes and duties from import of computer hardware and software.
- Hundred percent remittances of profit and capital gains for foreign investors without any approval.
- BTTB's implementation of digital divided network (DDN) service.
- Decision to link Bangladesh to global highway through submarine cable. Bangladesh has been linked with global highway through submarine cable by December 2005.

## CONCLUSION

The government shall use ICT systems within the public administration to improve efficiency, reduce the wastage of resources, enhance planning, and raise the quality of services. Government shall implement widespread ICT systems to provide nation wide coverage and access by any citizen to the government databases and administrative systems, which can be used to extend public services to the remotest corner. Bangladesh has a long way to go in a very short time to enjoy the fruits of ICT and the information age. It will only be possible when there will be thorough effective approaches of ICT interventions can be made available to the grass root level of the communities in this region, which ultimately would bring better governance through propagation of information at ease with improved access to the stakeholders.

## KEY TERMS

**Bangladesh Telegraphs and Telephone Board (BTTB):** At this moment, BTTB is providing basic telecommunication services through out the country and also providing carriers to communicate with the outside world. BTTB is also providing some value added services as dial-up and leased line Internet services, international private leased circuit (IPLC) services, digital subscribers line (DSL), telex services and packet switch data network (PSDN) services.

**CATV:** Originally "community antenna television," now often "community access television," but more commonly known as "cable TV." In addition to bringing television programs to those millions of people throughout the world who are connected to a community antenna, is an increasingly popular way to interact with the World Wide Web and other new forms of multimedia information and entertainment services.

**E-Development:** Refers to development policy and activities of the third world countries in which ICTs has a key role to play.

**Grameen Phone (GP):** The leading cell phone company in Bangladesh.

**Joint Review Commission (JRC):** A high-powered committee for software exports under Prime Minister's Office.

**Ministry of Posts and Telecommunications (MOPT):** A policy-making institution of the government regarding administration and development of posts and telecommunications. It also formulates laws, rules and regulations for the management and administration of posts and telecommunications

**National ICT Task Force:** A committee formed by the government of Bangladesh headed by the prime minister. This committee is entrusted to the development of Bangladesh ICT infrastructures and has exclusive power to establish and provide all ICT services and products.

**SMME:** Refers to small, medium, and micro enterprises.

**Telemedicine:** Refers to people's chances to communicate with doctor via telephone or over the Internet.

**Teledensity:** The number of landline telephones in use for every 100 individuals living within an area. A teledensity greater than 100 means there are more telephones than people. Third-world countries may have a teledensity of less than 10.

**Telegraph Act:** The Ministry of Posts & Telecommunications (MOPT) holds the responsibility of sector regulation. The Telegraph Act of 1985 is the primary law governing the sector and granted the government exclusive power to establish and provide all telecommunications services and products.

**UNCSTD:** Is United Nations Commission on Science and Technology for Development.

**United Nations (UN):** The most important international organization of our time. Its purposes are to maintain international peace and security; to develop friendly relations among nations; to cooperate in solving international economic, social, cultural and humanitarian problems and in promoting respect for human rights and fundamental freedoms; and to be a center for harmonizing the actions of nations in attaining these ends.

**Wireless Act:** The Wireless Telegraphy Act of 1933 governs the operation of one-way Radio Communications, Paging and Radio services. The BTTB Ordinance of 1979 provided BTTB the monopoly rights and powers for issuing license for telecommunications and wireless services.

# E-Enforcement in Digital Government

**Hans de Bruijn**
*Delft University of Technology, The Netherlands*

**Marieke Koopmans-van Berlo**
*Delft University of Technology, The Netherlands*

## INTRODUCTION

In recent years, there has been a significant rise in "e-enforcement." E-enforcement is the use of electronic tools in law enforcement. In this article, we consider two new forms of e-enforcement which have recently been introduced in Europe. These are Weigh in Motion with Video (WIM-Vid) and the digital tachograph. WIM-Vid is a system involving sensors in the road and cameras in order to register overloading of heavy goods vehicles. WIM-Vid was developed and implemented in the Netherlands and is currently attracting international attention. The digital tachograph replaces the analogue tachograph in all heavy goods vehicles within the European Union. The machine registers drivers' driving and rest times.

In this article, we focus on the special position of the clients of e-enforcement, the regulatees. Although e-enforcement is a form of e-government or digital government, the position of the client is quite distinct. Many definitions describe e-government in terms of service delivery (Chen, 2002; Devadoss, Pan, & Huang, 2002; Finger & Pécaud, 2003; Hiller & Belanger, 2001; Ho, 2002; Moon, 2002). These descriptions feature the concept of customer focus (Devadoss et al., 2002; Finger & Pécaud, 2003; Ho, 2002). The purpose of e-government should be to satisfy these customers, whether they are ordinary citizens or parties in private sector (Finger & Pécaud, 2003). The clients of enforcement, however, are offenders or potential offenders. These clients are characterized by the fact that they do not want the service and generally exhibit uncooperative behaviour (Alford, 2002). They may, for example, actively evade the "service" of enforcement, or commit information fraud (Hawkins, 1984). In this article we will see what the distinct position of the clients of enforcement means for the effects of e-enforcement.

## BACKGROUND

First we summarize the main theories on styles of law enforcement. Then we outline the state of the art in e-enforcement.

### Law Enforcement Theories

In the literature on enforcement, two constituent styles of enforcement are often distinguished (Hawkins, 1984; Hutter, 1997; Sparrow, 2000). The first style is that of "sanctioning," "compulsion," "coercion," or "penalism." This style centers around the idea that the violation of norms must be punished in order to ensure that the regulatee will comply with these norms in the future. Both the rules and the context are unambiguous; the regulatee simply has to obey the rules. Inherent in this approach is a unilateral and hierarchic relationship between inspector and regulatee. The focus is not on the relationship but on enforcing the norm.

The second style is called "compliance," "conciliation," "compromise," and "remedialism." Enforcement is seen as a multilateral process of consultation and negotiation, since inspector and regulatee are dependent on each other. For example, the regulatee may be unaware of technological developments, thereby inviting an educational approach from the inspector. Consultation and negotiation also arise from ambiguity regarding the norm, for example when a rule is contradictory or different rules contradict each other, or when the application of a rule is seen as being unreasonable.

The first style has a binary character. There is a rule and it is either broken or not. If it is broken, the inspector will take action. The second style is serial and incremental in nature (Hawkins, 1984). After all, negotiation is more a process of give and take. Improvements in the behavior of the regulatee will therefore take place gradually. In the first style, supply of information is essential to the inspector: without solid information on the regulatee's behavior, there can be no adequate sanctioning and enforcement. In the second style, information is important, of course, but interaction also plays a crucial role: good enforcement is strongly dependent on the quality of the relationship between inspector and regulatee. The regulatee fulfils the role of "obligatee" (Alford, 2002). It is therefore not self-evident that he will behave in accordance with the norm. In many cases, he will behave strategically and act as an opposing player in relation to the inspector (McBarnet & Whelan, 1999).

## E-Enforcement State of the Art

E-enforcement is the use of electronic tools in law enforcement. It is a form of digital government. "E-enforcement" is an abbreviation for "electronic enforcement" (Smith, McFadden, & Passetti, 2000) and is synonymous with "automated enforcement" (Retting & Williams, 1996; Smith et al., 2000; Turner & Polk, 1998; Wilmot & Khanal, 1999; Wissinger, Hummer, & Milazzo, 2000).

There is only a limited number of e-government and digital government publications that mention the area of regulation and law enforcement (Chen, 2002; Chen, Schroeder, & Hauck, 2002; Strejcek & Theil, 2002). Also, the e-government applications involved all concern government-to-government interaction (Hiller & Belanger, 2001). In this article, however, we are interested in the relationship between government and businesses or citizens. Critical publications on this type of e-government can be found in the literature on automated traffic enforcement.

The literature on automated traffic enforcement discusses the use of electronic tools for the enforcement of laws against speeding (Glauz, 1998; Perone, 1998; Wilmot & Khanal, 1999), running red lights (Ruby & Hobeika, 2003; Walter, 1998), entering railway crossings when gates are down (Meadow, 1998), failing to pay tolls and high-occupancy vehicle lane violations, electronic toll collection systems, vehicle inspection, weigh-in-motion stations and remote emission sensing (Bartoskewitz, Carson, & Curry, 1999; Bochner, 1998; Turner & Polk, 1998). Bochner (1998) reports that automated enforcement is used in over 75 countries throughout the world.

Automated traffic enforcement is found to be very effective in reducing violations and ultimately in reducing accidents (Glauz, 1998; Meadow, 1998; Perone, 1998; Ruby & Hobeika, 2003). Some authors mention that motorists may oppose the introduction of automated traffic enforcement by seeking to influence politicians (Bartoskewitz et al., 1999; Turner & Polk, 1998). None of the authors, however, mention or investigate opposition or strategic behavior among inspectees after the definitive introduction of the systems. It is this type of opposition which forms the focus of this article.

## TWO CASES ON E-ENFORCEMENT

For both cases, we outline the original method of enforcement and the method of e-enforcement. The complete case study descriptions including source references and description of the research method can be found in Koopmans-van Berlo (2003) and Koopmans-van Berlo & de Bruijn (2004).

## Weigh in Motion with Video

Overloading of heavy goods vehicles can take two forms. The vehicle as a whole can be overloaded or there is an excessive load on one of the axles. Both types of overloading cause damage to roads and dangerous situations. As overloading represents a form of unfair competition, both types of overloading are liable to punishment as an economic offense.

### Original Enforcement

Before the electronic enforcement system was available, inspectors and police conducted incidental checks at the roadside. Motorcycle brigades halted heavy goods vehicles on the road and led them to a parking space at the side of the road. The vehicles were selected by their appearance. Trailers with a large bulge on top or with sagging axles stood a good chance of being stopped and weighed, as did vehicles from haulage companies with a bad reputation or transport flows where there was a tendency towards overloading.

Once a driver had been led to the side of the road, he was required to drive his vehicle slowly onto a weighing platform and to stop at each axle. The weighing platform determined the load on the axles. If overloading was discovered, an official report was written out.

### E-Enforcement

A definition of "weigh in motion" is "the process of estimating the total weight of a moving vehicle and the part of that weight carried by each wheel, each axle or axle group or a combination thereof, by measuring and analyzing the dynamic tyre forces of the vehicle" (Katz & Rakha, 2002). An innovative application based on the WIM system has recently been developed in Europe, by linking it with cameras (WIM-Vid, video) and registration databases.

Induction loops are placed in the road to register the passage of traveling vehicles, along with sensors which record the axle configuration and the axle loads. The axle configuration indicates the type of vehicle, thereby specifying the norms which apply to it. Cameras above and beside the road photograph the registration number, time of violation, the hazardous-substances sign and the vehicle as a whole. An infrared camera is also in place for night photographs. All passing heavy goods vehicles are monitored 24 hours a day. The measuring points are indicated by road signs.

Enforcement officers can watch the images of overloaded heavy goods vehicles in real time, either on loca-

tion or remote. The data from the WIM-Vid system are automatically linked to the registration data of the RDW Centre for Vehicle Technology and Information, thereby connecting the information about the violation with the company name of the offending vehicle. From a legal perspective, only the weighing of vehicles using special (mobile) weighing platforms can provide valid evidence. Imposing sanctions in the event of an actual violation therefore requires that the measuring points be manned. WIM-Vid is used to select violators, who are subsequently checked for overloading using a weighing platform. Violators checked by the manning teams have to remedy the violation at the spot and always receive a penalty.

## The Digital Tachograph

Tired drivers drive less safely. This is the reason behind the existence of legislation governing driving and rest times for the drivers of buses and heavy goods vehicles. Violating these rules is an economic offence.

### Original Enforcement

A tachograph is a mandatory piece of equipment in heavy goods vehicles which registers the driving and rest times of the drivers. From 1975 until the present day, this machine has been analogue.

Drivers are obliged to insert a paper disc into the machine during their shift. A sensor in the gearbox measures the speed of the vehicle and the distance traveled, while a pen traces these details on the layer of wax on the paper disc. A driver takes his paper disc with him when he changes vehicle and while working he is required to carry his discs from the last eight days with him. The company is required to keep all of its drivers' discs on file for one year.

The Transport and Water Inspectorate conducts inspections on the roads and at companies. During the roadside checks, the enforcing officer asks the driver to produce his tachograph paper discs and he reads manually whether that driver has taken enough breaks and sufficient rest.

A company visit is only carried out if violations are suspected, for example on the basis of roadside inspections. Companies are required to store their drivers' tachograph paper discs for one year. During a company visit, the inspector takes away with him the pile of tachograph discs from the previous year. The discs are inspected by scanning them one by one in a computer program, which is able to detect violations. Companies are sometimes asked to submit their paper discs to the inspectorate on a voluntary basis.

### E-Enforcement

In 1997, the European Union Transport Council decided on the mandatory introduction of the digital tachograph. The planned date for introduction is August 2005. The digital tachograph is a piece of equipment that will be built into every heavy goods vehicle or bus. As with the analogue tachograph, the basis is a "motion sensor" in the gearbox and also the digital tachograph registers speed and distance and links these to date and time.

In order to link the data to a person, there is a driver's personal smart card. When a driver changes vehicle, he takes the smart card with him and inserts it into the tachograph of the next vehicle. The tachograph writes on the driver's smart card and to its own memory. If a driver should drive without a smart card, the tachograph will still register the data in its own memory, but without linking them to a name. The data are stored for 28 days on the driver's smart card and one year on the tachograph's memory. Each inspector has his own smart card. When he inserts this into the tachograph during a roadside inspection, he can download all the data from the tachograph's memory.

The company has special company smart cards. These allow the data from all the vehicles' hard disks to be downloaded to a company computer. Companies are obliged to store all data in one central file for one year. At a company visit, the inspector can view the entire database. In future the Transport and Water Inspectorate would like to see the companies submit their data to the Inspectorate a mandatory basis. Lastly, there are workshop smart cards. Each workshop with a permit to install digital tachographs has a smart card which allows full access to the tachograph (Anderson, 1998, 2001).

## CRITICAL ISSUES AND DILEMMAS

What we see in the case studies is that e-enforcement leads to better information, resulting in improved ways of working. Unfortunately the positive aspects are undermined by opposition or strategic behavior on the side of the regulatees.

## E-Enforcement Does Lead to Better Information

### Better Operational Information Improves Efficiency

In both case studies, the introduction of e-enforcement results in better operational information, while the effi-

ciency of information gathering also improves. Enforcement of the rules regarding overloading was originally carried out by means of incidental checks, but thanks to WIM-Vid checks can now be carried out at measuring points 24 hours a day. Where inspectors only used to have access to data on the heavy goods vehicles they pulled off the road, they now have data from all passing trucks. WIM-Vid therefore provides an overall impression of the entire haulage sector. This is beneficial to the quality of the information available to the inspector. The previous tendency of some inspectors to more or less ignore certain types of transport illustrates this point well. Before the introduction of WIM-Vid, these inspectors estimated that certain types of transport were hardly every guilty of overloading, based on their professional "tacit knowledge." The introduction of WIM-Vid was a revelation in this regard. Overloading turned out to be very much an issue in these types of transport.

A similar situation applies to the digital tachograph. The enforcement capacity can be deployed far more effectively and the quality of the information increases as a result. For example, the inspector can read the machine in the vehicle using a pocket computer. In the analogue system, the inspector had to read and interpret the paper disc manually. This was a complex task, which required a practiced eye. The digital tachograph stores the data of individual drivers for 28 days, instead of eight days. A company inspection can be completed more quickly thanks to the digital tachograph. Where inspectors originally had to work their way through a huge pile of paper discs, they now have all the data presented to them in one central file.

## E-Enforcement Provides Possibilities for Recognizing Patterns

A second observation is that e-enforcement leads to more advanced "intelligence." Because they store information on a large scale, both instruments make it possible to recognize patterns of behaviours. With both WIM-Vid and the digital tachograph it is possible to recognize patterns at company level. Which companies are frequent offenders, for which companies is violation incidental? This is possible because WIM-Vid automatically traces which company is responsible for the violation via the license plate and ranks the company dossiers from major to minor offenders.

The new technology also creates the possibility of pattern recognition according to type of violation. The introduction of WIM-Vid has led to the insight that 70% of cases of overloading concern the overloading of one axle (mostly the front axle). The main problem is not that drivers transport too much, but that the load is incorrectly distributed. Other examples of pattern recognition are the categorization of overloading according to type of vehicle, time of the offence, location of the offence, the vehicle's place of origin and according to whether or not the load contains hazardous substances. Categorization of this type subsequently influences enforcement. Once categories are visible, the inspector can target checks more specifically towards certain groups, times, locations and types of activity.

The possibilities of pattern recognition have consequences for the way in which the inspectors work. They shift the focus from the individual driver to the companies. Companies guilty of multiple violations are visited and confronted with the patterns detected. In addition to the tit-for-tat penalties resulting from enforcement at the measuring points, agreements can be made with the offending companies with the aim of achieving more structural solutions. The inspectors report that haulage companies carried out extensive adjustments to their fleets during the pilot studies. These technical solutions included fitting an extra axle to a vehicle, fitting a side loading door or fitting measurement sensors to help prevent axle overload.

The digital tachograph also offers opportunities for shifting the enforcement from individual to company level. Following introduction of the digital tachograph, the Inspectorate of Transport, Public Works, and Water Management is optimistic about the prospect of preselecting companies for in-company investigation, on the basis of data submitted. With the old tachograph this could only occur to a limited extent and on a voluntary basis (the inspector was dependent on the companies' willingness to submit the paper discs).

## But Opposition may Undermine the Positive Effects

The picture we have outlined so far would appear to strengthen the position of the inspectors. They have more operational information and more possibilities for pattern recognition at their disposal. In this way, e-enforcement offers the opportunity for an almost watertight control of the regulatee and for zero tolerance enforcement. However, the paradox of e-enforcement is that the power of 100% control is also its Achilles heel. E-enforcement results in binary and watertight control and assumes an enforcement context that is clear and free from ambiguity. The latter has proven not to be the case, however, and binary enforcement in an ambiguous context can lead to a loss of legitimacy.

## The Legitimacy of the Rules Comes Under Discussion

WIM-Vid shows that the majority of violations involve only one axle as a result of the way in which the truck is loaded. Regulatees are therefore not overloaded as such, but are only carrying too much weight on one axle. Many consider it unfair to strictly enforce single-axle overloading as an economic offence. After all the reasons for the overloading are not economic but technical. It is not possible to find a technical solution for single-axle overload for every type of heavy goods vehicle. The alternative would be that the drivers have to transport less freight, a solution that has major financial implications for the transporters. This raises the question whether a single-axle violation is serious enough to justify imposing such a sizeable loss of income on the offending company. Before WIM-Vid was introduced, single-axle overloading was hardly ever enforced. When this began to happen following the introduction of WIM-Vid, the sector argued in favor of a transitional period to allow companies to purchase models less susceptible to overloading when they bought new vehicles, instead of having to invest in expensive adjustments to existing vehicles. However, the government rejected this idea, its argument being that single-axle overloading had always been against the law, even if it was seldom enforced.

The digital tachograph shows violations of driving and rest times. However, there are many different kinds and degrees of violation. A driver who has been caught up in a long tailback abroad and who can still deliver his perishable load on time if he drives for an extra 30 minutes will likely do so without much hesitation, even if it does mean breaking the rules. It might also be the case that a driver is willing to take a break but cannot find a parking space. Violations of this kind, accompanied by mitigating circumstances, differ from violations that are committed deliberately.

In both cases, a binary attitude by the inspector—either a violation that must be penalized or not a violation—can be counterproductive. The legitimacy of the sanction becomes a matter for dispute. If the sanction is imposed regardless of such considerations, this can erode the legitimacy of the underlying rules. Once this has occurred, it drives out the regulatee's moral motivation for obeying the rules and it is conceivable that the sector will simply adapt its prices to cover any additional costs due to sanctions. In the haulage sector, such behavior can indeed be seen. Fines sometimes form part of a firm's budget calculations in advance.

## Strategic Behavior Remains Possible

The previous section brings us to one last observation. When the legitimacy of the rules is contested, this gives rise to strong incentives for strategic behavior. When a company or large parts of a sector engage in strategic behavior, the potential effect is large:

- Where the digital tachograph is concerned, a major risk is associated with the workshop smart cards. Workshop mechanics can use these smart cards to alter the settings of the digital tachograph. The history of analogue tachographs has shown that workshops were bribed into tampering with the machine. The bribing of workshops and the development of a black market in workshop smart cards could lead to digital tachograph fraud on a large scale. This is what Anderson expects will happen (Anderson, 1998, 2001).
- It also seems like an attractive proposition to find a way of manipulating the centrally downloaded data from all drivers in the company computer. These are the data that inspectors check during a company visit. The data are very well protected, but can we be sure that fraudsters will not eventually find a way to outsmart the technology? If they were to succeed in breaking through the security, the risk of fraud spreading is greater with digital technology than it was with analogue technology.
- WIM-Vid would also appear to be susceptible to strategic behavior at collective level. Half an hour after a measuring point is manned, the number of overloaded vehicles drops dramatically. After two hours there are almost no overloads at all. The inspectors think this is because the drivers communicate with each other and either take an alternative route or stop their trucks. This behavior also occurred before e-enforcement was introduced. These options for strategic behavior cast a different light on another observation. Companies that have received visits can no longer be found in the violation statistics afterwards. This could be because they now stick to the rules. But given the possibilities for strategic behavior, there is also the chance that they structurally avoid measuring points.

It has to be concluded that possibilities for strategic behavior do exist. The question of whether this strategic behavior actually occurs is difficult to investigate. After all, it is very much in the regulatee's best interests to conceal such strategies. However, we can conclude that

there are strong incentives for strategic behavior and that there are possibilities, technical and otherwise, for strategic behavior.

## FUTURE TRENDS

It is likely that the use of e-enforcement will increase in future. We see that the forms of e-enforcement grow more complex. The first applications as mentioned in the literature review (for example cameras against speeding, red light running, and entering railway crossings when gates are down) share some characteristics. They are based on only one variable concerning behavior, speed, or crossing, which is unambiguous and valid for all types of vehicles. The more recent applications, WIM-Vid and the digital tachograph, make calculations based on various variables, which differ for types of vehicles. They do not only automize the observation by humans, but enable new and more intelligent ways of working. They lead to aggregate information, patterns, and new insights about regulatees and violations. We expect e-enforcement to change enforcement radically. It is therefore very important to investigate not only the technological aspects of e-enforcement, but also the implications for new ways of working, in order to prevent the rise of opposition.

## CONCLUSION

The analysis given above provides us with an ambivalent impression of e-enforcement. First appearances would suggest that there has been a strong improvement in enforcement. By digitizing the information function, better and more reliable information can be obtained. This is beneficial in terms of the effectiveness and efficiency of the enforcement. New working methods also appear. Pattern recognition becomes possible and shift the focus from the individual driver to the companies.

A second look reveals some less positive aspects. Thanks to e-enforcement, the inspector has possibilities at his disposal for being able to enforce zero tolerance at operational level. Thanks to pattern recognition, e-enforcement also offers the possibility of reaching collective agreements with companies. But this process of interaction will be significantly disrupted if companies dispute the legitimacy of the rules and this legitimacy is partly eroded by the binary, zero tolerance type approach made possible by e-enforcement. Furthermore, e-enforcement can thereby create incentives for collective strategic behavior. The greater the controversy surrounding the rule or how it is applied, the less reservations companies will have in practicing such strategic behavior.

## KEY TERMS

**Digital Tachograph:** Digital machine in a heavy goods vehicle that registers a driver's driving and rest times.

**E-Enforcement:** The use of electronic tools in law enforcement.

**Law Enforcement:** All actions aimed at achieving behavior that conforms to the norm.

**Regulatee:** A person subject to enforcement.

**Strategic Behavior:** Behavior in one's own interests that frustrates the interests of an opponent.

**Weigh in Motion:** The process of estimating the total weight of a moving vehicle and the part of that weight borne by each wheel, each axle or group of axles or a combination thereof by measuring and analyzing the dynamic tyre forces of the vehicle

**Zero Tolerance:** Very strict law enforcement.

# E-Government Act of 2002 in the United States

## INTRODUCTION

The United States is frequently ranked among the most advanced e-government countries in the world (Accenture, 2004; United Nations, 2003; West, 2004). While many of these surveys emphasize the importance of technological issues, such as Web sites, interoperable data standards, and security protections, considerably less attention has been focused on the legislative environment that either facilitates or hinders the development of e-government at the national level. Like all countries, the United States has long grappled with the problem of how to centrally coordinate a diverse and sometimes incongruous collection of departments and agencies to achieve improved efficiencies, while maintaining a level of flexibility that enables these entities to carry out their specialized responsibilities effectively. This challenge can be made harder by the integration of information technology into government, by reifying organizational boundaries in the form of so-called "stove pipes" and "islands of automation." To combat these problems, national governments are attempting to use legislative means to harmonize a cacophony of independent initiatives, and establish benchmarks for oversight.

On December 17, 2002, President George W. Bush signed the E-Government Act of 2002 (116 Stat. 2899; P.L. 107-347) into law. Although there are many existing laws regarding issues such as information technology (IT) management, privacy, and information security, the E-Government Act of 2002 is the first national law that specifically addresses e-government in the United States. Prior to the passage of the E-Government Act, the law frequently cited as the most comprehensive information technology-related law was the Clinger-Cohen Act, signed into law in 1996, just 5 years after the development of the World Wide Web (1991) and at a time when the potential uses of the Internet were just beginning to be recognized by the larger, general public. The Clinger-Cohen Act provisions focus primarily on a narrow range of issues, including the decentralization of IT management within the U.S. federal government, pilot testing of new IT procurement procedures, and the establishment of chief information officer (CIO) positions in the major departments and agencies. In contrast, the provisions of the E-Government Act, described in greater detail below, address a much more comprehensive range of issues, suggesting that the integration of IT into government operations has reached a critical turning point. Some of these provisions include information security, IT management and training, the digital divide, and the creation of an Office of Electronic Government to coordinate and oversee e-government initiatives government-wide, among other duties.

## STATUTORY INTENT AND HISTORY

The E-Government Act of 2002 was enacted to enhance access to government information and the delivery of information and services to citizens, employees, and other agencies and entities (U.S. Congress, 2002). To meet this goal, the statute authorizes $345 million over 4 years for e-government initiatives. It also assigns considerable influence to the Office of Management and Budget (OMB) to ensure that information technology investments throughout the federal government embrace a citizen-centered, cross-agency, and performance-based strategy.

As defined in the statute, *e-government* refers to "the use by Government of web-based Internet applications and other information technologies, combined with processes that implement these technologies, to (A) enhance the access to and delivery of Government information and services to the public, other agencies, and other Government entities; or (B) bring about improvements in Government operations that may include effectiveness, efficiency, service quality, or transformation" (116 Stat. 2902). Both the term and the concept of e-government are relatively new in government parlance. The phrase appeared, without explanation, in the initial September 7, 1993, report of the National Performance Review (NPR) (Office of the Vice President, 1993, p. 112). A joint report of the NPR and the Government Information Technology Services Board, issued on February 3, 1997, gave the term

more prominence and substance (Office of the Vice President, 1997). Almost 3 years later, in a December 17, 1999, memorandum to the heads of executive departments and agencies, President Bill Clinton directed these officials to take certain actions in furtherance of "electronic government" (U.S. NARA, 2001, p. 2317).

President George W. Bush indicated his support for e-government initiatives early in his administration when he proposed the creation of an e-government fund. In advance of his proposed budget for FY2002, the President released, on February 28, 2001, *A Blueprint for New Beginnings: A Responsible Budget for America's Priorities*. Introduced as a 10-year budget plan, the *Blueprint*, among other innovations, proposed the establishment of an electronic government account, seeded with "$10 million in 2002 as the first installment of a fund that will grow to a total of $100 million over three years to support interagency electronic Government (e-gov) initiatives." Managed by OMB, the fund was foreseen as supporting "projects that operate across agency boundaries," facilitating "the development of a Public Key Infrastructure to implement digital signatures that are accepted across agencies for secure online communications," and furthering "the Administration's ability to implement the Government Paperwork Elimination Act of 1998, which calls upon agencies to provide the public with optional use and acceptance of electronic information, services and signatures, when practicable, by October 2003" (U.S. Executive Office of the President, Office of Management and Budget [OMB], 2001a, pp. 179-180). About 1 month later, on March 22, OMB announced that the Bush administration recommended doubling the amount to be allocated to the e-government fund, bringing it to $20 million. House appropriators, however, were particularly reluctant to provide more than a quarter of the amount sought by the President. While expressing general support for the purposes of the fund, they also recommended that the administration work with the House Committee on Government Reform and the Senate Committee on Governmental Affairs to clarify the status of its authorization. The E-Government Act establishes an E-Government Fund in the Treasury of the United States with specific levels of appropriations authorized through FY2006 and "such sums as are necessary for fiscal year 2007" (116 Stat. 2908).

Pursuant to an OMB Memorandum of July 18, 2001, an E-Government Task Force was established to create a strategy for achieving the e-government goals of the Bush administration. It subsequently identified 23 interagency initiatives designed to better integrate agency operations and IT investments. These initiatives, sometimes referred to as the Quicksilver projects, were grouped into five categories: government to citizen, government to government, government to business, internal efficiency and effectiveness, and addressing cross-cutting barriers to e-government success. Examples of these initiatives included an E-Authentication project, led by the General Services Administration to increase the use of digital signatures; the eligibility assistance online project (also referred to as GovBenefits.gov), led by the Department of Labor to create a common access point for information regarding government benefits available to citizens; and the Small Business Administration's One-Stop Business Compliance project (later renamed Business Gateway), designed to help businesses navigate legal and regulatory requirements. An additional initiative, a government-wide payroll process project, was subsequently added by the President's Management Council. In 2002, the E-Clearance initiative, originally included as part of the Enterprise Human Resources Integration project, was established as a separate project, for a total of 25 initiatives (U.S. General Accounting Office [GAO], 2002, 2003a). These projects became part of the *President's Management Agenda—FY2002*, submitted to Congress in August 2001 and featuring five interrelated government-wide initiatives: Strategic Management of Human Capital, Competitive Sourcing, Improved Financial Performance, Expanded Electronic Government, and Budget and Performance Integration (OMB, 2001b).

After the Clinger-Cohen Act of 1996, the E-Government Act takes the next step to improve IT investment and management, requiring OMB to provide a report to Congress annually on the status of e-government. Rather than simply identifying and reporting IT investment at each agency, the statute appears to have engendered a cultural change in IT procurement, from consolidating and integrating IT investments to encouraging performance-based, citizen-centered, cross-agency planning. The statute designates OMB as the lead organization for all federal executive branch IT purchasing and planning, and all federal executive branch agencies must comply with OMB guidance to ensure implementation of e-government.

## MAJOR PROVISIONS

The E-Government Act is organized in five titles containing sections which amend various titles of the *United States Code*. Title I of the statute, denominated Office of Management and Budget Electronic Government Services, amends Title 44, *United States Code*, with a new Chapter 36 on Management and Promotion of Electronic Government Services. In addition to defining key terms, Title I establishes an Office of Electronic Government within OMB, headed by an administrator, who is appointed by the President without Senate confirmation. The administrator assists the director of OMB with all functions assigned in Chapter 36, as well as those as-

signed to the director by Title II of the statute, and "other electronic government initiatives." The administrator is also responsible for assisting the OMB director, deputy director for Management, and administrator of the Office of Information and Regulatory Affairs "in setting strategic direction for implementing electronic Government" relevant to certain specified statutory authorities.

Title I of the statute also establishes a Chief Information Officers Council, chaired by the OMB deputy director for Management and composed largely of department and agency chief information officers. The council plays an advisory and coordination role. Other features of Title I are creation of the E-Government Fund to support e-government projects; establishment of a government-wide program "to encourage contractor innovation and excellence in facilitating the development and enhancement of electronic Government services and processes"; and mandating an annual e-government status report by the OMB director to Congress.

Title II of the statute, pertaining to Federal Management and Promotion of Electronic Government Services, specifies the responsibilities of agency heads regarding electronic government; mandates interoperable implementation of electronic signatures for appropriately secure electronic transactions with government; prescribes criteria for maintaining and promoting an integrated federal Internet portal; promotes individual federal court Web sites and agency use of IT to increase access, accountability, transparency, and public participation in the development and issuance of regulations; fosters improvements in the methods by which government information, including information on the Internet, is organized, preserved, and made accessible to the public; establishes privacy impact assessments for agencies when developing or procuring IT that collects, maintains, or disseminates personally identifiable information or when initiating a new collection of such information; and creates a federal workforce skills development program for using IT to deliver government information and services.

Title II also amends Subpart B of Part III of Title 5, *United States Code*, with a new Chapter 37 mandating an Information Technology Exchange Program, facilitating temporary assignments of federal employees to private sector organizations and of private sector employees to federal agencies to enhance IT skills. Other provisions mandate studies and evaluations of (1) community technology centers, public libraries, and other institutions providing computer and Internet access to the public; (2) the use of IT to enhance crisis preparedness, response, and consequence management of natural and man-made disasters; and (3) disparities in Internet access for online government services. Another provision tasks the administrator of general services with making a coordinated effort to "facilitate the development of common protocols for the development, acquisition, maintenance, distribution, and application of geographic information."

Title III of the statute, denominated the Federal Information Security Management Act of 2002, amends Chapter 35 of Title 44, *United States Code*, with a new Subchapter III on information security. It supersedes similar provisions found in Subtitle C of Title II of the Homeland Security Act of 2002 (116 Stat. 2135, at 2155). Excepting national security systems, Subchapter III prescribes a comprehensive program, under the direction of the OMB director, for ensuring the effectiveness of information security controls over information resources that support federal operations and assets. Covered agencies are required to have performed annually an evaluation of the effectiveness of their information security program and practices.

Title IV authorizes generally, unless otherwise specified elsewhere in the act, "such sums as are necessary" to carry out Titles I and II for FY2003–FY2007.

Title V of the statute, denominated the Confidential Information Protection and Statistical Efficiency Act of 2002, vests the OMB director with responsibility for coordinating and overseeing the confidentiality and disclosure policies established by the title. Subtitle A prescribes limitations on the use and disclosure of statistical data or information, and sets fines and penalties for violations of these limitations. Subtitle B, after identifying the Bureau of the Census, Bureau of Economic Analysis, and Bureau of Labor Statistics, as "designated statistical agencies," prescribes the responsibilities, as well as the business data-sharing ground rules and limitations, of these agencies.

## DISCUSSION

Compared to e-government legislation in some other countries, the U.S. E-Government Act is expansive and far reaching, reflecting an attempt to coordinate a sprawling array of individual projects while also capitalizing on broader changes taking place in the public sector in which governments are moving toward a model of governance that Goldsmith and Eggers (2004, p. 10) call "governing by network." Building upon the Clinger-Cohen Act, which is more modest in scope, the E-Government Act serves as the primary legislative vehicle to guide evolving federal information technology management practices by creating new administrative entities, standardizing policies and practices across intergovernmental lines, codifying both public-private partnerships and intragovernmental relationships, and promoting a variety of initiatives to make government information and services available online. In doing so, it also represents a continuation of efforts to realize greater efficien-

cies and reduce redundancies through improved intergovernmental coordination, and by aligning information technology investments. In addition, while the Bush administration's Quicksilver initiatives are separate from the E-Government Act, some of the goals of the Quicksilver initiatives are reinforced by the Act's provisions. For example, Section 216 addresses the development of common protocols for geographic information systems, which is also one of the objectives of the Geospatial One-Stop project (http://www.geo-one-stop.gov/). Section 203 directs agencies to adopt electronic signature methods. Likewise, the E-Authentication initiative strives to develop a government-wide approach to electronic identity systems (http://www.cio.gov/eauthentication/). In addition, some of the Act's broader provisions, such as those related to the development of privacy guidelines, information security standards, and the identification of means to bridge disparities in Internet access among citizens, contribute to the technological and regulatory infrastructure needed to support e-government generally.

However, while the law is still relatively new, the rapid pace of technological change and the drive to implement initiatives in a timely manner have raised a number of implementation issues that may arise during congressional oversight. One of these issues involves the recruitment and retention of IT managers, at both the CIO and project manager levels. As IT projects have become more integrated into the function of a department or agency, the role of CIOs has evolved as well. CIOs are reportedly being called upon not only for their technological expertise, but also to provide strategic leadership in the areas of policy, budget, and contract oversight (Webb, 2003). The CIO's relationship with top-level department decision makers can also be critical to successfully implementing e-government initiatives. This suggests that in selecting a department-level CIO, one needs to consider the strengths and weaknesses of choosing a career employee, who may have a deeper contextual understanding of the mission and functions of an organization, and recruiting a candidate from the private sector, who may bring a wider range of experiences and perspectives to the position (Michael, 2003a). Similarly, the increased size and complexity of IT projects has further underscored the need for strong project managers to carry out these initiatives. While it is not uncommon for IT project management to be just one of several duties assigned to an individual, some observers have suggested that IT projects with budgets of $5 million or larger should have dedicated, full-time managers. The possibility of requiring federal IT project managers to obtain some form of professional certification has also been raised (Michael, 2003b, p. 28; Michael, 2003c).

Another issue concerns information security. In a series of evaluations published since 1997, the General Accounting Office (GAO) has repeatedly reported that the largest federal agencies have made only limited progress in addressing computer security vulnerabilities, citing information security as a government-wide high-risk issue. Specifically, GAO has identified six areas of weaknesses: lack of senior management attention to information security; inadequate accountability for job and program performance related to IT security; limited security training for general users, IT professionals, and security professionals; inadequate integration of security into the capital planning and investment control process; poor security for contractor-provided services; and limited capability to detect, report, and share information on vulnerabilities or to detect intrusions, suspected intrusions, or virus infections (GAO, 2003b, p. 8). For e-government activities, service continuity is considered critical, not only for the availability and delivery of services, but also to build citizen confidence and trust. The risks of fraud and misuse of sensitive data are concerns, as well. Heightened concerns about homeland security and critical infrastructure protection have also drawn attention to the role of information security. The inclusion of Title III of the E-Government Act (referred to as the Federal Information Security Management Act) permanently reauthorizes and amends the Government Information Security Reform Act (GISRA), providing additional means for congressional overseers to assess this issue.

A third issue is the interoperability of technology. Interoperability refers to the ability of a computer system or data to work with other systems or data using common standards or processes. Interoperability is an important part of the larger efforts to improve interagency collaboration and information sharing through e-government and homeland security initiatives. It also represents a significant challenge as the federal government implements cross-agency initiatives, such as the E-Payroll and GovBenefits.gov projects, to eliminate redundant systems and facilitate a "one-stop service delivery" approach to e-government (OMB, 2003, p. 9). One means being used to address this issue is the development of a federal enterprise architecture, at the Web site http://www.feapmo.gov/. An enterprise architecture serves as a blueprint of the business functions of an organization, and the technology used to carry out these functions. While this blueprint is still in its early stages, federal agencies are being required to justify their IT investments based partly on their ability to make a strong business case to support each request, and based on how closely the project aligns with the federal enterprise architecture. Decisions made early in the development of the federal enterprise architecture can have significant implications for future IT projects, suggesting that regular assessments of this process may be necessary to help minimize any potential complications.

Other issues include, but are not limited to, balancing the sometimes competing demands of e-government and homeland security, measuring e-government performance, assessing and monitoring the quality of agency IT project "business cases," and balancing cross-agency funding approaches with oversight interests.

## CONCLUSION

The U.S. E-Government Act represents one example of a country's attempt to harness the transformational potential of e-government. To a certain degree, by virtue of its broad scope and diverse provisions, the E-Government Act suffers from some of the same problems that it was designed to address. With many of its provisions still in the early-to-middle stages of implementation, a number of significant technological and organizational obstacles remain. However, the E-Government Act, in conjunction with executive branch initiatives, such as those related to the development of a federal enterprise architecture, has advanced e-government considerably in the United States. Some of the accomplishments include increased government delivery of government information and services online, improved collaboration between departments, and a greater emphasis on information security. Future effects of the E-Government Act will depend upon ongoing implementation efforts, as well as the degree of oversight exercised by the national legislature.

## KEY TERMS

**Chief Information Officer:** The senior decision maker in an organization responsible for providing leadership and management of the information technology resources used to support the organization's operations.

**Electronic Government:** The use by government of Web-based Internet applications and other information technologies, combined with processes that implement these technologies, to (A) enhance the access to and delivery of government information and services to the public, other agencies, and other government entities; or (B) bring about improvements in government operations that may include effectiveness, efficiency, service quality, or transformation.

**Enterprise Architecture:** Refers to a strategic information base that defines the enterprise's mission; the information and technologies necessary to perform the mission; and the transitional processes for implementing new technologies in response to changing mission needs, including a baseline architecture, a target architecture, and a sequencing plan.

**Geographic Information Systems:** Information systems that involve locational data, such as maps or other geospatial information resources.

**Information Security:** Protecting information and information systems from unauthorized access, use, disclosure, disruption, modification, or destruction in order to ensure integrity, confidentiality, and availability.

**Interoperability:** The ability of different operating and software systems, applications, and services to communicate and exchange data in an accurate, effective, and consistent manner.

**Portal:** A Web site that serves as a gateway to a collection of information, services, and other resources related to a particular organization or activity.

# E–Government and Political Communication in the North American Context

**Jo-An Christiansen**
*Graduate of Athabasca University, Canada*

## INTRODUCTION

This article will introduce the concept of e-government, provide a model and background, and discuss emerging issues. Canadian examples will be drawn into the discussion as the country recognized as the leader in e-government (Accenture, 2004).

E-government (electronic government) is a component of e-governance (electronic governance). The context of e-governance includes such components as e-government, e-democracy, e-representation, e-consultation, and e-participation. E-government refers to those aspects of government in which information and communications technologies are or can be utilized and in which basic functions are to increase efficiency in administrative processes, to guarantee easy access to information for all, to provide quality e-services, and to enhance democracy with the help of new technological mediation tools (Anttiroiko, 2005). It can be seen to describe all of the processes (administrative and democratic) that combine to constitute public sector operations, as broadly defined by Grönlund (2002). E-government is defined as "the use of ICTs [information and communication technologies], and particularly the Internet, as a tool to achieve better government" (OECD, 2003). E-government involves goals of enhanced operational efficiency and enhanced effectiveness. Effectiveness gains are attributed to "a better quality of services and increased and better quality citizen participation in democratic processes" (Grönlund, 2002). E-government relates to how the government delivers information, services, and programs. It relates to who provides services and how the services are delivered (Lenihan, 2002). At the core of e-government is the provision of information. E-government tasks include who and how, while e-democracy deliberates on what is to be delivered. Determining what services are to be delivered is a function of policy deliberation. The ability to research policy issues is an important element of a democracy. Stakeholders can share in the responsibility for developing the policy agenda, policy outcomes, and policy effectiveness. Public participation in this process will be discussed under the topics of e-democracy, e-representation, e-consultation, and e-participation.

## E-GOVERNMENT MODEL

E-government and political communication can be modeled as a star topology. Members of the public eceive communications from the government and political representatives. The communication flow is unidirectional from the internal node to the external nodes. The single internal node is reminiscent of the root in the traditional government hierarchical form. The unidirectional information and communications flow is one-to-many or one-to-one. This unidirectional communication is a monologue vs. a dialogue. The agenda and content of the communication is determined by the central agency. Communication flow from the external nodes to the central agency occurs only in response to specific requests. The opportunities to participate in online services are determined by the central agency.

The primary attributes of e-government include information provision, service delivery, and program support. These components are altered in fundamental form due to their electronic structure. The government workflow is reconfigured due to electronic workflow and productivity implications.

Cremonini and Botterman (2002) define e-government as "the use of ICT to improve the efficiency, effectiveness, transparency, and accountability of government." They categorize participants of e-government, including citizens, businesses, other government agencies at the same hierarchical level, other levels of government, wider public sector (including nongovernmental agencies), foreign governments, and supranational entities. This expansive list of e-government participants may be involved in the information flow either to or from the government.

Information provision supports government transparency and accountability with implications for building a healthy democracy. The key distinction between e-government from e-democracy is this unidirectional flow with no dialogue and feedback provisions available at the point of contact. Accessible information is a basis for democracy and supports government legitimacy. Information sharing is a critical precursor to allow for e-democracy to develop. An understanding of the issues,

questions, and alternative solutions is necessary to support a deliberate and valid discourse available through e-democracy. As Lenihan (2002) points out, the Internet can provide more than a tool for disseminating documents. It can become a venue for discussion, debate, and engagement. E-democracy is based on this ICT extension of the democratic public sphere.

In Canada, this model serves to further a national vision. Canada's e-government goal is "to be known around the world as the government most connected to its citizens, with Canadians able to access all government information and services online at the time and place of their choosing" (Accenture, 2004, p. 68). The majority of Canadians have accessed e-government information, services, and programs. Of the 63.41% of Canada's population who are regular Internet users, 79% have visited an e-government Web site (Accenture, 2004).

In the United States, the E-Government Task Force clearly understands the merit of e-government. The Task Force stated:

*E-Government is critical to meeting today's citizens and business expectations for interaction with government. It will enable agencies to align efforts as needed to significantly improve service and reduce operating costs.* (Forman, 2002, p. 3)

E-government is based on a desire for time efficiency and cost effectiveness relating to the provision of information and access to services and programs. Connected members of society enjoy the ability to access government information quickly and easily. Government enjoys the efficiency of providing information, services, and program through online tools. Mass processing of transactions is time-efficient and cost-effective when compared to labor-intensive processes used in the past.

## TIME EFFICIENCY

In an average day:

- The majority of my work day is spent at a computer.
- I use the Internet to gain information necessary to complete professional and personal tasks.
- I may shop online.
- I am involved in online learning (e-learning).
- I communicate with friends and colleagues predominantly through e-mail.

The way I work, shop, learn, and communicate has radically changed due to the use of ICTs. The tools I use to complete my daily tasks are based on ICTs. My methodology has changed as well as my relationships with individuals and organizations with whom I communicate. Whom I contact, what tasks I complete, the amount of time resources, what information I obtain, and how I communicate with individuals involved have changed fundamentally due to the use of ICTs. My objectives are facilitated by online activities. Similarly, the objectives of organizations and governments are facilitated by my online activities. The symbiotic beneficial relationship (win-win) is an attribute of e-government.

E-government is based on citizens receiving information, services, and program support from government facilitated by ICTs. The government benefits from my use of the Internet in that this form of communication is very efficient from a human resource perspective. I also benefit from being able to find the answers to my questions through documented sources at anytime and from anyplace. For example, leading up to the recent federal election, there was news media coverage of the various party leaders relating to military spending. I was able to determine the exact amounts proposed in each party's budget and to read additional text on each party's platform. Telephoning party officials during work hours in order to request a mailed copy of each platform would have cost substantially more in human resources and time. Instead, the information was readily available to me with the click of a mouse, and I was able to make an informed electoral decision.

A growing number of Canadians are seeking government information similarly with the click of a mouse. In 1998, 8.2% of all households sought government information over the Internet. This figure increased to 29.2% in 2002 (Statistics Canada, 2004a). The number of Canadians visiting the federal government's Canada site has increased substantially. There were approximately 16 million visits to the Web site in 2003 (Government of Canada, 2004). The number of visitors increased 21% from 2002. Generally, client feedback has been positive, with 86% of visitors finding the information sought (Government of Canada, 2004). Citizens also are coming to expect online provision of information, services, and programs. The following statistics shared by Zussman (2002) clearly show the public's support for e-government initiatives:

- 77% of Canadians believe that the Internet will improve how they receive services from the government of Canada.
- 73% believe that putting services and information online is a good use of tax dollars.

## COST EFFECTIVENESS

Mass communications such as online provision of information is extremely efficient when compared to historical

labor-intensive processes. The E-Government Task Force asserts that a reduction in overlap and redundancy will reduce government costs and improve citizens' ease of access. The Task Force concluded the following:

*E-Government offers the opportunity to streamline activities, improving productivity by enabling agencies to focus on their core competencies and mission requirements. E-Government initiatives eliminate unnecessary redundancy, while improving service quality by simplifying processes and unifying agency islands of automation.* (Government of Canada, 2004, p. 7)

The cost-effectiveness of e-government has been established in various studies. Online transactions completed by individuals are inherently cost-effective in requiring less human resources be provided by government. A recent study conducted in Canada showed a significant cost savings. Costs per transaction averaged $44 for an in-person transaction, $38 for a mail transaction, $8 for a telephone (agent) transaction, and a mere $1 for an online transaction (Accenture, 2004). The figures vary per type of transaction, but generally provide cost-effectiveness through the use of e-government tools.

## POLITICAL COMMUNICATION

E-government extends beyond government processes to include political parties who also are increasingly seeking a Web presence. In Canada and the United States, Web sites are providing political party platform information, detailing candidate biographical information, selling party memberships, requesting political campaign contributions, recruiting volunteers, and often offering a means to communicate through an e-mail feedback form. In Canada, 58% of Canadian members of Parliament (MPs) have a Web site with 19% developing a Web site (Valeri & Lenihan, 2003). Of this group of MPs, only 27% use interactive tools such as an online feedback form or online surveys in order to allow citizens to express their views on issues (Valeri & Lenihan, 2003). A similar survey determined that 80.3% of MPs surveyed have a personal Web site, and 13.6% have undertaken online polling (Kernaghan, Riehle & Lo, 2003). Online dialogues relating to policy positions generally are not offered. The latter survey determined that 74.2% of MPs surveyed believed that the Internet was important or highly important in consulting with constituents (Kernaghan, Riehle, & Lo, 2003). Clift (2000) offered advice to wired elected officials (WEOs) seeking to enhance their online presence. Clift's (2000) top 10 tips include the following:

1. Use the Internet to communicate.
2. Use the Internet to disseminate information.
3. Develop multiple e-mail address identities on the Internet.
4. Promote e-democracy within your existing representative structures to enable wired public participation.
5. Use the Internet to connect with peers around the world.
6. Use the Internet to access information.
7. Use the Internet to access information smartly.
8. Use the Internet to be fed information automatically.
9. Use the Internet for intelligence.
10. Promote integrated services for all elected officials across the organization.

Kippen and Jenkins (2002) analyzed how political parties are responding to the challenges and opportunities of e-democracy. The authors discuss how e-democracy offers the potential to engage a greater number of voters and potentially to increase campaign funding and electoral success. This linkage has yet to be made and is considered of paramount importance. The authors astutely put the merit of the effort in context. They ask, "If political parties are too focused on the electoral process and ignore the citizen engagement efforts of e-government initiatives then how can they realistically hope to provide alternative views/approaches to the development of policy?" (Kippen & Jenkins, 2002, pp. 27-28). This issue is developed further in the article that discusses e-democracy and e-representation.

## BARRIERS

The vision of seamless government information and services provided through ICTs must address several barriers, including security of transactions, protection of privacy, digital divide, and globalization.

The Canadian government's Secure Channel is believed to respect individual privacy and to support secure online transactions through security and authentication services (Government of Canada, 2004). An e-government strategy must incorporate means to effectively control security of government systems. Security concerns are being addressed by the Canadian government through its e-pass authentication system, which is a public key certificate system allowing secure online transactions. Similarly, the United States government is developing an e-authentication project. System control capabilities are critical to both the operation of e-govern-

ment and to the involvement of the public. Citizens' perceptions and confidences in secure transactions are as important as the hardware and software security systems' capabilities.

An e-government strategy also must incorporate means to ensure privacy of personal information. Privacy concerns are raised when a proposed service leads to "an increased use of personal information, a shift from direct to indirect collection of personal information, use of personal information for purposes other than those for which it was collected, greater sharing of personal information, contracting out, or the creation of a common personal identifier" (Government of Canada, 2004, p. 24).

The United Nations (UN) recognizes two barriers to e-government: the digital divide and globalization. The primary challenge of e-government is considered the questionable inclusiveness of ICT access (UNDESA, 2003). The digital divide is a substantial issue with developing countries seriously lagging behind developed countries. Computer-literate individuals with access to ICTs may be a majority in many developed countries; however, this elite group is a minority when the global population is considered. The UN notes that approximately one-half of the world's population has never made a telephone call, and only 9.5% of the world's population has online access (UNDESA, 2003). Access to ICTs and functional computer literacy are essential yet largely missing in the developing world. A second barrier is the potential threat to governance institutions associated with a globally knowledge-empowered population. E-government is seen to shift the power balance between citizens and the state. The traditional government domain is impinged by global e-networks proliferating through ICTs (UNDESA, 2003).

The digital divide contributes to the democratic divide. Future research is needed to determine the impact of the digital divide on the political rights of individuals without ICT access. Access to political resources has implications for the efficacy of civic engagement. ICTs promise to mobilize civic engagement and to provide a public sphere for mass participation. This social benefit can be looked upon alternatively as a barrier. Depending on which side of the digital divide one is located, the balance of power may shift, thereby further reinforcing global and social divisions (Norris, 2001). As Norris (2001) warns, "Political resources available via the Internet will empower those with the resources and motivation to take advantage of them, stranding the disengaged farther behind" (p. 217).

Government On-line Advisory Panel (2003) calls for active involvement in order to enjoy the benefits of e-government. Civic engagement by four stakeholder groups—federal government officials, citizens, businesses, and the media—will contribute to e-government success. The panel believes that a communications and marketing strategy led by a service transformation champion is essential in order to engage these stakeholders.

## FUTURE TRENDS

The future of e-government is positive in light of the benefits for governments and citizens. Capitalizing on the benefits of online tools is challenging, given the rapid rate of technological change. Innovative approaches to issues may result in the implementation of yet unknown technological solutions. In the current state of change, we are unaware of potential solutions, as we may not even be cognizant of the problems. The future holds vast unknowns, and the approach taken by the networked society is a fascinating area for future research.

E-government is expanding to offer more services, programs, and communications online. E-democracy, e-representation, e-consultation, and e-participation are examples of e-government enhancements. The unidirectional communications flow of e-government is being displaced by bidirectional and multidirectional communications. The latest killer application is a focus on research activities. However, I believe that the critical issue will be at the other end of the ICT spectrum. The digital divide has implications for political relations based on access to ICTs. The democratic divide, a component of the digital divide, is the difference between those who do and those who do not use various digital resources to engage, mobilize, and participate in public life (Norris, 2001).

In Canada, there is a growing proportion of the population that has access to the Internet. In 2003, approximately 64% of Canada's population had at least one member of a household who used the Internet regularly (Statistics Canada, 2004b). The proportion of those who have ICT access has grown from the 2002 figure of 62% (Statistics Canada, 2003). However, the have-not group still constitutes one-third of Canada's population. The gap between the have and have-not groups has implications for each individual and also the social groups of which they are members. Access disparity has been shown to correlate to a person's level of income (Sciadas, n.d.). Other social characteristics of interest include the variables of age, education, ethnicity, geographic location, and gender. E-government provides information, services, and programs. There is political power having access. If individuals and particular social groups are marginalized, then the gap in the digital divide and political power allocations will widen. The have-not group is excluded from the benefits of e-government, which thereby widens social cleavages. As e-government advances, a proportion of the population is further marginalized and excluded from the increasingly critical provision of infor-

mation. The consequences of the digital divide are an important area for future research and social action.

The issue of online privacy also must be addressed. Does the public's expectation of online privacy mesh with ICT reality? The public has privacy rights relating to information held by government officials. The online environment challenges the government to maintain this level of personal privacy. With e-government, data is shared in some cases in order to improve horizontal management among departments. Sharing of information historically has been between an individual and a single government agency. In the era of e-government, this vertical and segregated management process is transposed into a horizontal and information-sharing process. Horizontal management of information coordinates services and data stores. This is a new management paradigm for a historically hierarchical bureaucratic structure. The sharing of information results in a diffusion of data responsibility and accountability. Accountability mechanisms are predominantly vertical, not horizontal, and changing these mechanisms will create cultural and organizational barriers (Richard, 2000). Successful implementation of the horizontal government structure and information flow is a challenge for government. As Stephen Rohleder stated:

*Governments need to integrate services seamlessly across horizontal and vertical levels of government. The technology challenges and the complexities of governance mean the task will not be easy, but only then will they be able to provide the truly seamless service that will drive broad take-up of services.* (Accenture, 2004, p. 2)

The Canadian federal government and, similarly, the United States federal government both are striving to implement an effective one-window main government portal in their respective countries. The integrated one stop model draws on the business effectiveness of offering consumer goods and services in a central location. A one-stop government portal is built on this premise of service consolidation and seamless communication flows. This ease of information flow promotes efficiency but at the cost of personal privacy, when confidential information is shared. Individuals unknowingly and unwittingly may have personal information residing in shared data banks. The protection of personal privacy is challenged in the e-government context and is an important area for future research.

## CONCLUSION

This article has discussed the attributes, benefits, barriers, and emerging issues relating to e-government. E-governance has the capacity to reengineer democratic government through e-government, e-democracy, e-representation, e-consultation, and e-participation. The Government On-line Advisory Panel asserted in their first report of 2002 and again in their final report dated December 2003 on the transformative capacity and magnitude of e-governance:

*We have been struck by the sweeping potential of this initiative both for the direct changes it is starting to bring and as a catalyst for far broader indirect change. Because this initiative, in its essence, involves changing the ways Canadians communicate with each other and government, it has the potential to change—and in largely unpredictable ways—the most basic relationships that underpin our society. ... All of this implies that government must be not simply restructured but reconceived to accommodate, but just as important to anticipate, the waves of change that will erode traditional relationships even as new ones are created.* (Government On-line Advisory Panel, 2003, p. 9)

The application of ICTs has implications for economic, social, and political contexts. Riley (2004) recognizes the transformative power of ICTs as "the sheer amount of information available, the ability to communicate information, and the value that individuals put on information, is bringing a new understanding of the nature of information itself." This change process is not without precedent. For instance, the Gutenberg printing press resulted in massive changes throughout society. Our ability to communicate was changed radically with its invention. Such change ripples through society and governments to reform communication processes. Computer networks offer a similar revolutionary change to communication patterns.

The *e* in e-governance, e-government, e-democracy, e-representation, e-consultation, and e-participation refers to *electronic* but could also refer to *enabling*. The Internet is a modern-era Gutenberg printing press with its capacity to change societal channels of communication and governance systems. "The tools of technology allow for an active exchange of information, which in turn allows for a significant shift in the government-citizen relationship" (Riley, 2001). The instrumentalist approach to ICTs is shared by the Commonwealth Centre for Electronic Governance, which stated:

*[E]-governnance is a tool. And like any other tool, no matter how powerful, it has limited value and relevance in itself. Its value arises from its application to specific goals and objectives. E-governance is really about choice. It is about providing citizens with the ability to choose the manner in which they wish to interact with their governments.* (Finger & Pecoud, 2003, pp. 7-8)

E-government is an emerging dimension of good governance. Future changes to governance attributable to the application of ICTs are unknown. The potential benefits and magnitude of the barriers associated with e-government and the wider context of e-governance are yet to be comprehended fully. E-government and its impacts on political communications and the democratic process are only beginning to be understood. The future will see further efforts being undertaken, evaluations being shared, and future projects being improved. The saying "the only constant is change" is particularly applicable as we continually strive to harness technological capabilities. With the speed of technological change, e-government promises to bring innovative enhancements to the relationship between citizens and their government.

## KEY TERMS

**Civic Engagement:** Encompasses three distinct dimensions: "political knowledge (what people learn about public affairs), political trust (the public's orientation of support for the political system and its actors), and political participation (conventional and conventional activities designed to influence government and the decision-making process)" (Norris, 2001, p. 4).

**Digital Divide:** Encompasses three distinct dimensions: "The global divide refers to the divergence of Internet access between industrialized and developing societies. The social divide concerns the gap between information rich and poor in each nation. And finally within the online community, the democratic divide signifies the difference between those who do, and do not, use the panoply of digital resources to engage, mobilize, and participate in public life" (Norris, 2001).

**E-Democracy (Electronic Democracy):** "The convergence of traditional democratic processes and Internet technology. It refers to how the Internet can be used to enhance our democratic processes and provide increased opportunities for individuals and communities to interact with government" (Clift, 2004, p. 11).

**E-Governance (Electronic Governance):** "The commitment to utilize appropriate technologies to enhance governmental relationships, both internal and external, in order to advance democratic expression, human dignity and autonomy, support economic development and encourage the fair and efficient delivery of services" (Riley, 2001).

**E-Governance (Electronic Governance):** "Seeks to realize processes and structures for harnessing the potentialities of information and communication technologies (ICTs) at various levels of government and the public sector and beyond, for the purpose of enhancing good governance. As a concept e-governance can be perceived to be contextually inclusive of electronic democracy (e-democracy), electronic government (e-government) and electronic business (e-business). As an initiative at a national, governmental, or community level, e-governance can be perceived within the context of a country's national information infrastructure which, in turn, can be perceived to be part of the emerging global information infrastructure ..." (Cremonini & Botterman, 2002).

**E-Government (Electronic Government):** "The use of ICTs, and particularly the Internet, as a tool to achieve better government" (OECD, 2003). It refers to those aspects of government in which information and communications technologies are utilized or can be utilized, the basic functions being to increase efficiency in administrative processes, to guarantee easy access to information for all, to provide quality e-services, and to enhance democracy with the help of new technological mediation tools (Anttiroiko, 2005).

**Information and Communication Technologies (ICT):** "Technologies for storage, processing, representing and transmitting information between humans, between humans and machines and between machines" (Cremonini & Botterman, 2002).

**Information Society:** "Involves rapid, broad and deep access to and exchange of information among all elements of society" (Cremonini & Botterman, 2002).

# E-Government and the Risk Society

**Michael Blakemore**
*University of Durham, UK*

## INTRODUCTION

The modern "risk society" does not necessarily focus on an increase in overall risk to citizens. It is more focused on trying to predict and reduce risk in the context of the speed and complexity of globalisation. Anthony Giddens observes that society is organising itself increasingly around the mitigation of risk, and Ulrich Beck notes that the assessment and mitigation of risk is undertaken in a systematic way (as cited in "Risk Society," 2005). While society has always been confronted by external risks (floods, earthquakes, etc.), the risks within e-government are primarily manufactured risks, produced by largely uncertain outcomes of the integration of information and by the ways in which information technologies are used within government. For example, CCTV (closed-circuit television) can be used in a planned manner to monitor and deter crime in public spaces, but an uncertain outcome can be the risk of all citizens being proactively monitored by government.

## BACKGROUND

Manufactured risks within e-government arise through two primary processes that are themselves aiming to deliver benefits to citizens. First, information about citizens is integrated and shared across functions of government so that services can be delivered more effectively to citizens. Included in this activity are the transformation of government, citizen-centric services, and the rebuilding of relationships between government and citizens, for example, the European Commission's (2005b) aspiration to "reconnect Europe with its citizens." Second, using information networks such as the Internet and digital television, government services are made widely accessible to citizens in locations that are suitable for them. The integration and sharing of information, within increasingly complex information systems, is intended both to increase the efficiency of government and to deliver services faster ("killing time"). The network availability of services is designed to make services available anywhere ("killing geography"). The emergent manufactured risks arise through what is termed the "dimensions of unintended consequences" (Lash, 2002, p. 50). For example, Windows XP, containing over 40 million lines of code, produces unexpected risks through security failures that were not predicted, and the users of XP to some extent are both users and testers of the operating system.

Manufactured risks in e-government are not scientific in the same sense that living next to a river entails a definable risk of flooding. Furthermore, the prioritisation of manufactured risks often is not a scientific process, but is a social, cultural, and political process. Thus, the political prioritisation of the risk of terrorism[1] in the USA influences many of the processes of governance, with significant investment into the integration of information for surveillance purposes (Roberts, 2004). Consequently there is a "cultural and institutional matrix" that determines how risks are constructed and prioritised (Bulkeley, 2001, p. 442). For example, regarding food safety, the prevailing approach to risk until recently was to regularly inspect food premises. That has changed in some nations to a risk-based approach (Food Safety and Inspection Service [FSIS], 2001) that uses information, analysis, and forecasting operations to identify where risks are highest and where staff resources should be invested in inspection: a move away from the routine and reactive to information-driven risk assessment.

## TECHNOLOGY AND INFORMATION INTEGRATION

While risk is linked to uncertainty, the e-government agenda assumes that more information and better services to citizens will serve linearly to help offset the impacts of the risk society. E-government is focused on the network society. It is a process that on one hand is promoted by governments as being a way in which to improve services to citizens and to engage citizens more effectively with governance. On the other hand, however, e-government is usually performed as certainty, a technological process that can downsize and reinvent government, saving money, improving cost effectiveness, and delivering government primarily through electronic channels. E-government is thus grounded in political planning, assuming that government can automate services and join them up seamlessly to provide citizen-centric services that are individually targeted and consumed via

information technologies, and assuming that information technologies will deliver predictable benefits and few disadvantages (Hudson, 2002).

Both the risk society and e-government involve the utilisation of technologies within organisations and institutions (termed enactment; Fountain, 2001). Underpinning the delivery of e-government is the process of the removal of human intermediaries between citizen and service: This is termed disintermediation. Underpinning the risk society is the process in which citizens are presented with an often bewildering range of advice and information about the identification of a risk and its evaluation, and the potential or proposed responses to risk situations: This is termed re-mediation. Consequently, central to both the risk society and e-government is the production, dissemination, and consumption of information. The production of information for e-government services requires greater attention to information linkage and integration, with associated risks that information quality and consistency may be variable, and privacy and confidentiality may be compromised, along with the risk that governments will engage in "function creep." Consequently, "government therefore needs to engage with the public and opinion-formers to explore and communicate the benefits and risks" (CST, 2005).

## CONTESTED INFORMATION

The risks, however, are not concentrated on the consumers of government services: the citizens and businesses. Legislation such as freedom of information (FoI) or policies to liberate access to public-sector information (PSI) can lead to government information being used, combined into market services, and critically evaluated by an increasing range of information users who may have locally produced data that are better in quality than government data. This process was seen with the UK 2001 Census of Population, when the cities of Westminster and Manchester successfully contested the official census figures. The basis of the challenge was a claim that the official national census had undercounted residents in the cities. Since much government funding is linked to the official population, there were adverse financial consequences. The enquiry into the census found that it was indeed in error (Statistics Commission, 2003). There is, therefore, a paradox of e-government in that the increased availability of information leads to an increased risk that government policies and information will be contested. There is a further lose-lose paradox for government as well in that no local government area will contest the official figures because the census overcounts its population, and the government cannot contest its own figures because they are official.

## COMMUNICATION AND TRUST

Risk increases as the historical routine life patterns (synchrony) are disrupted by the increasing speed across space (asynchrony) of modern society. It is not just that more information is being consumed by citizens, but also that the risk events are both exacerbated by citizens' consumption patterns and increasingly difficult to evaluate—the calculation of risk is ever more complex, and the dilemmas about whose risk calculation to trust (the cult of the expert is diluted with access to Internet-based information) also increase. By contrast, e-government is oriented strongly toward the synchronisation of information in predictably constructed services.

Hassan (2005) cited the example of the human form of mad cow disease (bovine spongiform encephalopathy, or BSE) that caused major scares, though low human death rates, in the United Kingdom in the 1990s. The UK government enquiry into BSE highlighted the potential contradiction emerging in the traditional precautionary principle toward health risk (Calman & Smith, 2001) and the relatively low probability of being infected with a rare but deadly illness:

> *The public was repeatedly reassured that it was safe to eat beef. Some statements failed to explain that the views expressed were subject to proper observance of the precautionary measures which had been introduced to protect human health against the possibility that BSE might be transmissible.* (Phillips, 2000)

Furthermore, the enquiry report criticised government agencies for not releasing information to the public since there was a tension between telling citizens that there was a risk that beef may be infected with BSE and the possible catastrophic decline in beef consumption leading to "the possible effect on exports and the political implications" should news become known internationally that UK cattle were infected with the disease (Phillips, 2000).

What BSE demonstrates is that the geographical, temporal, and structural complexity of globalised food chains, and of business supply chains, introduces manufactured risks that challenge the abilities of governments to process information. However, the more information is released into the public domain, the more likely it is that citizens will evaluate risks in an emotional and not a statistical way. With increased confusion and increased fear of risk there is a paradoxical decline in the communication of risk by government: Indeed, the fear of communicating a false risk can be politically more damaging than the noncommunication of a real risk. The outcome often is a reliance on "technoscience," the cult of the media expert, the consumption of multiple sources of new authority on the Internet (Burrows, Nettleton, Pleace, Loader,

& Muncer, 2000), in which "the authority and legitimacy of the state, science and technology are no longer taken for granted" (Schedler & Glastra, 2001, p. 347). This observation conforms also to what Lash (2002, p. 142) terms the "disinformed information society," in which citizens are faced with overwhelming volumes of information, and in which governments increasingly assume that citizens understand informational complexities and can evaluate information using technologies. There is thus the risk of a "spiral of mistrust," in which the government collects more information about citizens, citizens trust the government less, and the government responds by more information collection, resulting in "less privacy in this risk society" (Regan, 2002, p. 402).

## UNINTENDED CONSEQUENCES

Unintended consequences, and new manufactured risks, emerge also through the increasing availability of government information, whether it is through FoI or through commercialised services. Indeed, the ways in which risk is being shared in society is changing, particularly in the context of home ownership. Insurance risk historically has been shared across a broad geographical area such as a town. With access to detailed official statistics, it is becoming possible to assess insurance risk for individual properties. The intended consequence is that people do not have to pay more than they should for risks attached to their property. The manufactured risk, however, has been that certain properties can be rendered as noninsurable, as well as the enabling of the "non-insurability of an ever-increasing number of catastrophes" (Bougen, 2003, p. 254). The spiral of mistrust is therefore fed by the increased availability of government information (Environment Agency, 2003) that is used in commercial products and services to predict the risk of events such as flooding (Norwich Union PLC, 2004), which then suffer the "dimensions of unintended consequences" where property no longer is insurable and property prices suffer (ITV, 2004).

The spiral of mistrust further highlights the contradictions of e-government. On one hand, e-government is seen by governments as a mechanism through which citizens will overcome the crisis of trust in government and its institutions, and that will consequently build higher levels of trust with government (O'Neill, 2002). Goals here include encouraging citizens to participate more in governance, and making individuals and agencies of government more accountable to citizens. However, a countervailing message from capitalist governance is a more aggressive focus on the individual. E-government services are provided to be consumed in a climate of individualism, where the citizen increasingly has to take on key life-path risks that historically were the domain of government, for example, job instability, skills training and knowledge acquisition, and pensions and health well-being for old age. Consequently, "individualisation seems to be the corrosion and slow disintegration of citizenship" (Bauman, 2000, p. 36).

## SURVEILLANCE

A further informational paradox is therefore introduced: More information about the actors is required by all the other actors so that they can each evaluate the actions of the others. An emerging risk is that information availability and e-government will lead not to a participative society, but to an extension of what Michel Foucault termed a "disciplinary society" (Cutting, 2003). The literature on the information society frequently cites an information culture where an all-seeing government joins up information within e-government services and then uses that information to monitor citizens (the "panopticon"), and where the panopticon extends beyond government services into the public spaces of everyday life through CCTV systems, for example. Individualisation then has its counterpoint of disciplinary surveillance through political interventions in Europe, from the use of those that reduce the risk of children accessing unacceptable Web content (BBC, 2004), reduce the risk of cybercrime (European Commission, 2004b), and work to determine the risk of terrorist attack (European Commission, 2004a), to the use of satellites to monitor the actions of European farmers (Elliott, 2005).

The intended predictability of e-government consequently sits uneasily within the uncertainties of modern society, uncertainties that Bauman (2000) terms "liquid modernity." Bauman notes that the threats of surveillance through the informational panopticon lead to uncertain responses where "the many are watching the few" in what he terms a "synopticon" (p. 85). The synopticon sees the use of information by citizens through blogs, activist Web sites, and intermediary information services that provide easy access to the performance of politicians.[2] Yet another manufactured risk arises from the well-intentioned policy of e-government to make information accessible and useful. A citizen reaction to that is to demand ever-increasing ethical standards from politicians and from those public and private agencies and people involved in the provision of e-government services (Mullen & Horner, 2004).

Following on from this, the public and media scrutiny of government is becoming extreme, particularly as the diversity of actors, agencies, and intermediaries increase,

and "representatives will need to adapt their working practices so that they are not overwhelmed by new channels of connection with the public" (Hansard Society, 2002, p. 25). The commensurate decline in trust is leading to negative impacts on e-government developments such as e-voting, for "there is no such thing as a completely secure electronic system, and therefore e-voting will never be error free" (Moynihan, 2004, p. 526). The panopticon and the synopticon work in competition against each other, with e-government needing the construction of a more extensive information environment in an attempt to overcome the risk that contemporary society is "humanly unmanageable" (Robins & Webster, 1999, p. 106).

## INCREASING DIVERSITY OF SERVICES AND SERVICE PROVISION

There are, it must be stressed, positive examples of the interactive provision of information and risk. The geodemographics industry uses confidential information about individual citizens to construct risk assessment related to financial probity. The balance of risk to privacy, vs. the derived public good (Cate, Litan, Staten, & Wallison, 2003), enables individuals to travel the world and to undertake action at a distance in real time by purchasing goods with electronic banking cards, but this very ease of mobility produces manufactured risks in the context of illegal immigration, leading to the e-government promotion of electronic identity management for civilian services and for border control (European Commission, 2005a).

The communication of risk is often different between the private sector and government. The private sector often uses public-sector information to build products that inform citizens and businesses of information and metadata relating to environmental risks, while at the same time leaving it to the customers to decide the extent of the risk (Landmark Information PLC, 2003). Government, as we have seen with BSE, is usually expected to inform citizens of risks. In Hong Kong the Slope Information System provides online warnings to citizens of the risks of landslides in their vicinity (Hong Kong Government, 2003). This form of risk assessment is provided when the analytical capabilities of the citizens are insufficient for them to work out their own risk assessment. Deeply embedded into this system are trust and credibility, and the "eventual integration of the risk into the communal fabric requires prompt and accurate government information, multiple channels of information provision and framing, and opportunities for public reaction and communal sense-making" (Maxwell, 2003, p. 253) because government may not need to communicate risk when the risk of adverse reaction, such as mass panic, is higher.

## CONCLUSION AND FUTURE TRENDS: INCREASING SPEED AND UNCERTAINTY

Thus, the openness and informational freedoms of e-government are often threatened by the risk of the total openness of information. The risk of communicating, as noted above, is deepened in the post 9-11 environment by the risk of letting information remain accessible. The risk of global terrorism using publicly accessible information is regarded by some governments as being greater than the risks of information censorship or the removal of information through a process of data scrubbing (Federal Geographic Data Committee [FGDC], 2004). Risk, uncertainty, and the desire for e-government certainty continue to interact in uncertain and unpredictable ways, and the production of manufactured risks increases as e-government integrates and shares information through networked technologies. Citizens look to government for increased quality of services, freedom of information, and better information and advice. Yet, they will demand more protection from the risks of globalisation and cybercrime, while at the same time being required by government to absorb more of the risks themselves.

## KEY TERMS

**Citizen:** A member of a country or state.

**Disintermediation:** The removal of intermediaries from a government process.

**Information Integration:** Linking information within and across the agencies of government.

**Information Sharing:** The exchange and use of information beyond its original purposes.

**Risk:** Potential adverse effects that may occur from a process of e-government.

**Surveillance:** The visual and information monitoring of the behaviour of citizens.

**Technology:** Technical devices that are used within a governance and societal context.

**Trust:** Being confident in the processes and actions of government.

# E-Government as a New Frontier for Legal Theory

**Keith Culver**
*University of New Brunswick, Canada*

## INTRODUCTION

E-government has the potential to change fundamentally the organization of governments, and the governance practices used in relations with citizens and other governments. Legal theory is clearly affected by these changes. Yet there is no rush to publish on e-government in leading legal theory journals, and there is no visible surge in student demand for courses in e-government. Just as only some areas of governments in developed states have taken advantage of new information communication technologies, so only some areas of legal theory have engaged e-government. Issues in Internet governance and personal privacy dominate legal theory's engagement with e-government, while e-engagement of citizens plays an increasingly important yet still limited role in governments' interaction with citizens. Yet there are signs that this gentle pace may soon change, as leading jurisdictions approach completion of the first wave of service transformation at the same time as concerns regarding a digital divide recede under the growth of access to new information communication technologies. New opportunities for e-government may soon make e-government's progress revolutionary rather than evolutionary, and legal theory will be forced to keep pace.

## BACKGROUND

The central questions and methods of legal theory are relatively easy to identify, while the boundaries of legal theory are not, for reasons worth exploring in the context of e-government. The most general question is "What is law?" naturally asked along with "What is a legal system?" and "What is *a* law?" These central questions are often thought to be connected by their shared concern with law's "normativity" or special capacity to assert authority to issue nonoptional norms, which norm subjects typically obey under the guidance of legal officials. The dominant approaches to these questions can be roughly distinguished as descriptive or normative. Descriptive approaches (such as legal positivism and legal realism) use normatively or morally neutral methods in their attempt to describe and explain legal phenomena. Descriptive approaches typically claim the virtue of clarity in understanding legality and legal phenomena as they appear in diverse ways in diverse social situations. By contrast, normative explanations of legal phenomena (such as natural law or Marxist theories) simultaneously evaluate phenomena from the standpoint of normatively committed moral or political theory (Patterson, 1996). Normative approaches typically claim that such neutral analysis is impossible, and argue that the kinds of concepts employed in understanding law are necessarily applied in a normatively committed fashion which reflects our ultimately moral motivations for understanding law—to know how to improve it, to know when to criticize it, and to know how and when to provide justification for it.

Both descriptive and normative approaches may be found separately and in blended theories providing answers to legal theory's core questions, and in adjacent questions typically focused on particular jurisdictions' or eras' experience of law's capacity to require, make permissible, enable, and deny. This experience appears in various areas of legal theory, including discussion of the nature and justification of civil liberties, punishment, privacy, property, contract, and others. Investigations outside the core certainly affect the way core questions are answered, yet there is considerable debate regarding the conditions under which answers to the core questions ought to be changed in light of peripheral developments. These debates are particularly acute at the intersection of legal theory's core questions with theoretical dimensions of social scientific dimensions of disciplines whose focus includes legal phenomena: sociology of law, legal anthropology, and some dimensions of legal history. It is not unreasonable to ask at these junctures just where legal theory comes to an end, and a disciplinary investigation, for example, sociology of e-participation, has begun. Once core questions are left legal theory is not easily distinguished from surrounding disciplines, and mere focus on legal phenomena by a discipline naturally facing theoretical questions does not amount to "legal theory" in any informative sense of the term. It is advisable then, for reasons of clarity and to avoid unnecessary engagement in methodological debate, to confine this discussion

to the effect of e-government on legal theory's core questions, and within those borders to strive for clarity in understanding what, precisely, about the social phenomena of legality or lawfulness is affected, if at all, by e-government.

The early days of e-government brought little of obvious interest to legal theory's core questions. Many changes appeared to affect the business operations of government, and not the nature of government itself, providing increased efficiencies in existing processes under a thin veneer of innovation. Where processes and services were converted from a paper base to an ICT base, processes and services often remained largely the same (OECD, 2003). The institutional and sometimes constitutional inertia of existing "silos" of authority in government augur against units of government using the new ICTs to seek new methods of collaborative interunit policy making, to change services, or to change the way a service is delivered. Doctrines of ministerial responsibility, for example, have tended to establish decision-making hierarchies within the public service which cannot be easily changed simply because there is some merit to doing so and available technology to do so effectively. Similarly, provision of online "brochure ware" touting a department's function seems to be a novel mode of advertising and little more, as do haphazard attempts at ICT-enhanced public consultation. Indeed, to the extent that e-government technologies do not change the nature of government or citizens' interaction with government, e-government has no effect on the core questions of legal theory and a limited effect on adjacent questions. Two developments and their infrastructure have, however, generated issues of interest to legal theory's core and adjacent investigations. Let us begin with infrastructure.

## E-GOVERNMENT AND LEGAL THEORY TODAY

### Internet Governance

*Governance of the Internet* has implications for our understanding of the nature of legal system, sovereignty, and the legality of what is said to be international law. Any attempts to use distinctively legal norms to govern the Internet must recognize that while states may conceive themselves to have vital interests in certain uses of the Internet, the Internet is not the kind of thing which is at risk of being hoarded or occupied by a state in the absence of agreement to make it an internationally held and governed entity. The Internet is a nonterritorial communications method using largely nonproprietary standards to enable territorially located users to exchange information. The Internet is not itself dependent on any particular physical location or piece of enabling software. Precisely how the Internet's nonterritoriality and nonproprietary standards might matter to legal theory is presently emerging. The United Nations (UN)-sponsored World Summit on the Information Society (http://www.itu.int/wsis/) has given political clout to efforts to internationalize governance of technical standards, naming and other resource allocation, and Internet use policy and dispute resolution. The UN-sponsored Working Group on Internet Governance and the International Telecommunications Union are leading these efforts, which may soon displace prior acceptance of the U.S.-based ICANN (Internet Corporation for Assigned Names and Numbers) and the (IETF) Internet Engineering Task Force (IETF), and still earlier reliance on self-regulation carried out by volunteers. As the Internet grows in social and economic importance, the list of those seeking to influence the Internet's governance has grown, now including states, coalitions of states such as ASEAN and the G8, and international organizations of varying degrees of formality, including the World Intellectual Property Organization (WIPO), the World Trade Organization (WTO), and the Organisation for Economic Co-operation and Development (OECD) (Mueller, Mathiason, & McKnight, 2004).

Displacement of nationally based Internet governance by international bodies does not, however, automatically amount to international Internet governance via legal institutions of norms. Many legal theorists are skeptical regarding the legality of what is purported to be international law, pointing to its lack of an authoritative norm-setting body, lack of adjudicative bodies holding compulsory jurisdiction, and lack of enforcement power. If the legality of international law is itself in doubt, the legality of international norms which eventually emerge from the UN-gathered coalition of state and nonstate actors may be equally in doubt. The problem of assessing the legality of international Internet governance may be made even more complex by the nonterritorial and nonproprietary nature of the Internet. While the struggle goes on to internationalize governance of technical standards and naming, convergence of the Internet with technologies such as mobile telephony continues, and hacking and viruses and other free-flowing "pollutants" of the Internet threaten sovereign states' interests. Sovereign states may soon find themselves less interested in naming conventions, and more interested in issues whose importance to sovereign states gains them the attention of legal theorists, particularly issues concerning the security of national borders and national wealth. A wide range of descriptive and normative questions arise in this tension between state interests and an international resource. On what principled descriptive or normative basis could a distinction be made between a state's communications

capacity and legal jurisdiction over that capacity, and international Internet "space" beyond the proper regulatory authority of individual states? What institutions can generate legal norms capable of guiding governance of the Internet's nonterritorially located, nonproprietary standards for information exchange—and what normative considerations ought to guide choice of those institutions? Is a new category of genuinely international law—not merely bi- or multilateral agreement—created by the chosen institution and norms governing a nonterritorial, nonproprietary resource incapable of being owned by any one state?

## E-Service Delivery to Citizens

*Portal-based service transformation* is also bringing new issues to areas of legal theory, particularly those concerned with privacy, identity, and citizenship under law. A portal is a virtual, typically Web-based gathering point for services or information grouped according to some purpose, usually users' needs. In this context, "joined up" or "seamless" services are services from disparate government units brought together in a single access point for end users (OECD, 2003). Leading jurisdictions such as Singapore have achieved a great deal, using service categories such as the idea of a "life event," for example, seeking housing, to group services according to citizens' needs (www.ecitizen.gov.sg). Yet compelling evidence suggests that no government has achieved fully joined-up services, for reasons including ICT-platform interoperability, silos barring collaboration, and concerns regarding privacy and transactional security as sharing of personal information among government units may involve objectionable uses of personal information (UNDPEPA, 2003).

Privacy, security, and trust have emerged as critical practical issues for e-government advocates seeking to deliver services to citizens while complying with existing and emerging legislation and public expectations. The practical nature of these issues may strike many legal theorists as being outside the core questions of legal theory, and into the shared boundary with political theory and ethics, and perhaps technical issues in applied computing. At that border a familiar range of straightforward legal questions may emerge regarding the substantive adequacy of legal norms intended to protect citizens' physical and informational privacy, often conceived as a dimension of their personal security.

Yet there is more to privacy, security, and trust than these practical issues, and a range of questions relevant to legal theory's account of citizens have yet to be thoroughly investigated. Those questions concern the implications of the full meaning of "Internet": inter*networked* ICTs. Privacy, as a dimension of personal security, is typically taken to refer to our interest in controlling what others know about us in order to secure freedom of thought and conduct against others' interference with exercise of those freedoms. The exercise of privacy involves withholding of personal information to some desired extent, often involving highly context-dependent choices regarding the personal interests satisfied by relinquishing privacy. (To a lesser extent privacy connotes and is sometimes legally recognized as an interest in a more substantial sense of freedom, that of being left alone; but this sense may be set aside here in the context of an increasingly and nearly unavoidably urban and connected world.) The kind of public "trace" or persona created by selective disclosure of personal information has long been important in various ways. Consider, for example, many persons' interest not just in the fact of having a credit record, but in having an accurate credit record maintained and made consistently available across a network of users to enable him or her to secure credit as desired (Friedman, 2000). Contemporary worries regarding the technical adequacy of privacy safeguards may soon be turned on their heads by citizens' interest in taking fullest advantage of the efficiencies and service improvements available from joined-up services and information sharing across government departments. Citizens may yet become more interested in how and whether their digital persona can be preserved and developed, and not how privacy interests can be used to justify a lack of engagement with government. A range of descriptive and normative questions regarding the nature of citizenship and law's subjects may rapidly emerge. Might rights to security of the person be reasonably extended to digital persona? Could digital persona be meaningfully held liable for the consequences of choices—perhaps even automated choices resulting in automated law enforcement, for example, tracking fraudulent use of social services? And might multiple digital persona be held by the same originating legal agent, mirroring his or her dual citizenships, or special positional duties in specific contexts? Some of these concerns might become especially pressing as e-citizens take their digital personas from service delivery to public consultations and other exercises in democratic participation in law making or policy making.

## E-Government and Democracy

*E-engagement* of citizens raises concerns for both descriptive and normative approaches to legal theory, as technology may be implicated in reducing or raising fresh barriers to citizens' meaningful access to information, and participation in governance. Australia, Canada, the United States, and the United Kingdom have all engaged

in extensive e-consultation exercises, typically gathering public opinion regarding policy options (excellent links may be found at http://www.egov.vic.gov.au/Research/ElectronicDemocracy/edemocracy.htm). Consultations are typically Web-based exercises in provision of information, online deliberation (using tools such as discussion fora), and opinion gathering via questionnaires and similar mechanisms. E-voting is also being piloted in several jurisdictions, motivated by hopes of cost, reliability, and security improvements over paper-based ballots. These methods of e-participation may be particularly worth investigation in the context of some states' pursuit of internal devolution. In the United Kingdom, for example, Scotland and Wales have regained limited legislative authority and aim to exercise that authority in novel ways intended to redress a perceived lack of trust and engagement between government and governed. The Scottish Parliament, for example, is pioneering a Web-based e-petitions system, allowing anyone to petition the Scottish Parliament on a matter within its jurisdiction (www.e-petitioner.org.uk). Yet this experiment, like many others, has had limited success, for reasons including low participation rates and reluctance on the part of elected officials to share or surrender authority to the results of novel processes in which few citizens have participated.

In the absence of substantial effects on governance practices or the structure of government, legal theorists have had few reasons to suppose e-participation amounts to anything more than local attempts at reform to better enable specific political systems to strive for democratic ideals. To be sure, there are ontological issues regarding the possibility of "virtual community," speculation regarding the possible fragmentation of political discourse (Sunstein, 2001), and concerns regarding the digital divide and access to a virtual global civil society. Yet these debates are largely at the periphery of legal theory, at its juncture with sociology, political theory, and other investigations. Some beginning attempts have, however, explored the potential effect of e-petitioning and e-consultation on the relation between law's officials and private citizens and their role in constituting a discrete legal system. Increased citizen participation in consultative processes may blur the lines between officials' and citizens' roles in the formation and interpretation of laws, causing difficulties for state-based theories of law which look to the practices of officials to delineate the borders of a legal system and state containing that system (Culver, 2004). Where the nature of officials becomes obscure, it may become difficult to assess the borders of particular legal systems, and novel descriptive approaches may need to be devised. It remains to be seen whether these e-participation devices are utilized sufficiently to warrant further attention.

## FUTURE TRENDS: E-GOVERNMENT AND LEGAL THEORY TOMORROW

E-government has not yet caught the full attention of legal theory. Yet as the developments discussed above approach maturity as technologies and services, it seems this situation may change as e-government advocates will look beyond the current focus on business transformation and provision of transactionally secure citizen-focused services. In leading jurisdictions such as the United Kingdom and Canada, the first generation of e-government service delivery is nearly complete as more than 70% of central government services have been put online. At the same time the problem of the digital divide is changing. No longer are governments faced with the analytically simple problem of providing all citizens with Internet access. As technologies converge and Web-enabled mobile telephones become widely available, the new problem becomes one of a choice of the kind of government services and citizen engagement practices to offer to citizens. The next step is unlikely to come easily. In jurisdictions such as the United Kingdom, early enthusiasm and novel roles such as Andrew Pinder's service as "E-Envoy" have diminished. As Pinder's replacement charged with finding a new role for e-government in something other than an "E-Envoy" unit, Ian Watmore has become head of the newly founded E-Government unit reporting to the Minister for the Cabinet Office—a far less striking title, and an office clearly within an existing policy silo and not "running loose" as an innovator. Yet even as leading e-government states examine missed targets and cost overruns and consider whether e-government is worth the trouble, there are reasons to believe that e-government developments relevant to legal theory will continue to develop in ways which have substantial implications for thinking about legality, legal system, citizenship, and law's capacity to obligate.

Business transformation and operational efficiency do not exhaust the ideal of citizen-centered governance, and in cross-department standard setting, information sharing, and service we may see the core of e-government's "second generation" benefits for citizens. Portal-based service delivery has required departments and agencies to share responsibilities and to develop joint policy-making capacity. At the same time calls for increased public consultation on government policy have been matched by nongovernmental demonstration that the Internet is a powerful tool for provision of information, gathering of opinion, and coordination of political pressure. Supporters of Governor Howard Dean of Vermont, for example, used the Internet (http://archive.deanforamerica.com/) to convey information, raise funds, and via blogging to provide for debate amongst

Dean supporters. Similarly, protests against the WTO meetings of 1999 in Seattle were organized via continuously updated Web sites, and "smart mobbing" or text messaging of virtual and physical meeting points for protesters. These developments suggest that the empirical preconditions exist for significant changes to the roles of legal officials both elected and nonelected, and perhaps changes in the role of citizens as well. Historically evident gaps between legal officials' and citizens' knowledge of law and policy issues are rapidly closing as the Internet makes information available to all at the time and place of their choosing. This fact, taken together with the call for increased public consultation on policy issues, suggests that the role of representatives could change very rapidly, and the extent of that change ought to be subject to legal theory's scrutiny. From the perspective of descriptive jurisprudence, researchers might ask whether such changes amount to a functional shift in the identity of legal officials, as well-known international nongovernmental organizations (NGOs) bring their knowledge and influence to bear on relatively ill-informed local officials seeking public input on policy. Normative questions arise also. What does respect for autonomy require us to do for citizens if we have ICTs which enable an increase in the quantity and quality of citizens' interactions with elected representatives? Can the duties of elected representatives remain as they have traditionally been?

Questions about interaction between citizens and officials in law-making and law-varying practices do not stop within the boundaries of the state. As the European Union and the North American Free Trade Agreement (NAFTA) states form stronger economic and social ties, some states are recognizing regional claims to distinct identity. This practice can be seen in the United Kingdom's consideration of a Northeastern Assembly to join the nationalist-inspired assemblies of Scotland and Wales. As citizens are increasingly able to conduct business and maintain political allegiances via electronic means and without regard for time or distance, questions of cultural and state membership will be raised in new ways, and the protection (and sometimes surveillance) of digital personae may raise complex descriptive and normative questions regarding the nature and use of such personae. Perhaps more interestingly, and more clearly connected with orthodox legal theory, it seems possible that the way e-government makes time and distance irrelevant to commerce and political participation may also make the state appear less relevant as an object of allegiance. If the state becomes little more than a geographically or linguistic placeholder for specific treaties and cultural icons, it will no longer be clear that law's capacity to obligate resides in the state's demand for allegiance (and promise of protection).

## CONCLUSION

The second generation of e-government service delivery may soon cross national boundaries to fit economic and social regions, and e-participation may follow suit. If e-participation blooms to become the de facto basis for national and international policy making and additionally informs the content of legal norms, the sheer numbers of participants and shared practice establish an international law making, varying, adjudication, and enforcement system whose legality is beyond question. E-government on the back of the Internet might yet be the author of international law, and legal theory may become primarily global in focus, leaving the state an historical rather than logical creature. Change of this magnitude would certainly amount to a revolution in legal theory. Early attempts in legal theory to gauge the impact of incremental changes tend to suggest that legal theorists are preparing to engage the revolutionary change e-government may bring to the nature of government, methods of governance, and relations of citizens and officials to law and government.

## KEY TERMS

**Descriptive Legal Theory:** descriptive, explanatory, or otherwise nonjustificatory study of theoretical or general dimensions of law, legal system, and law's normative force in general and in specific departments of law, for example, international law, criminal law, tort law, environmental law, and so forth.

**E-Consultation:** most narrowly in the context of government relations to citizens, use of ICTs to enhance or replace attempts to solicit commentary and often discussion of proposed policies, legislation, or other commitments, often deployed in an attempt to demonstrate government accountability to citizens and to generate trust in government's decision-making process. More broadly, use of ICTs by government officials to provide information, solicit commentary on set options, or solicit novel options for policy or legislation.

**E-Petition:** an ICT-enhanced, typically Web-based, petition typically providing the terms of the petition, information related to the petition, signatures, and commentary, all accessible at the time and from the place of viewers' choosing.

**Normative Legal Theory:** morally, politically, theologically, or otherwise evaluative study of theoretical or general dimensions of law as described in the context of descriptive legal theory. Normative legal theory seeks simultaneously to understand and to evaluate legal phenomena, typically insisting that the act of understanding is necessarily simultaneously an understanding of that phenomena in light of its point or purpose.

**Silo:** metaphorical reference to vertical chains of authority and responsibility in government; in operation characterized by absence of sharing of problems, resources, authority, or responsibility despite apparent advantages to doing so.

# E-Government at Supranational Level in the European Union

*University of Salerno, Italy*

## INTRODUCTION

The term "e-government" became part of the political vocabulary toward the end of the 1990s. Previously, with the onset of new technologies, it found its place in the wider "semantic container," the information society. To respond to the United States and Japan's economic challenge, the European Commission drew up a "White Paper on Growth, Competitiveness, and Employment: Challenges and Ways Forward to the 21st Century" (the so-called Delors' White Paper). The construction of the IS is considered one of the five fundamental priorities of the Union to create a "common information area" based on ICTs and telematic infrastructure. E-government was the key element of significant community programmes (i.e., IDA [Interchange of Data between Administrations] and TEN-TELECOM [from 2002 renamed eTen]).

A decisive step toward the development of EU policies for e-government came with the approval, in June 2000, of the Action Plan "eEurope 2002: An Information Society for All." Guidelines were fixed for greater use of the Internet, and the initiative "Government online: electronic access to public services, [which] aims to ensure that citizens have easy access to essential public data, [...] [and, in order to improve] efficiency in the public sector, will require a re-thinking of internal organisation and of electronic exchanges between institutions" (Council of the European Union & Commission of the European Communities, 2000, p. 22).

A few months previously, based on numerous EC documents, the Council of Europe of Lisbon indicated an ambitious objective for the European Union: "to become the most competitive and dynamic economy based on knowledge in the world, capable of achieving sustainable economic growth, creating new and better jobs and more social cohesion." The so-called "Lisbon strategy" to permit Europe to recover the delay accumulated compared to the U.S., was intended to guide community policies up to 2010. It is in this context, interwoven with different and often conflicting pressures (economic competition and social cohesion, market logics, and the language of rights) that action plans are formulated and policies for e-government implemented in Europe.

## BACKGROUND: E-GOVERNMENT BETWEEN MARKET-POLITICS

The context of e-government in Europe is in the dynamic framework of three key issues:

1. The globalisation of the economy and the challenges posed by competitors on the global market
2. The construction of a European identity (enlargement, constitution, the existence of different models for European development and issues relative to the democratic deficit of the EU)
3. The exponential growth of the ICT sector and the Internet

E-government represents a core issue in these areas (i.e., effective implementation should lead through the integrated use of ICTs (3) and together with organisational change, to economic advantages for the public and private sectors (1), and a greater integration of the "European system" (2)).

The vision of e-government at EU level is quite differentiated. The EU strongly promotes open markets and competition while maintaining commitment to specific principles of the European public law tradition and human rights (embraced by the Fundamental Charter of Human Rights, integral to the EU constitutional framework). These factors have significant implications for e-governments policies, which embody the institutional expression of values such as human dignity, participation, and transparency (Van Cuilenburg & McQuail, 2003) to be safeguarded when implementing e-government solutions.

There is evidence that the development of e-government, more than acting as a catalyst for the processes previously described, has played the role of dependent variable. Thus, European strategies for e-government have been determined by economic and technological considerations rather than social or cultural factors.

If "the simultaneous existence of three divergent approaches—the EU liberal market model, the EU public service model and the EU national-cultural model—to the Information Society confers a unique character on the European communications market" (Venturelli, 2002, p.

79), policy decisions or policy perspectives have ended up being "*mainly technologically and/or commercially driven*" (Servaes & Heinderyckx, 2002, p. 98). Support for this view comes from the structure of many Community position papers (from the Delors White Paper to the Green Book on the Information Society of 1997), where a preference for deregulation and liberalisation endows the private sector with a much larger role (Kaitatzi-Whitlock, 2000) than the public authorities, which retain the residual role of "establishing new rules for the game" (Commission of the European Communities, 1994).

There have been remarkable repercussions on the development of e-government. The Commission has in fact left ample margins for Member States action, not only in terms of the principles of subsidiary and decentralisation, but also in the legal area. The Amsterdam Treaty (1997) gives the Commission no legal authority to intervene in relation to the public administrations of Member States. Consequently, any changes that concern the public administration cannot be imposed *top-down*, but must be *bottom-up*. The EU context is neo-liberal and increasingly market-oriented, although the form that this takes at national level is rather more differentiated than might be suggested (i.e., each country to its own specificities) determined by national political objectives and administrative traditions.

The EU has developed a new form of governance to tackle these new challenges: the open method of coordination (OMC) a soft-law instrument which allows the Union to fix guidelines which Member States must then translate into specific policies and benchmarking systems.

## CONSTRUCTING A EUROPEAN E-GOVERNMENT MODEL

Clearly, a coherent and united European Union policy on the issue of e-government does not yet exist, and no single document expresses the strategies pursued by the Commission. However, by analysing the documentation produced, it is possible to locate specific elements that enable us to outline a European model of e-government. Among the most significant documents, are "e-Europe 2005: An Information Society for All"—the continuation of the action plan "e-Europe 2002," "The Role of E-Government for the Future of Europe," and "E-Government in Europe: The State of Affairs," presented at the European Conference of Cernobbio (Italy) in 2003 (Leitner, 2003).

European e-government appears to be characterised by the following elements:

1. Close attention is paid to the technological and infrastructural dimensions: viz. in eEurope Action Plans, where reference is made to initiatives "[t]o stimulate the use of the Internet" and to create "a cheaper, faster, secure Internet" (Council of the European Union, Commission of the European Communities, 2000, p. 2) as well as for the diffusion "of broad band infrastructures" (Commission of the European Communities, 2002)
2. From the centrality of technical issues, interoperability emerges as an important factor: "[s]tandardisation in technology and harmonisation in legislation are just two ways to achieve this" (IDA, 2004, 24). Standardisation in organisations, infrastructure, procedures, and above all in semantic codes and legislation is needed, to encourage safe and clear interaction between Europe's public administrations. The Commission's working paper "Linking up Europe: The Importance of Interoperability for E-Government Services" (2003) and then an actual framework document, the "European Interoperability Framework for pan-European E-Government Services" (2004) is in this direction
3. By decentralising the context of decisions and policy implementation, in line with the principles of subsidiarity and regionalisation (reiterated in the White Paper on European Governance), the role of states, regions and municipalities is exalted. The declared objective is to enhance territorial and cultural specificities, although the legal limits posed by the Treaty are also relevant here
4. The preference for open source software, compared to proprietary brands: this is motivated by the need for interoperability and to reduce costs, although object of much criticism (CompTIA, 2004). This controversy has been fed by the confusion made in specific documents between open source software and open standards

Clearly, on the political plane, the most problematic issue is the reconciliation of objectives two and three (i.e., finding an uneasy (but necessary) balance between the *top-down* standardisation and *bottom-up* enhancement of territorial and cultural differences). These dynamics risk producing *top-down* policies centred on technology and a fragmented *bottom-up* policy concerned with decentralisation:

*Member States' preference for administrative autonomy has to be balanced against the Union's need for effective and uniform implementation. […] The European context suggests that administrative convergence is more likely to follow from attractiveness than from imposition.*

*Convergence is also more likely to be an artefact [sic] of substantive policies than the result of a coherent European administrative policy.* (Olsen, 2002, p. 6)

To identify areas of intervention of EU e-government policies, the measurement approaches that have been adopted are useful. The EU aims to measure "the percentage of basic public services available online." Member States have agreed to a common list of 20 basic public services, 12 for citizens and eight for businesses. Progress in bringing these services online will be measured using a four-stage framework: (1) posting of information online; (2) one-way interaction; (3) two-way interaction; (4) full online transactions, including delivery and payment.

Public services for citizens are:

1. Income taxes: declaration and notification of assessment
2. Job search services provided by employment centres
3. Social security contributions (3 out of the following 4):
   - Unemployment benefits
   - Child allowances
   - Medical costs (reimbursement or direct settlement)
   - Student grants
4. Personal documents (passports and driver's licences)
5. Car registration (new, used, and imported cars)
6. Application for building permits
7. Declarations to the police (e.g., in case of theft)
8. Public libraries (availability of catalogues, search tools)
9. Certificates (birth, marriage): request and delivery
10. Enrolment in higher education / university
11. Communication of change of address
12. Health-related services (e.g., interactive advice on the availability of services in different hospitals; appointments for hospitals)

Public services for businesses are:

1. Contributions paid by employers
2. Corporation tax: declaration, notification
3. VAT: declaration, notification
4. Registration of new companies
5. Submission of data to statistical offices
6. Customs declarations
7. Environment-related permits (including reporting)
8. Public procurement

The aim is to achieve a seamless e-government, and every European public administration must, in theory, deliver all public services online. However, it is clear from the various official documents, that e-government in Europe risks being reduced to the delivery and use of 20 public services online.

By identifying this list of services, the EU has attempted to negotiate a difficult balance. Consequently, emphasis is often on the administration (e-administration) rather than government (e-government). This means "neutralising" the process, attributing to it a lesser political relevance. Moreover, it is not considered that different views of e-government produce different impacts on the enjoyment of old and new fundamental rights (privacy, security, access, freedom of expression, *habeas data*) by citizens. As Strejcek and Theil (2002) state, in relation to changes in the balance of values that shape e-government policies, implementing e-government solutions can cause a conflict with the European Convention of Human Rights (ECHR), which should be integrated into policies. Clearly, no neutral model of e-government can exist.

The route pursued by the Union seems to be dictated by the legal limits imposed by the Treaty on the Commission's room for manoeuvre: the only option appears to be delineating a framework on e-government, leaving the development of Action Plans and local specifications to the States and Regions.

The fragmentation of EU-level policies, highlighted by the redundancy of bureaucratic and executive layers (see Table 1; Alabau, 2003) plus a "bottom-up fragmentation" deriving from the different approaches and objectives associated with each national context is the outcome. An example is "life events" that fall within the range of the twenty essential public services. As underlined by IDA, "in relation to life events there is currently no common set of life events mutually agreed between Europe's public administrations. The eEurope initiative identified a set of 20 basic public services for benchmarking. Among the Member States, wide divergences exist on what are considered life events, with, for example, Italy identifying 15, Ireland making do with 10, while the UK has 12" (IDA, 2003).

## TOWARD A "EUROPEAN ADMINISTRATIVE SPACE"

Clearly the future scenario is determined by the Lisbon (2000) objectives. Through initiatives such as IDAbc (Interoperable Delivery of Pan-European E-Government Services to Public Administrations, Businesses, and Citizens) and eEurope 2005, EU policies will continue to be "technologically and commercially driven." However, "what can be recognised from the many initiatives and

*Table 1. Summary of main bodies implementing the e-government policy of the European Union (Adapted from Alabau, 2003)*

| SUMMARY OF MAIN BODIES IMPLEMENTING THE E-GOVERNMENT POLICY OF THE EUROPEAN UNION | | | | | |

strategies toward e-government is a huge demand for holistic approaches going far beyond present-day technological developments" (Wimmer, 2002, p. 94). There is renewed interest, on the part of the Commission, in the demand for services and for citizen-customer needs and expectations regarding public services. We can find this trend both in eEurope 2005, where the task is to ensure that public services are fully available on line and actually used, and in the evolution of the IDA Programme, which has shifted over recent years from back-office issues to the delivery of services.

It is too early to say whether this will be a consolidated trend in the future. Significant initiatives albeit at a preliminary stage, such as a Web Portal for EU administration, are in act. This project, by the European Commission IDA Programme in December 2000, is an unprecedented opportunity for creating a "European Administrative Space" that favours citizens mobility within the EU and the constitutional right to good administration, as established by the Constitution, and drafted by the Convention on the Future of the Union. This policy, furthermore, is in the wake of the initiatives launched by the European Commission to facilitate innovative developments by means of European-wide projects such as the "eGov: an Integrated Platform for Realising On-line One-Stop Government" (Wimmer, 2002).

The different types of constitutions that co-exist within Europe influence e-government processes, as far as the implementation of the Treaty is concerned as well as Members' attempts to conserve autonomy. These are focal issues in the context of support for open source (OS) software. A review of statements accompanying OS policies and legislation at national, regional, and local level suggests that acquisition decisions are influenced by considerations such as dissatisfaction with the leading U.S. role in software development and the hope that the use of open source will encourage indigenous software industry, as well as the desire to reduce the cost of information technology.

These issues are the responsibility of the public administration, and the Commission merely provides incentives for the use of OS software. There is a risk that the many solutions adopted by national and regional decision-makers will have repercussions for the development of a European Administrative Space, which remains the main objective of e-government policies for the future.

## CONCLUSION

The reinforced position of e-government in the 2005 Action Plan shows that e-government is currently one of

eEurope's biggest challenges. The 2002 Action Plan aimed to bring government services online. The second task, addressed by the 2005 Action Plan, was to ensure that these services are widely used and that interactive services are available. Here, greater emphasis is on demand-side issues, such as awareness, confidence, security, and public service. The e-Europe mid-term review draws attention both to the progress made in areas that are considered crucial to the development of the Information Society and on the key challenges for the coming years. A slowdown in the growth of e-government services has been noted by a number of commentators, and this seems to characterise the development of e-government policies worldwide (Accenture, 2004). The causes are several, not least the scarce financial resources destined for the implementation of these policies (circa 0.05% of the total; Alabau, 2003). However, the limits on the Commission's interventions on the PA issue is much more significant: the OMC favours multi-level governance, but is also provoking dispersion in decision-making and content fragmentation. The Union is pursuing coherent and uniform strategies fixing guidelines, frameworks and standards, but must leave policy and strategy specifications to lower institutional levels. "Balancing the need to respect the diversity of internal structures of the Member States and the need for Members to adopt legal measures necessary to implement the Union's legally-binding acts is part of the general search for a balance between unity and diversity, common projects and national autonomy" (Olsen, 2003).

This explains the constant attention addressed by the Union for more infrastructure, an apparently neutral ground on which the Union is authorised to intervene. The Commission's desire to have a political role in the strategies and content of e-government is visible in many cases. The evolution of the IDA programme, which passed in a few years from the "exchange of data between administrations" (IDA) to the creation of a "network of administrations" (IDA II), right up to the development of "pan-European services of e-government" (IDAbc) is a case in point. The range of action has gradually gone from technological and infrastructural issues to the strategic running of front-office services. A key issue is how e-government policies can promote economic growth and improve European social and political democratic identity (Servaes & Heinderyckx, 2002). The process of legitimisation of the European project does not circulate merely through the flow of ideologies or rationalities of government, but also through instruments and practices (Barry, 2001). Pan-European services can give a substantial impetus to the Internal Market and its associated freedoms, as well as to European Citizenship, but wider and more informed debate of these issues is crucial (Centano, Van Balen, & Burgelman, 2004).

## KEY TERMS

**E-Administration:** The use of ICTs to support communication and information transmission within and outside the P.A.

**eEurope Initiative:** Launched by the EC—on 8 December 1999—"e-Europe: An Information Society for All." The initiative focuses on 10 IS priorities, from education to transport and from healthcare to the disabled for all Europeans.

**IDA:** Interchange of Data between Administrations. This Community Programme under the European Commission's Enterprise Directorate General supports the implementation of EU legislation, from internal market regulations to consumer and health policies, facilitating through ICTS information exchange between public administrations across Europe.

**Inter-Government Partnership:** Horizontal or vertical formalised cooperation between governments on the same level (e.g., local authorities, or between governments at different levels) (e.g., local and regional or national authorities, respectively).

**Interoperability:** Ability of ICT systems and business processes to exchange data and to enable sharing of information and knowledge.

**Open Source Software:** Any computer software whose source code is either in the public domain or, more commonly, is copyrighted by one or more persons/entities and distributed under an Open-Source licence such as the GNU General Public License (GPL).

**One-Stop Government:** A single point of access to electronic services and information offered by different public authorities. Online one-stop government requires that all public authorities be interconnected and that the customer (citizen, private enterprise or other public administration) be able to access public services via a single point, even if these services are provided by different public authorities or private service providers. It further requires that the customer be able to access these services in a well-structured way to meet his/her perspectives and needs.

**Portal:** Any well-used gateway to the Internet, especially those sites designed to serve as a "front door" or first page when accessing the Web. Portals typically provide large catalogues of other sites, powerful search engines for locating information and e-mail facilities or other Web services.

**TESTA I and II:** Trans-European Services for Telematics between Administrations. The IDA TESTA project started in 1996 and entered its second phase (TESTA II) early in 2000. It responds to the growing need for the exchange of information between European administrations. It envisages a European inter-administrative IP network, similar to the Internet in its reach and universality, but dedicated to inter-administrative requirements and providing guaranteed performance levels. Implementation of this vision requires a broad coverage, including all EU Member States, EFTA countries and EU accession candidates, once they have joined IDA. It also requires the connectivity to reach all administrations wishing to participate.

# E-Government Construction and China's Administrative Litigation Act

**Ruan ChuanSheng**
*Shanghai Administration Institute, China*

## INTRODUCTION

E-government has become a part of our society gradually as a derivative of the current information society. To adapt to international affairs, the country's economic development and social progress, China should expedite the transfer from a traditional superintendent government to a modern service government by building an e-government. However, there are many obstacles in the way of popularizing e-government. The "validity" and "reliability" of e-governance are key problems, because China's administrative legal system hasn't made specific laws and regulations on e-governance administration. In the current situation, it is of great and practical importance to discuss the new characteristics of e-government administration and understand the influence of information on the administrative legal system.

## BACKGROUND

Constructing an e-government means building a public-centered e-government through reorganizing the government by information technology, improving the public service, building up public participation, publishing government affairs and democracy, accelerating government office automation and, overall, sharing information resources and enhancing the efficiency of public administration, the rationality of public decision-making and the flexibility of government organs.

The e-government network project was sponsored by more than 40 Ministries and Committees of the State Council in January, 1999, in China. Driven by the central government, the Web sites of Ministries and Commissions of the State Council are getting more in numbers and richer in content. There is new progress in many fields, such as the issue and delivery of policy and information service. That is, the issue of the government announcements on the Internet, the application for import and export qualification, the collection of the suggestions on "The tenth five years' plan of the state economic development." The overall government information system will be accomplished by executing an e-government project, paperless documents, network decision-making and electronic public-service. E-government becomes a window through which the government displays its perfect image and provides its service for citizens, corporations and other organizations.

Since 2000, local governments accelerated their steps of e-government construction. For example, by the end of 2000, Beijing had already set up the public information platform and government affair network. A series of information databases that can handle the information of enterprises, population and city planning have been established. One hundred twenty-three branches of the Beijing government own the Web sites in the Capital Public Information Platform. In addition, at the beginning of 2001, Beijing Municipal stated that it will generally realize the network transaction of the examination and approval, administration, and service business for the enterprises and public within the next 2 years and realize electronic and network offices inside. Based on these, the e-government network system with perfect function, reasonable structure, high-speed broaband and interactive administration network will be completed by the end of 2005. The government affair informatization will be realized by using interactive artificial man-machine administration.

It is reported that there are nearly 4,000 fully qualified Web sites marked with ".gov" in different levels of local government in China. Most country-level governments have established their Web sites or home pages on the Internet and issued government affair information through the Web. Some developed areas did better than other regions. The network coverage of each district, county and bureau in Beijing is 94%. Sixty-five counties and cities in Jiangsu Province and 276 government organs in Shandong Province have their own Web sites. Henan Province has its network in four levels of governments (province, city, county, and countryside). Especially, Guangzhou established the high-class Government Information Network exchange platform, as well as a three-level government information network system, including city, district and street. At present, there are 56 Web sites, about 20 e-post offices and more than 300 databases for internal information and public service. The information resource exchange and sharing system has become shaped

in this way. Network offices include the administration of city planning, industry and commence, customs, taxation affairs, finance, human resources, employment, police affairs and population. For example, District Tianhe in Guangzhou completely automated its office and document transaction network.

## FUTURE TRENDS

Administrative litigation, namely judicial review, is not only one kind of legal supervision system for government administration, but also a kind of administrative legal relief system for the administrative counterparts. Such a supervision mechanism in national institutions aims at supervising the authority of the government so as to guarantee citizens' rights.

The construction of e-government brings challenges to China's legal system while benefiting the administrative counterparts and enhancing the efficiency of the government.

### The Challenge of the Legality Censor of the Administrative Procedure

The most important symbol of administration by law is the legality of administrative procedures. Administrative procedures contain the manner and steps of administrative action. Legality of the administrative procedure is a very important statutory requirement of the courts maintaining administrative action. E-government makes things complicated.

Whereas the control mechanism is weak in maintaining citizens' rights and interests, many countries constituted the administration procedural law to protect the legal rights and interests of the administrative counterparts, restrict the administrative action and prevent the government from abusing administration authority after World War II. Although China doesn't have a uniform administrative procedure act, many regulations on administrative action do exist. Each country's regulation on the manner of administrative action normally requests that the administrative action must be sufficient and positive in content.

"The parties should be informed in written form except some special cases" (Huaide, 2000, p. 232). Written form is different from oral form. Some solid materials are used as the medium to act on people's sight. Because paper is good for carrying, writing and preserving, it becomes the most popular writing material. Written form in our daily life refers to the paper used for writing. In the law documents, that is, "written form." Written form accords with the exact requirements of modern administration, so administrative law requires administrative organs to execute administrative action in written form, and this requirement turns out to be one of the essentials for the effectiveness and validity of administrative action. For example, Spain's Administrative Procedure Act (no. 55) prescribes that administrative action must be in written form unless other more suitable expressions or demonstrations are allowed. China's Administrative Sanction Law (no. 39) also makes it clear that the administrative sanction should be a formal and written one. Furthermore, in no. 3, the administrative sanction is action of nullity if it doesn't follow the legal proceedings. Using the written form can not only remind the government to be careful with its decision-making but also protect the legal rights and interests of citizens, corporations and other organizations who can prove the administrative dispute by bringing forth the written form of administrative action to the court when they are suing. Constituting law in written form becomes an obligation of the administrative organs.

E-governance is supported by an information network, so electronic documents come out. There are many differences between an e-document and a written one: (1) the automatic readability of information; (2) the reliance on an electronic system, as the e-document relies on certain electronic hardware, operating system and application software; (3) the non-information of the carrier. The paper document together with the handwriting and seal proves the original identity, while an e-document has no such identification; (4) flexibility of handling information. People can edit e-documents freely without being noticed. Most current administrative law and regulations do not prescribe e-government administrative action, so it is very difficult for the court to check the validity of the e-government action in the administrative litigation.

There will be more and more administrative cases concerning e-government. The legislative draft of administrative procedures stipulates that administrative organs have free judgment right on using e-administration while the administrative counterparts have free will. How to balance the relationship between administration and law is a new problem in front of the court. For example, if the administrative organ employed an action that the counterpart disliked, the party considered that the administrative action had no law gist and appealed discharging. What would the court do? According to the administrative litigation act, the court should discharge the administrative action when the procedure is transgressing. Discharging will frustrate the construction and improvement of e-government because it does accord with the national policy and the trend of law. But there is no gist for not discharging. Above all, we had better perfect the concerned legislation and justice explanation as soon as possible while having enough mental preparation for meeting unexpected trouble in the checkup of administrative litigation validity.

## The Challenge of Confirmation of Administrative No-Action

According to the Administrative Litigation Act of China (no. 11 item 8), an administrative counterpart has the right to prosecute when administrative no-action violates his or her personal right and property right. "Some explanations about the execution of 'Administrative Litigation Act of the Peoples' Republic of China' by highest court" (JianMiao, 1998, p. 165) specifically prescribes that the party has the right of prosecuting administrative no-action when the administrative organ has not replied nor made a decision within 2 months after it was requested, except for additional prescription of laws, rules, regulations and other criterion. The "administration admission law" under discussion has a specific prescription on the application sent by e-mail. If the administrative organs fail to open the e-mail sent by the counterpart, they cannot know the details of the application and contact information of the counterpart. That will result in the failure of informing the counterpart of changing the style of application in time. In this situation, the counterpart may figure the administrative organs have not replied or made a decision within the legal time limit and prosecute the administrative no-action. It is worthwhile to research how the court confirms the administrative organs make no-action for the application of the counterpart.

## The Challenge of E-Document Censor as Evidence

The evidence of administrative litigation refers to all data or means that can prove the truth of administrative cases. The counterpart submits an admission application to the administrative organs by e-mail before the deadline. If the administrative organ does not reply or make a decision within the legal time limit, the counterpart can consider that the administrative no-action affected his rights and interests and lodge administrative litigation to the court. In such a case, the court must censor whether the administrative organ received or opened the e-mail. The original carrier, style, time and maker of the e-document must be checked, too. Besides, the court must synthetically censor the e-document evidences, make an objective and fair judgment, confirm the relation between evidence and law case, and eliminate irrelevant evidence with judiciary morality, logic reasoning as well as living experience. Compared with traditional written documents, e-documents have some additional characteristics, such as being changeable, traceless and public. It is possible to change e-documents for certain illegal purposes. It is difficult to identify the original files, because e-documents are traceless. Publicity makes the danger of tampering with e-documents greater. They challenge the judge's professional qualification.

## The Challenge of Administrative Compensation Caused by E-Government

One of the purposes for e-government construction is to publicize governmental affairs. In other words, the counterpart is able to obtain information about law and regulation through a network. If some wrong information in the Web site brings property loss to the counterpart, it may result in a dispute on administration compensation. Since the government is obligated to issue the correct information, according to the principle on depending and protecting, the counterpart ought to be compensated for losing due to wrong information issued by the government. With the advance of our e-government construction and the development of an opening administration system, more and more government information will be issued through the government Web site. With the development of the economy and improvement of information construction in China, more and more citizens can access governmental affairs through a network expediently. The number of administrative compensation litigation on wrong information issued by the government will rise gradually. The rights and interests of the counterpart can be supported by the administrative compensate case cognizance. The government must be aware of the responsibility of issuing correct information and reducing mistakes on the Web site.

## CONCLUSION

The administration manner has so many new characters with the development of information technology in modern society. Such characters have an impact on the present administrative litigation system, more or less. Some can be forecasted preliminarily, some cannot. For sure, the government must execute administration under the law to establish the nomocracy. The development of e-government is no exception. The construction of e-government has become one necessary strategic measure facing the tidal wave of information. It is one important part of administration and nomocracy construction in the 21st century. We have to reflect on it in advance as well as envisage and respond to all kinds of new challenges and problems about e-government.

## KEY TERMS

**Administrative Action:** The action of administrative subject, according to administration law, refers to the action of state administrative agency and its personnel.

**Administrative Compensation:** In the case of unlawful administrative acts that infringe upon a citizen's personal rights and unlawful administrative acts infringing upon the property rights of a citizen, the liability is undertaken by the administrative agency.

**Administrative Litigation:** The suit that, if a citizen, legal person or organization considers that its lawful rights and interests have been infringed upon by a specific administrative behavior of an administrative organ or its personnel, is brought before a court in accordance with the law.

**Electronic Document Censor:** The censorship through the way of electronics communication.

**Readability of Electronic Information:** The quality of information presented in electronic form that makes it easy to read and understand.

# E-Government Development in Nanhai City, China

**Yao Yongling**
*Renmin University of China, China*

**Wang Junsong**
*Renmin University of China, China*

## INTRODUCTION

Nanhai is a small city which belongs to Foshan City (a district can also be called a city in some cities of China) and lies in the central part of Guangdong province. It is in the hinterland of Pearl River Delta, close to Hong Kong and Macau. It was in 1995 that the city began to develop e-government. In September of 1996, it became one of the first cities that started to operate the Internet in China. Since 1999, the city had transferred into the period of Internet application. It became the national experimental field of an informalization process in 2000 and of an e-government application project and national information security project in 2001. However, since 2002, lots of problems have been appearing due to overemphasis on the construction of an information infrastructure and noticeable projects. Chinese e-government has been at the stage of a realistic period, with data shared among departments since 2000. Some weaknesses of the appraised projects have been appearing because of short service for urban development and the requirements from the city administration. Therefore, this case is just a description of the periodical success and would be a problematic case of the process of Chinese e-government.

## BACKGROUND: E-GOVERNMENT IN CHINA

E-government can be described as being divided into three periods since the 1980s in China: that is, office automation (OA), sector administration with IT, and e-service of government. Each period is marked by the following.

### Office Automation (1980s)

The primary computer system used by the government was designed to work for economic statistic data analysis before 1980. Since the 1980s, the government had started to set up OA systems, which were also used at the provincial level. Most of the systems were organized by the secretariats in provincial governments. During that period, the systems were popularly used in the inner governments; the staffs of the systems were either full time or part time. Many governmental departments, such as industrial, commercial, revenue, financial, police departments and so on, had began to establish their own systems since that time.

### Sector Administration with IT (1990s)

With more users of OA, there were some special IT branches in the governments (Technical Division, Information Centers, etc.). Commercial departments, revenues, financial bureaus, and police bureaus built their special application systems. Three "Gold" projects had been started since 1993: Gold-Bridge, Gold-Gate, and Gold-Card. The projects were invested by the central government. The main parts of the projects were basic infrastructure, which would provide data transferring (Gao, 2004). This period was the primary stage of e-governance.

### E-Service of Government (2000-Present)

When the Internet became popular, governance-online was promptly carried out in China. The Chinese government carried out the Governance-Online Project in 1999. Going with the project, the number of Web sites whose domain names were ended up with "gov.cn" had reached 11,764 by December 31, 2003. The number of governmental home pages was more than 10,051. The ministries (26 of 29) and commissions of the state council have set up their own Web sites. Among them, nine of the home pages had an English version, 12 Web sites could provide services online, and 90% of the home pages had either an information board or querying database service. Additionally, 70% of prefecture cities' home pages had service windows for public affairs (Xue & Huang, 2004). Since

that time, some integrated e-governance projects have started to be planned and implemented. The projects were composed of e-service for social insurance in which five types of insurances were integrated into one. There was an official approving process on one Web site, city smart cards on one, integrated economic database, population database, urban geography information system, urban emergency commanding system, and so forth.

The development of e-government has a close relationship with the rapid growth of the economy in China. The characteristics can be represented as the following: Among basic infrastructure, information releasing, and data exchanging, the two former have been done better than the last one.

When the segmentation of e-government is divided into vertical and horizontal categories, the sector special service in the vertical segmentation is much better than the local e-governance in the horizontal one.

- The force to use IT comes mainly from the administrative command of government.
- The adopted IT techniques in China are almost on the same schedule with developed countries.
- The levels of e-government are obviously different among different regions and different departments.

The city of Nanhai just started OA systems earlier than other counties. It happened at the same time of national and provincial experiences. Therefore, there were some pioneer projects which got praise from the state.

## THE MAIN STRATEGY AND SITUATION OF NANHAI E-GOVERNMENT

Nanhai e-government is a typical example of local e-government in China. It has started the stage of sector administration with IT since 1995, which was the leading one with good infrastructure and good vertical and horizontal links in China. The features of Nanhai e-government were the connections of networks both in vertical and horizontal links. This created the fundamental framework of e-government. Through e-governance and e-finance management, a lot of sectors were also encouraged to use IT. These were successful strategies for Nanhai e-government.

### Vertical Link

A vertical link has been achieved at the city, town, and village levels. All the administrative organizations have built up the office local area network (LAN). Eighteen towns (or districts) of the city have established finance and account centers to manage their affairs online. On the other hand, other cities' information could not be encouraged by the government because the e-governance lagged behind the city information.

### Horizontal Link

At the same time with vertical links, all the departments have also been connected with the Internet in Nanhai. The governmental information network center and data exchange center have been set up. Some projects about management systems, such as family planning, land management, court register judgment, social insurant services, health system, and so forth, have become the typical ones all around the province and the country. For example, the application of GIS and GPS with the map of scale 1:500 provided the digital tools to optimize the allocation of land resources. On the other hand, horizontal links seldom happened in other cities, even in some metropolises. This will be the future situation of e-government in China.

### Using E-Government to Deal with Governance and Financial Affairs

An office automation system and finance management system had been established in Nanhai when the e-government program started. The financial settlement center was built in 2001. It could centrally manage the administrative organizations which let the local account open to the public. Public bidding was carried out on the network with some projects like pharmacy purchasing, engineering projects and land auction, and so forth, in Nanhai. In 2002, Nanhai first used "public assets management information system" to manage the public assets on the Internet in China.

### E-Governance Promoted the Informalization Process of the Whole City

E-governance promoted the civilian information in Nanhai city. Up to now, e-government had covered both city and town levels. Following this progress, all the 250 villages in the city had been connected by optical fibers; all the families could connect to each other through the Internet; the IT penetration rate to traditional industries had reached 65%; and all the schools have built computer rooms (Liang, 2002). As a result, long-distance education, e-hospital, selecting radio or TV channel by Internet, e-

shopping, and so on, had been popular in the city. On the other hand, other cities' information could not be encouraged always due to be the lagged e-governance.

## THE CONSTRUCTION EXPERIENCES OF NANHAI E-GOVERNMENT INFRASTRUCTURE

Nanhai has had a great success in e-government in China. It is because the mayor put information construction as the main strategy of the city development, which was known as "leadership project". During the whole process, some typical models and experiences were available to be shared with other cities in China.

The construction of e-government infrastructure was totally managed by the mayor.

There was a special organization (information commission) to manage the construction of information in the city. The commission consisted of three sections: an expert panel, information office, and network center. Among them, the expert panel was responsible for decision making; the information office was responsible for the planning and management; the network center was responsible for technical issues. At the same time, all the departments have built related organizations at different levels. Therefore, the information systems were harmoniously operated from high to low levels. This broke through the shortcomings of lack of special organization and made Nanhai enter the normal schedule of information progress.

### Unifying Infrastructure Construction

Two ways were adopted to unify the infrastructures. "Integrating three systems (television, telephone and computer) into one" and "one database network with spatial data, attributes data and network data" have been originally required to build a physical network on the basis of a public communicative network (Zhou, 2004). For a smooth process, the Nanhai information network center was invested by the science and technology office, post office, broadcast and television office. The center was responsible for planning, constructing, and operating the network of the whole city. As a result, the stock system was adopted to coordinate different benefits to avoid the disadvantage of disputes among departments. This allowed the information resources to be shared all over the city.

### Government-Driven, Market-Induced and Enterprise-Operated Model

The administrative system would be changed by a network with the government-driven, market-induced and enterprise-operated model. First, the government played only the role of collaborating and coordinating among different sectors and set up a public network to make a platform for the city information. Secondly, enterprises themselves developed the application systems. Thirdly, information construction was invested by different investors (foreign capital, folk capital, and all kinds of risky funds). Dozens of IT enterprises had grown up and become gradually a main part of the city information since 1995 (Gu, 2004). All the above factors promoted Nanhai into one of the first group of information cities in China during the second period of China.

## PROBLEMS OF NANHAI E-GOVERNMENT

Nanhai is only at the level of county administration which belongs to Foshan City. Like other cities in China, the legislation system of e-government is not perfect; the traditional ways are the obstacles; there is inefficient coordination among departments; it is lacking of IT professionals in governments. Among these problems, openness of information, benefits among departments, and the bottlenecks of experts are the key problems in Nanhai. Some of the problems are the ones which are ubiquitous in other cities in China; others are the unique ones which only happen in Nanhai.

### Two Issues about Information Policy

There is almost no independent intellectual property product in China. The computer system of e-government, including hardware, software, operating system, network administrative software, application system, database, firewall, network connect equipment, router, server, and modem are all imported from abroad. Almost all the TCP/IP protocol, computer CMOS chips are INTEL products; and the software is basically WINDOWS or NT. There are big gaps of system security and security protocol between China and the developed countries. This impacted on the network security in China.

Some questions are without answers. First, who can decide the contents of open information? Second, how to ensure the efficiency and accuracy of the opened information? There is no law or rule to deal with the two problems in Namhai until now. This problem belongs to the national level.

The reason that the standard of e-government is lagging behind the application is the lack of a uniform planning guide for local governments and departments. In January of 2002, a project team to standardize e-government was organized in Beijing by the information

office and standardization commission of the state. The team is now working on some standards.

## Interest Division Slows Down the Progress of Systems Integration

E-Governance and traditional governance exist simultaneously. This resulted in some conflicts. The suppliers of the constructing platform are multisources; the standards of hardware and software are different; different systems are difficult to integrate.

There are two approaches for the construction of e-government in China. One is horizontal connections among provincial governments. Another connection is inner sector links at different levels. Each of the connections has different planning systems. Therefore, it is difficult to share data between the two segmentations. The typical segmentation is among the three networks. The broadcast network, telecommunication network, and computer network are isolated systems. It is impossible to share data among them. For example, the broadcast department refused to be integrated with the telecommunication system because their market shares overlap. Another issue is the unreliability of benefits. There was a proposal in 2000 which let departments invest in developing IT technology. But finally, it was rejected because the departments did not like to invest more without specific corresonding income.

## More IT Professionals Required

With the rapid growth of information technology, large quantities of technical professionals are required. But a shortage of IT professionals and low IT skills of civil servants make the challenge of promoting e-government in China great.

First, many high-tech talents have gone abroad. In Beijing, for example, 82% of graduates of high-tech majors at Tsinghua University have gone to America, and the number was 76% at Peking University. At the same time, more and more high talents have joined in overseas-funded enterprises or foreign R&D organizations (Zhou, 2004). The loss of IT talents was especially critical, which has accelerated the shortage of talents for e-government in China.

Secondly, the civil servants cannot use information tools properly and so could not fulfill the demand of e-government. Although 65% of 17,000 servants in the central government have master certifications, the proportion is relatively lower in local governments. Some highly educated servants still do not have good computer skills.

Since Nanhai is only a remote area in China, it has always been hard to attract talents and information enterprises. The lack of techniques and talents would restrict sustainable development of e-government in the future. The bottleneck of IT professionals is another critical issue that Nanhai must meet.

## Unsustainability of Financial Resources

E-government is a rolling system with sustainable development. This needs continued financial support. The infrastructure of e-government was invested in by the local government, with less revenue from business. After the set up of the OA system, the project would be ended. There was no other income to finance the sustainable operating of the system. On the other hand, e-government serves the local economic development which provides demand for e-government service. Nanhai is a township city with weak economic power and requirements of business. This is the typical obstacle of local e-government in China.

# CONCLUSION

The success of Nanhai e-government mainly resulted from the administration of the city government from 1990 to 2000. It is city government that made the information strategy the number one in Chinese cities. As a result, most of the advantage resources were invested for the construction of city information infrastructure. The core of the whole informalization process is e-government. This made Naihai the leading city in China.

The importance of using e-government is much more than the construction itself. During the construction period, Nanhai was the pioneer. When the service of e-government is emphasized, the weakness of poor usage appears. In fact, e-service at local governments would be more important than that at the upper ones, which will become the windows to connect enterprises and the public. Hence, emphasizing the e-service at the local level should be the main issue for the transition of the administrative system in China.

Therefore, using the Internet as a service tool is more important than construction itself. It also indicates that it is even more difficult to change people's habits than to import the techniques.

## KEY TERMS

**CMOS:** CMOS is a widely used type of semiconductor. CMOS semiconductors use both NMOS (negative polarity) and PMOS (positive polarity) circuits. Since only one of the circuit types is on at any given time, CMOS chips require less power than chips using just one type of transistor. This makes them particularly attractive for use in battery-powered devices, such as portable computers. Personal computers also contain a small amount of battery-powered CMOS memory to hold the date, time, and system setup parameters.

**Geographical Information System (GIS):** "GIS is one kind of information system that handles spatial data. a set of tools for collecting, storing, retrieving at will, transforming, and displaying spatial data from the real world for a particular set of purposes" (Burrough, 1986, p. 6).

**Global Position System (GPS):** GPS is a satellite navigation system. It provides specially coded satellite signals that can be processed in a GPS receiver, enabling the receiver to compute position, velocity, and time.

**Gold-Bridge:** It is a program of constructing basic infrastructure of information in China. It includes projects of backbone network, satellite communication network, mobile Internet, fiber network, Internet phone, Internet information service, and technical reform network.

**Gold-Gate:** It is a customs network. It includes an information system with OA and legislation system in ports.

**Gold-Card:** It is a project of constructing a digital bank card. It includes various IC cards in different fields. For example, bank, telecommunication, transportation, commerce, travel, social insurance, family planning, taxation, and so forth.

**Governance-Online Project:** Since 1999, the central government has designed specific ways for investing in e-governance and adopted specific performance criteria to encourage the progress of e-governance at local governments. This program was planned all over the country and was called Governance-Online Project.

**Horizontal Segmentations:** This is an administration system at the same administrative level. For example, there are business commissions, agriculture commissions, industrial commissions, and so forth. which belong to Beijing government. It is difficult to be coordinated with each other because different commissions have to follow the upper departments of the central government.

**Leadership Project:** All the process of information construction is directly led by the mayor, including the investment, project design, test, and so forth. As a result, the resources for the construction can be easily controlled by the program team. The team leader may be the mayor.

**Local Area Network (LAN):** LAN is a computer network that spans a relatively small area. Most LANs are confined to a single building or group of buildings. However, one LAN can be connected to other LANs over any distance via telephone lines and radio waves.

**Office Automation (OA):** The use of computer systems to execute a variety of office operations, such as word processing, accounting, and e-mail. Office automation almost always implies a network of computers with a variety of available programs.

**Vertical Segmentations:** This is an administrative system with the same department at different levels. For example, business department of the state, business of the pr of the province, business bureau of the county, and so forth. All the business administrations are in the same managing system from upper ones to lower ones. Different departments will be different even though they are in the same province or county.

# E-Government Development in the Caribbean

**Barbara-Chiara Ubaldi**
*Fulbright Credit, USA*

## INTRODUCTION

While in theory, the benefits of e-government are numerous, global experience to date indicates that in reality they remain much more elusive. Given e-government's high impact on good governance and on the promotion of progress in developing countries, in order to better enable communities to benefit from e-government, it is important that the most adequate approach to the transition of a country or of a number of countries to the information society be identified in order for key issues to be addressed expeditiously, correctly, and effectively for an e-government that is at once as comprehensive as possible but also sustainable and meaningful.

This is particularly true for a region such as the Caribbean, which already came late to the assimilation of the industrial age paradigm and which still has to determine its role in the global information society as well as its digital age. While it is common belief that for the majority of countries e-government development is more efficiently and more effectively targeted through national programs tailored to specific needs and characteristics, this is not considered to be the case for countries in the Caribbean region.

Over the last five years, an unprecedented international cooperation for administrative reform and e-government capacity building has taken place in the Caribbean region (i.e., Anguilla, Antigua, Barbuda, the Bahamas, Bermuda, Barbados, Belize, British Virgin Islands, Cayman Islands, Dominica, Grenada, Guyana, Haiti, Jamaica, Montserrat, Saint Lucia, St. Kitts, Nevis, St. Vincent, the Grenadines, Suriname, Trinidad, Tobago, Turks, and Caicos Islands). Such an effort has involved many regional and international organizations (e.g., the United Nations, the European Union, the World Bank, the Interamerican Development Bank, the OAS, etc.); a lot of work has been accomplished to assist countries in enhancing the application of ICT to government functions in order to advance public sector reform, improve government services, enhance knowledge management and decision making, and promote economic and social development.

This international cooperation was carried out through a rich mix of ministerial consultations, working group meetings, meetings of experts, informal consultations, research and development, and country surveys. The rationale behind this kind of intervention was the conviction shared within the international community that a regional approach would permit dealing with the various issues related to e-government development more efficiently and more effectively.

## BACKGROUND

Acutely aware of policies and programs already being implemented at the national level, sharing the common goal of targeting the regional need for strengthened connectivity as a tool for greater prosperity, and with the support of international actors, Caribbean countries have agreed on having collectively drafted and endorsed agendas, strategies, and action plans for e-government development in the region1. The willingness to regionally address e-government development and implementation lies in the idea of gathering countries to work with regional organizations and agencies in order to develop cooperative and collaborative programs that would permit the lowering of overall budget costs related to e-government development and to gain greater efficiency at building infrastructure (Marcelle, 2004; Carr, 2004); to avoid problems and dissipation caused by uncoordinated, overlapping, and, in some circumstances, sporadic efforts and initiatives (Lederman, Maloney, & Serven, 2005); to facilitate the availability of a unique source of information cutting across individual nations for the international donors interested in the region; to put countries in a position where they can share knowledge and expertise (Kagami & Tsuji, 2002); to achieve greater equity between rich and poor countries (Murelli, 2002); to generate a Caribbean regional pride and a constructive competitive ethos that provides countries with mutual and moral support as well as growth of self-confidence in the face of shared challenges and difficulties (Kagami & Tsuji, 2001).

Although the numerous results achieved over the past few years through regional initiatives support the previously mentioned themes, it is important to consider that there still are many voices claiming how a regional approach is likely to be too challenging in a region that, in terms of population, is comparable to Argentina but with 20% of its area, and whose surface is similar to

Ukraine but with all of the blessings and problems of being a small island (Hilbert & Katz, 2002). Those sustaining such a position argue that in a context of different economic, social, political, and business characteristics, the Caribbean region shows great levels of heterogeneity, which inevitably reinforces the national focuses and weakens the regional perspective, thus making the implementation of a regional program for e-government development a highly demanding if not unachievable task (Hewitt, 2003).

Nonetheless, both at the regional and international levels, it is widely recognized that the adoption of a regionally coordinated approach to the conceptualization and implementation of ICT policies, to the reform of the legal and regulatory framework, and to the development of the organizational and infrastructural changes can facilitate the process of addressing and reducing the digital divide and can accelerate the integration of the Caribbean into a knowledge-based society (Murelli, 2002). Furthermore, the author believes that if the regional path can be regarded as a recommendable alternative for other regions worldwide, it appears to be an unavoidable choice for the Caribbean. This is a strong conviction that was matured and reinforced through extensive and substantial experience acquired while implementing e-government initiatives teaming up with Caribbean representatives from the governments and from the civil society and with leading world experts on ICT and e-government.

Following are thoughts devoted to some of the main arguments supporting this perspective on the utility of undertaking regional alliances for e-government development in the Caribbean.

## THE PERSPECTIVE OF A REGIONAL APPROACH

### Lacking Assets

The lack of financial resources in a large number of Caribbean countries is one of the main compelling reasons that over the past years have induced these countries to opt for a regional approach. Common belief is that it can facilitate the pooling of resources regionally accessible or of those made available by the international community.

Besides the fact that e-government projects often are implemented in Caribbean countries, where the enabling legal and regulatory frameworks are not in place and where the necessary policies and organizational structures have not yet been adopted or established, most of the countries also deal with insufficient assets and financing.

The situation is worse when e-government development is perceived as wasteful by the scarcely aware political class or by the barely informed civil society, who argue that it requires the engagement of substantial amounts of financial and human resources but does not result in the optimization of the government's operations and does not target citizens' high priority development objectives. Such allegations often are translated into political decisions that mandate a reduction of the funding for e-government. Ironically, these claims appear to be present more commonly within those Caribbean countries where e-government development is already limited by the lack of financial resources and political support. Thus, the sustainability of the accomplishments already achieved most likely is endangered, and the chances for future development are most certainly limited.

Moreover, on the financial side, evidence shows that the situation is aggravated as a consequence of the high heterogeneity of IT and e-government-related policies, laws, and regulations existing in the region. In fact, the majority of Caribbean countries appears to have undertaken many of the tasks related to policy development and implementation (e.g., adoption of strategies and action plans), legal and regulatory framework reform, and infrastructure and hardware and software upgrade in isolation from each other. Therefore, few are the cheap and readily available off-the-shelf software packages, and the need to develop unique programs restricts even more the capability of poorer countries to place services online.

By proceeding independently of each other, Caribbean countries increased the reciprocal costs of e-government development and enhanced the chances for wasting financial and human resources. Thereby, they somehow robbed each other of the opportunity to achieve economy of scales that would decrease the per-unit cost of official government Web sites or that would decrease the official cost of developing or acquiring applications within specific areas of e-government (e.g., e-accounting, e-taxation, e-procurement, e-justice, etc.). In light of this, the pooling of resources that facilitates the lowering of the overall budget costs related to e-government and the subsequent greater efficiency at building infrastructures constitutes the first argument that explains the rationale behind the largely supported idea of the utility to undertake regional alliances for e-government development in the Caribbean.

### Partnerships

Besides the need to mobilize essential resources in order to finance the establishment of an Information Society, the case for a regional approach to e-government development in the Caribbean also relates to the fact that the promise of e-government to potentially transform the way activities are run, services are delivered, interactions take

place, and information and knowledge are shared cannot be realized fully unless partnerships are created. If it is true that partnerships within and between countries are needed because e-government development cannot be the responsibility of the government alone, then experiences have proven that such a generic assumption fits even more in a context of small islands, drawing heavily from partnerships to overcome national incapability and to help governments achieve what they cannot accomplish alone.

The current situation evinces how some Caribbean countries have been more powerful than others in gaining international support through bilateral cooperation. However, the present circumstances also clearly show that the bilateral path of cooperation has not proven to be the most efficient one. As a matter of fact, if some countries lag behind due to the lack of support, then those that have succeeded in attracting aid often have focused on specific areas (e.g., e-commerce), losing sight of the global perspective (i.e., implementation of policies, laws, regulations, etc.). Therefore, they may have developed highly sophisticated applications but did not properly address key issues, thus hindering the development of a more coherent, balanced, and meaningful e-government.

In this context, the development of any regional strategic document into the reality of connectivity requires Caribbean governments to cooperate among themselves and with international organizations. Private sectors' energies, for instance, must be harnessed in providing for necessary broadband information networks and suitable applications, while governments ensure the legislation of appropriate policies and regulatory institutions to guard against private monopoly power and supplement the market to ensure access for the poor. Finally, the collective endeavor to address e-government development regionally would provide international donors that are interested in the Caribbean, one place to find information that cuts across individual nations so that the cooperation and coaction of a mix of main actors would be facilitated to the highest benefit of the recipients.

## Mutual Learning

Amid other reasons supporting the case for a regional approach to e-government development in the Caribbean is the argument that, thanks to the regional networks, Caribbean countries would avoid having to reinvent the wheel. Each country needs a speaking partner to learn from and with which to be able to share its experience; because no Caribbean country can be self-sufficient, each one needs input from the others in order to learn from experiences of trial and error within the region.

We should not forget that some of the challenges of a successful implementation of e-government consist of reengineering the internal processes, restructuring the public services, creating innovative citizen relations (Moore, 1998). The fact that small and large islands share similarities with regard to their political, economic, and social systems makes the case for regional cooperation even stronger. Such a conceived effort builds on the awareness of different needs as well as deep and common trust and on the belief in mutual benefits coming from a regional cooperation that would allow the countries to learn faster and better, to share experiences, to pool knowledge and expertise, to take new ideas on board, and to exchange good practices.

## Avoid Widening Existing Disparities

Among other things, Information Technology (IT) presently is transforming the way we access and share knowledge and information; it opens new vistas for humankind and offers possibilities to broaden and to accelerate the global integration of information networks, economic activities, and political as well as cultural pursuits (Zhen-Wei Qiang & Pitt, 2004). Therefore, while reconstructing the basis of national economic power, IT holds a great potential to change the global balance of power and for reducing the knowledge gaps both within developed and developing countries as well as within rich and poor countries of a same developing region. Precisely, casting a shadow on several inviting prospects are the asymmetries that still afflict the progress of information societies (Haacker & Morsink, 2002).

In relation to this, one of the principal causes of the asymmetries produced by the technological process in the Caribbean is the widening divide between those that actively can access and participate in global information networks and those that cannot. In consideration of the fact that the ability to utilize the information available on the Internet and, consequently, to translate it into knowledge for productive activities has become a critical factor; it is of pivotal importance to try not to increase communities' isolation or to enhance the digital divide within the region while developing e-government.

This supports the reasoning in favor of the adoption of a framework for regional cooperation within the Caribbean, which alleges that it would allow the reduction of the existing regional disparities with regard to the connectivity. Also, by placing countries in a position where they can share knowledge and expertise and by enhancing the linkages between national and regional organizations that work on similar objectives, the process of consultation, information sharing, and collaboration on joint projects would facilitate intra-institutional communication between regional cooperation institutions and their constituencies (Bayoumi & Haacker, 2002).

## Regional Agreements for Greater Equity

In line with the just mentioned argument encouraging a Caribbean regional approach to e-government is the importance of regional agreements in order to achieve greater equity between rich and poor countries in the region (Basdeo, 1989). Presently, e-government is not equally implemented within the Caribbean, and because of this, inequalities in critical success factors, such as the level of leadership, policies, laws, regulation reforms, strategic public investments, and investments in education and connectivity, may further increase without deliberate actions and improved coordination. A regional approach to e-government development undertaken in a phased manner can help to address these disparities, enhance the capacity of the less digitally advanced countries, and build a better knowledge infrastructure for the 21st century (Hoyte, Rainford, & Thomas, 1989).

## FUTURE TRENDS

In the Caribbean, pilot projects can help to establish the groundwork for productive forms of cooperation among member states. These should aim to increase the effectiveness of information exchange, launch common actions, and initiate cooperation (e.g., regional Internet exchange, regional electronic payment, coordinated border control system, etc.). In addition, harmonized ICT policies should facilitate the creation of larger markets and economies of scale, take steps to put in place policies and institutional frameworks that promote investment in a converged market, and support the development of cross-border connectivity. There is a strong need to expand the communication infrastructure in order to help to meet development goals, especially as the Caribbean regional economic community moves toward economic integration, establishing mechanisms for cooperative action by countries to harmonize national policies and strategies and to promote regional telecom buildout (Rao, 1995).

Any form of integration requires communications and networks, and the application of ICT is a particularly appropriate field for regional cooperation, in particular through the creation of joint mechanisms for developing, consolidating, and marketing high-tech products and services such as distance learning programs and software, together with region-wide networks. Progress in some of these areas within the Caribbean has been hindered by the total absence of regional standards and regulations to support the integration of telecom services. This situation is reflected, for example, in the diversity of technologies and standards used in the mobile telephone industry, which is hampering the physical integration of systems and the cost reductions associated with the expansion of the regional market. These tasks, therefore, should be priority lines of action for the Caribbean regional integration process in the immediate future.

## CONCLUSION

If the Caribbean countries as a region want to shrink significantly the existing digital gap between strong and weak usage of e-government services in the future, and if they want to increase extensively their position in the regional ranking, then they have to take advantage of any available method of regional cooperation.

The author's purpose was to assert that regional cooperation not only constitutes an additional path to shape ways to promote sustainable economic, social, and cultural development of the Caribbean countries in the emerging Information Society and to create a common platform for the exchange of experience, know-how, and projects; but it is also a way to assure that the Caribbean will find and maintain its particular optimum transition path toward the Information Society, notwithstanding the discrepancies among the different horizontal layers, the diagonal areas, and the vertical sectors at the national level, which create a fast-changing and complex scenario requiring constant evaluation. Not only do the regional networks allow the Caribbean countries to remain informed in a global context by knowing what is happening at the regional level, but they also are the key to generate a Caribbean regional pride and a constructive competitive ethos.

Therefore, if regional cooperation and integration have proven to be good alternatives for many regions worldwide engaged in realizing the opportunities of e-government, then the analysis included in this article seems to show that there are enough arguments in support of the idea that a collective approach represents an inevitable strategy in order for e-government to be implemented successfully in the Caribbean.

## KEY TERMS

**Best Practices:** The processes, practices, and systems identified in public and private organizations that perform a process or subprocess exceptionally well and is widely validated, codified, diffused, and recognized as improving an organization's performance and efficiency in specific areas in which they are shared with others in order to encourage reciprocity and knowledge sharing.

**Connectivity:** In IT terms, it refers to the ability to connect to or communicate with another computer or computer system, the Internet, or a Web site.

**Digital Divide:** The gap that exists between those who have and those who do not have access to technology (e.g., telephones, computers, Internet access) and related services.

**Economy of Scale:** The reduction in cost per item (unit cost) that results from large-scale production. The high capital costs of machinery or a factory are spread across a greater number of units as more are produced. This may be a result of automation or mass production; for example, in the car industry. Economies of scale also can be produced when entities (e.g., countries) that need similar services locate together, sharing the costs of their services; for example, in the case ICT acquisition and development.

**E-Government:** The application of Information and Communication Technologies within the public administration for the optimization of its external and internal functions.

**Good Governance:** The process of decision-making that is built upon transparency, accountability, the rule of law, and democracy.

**Information Technology:** Any equipment or interconnected system or subsystem of equipment that is used in the automatic acquisition, storage, manipulation, management, movement, control, display, switching, interchange, transmission, or reception of data or information. The term *information technology* includes computers, ancillary equipment, software, firmware, and similar procedures and services, including support services and related resources.

## ENDNOTE

[1] The Regional Agenda for Connectivity was approved by the Ministers of the Caribbean Community (CARICOM) responsible for Information and Communication Technology during the 23rd Meeting of the Conference of Heads of Government in July 2002 in Georgetown (Guyana) (http://www.caricom.org). The "E-Government Strategy for the Caribbean" was adopted by the 5th Ministerial Consultation on Regional Cooperation for E-Government Capacity Building held in Barbados on June 17-18, 2004; which was part of a broader initiative for administrative reform and e-government capacity building in the Caribbean, implemented by the Caribbean Centre for Development Administration (CARICAD), CARICOM, and the Division for Public Administration and Development Management of the United Nations Department of Economic and Social Affairs (http://www.unpan.org).

# E–Government Development Trends

**Monica Zuccarini**
*University of Florence, Italy*

## INTRODUCTION

Information technology is changing the role of government, its functions, and its power. The long process of transformation of public sector organizations and the applications of computer technologies have started the talk about electronic government.

In the last ten years, the debate concerning e-government has been the subject of various studies, promoting analyses, research approaches, and empirical surveys. Even so, there is still much confusion about the meaning of this term and the word e-government is often used in reference to e-voting, e-democracy, or e-administration. Therefore here we intend to provide the reader with some guidelines, trying to explain a concept that, although little more than ten years old, finds its roots in the ancient idea of the information society.

We can start by saying that e-government represents just a single fragment of the broad discourse about the impact of information technologies on society. It is not an administrative experiment but a permanent part of the governmental process. According to Jane Fountain's (2004) idea, we can define e-government as "the production and delivery of information and services inside government and between government and the public using a range of information and communication technologies" (para. 2). In this prospective, the Internet can be considered as a variable, which has been grafted onto the wider ground of factors leading to the transformation of government roles.

Moving from this point, e-government will be analyzed as an intersection of two main trends. The first of these is the overall transformation of public sector organization. In this respect, the Internet variable has to be considered in the entire process of the government reinvention that made scholars talk about a major new revolution after the industrial one. The second trend is the information society development, a process that started since the 50s catching very soon the interest of governments.

## BACKGROUND

Let's try, now, to observe the long process of modification, which, in the last 30 years, has involved the intrinsic nature of governments influencing their functions, structures, and processes. Welfare State crisis, economic, and ideological pressure, change of the public perception of government roles make United States and European scholars talk about *Reshaping the State* (Wright, 1994) and *Reinventing Government* (Osborne & Gaebler, 1992). A frame of general changes where the development of information technology becomes one of the main pressures leading to the transformation of government roles can be identified as such:

a. Creation of international markets, which has created problems of international and transnational administrative coordination, dimming governments identity and responsibility
b. Economic and fiscal pressure, which has caused problems of deficiency in public budget
c. Strong ideological prejudices of the new right theorists towards the state, *big government*, the inflated bureaucracy and the determination to re-plan State borders
d. Technological changes, explosion of information technologies that are strongly affecting traditional public bureaucracies and leading towards the introduction of the new public management (NMP)
e. General feelings of dissatisfaction and suspicion from public opinion towards governments. Although they have got various features in different nations, they share a common point, that is a charge of inefficiency, a lack of transparency and corruption against the public sector
f. Managerial revolution, which has strongly affected procedures and techniques in order to reach an upper degree of efficiency and flexibility. In fact, the proposal of a new public management (Hood, 1996; Pollitt, 1990) is based on the idea that most of the public sector problems are the results of bad management of governments (Peters, 1995)
g. Problems (only regarding European context) of coordination and regulation among different administrative cultures due to the process of Europeanization

Looking at these issues, it is easy to understand that information technologies are only a part of the wide series of changes involving all governments. But, at the present

time, they represent a flywheel for a deeper action of renewing. They are leading to the decentralization of the traditional functions concerning political/administrative direction of governments, aiming at a more flexible government structure, pushing a process that reduce discretionary bureaucracy.

In fact, the idea of *reinventing* an increment of the administrative effectiveness of a bigger responsibility of governors and of the efficiency of public administrations is regenerate since the 90s with the development of the modern computer science technologies. The new technologies and the Web make the government reform cheaper, faster, and better but bring about issues such as redesigning government structures and processes.

This is the reason why now it is important to take into consideration all the opportunities, challenges and problems that the "*e*" points out for governments: actually electronic government is more about government than about "*e*" (OECD, 2003).

## INFORMATION SOCIETY RESEARCH TRADITION AND E-GOVERNMENT

As the background analyses have shown, the importance of electronic media in governments began long before the term e-government appeared. Governments have always used new technologies as an instrument to improve the effectiveness.

The following pages will show that e-government is not only a segment of governments change but also a part of the larger discourse about information society. The studies on the information society began well before the e-government concept emerged: they started in the 60s, when the theoretical discussion developed different approaches on the production, elaboration, and distribution of information. Many scholars have discussed the development of the information and communication activity. The first was Fritz Machlup (1962), who pointed out that already in 1958 about 29% of the American gross national product was derived from what he defined as the "industry of the knowledge." In the same way Marc Uri Porat (1977) spoke about "the information economy" as a new field of the productive activity connected to the development of new technologies; Daniel Bell (1974) was the main theoretician of the post-industrial society; Peter Drucker (1998) and Alvin Toffler (1980) developed different aspects of information as a resource and Kennet Laudon (1986) with his *Dossier Society* put the first key matters on the development of new technologies.

If in the early 60s the analysis was concentrated predominantly on the American panorama, from the first half of the 70s until the beginnings of the 90s studies began to be expanded in other States and the initial interest for this type of theme began slowly to decrease. But the emergence of the Internet in the 90s focused the attention on the (global) information society with new actors and new situations (May, 2002).

The information society, driven by new technologies of information and communication, started a new revolution similar to the industrial one (Bell, 1974). In the governmental offices as in the factories, information technologies were introduced not only to increase productivity and profit, but also to ensure the managerial control on the productive process, to make the administrative procedure more efficient, to favor centralization and social control.

This is why the idea of an information society and a global society of knowledge interested governments and international organizations since the beginning. And they started to entrust to scholars and technicians hypotheses and projects of intervention.

In Japan in 1971, Yoneji Masuda was one of the authors of the national plan policy Jacudi (Japan Computer Usage Development Institute) for the bulky introduction of the new information technologies in Japanese society. In France Simon Nora and Alain Minc were the authors of the report on the information society *L'informatisation de la société* (1978). In the United States, Zbigniew Brzezinski, political theorist at Columbia University of New York and National Security Advisor of President Carter, was the main theorist of globalization. In his book, *Between Two Ages, America's Role in the Technetronic Era* (Brezinski, 1970), he outlines a global sight of the new society, defined "technetronic society"—a society established on technologies, particularly on information technology, and telecommunications—and introduces the idea of a "diplomacy of the net" that should replace the "diplomacy of force."

Today a growing number of non governmental organizations (NGOs) identify in the global information society a strong tool for economical development: examples are the *1998-99 World Development Report: Knowledge for Development* of the Word Bank (1998), the report of the United Nations *Knowledge Societies: Information Technology for Sustainable Development* (Mansell & When, 1998), and *Towards a Global Information Society* of the Organization for Economic Co-operation and Development (Oecd, 1997).

But it was in 1993 that a speech on the information society—after it had characterized for different years the policy on the economical development—took on a new development and became a part of the direct interventions of the government. On March 3, 1993, the American government during the Clinton administration developed the program of the *National Performance Review* (NPR)

with a double mission: *work better* and *cost less* (Osborne & Gaebler, 1992). It was a plan to reform public administration and to guarantee efficiency, effectiveness and responsibility of governments. In the initial report of the National Performance Review appears a paragraph in which emerged, for the first time, the expression "electronic government." However no definition was given for this term. The first definition was made four years later when, in the report Access America of the NPR, February 3, 1997, in which e-government was defined in reference to the use of information technology to perform or to increase the services of some governmental functions, mainly among the services directed towards the citizen.

The NPR program planned a thorough re-evaluation of two main areas, that of the analysis of implementation and of monitoring and measuring change, and it is in this context that the word e-government was introduced into public discussion for the first time. The idea of an electronic government, in fact, become part of the bigger discourse on *Reinventing Government* that started in the United States in the 70s and extend, incrementally, in all the nations. The goal was the decentralization of the key functions of internal decision-making for government decisions.

With the entrance on the stage of information technologies, in the 90s, the long process of reinventing was strengthened. There was an awareness that information technologies confer four main benefits to the reform process: economical benefit (producing the same results with lower a cost); increasing production (more outcome at the same cost); fast productivity (more outcome with equal costs and less time); improve the result.

E-government at first was used like a modern expression, a buzz word, and as often happens when a new limit comes to the attention of the public, different definitions of the concept came out as well as numerous attempts to scientifically legitimize the term. People started to apply the attribute *electronic* to different fields of new technologies and politics, causing confusion and lacking any real rigor, as well as adding very little to the sense of what was added by this new *electronic* factor.

In this way frequently, e-government has been seen as an administrative experiment rather than as a persisting part of the complex governmental process—often succeeding only in causing greater confusion between e-government and e-administration or e-government and e-democracy rather than developing any of the undoubted potential of these new methods of communication and implementation. Thus, the research on e-governments has moved in multi-directions. One aspect favors the position that enhances public administrations via information and communication technologies (ICT); an other aspect prefers the potential of ICT in developing more active citizenship and electronic democracy. In some cases, instead, the research reflects worries of certain scholars with regards to the increasing influence that the private sector approach has on the management of public resources, or the anguish about the threat to privacy by these new technologies, or more extreme apocalyptic images of an invisible State, without any power (Dyson, 1998; Tapscott, 1998). Several debates and works on this topic have also referred to e-government as a form of service delivery. This is not an incorrect assumption, but it does not represent the unique way to define e-government. It could appear almost restricting to consider e-government as a mere administrative experiment. In a more broad definition e-government can be considered as a governments' strategy, a new organizational model of the relationship between state, institutions, and citizens, and a new formula for the reinventing in which Internet becomes an important variable in to the widest factors that bring about governments to change.

## FUTURE TRENDS

The Internet creates a new arena or power for governments, and political and social scientists cannot neglect it. Pointing their attention on the central and strategic role of institutional actors involved and several problems that new technologies give rise to, scholars should go beyond the phenomenon of representation and dwell upon the knots it may cause. One of the main questions revolves around the role of the States, their functions of organizing, administrating, regulating, and controlling.

In the new globalized space, new actors are participating in the decision making process. The cooperation and interaction between State and public/private actors is increasing. Corporations, which own most of the technological know-how that governments are losing, represent a very strong reference point for governments. The Web symbolize a new arena to colonize, either for governments and corporations, where developmental countries—still waiting to acquire technological structures—become ideal markets to realize good profits. Then the open question is: are we in an electronic government era or are we rather going into a governing electronics era? Maybe modern technologies are deeply changing the government power and new actors are conquering more space in the decision making process. We cannot say exactly where these changes will bring us, but in the near future, it would perhaps be better to focus our attention not only on the changes in public administration but more on the new dynamics of power in the globalized political space and on what governments are doing for the construction of the "*e*" world.

## CONCLUSION

This article has observed the long process of modification, which, in the last thirty years, has involved the nature of governments. It has presented a frame of general changes where the development of information technology becomes one of the main pressures leading to the transformation of the roles of governments. However, according to how stated at the beginning, electronic government is more about government than about "*e*." New technologies are only a factor between many to enhance governments change. The real change is not the use of digital technologies in public offices but regards a new way of thinking for governments, a public space of power. Indeed, digital technologies create new arenas of power and interests that affect directional functions, government organizations, and control.

## KEY TERMS

**Digital State:** The idea of a state government that leads the nation in adopting digital technologies to improve services delivery.

**Digital Technologies:** The term refers to the technologies used in the digital age, from audiovisual technologies to the computer and Web-based technologies. Digital technologies are used to improve communication and also to store information and effect on consumption of mass culture.

**E-Democracy:** The term refers to the use of the modern digital technologies to improve democracy. The Web is considered as an instrument to spread democratic principle of transparency, information, and participation of citizen to political life. The Internet creates a new public space—apparently free of strict rules—able to allow the citizens to communicate with everybody, express their own ideas and participate to democratic process.

**Information Technology (IT):** The term refers to computing and telecommunication technologies used to handle information, to process, store, convert, transmit and retrieve data.

**National Performance Review (NPR):** The National Performance Review is the Clinton-Gore Administration's initiative to reform the way the federal government works. Its goal is to create a government that "works better and costs less." It is about change in the way the government performs.

**New Public Management:** It is a new philosophy to describe how management techniques from the private sector are being applied to public services. Its intention is not privatization, but the fortification of the state.

**Reinventing Government:** It is a process of government transformations and downsizing of the federal workforce started in the United States in the 70s and extending, incrementally, in all nations.

# E-Government for Building the Knowledge Infrastructure in South Korea

## INTRODUCTION

New information and communication technologies (ICTs) enable rapid information flows, which reduce the necessity for face-to-face contacts as well as geographical barriers. These also create network-based societies (Castells, 1996). E-governments can contribute to the enhancement of network-based societies. In the last five years, governments have made rapid progress worldwide in embracing ICTs for e-government. By 2004, 178 of 191 member states of the United Nations had a Web site presence (UNPAN, 2004).

All e-governments focus on the use of ICTs for the full range of government functions. In particular, the networking potential offered by the Internet and related technologies enables them to transform the structures and operation of government. As a result, e-government can be a major enabler in the adoption of good governance practices (OECD, 2001a; Ronaghan, 2002).

Regarding the OECD's work on governance, there is a strong belief that effective governance is an important requirement for the achievement of economic, social, and environmental objectives. Moreover, the OECD secretary general set out a draft statement of governance priorities for the 21st century, which, in 2000, indicated the experiences of OECD countries in building democratic and prosperous societies.

In order to practice good governance, an e-government is regarded as a strategic implementation that identifies various objectives such as effective leadership, coordination and policy coherence, and efficient investment and financing (OECD, 2001a). Additionally, e-government is recognized as one of the most significant factors to strengthen national competitiveness, particularly in a knowledge-based information society. This also serves as an important enabler in order for a government to offer high-quality civil services at low costs. As a result, e-government not only contributes to the informatization of citizens and businesses but also improves the productivity and transparency of public administration (Bertelsmann Stiftung, 2002).

Advanced nations already have launched various government-driven initiatives such as the E-Government Initiative in New Zealand and the U.S., and UK Online in the UK (Reeder & Pandy, 2002). Along with these advanced nations, South Korea also is consistently pursuing e-government initiatives with its world-class information infrastructure in order to transform the way of national governance (National Computerization Agency, 2002). The e-government project will bring about structural and procedural reform and is expected to serve as a springboard in order for South Korea to leap forward to become one of the leading nations in information and communication industries.

This article discusses which strategies the South Korean government focuses on and how it implements these in order to build the knowledge infrastructure. Furthermore, the article aims to analyze the methods of building the knowledge infrastructure based on ICT as well as the roles of the e-government to develop good governance.

## BACKGROUND

The development paths of building e-government in South Korea consist of three stages. The first stage of e-government began in 1986, when the government passed the Act on Promotion of Information and Communication Network Utilization and Information Protection. On the basis of this legal support, the project of National Basic Information System (NBIS) was first implemented. Later on, the project of Korea Information Infrastructure was initiated with a trend to build information superhighways in advanced nations, which started in the U.S. in the mid-1990s.

In the second stage, the government enacted the Framework Act for Informatization Promotion and the National Framework Plan for Informatization Promotion. This act and the plan were empowered in 1995. On the basis of this legal enforcement, the government began providing informatization services such as patent, customs, and procurement. As a result, the services evolved to a full-scale e-government by the end of the 1990s. Furthermore, the government appointed chief information officers (CIOs) in 1998 and continuously revised the National Framework Plan for Informatization Promotion to Cyber Korea 21 in 1999 (National Computerization Agency, 2002).

The final stage was an ongoing process that started in 2001. The government established the Special Committee for e-government in January 2001 in order to accelerate its efforts to implement e-government with maximum power. The members of the special committee were experts from the private sector and deputy ministers of related agencies. The special committee was under the presidency and has continuously supported and monitored key initiatives (Knowledge-Based

*Table 1. Development paths for building e-government (Author's adaptation based on Knowledge-Based E-Government Research Center)*

| Stage and Period | Major Framework |
|---|---|
| 1st stage (mid-1980s-mid-1990s) | National Basic Information system, Korea Information Infrastructure |
| 2nd stage (mid-1990s-late 1990s) | Framework Act for Informatization Promotion, National Framework Plan for Informatization Promotion, Cyber Korea 21 |
| 3rd stage (2001 - ) | Special Committee for e-government, Five-year Informatization Promotion Plan |

| Type | Initiatives |
|---|---|
| Innovation of services to citizen and business | 1. Single window e-government (G4C)<br>2. Social insurance service portal<br>3. Home tax service<br>4. National e-procurement service (G2B) |
| Enhancement of administrative efficiency | 1. National financial information system<br>2. National education information system<br>3. Local government information<br>4. Personnel policy support system<br>5. E-approval and e-document exchange |
| Establishing infrastructure for e-government | 1. E-signature and e-seal<br>2. Phased implementation of a government-integrated computer system (BPR/ISP) |

e-Government Research Center, 2003) (see Table 1). The key initiatives consisted of three types and 11 initiatives. These 11 high-payoff initiatives were implemented and have been in service since November 2002 (see Table 2).

After the 11 major initiatives, the government plans to drive another initiative named Beyond e-Government, which contributes to providing a wide range of citizens' needs and various value-added services. As part of this initiative, the government launched a five-year informatization promotion plan, e-Korea VISION 2006, in April 2002. This plan focuses on qualitative improvement rather than quantitative expansion, and its aim is to become the leading nation instead of following other leading nations. The e-government, which provides customized online services and open administration, is emphasized as the core strategy eliminating redundant and overlapping processes as well unnecessary paperwork.

## VISIONS OF E-GOVERNMENT AS STRATEGIES FOR NATIONAL COMPETITIVENESS

The South Korean government has set its visions of e-government in order to increase productivity and transparency through the strategic use of information and communication technologies in the public sector. This ultimately will contribute to strengthening the national competitiveness and to positioning South Korea as an advanced nation. To realize these goals, the government formulated the following three strategic objectives of e-government:

1. **A Government that Provides the Best Administrative Services to Individuals:** All administrative institutions disclose the processing of civil affairs so that citizens can apply for and be provided with administrative services at home through an online single window.
2. **A Government that Provides the Right Support for Business:** E-government creates new businesses by establishing ICT infrastructure. In addition, it supports venture businesses and fosters human resources. Furthermore, e-government refines laws and regulations for establishing standards of e-business as well as for creating a safe online marketplace.
3. **A Government with Improved Productivity, Transparency and Democracy:** E-government enables paperless administration through the electronic data interchange (EDI) system, which enhances the productivity and efficiency in public services. Due to the EDI system, it is fully possible that the entire workflow is processed electronically. As a result, the transparency of administration can be improved. Moreover, bilateral communication between the government and citizens contributes to creating a democratic e-government (National Computerization Agency, 2002).

In reality, however, the level of e-government compared with other advanced nations does not seem to be as prosperous as planned. The level of e-government is measured by three global indexes such as the e-government index, the information index, and the transparency index. Among these indexes, South Korea was in a weak position, particularly in the field of government transparency (Ministry of Information and Communication, 2003). Therefore, the government set its specified targets in order to belong to the leading group in the year 2008 (see Table 3).

Due to the little impact of government reform based on the 11 e-government initiatives, the Presidential Committee on Government Innovation and Decentralization intensified e-government initiatives as a key national strategic task to reform administration and civil services. The reason for this is that the limitations of laws and regulations and old practices have not been fully changed, since they were based on an off-line environment. Accordingly, the e-Government Working Committee revised the visions and principles for e-government in May 2003 (see Figure1). In order to approach the visions, the government finalized the e-government roadmap to include four areas, 10 agendas, and 31 key tasks (National Computerization Agency, 2004).

## ACHIEVEMENT OF E-GOVERNMENT AND BUILDING THE KNOWLEDGE INFRASTRUCTURE

Despite moderate performance of e-government at a global level, the South Korean government has achieved a tremendous result in terms of a knowledge-based society. First of all, there are two major frameworks based on the 11 key initiatives toward the e-government. The first one is the informatization of public administration services, and the other is the integration of critical public administration services. The former consists of six programs, and the latter is composed of eight programs (National Computerization Agency, 2002). With these services, the government aims to reduce administrative costs as well as to provide citizens a better quality of life. In addition, it focuses on improving the quality of service and operational efficiency (see Tables 4 and 5).

The 11 e-government initiatives completed informatization on a government-wide basis in civil service reform, integrated procurement, and national financial information. These efforts resulted in the world's highest-rated IT infrastructure, particularly in the broadband network to more than 1,400 rural areas by the year 2002.

Informatization of departmental and functional unit operation is regarded as the advancement and enhancement phase. Moreover, the government starts to offer integrated online services such as reporting and making payments over the Internet. Therefore, it is safe to say that these services advance e-government to the upgraded level (National Computerization Agency, 2004).

In addition, it is widely expected that the demands on state services such as health, welfare, and education will increase in the mid-term future (Ducatel & Miles, 1995). In order to improve these services, the government has established a social insurance service portal and a national education information system.

E-government initiatives have contributed to building a knowledge infrastructure drastically in South Korea. Looking at the IT expenditure trend in the 1990s, the growth of capital investment increased from 6.9 trillion won in 1990 to 41 trillion won in 1999, which accounted for 3.88% and 9.40% of the GDP, respectively. In particular, the government and corporations invested in telecommunication and technological hardware. As a result, the total amount of investment in software was relatively small (National Computerization Agency, 2002) (see Tables 6 and 7).

During the financial crisis at the end of 1997, the investment in the IT sectors did not decrease, which indicated that the government strongly held these sectors as the key industrial sectors for the national economic growth. At the same time, the government decided on a heavy investment in these sectors in 1999, in which there was a 40.68% increase compared to the year before.

Due to the heavy investment in IT sectors, which is based on the strategy of resource concentration, the status of South

*Figure 1. Visions and directions for e-government (National Computerization Agency, Informatization White Paper, 2004)*

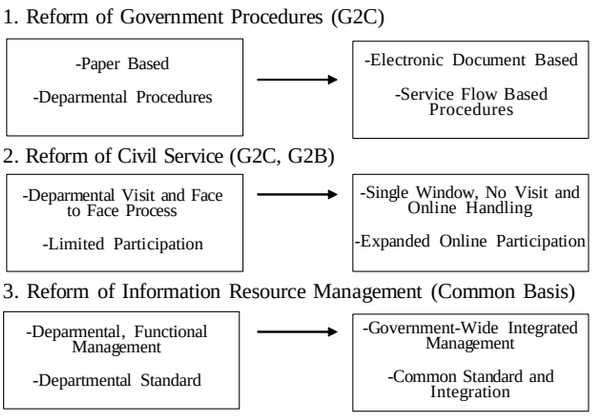

*Figure 2. Internet users per 1,000 people (2003) (International Telecommunication Union (ITU), International Informatization Index DB, 2004)*

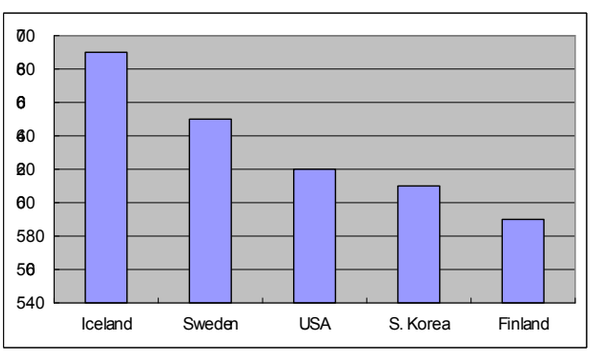

*Table 3. Present ranks of South Korean e-government and its targets (Ministry of Information and Communication, E-Government Roadmap, Republic of Korea, 2003)*

| Global Index | 2003 | 2008 (Targeted) |
|---|---|---|
| E-government index (UN) | 15th | In top 5 |
| Information Index (IDC) | 16th | In top 5 |
| Government transparency (TI) | 40th | In top 20 |

Korean informatization has increased continuously. As a result, South Korea is ranked in the world's top five, particularly in areas such as Internet users, broadband Internet subscribers, and CATV subscribers. These areas are regarded as key factors in order to realize a knowledge-based society and a knowledge economy (see Figures 2, 3, and 4). A knowledge-based economy is based on high technology

*Table 4. Results of informatization of public administration services (National Computerization Agency, E-Government in Korea, 2002)*

| Services | Achievements |
|---|---|
| Computerization of Passport Issuance | - **Reduced the waiting** time from two to three days to 20 minutes |
| Korea Intellectual Property Office (KIPO) Net | - **Increased online users** by an average of 430% (annually 3.3 million users)<br>- **Cutting costs** by 29.8 billion won (c. 29 million U.S. dollars) per annum |
| Computerization of Customs Administration | - **The world's first** end-to-end import/export declaration, acceptance, and release system<br>- **Reduced from two days to 2.5 hours** (four hours faster than the UNCTAD recommendation)<br>- **Annual savings** of 2.5 trillion won (c. 250 million US dollars) |
| One-Stop Service System for Export and Import Cargo (PORT-MIS) | - **Decreased the processing time** from two hours to two minutes<br>- **Annual saving** of 4.9 trillion won (c. 490 million dollars) |
| School LAN and Internet Access-ICT Use in Education | - **LAN construction** in 346 schools by 1997 (3.3% of the total schools), 4,902 schools by 1999 (42.8%), and 10,064 schools by 2000 (85.2%)<br>- **Connected** to the National Information Superhighway or Korea Education Network |

*Table 5. Results of the integration of critical public administration services (Computerization Agency, E-Government in Korea, 2002)*

| Services | Achievements |
|---|---|
| Government for Citizens (G4C) | - **Annual saving** of 1.8 trillion won (c. 180 million U.S. dollars) |
| Government Procurement Services (G2B) | - **87% of online transaction** in all trading activities<br>- **Key role** in the public and private sectors for stimulating online trading markets |
| Interconnected Information System for the Four Major Types of Social Insurance | - **Annual saving** of 5.4 trillion won (c. 540 million U.S. dollars) |
| Home Tax Services via Internet (HTS) | - **Annual saving** of 1.4 trillion won (c. 140 million U.S. dollars) |
| Informatization in Local Governments (Cities and Districts) | - **Completed 232** cities, countries, and districts throughout the nation<br>- **Reduced qualification screen services** from 21 days to three days |
| National Financial Information System | - **Real-time management** of imports, exports, earnings, and expenses<br>- **Annual saving** of 2 trillion won (c. 200 million U.S. dollars) |

manufacturing and knowledge-intensive services (Cooke, 2004).

## ANALYSIS ON E-GOVERNMENT IN SOUTH KOREA

The economic index of the IT industry shows that the production value in the IT industry has increased by an annual average growth rate of 18%, from 89.9 trillion won in 1998 to 205.4 trillion won in 2003. The share of this sector in total exports increased from 27.8% in 1999 to 29.7% in 2003, which accounted for 40.0 billion U.S. dollars and 57.5 billion U.S. dollars, respectively. This illustrates that the IT industry backed by the public and private sector's massive investment has risen as a major driving force for generating the nation's export as well as economic growth. As a result, South Korea takes a leading position in the fields of LCD monitors, semi-

|---|---|---|---|---|---|---|---|---|---|---|
| Public sector | Telecom | 54.2 | 54.4 | 52.6 | 48.1 | 41.6 | 35.7 | 33.8 | 31.3 | 27.6 |
| | H/W | 4.2 | 4.3 | 4.9 | 5.8 | 6.7 | 8.4 | 9.5 | 10.4 | 10.8 |
| Private Sector | Telecom | 17.1 | 17.3 | 17.3 | 17.9 | 21.2 | 20.7 | 19.8 | 20.6 | 23.5 |
| | H/W | 24.5 | 24.0 | 25.3 | 28.3 | 30.6 | 35.2 | 36.9 | 37.8 | 38.1 |

conductors, and mobile phones (Ministry of Information and Communication, 2003).

In order to build the knowledge infrastructure, the government increased its investment on the telecom sector, particularly in the beginning of the 1990s, while private corporations focused on their investments in hardware during the same period. However, this trend changed after the mid-1990s. The government and private corporations started to keep a balance between the two sectors, although the government still preferred to invest in the telecom sector. By contrast, private corporations invested in these two sectors with a good balance (see Table 8). This indicates that the basic knowledge infrastructure for building e-government was established with a heavy investment on the government's side in the beginning of the 1990s, and the private corporations began to invest in the telecom sector after the mid-1990s in order to maximize their business profits.

*Table 13. Informatization status in South Korea (National Computerization Agency, White Paper, 2004)*

| Classification | 1999 | 2000 | 2001 | 2002 | 2003 |
|---|---|---|---|---|---|
| Broadband Internet Subscribers (1k households) | 374 | 4,010 | 7,810 | 10,400 | 11,180 |
| Internet Users (1k) | 10,860 | 19,040 | 24,380 | 26,270 | 29,220 |
| Number of PC's (1k sets) | 11,530 | 18,615 | 22,495 | 23,502 | 26,741 |
| Mobile Phone Subscribers (1k) | 23,443 | 26,816 | 29,046 | 32,342 | 33,592 |
| E-commerce (%) | NA | 4.5 | 9.1 | 12.8 | 16.5 |
| Internet Banking Users (1k) | 1,230 | 4,090 | 11,310 | 17,710 | 22,754 |

The informatization budget of the government increased an average of 23% per annum from 1998 to 2002. It was 715 billion won in 1998 and increased to 1.6 trillion won in 2002, which accounted for 1% to 1.5% of the total budget (see Table 9). The public and private sector's heavy investment in the IT industry reached an average of 5.3% of GDP in the 1990s, which resulted in an improvement of national informatization index and ranking continuously. Regarding ITU International Informatization Index DB, South Korea raised its national informatization index from 52 in 1996 to 89 in 2003. Accordingly, its ranking was upgraded from 22$^{nd}$ to 7$^{th}$ in the same period (see Tables 10 and 11). In addition, UN Global E-Government Readiness Report (2004) ranked South Korea as the fifth in the world, which is even more advanced than in the ITU International Informatization Index DB (see Table 12).

## FUTURE TRENDS

The South Korean government will enhance the nationwide information infrastructure continuously. For it, the government has launched mid- to long-term vision and strategies such as Cyber Korea 21, e-Korea Vision 2006, and Broadband IT Korea VISION 2007. Moreover, the government is ready to cooperate with the private sector in order to strengthen the partnership between the two actors.

The early adaptation of broadband Internet networks has created various Internet business opportunities and an explosive demand for communication and entertainment. On the basis of the broadband Internet networks, South Korean society becomes a dynamic and innovative civilization due to its open and network nature of ICT that contributes to generating the country's next economic leap and to improving the quality of living for its citizens.

With drastic changes of global economic environment, the broadening of communication networks and the convergence of wired and wireless networks will be strengthened. Therefore, the government unveiled its Broadband IT Korea Vision 2007 to reflect changes in the information environment since e-Korea Vision 2006. The Broadband IT Korea Vision 2007 focuses on the following three directions: from quantitative expansion to qualitative improvement, from government-led industrial growth to industrial-led, and from a catch-up strategy to a leadership strategy (National Computerization Agency, 2005).

## CONCLUSION

It may be widely accepted that the 21$^{st}$ century is regarded as an information age. All advanced nations began to invest in building knowledge infrastructure, which is a basic precondition in order to establish e-government. This notion was intensified by the initiative of the information superhighway in the US in the beginning of the 1990s. Since then, many nations invested large-scale in IT sectors in order to preempt their leading position in the world. As a result, it seems to be that instituting an e-government is no longer an option but rather a mandate in the globalizing economic system.

South Korea is not an exceptional case. The government prepared to build an e-government since the mid-1980s, although its starting point was based on gathering national basic information. Since the 1990s, the government has followed the global trend to build information infrastructure.

With the e-government initiatives, the IT industry became the largest export industry, which accounted for 29.5% of the total exports in 2003. This also has contributed to creating the national economic growth. In fact, e-government initiatives have played roles in building the knowledge infrastructure as well as expanding the IT industry as a key strategic industry.

In line with the strong will of the government to build e-government as well as the heavy investment of the private sector in the IT industry, South Korea is positioned in the leading group, particularly in the areas of broadband Internet subscriber, Internet user, and cable TV subscriber. These areas are key factors to build the knowledge infrastructure. In the industrial perspective, this trend has enabled the generation of world-class IT products such as LCD monitors, semiconductors, and mobile telephones.

Regarding e-government, there are various opinions. In fact, most governments have experienced problems and difficulties when they implement large IT projects for building knowledge infrastructure. Moreover, governments are not alone in failing. Private corporations, which participated in the large IT projects, also faced similar barriers, even in advanced nations. Despite such political and economic risks, most

OECD member nations have expressed their ambitions to implement the e-government initiative. In order to minimize the risks, all governments have to learn to manage how to implement their initiatives based on their economic capacity as well as their technological capability (OECD, 2001b).

In the South Korean case, like other advanced nations, e-government initiatives have been a great ambition. The government provides three visions: the best administrative services to individuals; the right support for businesses; and the improvement of productivity, transparency, and democracy. Among these, administrative services have been improved in terms of time and cost, while productivity and transparency on the government side seem to have improved only slightly due to the low ranking of transparency index.

In summary, it is safe to say that e-government initiatives in South Korea have contributed to building knowledge infrastructure firmly as well as rapidly expanding IT industries. At the same time, however, there are still tasks to face in order to improve the productivity and transparency of the government.

## KEY TERMS

**G2B (Government to Business):** Services provided by governments to businesses based on ICTs.

**G4C (Government for Citizen):** Services provided by governments for citizens based on ICTs.

**Information Superhighway:** A highway in which information can be transferred with high speed through a broadband Internet system.

**Knowledge-Based Information Society:** A society in which ICTs are used for sharing and transferring knowledge and information.

**Knowledge Economy:** An economy in which more than 40% of employees are employed in high-technology manufacturing and knowledge-intensive services.

**Knowledge Infrastructure:** An infrastructure that enables the transfer and creation of knowledge.

**One-Stop Service System:** A system that provides comprehensive services in one place.

# E-Government in Shanghai

**Youwen Chen**
*Shanghai Administration Institute, China*

**Rong Yan**
*Shanghai Administration Institute, China*

## INTRODUCTION

Chinese e-government was launched at the beginning of 1990s. It is necessary to develop e-government not only for the appeal of information technology and the government's reform in the social and economic transition, but also for the demand of joining WTO (Wu & Zhang, 2003). Due to the developments in social organization, economy, and information infrastructure in China, e-government still remains at the initial stage (China E-government Research Center, 2002). Shanghai, as the largest and most flourishing city in China, is superior to other areas of China in hardware (information infrastructure, etc.) and software (e.g., "citizens' concept") (Qiao, 2004). Shanghai's experiences may be the example for other provinces and cities, for (1) the e-government of Shanghai was named as a model by National Informatization Commission (NIC) in 2001; and (2) Shanghai leads the development of e-government in China. For example, Shanghai is the first local government to construct governmental Web portal, to provide online services and to make legal rules about open public information. This article describes the development of e-government in Shanghai, analyzes its predicament, and probes into its future trends.

## BACKGROUND

### The Special Goal of Chinese E-Government

Governments around the world are embracing electronic government. From industrialized countries to developing ones, national and local governments are moving online (Improvement & Development Agency, 2002; Taylor, 2002). China is one of the countries following this trend even though its goals might not be exactly the same as Western countries who are promoting E-government as a way of realizing e-democracy (Bonham, Seifert, & Thorson, 2001; Phil Noble & Associates, Inc., 2001). Liu Yadong made it clear that Shanghai is focusing on IT as it leads to More Effective and Efficient Public Services (Liu, 2004). Therefore, e-government is broadly seen as the use of information and communication to promote more efficient and effective government.

### How E-Government is Generally Defined in China

According to citation review, the most popular definition of e-government in China is the following given by the World Bank:

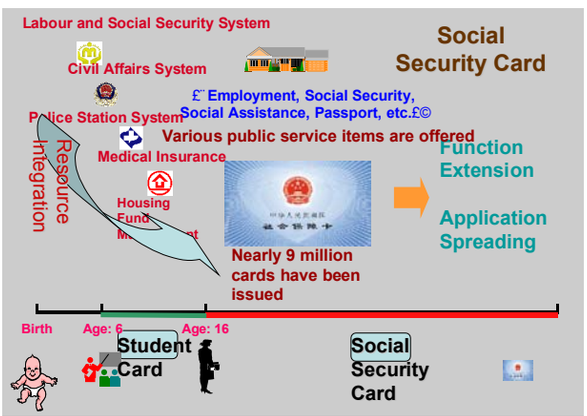
*E-government refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management. The resulting benefits can be less corruption, increased transparency, greater convenience, revenue growth, and/or cost reductions.* (The World Bank Group, 2003)

### Research Review of the E-Government of Shanghai

Despite this rapid growth of e-government in China, no studies were found that explored the content of either national or provincial Chinese e-government systematically (Xiang, 2004). Besides some speeches and official documents, research about the e-government of Shanghai is practically non-existent.

Our discussion is based on a study of e-government projects in which three primary categories were identified: e-governance, e-service, and e-knowledge. E-governance refers to linking citizens, stakeholders, and elected representatives to participate in governance of communities.

*Figure 1. Illustration of labor and social security system of Shanghai*



E-service involves securing and providing government services by electronic means. E-knowledge means using communication technologies to gain knowledge (Improvement & Development Agency, 2002). This text will analyze the e-government of Shanghai regarding these three respects as the frame combining with the reality of Shanghai.

## THE DEVELOPMENT OF E-GOVERNMENT IN SHANGHAI

In order to build the metropolis as the international economic center, the financial center, trading center and shipping center, Shanghai should play the role of the bellwether in the urban informatization. It will be the new theme of Shanghai development and the new motive power of social development as well. Although the building of Shanghai e-government is in its infancy, some achievements can be demonstrated, such as:

- Shanghai has accomplished the connection between official portal Web site (www.shanghai.gov.cn) and 47 municipal bureaus, 19 county's or district's governments, and 140 Web sites such as the People's Congress, CPPCC, public groups and so on (Gu, 2003).
- By the end of 2003, there were more than 1.421 million times that people visited the Web sites (Shanghai Municipal Informatization Commission, 2004).
- The design of government service base has changed according to the citizens' demands rather than administrative section's function. For example, Social Security Card (SSC) enables citizens to enjoy convenient public services (Shanghai Labor and Social Security Bureau, 2003). SSC, an IC card, is a key to operate more than 20 public services for citizens, such as medical care, unemployment benefit, and others. An information system, base of SSC, integrates a number of social services with public information.
- The online service way of dealing government affairs has been changed from only one section to joint sections (Shanghai Municipal Informatization Commission, 2004).
- The procedures of form downloaded and online registration have changed from one-way transmission into bilateral interaction by multi-alternative Internet (He, 2004).

## THE CURRENT SITUATION OF SHANGHAI E-GOVERNMENT

### Strengths of E-Government in Shanghai

#### Fairly Good Infrastructure

In Shanghai, several indexes (such as quantities of regular telephones, cellular telephones, libraries, and GDP per capita, etc.) are much better than those of other cities in China. Table 1 lists some indexes between Shanghai and Beijing. So, Shanghai's relatively perfect infrastructure has laid good foundations for the building of Shanghai informatization. It is one of the prerequisites for Shanghai ranking in a leading position among domestic cities.

*Table 1. Some indicators: Shanghai vs. Beijing*

| Index | Shanghai | Beijing |
|---|---|---|
| GDP (billion yuan) | 625.081 | 366.310 |
| per GDP ( yuan/person) | 46,718 | 32,061 |
| Population (ten thousand) | 1,711 | 1,456 |
| The length of long-distance optical fiber cable line (km) | 4,215 | 3,984 |
| The length of long-distance microwave line (km) | 313 | 266 |
| The capacity of mobile telephone switching exchange (ten thousand doors) | 1,547.0 | 1,351.0 |
| The capacity of long-distance automatic switching exchange (road-head) | 235,000 | 219,155 |

*Exchange rates (approx. in 2006): 1 CNY (Chinese Yuan) = 0.12 USD = 0.10 EUR*

### Relatively High Integrated Level and Approached Informatinized Indexes among Districts or Country in Shanghai

Obviously, it is easier to perfect the information infrastructure in a smaller area (a city) than in a larger area (a province). In Shanghai, there are about 19 districts and countries. Due to close-set geographical positions, they influence and infiltrate each other and their economic indexes are approached. In any case, possessing the powerful integrated economical and social act strength are the key factors that informatization level among all the districts or country in Shanghai rank high.

### Twin Wings Fly Together: Informatization for Both Citizens and Government

Informatization for both citizens and government are just like twin wings of Shanghai informatization. The goal of Shanghai e-government is to permeate the informatization into the traditional industries and operating mechanism. It is just like to "moist everything on earth gently and silently." Government at all levels armed by informatization, will fresh stronger vigor and accomplish high-efficiency management and service of government affairs.

## Weakness of Shanghai E-Government

### The Obstacles of Traditional Government's Administrative System and Mechanism

Most of the administration system and mechanism of Shanghai municipality were established and taken shape in the period of planned economy years. Although the situation has changed with the development of market economy, some profound problems are still existent. For example: some administration departments are unsuitable, their functions are crossed and overlapped, administrative procedures are fewer rational and handling public affairs are lack of transparency and so on. All these problems would become obstacles of government informatization.

### Lack of Integration of Information Systems within Each Government Administrative Section

To make good integrative programs and formulate unified standards are general experiences of developing government in foreign countries. Although Shanghai has made some practical regulations, they are not perfect. Were it not be improved, the coordination between governments and administrative sections would be very difficult and extravagant.

The problem how to renovate present resources effectively according to the unified programs and standards has been the key link of developing government informatization and e-government.

### The Basic Research of E-Government is Weak and without Profound Theoretical Foundation

In the building of e-government, people think high of "construction" and "technology" but neglect "research" and "management."

### The Talents Majoring in Government Affairs are Scarce

Although there are nearly 90,000 public servants in Shanghai, those who are familiar with the complete process of public affairs are few, and those who can assist building e-government are less.

### Challenges to Government Functionaries

Developing e-government means that the administrative model should be changed from traditional into informational and networked system. It requires higher quality for the entirety of government functionaries. At present, Shanghai government functionaries are lacking in informative knowledge and unacquainted in informative tools. Though government functionaries have been offered courses in basic computer skills, the requirements of the informatization of government are still to be met. Moreover, it puts forward higher requirement for enforcing traditional administrative power and playing supervision in market economy system according to the laws and regulations. Some government functionaries would meet threat for their ideology being out of time.

## FUTURE TRENDS OF SHANGHAI E-GOVERNMENT

According to the development of e-government and the fact of Shanghai, specially outlined in "the 11th Five-Year Plan" of Shanghai, the future trend of Shanghai e-government as follows:

1. Build a safe and reliable e-government platform with perfect function, unified standard for all government departments, districts, and counties in Shanghai. Their government affairs can be dealt and information can be exchanged on the interconnected network. Therefore, the working efficiency will be high and the administrative cost can be reduced.
2. Digitization, automation, and informatization are accomplished for files, official business, and administration of government organs at all levels in Shanghai. All the public files, meetings, supervisions, and information inquiries can be handled on network. More than 80% of public affairs can be dealt with on network.
3. Supply centralized public service by "one stop," "one procedure," and "one window." Release online news of government affairs promptly. Citizens cane obtain government's information and service conveniently by various kinds of terminal station such as Web site, telephone, IC card, and so on and supervise government affairs.
4. Make obvious progress on building of basic and strategic information resources such as data of population, legal persons, geographical features, and macro-economy conditions.
5. Build up the unified platform of e-government digital certificates and backup system for calamity. The information security system should be set up in conformity with informatization development.
6. Cards at all levels raise their consciousness of informatization and the ability to use information technology. Government functionaries should take part in the training of informatization and over 90% of them should pass its examination.

## CONCLUSION

According to following three aspects, Shanghai is reinforced to respond to the increasing demand for public services through e-government: (1) To speed up the transformation of government responsibilities; (2) To improve e-government according to the requirement of transforming government responsibilities—put more public service items online to make government services more accessible and efficient; (3) Shanghai citizens are quite familiar with IT and the concept of informatization–almost 5 million Internet users, 1.3 million family broadband subscribers, and 60% of household PC penetration rate, which make it possible to expand public services in the framework of e-government. E-government in Shanghai has many progresses in official portal Web site, citizen-oriented function, interactive online service and others. Although Shanghai has many advantages in developing e-government, there is much weakness also, for example, government's administrative system, or mechanism, lacking integrated information system, basic research, and talents being scarce. In the next years, Shanghai will elevate citizens' familiarity to the concept of informatization and the ability to use information technology, and build effective mechanism to invite citizens' comments on e-government.

## KEY TERMS

**Administrative System in Shanghai:** Shanghai administering 18 districts and one county. In the urban area, the administrative system in Shanghai is "two levels governments, three levels management, four levels networks." The "two levels governments" refer to the municipal government and district government. The "three levels management" refers to except municipal government and district government, the sub-district office (the agency of the district government) bears government's public management function too. The "four levels networks" means besides above-mentioned three levels management organization, the autonomy organization of the basic unit (residents committee or villagers' committee) gives play to the role of linking between people and government in the public affairs, thus formed networks of four levels in city management: the municipal government, district government, sub-district office, and autonomy organization at the basic level. In the suburb, the administrative system is "three levels governments, three levels management, four levels networks," only because the town government is a legal government's level.

**E-Government:** As to the traditional government, the core of e-government is making the existence form of government take place great change, through using modern information technology, network technology, and communication technology among the traditional governments, to form one platform of government combined reality and network virtue together. Therefore, the e-government is an electronic network government.

**Five-Year-Plan:** The "five-year-plan" is a kind of guiding policy of Chinese Government to national socio-economic development. "It originates from" the first Five-Year Plan which issued and implemented in 1953, and the time span of "the first Five-Year Plan" was from 1953 to 1957. Because of some reasons, there had cut off three years between "the second Five-Year Plan" (1958-1962 ) with "the third Five-Year Plan" (1966-1970 ). Analogizing sequentially, the time span of "the tenth Five-Year Plan" is from 2001 to 2005. The time span of "the 11th Five-Year Plan" which is planning at present is from 2006 to 2010.

**Informationization:** The informationization is a transition course. Pointing that the development of modern information technology (IT) will lead the mankind to the information-intensive society relying mainly on information industry from the industrial society relying mainly on traditional industry.

**Integrated Information System:** To the public affairs in one level government or an area, propose an integrated

information system. In order to prevent the government department turning into information detached islands when realizing the informationization.

**Interactive Service:** Through the e-government, the citizen, enterprise can carry on the communication with the government in the network, and the government can answer the citizen, enterprise pass the electronic way in conformity with the request too. That is to say, the government and citizen or enterprise can finish being bilateral interaction in the network, and even can finish the whole course of a certain public affairs.

**Official Portal Web Site:** A trans-departmental and comprehensive public affairs application system. On the informationization construction foundation of every government department, the citizen, enterprise and government's staff member can all insert every relevant government department's affairs application, organization content and information conveniently fast through the official portal Web site, obtain the individualized service, enable the suitable person to obtain the appropriate service in proper time.

# E-Government in the Information Society

**Lech W. Zacher**
*Leon Kozminski Academy of Entrepreneurship and Management, Poland*

## INTRODUCTION

The information society (IS), which nowadays is the emerging form of the organization of advanced societies (see e.g., Castells, 1996; May, 2002; Zacher, 2000a, 2000b), is governed more and more by the use of electronic devices and systems. That is why the concept of *e-government* was introduced and practically implemented. (For a historical perspective, see the article on Historical Perspective of E-Government).

## BACKGROUND: BASIC FUNCTIONS AND VARIOUS MEANINGS OF E-GOVERNMENT

Apart from the technical side (e.g., infrastructure, equipment, programs) *e-government* can be defined as a *set of practices or activities* of various kinds—ranging from political decisions, national legislation, international actions, and so forth, to public services for citizens on a local level—which use ICTs. Such practices can be not only high-level decisions and general regulations, but also information and services available for individuals, groups, communities connected with possible public support, job opportunities, on line payments, various advice and so on.

Thus, e-government can be defined as the production and delivery of services (including information) within government and between government and the public—using ICTs (see e.g., Fountain, 2004). In the broader definition, not only practices enhancing access to and delivery of services are mentioned but also more general aim—to improve relations between government institutions and citizens (Heichlinger 2004).

Electronic or in other words info-communication technology (nowadays mostly digital) is just a powerful new instrument of politics, decision making, public administration, and governance. So it can be evaluated from the point of view of its applicability, appropriateness, effectiveness and efficiency—all not only in a technical but also a political sense. On the other side citizens and facilitations of their life and activities (e.g., in business) can be the reference point. Under democratic political regimes, the latter is underlined.

Ideally, e-government should mean less management and more stewardship of government (all levels and agencies) and more citizens' participation. Therefore, e-government can be not only more efficient public services but also a *part of democratic process*. Alternatively e- government can be substantially commercialized (citizens become then customers or clients solely) and can be treated as a "technical tool." Of course, in practice some mixed solutions are possible and possibly most realistic (in any market economy).

E-government as it is now in the advanced countries (e.g., in the EU—see e.g., e-Forum and e-Europe Web sites) appears to be a fundamental issue especially on a local level. On this level, authorities and administrations have frequent and mostly direct contact with citizens and other stakeholders (e.g., companies, NGOs, foreign firms).

Applications of electronic instruments (or in other words ICTs) in politics, administration and management proved to be extremely useful and efficient at least in certain fields like

- Identification, recognition, and documentation of needs of various social groups which are consumers of public services
- Improvement of efficiency and also transparency and trust (making public all procedures and other information)
- Information policy (i.e., publications of various reports, official documents, projects and plans to be debated) and citizens' participation (by use of interactive media)

E-government as a result of the application of ICTs in public administration activities and having multifaceted impacts will enhance *e-governance* and *e-democracy*. Moreover, its transforming role makes it an important characteristic and a part of IS.

From the beginning e-government oriented predominantly to the needs of bureaucracy, and the information of its work, procedures, and so forth had to be more effective, relevant, and easier. Then the massive access to the Internet, online information, and better communication between public administration and citizens made a difference. The participation of citizens, clients, and various stakeholders in shaping and providing public ser-

vices became politically possible and technically feasible. Moreover, participation was often declared as an important social value under democracy. Therefore, the management of public matters was somewhat transformed—*via* e-government into e-governance.

Moreover, due to the integration of bureaucratic work and its networking, the public administration institutions served their clients much better (i.e., faster) without multiplied visits in these institutions, without multiple data presentations, without corruptive situations.

There were some necessary stages of e-government evolution (or rather its building). The initial step was always a simple *Web site*, which served as the first contact and source of information about the institution, its services, procedures, and so forth. The next step was to make the relation between the institution and its clients interactive. The interactive Web site is possible only if some technological, organizational, and legal conditions are fulfilled (e.g., some necessary connections between Intranet system of an institution with Internet as an external system, validity of electronic signature). Further stages of the evolution are the following:

- Multifunctional fully interactive portals
- Personalized portals providing integrated services
- One official portal for all public services providing an integrated packages of services

The sequence of evolutionary stages of e-government has not only a technological dimension. The consecutive changes shift the communication between citizens and public administration to *virtual space* (time and physical space are not important any more). Further change makes inner structures and competence pattern of public institutions meaningless as well. Moreover, these processes are accompanied by steadily growing depersonification.

## MAIN ISSUES OF E-GOVERNMENT

E-government is still *in statu nascendi,* in its developing stage, accumulating experience, improving functioning. Moreover, in some countries it is already well grounded in the mentality, organization of the public sphere, in politics. However, in some it is still a new concept not practically explored yet. This is the problem of the transition economies especially those joining EU. Of course, there are many challenges faced by public administration and public organizations in all countries trying to use ICTs to serve societies better.

There are at least four groups of challenges:

- Legal issues
- Accessibility issues
- Economic issues
- Social issues

The *legal issues* in e-government concern such questions like privacy, authentication, taxation, various e-submissions, also e-voting and e-government presence in the courts, and so forth. It is evident that the adoption of e-government (or in other words—e-government techniques) has to affect legal systems and legal practices.

The *accessibility problem* of e-government applications in countries advanced and rich, with good technical infrastructure, a high level of computer literacy is limited mostly to groups of citizens with some disabilities (physical, cognitive, hearing, and vision impairments). Therefore, these applications ought to be user-friendly and inclusive. A more difficult issue to solve is—in the context of e-government (or e-governance in broader sense)—what to do with an often quite large social margin or socially excluded people (e.g., former prisoners) permanently unemployed, homeless, very poor, illegal migrants, and so on. Of course, the solution cannot be in this case only techno-organizational.

Growing e-government throughout Europe and the world is costly, which makes it an *economic issue*. Until recently, the fascination of ICTs use in public administration overweighed the question of return on investment. E-government as a certain benefit for citizens' use of resources (always limited) should prove its economic validity and effectiveness.

*Social issues* were already previously discussed. What can be added here is that the accessibility issue also has financial and social dimensions. Needless to add that social adoption and use of e-government applications require learning, computer literacy, and so forth. Moreover, it is expected that broadly understood e-government (or rather e-governance) facilitates inclusion, participation, democracy. This also has an important political meaning.

E-government is not only about faster and better provision of public service. It can give groups of citizens and of individuals not only some satisfaction but also citizen or community identity, some possibilities to act and to interact with others, to enable sharing of experience. Groups and individuals are not separated and closed any more since the Internet gives them an opportunity to function in the "connected intelligence" system (to use the de Kerckhove term—Kerckhove, 1997). This somewhat external input will certainly contribute to local, regional, and national e-government and could be seeds for world e-governance.

## E-GOVERNANCE: MORE PROMISES

Needless to add that e-government and e-governance can have very different frameworks for their functioning and performance. In fact, they vary from country to country, from region to region, from continent to continent. All possible differences and specificities—in political and legal systems, historical traditions, level of citizens' social and political activism, knowledge of their rights and opportunities, skills of using ICTs—have influence. Moreover technical infrastructure and its—also financial—accessibility is what counts as well. Often the poor, unemployed, the disabled, the elderly can be excluded. That is why e-government should be oriented toward such goals as *social inclusion* and *citizen participation* on a significant scale. However such goals are political but ICTs can help greatly. In fact, they create a historical chance to make democracy inclusive and participatory.

The important feature of e-government is a *learning process* on all sides—authorities and public, public administrations, public sector organizations, and various stakeholders. In this process, new knowledge and new digital technologies have to be absorbed and deliberately applied. This in turn requires new skills, education, the proactive attitude of citizens (being also clients, customers, stakeholders, lobbyists, etc.). Therefore, e-government does not only mean improvement of efficiency and higher speed of delivering services to citizens. It generates a new *social space*. It is a part of the greater change, namely the change of the relation between government (power) and citizens. Historically the partners of these relations were not equal. The new role and the growing significance of information are making this situation more equal and advantageous from the citizens' side. Such things like mass media, info systems, or Internet are in fact commonly available (at least in the advanced countries). Thanks to radio, TV, computers and nets, even the new generations of mobile phones, widespread information becomes then an important *form of control* of people over political and administrative power, also to some extent over business. ICTs enable the sharing of knowledge on the political process and on administrative procedures with citizens. More and faster information, more transparency in decision making, and above all—more interactive procedures means simply more democracy in governance, more space for civil society (see e.g., Ester & Vinken, 2003; Keskinen, 1999; Okot-Uma, 2002; Van de Donk 2000). It helps with the legitimization of power and enhances the participation of people. So e-society (or IS) can be—normatively—characterized by *e-governance*, *e-government*, and *e-democracy*.

Needless to add however that the present practice is quite far from the desirable ideal (the distance from it differs greatly and depends on many factors and circumstances). The principles of *good governance*—defined by the European Commission (White Paper on European Governance published in July 2001) are *openness, participation, reliability, efficiency, consistence*. To achieve this, an appropriate information policy should be implemented. Information politics is the important issue in any IS (e.g., Dutton, 1999).

## TOWARD INTEGRATED GOVERNANCE

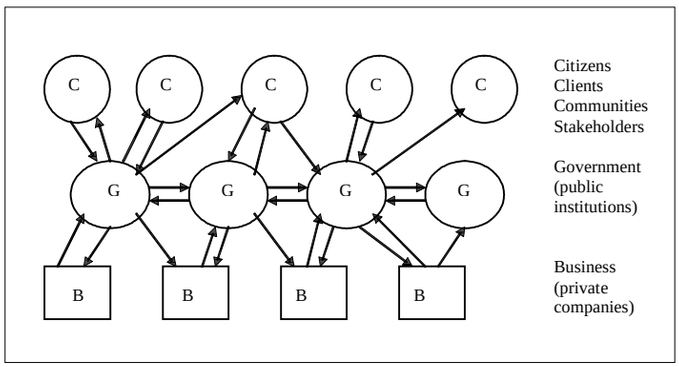
E-governance as being integrated is often called (see Heeks, 2001a) *integrated governance* (i-governance). This name reflects the integration of technology, information, procedures, and people. It is assumed that these are three components or rather subsystems of i-governance: e-government, e-democracy, e-business. E-government includes mostly structures, applications and procedures (this is technical and organizational orientation) of provision of public services. E-democracy however is rather politically oriented since it is connected not only with electronic communication and access to process, public services availability and possibilities of choice (see e.g., Browning, 1996). Citizens empower political actors. They can interact with political power and public administration and participate in decision-making processes (see e.g., Hague & Loader, 1999). This is important since public services provided to citizens often depend on policies and interpretation of legal regulations.

In turn, e-business is—but not exclusively—commercially oriented (e.g., provision of services to clients, commercial partnership, electronic transactions). Relations and information flows concerning the exchange of information and services provision are multiple here. They may be categorized as follows:

- Government to government (or public institution to public institution)
- Government to citizen (or public institution to citizen, consumers, other stakeholders)
- Citizens to government (or citizens, clients, stakeholders to public institutions)
- Government to business (or public institutions to private companies)
- Business to government (or private companies to public institutions)

This is presented schematically on the picture in Figure 1.

*Figure 1. The net (simplified) of relations and exchanges of citizens, government and business*



Therefore, e-governance creates technical, organizational, and network structure in an information society. Equal opportunities and empowerment of social actors makes it political dimension.

General evaluation of e-governance is positive since it makes possible to serve society better, to enable the rationalization of work, employment and management in public administration and public organizations; also it can be cost-effective; and above all it promotes democracy, participation, human activism. It is needless to prove that the successful implementation of e-governance principles and procedures depends on many—very differentiated nationally, regionally, locally—factors and circumstances, to name a few: e-literacy and e-readiness in society and public institutions, e-government strategies and policies, e-infrastructure, legal framework, and so forth. For Heeks, the strategic challenge is just e-readiness for e-governance (Heeks, 2001a).

## FUTURE TRENDS

### E-Future: Uncertain Predictions

It is worth noting that e-governance understood as e-authority or e-power in general (power structure and institutions, politics, power play, etc.) can lead to better legitimization of power, to more democracy, transparency, trust, participation, efficiency. However, it may lead also to more elitist, technocratic governance, to bureaucracy and to manipulation. ICTs do not exclude authoritarian rules, corruption, oppression, and terror. The trajectory of evolution of e-societies (see my article in this book on e-transformations of societies) are not really deterministic. In spite of the tendency to democratize the world's societies, the future is not certain whatsoever. There are counter—tendencies as well (e.g., due to the "clash of civilizations,") international terrorism, armed conflicts, social and political unrests, and turbulences in many places, also due to the growing criticism and opposition to the present type of globalization which is giving more to the rich and stimulating the digital divide (Chen, & Wellman, 2004).

On the other side in the longer time horizon e-transformations may disintegrate societies as organized presently. Some new forms may emerge and traditionally understood governance, politics and control will be modified somehow. Less and less of the state and its power structures, institutions and functions, more and more individualization (in the Net) and social atomization, changes of identity, closer, and closer relations between man and machines (such co-evolution plus growing artificialization of man will direct humanity towards a posthuman era—in the opinion of many futurists). It is in fact impossible to predict a distant future, because the current trends may change, people and their organizational forms may transform in a surprising way, moreover the divided and turbulent world may collapse. So the present visions of the e-future where semi-artificial humans, networked, living mostly in the Net, in virtual reality, with their fuzzy and multiple identity may never come true, but if they will—probably such notions like e-governance, e-democracy, e-government will not be applicable.

## CONCLUSION

### Further Research Questions

There are some timely research questions concerning above problematique. Their keywords can be arbitralily listed as follows:

- **Civilization or Age and Development Issues:** There are labels as new civilization (Toffler A. & H., 1994), information civilization (Hague & Loader, 1999), age (Heeks, 2001), age of network technology (Barney, 2000), digital age (Dutton, 1999).
- **State**, **Society**, **Citizens**, **Communities**, **Individualism:** There are labels like virtual state (Everard, 2000), network society (Van Dijk, 1999), digital citizen (Katz, 1997), virtual community (Rheingold, 1993, Wellman & Haythornthwaite, 2003), networked individualism (Wellman, 2001).
- **Democracy:** Some important terms were introduced and debated: anticipatory democracy (see Bezold, 1978), electronic democracy (Browning, 1996), teledemocracy (Becker & Slaton, 2000), democracy.com (Kamarck & Nye, 1999), digital democracy (Hague & Loader, 1999, Wilhelm, 2002), infocracy (Van de Donk, 2000).
- **Governance:** In this are some new ideas and postulates were formulated (e.g., capacity to govern) (Dror, 1999) was re-evaluated, future governance was extensively debated (e.g., Governance, 2001), governance in a networked world (Kamarck & Nye, 1999), electronic governance (Okot-Uma, 2002), e-government (Heichlinger, 2004), e-governance for development (Heeks, 2001a, 2001b).

The authors previously mentioned are just exemplary. Also, the list of the main problems can be supplemented (e.g., with technology area in which computer-mediated communication is an important issue—see e.g., Fuller, 1996, Herring, 1996, Hiltz & Turoff, 1978, Jones, 1998). Anyway, the question is how to integrate the above problem areas, approaches and methods used, how to make them mutually compatible. The answer lies in multi, inter- and—above all—transdisciplinary approaches and methods. Moreover the problematique discussed is rather new and or *in statu nascendi* so almost constant re-definitions, re-interpretation and re-evaluations seem to be needed in the future.

## KEY TERMS

**E-Democracy:** Refers to the democratic political system in which computers and electronic nets are used to implement its basic functions like information, communication, participation, and decision making.

**E-Governance:** Refers to public governance and is often identified with e-government but in a broader sense including politics (e-politics) and e-democracy.

**E-Government:** Various practices using ICTs applications to provide services by public administration to the society and to interact with various stakeholders.

**Information Society:** A society, which predominantly deals with production and applications of information in all fields of economy and social life. In the vast literature of the subject there are synonyms or closely related terms used: *information-rich society*, *informational society*, *cyber-society*, *e-society*, *network* (or *networked*) *society*, *virtual society*. They relate also to such term as *community*.

**Integrated Governance:** Integrates ICTs, information procedures and citizens in the process of achieving public goals; consists of three subsystems: e-democracy, e-government, and e-business.

**Teledemocracy:** Implementing media in the democratic process, mostly for information, opinion polls, referenda (i.e., mass participation of people).

# E-Government in the United Kingdom

**John Hudson**
*University of York, UK*

## INTRODUCTION

Like many of its western counterparts, the United Kingdom (UK) government has a long history of using IT in the administration and delivery of public services. Indeed, as early as 1959 mainframe computers were introduced in order to automate some routine aspects of public administration (Margetts & Willcocks, 1992, p. 329). However, it was not until the late 1970s and early 1980s—as the UK rose to the forefront of the emerging microcomputer industry—that IT featured in policy discourse in anything other than an extremely minor fashion. Even then—despite the appointment of Kenneth Baker as the government's first Information Technology Minister in 1981—the issue did not feature prominently and there was nothing approaching the equivalence of the neighbouring French government's review of the long-term social and economic policy implications of *L'Informatisation d'Societe* commissioned in 1976 by President Valéry Giscard d'Estaing (Nora & Minc, 1980). In fact, one former government minister claimed in his diaries that Baker's appointment to the government had more to do with finding a minor role for a politician piqued at his omission from the Cabinet than with Prime Minister Margaret Thatcher's belief in the importance of IT related issues (Lawson, 1992).

However, the agenda began to gather some pace following Thatcher's departure in 1990. Under the helm of Prime Minister John Major, the Conservatives introduced a number of important policies—including a series of industrially focused information society initiatives aimed at boosting the use of ICTs by business. In addition, prompted perhaps by the popular emergence of the Internet, other branches of government began to show a greatly increased interest in the issue. For instance, a Parliamentary committee—the House of Lords Science and Technology Committee (1996)—produced a major report on the implications of the information society for government. In addition, the publication of a major study on the same issue by the European Union (1994) added weight to the emerging agenda. Shortly before losing power in 1997, the Major government produced what was arguably the UK government's first systematic consideration of the implications of ICTs for government when it published an exploratory Green Paper titled *Government.Direct* (CITU, 1996). Though it came too late in the life of the government to advance its ideas any further than the discussion stage, it at least served to heighten the prominence of the agenda (Hudson, 2002).

## BACKGROUND

While the publication of *Government.Direct* was a landmark in the UK's e-government debate, it is fair to say that Tony Blair's incoming New Labour government would have given ICT related issues more prominence in any event. Indeed, while leader of the opposition, Blair famously announced to his party's annual conference that he had struck a deal with British Telecom to connect all of the UK's schools, hospitals, and libraries to the Internet. The announcement performed the dual function of showing that New Labour was both ready to govern and keen to exploit the potential of emerging Internet technologies.

However, Blair's government was in office for more than a year before they published any coherent plans for greater use of ICTs by government—in a broad discussion paper titled *Our Information Age: The Government's Vision* (Cabinet Office, 1998)—and almost two before more concrete policy objectives were published as part of the *Modernising Government* White Paper (Cabinet Office, 1999). Though detail was still thin on the ground, the publication committed the government to making 25% of its services available electronically by 2002 and 100% by 2008. A detailed plan of action was outlined the following year in *e-Government: A Strategic Framework for Government Services in the Information Age*, along with a new commitment to have all services available electronically by 2005 rather than 2008 (Cabinet Office, 2000). These major policy papers were supplemented with the publication of a series of complementary frameworks, guidelines, and regulations (e.g., CITU, 1999, 2000a, b). On top of this, important institutional changes were introduced, most notably the creation of an e-minister, an e-envoy (with his own well staffed office), and a series of departmental "information age government champions" responsible for pushing change forward. Finally, a number of other arms of government were charged with the task of bolstering government thinking in this area, most notably the Cabinet Office's Performance Innovation

*Table 1. Blair's key Information Age government targets*

- UK: best place in the world for e-commerce by end of 2002
- 100% of public services available electronically by end of 2005
- Universal Internet access by end of 2005
- Broadband available to every home by the end of 2008
- High usage of e-government services

Unit who published a weighty document—*e.gov. Electronic Government Services for the 21st Century* (PIU, 2000)—outlining the government's long-term vision (see Hudson, 2002).

Crucially, this agenda was about more than placing basic information about services online. Instead, the government wanted to "bring about a fundamental change in the way we use IT … [to] modernise the business of government itself" (Cabinet Office, 1999, p. 45). They suggested new technology had the power to join-up services that were presently delivered in a fragmented fashion by multiple government agencies through a centralized Web-based portal that would direct citizens to the full range of services relevant to their specific "life-episodes" (p. 47). More radically still, they suggested that as ICTs are likely to engineer a greater front-office/back-office split, there was no reason why private and voluntary sector organizations should not play a greater role in delivering public services—both in terms of back-office processing functions and client-facing front-end tasks (Hudson, 2002; PIU, 2000). Indeed, they envisaged a scenario in which there would be competition and choice for the citizen—between, for instance, the state managed portal for all citizens and more specialized private or voluntary sector maintained portals aimed at particular client groups (CITU, 1999). As the Performance and Innovation Unit (2000) put it at the time: "The vision for electronic delivery of government services is to move to multi-channel, mixed public and private delivery of citizen-focused services" (p. 20).

Alongside these plans for e-government, New Labour also committed themselves to a number of complimentary policy objectives at this time. Chief amongst these were the intentions to make the UK the best place in the world for e-commerce by 2002 and to deliver universal access to the Internet by 2005. The latter objective was, perhaps, less ambitious than it might sound, defined as access to the Internet via a neighbourhood Internet facility rather than in the home. However, it also included a commitment to making training available for those who needed it. Key in terms of meeting these access targets was the development of some 6,000 community based "UK Online" centres. As these programmes came to fruition in 2004, an important additional target was announced by Tony Blair: to make broadband available to every home by 2008. Around the same time, a new e-government target was also established: to ensure high use of electronic public services. Table 1 summarises the key targets.

## PROGRESS AND IMPACTS

As the 2005 target approached, the government maintained they were broadly on track to meet their e-enablement target: 75% of services were available electronically by the end of 2004 and they estimated some 96% would be by the end of 2005 (Cabinet Office, 2005a, 2005c). In global terms, the UK was performing well in many of the rankings of e-government performance at this time too. For instance, the UN placed the UK fourth in the world in terms of e-government readiness (UN, 2005) while a report published by the European Commission (2005) rated the UK as third best in the EU in terms of the sophistication of its e-government services. (See Table 2 for some of the key services.)

However, despite these successes, there are some notable weaknesses in the programme of reform to date. Chief amongst these is perhaps the very low usage of e-services: though the UK ranks highly within the EU for the quality of its services, it finishes bottom of the EU league table in terms of e-government usage by businesses and towards the bottom for usage by citizens (Eurostat, 2005). While there have been three (increasingly sophisticated) incarnations of the central government Web portal during the Blair era—open.gov.uk, UKOnline and, most recently, Directgov—it is fair to say that the visibility of these has remained relatively low given the hype surrounding the e-government agenda at its launch. Indeed, Tony Blair himself recently admitted whilst being questioned in Parliament that he did not know the URL of his government's flagship portal (House of Commons Liaison Committee, 2005, p. Q90). One might add too that the services available at present fall someway short of the radical vision for the reinvention of government trailed in 1999 and that most operate within existing agency boundaries rather than working across them, not least because individual government departments were given a target of getting 100% of their services online by 2005 but no target for working across departments or agencies. Moreover, government has struggled with the issue of online iden-

*Table 2. Examples of key UK e-government services*

NHS Direct
http://www.nhsdirect.nhs.uk/
A call centre based health advice line established in 1998 and backed by a complimentary Web based service, NHS Direct is one of the major success stories of the e-government agenda—though it is the call centre service, rather than the Web based one, that has had the major impact.

Directgov
http://www.direct.gov.uk/
The UK government's main Web portal. Launched in late 2004, it organises material around major "life episodes". It does not allow citizens to undertake transactions within the portal itself, but instead carries links to services provided by agencies across government.

Income Tax Self-Assessment
http://www.hmrc.gov.uk/
Arguably the first major transactional service to be placed online in the UK, it allows (registered) users to submit income tax assessment forms electronically. Introduced in 2000, the service was plagued by technical problems in its early days—and even suspended due to data security fears in 2002—and this hit take-up which was fewer than 1% of potential users by 2002. However, take-up increased substantially after this and by 2005 had reached 17% (1.63 million people). In part this increased take-up has been achieved through the use of accredited third party software by key intermediaries such as accountants.

Tax Credits Online
http://www.hmrc.gov.uk/
Similar in principle to the Self-Assessment online service (and operated by the same agency) this service allows citizens to check for a potential entitlement to tax credits (income top-ups for the low paid or those with children for instance) and then (for registered users) to lodge an application to claim them.

Transport Direct
http://www.transportdirect.info/
An integrated transport information portal that provides information on a range of different types of travel including road, rail, bus, and on foot. The main feature it offers users is the ability to provide information on routes and different transport options for journeys between different streets, suburbs, cities, and landmarks. Users can establish personalised accounts in order to tailor information to their own needs, and the site carries live information about service alterations and traffic delays.

Driving Skills Agency
http://www.dsa.gov.uk/
One of the first e-services to offer users an individual account, visitors to the site can book (and cancel) driving tests and take mock theory tests at this site.

tity verification and many of the transactional services can only be accessed following submission of a paper based registration form, while many others provide online information and downloadable forms but ask citizens to print off and mail in signed forms in order to complete transactions.

In addition, it is probably fair to say that attempts to foster public trust in e-government services have been undermined by a number of well publicized IT disasters, including: several short term withdrawals of a flagship site allowing citizens to submit their tax returns online following technical errors that threatened the security of users' data (*BBC News*, 2000, 2002); the suspension of a site giving access to the 1901 Census just five days after its launch because its technical infrastructure was unable to meet significantly higher than predicted demand for the service (National Audit Office, 2003); and the closure of the tax credits portal following the discovery of widespread organized theft of identity data and connected fraudulent tax credit claims (*BBC News*, 2005). Worse still, problems with major back office systems have hampered the delivery of key public services for a number of years too (see Public Accounts Committee, 1999). The most notable disaster is arguably that involving the Child Support Agency (CSA), whose Child Support Computer System (CS2) is not only due to be delivered years late and tens of millions of pounds over budget, but has caused a delay of several years in the introduction of a new policy framework for assessing child support

payments and placed considerable stress on both CSA staff and customers in hampering the efficient administration of tens of thousands of cases described as being "stuck" in the system (Work and Pensions Select Committee, 2004, 2005). While the precise causes of this—and similar—disasters is subject to considerable debate, many have suggested the UK government's lack of in-house expertise and its reliance on a small number of large IT contractors are particularly problematic. Indeed, Dunleavy et al. (2004, p. 36) have argued that "government-IT industry relations have become dangerously unbalanced" in the UK.

## FUTURE TRENDS

Despite these challenges, the UK government remains committed to its IT based modernization agenda, though there are signs that the substance of the agenda is shifting a little. Indeed, the Office of the e-Envoy, established to oversee the creation of e-government services, was disbanded at the end of 2004—along with the position of e-Envoy itself—and replaced with a more broadly based e-government unit. Whereas the former was primarily concerned with selling the idea of e-services, the latter is concerned with IT more broadly and its first head described his role as analogous to Chief Information Officer of the government (Arnott, 2004). This may be indicative of a more mature phase of e-government development, with the focus now shifting more firmly towards delivering organizational change rather than making existing services electronically available. A new digital strategy published in early 2005—*Connecting the UK*—reaffirmed the government's desire to tackle the digital divide (Cabinet Office, 2005b, p. 7) and a new IT strategy published at the end of 2005—*Transformational Government: Enabled by Technology*—restated the case for using ICTs to boost the quality and efficiency of services but placed a much firmer emphasis on the need to manage change carefully and to boost the professionalism and leadership of IT expertise within government (Cabinet Office, 2005c).

Ahead of these recent developments, a major cross-cutting review of efficiency conducted in 2004 (the so-called "Gershon Review"—see HM Treasury, 2004) placed a heavy emphasis on greater use of ICTs by government; indeed, it concluded that civil servant numbers could be reduced by some 84,000 in part because ICTs could make administrative processes more efficient. The review also suggested that savings could be made by migrating particular customer segments to electronic channels. The new IT strategy echoes these claims and is much more focused on the efficiency dimension of e-government than its predecessor. Indeed, the future trajectory of reform seems likely to be a more aggressively cost-focused one. A marker of this is that the old *Modernising Government* strategy stated that ICT "developments will not limit choice [or] end face-to-face dealings" (Cabinet Office, 1999, p. 53), while the new *Transformational Government* strategy argues

> *government should steer citizens and businesses to the lowest cost channels consistent with meeting policy objectives and customer acceptability. At an appropriate time, legacy channels should be closed ... unless there are compelling policy reasons that cannot be achieved by other means.* (Cabinet Office, 2005c, p. 11)

## CONCLUSION

As the first phase of Blair's e-government agenda reaches its end, it is clear that much has been achieved in terms of creating a substantial online presence for government but that much remains to be done if the aim is to deliver a significant shift in citizen-state interactions. Moreover, it seems clear too that some of the dotcom boom fuelled optimism that was evident in early policy pronouncements has been replaced by a more hard headed focus on cost savings and delivery. While the UK government has fared well in terms of meeting its main information age government targets and ranks highly in international league tables capturing various dimensions of e-government performance, the overall impact of e-government at the end of 2005 remains relatively modest given the substantial sums of money invested and the revolutionary rhetoric of most policy pronouncements. Whether the second phase of e-government signalled by the new IT strategy will improve on this record remains to be seen.

## KEY TERMS

**Directgov:** The UK government's citizen portal (www.direct.gov.uk)

**E-Government Unit:** Established in late 2004 as a division of the Cabinet Office and responsible for overseeing the use of IT across government.

**Government.Direct:** Title of the first UK government policy paper explicitly examining the implications of the Web for public services. Published as a Green Paper by John Major's Conservative Government in 1996.

**Office of the E-Envoy:** Established in 1998 as a division of the Cabinet Office to support the E-Envoy in promoting and overseeing the e-government agenda. Abolished in 1998.

**Modernising Government:** A White Paper published by the Blair government in 1999 that laid down the core principles of the first phase of their e-government agenda.

**Transformational Government:** Title of the Blair government's new IT strategy, published in 2005, that lays down the principles the second phase of its e-government agenda.

**UK Online:** A brand name used to package together some of the aspects of the early information age government agenda including the drive to boost Internet usage in the community and the second incarnation of the UK government's central Web portal.

# E-Government in Transition Economies

**Rimantas Gatautis**
*Kaunas University of Technology, Lithuania*

## INTRODUCTION

*In December of 2002, the Lithuanian government approved the concept of e-government. The objective of the e-government concept is to develop effective means that will allow for adapting of public administration to modern needs.* To achieve this purpose, the Lithuanian government identified e-government's implementation as one of political priorities. One step toward this purpose is the development of e-government, which ensures democracy, the promotion of e-business, the computerization of society, and the use of the Internet. Following the e-government concept's adoption, the Ministry of Interior affairs has been obliged to prepare a plan of measures necessary for implementation of the concept. The e-government concept describes the official approach towards the electronic government's phenomena in Lithuania.

## BACKGROUND

"[E-g]overnment enables and requires rethinking [of] how government is organized from the perspective of the [c]itizen and the functions the government performs to serve the needs of [the c]itizen." This is the excerption from the presentation of Lithuanian Prime Minister A. M. Brazauskas in World Information Technology Forum WITFOR'2003. The excerpt shows the necessity of e-government, which includes not only the implementation by IT means in public service, but also requires transforming the whole process of public administration in order to satisfy consumers' needs and ensures new quality in the relationship between public administration institutions and citizens or business subjects. Business firms, market conditions, and the culture and institutions of society need to undergo substantial change in a coordinated manner for ICT to diffuse throughout the whole economy in a way that supports the development of virtual community. It is the dynamic interdependence of these conditions that is the source of innovation and value creation in the new knowledge-driven economy. The agenda of research on the dynamics of adoption of new economy practices, innovation, and economic growth, as a result, needs to be expanded beyond the level of the firm. It needs to be built around the dynamic interrelationships between technological transformations, firms' organisational and knowledge-creating capabilities, emerging market and industry structures, and public institutions (Castels, 2000). Effective working of e-government may be possible only if it has the most important components: public administration, legal regulations, modern and safe ICT means of implementation, customers' possibilities and skills in use of ICT means (Wimmer, 2001). Therefore, this is the approach we use while preparing and implementing e-government in Lithuania. Without all of these components, it may not give the expected benefit, and also, it may be damaging.

## E-GOVERNMENT DEVELOPMENT IN LITHUANIA

### Legal Framework

Legislation of legal instruments doesn't make any essential problems for the implementation of public services in electronic means. The written document form and the electronic form are consolidated by technological neutrality and functional equivalence in Lithuania's Republic Civil Code, Public administration statute, and Archives statute. In the Civil Code of Lithuania's Republic, article 198 states that the document in electronic form is equal to the document in written form (for example, electronic data message, etc.), which includes these requirements:

- If it is transferred in telecommunication peripheral device
- If it is made by computer and saved in material medium in electronic form (if it's not for disposal)
- If the text protection is guaranteed (the function is done by electronic signature and other forms of data coding or blocking
- It is possible to identify the signature

In any case, the electronic document cannot be less worth than the paper document because of:

- It is electronic
- It has electronic signature

- It is transferred by telecommunication peripheral device
- It is made by computer and saved in material medium in electronic form

It is very important to state that the "written form" of a document in various public administration statutes cannot be evaluated as the one making troubles for usage and acceptance of the electronic form of a document. The assumption leads us to implementation of public electronic service (World Bank, 2003).

The attitude is certified by the change of Archives statute on March 30, 2004. The change consolidates common notion of a document without correlating it with the form of a document. It means that "a document" is the information stated by a legal or natural person in action despite its presentation, form, or medium.

Nevertheless, there are no essential difficulties in general statutes of Lithuania's Republic, although in statutes, which controls specific actions and act under statutes are some obstructions for services in distance in electronic way.

The Public Procurement statute is concerned with EU directives, but some of its attitudes may serve as disadvantages for transferring public procurement into electronic space. These attitudes concern submission of requisitions and proposals. Although the statute allows giving proposals for government electronicall, but on the other hand, the proposal has to be certified by other than electronic means. The detailed regulation of opening envelopes of proposals for electronic public procurement makes noticeable disadvantages.

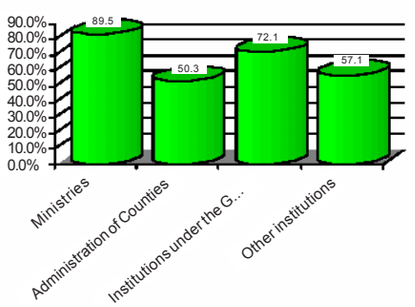
We may find in some statutes that the document in electronic form is not discriminated itself but the critics go to how the document is presented. There are some difficulties in transferring documents electronically, for example it is foreseen that the document may be transferred only by post, or some attitudes demand physical contact in transferring documents.

Another obstruction for electronic service is the requirement of special documents or property, such as a company's seal procuration, a personal passport or ID card, a driver's license, and so forth. It's possible to avoid these difficulties if we implement secure transferring of data from the data bases of public registry information systems or competent state institutions.

## Public Service

The public service survey was made in the end of 2003. Also state and self-government institutions on the Internet were evaluated on how they follow general requirements approved by the government of the Republic of Lithuania.

*Figure 1. Conformity Internet Web sites of the public authorities*



Public electronic service is usually available on the Internet. In the beginning of 2003, the government of Lithuania certified general requirements for state institution Web pages on purpose to standardize state institution Web pages, to secure their functioning, information actualities, trustiness, search possibilities, and so on. These requirements predict state institution Web pages on structure, information, administration, and appliance for disabled (SIC, 2004).

The survey exposed that general requirements are mostly fulfilled by Web pages of ministries—about 82%, counties administration Web pages—52%, institutions under the government of the Republic of Lithuania—64%, 7%, other institutions—63%. Information relevance and network application on WAP data transferring protocol have scanty accordance on the requirements.

Survey of juridical regulation and technological electronic service were done by an evaluation of European Community certified 20 public services (12 for citizens and 8 for business) rendering. Some of the services were parted, so then the general average was taken for evaluation. The level of public electronic service was evaluated sustained by Cap Gemini Ernst & Young's offered method, when the level of maturity is evaluated in stage 0—0%, stage 1 (information via Internet)—25%, stage 2 (one way interaction)—50%, stage 3 (two way interaction)—75%, stage 4 (full electronic case handling)—100%. In the end of 2003, the general public service rate was 43.8%. The services for business subjects proceeded faster—public services for citizens—average of 35%, and for business—average of 52.2%. The highest level of service (100%) for citizens is given by library, while searching in catalogues and presenting full text electronic publications. In business area, the highest level of service is extended by social fee for employers and submission statistical reports. Twenty-eight percent of all Internet consumers or 5.8% of the entire Lithuanian population applied at least once via Internet to public administration institutions during the year 2003. The research presented that more than half (53%) of consumers visiting public administra-

tion institution Web pages tried to know planned juridical acts projects and offer suggestions for its development. And only 17% applied to state or municipality officers responsible for relevant questions. (Ekonomines kosultacijos ir tyrimai, 2004).

Communication via Internet among citizens and business enterprises with public administration institutions is still not very active in Lithuania. Communication is influenced by a low rate of Internet use as well as incomplete information about Internet services (•ilionien, 2004).

All central authority and self-governance public electronic service is available on the Internet "Electronical Gateway of the Government" (www.govonline.lt, www.evaldzia.lt, www.epaslaugos.lt).

The first year after State Tax Inspectorate implemented electronic declaration systems, the income of 2003 declared via Internet more than 10% of all persons obligated to declare. Most of the institutions under the government of Lithuania (about 70%) had certified the documents of implementation in electronic service on the Internet or had planned to do so in the near future.

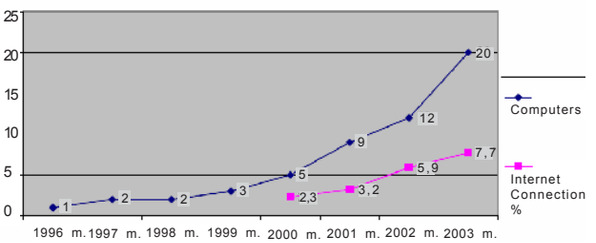
## Market Issues

The efficiency of public service on the Internet is influenced by society's possibilities and capabilities of using the service. Lately, the use of computers and the Internet has increased notably. Thirty-nine percent of inhabitants between the ages of 15-74 had used a computer (1st quarter—37%) in the second quarter of year 2003 in Lithuania. At the same time, 27% of inhabitants between the ages 15-74 of all residents in the state used the Internet (1st quarter—24%). And almost a quarter (23% or more than 600,000) state inhabitants used the Internet regularly; it means once a week or even more often (SIBIS, 2004).

The main locality for Internet use is usually the workplace. According to the data of the third quarter of 2003, 41% of all respondents use the Internet at work, 29% at home, 26% in educational institutions, and 20% in public Internet use places (for example, Internet bars, public Internet centers, etc.). The strong tendency is that computers and the Internet are used by mostly young people with high incomes who live in cities (SIBIS, 2004).

In 2003, Lithuania was characterized by the fastest Internet development in Baltic region: The number of consumers has increased to 25% (20-25% Internet consumers among state citizens). In the last three years, Internet consumer dynamics in newly joined EU countries were not as fast growing as in Lithuania. In two years, the number of Internet consumers has increased twice from the general number of the population, while in other CEE countries the growth was not so high (on average the growth was about 2-3% per year) (SIBIS, 2004).

*Figure 2. Increasing number of household computers and Internet connection 1996-2003m*



At the end of 2003, there were more than 350 public Internet access points in Lithuania where the service was free of charge. Public Internet access points are sustained by "public-private partnership." The government of Lithuania supported the initiative for private business alliance "Window to the Future." In 2003, 100 new public Internet access points from the state budget were established.

The rate of Internet usage at home is still comparatively low. In the third quarter of 2003, 20% of computers were in the household and Internet access was available in 8%. The results are influenced by the relationship between monthly household incomes and computer price. More than a third of households who don't have Internet access state that the equipment is too expensive and a quarter of them declare connection is expensive (high rate, subscription) (SIBIS, 2004).

# FUTURE TRENDS

## Governance

The government of Lithuania expressed its position for e-government implementation in the end of 2002, while they certified the concept of e-government, and in 2003 when they confirmed the action plan of the implementation. All state institutions of Lithuania are obligated to participate in organizing and implementing e-government projects. The Information Society Development Committee under the government of the Republic of Lithuania is responsible for e-government project coordination and observation. Strategic decisions are accepted in the Commission of Information Society Development, chaired by the prime minister.

The concept of electronic government implementation foresees general organizational and concrete state or municipality institutions' means for public service

using IT. The e-government action plan for implementation includes four groups of the nearest works: (1) juridical and organizational means, (2) creation of personal identification system, (3) technological development, (4) establishment of electronic service infrastructure.

## The Development of Public Administration

Lithuania's governmental institutions are responsible for a wide proceeding spectrum in relation with the state inhabitants and business entities. These functions were administrated by separate and independent public administration institutions and its subdivisions, if to look at historical point of view. There's also juridical proceeding repartition among the national, regional, and municipality governance level, which involves public and private juridical persons in public service. These factors cause parted public sector, which doesn't supply customers to be served applying in one institution but our citizens got used to get complex service in developing private business service.

The electronic government concept consolidated the one-stop shopping principle for public service. The principle appeals to public service integration oriented to a client. The research exposed that the main disadvantages are for complex public rules and confused procedures of many documents from various departments. These documents may be changed in interdepartmental data flows, and these procedures are defined in public administration acts. For example, when the individual applies to the social allowance, he or she needs to bring eight additional documents from the different public institutions. All this information could be collected by data flow channels, of course. The best decision appears to be one-stop shopping principle service by electronic means.

## Personal Identification

Electronic public service and IT security are very close. Certified government IT security implementation plan, IT security juridical regulation, consolidating main governmental functions security, foresee training skills of representatives' data security and ensure IT security implementation control.

Lately in Lithuania, electronic personal identification systems are widely used by business service structures and especially banks. E-government often is compared with e-business because both use the same facility, hardware, or software. However, there are essential differences between public and private sector proceeding models, which influence requirements for technical applications. The public service proceeding is related to juridical acts and the realization of responsibilities. Decisions are usually formalized hard because of influence of circumstances and the position of public interest as quality is more important than effectiveness. All public service impacted this way, when it is necessary to ensure inhabitants' privacy, data integrity in guarantee that public service would be for that person who asked for but not offending society interests. Personal identification and its data transferring integrity guarantee is the main assumption for 3rd and 4th interaction level and then the electronic signature becomes one of the main tools.

But we have to confess that's impossible to ensure consumer that his data transferred to public administration institution wouldn't be changed while we use personal identification means only. So then the institution becomes responsible to the consumer for his data retention. So the perspective of PKI technology remains, especially transferring special services for responsibility of documents perfection to electronic environment, but anyway security technologies would be selected by the risk factor. PKI technology electronic signature is implemented in electronic correspondence among the state institutions in tentative project.

## E-Inclusion

Much attention is given to balanced possibilities for all inhabitants to use IT and to involve a bigger part of the society in electronic consumers. The effort is of equal possibilities to all Lithuanian citizens to use the Internet and get accordant abilities to use IT means. The number of Lithuania's inhabitants who have computers and Internet access at home is not high (2003 accordingly 20% and 8%). Remarkable disjuncture is seen between the Internet consumers at home in Lithuania's largest cities and countryside (accordingly 16% and 1%). In Lithuania although Lithuanian GDP growth remains one of the highest in Europe and in 2003 it reached 9%, also in 2004 I st. quarter 7, 5%. But the real incomes of inhabitants cannot ensure that Lithuania will reach the rates of old EU countries average on the Internet connection. So if we wish to trace more people to use the Internet, Lithuania concentrates the problem in two directions: in applying franchise for people buying computers and Internet access and for establishing public Internet access points (PIAP). Seimas of the Republic of Lithuania considers Inhabitants incomes taxes statute's correction, which declares that inhabitants could pay part of computer or connection to the Internet price from the income-tax. By the project decree, there's foreseen to compensate about 29% price of computer and Internet connection for inhab-

itants. PIAP—is several computers working with Internet access where everyone may use it tax free in public places. The establishment of PIAP is organized by "public-private partnership" principle. The government collaborates with large private banks, telecommunications and IT companies alliance "Window to the future." PIAP is established in main cities from private capital finance and from state finance PIAP is formed in regions, where the number of Internet consumer is very low. It's anticipated to establish about 1000 PIAP till the end of 2005 in Lithuania, and it means that in almost all settlements to 1000 inhabitants PIAP would be working.

## CONCLUSION

E-government as socio-technical system is interrelated into network of knowledge stakeholders such as humans, machine agents, and artifacts like norms, laws, formal procedures, social and cultural practices, etc. Lithuania is facing just the first steps towards putting e-government into practice.

The concept of e-government outlines that e-government is a mean of government reforms and in the future it will help to proceed the development of public functions. One of the nearest purposes of Lithuania's government is all public services to transport into the Internet at the before mentioned third level till 2005. It is possible to do with equivalent development and one integral management of all responsible institutions.

The technological disadvantage related with slaw Internet, old software and its inconsistent, the lack of knowledge put the breaks. The sponsorship is a relevant question too. The public institutions declare that it is not enough support implementation and development of e-services. The problem is lack of competence, knowledge and ability to manage e-government implementation processes.

Effective information management and the creation of improved relations with consumers, partners, and suppliers can help to move the circle on: the government operates with private sector by creating business models, infrastructure and by providing services to end-users in public sector will help to develop e-government.

The implementation of e-government conception is just a little step toward good working e-government. Inevitable difficulties are emerged in the fields of changing models of decision-making, insufficient skills, information and communication infrastructure. There is need of permanent actions in this process, which will ensure: accessibility, trust, privacy, transparency, security, education, marketing and so on.

## KEY TERMS

**E-Government:** E-government refers to the use by government agencies of information technologies (such as wide area networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management.

**E-Inclusion:** E-inclusion is a social movement whose goal is to end the digital divide, a term used to describe the fact that the world can be divided into people who do and people who don't have access to—and the capability to use—modern information technology.

**Information and Communication Technology (ICT):** Includes ICT equipment (computer hardware, end user communications equipment office equipment and datacom and network equipment) plus software products, IT service and carrier services.

**One-Stop Shopping:** Public service integration which oriented to a client.

**Public Services:** Public sector is any part of a country's economy that is controlled or operated by the state or local government. The public sector often includes public services such as education or healthcare, and nationalized (government owned) companies and industries.

**Transition Economy:** Country that is moving from socialist toward a market (capitalist) economy.

# E-Government Issues in Switzerland

**Jean-Loup Chappelet**
*IDHEAP—Swiss Graduate School of Public Administration, Switzerland*

## INTRODUCTION

This short article gives an overview of e-government in Switzerland about 10 years after its introduction at the municipal, cantonal and federal levels. It outlines the technical and political difficulties recently encountered for the further development of online services at all levels and presents some good examples of what has been achieved so far. Opportunities for e-participation are also presented as a growing trend based on a few e-voting experiments at cantonal level. Since Switzerland is a multicultural country with four national languages, some of its e-government experiences and "lessons learned" can be useful in neighbouring countries with the same cultural background (i.e., Austria, France, Germany, and Italy).

## BACKGROUND

The term "e-government" (*cyberadministration* in French, *governo elettronico* in Italian, but interestingly, *e-government* in German on the site www.admin.ch/ch/d/egov) has been used in Switzerland (and its national languages) for around 10 years now: the first public Internet sites were launched by the city of Geneva and the Canton of Basel in December 1994. As of 1995, the Confederation inaugurated its main site, (www.admin.ch), to which were grafted, little by little, the seven Federal ministries. By the end of 1999, all the Swiss Cantons had official sites. In 2005, nearly all Swiss municipalities had a homepage. Only 59% of them, however, have a well developed site, whereas the others make do with mini-sites hosted by the Confederation or by their Canton. Today, a directory of official Internet sites in the public sector that is maintained by IDHEAP (www.gov.ch) contains around 2000 URLs. On an international level, Switzerland position has worsened over the past years: From 7$^{th}$ (in 2003) to 9$^{th}$ (in 2004) place in the World Economic Forum Network Readiness Index (WEF, 2005); from 15$^{th}$ to 20$^{th}$ place in the European Union Online Availability of Services study (DGISM, 2004), and from 11$^{th}$ to 62$^{nd}$ place in the Brown University Global E-Government Study (Brown University, 2004). See also (eVanti.ch, 2005).

Despite the efforts made over these 10 years, the barometer of e-government published in 2005 by the University of Applied Sciences, Bern (Brücher & Biswanger, 2004) reveals that public Internet sites are not well known by the population: the figures range from 51% of those taking the survey being aware of their cities' sites, to 41% for their canton's site, to 29% of them for the Confederation's site, and only 6% for the Swiss "national" portal, www.ch.ch. Moreover, the existing sites are only used by 14% of inhabitants, although 80% of the population has Internet access at their homes or offices. In addition, half of the surfers do not trust these public sites sufficiently to entrust them with their data. Finally there are few administrative services available online on a transactional basis: 493 communes offer such e-procedures out of 1,822 communes with a Web site, and only nine of them have more than 10 e-procedures (Barbey & Abbet, 2004).

Good examples of e-government, nevertheless, exist in Switzerland (see the following paragraph), and there is a need for sharing these among specialists. This, notably, is the role of the eVanti project (www.eVanti.ch), an initiative on the part of the Swiss Confederation that is similar to the approaches taken in the European Union (Good Practice Framework) and in the United States of America (Best Practices Committee). The conferences organised in 2004 and 2005 by eVanti.ch, presented a first qualitative panorama of what is taking place in the cantons and cities of Switzerland, as well as at Federal level (see for example, eVanti.ch, 2004a, 2004b, and 2005). A common language is necessary, and if possible, one exempt of poorly-understood American-English terminology. We should drop the "e" in front of each concept, as suggested by a seminal European report (Leitner, 2003), and concentrate on a comprehension of the "Internetisation" phenomenon in the public sector, in Switzerland as abroad.

## THE SWISS E-GOVERNMENT ICEBERG

On the basis of the experiences presented during the evanti conferences, we can affirm that an "e-government iceberg" exists in Switzerland as in many countries. The tip that is visible is constituted by the technical problems that this type of high-tech project cannot fail to encounter

and that often overwhelm discussion of it. But, as is the case for all icebergs, the part below the surface—meaning the other problems—is even larger than the part that is visible. There are in fact a multitude of other problems.

First of all, the bubble of the "new economy" exploded at the beginning of the 21st century, and there is now less enthusiasm for the Internet and thus also for its use by administrative entities. We have seen that there is little popular interest for the public sites, and this has led to a lack of interest on the part of the politicians who must vote budgets and lead projects. Moreover, the crisis within Swiss public finances at all levels no longer makes it possible to release the budgets essential to developing sophisticated sites. There are sometimes legal grey zones (Brücher, 2004). We also note a lack of co-operation in this area between the municipalities and their Cantons, with notable exceptions such as the Glarus Canton and the Neuchâtel site with its secure portal (www.ne.ch) which is based on a 20-year-old IT co-operation between this canton and its 62 communes.

As Glassey and Chappelet (2003) revealed, a fair number of Internet strategies have been published by the authorities, but few are applied consistently. In many instances, it is a case of re-inventing the wheel rather than pooling tried and tested solutions. Most of the norms that the recently formed eCH association (www.ech.ch) is to draw up are not yet available. In short, then, e-government in Switzerland—as is also frequently the case elsewhere—is still far too much the domain of information technology experts and not that of users and decision-makers. The same errors made during the early stages of introducing information technology into the administrations during the 1970s and 1980s are recurring.

On a more political level, many think that federalism, a form of Government which is engrained in the Swiss political system, is a hindrance to the development of e-government in Switzerland (Melillo, 2005). To follow this line, however, one would have to explain why such federalist countries such as Austria and Canada are on top of the e-government rankings. It is more likely that the causes of Swiss e-government difficulties can be found elsewhere, for example in the lack of a single national identification number for inhabitants, in the total lack of coordination of the IT infrastructure between the Swiss cantons and Confederation, in the lack of a federal e-government law, as well as in the very slow start of digital signature schemes (OFCOM, 2004, p. 38).

## SOME SOLUTIONS

Opportunities for a better e-government in Switzerland nevertheless abound. On a front office level, it is a case of facilitating relations with those administered in order to make these relations more practical and more user-friendly. The Canton of Vaud's Land Registry and its over three thousands daily subscriber visits is a good example (www.rf.vd.ch). In back office terms, it is a question of improving productivity and co-operation within the public service and of rendering administrative procedures transparent for those who use them. The CAMAC application, inaugurated in 2000, remains an exemplary case (www.camac.ch). This site links around 30 administrative services within the Canton of Vaud, the municipalities and those who issue tenders for construction work for the purpose of issuing construction permits faster and within the 30-day limit set my the law.

These cases of "Internetisation" all have tremendous potential for being more efficient (and thus creating savings). But we should not draw the line at achieving efficiency alone. The application of the Internet within administration can also be a catalyst for State reform inspired by the Reinventing Government movement as of the 1990s (Chappelet, 2004). Indeed, many Swiss e-government projects have been influenced by the ideas of New Public Management (Schedler, Summermatter, & Schmidt, 2003). Some examples follow.

The State must today be close to those it governs, and more transparent. The Swiss virtual front office (www.ch.ch), which provides information to inhabitants on administrative services and points them to the right source of information and at the right level, contributes to improved proximity although it is not well known yet. After a costly start, it is being reengineered to better fill the citizens' and businesses' needs. According to the New Managerialism ideas, the State must also become more entrepreneurial. The Swiss public markets' information system (www.simap.ch) facilitates this objective by stimulating competition and transparency regarding the purchase of goods and services by the Cantons, the major cities, and soon the Confederation. The State must also open up to new forms of public service provision. The SIMAP Association is an example of this. We could also mention the Municipality of Montreux Internet site, which is entirely outsourced to a private portal (www.montreux.ch), or the public/private partnership "Schools on the Net" intended to equip Swiss schools with Internet access and the teachers with the knowledge to make better use of Internet resources in their courses (www.PPP-esn.ch). Finally, the State should be more aware of its citizens' opinions. The experiences surrounding electronic voting in the Cantons of Geneva (www.geneve.ch/ge-vote), Neuchâtel and Zurich are making progress in this direction.

## FUTURE TRENDS

This reform, this modernisation of the State thanks to the Internet, is improving the classical compromise between efficiency and transparency, between economy and democracy. The French expression *cyberadministration* is thus no longer sufficient to describe the phenomenon that is beginning before our very eyes, and that involves all levels of the State and branches of government. The term *cyberEtat* (e-State) would be more appropriate. The State is not, in fact, a provider of personalized, online services alone. It goes beyond just having "clients" (those under its administration) who expect a personalised service, for it must also serve communities of citizens who interact with it on a collective basis. The traditional State task of drawing up and preserving public information within a certain territory, with its population and its rules, is undergoing a profound change thanks to the advent of the Internet. The territory's information systems, health networks, legislative and judiciary compendiums and its harmonised registers of persons and buildings are all examples of the type of collective services in Switzerland that are being and will be made available on the Internet to an increasing extent.

These services can serve as the basis for a renewal of democracy, frequently referred to as "e-democracy." This does not mean electronic voting alone, of course, but above all, greater participation on the part of the population in the process of drawing up laws and public policies. This participation can develop thanks to the availability, via the Internet, of public information and documentation on the one hand, and of means of communicating with public officials and elected representatives on the other. The Swiss Parliament's site is exemplary in this connection thanks to its eDoc section, which contains all the working documents for parliament members and its bulletin covering meetings that is made available only a few hours after the debates have taken place, permitting netizens to react directly to what an elected representative has said (www.parlement.ch). And one-fourth of the Swiss Federal MPs respond quickly to their e-mails (Chappelet, 2005). Interactive tools such as those simulating the outcome of a vote or an election are becoming widespread on political Websites, and can contribute towards shedding light on the debate and to affecting the outcome (Chappelet & Kilchenmann, 2005).

## CONCLUSION

These new methods of dialogue among citizens, their elected representatives, and the administration herald a new form for the State, also in Switzerland. Modern States, in fact, believe themselves to be mediators between citizens and society. The Internet revolutionises this relationship, moreover, since it facilitates it and renders it more easily accessible and more global. Little by little, we perceive everywhere the emergence of a virtual State—one that is global and without a territory. Administrative frontiers are fading. And this is maybe through such a "virtual State" that the presently impossible mergers of Swiss cantons will become thinkable in the future.

## KEY TERMS

**Cyberadministration:** The set of all public administration services offered on the Internet.

**Best Practices:** Successful e-government projects which can inspire similar projects.

**E-Government Iceberg:** A metaphorical view of the technical and non-technical problems encountered by e-government projects. The former (below the surface) are more important than the later (above the surface).

**E-Participation:** Participation of citizens through the Internet in the public affairs debates and decisions.

**Federalism:** A mode of state organisation used in several countries including Switzerland.

**Identification Number:** A number assigned to persons or businesses in order to identify them in a unique way within public administration departments.

**New Managerialism:** Set of ideas developed in the 1990s to apply the methods and techniques of management to public administration.

# E-Government Program of the Belgian Social Security

**Frank Robben**
*Crossroads Bank for Social Security, Belgium*

**Peter Maes**
*Crossroads Bank for Social Security, Belgium*

**Emmanuel Quintin**
*Crossroads Bank for Social Security, Belgium*

## INTRODUCTION

The Belgian social security consists on the one hand of three insurance systems (workers, self-employed workers, and civil servants), that cover a maximum of seven social risks (incapacity for work, industrial accident, occupational disease, unemployment, old age, child care and holiday pay—the so-called branches of social security), and on the other hand of four assistance systems (subsidies for the handicapped, guaranteed family allowance, minimum income, and income guarantee for the elderly), that grant people specific minimum services after checking their subsistence resources. In addition, a lot of public institutions at the national, regional or local level, or private companies entrusted with missions of general interest (e.g., energy, water, or public transport companies) grant benefits (e.g. tax or price reductions, free passes for public transport, etc.) to citizens based on their social security status.

In total, about 2,000 actors are responsible for the provision of social security and social protection in Belgium. More than 10 million citizens and 230,000 employers have very frequent contacts with those actors to claim their entitlements, provide information and pay their contributions.

## BACKGROUND

In the mid-1980s, an in-depth analysis of the functioning of social security proved that (Robben & Deprest, 2003):

- The organization of social security offices' business processes was not very customer-oriented and was certainly not coordinated among the various offices.
- Each social security office had its own set of paper forms with accompanying instructions, on the basis of which information was requested that was specifically necessary to calculate the particular contributions or grant the entitlements in the light of the particular social risk; in total some 80 different paper forms were used for data exchange between citizens and employers on the one hand and social security offices on the other with a total of about 2,000 pages of instructions.
- No possibility existed for an interactive exchange of data between the citizens and employers on the one hand, and the social security offices on the other.
- A direct exchange of electronic data was also not possible between the personnel administration software of an employer and the information systems of the social security offices, which led to an unnecessary and error-prone manual re-input of information.
- Social security offices very often asked the citizens and their employers to request information that was already available at another social security office in the form of a paper document, and to produce that document, rather than exchanging the information directly among themselves.
- Citizens and their employers thus had to inform many social security offices of a single event, following different legal concepts and administrative instructions each time.
- Since the exchange of data occurred on paper, processing was expensive and time-consuming.
- Citizens and their employers themselves had to claim their entitlements throughout the social security system and could not count on the automatic granting of all entitlements on the basis of a single declaration.

- Citizens and their employers did not have the necessary tools for checking the quality of the information before this was reported to the social security offices; this resulted in a relatively high percentage of errors and numerous subsequent contacts for the correction of errors, which could have been avoided.
- This all led to a very heavy administrative load and accompanying expenses for employers, which resulted in a brake on entrepreneurship, a smooth economic development, and growth in employment.

## PRIORITIES AND PURPOSES

The overall goals of the e-government program of the Belgian social sector are:

- to grant effective and efficient services with a minimum of administrative formalities and costs for all involved;
- to improve and radically reorganize the service delivery processes amongst the actors in the social sector, and between those actors on the on hand and the citizens and the employers on the other hand;
- to promote information security and privacy protection by the actors so that all the involved actors, citizens and employers can have justified confidence in the system; and
- to deliver integrated statistical information to the politicians and the researchers in order to support the social policy.

## STRATEGIC USE OF INFORMATION

Information is a prime production factor for most government bodies. Government revenues such as taxes and social security contributions depend on data about the income of citizens and company revenues; elections can only be held based on information about people residing within a country's borders; benefits and subsidies are granted taking information about the living circumstances of the duly authorized person and his/her direct environment into account, and so forth.

Thus, it is very important that all government bodies deal with information as a strategic resource. This implies effective and efficient treatment of information in compliance with basic data protection regulations, such as the Directive 95/46/EC of the European Parliament and of the Council of October 24, 1995 on the protection of individuals with regard to the processing of personal data and on the free movement of such data (Official Journal, 1995).

The e-government approach within the Belgian social security sector (http://www.law.kuleuven.ac.be/icri/frobben) is based on a clear vision of the use of information as a strategic resource:

- **Information Modeling:** Information is modeled in a coordinated way so that the model fits as closely as possible to the real world. By doing so, changes to the information model due to changing legal environments are avoided. This modeling takes into account as much as possible the expected use cases for the information. It can be extended and adapted flexibly when the real world or the use cases of information change.
- **Unique Collection and Reuse of Information:** Information is only collected by a social security institution for well-defined purposes and in a proportional way to these purposes. All information is collected only once, as closely as possible to the authentic source. This way of proceeding avoids the frequently repeated identical questioning of the citizens or the companies by several actors in the social sector. The collection occurs via a channel selected by the person from whom the information is collected, but preferably in an electronic way, using uniform services such as single sign on, notification of receipt for each message, and so forth. Information is collected according to the information model and on the basis of uniform administrative instructions operational for all actors in the social sector. Ideally, the supplier of information has the possibility of controlling the quality of information before its transmission to an actor in the social sector. This requires the public availability of software to check this quality. The collected information is validated once in compliance with an established distribution of tasks, by the most entitled institution or by the institution that has the most interest in a correct validation. Information is shared with and reused by the authorized users after the validation process.
- **Management of Information:** A functional task sharing is established indicating which institution stores and manages which kind of information in authentic form and makes it available to all authorized users. Information is stored in compliance with the information model. Information can be flexibly assembled according to ever changing legal concepts, which have to refer to the information model. Each institution has to report probable improprieties of information to the institution that is designated to validate the information. Each institution that has to validate information according to the agreed task sharing must examine the reported probable improprieties, correct them when necessary, and communicate the

correct information to every known interested actor in the social sector. Information is only retained and managed as long as there exists a business need, a legislative or policy requirement, or as long as it has historical or archival value, and then it is preferably presented in an anonymous or encoded way.

- **Electronic Exchange of Information:** Once collected and validated, information is stored, managed and exchanged electronically to avoid transcribing and reentering it manually. Electronic information exchange occurs using a functional and technical interoperability framework which evolves permanently but gradually according to open market standards, and is independent of the methods of information exchange. Electronic information exchange can be initiated by the institution that possesses information, by the institution that needs information or by the institution that manages the interoperability framework, in this instance the Crossroads Bank for Social Security (CBSS). The available information is used proactively for automatic granting of benefits, for prefiling when collecting information and for providing information to the persons concerned.
- **Protection of Information:** Security, integrity and confidentiality of information are ensured by integrating ICT measures with structural, organizational, physical, personnel screening, and other security measures according to agreed policies. Personal data are used for purposes compatible with the purposes of the data collection and are only accessible to authorized institutions and users according to business needs, legislative, or policy requirement. The access authorization to personal data is granted by an independent committee, after having checked whether the access conditions are met. The access authorizations are public. Every concrete electronic exchange of personal data is previously tested for compliance with the applicable access authorizations by an independent institution managing the interoperability framework, in this instance the Crossroads Bank for Social Security. Every concrete electronic exchange of personal data is logged, to be able to trace possible abuse afterwards. Each time the information is used for a decision, the information used is communicated to the person concerned together with the decision. Each person has the right to access and to correct his own personal data.

## CONCRETE RESULTS

Taking the above mentioned principles into account, a global review of the processes throughout the whole social security system has been carried out (Van Der Vorst, 2004; Viaene, Robben, Lahaye, & Vansteenberge, 1986). To improve the service delivery to the citizens and the companies, the Crossroads Bank for Social Security was created in 1991. The mission of CBSS is to be the motor of e-government in the social sector (http://www.ksz-bcss.fgov.be).

The Crossroads Bank for Social Security manages and uses a reference directory, showing:

- which persons/companies have personal files in which social security offices for which periods of time, and in which capacity they are registered;
- which information/services are available at any social security office depending on the capacity in which a person/company is registered at each social security office;
- which kind of information/service can be accessed, in what situation and for what period of time depending on in which capacity the person/company is registered with the social security office that accesses the information/service; and
- which users/applications want to automatically receive what services in what situations for which persons/companies in which capacity.

The Crossroads Bank for Social Security uses this reference directory

- to ensure preventively that a social security office only gains access to data it is allowed to access, and on people who are known to it;
- to route data requests to the social security office that can supply the data in question; and
- to transmit data reported automatically to the social security offices that can use the data in question to fulfil their duties.

The actual result can be summarized as follows (Robben & Deprest, 2003):

- All social security offices are connected to a network for electronic information exchange managed by the Crossroads Bank for Social Security, and have a legal obligation to request all information available in the network from each other electronically; they can mutually consult their databases and exchange electronic messages.
- Socially insured persons and their employers now need to make only a single declaration to the social security system as a whole in the following cases:
  - No later than the start of an employment relationship, an employer has to declare when

(date and time) the employee in question takes up his or her duties.
- Every three months, the employer has to declare what income each member of his staff has earned.
- When a social risk occurs, socially insured persons or their employers need only to declare information about that particular social risk.
- No later than the end of an employment relationship, an employer has to declare when (date and time) the employee in question leaves the company.

More concretely, the introduction of this system led to the following (Robben & Deprest, 2003):

- About 181 types of paper documents which citizens or their employers had to request from one social security office to pass to another social security office have been abolished and replaced by direct electronic data exchanges between the actors in the social sector; in 2005, 500 million electronic messages were exchanged.
- About 50 types of social security declaration forms have been abolished.
- In the remaining 30 social security declaration forms the number of headings has been reduced on average to a third of the previous number.
- Many declarations are made directly and electronically from employers' staff administration software packs and accountancy software packs.
- Citizens and their employers can make all social security declarations on the basis of standardized concepts and standardized instructions, and need to report data to the social sector as a whole only once.
- The number of contacts between the citizens and their employers on the one hand and the social sector on the other, has been drastically reduced, with a significant time gain as the result.
- Personal services to citizens and companies are offered.
- A huge number of social benefits and subsidiary rights are automatically granted without citizens or their employers having to make declarations anymore.
- Hospitals and pharmacists are freed from encoding about 100 million paper certificates a year concerning the insurance status in the healthcare sector; they now can read them electronically on the social identity card.
- According to a study executed by the Belgian Federal Planning Bureau, the rationalization of the data exchange processes between the employers and the social security offices implies an annual saving of administrative costs of more than 1 billion euros a year for the employers.

## SUSTAINABILITY AND TRANSFERABILITY

The Crossroads Bank for Social Security actively shares its experiences with interested institutions in Belgium and abroad. The approach has been described in several public documents and has received a Good Practice Label within the e-government Good Practice Framework set up by the DG Information Society & Media of the European Commission.

In 2001, the general manager of the Crossroads Bank for Social Security was asked by the Belgian federal government to elaborate an e-government plan for the federal public services, based on the successful experiences in the social sector. This plan, that is now being executed and permanently updated by the Strategy Cell Federal Civil Service Information and Communication Technology (FEDICT), has extended the above mentioned vision of the use of information as a strategic resource to the whole Belgian public sector and contained, amongst others, concrete projects such as the delivery of an electronic identity card to all citizens, and the creation of a Company Register, of a federal service bus, and of an integrated portal environment.

## FUTURE TRENDS

On its own initiative or on demand, the Crossroads Bank for Social Security will continue to extend its services to all actors in the social sector and to stimulate the reengineering of service delivery processes by creating value chains for the citizens and the companies based on a combination of back office integration and a user friendly front office. More concretely, the following projects are being executed

- The back office integration is continuously being extended to all public social welfare centers, to the sectoral complementary pension funds (private schemes supplementary to the legal old age schemes), to the institutions of the communities and regions entrusted with social missions, to the municipalities and cities and to the healthcare professionals; about 40 new types of electronic messages are planned.

- The automatic granting of benefits based on the social security status of a person will be generalized; indeed, a recently published law states that people who are entitled to complementary benefits on the basis of their social security status, as, for instance, a tax reduction, reduced telephone charges or a free pass for public transport, must not be asked anymore to submit a certificate; they are allowed to refuse the delivery of a certificate without losing the benefit; the institution that grants the complementary benefit has to consult the Crossroads Bank for Social Security to get information on the social security status.
- The Crossroads Bank for Social Security has proposed to the federal government the concept of the prefiled tax declaration of the natural persons; concretely, the tax declarations would be partially completed on the base of the data available in the social security network before being sent or presented on a portal to the natural persons; this would be a great step forward into administrative simplification.
- New electronic transactions will be developed for three target groups: the citizens, the companies, and the professionals of the social sector (e.g., the healthcare professionals); the transactions will be put at their disposal in an application to application mode or via portal sites; about 30 new transactions are planned, such as the online consultation of files and the online calculation of benefits; in that respect the electronic identity card will be used for electronic authentication and putting electronic signatures.
- The service delivery to citizens and companies will become multichannel enabled and be based on an integrated customer relation management; the services will be more personalized and self-service will be promoted
- Electronic payment facilities will be integrated in the service delivery.
- The use of the actual social identity card (the so-called SIS card) by all healthcare professionals will be promoted; the connection of the healthcare professionals to the network will also be stimulated; once these connections will be generally implemented and the electronic identity card will be delivered to all citizens, the social identity card can be abolished; the identification function will be taken over by the electronic identity card and the insurance status will be accessible via the network.
- An integrated e-workspace will be developed for the personnel of the actors in the social sector supporting among others knowledge management, document management, work flows, program and project management, e-communities, e-learning, and the labour relation; the e-workspace will be accessible to authorized users from anywhere and at any time by the use of a Web browser.

## CONCLUSION

The Belgian case was mentioned as a best practice in recent Web-based surveys on electronic public services ordered by the European Commission (Cap Gemini Ernst & Young, 2003). The success of the e-government program of the Belgian social security is due to the respect of a number of basic principles. As a conclusion, we want to put them forward as recommendations.

Do not look at e-government as a pure ICT event. Put the emphasis on an improvement of services and use a multidisciplinary approach. Have a good insight into the surroundings, the critical success factors and the stakeholders. Define a long term vision on integrated, customer-oriented service delivery, management of information as a strategic resource for all government activity, and interoperability. Optimize processes within each government institution, at each government level, and across government levels before their automatization. Standardize concepts and, where necessary, adapt regulation. Pay attention to change management, communication, and training.

Combine a long-term vision, profound process optimization and quick wins. Quick wins are useful to prove the efficiency of e-government and to motivate the public sector to change, but they have to fit with the long term vision. A race for quick wins does not stimulate development of well conceived systems based on reengineering.

Make the vision enforceable by citizens and companies and among government institutions, by formalizing it in regulation. Also adopt regulation to introduce uniform definitions of the information elements and attributes and the definition of legal concepts that refer only to the defined information elements and attributes, and to adequately regulate aspects such as privacy protection, information security, the protection against ICT crime, unique identification keys, the probative value of electronic information, the electronic signature, the equal access to public services, the transparency of administration, and so forth.

Make sure that available ICT components and information are reused to a maximum. Use already existing networks, means of electronic identification, authentication and authorization, interoperability frameworks and their accompanying basic services, portal environments, and the electronic information that is accessible from validated databases inside and outside of government. Through this, the efforts can be directed towards devel-

oping services with an added value, which are based on process improvements, while the multifunctional use of the same components is assured for all.

Also, develop multifunctional components, in conformity with open standards that are based on a flexible, modular, expandable, and service-oriented architecture, so that other developers of services can reuse the components.

See to a close cooperation with policymakers, other government departments, other governmental levels, users, mandated intermediaries and interest groups. Make sure that satisfactory consultations are held during regular contacts between the permanent representatives of the various stakeholders, so that a partnership is established.

Attune the service offer maximally to the needs and the logic of the users and involve them actively in the development of the services. Match the governmental processes with the own processes of the users. Assure user-friendliness.

Concentrate on a qualitative and interactive service offer, instead of a mere presence on the Web. Support users in the implementation of quality controls of the data, before these are transmitted to the government authorities, and use the available data proactively for an automatic granting of rights, prefiling of information in forms during data collection and a targeted provision of information to the users.

See to a good project management. Work incrementally and with prototyping, and give special attention to the roll-out by providing test and simulation environments, training and coaching for the users, and a multimodal contact center for the personal support of end-users.

See to it that proper measuring facilities are available, so as to assure permanent monitoring and improvement. Define the critical success factors in the area of performance, availability, quality, volumes, and effective use. Define the relevant measuring parameters for each of the critical success factors, the method and the frequency of such measurements for each indicator, and the reporting method. Assure that the measuring parameters are made available by the applications in the defined manner and in accordance with the frequency that was defined. Organize the follow-up procedures for measurement parameters, as a basis for permanent adaptation and improvement.

Make sure that the users have confidence in the electronic services that are provided. Develop an information security policy, which is designed to guarantee the availability, confidentiality, integrity, authenticity and auditability of the information systems. Give form to this information security policy in an integrated set of measures that warrant the basic principles with regard to information security.

## KEY TERMS

**Crossroads Bank for Social Security (CBSS):** Public social security institution created in 1990; driving force and coordinator of e-government in the Belgian social security.

**E-Government:** Use of information and communication technologies (such as wide area networks, the Internet, and mobile computing) by government agencies with the capacity to transform relations with citizens, businesses, and other branches of government. These technologies can serve a variety of different ends: better delivery of government services to citizens (especially those living in remote or less densely-populated areas), improved dealings with business and industry, citizen empowerment through access to information, and more efficient government management. The resulting benefits may be greater convenience, increased transparency and accountability in public decisions, revenue growth, less fraud and/or cost reductions (World Bank).

**Service Integrator:** Body that is both the motor and coordinator of e-government initiatives at a specific government level or a specific sector of the public services.

**Single Sign-On:** Concept whereby a single action of user identification and authentication can permit a user to access several services or systems where he has access permission, and that are offered by one or more suppliers.

**Interoperability Framework:** Framework in which several systems can operate and communicate together by using common standards.

**Reference Directory:** A database containing the following information:

- which persons/companies have personal files in which government bodies for which periods of time, and in which capacity they are registered;
- which information/services are available at any government body depending on the capacity in which a person/company is registered at each government body;
- which kind of information/service can be accessed, in what situation and for what period of time depending on in which capacity the person/company is registered with the government body that accesses the information/service; and
- which users/applications want to automatically receive what services in what situations for which persons/companies in which capacity.

# E-Government Readiness in East and Southern Africa

**Stephen M. Mutula**
*University of Botswana, Botswana*

**Justus Wamukoya**
*University of Botswana, Botswana*

## INTRODUCTION

Governments in East and Southern Africa, like their counterparts in developing and developed world, are under increasing pressure from donor agencies and non-governmental organizations to improve service delivery to citizens and at the same time be able to demonstrate accountability and transparency in the management of public resources (International Records Management Trust, 2004). Most countries in East and Southern Africa, largely began to appreciate the importance of sound public record management practices during the 1980s and 1990s. This period experienced increased donor pressure especially from the World Bank and the International Monetary Fund (IMF) through their structural adjustment programmes (SAPS) that was exerted on the recipients of global donor funding in an attempt to remedy the economic hardships that characterise most developing countries including those in Africa. Structural Adjustment Programmes were meant to provide the best opportunity to implement public sector reforms in order to promote better use of public resources and enhance accountability by governments to their citizens (Wamukoya, 2000).

To meet the accountability and transparency demands of the global donor agencies and also the need to meet the increasing demands by citizens for efficient delivery of services, governments worldwide are now taking advantage of the revolution that is taking place in information and communications technologies especially the Internet, the personal computer, the mobile phone, and other modern communication devices. The concept of e-government in its simplest form is now the catchword that is increasingly being used to imply the delivery of government services online. Heeks (2002) defines e-government as the use of information and communication technologies (ICTs) to improve the activities of public sector organisations. E-government is claimed as an efficient means to streamline public sector functions and increase citizen participation in the running of public affairs (Wamukoya, 2000).

Governments in East and Southern Africa like their counterpart in a developed world, are increasingly turning to e-government to streamline public sector functions and increase citizen participation in the running of public affairs (Wamukoya, 2000). However, in an attempt to implement e-government projects, countries in East and Southern Africa face numerous challenges such as lack of requisite skills and competencies in e-records management; lack of enabling policy and legislative framework; lack of standards and formal methodologies for managing e-record; and inadequate infrastructure.

## BACKGROUND

The countries of sub-Saharan Africa in general and many public sector institutions are turning to e-government by moving online, and conducting business using e-mail and the Internet. This has implications for information management with regard to accountability, transparency, accuracy, reliability, and security. For the purpose of this article, the countries of East Africa will refer to Kenya, Uganda, and Tanzania under the umbrella of the East Africa Community (EAC), while those of Southern Africa under the banner of the South African Development Community (SADC) will include: Angola, Botswana, Lesotho, Malawi, Mauritius, Mozambique, Namibia, South Africa, Swaziland, Tanzania, Uganda, Zambia, and Zimbabwe. Tanzania is both a member of EAC and SADC.

## HISTORY OF E-GOVERNMENT

The European e-government observatory, that has the responsibility to provide a synopsis of the e-government situation and progress in Europe notes that the concept of e-government, became more pronounced in the 1990s

and was aimed at enhancing progress towards an information society status (IDABC, 2005) as customers increasingly expected government to be accessible and convenient. In Canada, for example, the Government Online strategy paved way for the creation of e-government services in 1999 (Public Works and Government Services Canada, 2004). On the other hand, in the United States, Government Paperwork Elimination Act of 1998 compelling federal agencies to provide the public with the option of submitting, maintaining, and disclosing required information electronically instead of on paper was a significant stimulus for e-government development (Relyea & Hogue, 2003).

In Asia, Wescott, Pizarro, and Schiavo-Campo (2001) point out that governments in the region are only in the initial phases of adopting information and communication technology to improve financial management, streamline the delivery of government services, enhance communication with the citizenry, and serve as a catalyst for empowering citizens to interact with the government. Similarly, in Africa, Heeks (2002) points out that though governments have been using information technology for more than 40 years, key innovations such as computer networks, intranets, and the Internet started to emerge on the continent in the late 1990s. E-government phenomenon is therefore a new paradigm sweeping government enclaves both in developed and developing world. Oyomno (1998) points out that e-government is still undergoing development to provide an overarching conceptual framework. He points out that the development of e-government has evolved from merely using advanced ICT to deliver public services through to electronic service delivery as a new way of doing business in government, to currently locating e-government within the context of the emergent information and knowledge age.

## MEASURING THE DEGREE OF E-GOVERNMENT

The degree of e-government can be measured along a continuum of five stages namely, emerging, enhanced, interactive, transactional, and fully integrated or seamless (UNDP, 2002). At the emerging stage, a country commits itself to becoming an e-government player. At this stage, it has formal limited Web presence with static organisation and political information. In East and Southern Africa, amongst the countries at this stage include: Angola, Botswana, Malawi, and Lesotho. Similarly, the enhanced stage comprises of countries whose online presence has content that is usually dynamic and specialised such as government publications and legislations and is frequently updated. Countries in East and Southern Africa include: Kenya, Namibia, Mozambique, Tanzania, Uganda, Zambia, and Zimbabwe (UNDP, 2002). In contrast, the interactive stage is characterised by governments that have dramatic increase in access to a wide range of services, and capacity to search specialised databases, and download forms and applications. Within East and Southern Africa, only two countries, namely; Mauritius and South Africa have attained this degree of e-government (UNDP, 2002). Likewise, the transactional stage is characterized by governments that have secure transactions such as obtaining visas, passports, death records, licenses, and permits online. Within the East and Southern Africa region, only South Africa is reported to be moving towards this stage. At the seamless or fully integrated stage, the Website has capacity to access any service clustered along common needs in a unified environment. No country in East and Southern Africa has reached this stage (UNDP, 2002).

## E-READINESS PARADIGM

The degree of e-government depends largely on the level of e-readiness of the government concerned in various areas of its operations (Heeks, 2002). The concept of e-readiness like e-government emerged in the late 1990s when the term was first used by the Computer Systems Policy Project-CSPP (a public policy advocacy group of the United States information technology companies), when it developed the e-readiness assessment tool -the Readiness Guide for Living in the Networked World in 1998 to provide a unified framework to evaluate the breadth and depth of the digital divide at macro level between more and less developed countries. CSPP defines e-readiness with respect to a community that has high-speed access in a competitive market; with constant access and application of ICTs in schools, government offices, businesses, healthcare facilities, and homes; user privacy and online security and government policies which are favourable to promoting connectedness and use of the network (Bridges.org, 2001). In contrast, the Centre for International Development at Harvard University, defines e-readiness in relation to a society that has, the necessary physical infrastructure (high bandwidth, reliability, and affordable prices); integrated ICTs throughout business, communities and government (Bridges.org, 2001).

Heeks (2002) points out that the lack of e-readiness, contributes to the lack and potential failure of e-government initiatives. He identifies types of e-readiness that need to be considered in e-government plans. They include: readiness of data systems infrastructure in terms of quantity, quality and security of use for supporting government online; readiness of the legal infrastructure in

terms of digital signature and the capacity to interact with citizens, businesses, and other stakeholders online; readiness of institutional infrastructure that sets up the framework for government online; readiness of financial resources in terms of the necessary funds to meet the first investments; readiness of human capital in public agencies in terms of needed skills to launch government online strategies; readiness of technological infrastructure in terms of needed computing and telecommunication facilities for connecting public agencies from different ministries and different levels of government among them and with other stakeholders; and readiness of the political and administrative leadership to give vision and direction to government online initiatives.

Choucri et al. (2003) pointed out that the concept of e-readiness means different things to different people, in different contexts, and for different purposes. Consequently, as a result of the lack of unanimity on the definition of the term of e-readiness, a large gap exists between ideas and concepts, on the one hand, and practical applications and implications, on the other P. 4). Agriculture and Food Canada (2001) observed that the exact definition of what constitutes e-readiness was still open for debate and pointed out that, there were many degrees of e-readiness and each could include any one or more than one of the following activities: using e-mail as the most preferred communication method; using a Web site for internal and external communication; selling goods and/or services using the Internet; making travel arrangements using online Internet services; finding and purchasing computer equipment, software supplies and services through a company Web site; and sending electronic invoices to customers and receiving electronic bills.

The impetus for e-readiness initiatives both in developed and developing world is occasioned by the fact that ICT promises enormous benefits as part of the solution to economic and social problems facing countries. Moreover, it is felt that developing countries in particular, face the threat of being left behind if they do not address the growing intra and inter-country digital divide. In addition, international leaders and lending agencies are increasingly requiring recipients of donor funds to integrate ICT into their development aid programmes (SADC E-readiness Task Force, 2002, p. v). By harnessing the potential of ICTs, in all areas of human life, national and local governments have realised that they can now provide new and better responses to vital long standing issues such as poverty reduction, wealth creation as well as education, equity and social justice (Consulting and Audit Canada, 2004, p. 1). Similarly, an understanding of the e-readiness of a country or community is essential for providing baseline information that can be used for planning and also for making comparisons across regions, countries, and organisations (Minton, 2003; Rizk, 2004).

## E-GOVERNANCE SYSTEMS IN EAST AFRICA

The three East African countries of Kenya, Uganda, and Tanzania under the umbrella of the East African Community (EAC) as already pointed out, have developed a vision that is expected to guide the region e-government development agenda (East Africa Community, 2005). The EAC e-government framework covers all major aspects of regional cooperation such as online public services; e-education for public administration and e-business and entrepreneurial support. Each of the countries is making progress within the framework of e-government strategy. Tanzania for example, finalised and published its national ICT policy in March 2003 and has so far implemented various e-government initiatives in the area of civil service reform. One notable e-government success story in Tanzania is the integrated financial management system (IFMS). IFMS provides online accounting and payment activities in key government offices throughout the country and one bank account for the whole government (Oyomno, 2004).

In contrast, Kenya published its e-governance strategy in March 2004. The strategy is meant to: help government talk to itself, enhance its interaction with the citizens, and improve government services to the business community (Nyanchama, 2004). The Kenyan e-government strategy when fully implemented will find application in policing, voting, traffic management and more. It is expected that e-government will address inefficiency in business registration process that is currently bureaucratic and consumes so much time that some investors choose to go elsewhere. The same can be said of the judicial system where files get misplaced and thus delays the execution of justice (Nyanchama, 2004). The progress in the implementation of e-government strategy in Kenya include Cabinet's approval; creation of a Cabinet Committee to oversee its implementation; establishment of Permanent Secretary-level Committees to deal with institutional implementation. In addition, awareness creation in government, and public service is going on. Furthermore, in June 2004, structured networking cabling were reported to have been completed inmost government buildings. Moreover, training for technical staff and user training for civil servants is ongoing and all government ministries have information Web sites (Okongo, 2005).

In Uganda, the Interagency E-Government National Planning Team embarked on strategies to integrate ICT into the revised poverty eradication action plan for 2005/06. Moreover, 54 portals and ICT training centres and cyber cafes have been set up in 30 districts across the country. Furthermore, computerised driving licenses is being implemented and some five universities have set

up e-learning facilities (Bitwayiki, 2005). To date, e-government progress that has been made include the completion of the first phase of a multimillion-dollar integrated financial management system (IFMS).

In Tanzania, the government is making good progress in its e-governance plans. The progress so far made in implementing e-government include endorsement by Cabinet on April 20, 2004 of the e-government strategy. Key features of approval according to Sawe (2005) was the establishment of official point to coalesce and reinforce existing e-government initiatives; build wide area network to carry voice and data efficiently among all levels of government. Moreover, management information system strategy has been successfully piloted in three ministries. In addition, recruitment of staff to strengthen e-government support and continued ICT awareness of over 2000 civil servants have also been undertaken.

## E-GOVERNANCE SYSTEMS IN SOUTHERN AFRICA

The SADC member countries were assessed in 2004 for e-government maturity based on UNDPEPA e-government readiness levels that has been discussed earlier. The UNDPEPA e-government ranking of countries is based on an index computed from variables such as Web sites, telecommunication infrastructure and human resources. On the basis of the assessment, Botswana, Malawi, Lesotho, and Angola were placed in the emerging category. On the other hand, Namibia, Mozambique, Tanzania, and Zimbabwe were placed at the enhanced stage, while Mauritius and South Africa were at the interactive stage. At the seamless stage, only South Africa was listed (UN, 2004). The actual index scores were as follows: Mauritius (0.5055), South Africa (0.4902), Seychelles (0.4259), Botswana (0.3827), Swaziland (0.3647), Namibia (0.3290), and Lesotho (0.3250). These e-government indices were above the African average of 0.2528 but below the global average of 0.413. A similar assessment based on percentage of e-government utilization put South Africa and Mauritius in the high range (67-100%), while the rest of the countries were in the low range (0-33%) (UN, 2004).

Each country within the SADC region is making its own e-government progress. In South Africa for example, the government is using information technology to enhance community development and democratic space as part of the public sector reform measures to enhance transparency and accountability in the management of public resources (Benjamin, 2001). Community telecentres have been established across all the nine provinces in the country to enhance access to government information by the communities (Heeks, 2002). The South African government in 2004 launched the Internet gateway, giving individuals, organisations, and foreigners a single entry point to government services and information, organised according to user needs rather than government structures. The gateway has the information portal which carries comprehensive, information on government contacts, departments, events and projects, as well the latest government speeches, statements, notices, tenders and consultative documents (SouthAfrica.info reporter, 2004). Other important e-government development in South Africa include the Home Affairs National Identification System (HANIS), which was approved by Cabinet in January 1996. This system along with associated advanced technology such as an automated fingerprint identification system (AFIS) and smart card technology, are expected to enhance civic services management (Department of Home Affairs, 2002).

Geness (2004) outlines other e-government projects in South Africa that were being rolled out in 2004, such as Cabinet project to enable the President to monitor and evaluate performance of Ministers; integration of the Criminal Justice system to enable the electronic tracking and monitoring of events from commission of a crime, arrest through the court process leading to conviction, rehabilitation and re-integration into society; conversion of fingerprints into digital format; putting matric results online, small and medium-scale enterprises name reservation; deeds registration; information enquiry service; cross border permit applications, tax e-filing; school networking and education related projects.

In Mozambique, the government has successfully implemented an e-government pilot project connecting 15 national public administration entities in Maputo the capital. The project is called Government Electronic Network (GovNet), and is part of Mozambique's national Information and Communications Technology Policy Implementation Strategy. The strategy aims at improving public services and increasing transparency in the public sector. To date, the pilot has established a communications platform for the Ministry of Public Administration, Ministry of Finance, Ministry of Health and Ministry of Science and Technology, giving them a unified e-mail system, intranet, and document management system, as well as cost-effective shared access to the Internet (ITWeb, South Africa, 2005). GovNet is being used by over 500 government employees. Oyomno (2004) lauds Mozambique's successful ICT policy and implementation strategy attributing this success to strong institutional arrangement such as the ICT Policy Commission, political leadership in which the Prime Minister chairs the Commission, and finally the top-town approach and simple but powerful framework of implementing the e-government program.

In Namibia, the ICT Alliance -a non-profit organisation comprising of all ICT related bodies including the government and the private sectors exists to narrow the digital divide in the country. The Alliance plans to run a project code-named Wise Namibia, with the vision to give Namibians equal access and skills to use and benefit from the information society services and communication systems. The intention is to create a wide client base for e-governance and e-commerce. The Namibian government was reported in 2005 to have finalized an e-governance policy for the public service for Cabinet approval (AllAfrica.com, 2005).

In Mauritius, the vision of e-governance is to create a digital community which can foster personal involvement in government; bring government closer to the people and provide round the clock service (Aubeelack, 2004). Institutional mechanisms that have so far been put in place include ICT Ministerial Committee chaired by the Prime Minister, and three Ministerial Task Forces on e-government, e-education; cyber city and business parks. Moreover, the necessary regulatory framework has been promulgated as well as the liberalization of Telecoms sector. Furthermore, a new licensing regime has been put in place and a national telecommunication policy was elaborated in 2003. There is an ongoing capacity building program for all and specific training for civil servants. In addition, improvement on existing ICT infrastructure has been undertaken. Moreover, an e-government task force was set up under the chairmanship of the minister of Information Technology & Telecommunications. Other e-government projects include the computerization of passports and immigration services; trade-net or the electronic authorization by customs for delivery of goods, electronic submission of sea manifest by shipping agents, electronic declaration and processing of bills of entry at customs and transfer of containers and contributions network project (covering revenue departments such as income tax and value added tax). Moreover, a government one-stop Web portal that provides comprehensive information and delivers integrated services round-the-clock has been completed

In Lesotho, progress that has so far been made in e-governance include access to a computer by each government office and the networking of ten ministries (Sehlabaka, 2004). In contrast, in Botswana, the government in 2005 completed a national ICT policy that provides the roadmap for bringing all government services online (Department of Information Technology, 2004). The policy now awaits Cabinet approval before it is taken to parliament for enactment. In contrast, in Zimbabwe, the government Web site is populated with the ruling party content (Anzinger, 2001), while in Namibia, the government Web site includes the Ministry of Health and Social Services, a gateway providing specialised information services on health (Republic of Namibia, Ministry of Health and Social Services, 2002).

## PROBLEMS OF IMPLEMENTING E-GOVERNMENT SYSTEMS IN EAST AND SOUTHERN AFRICA

There are various problems being experienced by the countries of East and Southern Africa in their endeavour to implement e-government projects. The problems are of human resources, infrastructure, financial, political, and cultural nature. In Kenya for example, Nyanchama (2004) points out that critical ICT skills are generally lacking. Where they exist, they are not sharpened enough to cope with the anticipated task of realizing the e-government strategy. The e-government strategy in Kenya faces further challenges of the government workforce that has been brought up in an era when computers were a mystery to many. Eldon (2005) enumerates problems facing Kenya with regard to e-government to include among others: lack of commitment by the top leadership, high cost of hardware and software, and poor basic telecommunication infrastructure. Moreover, Kenya's telecommunications sector suffers from under-investment and political interference. For example, the country has not formulated an integrated national informatics policies, lacks a national ICT policy, and the slow pace of liberalisation of the telecommunication sector is of great concern. Similarly, Tanzania faces infrastructure problems that must be addressed to achieve effective e-governance. For example, the number of fixed telephone lines were 230,000 in 2002 in a population of 35 million giving a teledensity of 1.2% (Sawe, 2004). In Lesotho, (Sehbalaka, 2004) notes that very few homes have access to computers or the Internet. In addition, the country faces the problems of lack of commitment from senior officials and shortage of IT skilled personnel. Similarly, in Botswana, most of internet connectivity is in government and the country faces the problems of lack of coordination of efforts and resources, lack of national ICT strategy, fast changing industry and the acceptance of ICT in a predominantly resources based economy (Department of Information Technology, 2004).

The problems affecting countries of East and Southern Africa in their endeavors to implement e-government systems have not spared South Africa either which is regarded to have a well advanced telecommunication infrastructure. For example, 45% of the population in South Africa live in rural areas with less developed infrastructure compared to the urban areas. Moreover, by June 2000, teledensity in the country was just over 5.5 million or 14 telephones per 100 people with an estimated number of over 16 million cell phones and 2.1 million dial-up users

of the Internet in a population of 45 million people. In addition, PC penetration was 6.2% of the population and human poverty index was 20% in 2004 (Geness, 2004).

The issue of freedom of information is likely to affect the operations of e-government systems in East and Southern Africa. Within the two region, only South Africa and Zimbabwe have FOI legislation. Kirkwood (2002) notes that freedom of information (FOI) is a necessary pre-condition for an effective and participative democratic society in which government is both transparent and accountable to its citizens. Moreover, allowing citizens to obtain information is essential for full democratic participation in society, and passing legislation on access to information opens a dialogue between the government and the people. Further, without full information, the citizen cannot criticize policy. Similarly, without a voice and the right to put forward views, the citizen cannot contribute to political and social change. Through freedom of information legislation, an open and accountable administration is promoted. Freedom of information gives the citizen the right to establish what government does and what basis is used to decision making.

## MISSING LINKS IN E-GOVERNMENT INITIATIVES IN EAST AND SOUTHERN AFRICA

Within e-government environments, large amounts of e-records are generated and equally utilized. However, despite the increasing adoption of e-government in East and Southern Africa, e-records are not being effectively managed to enhance transparency and accountability in government. E-records are the recorded information, documents or data that provide evidence of policies, transactions and activities carried out in e-government and e-commerce environments (International Records Management Trust, 2004). The increasing use of ICT especially the Internet in government operations in East and Southern Africa has given impetus to the generation of e-records, touted in the developed world as strategic assets vital to the functions of the state. Like traditional paper records, e-records support the day-to-day operations of government services and interactions with citizens, private and public sector partners. By and large, in developed regions such as North America and Europe (Open Text Corporation, 2003) where government services have increasingly moved online, it is claimed that e-records are becoming the basis for confirming pension and other entitlements; registering births and deaths; verifying citizenship, certifying voting rights; enabling collection of taxes, supporting financial management and supporting litigation (International Records Management Trust, 2004). Given the inextricable nexus between e-government and e-records, accountability and transparency issues are less likely to be achieved unless these twin issues are integrated within governance systems. Similarly, the issue of FOI cannot be ignored in the equation involving e-government and e-records management. In the absence of an effective FOI legislation, e-government and efficient e-records management systems alone will not be able to achieve optimal results. FOI will assist in obligating governments to make information in their custody available to citizenry through e-government infrastructure.

The countries of East and Southern African as they increasingly move to embrace e-governance to enhance transparency, accountability in the management of public resources, should also consider issues of e-records management and freedom of information access for them to reap maximum benefits.

## FUTURE TRENDS

Though there is increasing focus by governments in East and South Africa to implement e-government programmes, little effort is going into programmes to enhance the management of e-records that are the main product of e-government transactions. E-government as already pointed out is aimed at enhancing accountability and transparency in management of public affairs. However, in the absence of a strong and effective institutional framework for management of e-electronic records, there is less likelihood that the virtues of e-government will be realised. Future research in East and Southern Africa should therefore focus on the nexus between e-government and e-records management as well as FOI and how the three can be implemented in tandem in order to realise the desired impacts. Moreover, e-government and e-records management alone will not be sufficient in the absence of an effective freedom of information legislation to compel government to enable access to information in its custody that citizens should have access to subject to defined regulatory restrictions.

## CONCLUSION

E-government and e-records management are inextricably intertwined. The two issues currently are the focus of public sector reforms both in developed and developing world. Governments in East and Southern Africa need to undertake various policy decisions and actions to enhance e-government and e-records management. Among these decisions should be the incorporation of e-records management as a fundamental component of ICT and e-

government strategies. For this to be achieved, governments need to embrace innovative initiatives such as public sector reforms aimed at re-examining records management practices to ensure efficiency and productivity in the provision of government services to citizens. Furthermore, any e-government initiative should be viewed within the broader context of public sector reform agenda and must be accompanied by a thorough process reengineering, organisational redesign and skills development programme if it is to realise maximum value. Such e-government strategy should also incorporate records management policies, skills development, infrastructure issues, attitude change, and work practices. Similarly, employing competent and trained ICT staff will provide the basic platform on which to build successful e-government and e-records management strategies.

## KEY TERMS

**Accountability:** Obligation of government, public services, or funding agencies to demonstrate to citizens that contracted work has been conducted in compliance with agreed rules and standards.

**East Africa:** The countries of Kenya, Uganda, and Tanzania under the umbrella of the East Africa Community (EAC).

**E-Government:** The use of ICTs to improve the delivery of government services and information, enhance efficiency and accountability of public administration and strengthen economic performance.

**E-Readiness:** The preparedness of a country or community to participate in the networked world.

**E-Records Management:** The application of records management principles in an electronic Environment.

**Freedom of Information (FOI):** Policy pertaining to the release of certain requested information to any member of the public regardless of the reason for the request subject to universally accepted restrictions.

**Good Governance:** The administration of government, public or private sector services that are efficient, fair, open, and impartial.

**Public Sector Reform:** The restructuring of public service for good governance and development. It is aimed at making services more efficient and responsive to the needs of the citizens.

**Southern Africa:** The countries of: Angola, Botswana, Lesotho, Malawi, Mauritius, Mozambique, Namibia, South Africa, Swaziland, Tanzania, Uganda, Zambia, and Zimbabwe under the banner of the Southern African Development Community (SADC).

**Transparency:** A global standard for state institutions and international organizations, requiring openness in the management of public affairs.

# E-Government Regimes

**Francesco Amoretti**

## INTRODUCTION

The internationalization of the reform movement is changing the ways in which governments operate throughout the world (Kettl, 2000). The ICT revolution is fast spreading its reach from private enterprises to bureaucratic agencies. As a result, electronic government (e-government) is both encouraging reform and, in itself, is a way of reinventing traditional structures and procedures and improving how the machinery of decision-making works. The scale of e-government developments is the subject of much research on a global perspective (Kamark, 2004). They show different and conflicting theoretical and ideological paradigms, but very little effort has been made to formulate a framework to define the e-government regimes that emerge in different political and institutional contexts. Since the characteristics of the World Wide Web (WWW) become the parameters from which to evaluate the public organizations and their capacity to innovating in regard to technology policy, the dominant vision of e-government emphasizes service delivery. As Forlano said (2004, p. 35) "the case studies ... bring to life common classification of e-government stages … ," not to a typology focused on political and institutional features. In this way, a crucial point is underestimated; namely, that the restructuring of the administrative apparatuses because of the WWW is a *political choice*, and does not take place in a institutional and ideological vacuum, which at the end of the day expresses its nature, whether democratic or otherwise (Barber, 1999).

## BACKGROUND

The strands of thought that have been used—and are still used—to understand and provide the normative guidelines for electronic government have tended to follow intellectual paradigms already well known in the social sciences.

First, e-government assumed the characteristics of a coming revolution. The information highway would enable the reformed logic of political and institutional power to cope with the expectations of citizens. Later, the coming revolution became the revolution betrayed. Few, if any, of the promises had been realized, and the suspicion was that from the very beginning, initiatives to achieve e-government were mystificatory: They merely fed into the democratic utopia while the web of electronic control by the administrative and executive power were extended. They were constructing a new *panopticon* (Campbell & Carlson, 2002).

Finally, a different paradigm was diffused, which makes little use of the evocative metaphors of apocalyptic scenarios: neither a revolution, nor a *panopticon*, nor a Big Brother. Instead, an evolutionary paradigm that follows the stages in the development of e-government (Layne & Lee, 2001; Schelin, 2003).

The widespread diffusion of the ideology of best practice sinks its roots into this cultural humus, suggesting that there are practices of electronic government which, once they have been adopted as a model, represent the ultimate aim of the processes of modernization of the administrative and institutional systems at the most diverse levels. That the map of best practices should also include experiences that come from non-Western countries that do not share the liberal-democratic ethos serves merely to isolate the technological and organizational component of the re-engineering strategies from the wider context of the relationships and political significance of e-government. In short, more attention is paid to the suffix "e" than to the effective use of information and communication technologies (ICTs) in redefining the delivery of public services, than to the term "government." Here, there is a strong temptation to refer interchangeably to e-government and online service delivery (West, 2004), obscuring the political meaning and transformational potential of e-government.

In contrast, we find a greater attention to the transformation of the state bureaucracy and apparatus, due to rising levels of Internet use by governments, the private sector and society in general, in studies that, far from the evolutionary perspective, consider alternative pathways that confront the advanced industrial countries.

E-government used here is defined as the use of ICTs as a tool to achieve better government. The impact of e-government at the broadest level is simply better government—e-government is more about government than about "e." The demands of Web-enabled government are analyzed in the context of the extensive changes in public-sector organizations that have characterised reform movements in the liberal democracies for more than 20 years (Dunleavy & Margetts, 2000).

Given the obviously central role that ICTs play in its creation, it would be easy to conclude that e-government is primarily a technical exercise rather than a collection of political and social choices involving special technical considerations. But, to realize its promised benefits of transformation and engagement, e-government must also be seen as being about *normative and political processes*, rather than just the act of automation itself (Riley, 2001).

The use of ICTs can encourage greater citizen engagement and can be a liberating and democratizing force within government, although ICTs can also be extremely effective instruments of control and authoritarianism. It is a function of the policy choices that governments are making with respect to how that technology is implemented and utilized, and of the political, social and economic context of a country (Rose, 2005).

## A TYPOLOGY OF E-GOVERNMENT REGIMES

To obtain a typology of different kinds of e-government regimes, we consider first the policies that define the architecture of the network. The nature of the code of cyberspace is a determinant factor in order to specify the processes and characteristics of different regimes of e-government. This code can be more or less open or closed. The selection of one or the other code prefigures a certain type of Net Architecture. Architecture is a kind of law: It determines what people can and cannot do in the real life as in the virtual one (Lessig, 1999).

Nevertheless, the code's effect will depend on the preexisting or current governance practices of a state at the global, national and local levels. Governance is not an abstract idea; it refers to the ways in which the different political levels, the diverse actions and practices inspired by various beliefs and traditions shape policies (Bevir, Rhodes, & Weller, 2003).

From the combination of those factors, four types of e-government regimes emerge, which are described below.

## REFORM-ORIENTED E-GOVERNMENT

Every e-government policy is reform-oriented, as they imply a top-down process, and the presence of a strong leadership seems to be one of the main conditions for the success of these policies (Lenihan, 2002; OECD, 2003). Nevertheless, the characteristics associated with this category are not universal, being linked with the experiences and practices of e-government in which the leadership and administrative and legislative networks that are subordinate to it, and favor a formally open network architecture that guarantees relevant democratic values and principles.

It is the original spirit of the ideology and action of Al Gore (1993-1997) that enabled the United States (U.S.) to enjoy a considerable cultural and technological advantage on the issue of e-government, to the extent that a transition has already occurred from a top-down approach centered on the characteristics of the techniques to be promoted to a bottom-up approach geared towards creating an environment favorable to this diffusion by involving all social actors, including citizens and businesses, in particular (Heeks, 1999).

Another example of reform-oriented e-government policies is the United Kingdom's (UK) experience at the end of the 1990s. The labor government's reform agenda has e-government at its heart, playing an instrumental role in joining up organizations to create citizen-focused public services. In the first e-government publication post-1997, *Our Information Age*, and in the *Modernising Government* white paper (1999), ICTs are a tool for both departmental reform and improvements in service delivery to reorientate it to the needs of citizenry (Organ, 2003). The government's strategy, which required massive coordination at the center, emphasized furthermore the political and institutional meaning of the technological innovations. When the UK *Citizen Online Democracy* (UKCOD) went online, Prime Minister Tony Blair observed that "The *Have Your Say* Web site is a historic opportunity for the public to play a meaningful part in the framing of new legislation … I support this initiative to help modernize and enhance British democracy in future as part of the legislative process." With cabinet office support, UKCOD had created a constitutional innovation which, if "Blair's hope is realized, will serve as a precedent for the future democratic governance" (Coleman, 1999, pp. 203-205).

This embraces in a definitive manner those e-government practices that reflect, at various levels—supranational, national and local—a strong political will to implement institutional change and to modernize administrative structures (Panagopoulos, 2004). The choice of an open architecture is not made to keep up to date, but rather to re-establish the system, even though it has not yet matured within it all of the resources and conditions necessary to achieve this objective.

In many cases, these initiatives demonstrate many limitations and ambiguities. Their capacity to enable citizens to participate effectively in decision-making processes is minimal, and the institutional mechanisms provided by the administrative apparatuses to receive and transmit demands from below—or rather, from the network—have revealed themselves to be weak or inadequate (Ward, Gibson & Lusoli, 2005).

## AUTHORITARIAN E-GOVERNMENT

New communication technologies have long been viewed as unequivocally on the side of political freedom, and not only in Western democracies. It seemed reasonable to believe that it would have a devastating impact on dictatorships.

In societies where the government holds all political power and is willing to crack down hard on any dissent, a mere connection to the outside world is not enough to force change. Many regimes may choose to forego the Internet's benefits to maintain political control (Kalathil & Boas, 2003).

The most important and interesting example is China, which has the world's third-largest number of Internet connections, after the U.S. and Japan. China, as Singapore, has promoted more widespread access to the Internet and has tried to limit the medium's potential challenges through a combination of content filtering, monitoring, deterrence and the promotion of self-censorship (Rodan, 1998).

The leadership has also developed a number of equally significant proactive strategies designed to use the Internet to strengthen the Chinese state (Tsui, 2003). Through both overt measures (such as e-government procedures and the design of a nationwide Intranet) and more subtle means (such as channelling online content towards support for the regime), the Chinese state has shown that it can use the Internet to enhance the implementation of its own agenda.

The first of these proactive strategies involves the computerization of government—an e-government plan designed to strengthen state processes by transforming the bureaucracy. The regime seeks to streamline many of its government operations through networked information management and to consolidate Beijing's central authority through more efficient communication with provincial governments. Although its ambitions for e-government far outstrip its achievements, a number of departments and bureaucracies have established home pages or placed databases and archives on the Web. While these actions are part of a genuine effort to increase transparency and address citizens' concerns with government processes, they also facilitate the state's goal of efficient intra-governmental communication.

The Chinese government has also employed top-down directives, harsh regulations and punitive measures to send a lesson to those who might be tempted to use the Internet for political organization or the dissemination of forbidden messages. This is a form of modernization from above, in which political control over the network and, therefore, the limitations on citizens' freedoms, play an essential role.

In the majority of cases that fall into this category, the e-government policies express a dual circuit of exercise and legitimation of power. This is a kind of "Dual State": the authoritarian one, based on tight control of cyberspace and, therefore, on the limitation of rights; and the modernizing one, which presents itself with the attributes of efficiency and a managerial outlook, and which used new technologies to rationalize the bureaucratic and administrative apparatuses to favor the economic and social growth of the country.

## MANAGERIAL E-GOVERNMENT

In the last few decades, private administration has became a model for running public bureaucracies. The drive for reinventing public government has heavily relied on the doctrine of the new managerialism for introducing the three Es—economy, efficiency and effectiveness—as the new guidelines for the public servant's behavior. As a result, the dominant trend in western democracies has become one of blurring boundaries between private and public administration. This is true in terms of organizational patterns as well as on normative grounds, where principles of economic efficiency are becoming the main legitimizing criterion for governmental policy-makers (Kettl, 2000).

Despite the fact that it is often surrounded by ambitious and persuasive rhetoric, this model is focused almost entirely upon utilizing technology to boost bottom-line performance in terms of achieving cost savings, often by reducing the level of staffing infrastructure associated with service maintenance and delivery.

Many governments are adopting and adapting the tools used by big e-commerce firms to understand how people use official Web sites. And the once unconditional support for e-government programs is being replaced by growing demand for a return on investments, that means a shift to the idea that innovations should be driven by considerations of value-for-money.

E-government programs typically bear a political agenda of government by the market, based on the assumption that market relations in the public sector are better at meeting people's needs than conventional forms of public administration. The practices of managerial e-government represent both challenges and opportunities, but within an incremental logic of development that does not alter the normative and ideological preconditions of public action in a market economy.

The attention appears to be concentrated on issues of efficiency, the reduction of costs, the development of e-commerce and other market-orientated needs. It is necessary to implement e-government, because in the information society, if one of the actors—the public sector, for example—remains tied to traditional forms of

communication and does not embrace the new technology, this creates an obstacle for the other actors as well.

The move towards managerial e-government practices has profound implications for the fundamental relationship between citizen and government. In fact, the gradual shift in the meaning of e-government emerges with particular clarity precisely from the way in which the notion of the citizen is conceptualized. The term citizen-centric is used to encompass not only the interests, needs, experiences and expectations of the private citizen as an end-user and contributor to the funding of public services, but also the views of other key stakeholders, including internal clients of public-sector organizations as well as other groups drawn from commercial and voluntary sectors. This approach thus emphasizes the effective changes that have occurred in the way in which the public sector organizes itself to do business (Milner, 1999). This suggestion was quickly taken up, as the most recent observations confirm (Accenture, 2003).

## OPEN E-GOVERNMENT

E-government policies as a source of new experiences of democratic participation, thanks to the transparency and openness of governmental processes, are still at initial stage, with some pioneer experiences, especially in Northern Europe at the regional and local level (Kersting & Baldersheim, 2004). Among the first experiments of e-democracy, including that of the city of Santa Monica's Public Electronic Network (PEN), the fundamental aim is to give more vitality to democracies using an interactive electronic network as channels for access to political information and participation in decision-making (Tsagarousianou, Tambini, & Bryan, 1998).

This is a committed aim endorsed by Erkki Liikanen, member of the European Commission and head of the Enterprise and Information Society section. At the conference on *Local eGovernment in the Information Society* held in March, 2003, in Barcellona, he said:

E-government should help to make democracy function better. This is about increasing democratic participation and involvement. … "Open government" also means increased transparency and accountability. … This means that e-government should provide equity; that is, equal rights and opportunity for participation for all. In other words, realizing inclusion. Equity matters for social justice. It is about what we consider to be fair and just in our society … (from http://europa.eu.int/comm/press_room/index.htm).

Compared to the early 1990s, there is greater awareness of the centrality of policies for the structuring of network environments as a premise for e-government and e-democracy policies. This awareness has emerged in relation to the use of open-source software within the public administration (Ghosh et al., 2002).

However, open-source software is not solely about code and software. The movement's ability to organize itself around democratic ideals and develop a product in a joint learning experience is an invaluable source of inspiration for the whole society. In this respect, the open-source movement is not a traditional representative democracy, either. The democratic values are constituted of the principles that everyone can get insight, everyone can give their contribution and everyone can change the result of decisions (by adjusting the code). It represents a civil society that is self-organized as a form of pragmatic technocracy, built on the same democratic values that created the Internet and with an open result. New practices and traditions can evolve to ensure that democracy does not stagnate. The values and commitments espoused by these groups are democratic, and can be seen as a counter to some of the very undemocratic values associated with the prevaling neoliberal order (Dahlgren, 2005).

Even if the consequences of experiments to formally incorporate the Internet into the political system have not been overwhelming, open government is a combination of institutional practices and cultural ethos relevant to contemporary democracies, where the architecture of the network, in adapting itself to various contexts, configures itself in a way that safeguards the fundamental entitlements of individuals, encourages ballot participation (*e-vote*) and contributes to the processes of drafting and implementing policies (*e-rulemaking* and *e-legislature*).

## FUTURE TRENDS

E-government practices demonstrate that the democratic potential of the Internet has been marginalized as a result of the ways in which the use of such technology has been framed by governments—national, supranational and local. The managerial model of interaction, founded in many cases on the emulation of private sector management practices, has assumed dominance at the expense of other possibilities. E-government programs are more and more customer-centric, and exibit greater maturity in their business services than in their citizen services (Chadwick, 2003).

This trend is further reinforced according to recent data, as well "a new decided efforts to integrate vertically—across national, state/regional and local level of government" (Accenture, 2004, p. 4). The managerial model is re-shaped to that of a corporate type. This development has become extremely important, above all,

in the aftermath of the events of September 11, 2001. Many countries have adopted laws, measures and actions poised to place the Internet under the tutelage of security services (Lyon, 2003).

The technology to achieve this is being incorporated into the Internet's infrastructure, into its architecture. In this sense, the architecture of the network expresses the interpenetration of two different logics: the corporate (since its structure is based on software standards produced by business policies) and the political, which intends to control the Internet.

Thus, as recent developments are pushing e-government practices in many democratic systems towards a critical threshold, it would not appear that the Internet is seriously threatening the authoritarian e-government regimes. Some suggest that because the medium allows unprecedented access to multiple sources of images, news and ideas, it can challenge state hegemony over the distribution of information and ideologies. Certainly, in some cases, as in China, the government has lost much control over the information and images that now circulate through Chinese society. Both the new political leaders and China's private enterpreneurs and technical elites, however, have shown little interest in promoting democratization. The political leaders think they can solve China's problems, above all, stay in power and direct China's modernization and integration with the global economy (Natham, 2003).

In this scenario, characterized by the combination of political control and corporate logics, the open e-government experiences are far from straightforward but, nevertheless, achievable in e-democracy implementation at a local level in four principal areas: online consultations integrating civil societal groups with bureaucracies and legislatures; internal democratization of the public sector itself; involvement of users in the design and delivery of public services; and diffusion of open-source collaboration in public organizations (Chadwick, 2003; Coleman, Macintosh, & Lalljee, 2005).

## CONCLUSION

Research on e-government bears little trace of contributions that show how cyberspace can be shaped into a wide variety of architectural configurations, with the result that the choice we now face is one about the kind of architecture that cyberspace should have. This tends to encourage a lack of attention for a technological domain that structures and regulates the relationship between individuals and political authority.

The prevailing concern with the transformation of Western political systems, or those that can be assimilated to Western models of organization of political power and the state, does not facilitate understanding of the above perspective. Variations, when they are identified, are in actual fact, treated as fluctuations within a single family, rather than differences that can give rise to distinct types of regime.

Moreover, precisely because the Internet is a global phenomenon, these distinctions are essential, and they also recover the dimension of comparative analysis in relation to the understanding of electronic government that the logic of cyberspace appears to erode.

## KEY TERMS

**Constituent Policies:** It regards all state policies that establish structures and rules for the game, and attributes spheres of authority within whose confines future government policies can be created.

**E-Legislature:** It refers to how political institutions—parliaments and parties—have been making use of ICT as evidence by developmental characteristics for their Web sites. There are four distinct (but possibly correlated) dimensions for describing such use: (1) information, (2) bilateral interactivity, (3) multilateral interactivity, and (4) user friendliness.

**E-Rulemaking:** It refers to how ICT is changing the dynamics of the rulemaking process; above all, the potential or likely effects of information processing on the bureaucracy.

**Filtering Technologies:** Software systems able to scan Web pages, blocking vision of them if they contain elements belonging to a blacklist created before.

**Freenet:** Free software that lets you publish and obtain information on the Internet without fear of censorship. To achieve this freedom, the network is entirely decentralized and publishers and consumers of information are anonymous. Without anonymity, there can never be true freedom of speech; and without decentralization, the network would be vulnerable to attack. Communications by Freenet nodes are encrypted and routed through other nodes to make it extremely difficult to determine who is requesting the information and what its content is. Users contribute to the network by giving bandwidth and a portion of their hard drive (called the "data store") for storing files. Unlike other peer-to-peer file-sharing networks, Freenet does not let the user control what is stored in the data store. Instead, files are kept or deleted depending on how popular they are, with the least popular being discarded to make way for newer or more popular content. Files in the data store are encrypted to reduce the likelihood of prosecution by persons wishing to censor Freenet content.

**Free Software:** According to the Free Software Foundation (FSF) definition: "Free software is a matter of the users' freedom to run, copy, distribute, study, change and improve the software. More precisely, it refers to four kinds of freedom, for the users of the software: (1) The freedom to run the program, for any purpose; (2) The freedom to study how the program works and adapt it to your needs. Access to the source code is a precondition for this; (3) The freedom to redistribute copies so you can help your neighbor; (4) The freedom to improve the program, and release your improvements to the public, so that the whole community benefits. Access to the source code is a precondition for this. A program is free software if users have all of these freedoms" (FSF, 2006).

**Governmental Openness:** It is a measure of governmental response to citizens' demands for information and services from government organizations.

**Net Architecture:** The way a network (with its software and hardware components) is designed to work, enabling or not such actions to the administrator as to the final user.

**OpenGov:** It is an open-source e-democracy software platform designed as a scalable and free avenue for open and participatory government and bottom-up decision making in other organizations. It is a project of the MIT School of Architecture and Planning (see http://ecitizen.mit.edu).

**Open-Source Software:** The Open-Source Initiative (OSI) defines Open Source as software providing the following rights and obligations: (1) No royalty or other fee imposed upon redistribution; (2) Availability of the source code; (3) Right to create modifications and derivative works; (4) May require modified versions to be distributed as the original version plus patches; (5) No discrimination against persons or groups; (6) No discrimination against fields of endeavor; (7) All rights granted must flow through to/with redistributed versions; (8) The license applies to the program as a whole and each of its components; (9) The license must not restrict other software, thus permitting the distribution of open-source and closed-source software together.

# E-Government Strategies for Poverty Reduction in Africa

**K. M. Baharul Islam**
*United Nations Economic Commission for Africa, Ethiopia*

## STRATEGIES FOR E-GOVERNANCE IN AFRICA

The United Nations Economic Commission for Africa (ECA) launched the African Information Society Initiative (AISI) in May 1996, which serves as a guiding framework for building the information and communication infrastructure in Africa. Since the launch of AISI, ECA has been supporting member states to embark on the development of National Information and Communication Infrastructure (NICI) policies, plans and strategies, which are instrumental to materialize the visions enshrined in the AISI at the national level and to create an environment conducive for information and communication technology (ICT)-led development initiative. Thus far, more than 30 countries in the continent have embarked, in one form or the other, on the development of national ICT strategies, and more countries have expressed interests to initiate national ICT policies.

One specific element of the NICI process is to realign the country's development goals, more precisely the Poverty Reduction Strategy Paper (PRSP) objectives, with the emerging ICT Policy. It is not an easy task, as traditionally the decision makers see ICT as a completely separate domain and often fail to see the role of ICT as a tool to attain the PRSP goals. Therefore, The Gambia NICI process was deliberately geared towards centering ICT policies and plans on the country's declared PRSP elements. The NICI policy that was developed consciously mapped the route to underlay the ICT tools that will help the country reach its PRSP destination swiftly, efficiently and more responsibly to the people.

This article illustrates an e-government strategy built on the objectives of poverty reduction as illustrated by a case study of The Gambia e-government strategy and NICI policy. The process and its evolved mechanism might serve as a model for e-government strategy and policy developers, planners and all stakeholders in general working in the area of digital governance.

## NICI PROCESS: A CASE STUDY OF THE GAMBIA

The NICI process in The Gambia, as indicated above, is geared towards recognizing the areas where ICT would contribute to attaining the overall objectives of the four strategic issues identified in the PRSP besides other priority areas (called "Pillars") of NICI:

1. Enhancing the productive capacity of the poor.
2. Enhancing access to and the performance of social services.
3. Local-level capacity building.
4. Promoting participatory communication processes.

A captious analysis of the prevailing socio-economic condition in The Gambia further highlights the challenges faced by the country in attaining those visionary goals. The e-readiness baseline survey conducted by the National Technical Committee for eGovernment (NATCOM) in July 2003 with technical assistance from ECA was used to map the prevailing status of the country in terms of ICT infrastructure and plans.

During consultative meetings with various stakeholders from all sectors of the society—government, private and the civil society—efforts were made to further pinpoint vital developmental issues concerning poverty alleviation at the grassroots level that a comprehensive NICI policy for the country should address. The consultations were used to highlight and espouse the role of ICT not as an end itself but as a means to achieve the PRSP goals. These consultations led to the shaping of a vision statement that underlines the link between poverty reduction strategy and ICT policy:

*To leverage the benefits of ICT for a people-centered, free market-based and export-oriented socio-economic development strategy built on principles of public-private partnership for wealth creation.*

In other words, the NICI policy was aimed at supporting the strategic objectives of the PRSP:

*To achieve higher growth rates in all spheres of socio-economic activities using ICT as a platform to exchange data, information, knowledge and a tool to implement applications and provide services in order to 'leapfrog' several stages of development through a participatory approach in building human resources and a conducive environment.*

The PRSP priorities in The Gambia are focused on "attaining a high level of economic growth with a special focus on the critical areas of private sector development, agriculture, natural resources, tourism, trade, industry (SPA II, 2000), and a timely attainment of the Millennium Development Goals (MDG)." According to the September 2001 report of the World Bank (World Bank, 2001) on attainment of these objectives, The Gambia is on track toward the attainment of universal primary education by 2015, moderately off-track towards halving the 1990 illiteracy rates by 2005 and on track towards gender equity in primary and secondary education. The Gambia was the only country listed as being on track towards reducing infant and child mortality rates by two-thirds by the year 2015, and is also reported as being on track towards attainment of the target on access to clean drinkable water.

Therefore, the first phase of the extensive consultations under NICI Process boiled down to four critical poverty alleviation goals, addressed under the SPA-II for The Gambia as follows:

1. Enhancing the Productive Capacity of the Poor.
   - 1.1 Promoting labor-saving devices for women.
   - 1.2 Providing access to credit.
   - 1.3 Reorganizing agricultural research and development (R&D) to encourage labor-intensive agriculture and development of small ruminants.
2. Enhancing Access to and the Performance of Social Services.
   - 1.1 Expanding access to basic social services in rural areas.
   - 1.2 Delivering responsive social programs to the poor.
   - 1.3 Enhancing sustainability and quality of social services.
3. Local-Level Capacity Building.
   - 1.1 Political and legislative framework for decentralization.
   - 1.2 Empowerment of local government authorities to assume decentralized responsibilities.
4. Promoting Participatory Communications Processes.
   - 1.1 Enhancing participation beyond consultation.
   - 1.2 Addressing gender at national and local levels.
   - 1.3 Institutionalizing dialog between government, civil society, and donors.

## POVERTY REDUCTION STRATEGY IN THE GAMBIA

The Gambia is among the poorest countries in the world. It was ranked 155 (out of 177) in the UNDP Human Development Index (UNDP, 2005). A series of exogenous shocks in the 1970s and 1980s, coupled with inappropriate policies, led to a decline in average GDP growth from 7.25% during the '70s to 3.25% during the late 1980s. The narrow resource base is a major inhibiting factor to economic resilience, aggravated by a high population growth rate.

Positive results in terms of stabilization under the economic reform program and its successor program (PSD) could not be sustained as the economy suffered adverse shocks, including the coup of 1994, which adversely affected tourism and aid inflows, devaluation of the CFA franc (Communauté Financière Africaine/African Financial Community franc) and declining world market prices for the primary export crop, groundnut. Consequently, real GDP growth declined from 5% in 1992 to about 1.7% during 1993-1996. Since 1998, the pursuit of prudent macro-economic policies and implementation of broad-based structural reforms have, together with favorable climate conditions, resulted in an improvement of the economic environment and laid the foundations for a sustained recovery. Real GDP growth increased to 5.3% between 1998 and 2001, and offers hope in the renewed effort to reduce poverty. The emerging situation presents an opportunity to investigate ways in which government can consolidate the achievements of successive stabilization programs and embark on pro-poor growth.

The outlook for economic performance in The Gambia remains gloomy, as the crop failure in 2002 and the rise in inflation are likely to have increased the level of poverty. Implementation of the PRSP has been weak due to limited capacity, absence of donor support and inadequate prioritization by the government (IMF, 2004). The government has committed itself to address these issues during the preparation of the 2005 budget.

On the brighter side, real GDP is estimated to have grown by 7% in 2003, largely on account of a recovery in agricultural output following the crop failure in 2002. The external current account deficit is estimated to have improved, and inflation as measured by 12-month changes in the official consumer price index (CPI) was 18% at the end of 2003. There are no reliable data yet for 2004 on real activity or the external account. The CPI inflation rate, however, declined from 18% in January to 16% in April, 2004. The overall fiscal deficit remained unchanged from 2002 at 4.5% of GDP in 2003.

Against this backdrop of structural and stabilization, reforms implemented so far focus on creating an enabling environment for private-sector activities, which include

the establishment of The Gambia Investment Promotion and Free Trade Zone, Gambia Public Procurement Agency and National Tourism Authority. Other key reforms are recognized in several other sectors for increased economic performance, with programs that support national governance and poverty-reduction programs. The major macroeconomic policies of the government includes:

a. Maintain real GDP growth of about 7% for the year 2004
b. Limit average annual inflation to 14.5%
c. Contain the external current account deficit (excluding official transfer) to about 14.5% of GDP
d. Replenish gross international reserves to about 5 months of imports of goods and services.

## LINKING DEVELOPMENT INTENT TO DIGITAL GOVERNANCE

The paradigm shift in the poverty-reduction initiatives in the recent decades has "gradually replaced the prescriptive, mainly donor-driven structural adjustment programs (SAP) of the seventies and eighties." A new vision of development cooperation based on "… partnership, ownership, country leadership, broad-based participation, development effectiveness and accountability" is a welcome change for highly indebted poor countries such as The Gambia (SPA-II, 2002).

Though the beneficial impacts of ICT in the overall development of a country is hardly questioned, incorporating the ICT tools in the "transformational" process, developing economies into the emerging information society is a delicate scenario (UNITF, 2003). While the link between ICT initiatives and socio-economic development results are to still to be thoroughly researched, the controversy continues to surround ICT interventions in development programs doubting these efforts being "techno-quick fix" or "unacceptable tradeoffs" in terms of investments (UNITF, 2003).

Socio-economic development of any society engulfs a much wider area today. Beyond money matters, it touches more humane aspects of people's lives, like standards of living. To cover this dimension of development, our initiatives should offer multiple opportunities to achieve economic prosperity as well as to improve quality of life. In other words, the issue here is whether we are following an agenda for "ICT development" as sectoral growth only or as a comprehensive strategy with an ultimate poverty alleviation goal. More precisely, under our PRSP activities, are we ready to sustain ICT-led initiatives with in-country human resources, budgetary allocations and supporting regulatory environment as an integral tool for poverty reduction?

The development of an e-government strategy for The Gambia, therefore, provided an opportunity to deliberate on the goals of the country's development efforts, specifically those aimed at poverty reduction as well as the use of ICT tools in increasing efficiency and transparency of its administrative structures, institutions and functioning. This collective reflection led to a road map from poverty alleviation objectives to the delivery of services at the doorsteps of the poor.

## ILLUSTRATING THE PRSP-BASED ICT POLICY

The NICI policy of The Gambia contains a number of items that covers the PRSP objectives and tries to support those goals through ICT-led plans of action. However, it is observed that a number of social, cultural, religious or other factors positively or negatively affect the adoption and diffusion of ICT. For instance, certain cultural or religious practices may prevent women from leveraging the benefits of ICT as compared to their male counterparts. Therefore, potential linkages between different areas of the economy focusing on cross-sectoral issues will help us forestall potential problems in this regard. The following table illustrates some of the major initiatives proposed for the next 5 years and how they respond to PRSP goals (Table 1). This is a tentative list as emerged from country-wide consultations with stakeholders and from a presentation made by participants at a National Workshop in Banjul the end of 2004. Many other activities and action items were included in the final NICI policy and plan that was validated by a national meeting of stakeholders in April, 2005.

Further, as discussed earlier, the MDGs and their timely attainment constituted a benchmark for the development initiatives in The Gambia. While developing the NICI policy and plans, the goals for the sustainable human development were taken care of by mainstreaming ICT-led action plans against each of the MDG goals. Poverty reduction is at the root of the human development efforts, and this has been incorporated in the NICI policy and plans through attending the PRSP objectives (Table 1). The other MDGs, like universal primary education, have been seen as a "social interaction" dimension of development and, as such, ICT are intended to be used as a tool for more efficient and cost-effective channels of teacher training, especially through Open and Distance Learning (ODL) mode, multimedia instructions as well as for educational planning and administration (e.g., Education Management Information System). The prevalent bias in educational opportunities towards the urban and male population in Africa can well be minimized through

*Table 1. Poverty reduction—ICT policy/e-government linkages*

| PRSP Objective | NICI Policy & Plans |
|---|---|
| **1. Enhancing the Productive Capacity of the Poor** | |
| a. Promoting labor-saving devices for women. | Rural Multimedia Centres for Women |
| b. Providing access to credit. | Credit / Loan Opportunities Information online |
| c. Re-organizing agricultural R&D to encourage labor-intensive agriculture and development of small ruminants. | Agricultural Information Systems for rural community information centres |
| **Enhancing Access to and the Performance of Social Services** | |
| a. Expanding access to basic social services in rural areas. | Launching e-government initiatives/ providing access at local area councils |
| b. Delivering responsive social programs to the poor. | |
| c. Enhancing sustainability and quality of social services. | |
| **Local-Level Capacity Building** | |
| a. A political and legislative framework for decentralization. | Local government leadership training for local government representatives |
| b. Empowerment of local government authorities to assume decentralized responsibilities. | |
| **Promoting Participatory Communications Processes** | |
| a. Enhancing participation beyond consultation. | Planning Feedback / Local Govt Representative Links up to the National Assembly level |
| b. Addressing gender at national and local levels. | Women Bureau's Rural Multimedia Centres as the participatory hub/link to the national development processes/programs. |
| c. Institutionalizing dialog between government, civil society and donors. | NGO/CSO links through NGO associations (e.g., TAGNO, Action Aid in The Gambia) |

judicious use of appropriate ICT tools for delivery of knowledge and information at the doorsteps of the rural and marginalized sections (women/youth) of society. That brings us to another prime MDG: gender equality and empowerment of women. The most prominent obstacle to women's access to knowledge and information leading to the limited opportunities for their economic upliftment is their restricted mobility. With access to ICT facilities, women can overcome both physical and socio-cultural distance and increase their capacity for income generation. The recently opened Rural Multimedia Centers for Women in The Gambia under the auspices of the Women's Bureau is an early fruit of the NICI plan. More such centers are going to rise in the near future. Social-service delivery aspects of the national e-government strategy also addresses other MDGs, focusing on reducing child mortality; improving maternal health; and combating HIV/AIDS, malaria and other diseases.

## FUTURE TRENDS

In developing ICT policies and e-government strategies for poverty reduction, an "ACTION" model may be followed through as six phases in the NICI process:

- *A*nalysis
- *C*onsultation
- *T*argets/Pillars
- *I*ntegration
- *O*rganization
- *N*ational Commitment.

In this process, the MDG should be focused as the common ground between the NICI and PRSP processes. Success stories from various parts of Africa, like the Virtual Extension Research and Communication Network (VERCON); Rural Radio; Farmers Information Network (FarmNET); and Information Management Resource Kit (IMARK), should be scaled up.

As content is the key for information and communication, the pro-poor ICT initiatives should attend to the increase in youth and adult literacy in a long-term approach to poverty reduction through ICT tools. In providing a channel of communication between public and the government, ICT facilities should be available to the marginalized to carry crucial feedback to the poverty-reduction initiatives for further review and planning of the PRSP. Traditional ICT tools, like community radio broadcasts, can be used to empower rural women with opportunities to opt for innovative and small entrepreneurial solutions in villages.

Geo-information systems should be used in poverty mapping and planning interventions, as geo-information helps identify, based on calligraphic representations, what needs to be done and how to plan such programs. Online resources for entrepreneurs should be supported in a regional basis and more local specific sites in this line should be initiated. ICT is traditionally seen as a separate sector or department, putting it apart from other sectors like agriculture or education. To attend to the poverty-reduction need of the region, the cross-cutting nature of ICT as a tool for development should be recognized with both fund allocation from national budgets and a participatory multi-sectoral approach in program implementation.

## CONCLUSION

To sum, poverty alleviation strategies all over the world focus on the basic humane issue of improving the quality of people's lives. In pursuing this prime objective, many a time we create a straightjacket agenda, narrowing our vision to a few sectoral and specific goals. NICI policies and plans, as envisaged under the AISI framework, seek to broaden that view, integrating the country's PRSP to the NICI policies and plans and sew all cross-sectoral issues in an ICT thread to support the poverty-reduction strategies in a more efficient and responsive way. In all these ICT-led action plans, what the NICI policy aims to achieve is not the development of the ICT sector itself (though it may form a sectoral agenda itself), but the socio-economic development of the people through pragmatic use of ICT. To conclude with the words of Dr. Ben Ngubane, the Minister for the Arts, Culture, Science & Technology of South Africa:

*The impact of Information and Communications Technology (ICT) on development has been amply charted in the last decade of the outgoing century as a multi-dimensional, multi-stakeholder and pervasive process. So significant is this impact that those that have the capacity to apply these technologies have witnessed rates of development that continue to fuel the Digital Divide.* (COMNET-IT, 2001)

## KEY TERMS

**African Information Society Initiative (AISI):** An action framework launched by the UN Economic Commission for Africa. It has been the basis for information and communication activities in Africa for the last 6 to 7 years. AISI is not about technology; it is about giving Africans the means to improve the quality of their lives and fight against poverty. See www.uneca.org/aisi.

**Economic Growth:** Economic growth reflects the increase in the production of goods and services over time, and is often used as a measure of increased material well-being generated through economic activity. Economic growth is driven by greater use of inputs (such as labor, capital and natural resources) and/or growth in productivity. It is usually reported as a percentage increase in Gross Domestic Product (GDP) for a country or Gross State Product (GSP) for a state.

**Education Management Information System (EMIS):** An information system is the basis of management, planning and evaluation of an education system. The objective of an EMIS is not only to collect, store and process information, but also to help in education policy-making by providing relevant and accessible information. EMIS was originally designed to be a management tool, but is gradually being perceived as an indispensable tool and support system for the formulation of education policies, their management and their evaluation.

**E-Government/E-Governance:** While e-government is defined as a system of government services and information delivery to the public using electronic means, e-governance allows direct participation of constituents in government activities. E-governance is not just about government web sites and e-mail or service delivery over the Internet. It is not just about digital access to government information or electronic payments. *It will change how citizens relate to governments as much as it changes how citizens relate to each other.* It will bring forth new concepts of citizenship, both in terms of needs and responsibilities. E-governance will allow citizens to communicate with government and participate in the governments' policy-making, and will allow citizens to communicate each other. E-governance will truly allow citizens to participate in the government decision-making process and reflect their true needs and welfare by utilizing e-government as a tool.

**Geo-Information:** Geographic information or geo-information provides the common language and reference system to establish linkages and balance between economic, environmental and social capital to improve upon the basis for societal response. Access to spatial data and the policies governing that access are crucial in shaping policies, programs and projects. Geo-information forms an essential part of the knowledge available in modern information and communications science. It is required at all levels of administration, the economy and science, and by the public at large. It is the basis for planning in numerous fields. It helps governments and communities plan for homeland security, ensure critical infrastructure, protect the environment and deal with public health and safety issues as well as day-to-day resource management decision-making.

**Gross Domestic Product (GDP):** The most comprehensive single measure of aggregate economic output. It represents the market value of the total output of the goods and services produced by a nation's economy, and the value of all final goods and services produced in a country in 1 year. GDP can be measured by adding up all of an economy's incomes (wages, interest, profits) or expenditures (consumption, investment, government purchases and net exports)—exports minus imports.

**Information and Communication Technologies (ICT):** The term ICT is used to describe a range of technologies for gathering, storing, retrieving, processing, analyzing and transmitting information. Advances in ICT have progressively reduced the costs of managing information, enabling individuals and organizations to undertake information-related tasks much more efficiently, and to introduce innovations in products, processes and organizational structures.

**Information Management Resource Kit (IMARK):** Effective information management is increasingly critical in the digital era, involving a range of issues covering

standards, smart working practices and software. FAO has initiated a partnership-based e-learning program known as IMARK, which trains individuals in the effective management of agricultural information. See www.fao.org/imark.

**Information Society:** There is currently no universally accepted concept of what exactly can be termed information society. Most theoreticans agree that we see a transformation that started somewhere between the 1970s and today and is changing the way societies work fundamentally. Broadly speaking, it refers to a society where the creation, distribution and manipulation of information is the main activity. It can be used in relation to an organization bringing together people, ideas and issues involving information.

**Knowledge Economy:** Knowledge economy is based on the production, distribution and use of knowledge as the main driver of growth, wealth creation and employment across all industries. It does not rely solely on a few high-technology industries for growth and wealth production, but also on the application of knowledge in traditional industries, such as mining

**Millennium Development Goals (MDG):** The eight MDGs were agreed at the United Nations Millennium Summit in September 2000, and nearly 190 countries have subsequently signed up to them. The goals range from halving global poverty and hunger to protecting the environment, improving health and sanitation and tackling illiteracy and discrimination against women. Alongside the goals, a series of 18 targets were also drawn up to give the international community a number of tangible improvements to aim for within a fixed period of time, and also make it easier for them to measure their progress to date. The intention is that almost all of these targets will be achieved by 2015. Unfortunately, although improvements have been made in many areas in sub-Saharan Africa, for example, the number of people living in poverty there is still greater now than it was in 1990. See www.un.org/millenniumgoals/.

**NICI Process:** The whole exercise of national consultations in various phases and subsequent deliberations at various stages and platforms leading to the drafting, validation and adoption of a country's NICI policy, plans and strategy. In The Gambia, the process started in May 2004 and, after a series of consultations with stakeholders and workshops, the draft NICI policy is now due for validation and adoption in February 2005.

**National Information and Communication Infrastructure (NICI):** NICI includes physical infrastructure and the equipment used to host, process, transmit or display data, text, voice and images and also relates to regulations, enabling environment and procedures. NICI also encompasses development of human resources in the public, private and civil society sectors engaged in building infrastructure; creating applications and value-added services; carrying out training programs and training users; acquiring and selling equipment; as well as providing Internet and other ICT services.

**Open and Distance Learning (ODL):** ODL is learning where there is some flexibility and control in the hands of the learner as to when, where and how he or she will learn, balanced by structure and support from a provider. ODL includes any provision in which a significant element of the management of the provision is at the discretion of the learner, supported and facilitated by the provider. This ranges from traditional correspondence courses, online provision and interactive CD-ROMs to open learning centers and face-to-face provision where a significant element of flexibility, self-study and learning support is integral to the provision.

**Poverty Reduction Strategy Papers (PRSP):** PRSP are prepared by member countries in broad consultation with stakeholders and development partners, including the staffs of the World Bank and the IMF. Updated every 3 years with annual progress reports, they describe the country's macroeconomic, structural and social policies in support of growth and poverty reduction, as well as associated external financing needs and major sources of financing.

**Rural Radio:** Recognizing that the current world food situation poses one of the worst crises facing humankind, FAO has, since the 1960s, recognized the crucial role radio can play in helping to redress this crisis, as well as bring about rural development and poverty reduction. The organization has been associated with attempts at finding ways of maximizing its use and impact. The basis of this work has been an understanding of the nature of rural radio itself and its suitability for food security and sustainable development. See www.fao.org/sd/ruralradio/en/index.html.

**Virtual Extension and Research Communication Network (VERCON):** VERCON aims to harness the potential of the Internet and apply it to strengthening and enabling linkages among the research and extension components of the national agricultural knowledge and information system. The overall goal of VERCON is to improve, through strengthened research-extension linkages, the agricultural advisory services provided to Egyptian farmers and, in particular, to resource poor farmers to increase production in food and agriculture with the goal of raising farm incomes. See www.vercon.sci.eg.

# E-Government, Service Transformation, and Procurement Reform in Canada

**John Langford**
*University of Victoria, Canada*

**Jeffrey Roy**
*Dalhousie University, Canada*

## INTRODUCTION[1]

New organizational arrangements are required to underpin emerging public sector service transformation initiatives with a substantial electronic government (e-government) dimension. These arrangements are both internal to government, involving new collaborative relationships among service delivery agencies and reform of procurement processes, and external, involving the formation and management of strategic relationships between private sector information technology (IT) vendors and public service providers.

This article explores the relational context of service transformation by first examining some current initiatives in Canada—at both provincial and federal levels. These case studies reveal the nexus between digital technologies, internal organizational change, and public–private sector interactions. They also reveal the emergence of new collaborative mechanisms between both sectors, especially in the initial phase of relationships where the IT-enabled service transformation is being mutually defined.

This heightened level of collaboration also represents a significant departure from traditional government procurement models—where inputs are defined by public authorities and then secured in the marketplace from qualified vendors. E-government—and service transformation initiatives in particular—are consequently driving a rethinking of the role and purpose of procurement mechanisms in an increasingly digital and interdependent environment.

Many political and administrative quandaries remain, however, as governments struggle to achieve a balance between traditional public interest principles such as probity, transparency, and accountability, and the rising importance of strategic collaboration. Building on the case studies and a review of current efforts at procurement reform, this article offers and assessment of how this interrelationship between service transformation and public–private collaboration is likely to shape future e-government-based service transformation efforts in Canada.

## SERVICE TRANSFORMATION AND COLLABORATION

As more citizens have flocked to the Internet for online services in areas such as banking and retail shopping, governments have begun to identify parallel opportunities for the application of online services in the public sector. Initially, the impetus for utilizing online channels to deliver information and services was couched in terms of financial savings: many business models were developed by government officials and consultants demonstrating the savings accorded to online methods of service delivery versus more traditional channels such as face-to-face facilities or telephone call centres.

Most of these initial models proved to be wildly optimistic due to forecasts predicated on massive transaction cost savings from Internet communication (relative to paper and telephone) or strong, short-term growth in demand for online services, relative to other channels (Roy, 2003). Nonetheless, new organizational and technological models for delivering services both online and via more traditional channels are taking hold—and beginning to generate encouraging results.

One of the most widely recognized examples of a unique service transformation involving the internal integration of government services and the establishment of a public-private partnership is that of Service New Brunswick (SNB). SNB is a crown corporation of the provincial government that has a dual role: to provide the people and business owners of New Brunswick with the greatest ease and access to government services, and to maintain authoritative public information through its three registries (real and personal property and corporate affairs).

SNB has been aggressively making use of its autonomy as a crown corporation (in comparison to a tradi-

tional line department) to forge collaborative relationships with industry. Central to its citizen-centric mission is the formation of "gBiz" in partnership with CGI (a Canadian technology solutions provider), a comprehensive and integrated framework for transactional service delivery. The company and the government shared in the financing of the development of this system, much as it is now sharing the revenues from licensing arrangements between CGI and other governments in Canada and elsewhere.[2] SNB now conducts more than 40% of its transactional business online and it is expanding into a variety of other collaborative projects with companies designed to jointly develop solutions for New Brunswick that can be marketed and sold elsewhere.

One notable model in the United States is New York City's NYCServ Epayment Project that is indicative of the parameters of a service-delivery architecture predicated on more citizen-centric services using a range of integrated channels:

*The NYCServ application streamlines and integrates three key business processes for the city of New York—processing payments, conducting adjudication hearings, and tracking towed vehicles. It has four separate revenue channels: walk-in payment centers, Internet, interactive voice response (IVR) and kiosks. The system processes 1.9 million receipts for a total of over $6 billion in 2003. ... It was developed by an integrated team of approximately 20 per cent Finance Department staff and 80 per cent IBM staff.*[3]

These examples are exciting and provocative, but in general, such fundamental electronically based service transformations have been problematic. Although one can envision the potential for some form of efficiency gains through automated work practises, it is hardly a straightforward calculation—as any financial savings incurred over time must be weighed against the upfront investment costs of new technological systems and the corresponding training, organizational development, and inevitable technological upgrading requirements.

Within the Canadian context there are few examples of genuine long-term service transformation collaborations. One such example is a current collaborative undertaking between BC Hydro and Accenture Consulting that illustrates the evolution of outsourcing into new relational forms of governance tied to joint management and results-based accountability including costs and compensation. This unique, 10-year partnership arrangement is predicated on the formation of a new organizational entity, a limited liability partnership jointly accountable to both parties.

BC Hydro is contractually guaranteed to realize $250 million in cost savings over the 10-year period (by virtue of spending $1.45 billion for services that would have cost $1.74 billion under existing internal systems), as well as agreed-upon measures of performance improvement in customer service (as determined by customer service mechanisms, comparative benchmarking, and a service-level metric system formulated and utilized in concertedly by both partners). In order to generate these sorts of results, the formation of the new entity (with limited and specified functional responsibilities[4]) enables Accenture to develop new and more innovative business processes aimed to the desired outcomes. Notably, all of the previous employees from the government agency have been offered private sector employment on equivalent salary and benefit terms, and labour representation and collective agreement terms remain unchanged.

Despite the relative novelty of this level of complexity and relational activity, the stakes in such initiatives are enormous since if partnerships fail, so too does e-government. This message was underscored some time ago: if IT projects cannot be managed well, the infrastructure for broader organizational renewal and performance improvements can only suffer (OECD, 2001). Moreover, the track record of managing IT has not been encouraging and as discussed above, there is no quick solution for how governments should organize themselves to partner, nor is there agreement as to the optimal scope of partnering activity.

To address such concern and risk, two important trends are becoming apparent in service transformation initiatives. First, affected government agencies are spending far more time up front working out the shape of the long-term service transformation. Second, government and industry are engaging in much higher levels of collaboration earlier on in the partnership development process, not only defining objectives but also preparing the groundwork to achieve them. These shifts are notable departures from traditional public sector management processes that have typically internalized preparation within the government body looking to procure outside services of one sort or another—defining the need in isolation from the very organizations with whom the work will ultimately be undertaken (Dutil, Langford, & Roy, 2005). Two case studies below explore this shift in more detail.

## TWO CASE STUDIES

The first case study comes from the Ministry of Sustainable Resources in the Provincial Government of British Columbia which was faced with the challenge of electronically integrating the collection and delivery of land, resource, and geographic information of 19 separate agen-

cies (in order to make use of this information on cross-ministry issues and provide more accurate, integrated informational resources to external stakeholders in industry and communities).

An integrated land and resource registry (ILRR) for British Columbia (BC) will be a spatially enabled, efficient, and accessible electronic register of all legal interests in crown and private land and resources, which serves the business needs of a diversity of users and clients. The major objectives of the project are to first, design and implement an integrated system of registries (including a business architecture redesign), and second, outline an implementation plan and initiate the building of a new system meeting government's expectations for a single registry that is accessible, efficient, and affordable, thereby securing public interests in effective land and resources management.

There was no simple IT solution because:

- Determining ownership and rights for a parcel of crown land requires converting transactions into registry-like information.
- The complexity of transactions leading to rights increases daily as government changes processes in response to business needs.
- Such technology would be very complex, ever changing, and costly.

In 2002, a phase one contract to complete the business strategy and transitional plan for Integrated Registry Project was awarded to Fujitsu Consulting. The business model and transition strategy were assembled using information gathered from internal and external stakeholders on current business practices and future requirements. It documented the best practices observed elsewhere, the conceptual solution and the reason for adopting this solution in preference to other alternatives.

In 2003, a request for proposals (RFP) was issued seeking to establish a partnership with a lead project consultant. The RFP was built on the recommendations put forth in the Business Strategy and Transition Plan done by Fujitsu. Sierra Systems won the competition, becoming the new lead consultant for ILRR Project. The Business Requirements document (completed by Sierra Systems on February 23, 2004, and available under *Program Documentation*) includes:

- ILRR goals, objectives, and principles;
- Expected use cases; business process that result in creation, maintenance, update, or removal of registered interest in land and resources;
- Existing business process and where they interface with ILRR, as well as required changes to business processes;
- Legislation, regulation, and policy requirements; and
- Business transition plan.

Implementation of the proposed system is proceeding on time and on budget as a result of the foundational elements jointly arrived at via two separate, planning stages—each involving a different private sector partner. This experience underscores the degree to which the business model can be developed in a collaborative fashion and it is possible for the work to be compartmentalized into different phases with different partners thereby avoiding supplier dependency and taking advantage of a wider range of private sector skills and competencies.

Ministry officials worked with Fujitsu Consulting in order to develop clarity about the organizational needs of the project before commencing with an eventual procurement tendering process that resulted in a long-term collaborative arrangement with another technology company, Sierra Systems. Representatives from both companies and the government reported that it was only through openness, transparency, and constant communication between the sectors that the right model was executed to guide the approach now being put in place.

The government of Canada is proceeding in a similar manner in preparing for an eventual service transformation initiative on a government-wide scale. Known as Modernizing Services for Canadians (MSC), this project is a 3-year business transformation initiative (2002-2004) that was undertaken in order to "renew HRDC[5] policies, programs, services, and service delivery by focusing on what citizens need in a way that supports citizen's full participation in the workplace and community." By building a new citizen-centred foundation for HRDC policy, programs, and service, MSC is changing the focus of HRDC from the business of conducting transactions to a new emphasis on building relationships with citizens. It is transforming the current complex delivery network into a single integrated service delivery network that provides seamless, multichannel service to Canadians.

Government managers responsible for this initiative are taking a very deliberative approach to defining exactly what a citizen-centred transformation should look like in the context of their core business lines and their relationships with key stakeholders inside and outside of government. In order to do so, the lead department responsible for this initiative has engaged the expertise of four leading IT consulting companies (IBM, CapGemini, CGI, and Accenture) to assist in defining the vision, clarifying the objectives, and establishing strategies for proceeding with change. One result of this type of preparation has been a detailed business plan that—among other things—sets out a comprehensive approach to

planning, testing and deploying core IM and IT foundational elements to support the business transformation.

The unique aspects of the collaborative relationships underpinning MSC centre primarily on the level of upfront preparation and investment focused on both conceptualizing the opportunity to use ICT to transform service delivery and creating a detailed business plan to move down this path: typically governments define their needs internally within the confines of their own planning processes and then proceed to procure external services and solutions. The four companies were selected in 2003 through a competitive RFP process that awarded each firm with a 2-year agreement for deliverables defined within the MSC strategic framework. Many of these companies had also participated in the initial, Year One (2002) MSC visioning and preliminary research phase.

Conceptualizing the opportunity involved building on the government of Canada's previous and ongoing experiences with related initiatives—notably GOL. At the same time, however, engaging the affected service agencies and private sector companies became central to preparation for the next steps. Those leading MSC within the federal government sought to:

- Learn from best practises around the world (via leading companies with global reach extending across diverse public sector clienteles) and build support across government through education and preparation;
- Actively engage the private sector companies in the management and governance of MSC initiatives; and
- Leverage the early experiences of pilot initiatives within a single department (HRSDC) in terms of integrated, multichannel service delivery.

These three directions form the nucleus of the collaborative effort within government and between government and its industry partners. This collaborative work contributed directly to the preparation of the MSC vision, the major output of MSC Year One. Global research undertaken with the private sector produced key findings, lessons learned, and proven approaches. This knowledge was then applied to the foundational work of Year One in developing citizen-centric service strategies, privacy, client segmentation, integrated channel management, enterprise-wide-enabling solutions, and organizational change.

The collaborations within the federal government and between the government and its industry partners have been largely focused on mapping out the requirements of MSC as it evolves into the single largest service transformation process in the Canadian public sector. A key to the success of this effort has been to undertake a highly deliberative and analytical approach to developing both a vision of service delivery and a comprehensive business case for investments and change in moving toward that vision. A comprehensive set of elements for the business plan have been fostered in concert with industry experts, including IT/IM renewal; human resource management; change management; risk management; and a performance evaluation framework.

One of the key challenges of both designing and pursuing the MSC vision is the significant cultural transformation required to work across traditionally separate units within the affected departments, as well as across the various departments themselves. This type of change requires leadership and champions at the political level—as well as within the public service.

There have been three major impacts of these collaborative relationships:

- First, early results from pilot initiatives have demonstrated the potential of integrated, multichannel service delivery strategies to improve services improvements and save money;
- Second, significant organizational capacities have been developed (across IM/IT, HR, change management, and performance measurement) within the federal government that are necessary elements of the foundation for pursuing the wider service transformation agenda, both within the lead MSC departments and on a government-wide basis; and
- Third, in moving forward to leverage these opportunities and capacities, MSC has been instrumental in laying the groundwork for a more ambitious government-wide effort at service transformation.

The nexus of the first and second points underscores the significant dimensions of undertaking an enterprise-wide approach to service transformation for the government of Canada. Traditionally accountability structures that reinforce individual ministerial accountability and thus separate organizational structures (or silos) have shaped for some time the decision-making culture of government. Shifting to a citizen-centric approach on a government-wide scale is thus a major effort, and one that also underscores the importance of not viewing the service transformation agenda as a technology project (i.e., electronic service delivery within a multichannel environment), but rather as an encompassing agenda for organizational adaptation and performance improvement (Oliver & Sanders, 2004).

With regards to the third point, the potential emergence of a new Service Canada model in 2005 would mark the transition to realizing the goals of convergence and better government-wide coordination capacities to realize citizen-centric service delivery. As a result, the govern-

ment has begun to augment its analysis and understanding of citizen demand for online service delivery and the evolution of multichannel usage that will drive the next phases of service transformation (Roy, forthcoming).

## PROCUREMENT REFORM QUANDARIES

In response to this widening scope of collaboration, new procurement and relational capacities are being sought by governments. Comparative research would suggest that no single option is without difficulty (Dunleavy, Margetts, Bastow, & Tinkler, 2003; Gronlund, 2002; UNDPEPA, 2003). Accordingly, a partnership-based approach to procurement has been slower to emerge in Canada, with the government of Canada in particular preferring a more cautious approach to such issues (Charih & Robert, 2004). The results are significant levels of concern and frustration caused by ongoing difficulties that have plagued large IT projects (Borins, 2004; Langford, 2002; Weil & Broadbent, 1998).

The necessity of significantly reforming procurement systems in the Canadian public sector is now widely agreed upon as a key issue—even as agreement on specific changes remains elusive (Allen & Roy, 2002; Jordan, 1999; Kieley et al., 2002; Langford & Harrison, 2001; Mornan, 1998).[6] The governments of Canada and the province of Ontario have both responded in late 2004 with separate but similar reviews of IT management and procurement in order to probe both root causes and potential solutions. The presentation of the technology sector's leading industry association (Information Technology Association of Canada [ITAC]) to the Ontario review panel offers insight on the current situation in terms of both challenges and potential avenues for reform:

- Many business transformation projects have not met expectations in terms of schedule, cost and requirements;
- IT enabled transformation projects are seen as high risk;
- The reputation of the IT industry and its customers as a whole is impacted by these troubled projects; and
- This has occurred in the private sector as well as government (ITAC, 2004).

In their presentation, ITAC presents a study of IT project failures for which the top three causes are: a lack of clear link between the project and the organization's key strategic priorities including measures of success, a lack of clear senior management and ministerial ownership and leadership, and a lack of effective engagement with stakeholders. In terms of making headway in such an environment, ITAC suggests a range of improvements that while varying in scope and purpose tend to converge around the creation of more flexibility and trust between industry and government. This will be achieved through procurement process reform and a shift to a more inclusive and participative governance approach for each project in order to adapt to changing circumstances while ensuring an ongoing and mutual commitment to agreed-upon objectives, constraints, and degrees of freedom.

ITAC points to the province of British Columbia, which has been among the most aggressive subnational jurisdictions in encouraging public-private partnerships, as an example of the type of procurement to partnering reframing that is required:

The Province of British Columbia has developed a Joint Solutions Procurement Process for the evaluation and selection of vendors in large IT projects. Its basic principle is to engage the private sector bidders in a joint discovery of the risks and benefits of the initiative to assess the capacity, commitment and capability of the private sector bidders. The procurement process follows defined gates where information is disclosed and discussed and the field of potential vendors is finally reduced to two. The final stage engages the finalists in competing bids based on a range of criteria relevant to the business outcomes sought by the government. (ITAC, 2004, p. 13)

This type of procurement approach—emphasizing results and outcomes and innovative solutions for achieving them, is consistent with a lessening emphasis on static, upfront measures of cost and price and a greater reliance on more performance-driven and collaborative-based project management. Although rather novel, the BC government is committed to using such an approach in the future formation of IT partnerships. Similarly, it is this type of approach that will likely be required within the contours of the next phases of the federal MSC initiative—and the emergence of a new Service Canada model to more aggressively pursue citizen-centric service delivery on a government-wide scale.

In moving toward models allowing for greater relational flexibility and creativity, the challenge is to rebalance procurement's control emphasis with the necessity of collaboration. The following distinction is reflective of the tone of the dialogue that is emerging in many jurisdictions and it points to the importance of creating meaningful and tangible linkages that recognize and structure interdependence in an appropriate fashion:

- **Cooperation:** Informal relationships that exist without any commonly defined mission, structure or

planning; and *Collaboration* – A more durable and pervasive relationship involving shared structures and joint authority, a full commitment to a common mission and pooled resources, risks and rewards (Mattessich, Murray-Close, & Monsey, 2001).

Incremental reforms to traditional procurement mechanisms have often sought to facilitate some cooperation between industry and government—but collaboration has been extremely limited, particularly in terms of upfront planning and solutions designing. In contrast, due to growing complexities of new technologies and organizational transformations, the importance of strategic relations is increasingly recognized as an imperative for effective public sector performance: indeed, such a philosophy has been driving BC's reforms (Andison, 2004). A current review of procurement at the federal level underlines the point as well, contrasting the public sector's emphasis on a competitive and adversarial culture with suppliers to the approach used by successful companies and even some governments elsewhere: "successful private sector companies and other jurisdictions avoid an adversarial approach by adopting more strategic relationships with their suppliers" (PWGSC, 2004, p. 24).

Prodded by international experiences and growing provincial reforms, such as those being pursued in BC, federal recognition of such issues is encouraging. Two key tests of more holistic public sector reform in Canada will be (1) whether political leadership will emerge to oversee a more strategic orientation with industry partners than has been the case to present; and (2) if such political support is forthcoming, whether the procurement function will be significantly reorganized and bolstered in strategic importance to reflect a new mix of competition and control on the one hand, and strategic collaboration and relational management on the other. These issues are central to the public sector as a whole since next stages of e-government service transformation initiatives are envisioned to be multijurisdictional, raising the stakes considerably for such matters.

## CONCLUSION

A key question that will determine the effectiveness of the Canadian public sector in achieving the promise of e-government is the extent to which such encouraging, collaborative practises within government and between the public and private sectors, as illustrated in the cases above, represent a sufficiently powerful force to alter the broader institutional environment within which such partnering occurs. While the level of discussion and consultation ongoing presently would suggest a widening appetite for reform, both the structural and cultural barriers to more collaborative governance are deeply engrained and extremely difficult to alter (Allen, Paquet, Juillet, & Roy, 2005b).

Such considerations become more consequential when you realize that the service transformation and e-government agendas of most governments result in a widening scope of partnering since governments are under pressure to achieve government-wide capacities for information sharing and service integration. Unlike previous eras of reform that encouraged individual departments and agencies to tailor their own policies and management systems to their own specific mandates and needs, the necessity of more horizontal governance essentially creates the need for two simultaneous and interrelated levels of collaboration—one within governments and the other between the public and private sectors.

## KEY TERMS

**Business Process Outsourcing (BPO):** BPO is the outsourcing of back-office and front-office functions typically performed by white-collar and clerical workers. Examples include accounting, human resources, and medical coding and transcription.

**Contract:** A contract is an obligation, such as an accepted offer, between competent parties upon a legal consideration, to do or abstain from doing some act.

**Co-Sourcing:** Co-sourcing is where a business function is performed by both internal staff and external resources, such as consultants or outsourcing vendors, with specialized knowledge of the business function.

**E-Government:** The public sector usage and deployment of information and communication technologies across both policy-making and service-delivery processes.

**Governance:** Formal or informal mechanisms for coordination either within or between organizations.

Insourcing: Insourcing is the transfer of an outsourced function to an internal department of a company, to be managed entirely by employees. The term has also been used to describe foreign companies locating facilities in the United States and employing U.S. workers.

**Joint Solutions Procurement:** For procurements of large-scale, long-term services contracts or where some form of transformation to the business is taking place, a more collaborative process may be the preferred approach.

**Outsourcing:** Outsourcing is the management and/or day-to-day execution of a business function by a third-party service provider. Outsourcing can be provided on or off premises, in the same country or in a separate country.

**Procurement:** The process of obtaining materiel and services which includes the determination of requirements and acquisition from a supply system or by purchase from the trade.

**Public-Private Partnership (P3 or PPP):** A public–private partnership is an arrangement for service delivery, whereby government and private enterprise pool their skills and resources to meet a particular objective.

**Request for Proposal (RFP):** An RFP is a document that requests prospective service providers to propose terms and conditions for a solution (or solutions) addressing a set of requirements.

## ENDNOTES

1 The authors are grateful for the helpful comments of the blind reviewers.

2 Examples include the municipality of Kingston, Ontario, and Suffolk Country in the United Kingdom. Interestingly, the new business model formed by Accenture and BC Hydro is also envisioned to be marketable to other utility organizations (although no financial revenue sharing between these parties has been stipulated at the outset of this example).

3 This New York City initiative, though large on a municipal scale, is hardly unique: it was recognized as a leading example of such schemes, indicative of a trend of such efforts emerging in cities and states across the country. For a complete profile of all initiatives, see "Effectiveness Through E-Payments: Current Learning and Suggested Best Practises," available online at the National Electronic Commerce Coordinating Council (www.ec3.org).

4 They include customer services, IT services, network computer services, human resources, financial services, purchasing, and building and office services.

5 HRDC stands for Human Resource Development Canada, until 2004 the largest federal department in terms of program and service delivery responsibilities (including areas such as skills training, employment insurance, pensions, child assistance programs, student loans, and others). In 2004, the new government split this entity into two, distinct departments (Human Resource and Skills Development Canada on the one hand, and Social Development Canada on the other). This organizational change has had no direct impacts on the governance of MSC, a project that remains jointly managed by both of these units.

6 The evolution of private sector language is revealing in this regard. IBM views itself increasingly as a consulting company and a provider of solutions (disengaging itself from many of its previous production functions), EDS speaks of Co-sourcing, and Accenture consulting points to Business Process Outsourcing—a mix of outsourcing and jointly managed organizational mechanisms.

# E-Learning as Social Inclusion

**David Casacuberta**
*Universitat Autonoma de Barcelona, Spain*

## INTRODUCTION

When talking about excluded people and how to develop programs towards digital and social inclusion, there has been little research to individuate targets. So far, there seems to be only two main subdivisions:

- People with either sensorial or motor disabilities who may benefit from specific technologies in order to assure accessibility to digital content.
- People that are digitally illiterate and therefore have to be taught the basics on using the computer and basic applications.

Nevertheless, it is quite clear that the digital divide is a multidimensional phenomenon, and therefore, that digital inclusion strategies will benefit a lot if more specific strategies are developed, individuating problems and solutions related more closely to individual experiences. The aim of this article is to show how e-learning can be used as an e-inclusion tool to help excluded people improve their lives and be socially included.

## BACKGROUND

Most public projects backed by governments, concerned with digital inclusion, tend to centre their focus on issues of hardware: donation of computers, cabling homes, the use of wireless devices, and so forth. Though such issues are obviously unavoidable, they are not the end-all be-all of the digital inclusion matter.

Moreover, as stated in the introduction, the ultimate beneficiary targeted is all too often ill-defined. Generally benficiaries are of two types:

First, we have people with disabilities, in which case, the targeted beneficiary is usually well analysed and segmented into specific groups, given that considerations are different for the blind, the colour blind, the visually impaired, and so on. A quick and serious introduction to accessibility and the Internet can be found at Lawrence and Giles (1999).

Then, we have the general fall-out of the so-called digitally excluded, in which case, the single identifying characteristic is one of computer illiteracy. Thus, one finds little distinction made among such diverse targets as senior citizens, the unemployed, convicts, disadvantaged youth, and so forth. The blanket approach taken for all these groups is to organise practical courses wherein these diverse individuals are taught the how to of surfing the Net, e-mailing, and like activities.

Considering the undifferentiated reasoning underlying such tactics specious, governments should consider alternative approaches to develop e-inclusion processes. A good possibility, which starts to be seen in several European Union (EU) co-financed projects, is to create ambitious e-inclusion programs based on the following imperatives. One of the best introductions for understanding these news imperatives is Warschauer (2003).

1. Overcoming mental barriers as opposed to simply technological ones. Most analyses, like several studies from the Eurobarometer, show that the major causal factors of marginalisation from the information society are those such as the mistrust often felt toward new technologies and the lack of any content attractive or useful to either the socially excluded or those at risk of being so.
2. An approach based on empowerment. It can be held that what is important is not so much knowing how to use, for instance, Netscape or Outlook, but rather the educational and liberating potential of new technologies. We seek to make the Internet an instrument for integrating the socially excluded by using it to equip them with the skills that will make them employable in the information society. Furthermore, we seek to develop their capacity to think critically, to form their own political views, and to organise themselves as citizens and cultural groups. The potential realisation of such substantial goals advocates thinking about ICT (information communication technologies) in more social terms rather than through a reductive technical approach.

## STRATEGIES TOWARDS SOCIAL INCLUSION USING E-LEARNING

The following is a list of the five strategies that, at this stage in the research, seem the most promising in terms of

establishing the best practice in the use of e-learning for social and digital inclusion.

First, the strategy of combining teaching ICT with other non-digital knowledge is equally important to social inclusion. An example of this approach is the case of a gypsy community wherein computers were used as a tool to prepare for a driving exam. The usefulness of this tool was enough to convince several adults from the community to participate in e-learning activities. Similarly, it has been found in other best practices that, in order to motivate adults to use such tools as Microsoft Office or a Web browser, it was vital to show to them how such knowledge would help them find employment. You can see that strategy more clearly described at www.5d.org, which describes in detail the specific e-learning devices and methodology used. This is an effective strategy for three reasons. First, the students are much more motivated, since they associate learning ICT with something of genuine concern to them, obtaining a driver's licence, a job, and so forth. Second, there is an efficiency factor to combining learning purposes; that is, at the same time the learners acquire Internet skills, they also acquire others such as learning how to drive. Third, the fulfilment of the goal of social inclusion is greatly enhanced, given that not only digital skills are imparted, but also other skills which, though not digital, are nonetheless vital to social inclusion.

The second key strategy is communication. Our analysis of failures has demonstrated that if the proposal is not properly communicated, it will not fulfil its objectives. There are innumerable Web sites dedicated to helping women or immigrants that, however well they may be designed and organised, do not succeed in doing so because the 'target' does not know they exist. Communication needs to be appropriate to both the target and its geographical situation, that is, if it is local, national, or international in character. Furthermore, it must make use of non-digital means to deliver the message, given that the target group is precisely the digitally excluded.

A third strategy is to establish peer to peer teaching systems. That is, in the degree to which it is possible, it is desirable for the students to teach each other. This can be structured either formally or informally. In the former case, the students are 'promoted' to the level of teachers; the important implication here is that if enough students are inspired to adopt a teaching role, sustainability is guaranteed. Meanwhile, in less formally structured situations, the help the students offer significantly reinforces the cognitive relevance of what has been and is explained and greatly boosts motivation. Again, the 5D project (www.5d.org) used this strategy also with impressive results within the gypsy community.

The fourth strategy is to create informal environments and has the advantage of being applicable for various target groups. For instance, the traditional class environment for teaching computer skills can be very boring for children who are not used to it. Organising something more informal and experimental, where the children use the computer as a toy, can be highly effective. Likewise, such formal teaching environments might be intimidating for immigrants whose cultural background is significantly different from the host country's. They may feel more comfortable in less formal circumstances. Moreover, much the same can be said with regard to certain groups of women and senior citizens. A very interesting example is the collective Herein in Austria who adapt Web sites for e-learning projects with migrants to the cultural specificities of the migrant's culture, making it therefore easier to access and use (www.herein.at).

The fifth strategy is to use teachers similar to the students themselves, something that is particularly well documented in cases of e-learning focused towards women. Since digital technology tends to be thought of as man's world, adolescent girls often do not feel motivated by it. Hence, it can be advantageous to use female monitors to explain the use of a given e-learning environment, as well as female avatars to present content. Though the effect may be a subconscious one, it can be important nonetheless, as it goes towards breaking the stereotype that only men can handle ICT. A similar phenomenon has been observed in the case of immigrants; an instructor from the same culture tends to be more motivating, however well the immigrant speaks the local language. A good example of this is the Eclectic Technology Carnival organized by Genderchangers (www.genderchangers.org) who arrange specific events for women, using female professors, arranging more relaxed environments, and selecting content and ways to present them which appeal more to women.

## FUTURE DEVELOPMENTS

After a careful analysis of real e-learning practices towards e-inclusion, considering the key strategies and analysing where information and technological advances were more needed and relevant, we have found the following five key areas which are good starting points for both implementation and further research:

### Social Solutions to Social Problems

Although there is always some co-influence between technology and social practices, we should not forget that social practices define how technology is finally used, and not the opposite. A good argumentation of this thesis can be found in Marzo (2003). We should neither forget that digital technologies are never neutral. If not

used appropriately, they can expand the social divide, instead of diminishing it. If we want to have a really inclusive information society, we need to address the social problems that have turned people into the digitally excluded, and not only consider the ones derived from lack of structure. When digital exclusion is considered, not everyone has been created equally. There is an important qualitative difference between someone who is already excluded and needs to understand and use ICT, and someone who only needs some formal knowledge to jump in. This is a general principle which we think should permeate research in interacting with computers: instead of simply analysing the technical features offered by the provider or studying the *de facto* use by some groups, think creatively about the social uses of digital technology and find new uses and strategies that are more meaningful for excluded people.

## Community and Awareness

Learning communities is a hot subject nowadays. Nevertheless, they are mostly viewed as mere instrumental concepts towards improving learning. Again, this is useful, but it is not enough. ICT offers us wonderful social software which can be used in original ways to help real communities to expand their political, social, and cultural horizons. Isolated communities can use digital technologies to be better known and respected in society. The dispersed ones can use several digital tools to stay in touch and continue developing their own lifestyles and culture. We should also keep in mind all the awareness power that lies in the Internet to describe and fight social exclusion. This strategy is key when we are considering rural isolated communities and migrants that are working far away from their homes. They can also become an important measure to fight sexism in the computer world and help women to join and transform ICT. An excellent analysis of how social capital permeates digital networks can be found at Huysman and Wulf (2004).

## Towards the Transparent PC

Computers and software improve and new features are developed every year and therefore become more difficult to use. This may be fine for users that are familiar with ICT. However, it makes thing worse every year for the digitally excluded, especially when older people or people with disabilities are considered. In fact, we consider this "new feature" strategy deeply wrong from a social and educational point of view. We need to reverse it. We have to consider strategies and technologies to make them more intuitive and easier to use. Our grail, as the title suggests, is a transparent computer; something that it is so easy to use that it needs almost no instruction. A camera or a car are fairly intuitive technologies. To take a picture, you just direct the camera to the place you want to photograph and click the button. If you want to turn right, you just move the wheel right. Why can ICT not be like that? A comprehensive and powerful description of such tendencies can be found in Norman (1998).

## Problem Solving Methodology for Digital Content

Because our target has specific needs, we need to avoid academicism, and to construct courses that are useful, practical, and motivational. This surely implies something that is usually neglected when thinking about learning strategies in digital media: the specific social and cultural context. Lack of trust and of motivation are important barriers towards e-inclusion. We will never cross those gates if we just create the typical "how-to" courses. Besides, information society becomes more and more competitive. In a few years, just knowing how to use a word processor or an e-mail client will not make any difference in the job market. This is another reason to search for problem-solving methodology. A general course on how to use graphic edition software is of little use, but a problem solving course on how to make flyers for clubs is both a good motivator and even a job opportunity for an unemployed youngster in a challenging neighbourhood. For more information, see Alexander, Ishikawa, and Silverstein (1979) and Gardner (1998).

## Internet for Everybody

Software technologies are plastic enough to be adapted to any specific need a special collective may have. Unfortunately, very few companies, administrations, or individuals use that characteristic. We need to raise awareness on that topic among software and hardware producers, Web designers, and educators. Here, research is key in order to find both market and cognitive strategies to turn adaptation towards accessibility more and more common.

When accessing culture, physical barriers like distance or architecture are a challenge to people with mobility problems. Books are of no use to people with visual difficulties. It is a shame that most digital cultural products, which can avoid these barriers easily, are not really adapted to these people's needs.

# CONCLUSION

In summary, e-learning towards e-inclusion, needs to combine both technical and cognitive approaches. Teach-

ing technical skills involving the use of a computer or Internet turn out to be useless if unaccompanied by motivation and contextualisation. New solutions have been all too often overlooked, due to the predominance of an exclusively technical focus on the issue. In essence, the strategies put forth are moving towards a new paradigm, one based upon more informal teaching environments, wherein the communication among peers is fundamental, and damaging stereotypes regarding new technologies are avoided. Of course it goes without saying, that these practices are all unviable without a necessary minimum of infrastructure, that is, access to a computer and the Internet. However, it is just as clear that investment based on providing technical means is ineffective when unaccompanied by a new methodology, one based on contextualisation and motivation. Rather, the battle against the digital divide must be waged on both fronts.

Digital inclusion does not mean merely to teach people how to surf the Web or how to send e-mail. These are only the building blocks. We need to do a lot more to ensure that excluded people can use the Internet to expand their competences and capacities to empower themselves and achieve a better life. Future research in the topics listed in the Future Developments section will be of great help in improving both our knowledge and the practical strategies to teach excluded groups how to interact with computers and become more included in society.

## KEY TERMS

**Digitally Excluded:** Those people that, due to a variety of reasons, from cultural to social and economical, are not able to access computers and the Internet. The reason may be lack of access to them or lack of knowledge to use them.

**E-Inclusion:** There are at least two different ways to interpret this term: (1) the process to teach people how to use computers and therefore help them to avoid the digital divide; (2) the process to include people socially using ICT.

**E-Learning:** A series of learning processes and strategies that use the interactive powers of ICT in order to facilitate access to knowledge and continuous training, and use innovative learning techniques. The mere access to noninteractive material, for example, a book in HTML format, should not be considered e-learning *per se*.

**Learning Communities:** A term originally developed in the higher education context, referring to the process to link several courses together so students are able to get deeper understanding of one subject, as well as developing multidisciplinary studies. Learning communities also facilitate the communication between students and the possibility to access different professors.

**Problem-Solving Methodology:** Originally, a methodology from artificial intelligence that tried to mimic using computers the way humans solve problems. Nowadays it is also used in e-learning projects in order to present the information in a more interactive, suitable, and helpful way.

**Social Capital:** In the context of this article, we use the term to refer to the value that one gains when joining a network.

**Transparent/Invisible Computer:** A metaphor invented by Donald Norman referring to the need to create digital interfaces and devices that are so intuitive that they are very simple to use, so simple that one does not need special training to start doing things with it.

# E–Learning through HCI

**Claude Ghaoui**
*Liverpool John Moores University, UK*

**William A. Janvier**
*Liverpool John Moores University, UK*

## INTRODUCTION

E-government is using electronic technology to streamline and/or to improve the business of government and, as a result, to improve its citizens' personal services; for example, patient hospital appointment booking systems, electronic voting, and the development of e-education. E-education and, from this, e-learning depend not only on the quality of the content but also on that of the human-computer interaction (HCI) generated by designers and implementers of a system.

HCI is a cross-discipline subject that covers a wide area of topics, many of which need to be considered in e-learning, that directly affect the student, the tutor, or the administrator. HCI delivering e-learning includes issues such as psychology, sociology, cognitive science, ergonomics, computer science, software engineering, users, design, usability evaluation, learning styles, teaching styles, communication preference, personality types, neurolinguistic programming language patterns, and so forth.

This article considers interpersonal communication and the effective transfer of knowledge from one human to another (e.g., a teacher to a learner) in the real world; it then postulates on their replication in distance/e-learning. The article focuses on the factors required for effective e-learning in the field of HCI for education. In particular, it introduces the concept of using communication preference (CP) and learning styles/personality types (LS) in an intuitive interactive tutorial system (in TS). The development of WISDeM (Web Intuitive/interactive student distance education model) by the authors significantly exemplifies this in its evaluation results.

## BACKGROUND

In this section, we discuss distance learning, learning and teaching, CP, LS, neuro-ergonomics, neurolinguistic programming (NLP), and NLP language patterns.

### Distance/E-Learning

Distance/e-learning is training that can be (1) live instruction that is conveyed in real time via telecommunications facilities, (2) accomplished on a point-to-point basis or on a point-to-multipoint basis, and (3) conveyed in many forms (teleseminar, teleconference, electronic classroom, using text and/or audio and/or video). In essence, a live tutor or computer tutorial system trains the learner when the learner is at a different geographical site and sometimes at a different time. Currently, the live tutor has the ability to adapt to the learner as relevant—computer tutors do not replicate this ability.

Lawler and Yazdani (1987) consider that a computer tutor, in order to provide adaptive instructions, must have a strategy that translates its tutorial goals into teaching actions and that, as a consequence, research on teaching strategies is central to the construction of an intelligent tutoring system. Programming the computer tutor can adapt it dynamically at runtime to (1) focus on the fluctuating cognitive needs of a single learner over time and (2) output content and form of knowledge and/or instruction to the learner's understanding of the subject matter. In order to provide adaptive instruction, a tutor must have a wide range of instructional actions (the principal of versatile output). One learner may need a definition; another may need an explanation. Ghaoui and Janvier (2004) ask, "What about changing the output to match both the learner's communication preference and learning styles?"

### Learning and Teaching

Every teacher is a learner; thus, while we consider learning and the way we learn, the corollary is that teachers use their learning experiences to teach and to develop their own preferred teaching styles. Cotton (1995) considers that learning usually is the active process in which the learner remembers the input of an instance and interprets this input subject to preconceptions. The input and retention of some instances can be the result of passivity (e.g.,

knowing that an insect bite can hurt normally is not the result of active learning). Learning enhances the ability to learn that practice makes perfect.

Gagnon, Collay, and Gagnon (2001) consider that the art of constructing meaning out of instances results in a learner learning to learn (constructivist learning). Crucially, this is a cognitive mental activity. While the input of instances well may depend on physical action, the cognitive consideration of those inputs depends on reflection of those inputs (reflective learning) (Coffield, Mosley, Hall, & Eccleston, 2004). There are many styles supported and adopted by teachers for passing on their own knowledge to students, while students exhibit their own personal learning styles based on their personality and life experiences (Janvier & Ghaoui, 2002).

A basic point to remember is that in order for conscious communicative learning to take place, passage of information between the teacher and the learner relies on the use of a jointly understood language, and the use of words is subject to the possibility of misinformation. What the learner understands words to mean may not be what the teacher means, which can be exemplified by the following problems: (1) *preconceived ideas*—the learner tends to ignore what he or she thinks is known or is like something that is known; (2) *ashamed to admit lack of knowledge*—the learner does not like to admit that the communication being used is not understood; and (3) *loss of interest in the communication*—clarification and confirmation of understanding is essential (Cotton, 1995).

A learner usually transfers sensual input into permanent input by rehearsal— the repeated exposure to a new idea or fact—the way the brain revisits experiences while we sleep. Waking up with some instantaneous inspiration is not instantaneous; the brain has been working at the subconscious level before recall makes it conscious (Catania, 1992). A learner also requires the correct type of feedback; inappropriate feedback or classical conditioning (e.g., destructive criticism) creates an ever-increasing barrier to learning (Cotton, 1995).

A tutor has a preferred style of communication, which influences his or her choice of teaching style or theory in a given instance. If this communication style matches the student's preferred communication style, then excellent communication takes place, if not, communication is less effective. Thus, in order to be fully effective, a tutor needs to temporarily adjust his or her communication style to that of the student's (Catania, 1992).

## Communication Preference

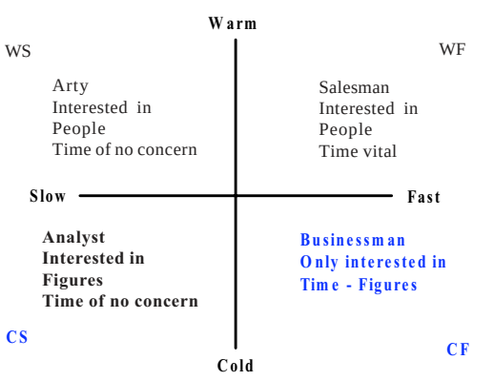
Everyone has his or her preferential technique(s) in order to exchange ideas with others, acquire knowledge, and pass knowledge along to a third party. This is called communication preference, which has been the basis of much research (Janvier & Ghaoui, 2003b). Almost all learning is external to the body; one of the five senses (touch, sight, taste, hearing, and smell) introduces it. The input is filtered, interpreted, and assessed against previous input, beliefs, and concepts using perceptual constancy, perceptual organization, perceptual selectivity, and perceptual readiness. Stored instances are not a true representation of the actuality due to the fact that they already have been distorted by the subject's own interpretation of the facts as perceived by the inner voice, eye, ear, nose, and taste (Cotton, 1995).

## Personality Types

Different personality types require different communication treatment. It is possible to plot all these types somewhere on the WC/SF scale, as seen in Figure 1.

- **WS types** prefer the company of others, are slow to make decisions, take their time, and sometimes will not make a final commitment. They get along very well with other WS types and often communicate well with WS and WF types; they do not like the CF type. They can be categorized as *Arty*.
- **CS types** prefer their own company, are slow to make decisions, take their time, and sometimes will not make a final commitment. They are very precise, and they get along very well with other CS types. They often communicate well with WS and CF types; they do not like the WF type. They often are categorized as *Analytical*.
- **WF types** prefer the company of others, are fast to make decisions, and often make a commitment before thinking it through. They get along very well with other WF types and often communicate well

*Figure 1. Personality types (Janvier, 2004)*



with the WS and CF types; they do not like the CS type. They often are categorized as *salesmen/conmen*.

- **CF types** prefer their own company, are fast to make decisions, and often make a commitment before thinking it through. They get along very well with other CF types and often communicate well with the CS and WF types; they do not like the WS type. They often are categorized as *businessmen*. (Janvier & Ghaoui, 2003b; Myers & Myers, 1995)

In order for effective communication to take place, the communicator and the subject need to be close to each other's type. The communicator has the responsibility to move and adapt style. Fortunately, although dominant personality types are fixed at about the age of 18, subjects use their Jungian secondary functions, tertiary functions, and so forth, as required. Between the ages of 12 and 20, we develop and use the auxiliary function as a powerful support to the dominant function. From ages 20 to 35, we begin to use our tertiary function more frequently and with better success. From 35 to 50 we pay attention to our inferior function, and from 50 onward, we tend to use all four functions in a rounded manner. Research indicates that people without a strong auxiliary function to complement their dominant function have problems dealing with communications; the introverted personality type tends to hide the dominant function and show the auxiliary function to the world; the extroverted type shows the dominant function (Murphy, Newman, Jolosky, & Swank, 2002; Wilson, Dugan & Buckle, 2002).

## Neurolinguistic Programming and NLP Language Patterns

NLP can be defined as "the Study of the Structure of Subjective Experience and what can be calculated from it" (Sadowski & Stanney, 1999). Subliminal communication occurs in any face-to-face communication when the senses, mainly iconic, receive body-language input. In particular, the eyes convey a myriad of signals of which eye accessing cues are particularly useful. The name neurolinguistic programming comes from the disciplines that influenced the early development of its field, beginning as an exploration of the relationship between neurology, linguistics, and observable patterns (programs) of behavior (Pasztor, 1998; Sadowski & Stanney, 1999; Slater, Usoh & Steed, 1994).

John Grinder, a Professor at the University of California at Santa Cruz and Richard Bandler, a graduate student, developed NLP in the mid-1970s. They were interested in how people influence one another, with the possibility of being able to duplicate the behavior and, thus, finding a way to influence people. They carried out their early research at the University of California at Santa Cruz, where they incorporated technology from linguistics and information science and knowledge from behavioral psychology and general systems theory, and developed their theories on effective communication. As most people use the term today, NLP is a set of models on how communication influences peoples' subjective experience. It is more a collection of tools than any overarching theory. Much of early NLP was based on the works of Virginia Satir, a family therapist; Fritz Perls, founder of Gestalt therapy; Gregory Bateson, anthropologist; Milton Erickson, hypnotist; and Stever Robbins, NLP Trainer (Bandler & Grinder, 1990).

It is possible to make eye movement cognitive by observing the direction in which the eyes are moving during conversation. When eyes move in a certain direction, one can detect if the subject's thinking is visual, auditory, or kinaesthetic/emotional. Eye dominance governs eye movement with right-eye dominance signals going to the left cortex and left-eye dominance to the right cortex.

Assuming that the subject is right-eye dominant, the following pertains:

- **Visual Remembered:** (Eyes up to the left)—recalling past images
- **Visual Constructed:** (Eyes up to the right)—vision conceptualization
- **Auditory Remembered:** (Eyes to the left side)—recalling past sounds
- **Auditory Constructed:** (Eyes to the right side)—conceptualization
- **Auditory Digital:** (Eyes down to the right)—talking to himself or herself
- **Kinaesthetic/Emotion/Feelings:** (Eyes down to the left)—feels emotions, sense of touch, or muscle movement (Pasztor, 1997, 1998; Sadowski & Stanney, 1999).

Craft (2001) explores relationships between NLP and established learning theory and draws a distinction between models, strategies, and theories. Craft (2001) argues that, while NLP has begun to make an impact on education, it remains a set of strategies rather than a theory or a model. NLP well may be a set of strategies; however, research has shown that this set of strategies results in increased memory retention and recall. For example:

- Pasztor (1998) quotes the example of a student with a visual NLP style, whose tutorial learning strategy was based on "listen, self-talk," and sport-learning strategy was based on "listen, picture, self-talk";

the former did not achieve memory store/recall, while the latter did.
- Pasztor (1998) reports that rapport with a partner is the key to effective communication and that incorporating NLP in intelligent agents will allow customization of the personal assistant to the particular habits and interests of the user, thus making the user more comfortable with the system. Introducing the correct submodality (visual, auditory, kinaesthetic) will enable the subject to more easily store and recall instances in/from memory.

It is argued that inviting a subject to *see* invokes iconic; to *hear* invokes auditory; and to *feel* invokes kinaesthetic recall (Pasztor, 1997).

## MAIN ISSUES IN REPLICATION

In this section, we cover a successful example of an actual replication of HHI in HCI.

### Replication in a HCI Distance/ E-Learning Tool

HCI distance/e-learning tools have been widely developed both commercially and as academic research tools:

- Two good examples of commercial tools are Blackboard™ and WebCT™, which concentrate on a general menu and offer individual, synchronous, and asynchronous learning/communication; these cover the general requirements of most educational establishments.
- There are many types of academic research tools that include artificial intelligence (AI) and/or an intelligent tutoring system (ITS).

Murray (1997) postulates that while ITSs are becoming more common and proving to be increasingly effective, each one still must be built from scratch at a significant cost. Domain-independent tools for authoring all aspects of ITSs (domain model, teaching strategies, learner model, and learning environment) exist and go beyond traditional computer-based instruction while trying to build models of subject matter, instructional, and/or diagnostic expertise. They can be powerful and effective learning environments; they are very expensive in time and cost and difficult to build. To launch effective systems requires a paradigm shift from a storyboarding to a data-based authoring paradigm. Fundamental is the separation of database content from instructional methods, where authors represent their knowledge explicitly and modularly, to the creation of explicit representations of the content and the instructional strategy.

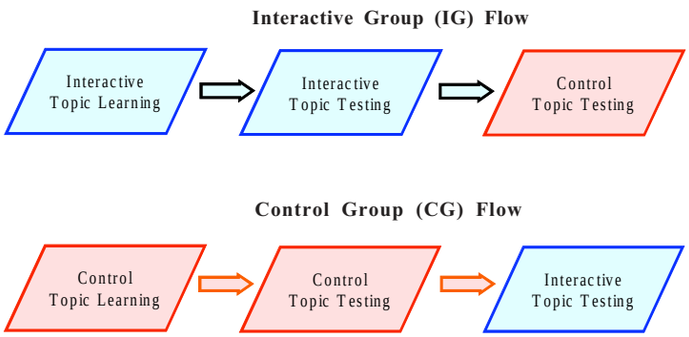
Of particular interest are Ainsworth et al.'s (2002) REDEEM and Ghaoui and Janvier's (2004) and Janvier and Ghaoui's (2003a) WISDeM. All of them use approaches that combat the problem that ITSs are difficult and expensive to build.

- REDEEM is an authoring tool that authors pedagogy that is concerned primarily with the development of tutoring strategies, not with the construction of domain material that allows the tutor to create content with freedom and then to link this content with the teaching strategy selected for each individual student as selected by the tutor.
- WISDeM is an authoring tool that is concerned primarily with ensuring that the student receives knowledge in a way that is commensurate with his or her communication preference and learning styles. This removes the tutor's preconception of personality type in exchange for two psychometric tests that form the basis of the student's profile.

Janvier and Ghaoui's (2004) research has shown that 60% of students are extroverted, and 40% are introverted (see Personality Types evaluation results). An introvert tends to show his or her secondary Jungian Function (Kakabadse, Kousmin, & Chatham, 2004) and not what he or she really requires; this is hidden. Research shows that a student's basic learning style is established before he or she joins higher education; however, outwardly, the student will use his or her secondary and tertiary Jungian Functions, if it is more appropriate. Thus, the introvert often will use his or her secondary extrovert function to mask the introverted nature (from experience, the introvert has found that it is more appropriate) (Janvier & Ghaoui, 2003b; Wilson et al., 2002).

WISDeM (Janvier, 2004; Janvier & Ghaoui, 2003b, 2004) has been developed successfully to offer a Human-Centered Generic intuitive interactive tutoring system (inTS). It was designed to cover all normal DLT requirements for higher education. It includes one-to-one interaction between student and tutor. The system replaces the tutor and replicates, in part, tutor-student live interaction. The project thesis is as follows: "Matching neurolinguistic programming (NLP) language patterns in an online distance learning tool, with the learner's communication preference and learning styles, will provide an intuitive tutoring system that will enhance human-computer interaction and communication and, thus, enhance the storing and recall of instances to and from the learner's memory, thus enhancing learning." The evaluation of the model indicated that the memory retention made by the test students compared to the control students evidenced

*Figure 2. Interactive group flow and control group flow charts show how the two groups completed the evaluation exercise in order to ensure comparative analysis between both types of interfaces and comparison of the interface components for both types (Janvier, 2004)*



greater memory retention of about 10%. The statistical analysis of the results using both one-way ANOVA and two-sample T-Test gave a *P-value* at 0.005, thus providing a very strong indication that the thesis hypothesis is strongly supported (Clarke & Cooke, 1978; Thompson, 1992; Yates, Moore, & Starnes, 2002) for statistical evidencing.

The evaluation involved 97 students (86 male, 11 female).

- Students were drawn from the 3rd-year degree computer science course and, thus, evidenced similar experience and knowledge.
- Communication preference varied (visual (V) - 67.01%; auditory (A) - 27.84%; and kinaesthetic (K) - 5.15%) compared to VAK communication preference, as reported by researchers as V = 60%, A = 30%, and K = 10% (Brown, 2001; Catania, 1992; Cotton, 1995; Janvier & Ghaoui, 2003b)
- Personality types provided a split between extroverts (59.79%) and introverts (40.21%).

Direct observation, used for the evaluation, required the creation of two groups—the interactive group (IG) and the control group (CG)—in order to extract comparative information on the use of both types of interface; thus, both groups needed to experience the two types of interface interaction (see Figure 2).

The IG used the interactive interface first and then the non-interactive interface; the CG used the non-interactive interface and then the interactive interface. In this way, each group experienced both interface types, and comparative results were compiled that allowed definitive evaluation of the experiences of both groups.

The concept for each approach is to allow a student to experience either the intuitive interactive interface (IG) first and then experience the non-intuitive interactive interface (CG), or vice-versa. This achieves four objectives for the analysis:

1. It allows the student to experience both types of interface, which enables him or her to be able to make comparative assessment of the two types of interface and to provide subjective feedback.
2. It allows the evaluator to collect observational feedback, to ask specific questions about the student's reactions to the two interfaces, to rate this subjective feedback, and to make notes about the student's feelings concerning his or her experience; this information is used in the anecdotal and subjective analysis.
3. It allows the system to collect hard data for the statistical analysis.
4. It allows comparison of the gain in knowledge retention of one route with the other.

## Summary of the Evaluation Results

The evaluation results indicate that WISDeM's intuitive interactive system is likely to make a significant improvement to student learning and remembering. Measuring the evaluation results against the success criteria provided the following:

- Do IG students demonstrate a larger gain in correct marks scored when answering the questions (in the Q&A facility) than the CG students do?
  **Yes**. P=0.005 (means of 15.00:4.22). This is a signifi-

cant result that strongly supports the hypothesis that the inITS improves remembering; it is strong enough to warrant further research.

- Does memory retention improve more by the IG students than the CG students do, as evidenced by higher comparative marks?
  **Yes**. P = 0.036 (means of 70.00:55.00). This is a significant result that quite strongly supports the hypothesis that the inITS improves memory retention.
- Is the increase in the correct mark's score for the IG route greater than the CG route*?*
  **Yes**. P = 0.036 (means of 70.00:55.00). This is a significant result that quite strongly supports the hypothesis that the inITS improves memory retention.
- Does the IG route, compared with the CG route, increase memory rehearsal?
  **Yes**. The interactive students used the facility buttons 10.21 times each and evidenced use of facilities not offered to the control students, whereas the control students used the facility buttons 8.93 times each. This indicates that the IG student appeared to be more involved and demonstrated greater interactivity.
- Is the IG route, compared with the CG route, evidencing a greater increase in enjoyment of and interest in using the system and, therefore, encouraging learning (greater use of facilities [links and buttons] equates to success)?
  **Yes.** The anecdotal data evidenced this. They also evidenced greater use of the facilities by the IG students, compared with the CG students. This indicates that the IG student appeared to be more involved and demonstrated greater interactivity.

In each instance, the evaluation indicated support for the criteria and hypothesis, pointing the way for further research. (Janvier, 2004)

## FUTURE TRENDS

All current tools seem to heed HCI principles except, for example:

- Accessibility, a vital component in the creation of an effective DLT.
- Creating an effective student model before the student uses the DLT; this model takes cognisant of the student's communication preference, learning styles, and motivational factors.
- Avatars that are designed to interact with the student, where the student has full control of the avatar's features and voice and where the avatar's features demonstrate a student-mirror image visage in reacting to sensual input (eye gaze, pupil size, eye movement [iconic, auditory, or kinaesthetic]).

## CONCLUSION

The importance of this research is that it indicates the following:

1. The replication of human-human interaction, as evidenced by well-trained councillors interreacting with their clients on a one-to-one basis, can be introduced into a Distance Learning Tool.
2. CP and LS introduction is likely to significantly improve the tool for its students.
3. An inTS can have CP and LS/personality types replication incorporated successfully, thereby enhancing memory retention.
4. The inclusion of the CP and LS facility in e-learning tools is likely to improve effectively the target results for which the government is striving in e-learning/e-education.

## KEY TERMS

**Avatar:** An image that represents a user in a multi-user virtual reality space.

**Communication Preference:** The art and technique of selecting your own preferred words in order to effectively impart information or ideas to others.

**Distance Learning:** Learning that takes place when the instructor and student are separated by space and/or time. The gap between the two can be bridged using technology, such as audiotapes, videoconferencing, satellite broadcasts, and online technology, and/or more traditional delivery methods such as the postal service.

**Human-Computer Interaction (HCI):** Human-computer interaction is the study of how humans interact with computers, and how to design computer systems that are easy, quick and productive for humans to use.

**Human-Human Interaction (HHI):** The way a person acts and reacts to another person or persons. It is the mutual or reciprocal action and interacting between two people, where each takes conscious or subconscious notice of each other's body language and verbal communication in order to govern the way each person responds.

**Intelligent Tutoring System (ITS):** An ITS consists of (1) a user interface; (2) an expert model or knowledge model representing the domain expert's subject matter; (3) a student model or learner model representing the student; and (4) an instructional model that holds the pedagogical data.

**Learning:** The cognitive process of acquiring or refining skill or knowledge and the storing of these in long-term memory.

**Learning Styles:** The 16 styles made up of these four couplets types: Extrovert|Introvert, Sensing|Intuition, Thinking|Feeling, and Perception|Judgement.

**Modalities:**

- **Auditory:** Use of auditory imagery: hearing, tonality, pitch, melody, volume, and tempo;
- **Kinaesthetic:** Use of emotional, feeling, movement imagery: intensity, temperature; and
- **Visual:** Use of visual imagery: sight, color, brightness, contrast, focus, size, location, and movement.

**Neurolinguistic Programming (NLP):** The study of the structure of subjective experience and what can be calculated from it.

**Neurolinguistic Programming Language Patterns:** The use of words or similar constructs: "See" for iconic, "Hear" for auditory, and "Feel" for kinaesthetic subjects both in language and text at the relevant times.

**P-Value:** Represents the probability of a result of a test of association having occurred by chance, if there actually was no association among the variables. Probability values only can lie between 0 and 1, and P-values never actually reach 0 or 1. If the P-value is less than 0.05, it signifies that a result like this only could have appeared by chance 5% of the time, if no association actually existed, which is a statistically significant finding.

# Electronic Business Models Design for Public–Private Partnerships

**Euripidis Loukis**
*University of Aegean, Greece*

**Elena Tavlaki**
*University of Aegean, Greece*

## INTRODUCTION

Public-private partnerships (PPPs) provide an alternative model for producing and delivering public services, both the traditional public services and the electronic ones (i.e., the ones delivered through electronic channels, such as the Internet or other fixed or mobile network infrastructures; Aichholzer, 2004; Andersen, 2003; Broadbend & Laughlin, 2003; Jamali, 2004; Lutz & Moukabary, 2004; McHenry & Borisov, 2005; Nijkamp, Van der Burch, & Vidigni, 2002; Spackman, 2002; Wettenhall, 2003). The basic concept of the PPP model is that the public and the private sectors have different resources and strengths, so in many cases, by combining them, public services can be produced and delivered more economically and at higher quality. In this direction, a PPP is a medium to a long-term relationship between public organizations and private-sector companies, involving the utilization of resources, skills, expertise, and finance from both the public and the private sectors, and also the sharing of risks and rewards in order to produce some services, infrastructure, or other desired useful outcomes for the citizens and/or the businesses.

Information and communication technologies, and in particular the Internet and WWW (World Wide Web) technologies, have opened a new window of opportunity for a new generation of PPPs for offering new electronic public services in various domains, for example, for developing and operating public information portals (Andersen, 2003), electronic transactions services (Lutz & Moukabary, 2004), electronic payment services (McHenry & Borisov, 2005), value-added services based on public-sector information assets (Aichholzer, 2004), and so forth. However, before such a new service is developed, it is of critical importance to design systematically and rationally its business model, which, according to Magretta (2002), incorporates the underlying economic logic that explains how value is delivered to customers at an appropriate cost and how revenues are generated. Vickers (2000) argues that most of the failures of e-ventures (also referred to as dot-coms) are due to the lack of a sound business model or due to a flawed business model. However, most of the research that has been conducted in the area of e-business models is dealing mainly with the description and abstraction of new emerging e-business models, the development of e-business-models classification schemes, and the clarification of the definition and the components of the business model concept, as described in more detail in the next section. On the contrary, quite limited is the research on e-business-models design methods despite its apparent usefulness and significance; moreover, this limited research is focused on private-sector e-business models. No research has been conducted on the design of PPP business models for offering electronic services.

In the next section of this article, the background concerning PPPs and e-business-models research is briefly reviewed. Then a new framework for the design of e-business models is presented, which has been customized for the design of PPP business models for offering electronic services. Next, the above framework is applied for the design of a PPP business model for the electronic provision of cultural-heritage education for the project E-Learning Resource Management Service for the Interoperability Network in the European Cultural Heritage Domain (ERMIONE) of the eTEN Programme of the European Union (Grant Agreement C517357/2005). Finally, the future trends and the conclusions are outlined.

## BACKGROUND

PPP is defined as "an institutionalized form of cooperation of public and private actors, which, on the basis of their own indigenous objectives, work together towards a joint target" through "leveraging joint resources and capitalizing on the respective competences and strengths of the public and private partners" (Jamali, 2004, p. 416). Even though in the past various forms of public-private mixing arrangements had been used (such as mixed enterprises, outsourcing, subsidization, etc.), the concept of PPP appeared in the early '90s when the Private Finance

Initiative (PFI) was introduced in Great Britain; it envisaged that private companies would design, build, operate, and finance hospitals, schools, prisons, and so forth, and the government would agree to purchase their use as a service for a fixed period of time (Spackman, 2002; Wettenhall, 2003). The evolution of the PFI concept resulted later in the PPP concept. In general, PPPs shift government ministries and agencies from financing, owning, and operating assets to contracting the private sector to finance, build, and operate assets, and to deliver public services using these assets. The private sector is paid for these services, or is given a share of the income generated from them or some other rights. The main drivers for PPP have been improving efficiency in the production and delivery of public services, and finding alternative methods of financing the investments required for developing public infrastructure and for offering public services.

A wide spectrum of PPP forms have been used for achieving various public-sector objectives, such as public-infrastructure building (e.g., roads, bridges, hospitals, energy stations, telecommunications, etc.), urban-areas renewal, rural-areas development, the solving of various social problems, environmental protection, education, the provision of community-based services for disadvantaged children, technology research and development, and so forth (Jamali, 2004; Nijkamp et al., 2002; Spackman, 2002; Wettenhall, 2003), and recently for the provision of electronic services (Aichholzer, 2004; Andersen, 2003; Lutz & Moukabary, 2004; McHenry & Borisov, 2005). However, the relevant literature strongly emphasizes that PPP has resulted not only in successes but also in failures (e.g., Jones, 2005). The central critical success factor of a PPP is to reconcile the different values and objectives of the participating public and private actors (Pongsiri, 2002); in this direction, it is of critical importance to develop an appropriate regulatory and contractual framework that accomplishes the following:

- provides assurance to the public sector that the PPP operates efficiently and in line with their policy objectives (e.g., economic development, environmental protection, various social policy objectives, etc.) without opportunistic or inappropriate behaviors from the private actors
- provides assurance to the private actors concerning their protection from expropriation, the arbitration of commercial disputes, respect of contractual agreements, and legitimate recovery of costs and profit proportional to the risks undertaken

In general, the whole business model of a PPP is of critical importance for its success. The business-model concept has been created and used in management study and practice as a unifying unit of analysis that incorporates a number of important decision variables and parameters, which are of critical importance for the success of entrepreneurship and business, and for the development of theory in this area (Morris, Schindehutte, & Allen, 2005). Pateli and Giaglis (2004), based on an extensive literature survey, classify the research that has been conducted on e-business models into eight subdomains: definitions, components, taxonomies, conceptual models, design methods and tools, change methodologies, evaluation models, and adoption factors. They also argue that most of this e-business research lies mainly in the first three subdomains (definitions, components, taxonomies), while limited research has been conducted in the other five subdomains.

Historically, the first research stream in this area focused on the clarification of the definition and the components of the business-model concept. There is no generally accepted definition of a business model; in the relevant literature there are many definitions, which can be grouped into three categories according to their basic focus. The first category of definitions focuses mainly on the economic model, that is, how revenue and profits are generated. For example, Stewart and Zhao (2000) define the business model as "a statement of how a firm will make money and sustain its profit stream over time." The second category of definitions focuses on the value created for the customer and on the value-production architecture. For example, Linder and Cantrell (2001) define a business model as "the organization's core logic for creating value." The third category of definitions focuses mainly on the strategic level. For example, Slywotzky (1996) defines a business model as "the totality of how a company selects its customers, defines and differentiates its offerings, defines the tasks it will perform itself and those it will outsource, configures its resources, goes to market, creates utility for customers and captures profits." Based on a synthesis of existing definitions of business models, Morris et al. (2005) propose the following definition: "A business model is a concise representation of how an interrelated set of decision variables in the areas of venture strategy, architecture and economics are addressed to create sustainable competitive advantage in defined markets."

Other researchers adopt the approach of defining the business-model concept by specifying its primary elements and their interrelations. Characteristic is the approach of Timmers (1998), who defines a business model as "an architecture for the product, service and information flows, including a description of the various business actors and their roles; a description of the potential benefits for the various actors; and a description of the sources of revenues." In the same line, Weill and Vitale (2001) define a business model as a description of the roles and relationships among a firm's consumers, customers,

allies, and suppliers that identifies the major flows of products, information, and money, and also the major benefits to participants.

Another stream of research in this area is dealing with the identification of emerging e-business models and their classification into taxonomies or generic e-business models. Several taxonomies have been proposed based on different classification criteria and dimensions. Timmers (1998), using the degree of innovation and the functional integration as classification criteria and dimensions, identifies 11 emerging generic e-business models: e-shop, e-procurement, e-auction, e-mall, third-party marketplace, virtual community, value-chain service provider, value-chain integrator, collaboration platform, information brokerage, and trust and other relevant services. Tapscott, Ticoll, & Lowy (2000) introduce the concept of electronic-business webs, which can be considered as fundamental types of e-business models that are differentiated in two primary dimensions: the level of economic control by one of the participating actors and value integration. Based on these dimensions and criteria, the authors identify five fundamental types of electronic-business webs: agora, aggregation, alliance, distributive network, and value chain. Lam and Harrisson-Walker (2003) argue that the main dimensions for classifying e-business models should be associated with their strategic objectives. Using the value-based objectives and the relation objectives as classification dimensions, they group existing e-business models into six basic types: Internet merchants and portals, brokerage networks, Internet promoters, virtual product differentiation, interactive networks, and image building.

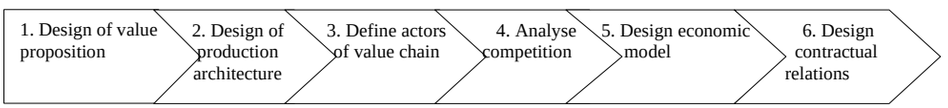
However, limited research has been conducted on the design of e-business models; this limited research focuses on e-business models implemented exclusively by private enterprises. No research has been conducted on the design of PPP business models for offering public electronic services. Morris et al. (2005) proposed an integrated framework for characterizing business models consisting of six significant design decision components (questions to be answered when designing a business model), which are further analysed into subcomponents (subquestions) intended to structure and assist both the description and the design of business models. Also quite interesting is the research work of Shubar and Lechner (2004), which resulted in the IDEA (identify new design possibilities, design new business models, evaluate business models, aggregate to the new value chain) framework for the redesign of existing business models, taking advantage of new technologies; however, the IDEA framework does not support the development of business models from the beginning, but only through the evolution of existing business models, which might result in much less innovative business models.

## A FRAMEWORK FOR PPP E-BUSINESS-MODELS DESIGN

In order to fill the above research gap, we have developed a generic framework for the innovative design of electronic business models, defined as business models aiming at offering electronic informational, communicational, transactional, and other services through various electronic channels, such as the Internet or other fixed or mobile network infrastructures from the beginning without relying on previously existing ones. Also, we have customized this framework for the design of PPP business models aiming at offering electronic services. The objective of the framework is to design the four most important components of the e-business model: the value proposition, value-production architecture, actors, and economic model. The framework consists of six stages, which are shown in Figure 1; their execution should follow an iterative approach so that each iteration takes into account the results of the previous ones and provides a better and more detailed design.

It is assumed that as input we have only a rough and basic description of the electronic service under consideration. In Stage 1, the value proposition is designed. Initially, the targeted segments (user groups) are identified, and for each of them the basic elements of the service (capabilities offered) are defined. For this purpose, with some enhancements, the buyer utility-map framework is used, which has been developed by Chan Kim and Mauborgne (2000) in order to support the design of products and services with high levels of utility. According to this framework, the experience of the user of a product or service is in general created during a cycle consisting of six distinct phases: purchase, delivery, use, supplements, maintenance, and disposal. Moreover, according to this framework, cutting across these phases there are six basic levers of utility, with this term

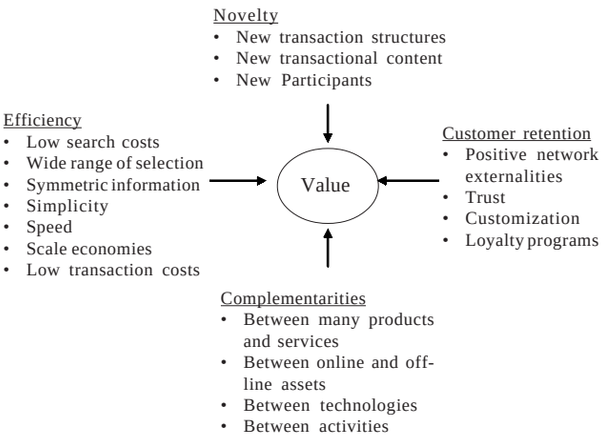
*Figure 1. Stages of the framework for PPP electronic business-models design*



meaning the ways in which we can offer utility to the user of the product or service: increasing user productivity (by offering him or her capabilities for accomplishing a task better and faster), reducing his or her risk, and offering simplicity, convenience, a fun image, and environmental friendliness. Based on the above principles, for the systematic design or improvement of a product or service, we construct a 6x6 table (utility map) with the above six phases horizontally and the above six levers of utility vertically, and we try to fill as many of these cells as possible, and each cell with as many product-service elements and capabilities as possible. In order to make this buyer utility map more appropriate for designing electronic services, we enhanced it by adding to the above buyer experience cycle two additional phases—the phase of search (in the beginning of the cycle before the phase of purchase) and the phase of customization (between the delivery and the use phases)—since, according to the relevant literature (e.g., Amit & Zott, 2001), the most important sources of the value created by electronic channels are the extensive search and customization capabilities they offer. We can use this enhanced buyer utility map for designing the elements and capabilities of the new electronic service, and also for analysing similarly other existing competitive services (electronic or physical) and comparing them with the new service; this comparison may give very useful indications for enriching the utility map of the new service with additional elements and capabilities. In this way, an initial list of the elements of the new service can be developed.

However, in order to exploit to the highest possible extent the capabilities offered by the specific electronic channel for which we design the new service (e.g., the Internet or any other fixed or mobile network infrastructure), we can use additionally a value model of this channel, which incorporates the main sources of value the specific channel can create. For designing Internet-based electronic services, we can use the model of the sources of value creation in Internet e-business developed by Amit and Zott (2001). It has been constructed based on an extensive theoretical background concerning virtual markets, value-chain analysis, Schumpeterian innovation, resource-based view of the firm, strategic networks, and transaction-cost economics, and also on an extensive case study (detailed study of 59 successful public e-business companies from the USA and Europe). This model is shown in Figure 2. According to this model, there are four basic sources of value creation in Internet e-business: efficiency, novelty, complementarities, and customer retention; each of them is also analysed into a number of specific value drivers. For each of the value sources and drivers of such a value model, we try to devise relevant elements of the new service, which are based on this specific value source or drive, and in this way we

*Figure 2. Sources of value creation in Internet e-business*



enrich the above initial list of capabilities of the service. This approach enables us to generate new ideas for innovative capabilities of the new service by exploiting the extensive theoretical background and practical experience incorporated in such value models. Moreover, taking into account the existing public policy objectives and the existing information concerning the value criteria of the targeted segments (user groups) concerning similar services (electronic or physical), we can further enrich the above list of elements of the new service. This final list of elements is examined in order to define which of them constitute basic public services (taking into account the culture and the expectations of the society and the existing public policy objectives) and therefore need special treatment in the PPP contractual agreements (in Stage 6) concerning price, quality, and availability.

In Stage 2, the production architecture is designed, consisting of all the activities that have to be performed in order to deliver the value (i.e., offer all the service elements and capabilities) defined in Stage 1. For the design of the production architecture, we can use the value-chain model of M. Porter (1980, 1985, 1996), which includes five categories of primary activities: inbound logistics, operations, outbound logistics, marketing and sales, and service. We can also use the two additional value-creation configurations that have been proposed by Stabell and Fjeldstad (2001) for analysing complex services: the value shop, which includes five categories of primary activities—problem finding, problem solving, choice of alternative, execution, and control and evaluation—and the value network, which includes three categories of primary activities—network promotion and contract management, service provision, and infrastructure operation. Moreover, for the same purpose, we can use the virtual value-chain model proposed by Rayport

and Sviokla (1995) for analysing the production of information goods, which includes five categories of primary activities: information gathering, organizing, selecting, synthesizing, and distributing. The production architecture of the new service can be based on one of the above models or a combination of them. Its structure can be either the classical linear one (each activity is fed by one previous activity and feeds one following activity) or a network one (some activities can be fed by more than one previous activities and/or feed more than one following activities), taking into account the evolutions that have taken place in several industries from simpler linear structures to complex network structures (Gulati, Nohria, & Zaheer, 2000; Li & Whalley, 2002). The design of the production architecture starts from the value proposition and moves backward. Initially we determine the direct activities required for delivering the value proposition (i.e., offering the service elements and capabilities) defined in the first stage, then for each of them, we determine the direct activities it requires as inputs, and so forth. In this stage, we can also use the value-chain model of Walters and Lancaster (2000) and the strategic value-creation-networks framework of Jarillo (1995).

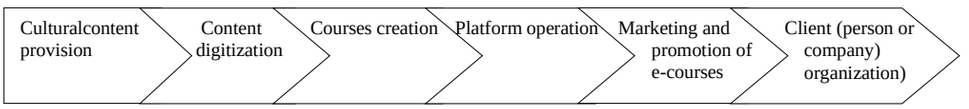
In Stage 3, for each of the value-production activities defined in the second stage, the most suitable actors (i.e., class of private- or public-sector organizations) for executing it are determined based on the resource-based theory (Barney, 1999; Barney, Wright, & Ketchen, 2001) and the framework of Talluri, Baker, and Sarkis (1999). In particular, for each activity the resources and capabilities required for executing it efficiently and effectively, and its critical success factors are determined; based on them, various alternative classes of actors, that is, alternative types of private- or public-sector organizations who could undertake it, are initially identified, and then among them the most appropriate class is selected. In this stage, it is of critical importance to decide for each of the above activities whether it should be undertaken by the public or the private sector, taking into account the strengths, the weaknesses, the resources, and the capabilities of each. It is of critical importance in a PPP to combine properly and leverage the strengths of both the public sector (e.g., higher responsibility and accountability to society) and the private sector (e.g., higher efficiency, technical expertise, etc.). However this decision might have to be reexamined in the light of the results of the fourth stage.

In Stage 4, for each of the activities of the production value chain defined in the second stage, an analysis of the competitive power of the potential actors is performed based on the five-forces framework of M. Porter (1980, 1985, 1996). According to this framework, the competitive power depends on the intensity of the following forces: threat of new entrants, threat of substitutes, bargaining power of suppliers, bargaining power of buyers, and competitive rivalry; a higher intensity of these forces results in lower competitive power. From this analysis, we can identify activities executed by private actors having a very high level of competitive power (e.g., in cases of oligopolies with a small number of possible players, or in cases of high switching costs, etc.) who might dominate in the provision of the service. Such a situation is not acceptable in a PPP, therefore it might possibly necessitate the reconsideration of the decisions of the third or even of the second stage.

In Stage 5, the economic model is designed; that is, it is decided how revenue will be generated from the users of the service or from other sources (e.g., from advertisement, subsidies, etc.). For this purpose, we can take into account the revenue models proposed by Olla and Patel (2002; e.g., flat fee, volume based, per transaction, per message, session based, etc.) in combination with the price corridor model of Chan Kim and Mauborgne (2000). However, for the elements of the service that have been defined in the first stage as basic public services, a different economic model might have to be designed (e.g., with lower prices).

Finally, in Stage 6, the contractual relations among the public and private actors who will participate in the value-production architecture are designed, which according to the relevant literature are of critical importance for the success of the whole PPP due to the different values and objectives of the public and private actors, as mentioned in the previous section. Such PPP contractual relations are usually characterized by high complexity since they should define in detail the rights and the obligations of all involved parties, and also include numerous clauses for possible violations of obligations and corresponding penalties (e.g., if party A violates its obligation OAi, then penalty PAi will be imposed on A, etc.). The design of these contractual relations is based on the $e^3$-value modeling methodology and its extension (Gordjin, 2002; Gordjin & Akkermans, 2003; Kartseva, Gordjin, & Tan, 2004). The basic version of this methodology allows the formal representation of collaborative value creation through the cooperation of several actors who exchange objects of economic value (e.g., products, services, money, etc.) based on a number of basic concepts, such as the actor, value object, value exchange, value interface, dependency path, and so forth (see also Figure 4). In this way, the design and communication of the rights and obligations of each involved party can be supported. Its extension, referred to as $e^3$–value+, allows also the formal representation of subideal situations, in which one of the involved parties violates its obligations (i.e., does not deliver one or more of the value objects it was contractually obliged to deliver to another party); in this way, the design of clauses for possible violations of obligations is supported.

*Figure 3. Production architecture for e-learning of cultural heritage*



## APPLICATION

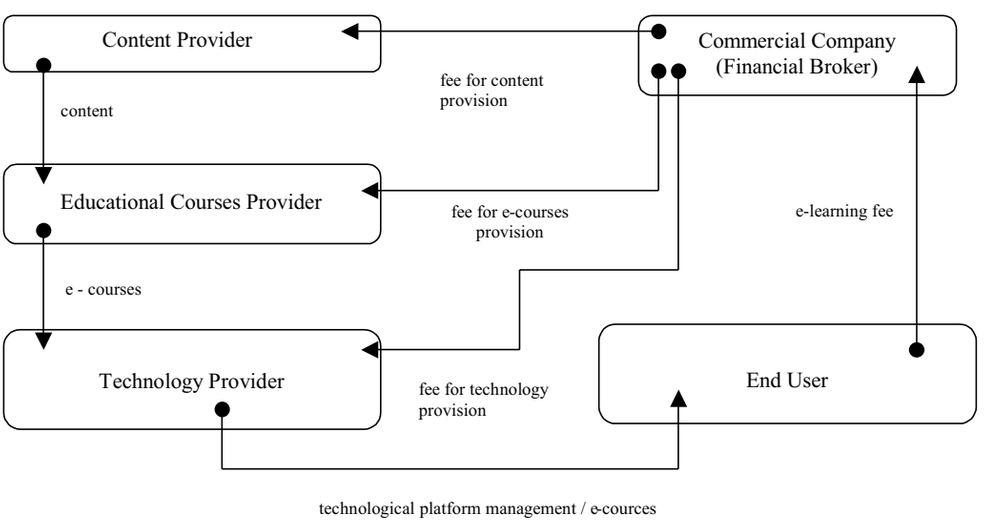
The above framework has been applied for the design of a PPP business model for the electronic provision of cultural-heritage education (e-learning) for the project ERMIONE of the eTEN Program of the European Union (Grant Agreement C517357/2005). The basic objective of this project is to provide all interested persons (e.g., artists, teachers, students, etc.) and cultural and educational institutions in Europe, or even all over the world, with a wide range of high-quality content and training courses about the European cultural heritage, coming from cultural and educational institutions (e.g., museums, collections, libraries, archives, archaeological sites, universities, etc.) dispersed all over Europe. In Figure 3, we can see the corresponding value-production architecture: In order to create e-courses in the domain of cultural heritage, owners of cultural-heritage assets (e.g., museums, collections, libraries, archives, archaeological sites, etc.) initially provide relevant content, which is digitised. This digitised content is then used by educational institutions (e.g., universities) in order to create e-courses. Next, these e-courses are uploaded on an e-learning platform, which is managed by a technology provider. Finally, these e-courses are marketed and promoted by an experienced commercial company.

The corresponding collaborative value-creation model based on the $e^3$-value methodology is shown in Figure 4. We can see the main actors involved in the provision of e-courses in the area of cultural heritage (content provider, educational courses provider, technology provider, and commercial company) and the value objects they exchange.

## FUTURE TRENDS

The need for developing and operating complex informational and transactional e-government services using various electronic channels, such as the Internet or other fixed or mobile networks, will necessitate extensive PPPs in the near future between public organizations of various levels (e.g., municipalities, regions, ministries, etc.) and private organizations of various sectors (e.g., from the ICT industry, banking, etc.). Therefore, it is necessary to develop effective methods for designing systematically and rationally the business models of these PPPs so that they finally offer highly valuable electronic services,

*Figure 4. Collaborative value-creation model for the provision of e-learning in the area of cultural heritage*



combine properly, and leverage strengths of multiple public and private organizations, and at the same time reconcile their different values and objectives; these design methods should combine knowledge from various areas (e.g., management science, public administration, information systems, etc.) and also incorporate the experience gained from previous PPPs, especially from PPPs that enable the provision of electronic services (e.g., basic problems and difficulties, critical success factors, etc.). Also, it is necessary to apply and evaluate such methods in real-life situations so that we can identify their advantages and disadvantages.

## CONCLUSION

In this article, framework for designing PPP business models for the provision of electronic services has been presented. It supports the definition of the value proposition (elements and capabilities of the service), the value-production architecture (activities that have to be preformed in order to provide the service) and the actors who will participate in it (both public and private organizations), the economic model (i.e., how revenue will be generated from the users of the service or other sources), and finally the contractual relations among the actors (rights and obligations of each actor, and clauses concerning possible violations of obligations and corresponding penalties). This framework has been used in order to provide a solid ground for the ERMIONE project of the eTEN Program of the European Union and to design its basic PPP business-model concept. Taking into account the fact that, as mentioned in the previous section, growing PPPs are expected in the near future for the provision of various types of electronic services to citizens and enterprises, such a framework can be very useful for the design of successful PPPs with solid foundations: clear and attractive value propositions, appropriate actors with clear roles and well-defined and fair relations among them, and power balance, avoiding too powerful private players who might cause unacceptable situations and finally degenerate the PPP. Further research is in progress by the authors in order to further elaborate this framework, enrich it with experience gained from existing PPPs for electronic services provision, and also evaluate it in more real-life situations.

## KEY TERMS

**Business Model:** A concise representation of how an interrelated set of decision variables concerning value proposition, value-production architecture, value-production actors, and economics are addressed, aiming at the introduction and the sustainable success of a product or service.

**Electronic Business Model:** A business model aiming at offering electronic informational, communicational,

transactional, and other services through electronic channels, such the Internet and other fixed or mobile network infrastructures.

**Electronic Learning (E-Learning):** The use of information and communication technologies for the creation of enhanced learning experiences, aiming at improving the knowledge and skills and/or changing the attitudes of a target group on a specific topic.

**Public-Private Partnership (PPP):** "An institutionalized form of cooperation of public and private actors, which, on the basis of their own indigenous objectives, work together towards a joint target" through "leveraging joint resources and capitalizing on the respective competences and strengths of the public and private partners" (Jamali, 2004, p. 416).

**Value Model of an Electronic Channel:** The main sources of value that a specific electronic channel can create (i.e., ways to create value using this electronic channel); for example, for the case of the Internet, the main sources of value are efficiency, novelty, complementarities, and customer retention.

**Value-Production Architecture:** A set of activities that have to be performed in order to deliver a value proposition (i.e., offer a predefined set of service elements and capabilities); its structure can be either linear (each activity is fed by one previous activity and feeds one following activity) or network based (some activities are fed by more than one previous activities and/or feed more than one following activities).

**Value Proposition (of an Electronic Service):** The set of useful elements of the service (i.e., the set of useful capabilities offered to the users).

# Electronic Campaign Finance Reform in the American States

**Ramona McNeal**
*University of Illinois at Springfield, USA*

**Mary Schmeida**
*Cleveland Clinic Foundation*

## INTRODUCTION

With every new election cycle in the United States, there is a call for campaign finance reform. These regulations have come in a variety of forms, each having the goal of rebuilding trust in the voting system and government in addition to regulating election finance. With an eye toward building trust, beginning in the early 1990s, state (as well as local and federal) campaign finance regulatory agencies started implementing campaign reporting procedures that required either the replacement or augmentation of paper filing systems with electronic systems. It is hoped that these new procedures will make summaries and analyses of contributions and expenditures more easily accessible to the public as well as to government watch dogs such as interest groups and the media.

The adoption of these electronic reforms (e-disclosure laws) is representative of a public service trend in the United States. Over the last several years, federal, state, and municipal governments have moved increasingly toward government adoption of electronic government (e-government) practices that "refer to the delivery of information and services via the Internet or other digital means" (West, 2004, p. 2). Each of the 50 states has implemented some type of e-government, and the federal government has created a central portal for federal services (West, 2003).

This trend toward adopting e-government has not taken place without comment; it has been accompanied by speculation of the impact to both citizens and government units alike. It has been argued that because e-government can deliver services and information around the clock, it may make government more efficient and transparent to the public (Norris, 2001; West, 2003). It also has been suggested that it will make government more responsive to the public through its ability to provide communication options that are quicker and more convenient for users (Thomas & Streib, 2003). Furthermore, an online presence may reduce government costs and allows the timely update of materials and information more quickly than in traditional distribution methods (Pardo, 2000). Others (Jaeger & Thompson, 2004; Pardo, 2000) argue that e-government has the ability to increase political engagement and to create a more participatory democracy. These benefits may increase the likelihood that Internet-based reforms have a greater likelihood of adoption. Interest groups who campaign for electronic disclosure laws in order to reduce corruption and to increase transparency may find themselves aided by public administrators attracted to the cost-cutting promises of e-government.

## BACKGROUND

Since U.S. states vary substantially in election activities, they have used different approaches in an attempt to regulate campaign finance. There are a number of factors, including geographical area, party balance, inter-party competition, interest group organizational strength, legislative professionalism, term limits, and use of the initiative process, that determine what type of campaign finance laws are needed (Thompson & Moncrief, 1998). Given this wide scope of factors, many different scenarios have been played out. Nevertheless, the overall trend shows that states have moved to stricter laws than the federal government has (Drage, 2000).

Adoption of campaign finance reform at the state level parallels that of the federal level. When the U.S. national government initiated reforms in the late 1800s, the states followed suit. New York in 1890, Massachusetts in 1892, and California in 1893 passed disclosure requirements for both money receipts and expenditures. A number of states during this time period also passed laws banning contributions from certain industries such as banking and insurance (Center for Responsive Politics, 2000).

Just as with the federal government, there was a substantial push for reform at the beginning of the Progressive Era (late 1800s to early 1900s), and then enthusiasm for policy adoption dissipated. It would take until the early 1970s, when the public expressed extreme out-

rage over Watergate, to refocus both federal and state attentions on campaign finance laws. In 49 of the 50 states, legislatures responded by implementing reforms. Even so, the laws passed were far from standard and varied in their effectiveness. Most reforms were not accompanied by adequate funds in order to sufficiently enforce them (Center for Responsive Politics, 2000).

In the last three decades, campaign finance reform has been an active area for legislation at the state level. Recent state efforts have focused on lowering contribution limits, increasing disclosure requirements, and public financing of campaigns. Of these various reform measures, increased disclosure requirements have become the most prevalent. Twelve states passed legislations mandating electronic filing of and access to campaign finance information for the 2000 elections. In 1997, 15 states passed laws facilitating electronic filing, and seven states followed in 1998. Many of these programs were voluntary. When California initiated its electronic disclosure policy in July 2000, for example, only candidates and committees connected with a campaign for state office that received more than $50,000 in contributions were required to file electronically (Drage, 2000).

By 2003, only four states (Montana, South Carolina, Tennessee, and Wyoming) did not have some form of computer-aided filing system for campaign finance, lobbyists, or personal financial disclosure statements. Although most states have some electronic filing requirements, the implementation and scope of these laws vary considerably across the states. While many states require lobbyists and candidates to file their financial information online, others require financial statements to be reported using standard paper forms, but then the information is uploaded online. In Alabama, Arkansas, Mississippi, South Dakota, Vermont, and West Virginia, paper financial statements are scanned and posted online. In Delaware, Kansas, and North Dakota, the data from paper financial statements are entered manually and then posted on the Web (Center for Government Studies, 2002).

In addition to varying on how campaign finance information is posted online, the states also differ with respect to what information is provided. By 2003, the number of states requiring both the occupation and employer of donors to be listed had risen to 29; five required only the employer, while two asked only for the occupation. The remaining states did not require either occupation or employer information. While 40 states require expenditures either for or against a candidate to be disclosed, only 23 states require expenditures made close to the election to be posted before the election. Finally, only 27 state Web sites provide databases for campaign contributions, while 17 offer databases on expenditures (Campaign Disclosure Project, 2003).

## THE IMPLEMENTATION OF POLICY

What factors explain the extent and variation of implementation of electronic disclosure initiatives in the states? Policy literature suggests that politics, public demand, and government resources are important determinants of policy variation (Mooney & Lee, 1995). These factors differ in importance, depending on the type of policy. The factors associated with adoption of electronic campaign finance laws are difficult to predict, because this reform does not fall neatly into any existing policy typology. Electronic campaign finance reform can be conceptualized as both administrative (procedural) reform policy and as regulatory policy. Regulatory policy involves the government enforcing rules of conduct directed at specific groups or individuals, while administrative rules dictate how policy is carried out. The adoption of these two forms of policy is driven by different factors. McNeal, Tolbert, Mossberger, and Dotterweich (2003) found that when e-government is adopted as an administrative reform, it often is driven by the goals of cost reduction and increasing efficiency. Unlike regulatory policy, it does not involve the direct and coercive use of government power over citizens and is not very salient among the public. On the other hand, implementation of regulatory policy is highly volatile and controversial (Ripley & Franklin, 1980).

McNeal, et al. (2003) found that instead of being driven by political forces, administrative policies largely are driven by professional networks. More generally, research has long shown that professional networks of generalists (e.g., governors and legislators) and specialists within state agencies influence innovation and diffusion (Walker, 1969, 1971; Grupp & Richards, 1975). This exchange of experiences and information between networks of innovators and potential adopters is at the heart of policy diffusion (Rogers, 1995).

Because electronic campaign finance reforms represent both regulatory and administrative policy, it is likely that both interest group activities and professional networks would influence adoption and implementation of the policy. Regulatory aspects of state campaign finance reforms are likely to engage affected interest groups in government such as the National Council of State Legislatures. It also would be expected to connect with good government groups and civil rights organizations that have been leaders in campaign finance reform in the U.S. Normally, their role would be more political than the organizations of state professionals. Campaign finance reform policy might prove to be an exception to this rule, because in this circumstance, organizations of state professionals represent one of the affected interest groups.

Additionally, groups normally not associated with campaign finance reform have become involved with the

policy area. The involvement of these groups can be attributed to entrepreneur efforts. One such policy entrepreneur is Randy Kehler, a founder of the nuclear-freeze movement. He took up the fight for campaign finance reform after becoming frustrated when every attempt to get the issue passed into law was blocked by Congress, despite overwhelming public support for a nuclear-freeze policy. He concluded that money (not public opinion) was the deciding factor in legislation. As a result, in 1989, he formed the Working Group on Electoral Democracy (WGED) in order to push for campaign finance reform. His group began looking at the campaign financial records for every state and worked to match donors with politicians and voting records. In 1993, the group released a series of reports that showed the influence of money in state elections. These reports helped to mobilize a number of organizations to participate in the fight for electoral reform. These groups included a number of environmental organizations, lesbian and gay rights groups, feminist organizations, peace groups, and AARP—groups that initially had not considered campaign finance an issue that was relevant to them. The message used to bring other groups into the fight was that before any other kind of change can become a reality, campaign finance policies must be strengthened (Orlando, 2000).

The literature suggests that actors with different motives were involved initially with the adoption of electronic campaign finance reforms. There were administrators who pushed for e-government procedure in an attempt to increase efficiency and to cut costs and interest groups who were hoping for increased transparency and reduced corruption. However, passing policy into law is not the same as implementing it. Mossberger, Tolbert, and McNeal (2005) found that states who were early to initiate e-government rules did not necessarily remain innovators in this policy area. They found that while cost cutting was a motive for many states to adopt e-government measures, only states with resources to invest in the necessary technical capacity and infrastructure were able to continue to maintain and innovate these procedures over time.

Although there is extensive literature on policy adoption and implementation, there is little that specifically examines the adoption of campaign finance reform. Ironically, this has been the result of inconsistent state policy in the disclosure of campaign finance information. After examining state campaign finance laws for possible trends, Sorauf (1988) concluded that the only detectable trends were a few regional patterns. These findings were attributed to very poor data collection methods at the state level and no scientific or journalistic effort to examine the topic. Hogan (2000) echoed the same concerns. He undertook a study to determine the factors that influence the costs of state elections and noted that data collection was the most difficult aspect of his research.

Even though there is limited policy research on campaign finance policies at the state level, the increased availability of campaign finance information on the Internet is changing this. Recently, McNeal, and Schmeida (2005) lent support to the adoption and implementation literature with their research on the implementation of electronic campaign finance disclosure laws. As predicted, they found that interest group activities influence the presence of electronic disclosure policy. Their research also indicated that state resources were positively related with the scope of implementation of these policies. This finding is not surprising. In their 1999 study of e-disclosure implementation, the California Voter Foundation (1999) discovered that in a number of states, e-disclosure laws had not been implemented, even though such a policy had been passed several years previously. In each case, the problem appeared to be financial; they simply could not afford the necessary infrastructure.

## FUTURE TRENDS

There are factors to consider when predicting the future of electronic campaign finance disclosure policy in the U.S. The first is its history of campaign finance reform. For much of its history, there have been only incremental changes in this policy area. The exceptions were during the Progressive Era and the 1970s, when there was a flurry of legislation and dramatic changes in campaign finance reform. A number of factors worked in conjunction to bring this about, but the most important elements were scandal and the media. During the Progressive Era, the elements of scandal were provided by the party machines that dominated politics at that time, and during the 1970s, it was Watergate. Both received considerable media coverage. During the Progressive Era, media attention was supported by new technical advances such as photography and muckraking journalism, crusading journalism during this period that was focused on the exposure of corruption in industry and business (Davis, 1994). In general, the adoption of campaign finance reform in the United States follows a trend of long periods of incremental change with occasional periods characterized by a flood of legislation and significant policy changes.

A second factor to consider is the rate and extent to which e-government is being adopted. In the United States, the impetus behind the adoption of e-government is cost cutting and efficiency. This is a result of e-government being promoted in the mid-1990s by the Clinton administration as part of its effort to reinvent government. In other countries, a pattern of policy adoption has been somewhat different, with e-government

being touted as new public management reforms or as a means of increasing political participation (Chadwick & May, 2003; Fountain, 2001).

There is evidence that following the initial enthusiasm to jump on the cost-cutting bandwagon of e-government, the US has continued to make inroads in adopting e-government practices. West (2005) has methodically analyzed Web sites for all 50 states since 2000 and has found considerable technical development among the states with advances in areas such as online security and conducting online transactions. Nevertheless, the greatest use of e-government is still that which requires the least technical infrastructure: posting information. As illustrated by the inability of some states to implement required e-disclosure laws, financial and technical roadblocks are slowing the spread of e-government practices. Although there is both interest groups and administrative impetuses for adopting e-disclosure laws, these barriers may mean that the implementation of this policy area, like most campaign finance reforms, is more incremental then dynamic.

## CONCLUSION

There is a long history that suggests that scandal and media attention act as catalysts to the adoption of campaign finance reform in the United States. The Internet has added supplementary motives when reform also can be regarded as an e-government measure. There are now different forces inside and outside of state governments that influence the adoption of electronic campaign finance reforms. Administrators often work to adopt e-government procedures in order to reduce costs and increase efficiency, while interest groups have crusaded for more stringent disclosure laws in order to increase transparency and to reduce corruption. The addition of administrative support may help to overcome the barriers associated with the reluctance of decision makers to pass laws that are not in their own best interests.

Although the adoptions of these laws have attracted the support of actors with varying motives, this does not guarantee their success. E-government literature and the history of electronic campaign finance disclosure laws suggest that successful implementation requires governments to have the necessary resources to invest in the technical capacity and the infrastructure to maintain this policy. This suggests that in the short run, the requirement of significant infrastructure may negate the additional support of cost-cutting administrators brought to the battle over campaign finance reform.

## KEY TERMS

**Electronic Campaign Finance Disclosure Laws:** Campaign-reporting procedures require either the replacement or augmentation of paper filing systems with electronic systems.

**Electronic Government:** The delivery by government of information and other services by electronic means such as the Internet.

**Electronic Government as an Administrative Reform:** E-government services that facilitate communication between government and citizens and whose adoption often is driven by the goals of cost reduction and increasing efficiency.

**Muckraking Journalism:** A form of crusading journalism that was focused on the exposure of corruption in industry and business. This form of journalism was prominent during the Progressive Era and aided the movement's efforts to reform government.

**Policy Entrepreneur:** An individual who, acting in a leadership capacity, invests considerable time, money, and effort into the passage of a particular policy issue.

**Regulatory Policy:** Public policy that involves the government's enforcing of rules of conduct directed at specific groups or individuals. This type of government action involves the coercive use of government power over citizens and is very salient among the public.

**Working Group on Electoral Democracy (WGED):** A group formed in 1989 by Randy Kehler, a founder of the nuclear-freeze movement. This campaigned finance reform group worked to mobilize other organizations through the use of public campaign financial reports to show linkage between money and public policy adoption.

## INTRODUCTION

Two parallel evolutions are currently challenging the functioning and the legitimation of the traditional nation-state: globalization and the rapid development of the information and communication technologies (ICTs). Both come together in the new concept of "electronic governance" or "e-governance." Indeed, globalization in all its forms (i.e., financial, economic, cultural, technological, and ecological globalizations) is increasingly putting pressure upon the nation-state. Collective problems, such as climate change or organized crime, can no longer be solved by nation-states only, let alone by one single nation-state. In fact, such problems require not only the supra-national approaches and institutions, but also the involvement of non-state actors, in particular of civil society and the private sector. Simultaneously, the ICTs are gradually penetrating all realms and all levels of society, and as such increasingly affect both production processes and state-society transactions.

If "governance" can be defined as the growing involvement of non-state actors into collective problem-solving at all levels of society (i.e., from the local to the global levels) (e.g., Finger, 2004; Mayntz, 1999), "e-governance" then means the active usage of the ICTs for such collective problem solving. In this article we want to both offer an understanding what e-governance is and could be and outline of the different dimensions and forces which currently lead up to e-governance practices. Consequently, our article is structured as follows: in a first section, we will present and critically discuss the state of the literature on e-governance. In a second section, then, we will show how governance and the ICTs are currently coming together, and subsequently propose a definition of electronic governance.

## BACKGROUND: A CRITICAL OVERVIEW OF THE LITERATURE

If one critically examines the quite recent literature on e-governance, one can identify three different approaches, each coming to e-governance from a different perspective, namely (1) from a public sector reform perspective and (2) from a governance perspective.

### E-Governance through the Lens of Government

As a matter of fact, most of the currently available literature on e-governance is rooted in ICT-driven government reform projects. Here, the ICTs are used to increase operational efficiency and at times a better customer-orientation (Cluff, 2002; Marche & McNiven, 2003; Prattipati, 2003; Schedler, Summermatter, & Schmid,, 2004; Turner, 2002;). As a result, the words e-government and e-governance are used almost synonymously. For other scholars, e-governance means the utilization of ICT to improve democratic processes at the various levels of political activity in a state (Macintosh, 2004; Pratchett & Lowndes 2004; Christin & Trechsel, 2004). This is also referred to as e-democracy, and refers to use of ICTs in (any) democratic process (e.g., Grönlund 2002; Malkia et al. 2004) (i.e., consultations, participation, and policy making). However, among politicians only the voting part was taken up as they wanted a quick fix to the decreasing turnout at elections. Hence, also in the EU, e-democracy means e-voting.

The application of ICT in the area of government and politics is considered to have a transformative impact on the existing structures of the state, the legal system and the functioning of government in general, in that processes and transactions are becoming more efficient and more transparent, and that overall citizens are better served (Mälkiä et al., 2004; Zwahr, Finger, & Müller, 2005). Another stream of research that looks at the transformative aspects of e-governance is research in digital government. It examines the impact of ICT on government institutions, its governance structures and information processing (Fortes 2003; Fountain, 2001, 2003).

### E-Governance through the Lens of Governance

Globalization is without doubt one of the buzzwords of the late 20th and the early 21st centuries and is considered to

bring both successes for national economies as well as an increasing external pressure on the nation-state. States aim at participating in the global process of communication and trade on the one hand, but are on the other hand limited to their national institutions, especially in the fields of fiscal, economic, and social policy. Yet, new collective problems of global (i.e., transnational) nature emerge, such as for example climate change, unemployment, or pollution problems. These problems can no longer be solved by a single nation-state alone. Moreover, such problems affect numerous stakeholders at all levels of society (i.e., from local to global) and as such can only be solved in a joint effort among all stakeholders (Beisheim et al. 1999; Mayntz, 2002). Thus, in the context of globalization, states increasingly need to share their power with other actors, be they from the private (businesses, business organizations) or the third sectors (civil society, non-governmental organizations). The fact that the state is no longer powerful enough to impose its solution thus is characteristic of the passage from government to governance (Finger, 2002, 2003).

On the level of firms, the situation is actually similar. Embedded in a national economy, firms are increasingly engaging on global markets. In this process, multi-national firms are exposed to new economic challenges and political environments which they have to cope with. Furthermore, the influence of external interest groups such as unions or non-governmental organization is shaping the decision-making process of firms. Decision making and corporate governance in and of firms is thus more and more incorporating the interests of external stakeholders and interest groups (Greenwood & Jacek, 2000; Ronit & Schneider, 2000). In the firm also, we are moving from traditional top-down government (shareholder value) to governance (stakeholder value).

In both cases, the literature on e-governance is exploring the role of the ICTs when it comes to solving either collective or corporate problems (Finger & Pécoud, 2003). Examples of such research are the investigation of e-participation systems in Europe or the study of ICT based citizen involvement in public and corporate decision-making (Bishop, Kane, & Patapan, 2002; Womenspace, 2003).

### Critical Analysis

In short, both approaches acknowledge that there is a strong relation between the utilization of the ICTs and governance. In the case of "government governance," the major concern is the optimization of traditional government processes (performance optimization: efficiency and effectiveness). However, they are not concerned with the transformative impact the ICTs can have on the overall politico-administrative system. Often, the term e-governance is simply used as a substitute for e-government, which actually describes much better what these authors have in mind. The stream of literature that is concerned with the transformation of the nation-state and the firm, is much more interested in the transformative role of the ICTs, yet this research is so far only little advanced.

## THEORETICAL CONSIDERATIONS ON E-GOVERNANCE

One must acknowledge that there are indeed currently totally separate schools of thought which come together in the concept of e-governance. In this section, we try to integrate these schools of thought by starting out with governance and integrating in there the ICTs.

### From Government to Governance

In order to understand the evolution of the recent years from government to governance, one has to recall the main functions a state generally performs, namely policy making, service delivery, and regulation. Policy-making refers to the process of developing policies in either a state or a firm. A national public policy might be that each citizen has the right to receive a basic healthcare service. In a firm, a corporate policy can be that enterprise resource planning is done with only one specific type of software. The process of how such a policy is developed, debated, and finally implemented is all part of policy-making. The service delivery function comprises all activities involved in providing a service. In the case of states, the provision of basic healthcare is a public service, while it is a firm's core business to produce goods and services. The third function, regulation, represents the controlling activities that need to be performed in order to ensure that services are delivered properly, particularly according to the agreed policies.

While all three functions remain necessary in both states and firms, it becomes less and less obvious, over time, that all these functions are performed within the state or the firm. Indeed, the phenomenon of governance precisely highlights the fact that other—non-state or non-firm—actors are increasingly involved in performing these functions. This has become particularly visible in the case of the policy-making function, where non-state actors (businesses and non-governmental organizations) are now actively involved in shaping state policies, while at the firm level all kinds of stakeholders (as opposed to shareholders) increasingly have their say in company policy. Similarly, the service delivery function is increasingly being outsourced (and even privatized in the case of the public sector). Here too, non-state and non-firm actors increasingly come to play a

*Table 1. The role of ICTs*

| | |
|---|---|
| Mirroring | The ICTs are utilized to mirror an existing physical processes or structures (e.g., a production process or an organizational structure) into an electronic model of the physical environment. In doing so, the complexity of the system is reduced and the logical relations between the actors are becoming more transparent. The electronic model is used to create new knowledge about the functioning of the physical environment. This can, for example, be the identification of the financial flows or the discovery of the power relationships among. |
| Steering and Controlling | As a result of the knowledge which has been created through this mirroring process, the physical environment can now be better manipulated. Such intervention can be either an organizational change or even the substation of the physical process or structure by an ICT system. |

role. And even in the case of the regulatory functions non-state and non-firm actors not only emerge but increasingly become powerful. Furthermore, and not astonishingly, this evolution from government to governance is accompanied by a process of multiplication of levels, where the functions are performed simultaneously at the local, the regional, the national, and the global levels by actors who can be themselves local, regional, national, and global.

## The Transformative Role of the ICTs

ICTs are not an end in themselves. As such, the ICTs, in the above passage from government to governance, mainly contribute to improve processes and operational effectiveness. However, this is perhaps a too neutral view of the roles ICTs play. Indeed, scholars have shown, for example, that the use of ICT can lead to a creative destruction of traditional organizational forms and gives rise to new forms of organizing economic activities (Tucci et al., 2003). As such, the role played by the ICTs can be both positive and negative. In firms, for example, an emerging trend is the use of business intelligence systems so as to improve governance processes. In government agencies, web-based technologies are applied to increase operational performance, such as process optimization, or even to support public service delivery (Schedler, Summermatter, & Schmidt, 2003).

A more systematic analysis of the roles played by the ICTs in organizations and institutions shows that they have mainly two functions (i.e., mirroring and steering/controlling), whereas the second builds on the first (Applegate, 2002; Renken, 2004).

# CONCLUSION: INTEGRATING ICT INTO GOVERNANCE

We can now easily see how the two evolutions–the increasingly transformative role of the ICTs and the transformation from government to governance in both states and firms–can be combined into the current concept and practice of e-governance. Consequently, the question is how the ICTs can be used for collective problem solving in complex organizations and institutions (i.e., governance systems), involving states, firms, and civil society and taking place simultaneously at local, regional, national, and global levels. Furthermore, one can break down such governance into the policy-making, the service delivery, and the regulatory functions.

This definition of e-governance opens of course significant new possibilities for research. For example, one may study how, at the firm level, the ICTs affect corporate governance practices, or how they are being used for regulatory purposes. Also, one may want to examine how the ICTs are used by external interests groups who want to gain influence on decision or policy making within the firm. In the case of the public sector, one may want to study the role played by the ICTs in coordinating the various levels of governance in a given area (e.g., air transport).

Examples of current e-governance practices can be found both in the private and in the public sector. Let us briefly outline a current example of e-governance in the in the traditional network industries.

In the postal sector, the final delivery of standard mail is, in many countries, still a monopoly of the sector incumbents. Liberalization efforts are failing because the incentives to infuse competition are too low. Regulation is one function of governance and market creation is a means to regulate the liberalization process in the postal sector. While the creation of markets is being very effective in other sections of the postal value chain, the liberalization of the final mail delivery is posing a significant problem. The problem is due to the universal service obligation of the operator, and thus hinders new entrants to compete on this level of the value chain. Furthermore, this obligation has created several administrative obstacles for market creation, such as cross-subsidizations or non-neutral funding of incumbents (OECD, 2004). This situation represents a governance challenges, because it involves both the states and the firms and is taking place simultaneously at various political levels. Furthermore, the question of how to infuse competition

into the final delivery of mail can be broken down into the policy-making, the service delivery, and the regulatory function of governance. One approach to the resolution of the problem might be the transformation of the final mail delivery from physical to electronic mail delivery. In doing so, coordination and expensive transportation costs can be reduced. The attractiveness for new operators to compete is thus increasing. As a result, in the postal delivery as well as in policy-making and the regulatory function, a significant impact can be achieved through the application of e-governance.

Overall, e-governance thus characterizes an evolution by which the ICTs are increasingly used to support governance mechanisms at all levels, involving all types of actors, and all governance functions. While this will become a growing field of practice, the role of academia will be to develop the theories and concepts that must underlay such practices.

## KEY TERMS

**Electronic Governance:** The active use of the information and communication technologies for collective problem-solving at various political levels involving State and non-State actors.

**Governance:** The growing involvement of non-State actors in collective problem-solving; the multiplication of political levels at which such collective problem-solving occurs.

**ICT:** Information and communication technology.

**Network Industry:** Industry that is dependent on physical infrastructures, such as the postal or the telecommunications industry.

**Policy Making:** Policy-making refers to the process of developing policies in either a state or a firm.

**Regulation:** Represents the controlling activities that need to be performed in order to ensure that services are delivered properly, particularly according to the agreed policies.

**Service Delivery:** A process that comprises all activities involved in providing a service to somebody.

# Electronic Government

*Örebro University, Sweden*

## INTRODUCTION

Digital government, electronic government, online government, wired government, virtual government—there are many terms used to refer to the contemporary strong focus, in practice as in research, on increasing the amount and sophistication of information and communication technologies (ICT) use in government and governance processes. While the terms are largely used as synonyms, there is no unambiguous definition of the field. Some use the terms to refer specifically to government services to citizens (G2C), but definitions by influential actors typically define electronic government in governance terms. The former definitions typically focus on efficiency issues, often directly concerning the ICT components, while the latter ones concern effectiveness and focus on systems aspects, organizations, and social systems in general, rather than individual components. While reduced cost per delivered form is a typical measurement emanating from research following from the first kind of definition, reduced corruption is one from the latter. This article investigates the content of the electronic government (e-gov) field briefly by exhibiting (1) definitions, theoretically anchored ones as well as definitions-in-use emerging from practice, (2) examples of work, including steps in the development over time, (3) models for evaluation, and (4) considerations about the future of the phenomenon based on the development so far. Altogether this gives a view of a vast field, not unequivocally defined but in practice framed by a number of similar practices, strategies, critical issues, and technologies. It is also regularly monitored globally by methods commonly used. While these are not uncontested and subject to different technical, social, and business-oriented viewpoints, they do contribute to the framing of the field as a practice.

## BACKGROUND

The term *e-gov*, as well as the synonyms mentioned in the previous section, emerged in the late 1990s, but the history of ICT use in government organizations can be traced back to the beginnings of computer history. A scientific literature on "IT in government" goes back to the 1970s (Danziger & Andersen, 2002; Kraemer et al., 1978). This literature concerns Information Technologies (IT) use within government, while the recent e-gov literature often concerns external use, such as services to the citizens (Ho, 2002). More recently, picking up the discussion in the Internet era, there are some classics, including Bellamy and Taylor's (1998) *Governing in the Information Age* and Tsagarousianou (1998) *Cyberdemocracy*. The first textbook to use the term *electronic government* was *Electronic Government: Design, Applications and Management* (Grönlund, 2002), and the latest, as of this writing, is *Implementing and Managing eGovernment* (Heeks, 2005). The differences between the two in terms of the underlying empirical material is a telling story about how rapidly the field of practice has evolved over just a few years. In early 2000 there were very few cases; today they abound. Yet, as Grönlund (2004, 2005b) shows, research is still much about storytelling and "lessons learned", and little about theory testing and theory development.

E-gov started as a practitioner field, basically convening practitioners struggling to meet the new challenges of the Internet medium by implementing new systems creatively. If a single event should be pinpointed as a starting point it would be the U.S. National Performance Review, started in 1993, which placed a strong emphasis on the role of e-government in federal services (Gore, 1993; Salem, 2003). Led by then Vice President Gore, strongly coupled to the Clinton administration's strong focus on improved economy, it was given a high profile and relied heavily on the then new Internet technology with the effect of policy and technology mutually promoting each other.

While there are several terms, many largely refer to the same phenomena and are used interchangeably, such as *digital* and *electronic* government. In the following the term *e-gov* will be used simply because it is short and, together with the complete version *e-government* most commonly used, as Table 1 shows. A further note to the table data is that "governance" also returns a large number of hits.

The fact that the terms in Table 1 are commonly used as synonyms does not mean, however, that there is an unambiguous definition. There are both wide and narrow definitions. Government and governance are generally used confusingly in research. There is also some confusion over whether "electronic democracy" should be included or be seen as a separate field. Shared by all

*Table 1. Occurrences of commonly used terms. The search was made at Alta Vista on August 4, 2005. The search was made for the phrase, not separate terms (e.g., "electronic government"). The search was made using the "site collapse" function, which means that a maximum of two pages per site are displayed.*

| Area | Search term | Occurrences |
|---|---|---|
| Government | E-government | 9,460,000 |
| | E-gov | 3,010,000 |
| | Electronic government | 843,000 |
| | Online government | 601,000 |
| | Digital government | 425,000 |
| | Virtual government | 42,000 |
| | Wired government | 3,470 |
| Governance | E-governance | 531,000 |
| | Electronic governance | 47,800 |
| | Digital governance | 9,900 |

definitions is that e-gov includes a comprehensive strategic approach to government organization rather than piecemeal automation of discrete functions.

E-gov can be defined theoretically by setting "visions", operationally guiding definitions based on some theory, or by inducing from ongoing activities arriving at descriptive definition. Below we give examples of both.

## DESCRIPTIVE DEFINITIONS

Defining the e-gov field inductively can be done in different ways. Grant and Chau (2005) offer a framework designed to be generic, not country-specific, containing five categories based on a comprehensive review of events in the field of practice (p. 18):

1. Service delivery (service automation and information, interactive services, CRM—customer/citizen relations management);
2. Citizen empowerment (e-participation/democracy, collaboration/partnerships, CRM)
3. Market enhancement and development (collaboration/partnerships, globalization)
4. Exposure and outreach (globalization, marketing e-gov)
5. Infrastructure consolidation and standardization

Another way of inductively defining the field is to directly use researchers' and practitioners' categories which can be found in calls for papers and proceedings from the multitude of e-gov conferences. These tend to emphasize critical issues rather than just activities. For example, there is less about exposure and outreach and more about security, trust, knowledge management, and reorganization. Table 2 shows one example, which, although only one sample, is quite illuminating as it comes from one of the largest e-gov conferences attracting both researchers and practitioners, and the list of topics is quite similar to other conferences in the field.

*Table 2. Call for Papers for DEXA EGOV 2005 (Source: http://falcon.ifs.uni-linz.ac.at/news/cfp_e-Government2005.html)*

| |
|---|
| 1. Frameworks and guidelines for e-government and e-governance |
| 2. E-government policies, strategies and implementation |
| 3. Methods and tools for e-government research |
| 4. Participation, e-democracy and e-voting |
| 5. One-stop government, electronic service delivery, mobile services |
| 6. International and regional projects, case studies and best practice |
| 7. Administrative process design and change, collaborative activities, legal interpretation |
| 8. Trust and security: provisions and instruments |
| 9. Knowledge management, public information, decision process support |
| 10. Interoperability and standards, semantic standardization |
| 11. Change management and new organizational arrangements: public-private-partnerships, virtual teams |
| 12. Legal, societal and cultural aspects of e-government |
| 13. International dimensions: cooperation, comparisons, networks |
| 14. Teaching e-government |

The difference between these two ways of framing e-gov points to the problem with inductive definitions: they tend to focus on what has happened, not what will happen. In that sense the DEXA EGOV list may be more accurate as research observes problems in current practice and are interested in finding solutions.

Categorizations can also be done at different levels of granularity. While the DEXA categories are rather specific, Andersen and Henriksen (2004) investigate 110 e-government journal papers and find four general themes pertaining to how ICT use affects the role of government:

1. Conceptualization of e-government,
2. The governmental role in technology diffusion,
3. A governmental administrative e-service focus, and
4. Democracy and involvement of citizens.

Another attempt in a similar vein is made by Grönlund (2005) who relates conference papers to various aspects of governance (Table 3). One hundred seventy papers from three major e-gov conferences were classified by title, keywords, and contents into several themes. These themes are associated with four important aspects of governance and government:

1. A systems Perspective: all government agencies together rather than individual organizations or subsets of government organizations (an efficiency perspective)
2. The governance system (an effectiveness perspective)
3. Social aspects
4. The relation between government and citizens

As this brief review shows, inductively constructed definitions reveal e-gov as a large practice with many topics but leave us wanting as for the thrust of the field. Why has *e-gov* emerged as the umbrella term for all these very different subfields included? To answer that question we now turn to theoretically motivated definitions.

*Table 3. Research themes aggregated from three major e-gov conferences in 2003: DEXA EGOV, HICSS (Hawaii International Conference on Systems Sciences), and ECEG (European Conference on Electronic Government) (Grönlund, 2005)*

| Fields | Themes |
|---|---|
| **Government in a systems perspective: all government organizations together** | Reorganization |
| | Infrastructure |
| | Efficiency, rationalization |
| | Self-service |
| | E-commerce-inspired systems |
| | Interoperability |
| | Standards |
| | Ontologies |
| | Change management |
| | Legal environment |
| | Process management/process remodeling |
| **The governance system** | Outsourcing |
| | Value-added services by third parties |
| | Virtual communities |
| | Community network |
| **Social aspects of e-gov: "Society, the home of all people"** | Universal access |
| | Design for all |
| | (Bridging) digital divides |
| | E-democracy |
| | Participation |
| **The relation between government and governed** | User value/citizen satisfaction |
| | Societal value (effectiveness) |
| | CRM |
| | Call centers/service centers |
| | The role of civil servants |
| | Governing the Internet |
| | E-service models, government business models |
| | Voting |
| | Control, security, surveillance, privacy |

## THEORETICALLY MOTIVATED DEFINITIONS

Around the turn of the millennium, governments across the globe set up definitions of electronic government as foundations for national strategies to achieve excellence based on use of Internet technology. The general theory behind all these are that ICT can contribute to a number of advantages, both for governments and users/citizens. This theory may certainly be contested (Scholl, 2005), and closer scrutiny reveals that it comes in many forms, ranging from outright technology determinism to a cautious belief that technical development will, when wisely applied, help make government better. Grönlund (2002) reviews some of the definitions from (then, and still) leading countries and finds them similar and typically explicitly mentioning three goals:

1. more efficient government
2. better services to citizens
3. improved democratic processes

These definitions still remain, as they are implemented in official documents and government reform programs. Over the past few years, the point about improved democratic processes has often been played down, both in practice and in definitions. One example illustrating this change in emphasis is the U.S. 2002 E-Government Act, defining e-government as:

"the use by the Government of web-based Internet applications and other information technologies, combined with processes that implement these technologies, to:

a. enhance the access to and delivery of Government information and services to the public, other agencies, and other Government entities or
b. bring about improvements in Government operations that may include effectiveness, efficiency, service quality, or transformation". (U.S. Congress, 2002)

However, this limitation is contested in practice as the following definition shows. The Centers for Disease Control and Prevention (CDC) is one component of the Department of Health and Human Services, the principal agency in the United States government for protecting health and safety. Hence, the CDC Web site is a good example of electronic or digital government in operation.

*Digital government—also called e-government or virtual government—refers to governance affected by Internet use and other information technologies (IT). Digital government is typically defined as the production and delivery of information and services inside government and between government and the public using a range of information and communication technologies.* (Fountain, 2001, 2002)

*The definition used here also includes e-democracy, that is, civic engagement and public deliberation using digital technologies.* (Fountain, 2005)

As we can see here, the term *digital government* is used as a synonym to e-government. While *digital government* is a term frequently used in the US, electronic government is the term preferred internationally, including the United Nations (UN), the EU, the World Bank, and other international actors. Note also that e-government refers to governance, something that many researchers have tried to avoid by defining e-government in more narrow ways, usually for the purpose of being able to measure phenomena more strictly.

Most definitions are designed to address the broader development towards better government. What all recent definitions by major organizations share is that they acknowledge the need for organizational reform to go hand in hand with technology implementation, and focus on the role of government in society. Two sample definitions illustrate this.

*E-government refers to the use by government agencies of information technologies that have the ability to transform relations with citizens, businesses, and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management. The resulting benefits can be less corruption, increased transparency, greater convenience, revenue growth, and/or cost reductions.* (World Bank, 2004)

The e-gov efforts by the European Union are based on the definition:

*e-Government is the use of Information and Communication Technologies in public administrations combined with organizational change and new skills in order to improve public services and democratic processes.* (EU, 2004)

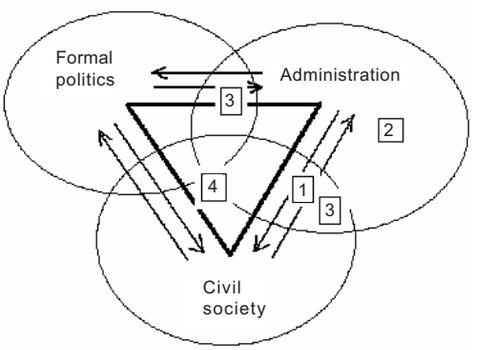
These definitions are about governance rather than government as they define e-gov in terms of its outcomes for socity. The distinction between government and governance has since long been made in political science, but e-gov practice and research tend to use confusing terminology. In short, government refers to what is happening within government organizations, while governance refers to the whole system involved in managing a society. While "government's foremost job is to focus society on achieving the public interest … governance is a way of describing the links between government and its broader environment—political, social and administrative" (Riley, 2004). Another way of describing the relation is that while government is about certain specific activities with a short-term perspective, governance is about processes and outcomes in the long run. Table 4 illustrates this difference by pairing concepts that belong together but emphasize either of these two sides. For example, while "rules" are what governments set up, "goals" are why they do it and "performance" is how they will be evaluated.

As we have seen in the previously discussed definitions, in e-gov practice the term *e-government* is dominating, even when governance is concerned. For example, the World Bank defintion mentions items like *corruption reduction* and *citizen empowerment*, which clearly belong in the right-hand column of Table 4. This conceptual

*Table 4. Government compared to governance (Source: Riley, 2004)*

| **GOVERNMENT** | **GOVERNANCE** |
|---|---|
| superstructure | functionality |
| decisions | processes |
| rules | goals |
| rules | performance |
| implementation | coordination |
| outputs | outcomes |
| **e-government** | **e-governance** |
| electronic service delivery | electronic consultation |
| electronic workflow | electronic controllership |
| electronic voting | electronic engagement |
| electronic productivity | networked societal guidance |

*Figure 1. Different e-gov definitions plotted on the e-gov domain. Arrows indicate influence, circles indicate domains of control, the triangle represents information systems by which the spheres communicate. Intersections indicate transaction zones where control is negotiated by, for example, lobbyists and media on the left-hand side, intermediary service deliverers on the right-hand side, and professional interaction in government boards and committees on the top side. (Adapted from Molin et al., 1975, p. 16)*



confusion is likely one we will have to live with as the term *e-government* is much more frequently used.

The distinction between governance or government makes a big difference in terms of what counts as e-gov information systems, as a look at broad and narrow definitions will show. Figure 1 illustrates the governance domain using a textbook model of society as consisting of three distinct but interrelated spheres: the political, the administrative, and the civil society one. All are mutually dependent by a large number of relations, and integrated by a large number of information systems which are increasingly using ICT. Governance obviously concerns all three spheres, while government can be taken to mean either just the administrative one or the political and administrative in combination. While all the e-gov definitions presented so far discuss e-governance, other more limited definitions exist. For example, OECD (2003) distinguishes among four types of definitions (plotted on Figure 1):

1. "Internet (online) service delivery and other Internet-based activity such as e-consultation" (i.e., mainly the transactions between government administration and citizens in the right-hand side of Figure 1).
2. "E-government is equated to the use of ICTs in government. While the focus is generally on the delivery of services and processing, the broadest definition encompasses all aspects of government activity" (i.e., mainly the right-hand side of the figure but with focus on Administration).
3. "E-government is defined as a capacity to transform public administration through the use of ICTs or indeed is used to describe a new form of government built around ICTs. This aspect is usually linked to Internet use" (i.e., mainly the Administration sphere and the processes linking administration and formal politics).
4. The OECD's own definition, "The use of ICTs, and particularly the Internet, as a tool to achieve better government" (OECD, 2003, p. 23) clearly concerns the whole figure as "better government" must be measured from outside, what good it does for society.

This review shows that while influential definitions of e-gov today include contextual and societal aspects and hence go beyond single government organizations and indeed government as a whole, the OECD taxonomy reveals important differences. Definitions to some extent are mutually exclusive—you cannot measure efficient service delivery, as of definition type 1, and claim this is an exhaustive measure of "a capacity to transform government". Hence, there is no clear way of summarizing all definitions into one. Also, many definitions are normative and hence, while potentially operationally efficient, not useful for scientific descriptive purposes. However, as the Figure 1 illustrates, because major definitions concern the effectiveness of large and complex social systems with ambiguous goals involving many actors, they have to do with communication processes rather than information storage and retrieval. Let me therefore, in conclusion, suggest two definitions that are inclusive in that they

cover the activities involved in the e-gov field, descriptive rather than normative, and theoretically correct in that they observe the difference between underlying concepts of government and governance.

- **Electronic Government:** The use of ICT in communicative processes involved in government activities.
- **Electronic Governance:** The use of ICT in governance processes. The only difference from Electronic Government is that governance processes may not involve government. For example, the activities of partisan NGOs may be included.

While descriptively correct, these definitions may not be operatively guiding in a way that practitioners would like. Also, they do not delimit the field in a way that excludes fields previously defined, for example, "IT in government", as discussed herein. The latter fact means that the definitions are imperialistic in that they subsume earlier definitions.

## E-GOV EVALUATION MODELS

To monitor the development, there are a number of more or less recurrent benchmarking studies covering various areas, the EU, the US, and worldwide (e.g., Accenture, 2004; UNDESA, 2003; West, 2003). Early measurements typically employed some of the ladder models around, usually the 4-step one. For example the EU has used the following model for repeated measurements since 2000:

- **Stage 1, Information:** The information necessary to start the procedure to obtain this public service is available on-line.
- **Stage 2, One-way Interaction:** The publicly accessible website offers the possibility to obtain in a non-electronic way (by downloading forms) the paper form to start the procedure to obtain this service. An electronic form to order a non-electronic form is also considered as stage 2.
- **Stage 3, Two-way Interaction:** The publicly accessible website offers the possibility of an electronic intake with an official electronic form to start the procedure to obtain this service. This implies that there must be a form of authentication of the person (physical or juridical) requesting the services in order to reach stage 3.
- **Stage 4, Full electronic case handling:** The publicly accessible website offers the possibility to completely treat the public service via the website, including decision and delivery. No other formal procedure is necessary for the applicant via "paperwork". (DGIM, 2005, p. 7)

This type of model focuses on technology. There are several similar ones, for example, US researchers often refer to a model by Layne and Lee (2001). Sometimes the last step is named "integration", indicating the current strive towards standardizing data definitions across government agencies so that all processes can be built electronically independently of which, or how many, agencies are involved. The current name for this ideal is "Enterprise Architecture", a term for considering government in a holistic perspective including political and service goals and the means for achieving those: business processes, information systems, data definitions, and review of performance.

More recently, models focusing on organization, in particular integration across government, have emerged. For example the UN uses a 5-stage model to measure e-government evolution:

1. Emerging presence
2. Enhanced presence
3. Interactive presence
4. Transactional presence
5. Networked presence

While the first four stages roughly correspond to the EU model, stage five is characterized by "integration of G2G [government-to-government], G2C [government-to-consumer], and C2G [consumer-to-government] (and reverse) interactions. The government encourages participatory deliberative decision making and is willing and able to involve the society in a two-way open dialogue" (UN, 2004, p. 17). This model is designed as a part of a multicriteria measure of "e-government readiness". The complete set of indices includes a Web Measure Index (the five points the previous example), a Telecommunications Infrastructure Index, and a Human Capital Index (e.g., education level). There is also an E-participation Index including measures of e-information, e-consultation, and e-decision-making (UN, 2004, pp. 16-19).

While the UN index may be seen as inspired by social concerns, there is also increasing evidence of a more business-like approach to government. For example the latest e-government measurement by Accenture (2005) is titled "New Expectations, New Experiences", and focuses on citizen satisfaction. Accenture uses an adoption pyramid including seven consecutive steps: awareness, familiarity, interest, use, satisfaction, and advocacy (Accenture, 2005, p. 25). This new approach is inspired by the finding that online presence is not enough; unless there is demand, there will not be use, and the Accenture

report concludes that "leadership in customer service" (first part of the report title) is what it takes to take e-gov further. They survey a number of countries and find that the level of Internet penetration does not entail a certain level of use. While, for example, Finland and Sweden rank high on both scales, UK and Japan have almost as high Internet penetration but only half the use (p. 25).

We have seen here that while early e-gov status measurements focused on technical aspects of Web presence there is now a shift towards measuring government readiness and citizen or customer satisfaction. This indicates organizational and social aspects are gaining ground complementing the early technology focus.

## FUTURE TRENDS

As for the terms *e-government*, and others discussed here, it is likely they will vaporize gradually over the coming years. ICT tools will become so integrated in government and governance processes that it does not make sense to point them out specifically. The phenomenon of e-gov will hence become even more omnipresent, and following from that various aspects of the redesign of processes will be discussed rather than the "e" itself (or the "m"—"mobile government" is one of today's commonly used technology-induced keywords for discussing technology use in government).

According to the most common e-gov visions-in-practice today, the ultimate goal is to achieve step four in the ladder model of the previous section. Technically, this may indeed be as much as can be done. But the implications of e-gov do not stop with that; there must be a reason for wanting to get there. The obvious reason is making government more effective, but, as critics have already pointed out, an economically efficient government does not necessarily lead to the most efficient governance. For example the register-data-only-once vision has been challenged for being privacy intrusive. The self-service ideal has been challenged for excluding many people who lack economic means to have a computer, or lack the skills to use them. Further still, even if such things are well catered for, more ICT use will have consequences for the way government communicates with society, and within itself.

The Enterprise Architecture vision (which is technically approaching already today in many countries, such as UK, U.S., and Canada) means government must be handled more as a whole. There will be more limitations imposed on each agency in terms of data definitions, interfaces with other agencies, and communication with citizens. This means a more top-down government management mode.

The standardization of government also means that the interface with citizens will change. This change will not entirely be defined by government but by designers of the main software. The interaction styles and standard interactive features will be those that software vendors put into their systems. Government agencies will not find it worthwhile to redesign these; they will only fill them with local content. This means government interaction with citizens will be more similar across agencies and indeed across countries. Maybe this is the true meaning of e-gov—the communication styles which can be implemented in a desktop computer, a PDA, and a mobile phone are those which will become the norm, and government practices will adjust accordingly.

The use of computers in almost every government contact will also mean these will become more formal. Because everything is written, everything has to be legally correct. Because everything has to be legally correct, it will increasingly be centrally produced for reasons of higher quality and better quality control (on top of economic reasons). This means local staff will have less freedom to act with their own judgment. In some countries this is considered an enormous step forward as evils like corruption can be more easily fought. In other countries it is viewed as decreasing service level due to less face to face communication.

The self-service model will lead to users becoming more knowledgable about how government works, as they will increasingly have to find that out for themselves by surfing Web sites, interpreting voice menus, and sms-replies. Where this leads is open to future research, but if knowledge is power, certainly citizens of the near future will have more of it.

There are many issues not yet researched concerning the impacts of e-government. We have shown here that there is an increasing interest in governance processes, but also a trend towards more business-like management and "service orientation" in government. Finally, global dissemination is clearly on the way and there are many hopes for e-gov to help structure government operations worldwide, as the World Bank definitions showed.

## CONCLUSION

This article shows that e-government in many definitions is taken to mean e-governance. A definition covering the major practitioner definition could be "ICT use in governance processes." Although current e-gov practice is technologically oriented, both definitions from international actors and emerging evaluation models emphasize social concern and interest in value for users/citizens, including not only "services" but also participation. There is no doubt that the main driving force behind e-government is making government more efficient, but there is also no doubt that the communication style of e-govern-

ment will have consequences for the relations between governments and citizens, and hence for both individuals, government organization, and government employees. The consequences are still to be seen. There are many interesting developments that cannot yet be measured on a national or international level because they have not yet become so large that they can be seen in national statistics.

## NOTE

The key terms are the author's own definitions. As this article has shown, there are many definitions around.

## KEY TERMS

**Electronic Government:** The use of ICT (Information and Communication Technologies) in communicative processes involved in government activities. Synonym to digital government.

**Electronic Governance:** The use of ICT in governance processes. The difference from Electronic Government is that governance processes may not involve government.

**IT in Government:** A term used to refer to IT use in internal government processes in the Information Systems literature from, mainly, the 1970s and 1980s.

# Electronic Government at the American Grassroots

**Donald F. Norris**
*University of Maryland, Baltimore County, USA*

## INTRODUCTION

During the past 10 years or so, governments in the United States have rushed to adopt and implement electronic government or e-government (defined as the electronic delivery of governmental information and services 24 hours per day, seven days per week, see Norris, Fletcher, & Holden, 2001). Today, the federal government, all 50 state governments (and probably all departments within them), and the great majority of general purpose local governments of any size have official presences on the World Wide Web through which they deliver information and services and, increasingly, offer transactions.

In this article, I examine the current state of the practice of e-government at the grassroots in the U.S.—that is, e-government among American local governments. In particular, I address the extent of local adoption of e-government, including the reasons for adoption, the relative sophistication of local e-government, and barriers to and initial impacts of e-government.

## BACKGROUND

It is important to study e-government at the American grassroots for at least four reasons. The first is found in the sheer numbers of local governments. The 2002 Census of Governments reported that there are nearly 88,000 local governments in the U.S., including 19,431 municipal governments, 3,034 county governments, and 16,506 town and township governments, for a total of 38,971 general purpose local governments (U.S. Bureau of the Census, 2002). Second, as I will show in this article that 95% of local governments of 10,000 or greater in population have Web sites for e-government purposes. These two reasons combined mean that the vast majority of Americans have at least the potential to interact with and be affected by local e-government. Third, governments at all levels in the U.S. are spending an enormous amount of money on e-government, annually up from $1.5 billion in 2000 to an expected $6.2 billion in 2005 (Gartner Group, 2000). Fourth, local governments are the closest governments and provide the greatest numbers of services to the people. Thus, these governments have the greatest immediate impact on the peoples' lives. For at least these reasons, then, it is important to understand how and why e-government has been adopted, the functions it performs, how it has evolved, and its impacts.

## DATA AND METHOD

In this analysis, I use data from three nationwide surveys, as well as evidence from focus groups that I conducted in 2002, to help understand e-government at the American grassroots. The surveys were conducted in 2000, 2002, and 2004 by the International City/County Management Association (ICMA) and Public Technology, Inc. (PTI) about local e-government (ICMA/PTI 2000, 2002, 2004). The 2000 survey was mailed to all municipalities with populations greater than 10,000 and all counties with either the council-administrator (manager) or council-elected executive form of government. The response rate was 50.2%.

The 2002 and 2004 surveys were mailed to all municipalities of 2,500 or more in population and all counties with either the council-administrator (manager) or council-elected executive form of government. The response rate to the 2002 survey was 52.6% and to the 2004 survey was 42.4%. In order to provide for direct comparisons between the surveys, I used data from all responding counties but only from municipalities with populations greater than 10,000 from the 2002 and 2004 surveys. With a few exceptions, the respondents to all three surveys were reasonably representative of U.S. local governments as a whole. (For a more detailed discussion of the survey responses, see Holden, Norris, & Fletcher, 2003; Norris, 2005b; Norris & Moon, 2005)

In addition, I employ data from focus groups that I conducted in the fall of 2002 among officials of 37 U.S. local governments that were on the leading edge of e-government adoption and use (Norris, 2003; Norris, 2004a; Norris, 2004b; Norris, 2005a; Norris, 2005b)[1] The focus group is a well recognized method of qualitative data collection, especially in market research but also in research in various disciplines in the social sciences. Focus groups involve researcher facilitated data collection from

*Table 1. Web site adoption*

| | 2000 | | | 2002 | | | 2004 | | |

| | | No. | % | | No. | % | | No. | % |
| A. Does your government have a Web site? | Yes | 1573 | 83.6 | Yes | 1866 | 87.7 | Yes | 2491 | 95 |
| | No | 308 | 16.4 | No | 262 | 12.3 | No | 132 | 5 |
| | Total | 1881 | 100 | Total | 2128 | 100 | Total | 2623 | 100 |

group interaction on a pre-determined topic and include three components: data collection, interaction through group discussion, and active participation by the researcher in shaping the discussion (Morgan, 1996) (For more information about the focus group methodology in general, see Merton, 1987; Merton & Kendall, 1946; Morgan, 1993; Morgan, 1996. For a more detailed discussion of the focus group method as applied to this research see Norris, 2004a; Norris, 2005a, 2005c).

The focus groups included chief information officers (CIOs) or their equivalents and top administrative or policy officials from 37 local governments that had adopted e-government, and that at that time were considered on the leading edge of e-government (Appendix A). These persons constituted a body of key informants with critical knowledge of and insights into their governments' adoption of e-government and issues related to it.

## E-GOVERNMENT ADOPTION

Beginning in the mid-1990s, local governments in the U.S. started establishing official sites on the World Wide Web. According to the 2000 survey——that is within about five years of the beginning of the e-government—83.6% of these governments had established Web sites from which they delivered governmental information and services (Table 1). Local government Web site adoption increased to 87.7% in 2002 and to 95.0% in 2004. In 2000, about two-thirds of local government Web sites were three years older or less. If we extrapolate that finding to 2005 (five years later), two-thirds of local government Web sites are eight years old or less today (Table 2). Thus, local e-government is a relatively young phenomenon that has been adopted very rapidly in nearly all local governments in the U.S. with a minimal level of population (10,000 or more).[2]

Previous studies have shown that a statistically significant relationship exists between local government population and adoption of leading edge information technologies (Norris & Demeter, 1999; Norris & Campillo, 2000; Norris & Kraemer, 1996) and between population and the adoption of e-government (Holden, Norris, & Fletcher, 2003; Moon, 2002; Norris & Moon, 2005). These studies employed data from a 1997 survey of computers and local governments and the 2000 and 2002 e-government surveys. Although I did not run tests of statistical significance for the relationship between population and e-government adoption for the 2004 survey data, based on previous work it is highly likely that this relationship exists.

Prior studies have also found that adoption of both leading edge information technologies and e-government may be related to type and form of government (municipal type and professional manager form being positively related), (Holden, Norris, & Fletcher, 2003; Moon 2002; Norris & Campillo, 2000; Norris & Demeter, 1999; Norris & Moon 2005). I did not run tests of statistical significance on the 2004 survey data. Here again, however, there is reason to believe that statistical significance would be obtained if such a test were conducted, there being so few differences between the results of the 2000, 2002, and 2004 surveys.

Although the surveys show how many local governments have adopted e-government and how rapidly, the surveys did not ask why local governments adopted e-government. The hype surrounding e-government predicts that governments will adopt e-government in order to provide services more effectively and efficiently; that they will engage in (usually unspecified) governmental reform and in (equally unspecified) governmental transformation; and that governments adopt e-government as part of a broader plan or strategy for improving the delivery of governmental services (see, for example, Garson, 2004). Based on data from focus groups of officials in governments on the leading edge of e-government, these reasons turn out not to be true.

*Table 2. Age of Web site*

| | 2000 | |
|---|---|---|
| | No. | % |
| Three years or less | 803 | 68.5 |
| 4-5 years | 318 | 27.1 |
| More than 5 years | 52 | 4.4 |
| Total | 1173 | 100 |

*Note: The question about age of Web site was not asked in the 2002 and 2004 surveys.*

*Table 3. Reasons for e-government*

| Responses | Total |
|---|---|
| Information and Services | 25 |
| (Information) | (15) |
| (Services) | (10) |
| Efficiency, economy, and related | 13 |
| Citizen contact, access, oriented, centric | 10 |
| Demand Total | 7 |
| (Elected officials demanded) | (2) |
| (Citizens, businesses demanded) | (2) |
| (Perceived expectations/demand) | (3) |
| IT department led or pushed | 7 |
| Economic development, tourism, advertising the city or county | 6 |
| "Keeping up with the Joneses" | 6 |
| Other | 9 |
| **Total reasons given** | 83 |

The principal reasons that local government officials gave for adopting e-government are much more prosaic (Table 3). The focus groups' 37 responding local governments provided 83 reasons for adopting e-government: 25 were to provide information and services, 10 were for citizen contact or access, and six were for specific functions (usually economic development or tourism). Thus, 41 of the reasons involved providing services or information. Seven responses indicated that actual demand either from elected officials (2), or citizens or businesses (2), or perceived demand (3) were reasons for the adoption of e-government. An additional seven said that e-government had been adopted because the IT department pushed it. Six said "keeping up with the Joneses"—meaning that local government could not be in the position of not adopting e-government if everyone around them was doing so. Nine reasons were coded "other." This left only 13 reasons that were related to efficiency and economy, and none of the reasons given for adopting e-government involved governmental transformation.

## WEB SITE SOPHISTICATION

In the past few years, several studies have examined the Web site content (e.g., Kaylor, Deshazo, & Van Eck, 2001; Stowers, 1999; West, 2003a, 2003b, 2004a, 2004b). For the most part, these studies have concluded that governmental Web sites around the world are at either stage one or two of development that the principal normative models of e-government predict (e.g., Baum & di Maio, 2000; Hiller & Belanger, 2001; Layne & Lee, 2001; Ronaghan, 2002). In other words, governmental Web sites are mainly informational and provide users with only a limited number of opportunities for online transactions. For the purposes of this article, I used the survey data to describe the transactional capabilities of local government Web sites. This description also provides a rough indication of Web site sophistication. That is, the greater the number of basic transactions and the greater the number of more complex (e.g., financial) transactions, the more sophisticated is the Web site.

According to the 2004 survey, the Web sites in majorities of local governments provided a few relatively easy, non-financial transactions. These include council agendas (73.6%), codes and ordinances (71.3%), employment information and applications (60.5%), and downloading forms for manual completion (57.9%). See Table 4. These

*d. These questions were not asked in the 2002 survey.*
*e. This question is a combination of the previous two questions for the 2002 survey.*

are essentially one-way transactions that are not especially difficult to automate on Web sites. Additionally, 61.4% of these Web sites provide the opportunity to communicate with officials (presumably by e-mail).

Once the "low hanging fruit" has been picked—that is, the easy transactions have been automated—few other functions, services or information have been made transactional on local government Web sites. For non-financial matters, only three functions or services have been made transactional by more than one in four local governments (and none by more than 30%)—requests for service (28.6%), interactive maps (27.5%), and requests for records (25.7%).

In terms of financial transactions—which clearly are fraught with more policy, technical and security difficulties than non-financial transactions—none achieved greater than 10% adoption on local government Web sites. Only one in ten local government Web sites provides for the on-line payment of utility bills (9.8%) and taxes (9.2%), and fewer still (7.7%) permitted the online payment of fines and fees.

## BARRIERS TO E-GOVERNMENT

These data show that the great majority of U.S. local governments with populations of 10,000 or greater have adopted Web sites from which they provide governmental information and services, and that they did so very quickly following the beginning of e-government. However, to date, local government Web sites are not especially sophisticated. The obvious question is why? One way to answer this question is to examine what the survey results say about perceived barriers to e-government (Table 5). Here, majorities of the responding governments said that lack of technology or Web staff (55.7%) and financial resources (57.2%) impeded their ability to implement e-government. Interestingly, responses in 2004 in both areas showed increases over 2002 (+5.9% for technology/Web staff and +10.5% for financial resources). Other notable barriers included lack of technology and Web expertise (36.1%), issues regarding security (34.2%), justifying return on investment (ROI) (31.1%), convenience fee issues (28.2%), and privacy issues (25.7%).

In addition to the barriers reported in the surveys, the focus groups also help us to understand why local government Web sites remain mainly informational. Nearly all of the focus group participants agreed that one reason is to be found in the cost of the transactions to the local governments. If local governments permit "customers" to engage in online transactions using credit cards, these governments have to pay the fees of the credit card companies. This represents a loss of revenue that few local governments feel they can justify and cannot recover this loss elsewhere. Second, few local governments are willing to charge additional fees to cover the cost of online transactions. Officials feel that to charge fees would be inequitable, that their residents (read, voters) would oppose fees, and that fees would also be a disincentive for use of online transactions. Whatever the reasons, few local governments offer online transactions on their Web sites at this writing, and the movement toward offering more online transactions (especially financial transactions) is glacially slow.

*Table 5. Barriers to e-government*

| | 2000 | | 2002 | | 2004 | |

## E-GOVERNMENT IMPACTS

Numerous claims have been made in the scholarly and trade literatures that a wide range of (nearly always) positive impacts will occur as the result of e-government (again, see Garson, 2004). Few of these claims are grounded either in the empirical literature about IT and government (which can significantly inform the study of e-government) or in the nascent but growing empirical literature about e-government (see Norris & Zimmerman, 2005; and Norris & Lloyd, 2004). Nevertheless, among other things these claims suggest that e-government will result in

*Table 6. Impacts*

| | 2000 | | 2002 | | 2004 | |
|---|---|---|---|---|---|---|
| | No. | % | No. | % | No. | % |
| Increased demands on staff | 344 | 21.9 | 616 | 28.9 | 687 | 26.2 |
| Changed role of staff | 323 | 20.5 | 570 | 26.8 | 719 | 27.4 |
| Business processes are being re-engineered | 283 | 18 | 453 | 21.3 | 518 | 19.7 |
| Business processes are more efficient | 214 | 13.6 | 367 | 17.2 | 501 | 19.1 |
| Reduced time demands on staff | 135 | 8.6 | 319 | 15 | 547 | 20.9 |
| Reduced administrative costs | 79 | 5 | 147 | 6.9 | 235 | 9.0 |
| Reduced number of staff | 11 | 0.07 | 23 | 1.1 | 57 | 2.2 |
| Increased non-tax-based revenues | 10 | 0.06 | 16 | 0.8 | 27 | 1.0 |
| Citizen contact with officials | | | | | 836 | 31.9 |
| Improved customer service | | | | | 1182 | 45.1 |
| Improved communication with public | | | | | 1392 | 53.1 |
| Other | | | | | 79 | 3.0 |

greater efficiency and economy in governmental operations, staffing reductions, the re-engineering of business processes, increased revenues, greater citizen contact with government, and improved customer service.[3]

Both the surveys and the focus groups examined e-government impacts. I begin with data from the surveys. The data in Table 6 show that in 2004 only 2.2% of local governments said that e-government has reduced the number of staff, 9.0% of governments reported that it has reduced administrative costs, and 20.9% said that it has reduced time demands on staff. One in four said that e-government has increased demands on staff (26.2%) and changed the role of staff (27.4%). Fewer than one in ten local governments (9.0%) reported that e-government has reduced costs, and only 1.0% said that it has increased revenues. However, nearly one in five also reported that business processes are being re-engineered (19.7%) and have become more efficient (19.1%) due to e-government.

The areas in which local governments reported the most positive results from e-government were communication and customer service. Over half (53.1%) said that e-government has improved communication with citizens, while nearly one-third (31.9%) indicated that it increased citizen contact with officials. Finally, nearly half (45.1%) reported that e-government has improved customer service.

The focus group data augment the surveys and also portray a somewhat different picture. The first responses are from closed ended questions that I asked of the focus group participants (Table 7). Here, the top two positive impacts (each achieving unanimity or near unanimity) were increased contact with citizens (39) and re-engineering of business processes (36). Other significant positive impacts included increased efficiency of business processes (31) and that e-government met or exceeded initial expectations (28). Two reported impacts should be considered neutral–changed role of IT staff (38), and changed role of line staff (34). In discussing these two impacts, the focus group participants felt that the primary change in the role of IT staff was that they now were involved in creating and maintaining Web applications vs. creating and supporting legacy applications. Additionally, the participants felt that as the result of e-government, IT organizations have become more end-user centric and operate on more of a "service" orientation. (Interestingly, this continues a trend in IT department orientation begun by the PC revolution). The principal change for line staff is that many of them are now involved in providing and managing content for their departments' Web pages.

*Table 7. E-government impacts: The focus group data (Responses to closed ended questions—n=39)*

| | |
|---|---|
| Increased citizen contact with government | 39 |
| Changed role of IT staff | 38 |
| Business processes are being re-engineered | 36 |
| Changed role of line staff | 34 |
| Business processes are more efficient | 31 |
| Added costs to IT | 30 |
| Met or exceeded initial expectations | 28 |
| Added costs to line departments | 27 |
| Increased work for IT on staff | 24 |
| Increased the number of staff in IT | 12 |
| Produced new revenues | 9 |
| Reduced number of staff in line departments | 1 |
| Increased work for staff in line departments | 0 |

Although not part of this set of questions (and, therefore, not found in this table), nearly all of the focus group participants said that e-government is a *net add-on* to what local governments currently do–not a substitution for it. E-government is just *one more way* to deliver information and services. This can also be seen clearly in the participants' responses to the following closed-ended questions: e-government added costs to the IT function (30); added costs to line departments (27); and increased the work load of IT staff (24). (At the same time, however, the participants did not believe that e-government had increased the workload in line departments). These results (increased costs and work load) must be viewed as negative impacts.

Another potential positive impact according to the hype surrounding e-government is the substitution of technology for staff and, thus, reducing both staff and workload. According to the focus groups, this has not occurred. As shown above, 24 respondents said that e-government has increased the workload in IT departments. Moreover, 12 respondents believed that it has resulted in increases in the size of IT staffs. Further discussion revealed that in several other governments, IT staffing needs had also increased due to e-government. However, for budgetary or political reasons, it had not been possible to add positions to the IT department. Only one respondent noted that e-government had permitted a reduction in the number of staff in other departments.

The portrait that emerges from the focus groups' responses to the closed ended questions indicates that while e-government appears to have produced some positive impacts in its early days, the number of positive impacts is relatively small. At the same time, however, several other expected positive impacts have not occurred and some negative impacts have occurred.

I also led the focus groups through extensive open-ended discussions of e-government impacts during which I asked them to note their greatest disappointments with and their most pleasant surprises from e-government (Table 8). There was a strong consensus (28 participants) that a major and important positive impact or pleasant surprise resulting from e-government was its citizen centricity. The participants believed that e-government served citizens well by making governmental information and services available electronically 24 hours per day, seven days per week. As several said, now citizens can be online and not in line. They also felt that e-government promoted greater openness and responsiveness of government. For these reasons, they felt that e-government was popular with citizens.

*Table 8. E-government impacts: The focus group data (Responses to open ended questions – n=39)*

| **Positive Impacts** | |
|---|---|
| Citizen centric, openness, responsiveness, popularity | 28 |
| BPR, productivity, efficiency, effectiveness | 7 |
| Improve government image | 6 |
| Speed or ease of e-government implementation | 6 |
| Services 24/7 | 4 |
| Other | 21 |
| Total | 73 |
| **Negative Impacts** | |
| Internal governmental issues impeding e-government | 19 |
| Time to market | 8 |
| Vendor problems | 7 |
| Workload and cost | 7 |
| Slow citizen uptake | 6 |
| Legacy system problems | 5 |
| Marketing difficulties | 5 |
| Privacy and security issues | 4 |
| Other | 30 |
| Total | 91 |

Beyond this single area of consensus, however, responses regarding positive impacts and pleasant surprises did not show any particular pattern. Seven participants gave answers that could be interpreted as suggesting that greater efficiency of government, often through business process re-engineering, was a positive result of e-government. Six said that a positive impact of e-government was that it helped to improve the image of government to citizens. Six focused on the ease of implementing e-government applications (vs. legacy applications) as a pleasant surprise. Four pointed to the availability of services 24 hours a day seven days a week as a positive result. All other responses (21) were too scattered to categorize.

Regarding negative impacts and disappointments, nearly half (19) of the participants registered their disappointment that internal governmental barriers (most often turf, departmental autonomy, and lack of inter-departmental cooperation) impeded e-government. While not a direct consequence of e-government, these impediments nevertheless made e-government implementation and diffusion within individual governments more difficult. Other negative impacts or disappointments included: time to market (8), by which these participants meant that they were disappointed with how long it took to roll out e-government applications[4]; vendor problems (7), meaning primarily that the IT vendors were not fully ready to support e-government applications; slow citizen uptake (6)[5]; problems integrating legacy systems with e-government (5); marketing difficulties, meaning difficulty getting word out to internal and external publics about the availability and potential of e-government (5); and privacy and security issues (4). Other responses (30) were too disparate and unrelated to categorize.

In conclusion, evidence from the surveys and the focus groups show, first, that relatively few governments report any impacts at all from e-government. Second, many of the expected positive impacts have not occurred, and third, some negative impacts particularly relating to staffing and budgets, have occurred. The picture that emerges is not nearly as rosy as the hype suggests. However, because e-government is relatively young, impacts can be expected to change over time as e-government continues to evolve, becomes more stable, and maturates.

## FUTURE TRENDS

Local e-government in the U.S. is young, has been adopted very rapidly and continues to evolve, yet remains mainly informational. It is moving in directions predicted by the principal normative models of e-government quite slowly and nowhere is it achieving the potential positive impacts claimed by its most ardent advocates. Nevertheless, the potential exists for e-government to yet become something that at this writing it is not—whether for good or ill. Given the findings in this article, what can reasonably be expected for the immediate future of local e-government in the U.S.

First, it would appear that e-government is not transformational, at least yet. This finding is highly consistent with findings from the literature on IT and government (e.g., Kraemer & King, 2006). Second, it would also appear that e-government, like IT and government before it, is incremental. Third and following from points one and two, the trajectory of local e-government that has been observed to date will likely continue into the foreseeable future. That is, local e-government will be mainly informational with increasing opportunities for interactivity and a small but growing number of transactional capabilities. At least in the near term, the optimistic views espoused by e-government advocates and by scholars whose work is not grounded in empirical studies of e-government and IT and government that e-government will become fully integrated and transformational will not be met. Furthermore, based on the empirical scholarship on IT and government and on e-government, there are few reasons to believe that these expectations will be met in the longer term.

## CONCLUSION

Local electronic government in the U.S., at least as measured by the adoption of official sites on the World Wide Web, is widespread and has achieved mainstream status. In less than a decade from its beginning, more than nine in ten grassroots governments with populations of 10,000 or more have adopted e-government. However, at this writing, local e-government is mainly informational, providing only a few online transactions. Nearly all of the online transactions are relatively basic—downloading minutes, codes and ordinances, and employment forms; requesting services and records; and communicating with officials via e-mail. Fewer than one in ten local governments provide for online financial transactions.

Local governments cite a number of barriers to e-government that may help to explain why e-government remains mostly informational. These barriers principally include lack of technology and Web staff and expertise, lack of financial resources, issues around security, privacy and convenience fees, and justification of ROI. Finally, local governments are slow to implement financial transactions because of the potential loss of revenue from having to pay the charges of credit card companies, and the unwillingness of local officials to impose fees to offset those charges.

In terms of impacts, few governments surveyed reported many impacts at all. And the direction of the reported impacts was not always positive–as the hype has predicted. E-government has not reduced staff, increased revenues, or reduced costs. Only a modest number of governments reported that e-government promoted business process re-engineering and process efficiency or reduced the time demands on staff. Larger fractions reported that it increased demands on and changed the role of staff. To the extent that there is good news in reported impacts it is that most of the surveyed governments said that e-government improved communication with the public and improved customer service. Additionally, the focus group responses both affirmed positive impacts from e-government (e.g., citizen centricity, greater citizen contact, re-engineering, etc.), but also noted more negative impacts (e.g., increased costs to IT and line departments, increased work for IT departments, and increased staffing in IT).

For several reasons and especially because local e-government is costly and has the potential to directly affect the lives of nearly all Americans, scholars should continue to examine local e-government using a variety of qualitative and quantitative research methodologies. Continuing research is needed to keep up with the practice of e-government and to ascertain its impacts of both within and among local governments and on their principal stakeholders—the citizens and taxpayers of America's grassroots governments.

## KEY TERMS

**Business Process Re-Engineering:** Use of systems analysis and other management techniques to improve and make business processes more efficient; often done in concert with implementation of new IT systems.

**Citizen Centricity:** Making governmental services more available and user friendly to citizens.

**E-Government:** Electronic delivery of governmental information and services 24 hours per day, seven days per week.

**Focus Groups:** Qualitative research method involving researcher-facilitated data collection from group interaction on a pre-determined topic that includes three components: data collection, interaction through group discussion, and active participation by the researcher in shaping the discussion.

**Grassroots:** Governments that are closest to and provide the greatest number of services to citizens.

**Legacy Systems:** Traditional computer software employed to conduct the internal business of running a government (e.g., billing, accounting, budgeting, payroll, inventory management, etc.).

**Local Governments:** Governments that are the closest and provide the greatest number of services to people. Local governments include municipal, county, town, and township.

## ENDNOTES

[1] The focus group research was supported by the National Science Foundation under Grant IIS-0131554.

[2] Web sites do not encompass all of e-government; but they do constitute the vast majority of it today.

[3] Although it is beyond the purview of this paper, many claims are also made that e-government is transformative; that is, it will fundamentally transform government from its current state to one that is more citizen centric, including greater citizen involvement in governmental deliberations and decision making. Empirical studies of whether e-government is or is not transformative have yet to be conducted.

[4] Note, however, that most felt that, on the contrary, e-government applications were much easier to develop and roll out than legacy applications.

[5] Note that this is contrary to the view that e-government increased citizen contact and citizen centricness (but only five respondents so reported and most were from jurisdictions where citizen uptake had not been stellar).

# Electronic Government-to-Government Collaboration

**Euripidis Loukis**
*University of Aegean, Greece*

## INTRODUCTION

Most of the effort of e-government researchers and practitioners today is focused on G2C (government-to-citizen) and G2B (government-to-business) e-government, aiming at the development of information systems that offer to the citizens and businesses the capability to communicate and perform their transactions with the public administration (e.g., various declarations, applications, etc.) electronically, over the Internet or other electronic channels. Taking into account that the quality of most public administration policies and services (delivered through physical or electronic channels) depends to a large extent on the extent and the quality of the collaboration among many involved public organizations (e.g., ministries, regions, prefectures, municipalities, and so forth), it has been widely recognized that much more research is required concerning the exploitation of information and communication technologies (ICTs) for supporting and enhancing government-to-government (G2G) collaboration (Lenk & Traunmüller, 2002; Leitner, 2003; Traunmüller & Wimmer, 2003, 2004; Scholl, 2005). According to Scholl (2005),

*current e-Government research might possibly suffer from the iceberg phenomenon, where most attention is dedicated to the above surface phenomena (i.e,. G2C and G2B e-Government), while "sub-surface" phenomena (such as the G2G e-Government, etc.) not readily available to scientific scrutiny have been spared.*

The collaboration among public organizations, from the same country or even from different countries, has become today much more important and at the same time much more complex than it was in the past, mainly due to the globalization of the economy (resulting in increased interdependence among national economies), the development of various super-national entities (such as the European Union, the North American Free Trade Association (NAFTA), etc.), the continuous growth of the new digital economy, and so on. Also, the growing complexity and the international nature of many problems of modern societies necessitate extensive collaboration among many public organizations of various administrative levels, competences, and mentalities, from one or more countries, for the design and implementation of effective public policies for managing these problems. Additionally, in most cases, the participation of representatives of citizens and enterprises is necessary as well. For example, the design and implementation of environmental policies for a wider area, such as for a wider river basin or lake area, requires extensive collaboration among several public organizations of different administrative levels, competences (e.g., concerning environment, agriculture, forests, industry, tourism, etc.), and mentalities. These public organizations initially have to exchange experiences, knowledge, and views on the environmental problems of the area. Afterwards, they have to design collaboratively effective policies for managing these problems; then follows the collaborative implementation of these policies, which very often includes long and complex interorganizational processes, for example, to grant various licenses for projects or activities having an impact on the environment of this area, and so forth. Also, periodic evaluations of these policies and their implementation are required in order to identify weaknesses, and if necessary, to proceed to corrective actions. The growing importance of the various types of public sector interorganizational networks (e.g., policy networks, service delivery networks, knowledge networks, etc.) have been strongly emphasized in the relevant research literature (e.g., Dawes, 2005; Provan & Milward, 1995; Raab, 2002, etc.), which investigates their basic characteristics, forms, performance, and critical success factors.

However, the G2G collaboration required for the design of effective public policies today is based mainly on physical meetings of various interorganizational physical committees, which are costly in terms of time and money, and very often inefficient, unproductive, and slow. Also, the G2G collaboration required for the implementation of these public policies and the production and delivery of the corresponding services is based on the exchange of information among the involved public organizations using "paper documents", which is costly, slow and inefficient as well. Therefore, it is of critical importance to support electronically the various types of G2G collaboration required for the design of effective public policies (strategic level) and the implementation of them (opera-

tional level). Moreover, the realization of the highly innovative vision of integrated electronic service delivery (online one-stop government) (Kraaijenbrink, 2002; Wimmer, 2002), through virtual public agencies, these terms denoting single access points to many related electronic transactions and services—usually the ones required in a particular life event of the citizens or enterprises, or by a particular group of citizens or enterprises—which are managed by several different public organizations, will necessitate extensive electronic support of G2G collaboration (mainly at the operational level).

In this direction, this article presents an integrated G2G collaboration platform, which has been designed, developed and evaluated in the project ICTE-PAN (Methodologies and Tool for Building Intelligent Collaboration and Transaction Environments for Public Administration Networks) of the Information Society Technologies (IST) Program of the European Union (IST-2001-35120) (http://www.eurodyn.com/icte-pan). In particular, the next section provides the background concerning the electronic support of G2G collaboration. Then the architecture and the basic components of this G2G collaboration platform are presented. In the final two sections the future trends and the conclusions are outlined.

## BACKGROUND

The development of information systems (IS) which can electronically support the collaboration (e.g., the communication, the interaction, the information or knowledge exchange, the coordination of actions) among the members of a team, who can be either remote or at the same place, both at the strategic and at the operational level, has attracted considerable research interest. This research has resulted in the development of various types of software tools, which can electronically support various types of collaboration, collectively referred to as groupware (Beaudouin-Lafon, 1999; Lococo & Yen, 1998; Ehrlich, 1999; Munkvold 2003a, b; Thomas, 1996), and has given rise to a new research field, referred to as computer-supported collaborative work (CSCW), dealing with the exploitation of ICTs for supporting and enhancing collaboration.

According to Ehrlich (1999), groupware generally supports one or more of the following four basic elements of the teamwork: communication, meetings, information sharing, and coordination of actions. As main groupware tools for supporting communication he mentions videoconferencing, shared whiteboard, group editors, shared documents-applications, media spaces, and e-mail. As groupware tools for supporting meetings, he reports various kinds of software that allow participants to enter ideas and comments on the ideas of the other participants, vote on various issues, and so forth, such as the electronic meeting systems. Information sharing is usually based on enabling any member of the team to store a message or document in a database, which is accessible by all the other members of the team. As main applications for this purpose he mentions electronic bulletin boards and document repositories. Finally as the main groupware applications for supporting the coordination of the actions of the team members, he mentions Workflow Management Systems and Calendar & Scheduling Systems.

In Figure 1 we can see another classification of groupware tools (Lococo & Yen, 1998), which is based on the following two dimensions: (1) whether they support collaboration among participants located at the same place (collocated) or at different places (remote) and (2) whether they support synchronous or asynchronous collaboration.

Groupware tools can be also classified according to the type of collaboration they support into the following two categories:

a. Structured collaboration support tools, such as the workflow management systems
b. Unstructured collaboration support tools, for example, the group decision support systems, the forums, and so forth

Moreover, in this area considerable research is conducted concerning the effectiveness of computer supported collaboration and its critical success factors, especially in the case of virtual teams with remote participants (Furst et al., 1999; Larsen et al., 2002; McDonough et al., 2001; Munkvold, 2003a). The main conclusion of this research is that the effectiveness of computer supported collaboration depends both on technological factors, mainly associated with the capabilities and the appropriateness of the utilized ICT, and also on non-technological factors—mainly on organizational, structural, process, and human factors. The most important of these non-technological factors are the design of the team, the organizational context in which it works, the synergy that will be developed among its members, the processes that will be followed by the team and the material resources available to it. Additionally, of critical importance is the planning and organization of the implementation project.

Of critical importance for the electronic support of the collaborative design of public policies, that is, of the G2G collaboration at the strategic level, can be the group decision support systems (GDSSs). As GDSS is defined, it is a collaboration support environment, which supports group decision making processes, aiming at improving the productivity and effectiveness of decision making, by facilitating the exchange of information and knowledge among the members of the group, speeding up the decision-making process and improving the quality of the resulting decisions (Lewkowicz & Zacklad, 2002; Turban & Aronson, 2001). Most GDSSs include a forum component, which enables a synchronous or asynchronous electronic discussion on a specific topic among several participants: each participant can enter an opinion on this topic, and also read the opinions that have been entered by the other participants on the same topic. Also, some Forums additionally offer to each participant the capability to enter an opinion on another opinion that has been entered by another participant on this topic (multithread electronic discussion). In this way, a high level of interaction and collaboration among the participants can be achieved.

At the operational level, of critical importance for the electronic support of the G2G collaboration required for the efficient and effective implementation of public policies (e.g., for the production and delivery of the corresponding services, the examination of applications for permissions or allowances, the enforcement of laws, and so forth) can be the workflow management systems (WFMSs). According to the Workflow Management Coalition (WfMC) (http://www.wfmc.org), a non-profit, international organization of WFMS vendors, users, analysts and university-research groups aiming at the promotion and development of these systems, a WFMS is defined as a system offering the capability to define, manage and execute workflow processes through the execution of software, whose order of execution is driven by a computer representation of the workflow process logic (WfMC, 1995). A typical workflow process consists of a predefined sequence of steps (called activities); each of them is in general executed by one or more human individuals (called "actors") who can be supported by software applications. The WFMSs in general offer three categories of functionality: (1) build-time functions (they concern the definition and modelling of the specific workflow process we intend to support with the WFMS), (2) run-time control functions (they concern the automation and management of the workflow process for each individual work case and the sequencing of the required workflow process activities, based on the above workflow definition model), and (3) run-time interaction functions (they concern the interaction with human individuals and software applications for each individual work case). The achievement of interoperability between different WFMSs has been the basic target of several technical committees of the WfMC, which have produced several frameworks and specifications for this purpose (e.g., WfMC, 1996, 2001). However, these WFMS interoperability frameworks and specifications have not yet been used sufficiently in practice. For this reason the interoperability between WFMSs of different public organizations, which is often required in order to support the operational collaboration between them, still presents significant complexities, difficulties and costs.

In general, it is common that for the electronic support of G2G collaboration at the operational level some degree of interoperability between the internal ISs of several public organizations is required. There are many definitions of the concept of interoperability. According to Guijaro (2004), interoperability between two ISs is defined as the capability to exchange interpretable data and functionality between them. The European Interoperability Framework (EIF) (European Commission, 2004a, 2004b) adopts a wider definition of interoperability, which includes not only ISs, but also the business processes they support: "Interoperability means not the ability of information and communication technology (ICT) and of the business processes they support to exchange data and to enable the sharing of information and knowledge". Although initially the interoperability efforts were focused mainly on technical issues (aiming at achieving technical interoperability), it was gradually realized that in many cases it was necessary to address as well difficult issues associated with the meaning (semantics) of the exchanged information (for achieving semantic interoperability) and also with the interconnection of the corresponding business processes of the cooperating public organizations (for achieving business processes interoperability).

Many countries in order to facilitate and reduce the costs of achieving interoperability between the ISs of their public organizations (mainly for the integrated delivery of electronic services based on a life-event approach) have developed interoperability frameworks, which include guidelines, specifications and standards concerning the ways of interaction between ISs. As a typical example we can mention the E-Government Interoperability Framework (e-GIF) of the United Kingdom (Cabinet Office—United Kingdom, 2005a, 2005b). It "defines the essential prerequisites for joined-up and Web-enabled government" and includes "technical policies and specifications for achieving interoperability and ICT systems coherence across the public sector", mainly concerning four basic areas: interconnection, data integration, content management metadata, and e-services access. It is supplemented by E-Government Metadata Standard (based on Dublin Core), Integrated Public Sector Vocabulary/Government Category List, E-Government Schema Guidelines for XML, Government Data Standards Catalogue, and Security Policy Framework (http://www.govtalk.gov.uk). Similar interoperability frameworks have been developed in other countries as well, such as Germany (http://www.kbst.bund.de), France (http://www.adae.gouv.fr), Greece (http://www.infosociety.gr), and so forth. Between them there is a large degree of conformity concerning the technical standards they have selected; they are all based on the technologies of the Internet and the World Wide Web.

The achievement of interoperability between the ISs of public organizations of different countries is much more difficult and costly, due to their different organization, administrative culture, legal framework, business processes, and so forth. In this direction the European Union has developed the European Interoperability Framework (EIF) (European Commission, 2004a, 2004b), aiming at facilitating and reducing the cost of achieving interoperability between ISs of public organizations of its member states at the technical, the semantic and the organizational level, both within and across different policy areas, and at supporting the implementation of pan-European e-government services. Also, in the USA the Federal Enterprise Architecture Framework has been developed (Bellman & Rausch, 2004; Office of Management and Budget—USA, 2005), in order to facilitate the horizontal (cross-federal) and the vertical (federal, state, and local) integration of ISs of public agencies (and in general the cross-agency collaboration), and also reduce overlapping concerning ICTs. It consists of five reference models: the performance reference model, the business reference model, the service component reference model, the data and information reference model, and the technical reference model (http://www.whitehouse.gov/omb/egov).

However, most of these public administration interoperability frameworks have not yet been used sufficiently in practice, and need further elaboration and development; therefore the interoperability between ISs of public organizations still presents quite significant complexities, difficulties, and costs.

## AN INTEGRATED G2G COLLABORATION PLATFORM

In the ICTE-PAN project (http://www.eurodyn.com/icte-pan) has been developed an integrated G2G collaboration platform named MERMIG (in Latin characters the Greek word for "ant") (http://www.mermig.com). Its design has been based on one hand on the study of the relevant literature on groupware tools and CSCW, and on the other hand on, the detailed analysis of the requirements posed by four representative real-life pilot projects, which were implemented as part of the ICTE-PAN project, aiming at the electronic support of collaboration in four European public organizations (National Environment Research Institute of Denmark, Ministry of Environment of Lower Saxony, Province of Genoa, University of Aegean) which participated in the project as user-partners:

- the (less detailed) examination of the requirements posed by 150 additional collaborative processes from various public organizations of European Union member states,
- the relevant recommendations, standards and specifications of many European Commission Programs, such as the Interchange of Data between Administrations (IDA) Program, and so forth.

A basic objective of this platform was to support the required G2G collaboration throughout the lifecycle of a public policy, both at the strategic level (collaborative design of public policy) and at the implementation level (collaborative implementation of public policy). In this direction for the design of the platform was taken into account the theoretical framework for public policies proposed by OECD (2003), which considers the whole policy making process as a cycle of policy preparation, implementation, and evaluation activities, consisting of five stages: agenda setting, analysis, policy creation, implementation, and monitoring. Also, we adopted a knowledge-based public policy and decision-making view based on the theoretical framework proposed by Holsapple and Whinston (1996). According to this view, public policies, and decisions are considered as pieces of descriptive or procedural knowledge referring to an action commitment for managing a social problem; therefore the public policy

*Figure 2. Discussion tree in the consultation module*

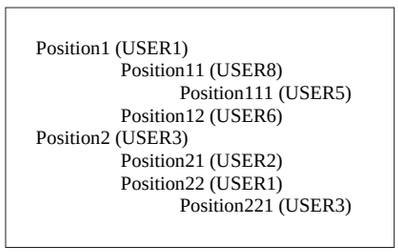

*Figure 3. Consultation ontology*

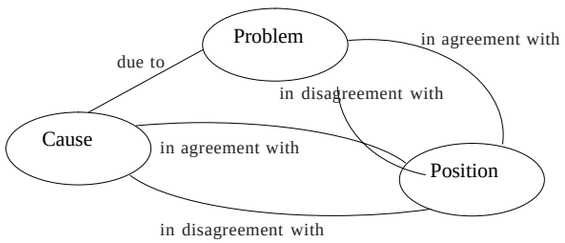

and decision making process can be viewed as a collaborative production of new knowledge, providing a refined understanding of the problem or evidence justifying or challenging alternative actions that might be followed.

Based on these requirements and on the above theoretical frameworks, the modules of this G2G collaboration platform and their functionality were designed, taking into account the features of the existing groupware tools, and also designing innovative features where necessary. The main modules/services of the platform are:

1. Consultation
2. Structured consultation (based on a predefined ontology)
3. Extended workflows management
4. Extended workflows modeling
5. Document management
6. Content management
7. Advanced search
8. Calendar

In particular, the G2G collaboration platform offers initially the capability to create a virtual team, define its members, create its virtual workspace with all the above modules/services (or some of them), and then define for each member his/her access rights to these modules/services. Very important for the support of G2G collaboration at the strategic level, especially for the agenda setting, analysis, policy creation, and monitoring stages, is the consultation module. It offers the capability to organize an electronic consultation on a topic: in the window of the consultation each member of the virtual team can enter "positions" (e.g., views, opinions, etc.) on the topic of the consultation, read the positions entered by the other members on this topic, then on each of these positions enter new positions, and so on (multithread electronic discussion). In this way a discussion tree is created, similar to the one shown in Figure 2, consisting of interconnected positions of the participants, which constitutes a synthesis and visualization of their experiences and knowledge on this topic.

However, from the requirements analysis it was concluded that very often a higher level of organization, structure and focus is necessary in public policy consultations in the public administration, especially if the topic is highly specialized and complex, and the participants are heterogeneous (e.g., of different background, mentality, etc.). For this purpose an innovative structured consultation module was developed offering to each member the capability to enter semantically annotated positions, based on a predefined consultation ontology. According to Gruber (1993) an ontology is defined as a "formal explicit specification of a shared conceptualization". Usually an ontology constitutes an abstract conceptual model of a particular domain, which identifies the kinds of entities existing in this domain and the kinds of relations among them. As consultation ontology is defined the set of the allowed kinds of positions that the participants can enter in a consultation, and of the allowed relations among them. For example, in a structured consultation on the environmental situation of an area, the participants may be allowed to enter only the following three kinds of positions: problems (i.e., environmental problems of the area), causes of each of these problems, and positions in agreement or disagreement with these problems or causes. In this structured consultation the consultation ontology is shown in Figure 3.

The discussion tree that will be gradually created from this structured consultation will be similar to the one shown in Figure 4. In this way we can achieve a higher

*Figure 4. Discussion tree in the structured consultation module*

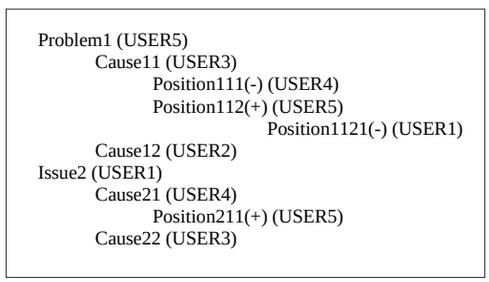

*Figure 5. Ontology of public policy design and implementation*

**Legend**
gsqr = generalise, specialise, question-replace
soc = supports, objects-to, comments-on

level of discipline and homogeneity in the contributions of the participants, who are often of different background, experience and mentality, usually belonging to several different public organizations from the same country or even from different countries, and therefore a higher level of organization, structure, focus and effectiveness of the consultation. Moreover, this semantic annotation of the contributions of the participants enables a better processing, exploitation and management of them, and in general sets the foundation for a more efficient knowledge management.

In order to support and guide the definition of the specific ontology of a structured consultation, an ontology of public policy design and implementation has been developed and incorporated in this Structured Consultation module (Loukis, 2004). This ontology consists of the main concepts (that is, kinds of discussion elements) used in public policy design and implementation, and the relations among them. It is shown in Figure 5. It is an "horizontal" ontology, since it can be used in all thematic areas of government activity. For the development of this ontology we have taken into account the ontologies of existing argumentation systems, such as the gIBIS (Conclin, 2003; Conclin & Begeman, 1988, 1989) and the HERMES (Karacapilidis, 2000), and we have complemented them with additional concepts and relations in order to cover the whole public policy lifecycle.

For defining the specific ontology of a new structured consultation we can use an appropriate small subset of the concepts and relations of this ontology of public policy design and implementation, possibly in combination with additional concepts and relations not belonging to this ontology. In general, a structured consultation in order to be efficient and effective should focus on not more than 3-4 concepts and 5-6 relations among them, since more concepts and relations in the same structured consultation might cause confusion and result in inefficiency and ineffectiveness.

The MERMIG platform also supports the required G2G collaboration at the operational level for the implementation of public policies (e.g., for the production and delivery of the corresponding services, the examination of applications for permissions or allowances, the enforcement of laws, etc.), which is usually based on lengthy and complex processes, with the extended workflows modeling and the extended workflows management modules. These two modules offer the capability initially to define/model (in XPDL (XML Process Definition Language) (Workflow Management Coalition, 2005) and then to automate and manage an extended workflow, which includes both single person activities (i.e., activities executed by only one person) and collaborative activities (i.e., activities of unstructured or structured consultation type, in which several persons participate). In this way the concept of the classical workflow, which consists only of single person activities, is extended in order to cover administrative processes including various collective decision-making and consultation phases (e.g., performed by various types of committees), which are quite usual in public administration for planning, budgeting, granting licenses/permits, and so forth. For example, the process of examining applications for granting licenses/permits for significant activities of citizens or enterprises usually includes initially a number of single person activities (e.g., examination of the application by a number of public servants from administrative, financial, technical, and other viewpoints), then it includes some consultations (e.g., among the Directors of the main public organizations involved, etc.), then some more single person activities (e.g., detailed examination of some critical aspects of the application, composition of administrative decision documents, etc.), and finally one or more consultations (e.g., for final decision making). Also, activities planning and budgeting in public administration very often includes a sequence of consultations with many participants, usually in combination with some single person activities between them.

The extended workflows modeling and management modules enable the electronic support of a very broad range of big and complex G2G collaboration tasks of various degrees of structure, which can well be modeled as extended workflows consisting of single person activities and collaborative activities. Each of these activities can invoke another module of the platform, such as the consultation module, the structured consultation module, or other modules (e.g., the document manager, the content manager, the calendar, etc.), or even other external applications.

It should be emphasized that these two modules of MERMIG offer the capability of hosting and implementing big and complex G2G inter-organizational processes (with some activities performed by public organization A, some other activities by public organization B, etc.), totally on this platform (by giving appropriate access to it to all the involved public organizations, so that each of them can access only the activities). This centralized approach offers the big advantage of avoiding the complexities, difficulties and costs we would face by following a more decentralized approach for achieving interoperability among the heterogeneous IS of all the involved public organizations. These complexities, difficulties and costs are, as mentioned in the previous section, still quite significant, despite the various interoperability frameworks that have been developed. However, if such a centralized approach is not feasible (e.g., for legal, political or administrative reasons), and a more decentralized approach is necessary, then it is possible to interconnect the platform to existing IS of the cooperating public organizations easily and with minimal effort and cost, due to the inherent interoperability capabilities of the platform (since its design has been based on the service-oriented architecture (SOA) paradigm, and for its implementation has been used the J2EE Connector Architecure (JCA)).

## FUTURE TRENDS

Already two applications/evaluations of this G2G collaboration platform have been performed. The first of them was in the four real-life pilot projects, which were implemented as part of the ICTE-PAN project, as mentioned in the beginning of the previous section, aiming at supporting collaboration in the four European public organizations (National Environment Research Institute of Denmark, Ministry of Environment of Lower Saxony, Province of Genoa, University of Aegean), which were the user partners in this project. The corresponding evaluation was based on the ISO/IEC 14589 and ISO/IEC 9126 standards (Loukis et al., 2005). The second one concerned an electronic consultation on a public policy issue, and the corresponding evaluation was based on the Technology Acceptance Model (TAM) (Karacapilidis et al., 2005). In both these applications the results of the evaluations were positive.

Moreover, this platform is already used in several other projects, which will give more opportunities of additional evaluations in real-life G2G collaboration types. The most important of these projects are (http://www.mermig.com):

- The IST project SecurE-Justice (http://www.secure-justice.org), which aims at creating a secure environment for electronically supporting the collaboration among the numerous police and judicial au-

thorities involved in a penal trial, in the whole lifecycle of a criminal case (including the phases of investigation, collection of evidence, debate, and judgment)
- The IST project Intelcities (http://www.intelcities.com, intelcities.iti.gr/intelcities), which aims at providing electronic support of the required collaboration among all the public authorities involved in the management of a big city, such as city authorities, regional agencies, national government agencies, utility providers, transport services providers, and so on (and also nongovernment organizations, citizens, enterprises, etc.)
- The project of developing an integrated environment for supporting the required collaboration among the Departments of the General Prosecutor's Office in Georgia

Concerning the area of electronic G2G collaboration, considerable research is in progress, mainly focused on supporting the G2G collaboration at the operational level, which is expected to increase in the future. It is dealing with understanding the numerous technical and nontechnical issues faced for achieving G2G operational interoperability at the IS and at the business process level, elaborating solutions for them and developing interoperability frameworks, and also evaluating their applicability in real-life situations. However, we believe that more research is required in the future on the much more difficult and demanding problem of providing electronic support of G2G collaboration at the strategic level for the design of public policies.

## CONCLUSION

In this article initially the fundamentals of electronic collaboration are outlined. Then the G2G collaboration platform MERMIG is presented, which has been developed in the ICTE-PAN project, and can electronically support a wide range of G2G collaboration forms, virtual committees and inter-organizational networks in the public administration. This platform possesses significant innovative features and capabilities:

1. It can support G2G collaboration both at the strategic level (for the design of public policies) and at the operational level (for the implementation of public policies).
2. It includes a module for supporting structured consultations, based on predefined ontologies.
3. It includes modules for modeling, automation, and management of extended workflows.
4. It incorporates an ontology of public policy design and implementation.

A more detailed description of this G2G collaboration platform has been published in other papers (Loukis & Kokolakis, 2003; Loukis & Kokolakis, 2004).

## KEY TERMS

**Computer-Supported Collaborative Work (CSCW):** A research field dealing with the exploitation of ICTs for supporting and enhancing collaboration among the members of a team (remote or collocated) who are working for the achievement of a shared objective.

**Extended Workflow:** A workflow consisting of both single person activities (i.e., activities executed by only one person) and collaborative activities (i.e., activities of unstructured or structured consultation type, in which several persons participate).

**G2C (Government-to-Citizen) E-Government:** Use of ICTs for offering to the citizens the capability to communicate and perform their transactions with the public administration (e.g., various declarations, applications, etc.) electronically, over the Internet or other electronic channels.

**G2B (Government-to-Business) E-Government:** Use of ICTs for offering to the businesses the capability to communicate and perform their transactions with the public administration (e.g., various declarations, applications, etc.) electronically, over the Internet or other electronic channels.

**G2G (Government-to-Government) E-Government:** Use of ICTs for supporting the collaboration (e.g., the communication, the interaction, the information/knowledge exchange, the coordination of actions) among public organizations for achieving a shared objective, both at the strategic level (e.g., for the collaborative design of effective public policies) and at the operational level (e.g., for the collaborative implementation of public policies and provision of corresponding services to citizens and businesses).

**Group Decision Support System (GDSS):** A collaboration support environment, which supports group decision making processes, aiming at improving the productivity and effectiveness of decision-making, by facilitating the exchange of information and knowledge among the members of the group, speeding up the decision-making process and improving the quality of the resulting decisions.

**Groupware:** Software tools, which can electronically support various types of collaboration (e.g., communication, information/knowledge exchange, interaction, coordination of actions) among the members of a team (remote or collocated) who are working for the achievement of a shared objective.

**Interoperability:** the capability to exchange interpretable data and functionality between ISs and the business processes they support.

**Interoperability Framework:** A set of guidelines, specifications and standards concerning the interaction between ISs of different organizations, which aims at facilitating the interoperability between them.

**Ontology:** A formal explicit specification of a shared conceptualization; usually it constitutes an abstract conceptual model of a particular domain, which identifies the kinds of entities existing in this domain and the kinds of relations among them.

**Structured Consultation:** A consultation in which each participant is allowed to enter only some pre-defined kinds of semantically annotated positions, with only some pre-defined allowed relations among them (defined by the consultation ontology).

**Workflow Management System (WFMS):** A system which offers the capability to define, manage and execute workflow processes through the execution of software, whose order of execution is driven by a computer representation of the workflow process logic.

## INTRODUCTION

New public management (NPM) conceptualised public administration as a business, to be managed with business-like techniques. Since services had to be assessed by the criteria of quality, efficiency, and satisfaction of citizens, the public sector had to reorganize its processes. As strong emphasis was on the services, improving their delivery was expected to facilitate achieving the above criteria. The terms of the NPM approach such as "customer focus, managing for results, and performance management" have become part of the standard language of public administration (Ali, 2001; Bekkers & Zouridis, 1999; Crossing Boundaries, 2005; Spicer, 2004).

## BACKGROUND: ICTS IN IMPROVING PUBLIC SERVICE DELIVERY

Information and communication technologies (ICTs) are considered to raise the speed and quality of the public service delivery. Expected increase in public access to government services and information leading to more openness, facility for remote communication and transactions, scope for citizens' virtual participation in democratic processes, reduced costs of public services, rebuilding relationships between governments and citizens, and enhancing the efficiency and effectiveness of delivery so that services can be accessed by citizens at any place/time were the reasons to embrace the ICTs (Ali, 2001; Bekkers & Zouridis, 1999; Phythian & Taylor, 2001). Many developed countries have decided to utilize ICTs for delivery of public services. The Canadian government wanted to achieve the status of the government most connected to its citizens, enabling them access to all government information and services online at the time and place of their choosing by 2004 (Government of Canada, 1999). The Prime Minister of the United Kingdom set a target of making all central government public services available over the Internet and the Web by 2005 (National Audit Office, 2002). Australia had set a more ambitious target for electronic service delivery (ESD) of 100% of all appropriate services electronically on the Internet by 2001. The United States and Germany were rated highly for interactivity and transparency of government Web sites. Similar to the above, various governments have set targets of interest in improving public service delivery through electronic channels has been rising.

## ESD—AN OVERVIEW

With regard to transactions over the Internet, viz. the ESD, there are different definitions. The e-Europe 4-stage framework defines the transactions as follows (Scottish Executive, 2004).

- Online information about public services
- One-way interaction, for example, downloading of forms, discussion forum, e-mail
- Two-way interaction, for example, forms returned electronically, e-mail response
- Full online transaction, for example, full electronic interaction including order, delivery, payment, and posting of transactions

West (2004) states that features are defined as services only if the entire transaction can occur online … if a citizen has to print out a form and then mail it back to the agency to obtain the service, we do not count that as a service that can be fully executed online. Searchable databases count as services only if they involved accessing information that results in a specific government service response" (p. 5). He assessed that North America (including the United States, Canada, and Mexico) offered the highest percentage of online services with 53% of sites having fully executable online services. The Pacific Ocean islands (43%), Asia (30%), Western Europe (29%), and the Middle East (19%) were the other regions, in that order. Of the 198 nations analyzed by his study, Singapore had the largest number of services, with an average of 9.5 services across its various government agencies. Bahrain (5.0 services), China (3.2), the Bahamas (3.0), the United States (2.9), Hong Kong (2.5), Australia (2.3), and New Zealand (2.1) were notable countries.

Ronaghan (2002) feels that "all government services can be classified under one of three fundamental categories: informational, interactive, and transactional" (p. 8). As services are the public face of governments, providing the citizens an efficient and alternative medium to interact with the service providers became the primary objective of e-government initiatives. For this article, Ronaghan's classification is used.

## CRITIQUE OF ESD

It has been cautioned that the Internet is just another medium for service delivery. Lack of connectivity to the Web, inferior technology, limited e-mail capacity, and absence of intranets have to be addressed before realistically expecting online service delivery to be effective. Ronaghan (2004) considers that, "online service delivery should be thought of as complementary rather than accepting the more popular view that it will ultimately replace many traditional channels for public service delivery" (p. 4). Bekkers and Zouridis (1999) have reservations on the use of ICTs for service delivery due to democratic implications. They question "the consumer model of democracy and its contribution towards improved democratic relationships between citizens and public administration" (p. 190). There has been a concern among "academics, activists and elected officials that government Web sites might focus more on providing services, and less on facilitating civic involvement. This type of service orientation, they argue, treats citizens as consumers rather than partners in government, and thus inhibits public engagement with the nation's political environment" (Ronaghan, 2002, p. 9).

There are criticisms that in order to catch up with the private sector, the public sector has largely mimicked what the former has done in e-commerce and adopted it as a model for delivering electronic services (Kaylor, Deshazo, & Van Eck, 2001). The other criticism is that e-government focuses upon relatively simple transactions. According to Anttiroiko, "the traditional representative system gives citizens two basic roles, those of voters and service users." He hopes that the experience gained in Finland will certainly help when designing new forms of citizen-centred e-governance not only in Finland but also in other advanced information societies (Anttiroiko, 2004). Lenk (2002) points out that "the activities of public sector organisations are much more diverse than a focus on 'services' suggests" (p. 88). We hope that the widespread concern expressed by scholars on the hitherto "service users" dimension of the citizens in e-governance projects and confining the e-services to less complex services would result in due attention for the role of the citizen as "voter." Similarly the complex nature of services needed by the citizens might be addressed while implementing e-governance across the globe.

## E-GOVERNANCE IN INDIA

India, a leading advocate of e-governance in the developing world was assessed to possess an e-government index of mere 1.29, indicating a minimal e-government capacity (Ronaghan, 2002). E-governance efforts in India so far have been targeted towards higher-level government organisations. A few local governments have adopted e-governance. Norris and Moon (2005) noted that "relatively few governments in the United States at any level and of any size have developed truly sophisticated e-government offerings. Most e-government in the United States today is principally informational—that is, it involves the one-way transmission of information from government to citizens, usually by way of static information pages ("brochureware"), downloadable forms, and e-mail (p. 64). Earlier, Edmiston (2003) acknowledged that in the United States "most state and local government Web sites today remain in this (publishing) stage. Currently, information tends to be quite substantial, but the ability to interact with government online, which is the next step, is much more limited, especially at the local level" (p. 26).

## LOCAL E-GOVERNANCE

Regarding e-government in The Netherlands, Leenes and Svensson (2002) stated that "large national organisations implement Electronic Service Delivery (ESD) fairly successfully, while municipalities are slow to adopt ESD. This is a pity, since municipalities account for over 70% of the public services. Carbo & Williams (2004) said that around 80 % of citizens' transactions are occurring at the local government level. With regard to the United States, Norris, and Moon (2005) stated that "grassroots governments are closest to citizens and deliver the greatest number of services directly to the people" (p. 65). However, they claimed that even in United States, "local government Web sites, measured by the number of online transactions available, are not particularly sophisticated" (p. 75). In India too, only a few local governments have adopted e-governance and are delivering services electronically. The primary cities of New Delhi, Mumbai, Kolkota and Chennai are nowhere near these few cities. They have Web sites, which fall under "brochureware" and contain a substantial number of "dormant" or "desert sections."

Some of these Web sites can also be termed "static Web sites." Thus, they fall under the category of "First generation e-government."

Hence, the efforts made independently by a secondary city, Visakhapatnam, assume significance. Its achievements in ESD and e-democracy attracted the attention of Steven Clift, a well-known e-democracy proponent (Clift, 2003). A profile of this city's ESD would enable other local governments to make informed decisions about the services that a municipality can deliver using electronic channels.

## VISAKHAPATNAM MUNICIPAL CORPORATION (VMC)

Visakhapatnam is the second largest city in the State of Andhra Pradesh. The municipal authority started in 1858, is covering an area of 111.60 sq.kms serving 1.2 million people. This city government, VMC, is considered as a pioneer in implementing e-governance among the local governments in India (Venkatakrishnan, 2003).

Visakhapatnam's e-governance efforts revolve around its dynamic Web site. This transactional Web site claims that information technology can play a major role in improving the delivery of services, and Information Technology is all about connectivity. Connectivity brings proximity, which makes the delivery of services better. In the context of the Visakhapatnam Municipal Corporation, there is a tremendous possibility for utilising the Information Technology tools for providing better services to the citizens of the city. The Municipal Corporation of Visakhapatnam envisages delivering a host of civic services by using the Information Technology platform" (http://www.visakhapatnammunicipalcorporation.org/Saukaryam/Saukaryamentails1.asp).

## SCOPE FOR CITIZENS' PARTICIPATION

The Web site mentions that CITIZENS are the partners in the vision of delivering services electronically. This displays the VMC's attitude in treating the citizens as decision makers rather than mere recipients of services. The Web site has provisions for a citizens' forum, providing feedback to the city administration, chat facility, contacting the municipal commissioner, and conducting polls on various civic issues. A recent posting on the citizens' forum goes to the extent of questioning that the complaints and suggestions section of the Web site is down these days purposefully. There was also a criticism by one of the complainants in this citizens' forum that the issue brought to the notice of the city administration by him long back still remains unattended. Displaying such postings prominently in the Web site demonstrates the healthy democratic practices followed by VMC. A section of the Web site invites suggestions from the citizens on various issues such as sanitation, street lighting, taxation, roads, administration, water supply, births/deaths, beautification, city planning, and others. In addition to the prize-winning suggestions, a few other appreciable entries are exhibited in this Web site. A citizen charter outlining various responsibilities and functions of VMC and aiming at "streamlining public service and informing the citizens of their rights and responsibilities" (http://www.visakhapatnammunicipalcorporation.org/citizenscharter/citizenscharter1.asp) too exhibits the citizen centric nature of the government. These provisions to a large extent counter the criticisms that there is limited scope for the citizens to perform their role as voters in governance systems adopting ESD.

## INFORMATIONAL SERVICES

In India a large number of governments (national, provincial, and local) are operating. Therefore, availability of correct information itself ensures the transparency and leads to good governance. In its Web site, VMC provides details such as a procedure for obtaining a building permit, the time limit for grant or refusal of a building application, requirements for sites and factory/industrial, educational, institutional and public office, commercial/mercantile and residential buildings, security deposits, lighting and ventilation requirements, mandatory inspections, and issue of a fit-for occupation certificate by local authorities. These rules are very much relevant for any existing or proposed construction and have been arranged in a sequential order on the Web site. It makes it easier to navigate.

Sanction of building permission is an area where citizens faced innumerable problems from the street-level bureaucracy of the local governments across the country. In VMC, once an application is submitted for building permission, a number is allotted to the application. Using this number, any applicant can log into the Web site and check the status of the application. This might reduce the number of trips one has to make to the local government office to get the permission for building construction. A summary of pending building plan proposals can be obtained through this Web site. Anyone can use this information, especially the elected representatives to make the officials of the VMC more accountable by raising the issue in the council meetings. Similarly, around 120,000 property and water tax assessments in the city have been computerized. Anyone can visit the Web site

and get details of calculations made by the VMC to arrive at tax dues by entering the relevant unique assessment number. This also ensures transparency.

The procedure for valuation of property tax has been prominently provided in the Web site. Prevailing rates of taxation, calculation methodology and examples have been linked to this page making the information much easier to obtain. This reduces the scope of manipulation by the lower level bureaucracy who might harass the citizens for pecuniary benefits. Reports on ward wise collection of various revenues can be generated from the Web site. They can be compared with the ward wise works and allocation of resources. The demand collection and balance (DCB) statement for house tax can be generated from this Web site for all city wards. (http://www.visakhapatnammunicipalcorporation.org/PropertyTax/dcb.asp). This statement, showing details of outstanding dues in each ward, would enable the city administration to concentrate on lagging wards.

The search for building plans approved by the VMC year-wise or by using the building application number or applicant's name or location of the building would display the specifications, approved plan details and other information such as applicants and architects. Approved layouts for housing are also mentioned in the Web sites. This information on building plans and layouts are a boon to prospective purchasers of land, apartments, and buildings.

Information regarding officers responsible for various functions and their contact details provided in the Web site enable the citizens to contact the concerned officer directly to get any service provided by the VMC. Information about water supply, an important service provided by the local governments in this part of the world, is available in the Web site. This includes important aspects such as status of water supply, distribution timings in various locations in the city, and names of persons concerned with water supply. A click on any ward in the map displays the water supply, public health and sanitary services arrangements, and location of various public facilities in the ward.

Further, tender notices issued by the VMC are available on the Web site, department wise (civil, electrical, health, etc.) and class wise. Efforts have been made to electronically procure the services needed by the VMC in a transparent manner by displaying details such as estimated cost, sanction date, contractor name, and stage of work for various works. The search facilities in the Web site would enable anyone to find out the works in various wards by different departments such as civil, electrical, mechanical, underground drainage system, and water supply. The number of the work, its name, estimated cost, sanction date, work order date, project completion date, name of the contractor and stage of work, can be learned. The Web site clearly acknowledges the citizens' right to information by stating that "Every citizen has a right to know about the functioning of the government machinery as it is directly related to him ... The Web site will give online information related to how your property tax is arrived at, related procedures and Government rules, Building rules, regulations etc. and anything you do not have an access to, but need nevertheless" (http://www.visakhapatnammunicipalcorporation.org/Saukaryam/yourrighttoinfor9.asp). The spirit of openness and transparency demonstrated by these statements have been matched by the display of information in the Web site.

## INTERACTIVE SERVICES

Various sections of the Web site provide facility to contact the Commissioner (CEO of the Corporation) and Mayor on any subject related to the corporation. A page about the citizen forum helps any citizen in posting a message about any aspect of the city. Polls on various issues of urban governance have been conducted so far through this Web site. There is an upward trend in the number of voters participating in these electronic polls. Chat facilities are made available for enabling interaction among citizens.

## TRANSACTIONAL SERVICES

Transactions that can be completed through the Web site or through the nodes available in the civic service centres or at the banks connected with the server of VMC can be termed as transactional services. In the case of VMC, online facilities for payment of property tax, water tax, registration of birth and death by individuals and hospitals, learning the status of the building plan/application, registration of complaints/suggestions, and learning their status can be considered as the major transactional services. In online counters of various banks, anybody can pay the dues to the VMC by presenting the relevant assessment number. Once payment is made in the bank connected to the main server at VMC, necessary updating is carried out automatically at the main server.

The possibility to make payments at the banks and citizen service centres operated by the VMC enables citizens not having access to the Internet and it addresses the problems of "digital divide." Moreover, online payments can be made using the credit cards of various banks. Such facility is extended to the registered users only with a view to serve the genuine users. Similar registration is necessary for birth and death registrations and for the home delivery of these certificates. Details of online complaints would be forwarded to the concerned

officer for immediate attention. They would also reach the database for monitoring the grievances settlement.

## OTHER FEATURES

The VMC Web site has been effectively used for campaigning on civic issues such as rain water harvesting, public participation in city sanitation, greening the city, adoption of various projects and the save water campaign. Provision of information by topic has made it simpler and the Web site is easily navigable. Every single page also has links to relevant subtopics. For instance, the page on birth registration will be having links to related aspects like a note on birth and death registrations, rules relevant to the registration, and download of various forms. The volume of services such as online payment through the banks is increasing continuously since the introduction of the facility in December 2000. The number of banks involved and transactions and the amount remitted in these counters show a steady increase. Even on Sundays, payments due to the VMC have been made through bank counters, which operate on holidays as well. Further, the number of visitors to this Web site shows an upward trend.

VMC's e-governance effort by collaborating with various private operators either for accepting online payment, or for designing, hosting, and maintaining the Web site, or laying the optic fibre in all parts of city, is a good example of public-private partnership in local public service delivery. Thus, it is a unique experiment in local e-governance in India. The ability to generate reports on various electronic transactions is an additional benefit of this Web site. This would help in not only gauging the performance of the corporation, but also in reducing the workload of the various categories of its employees. The corporation can effectively redeploy them for carrying out other pressing requirements.

## FUTURE TRENDS

As outlined earlier, the service delivery aspect of public administration is becoming more relevant in all parts of the world. Due to the decentralization movement across the globe, the local government functions are likely to increase many folds. These grassroots governments, already saddled with the responsibility of delivering a substantial number of public services, are facing declining revenues. When more functions are transferred from higher-level governments with less revenue sources, they have to adopt innovative methods to deliver the public services. The initiatives taken by a few local governments to adopt ESD might be an answer in this regard. Hopefully, most of the local governments in the world would resort to ICTs in the future. This might lead to questions raised earlier such as addressing the role of the citizen as a voter as well, protecting the information privacy of the citizens, and digital divide. Satisfactory answers to these questions are essential while adopting the ESD in a large scale. Further, there is a need to integrate various levels of government leading to "joined up government" so that the citizens can access the services from just one Web site rather than visiting many Web sites.

## CONCLUSION

Though VMC is a pioneer in ESD in India, there is enormous potential to improve by increasing the range of transactional services from a few to a maximum possible. There is a necessity to mention the privacy policy of VMC in the Web site and reorient it to protecting the privacy of individuals. Though there are a substantial number of visitors to this Web site, the number of participants in the civic polls is miniscule. Continuous research and interaction with its citizens and exchange of experiences with a few leading cities in the world with regard to ESD would help VMC update itself with the changes. If such shortcomings were overcome by incorporating necessary changes in its e-governance policy, VMC would continue to be a model to other city governments in various parts of the world. The local governments, which have tried to use ICT for service delivery, have just taken a first step towards e-governance. They have to go a long way before realising the ultimate objective of e-democracy and complete local e-governance. Concerted efforts have to be made to scale up faster and deliver value to the citizens.

## KEY TERMS

**Desert Sections:** The sections of the Web site which did not have any appreciable number of visitors.

**Dormant Sections:** The sections of the Web site which have not been revised for a long time.

**Dynamic Web Sites:** Web sites which are updated frequently and visited regularly by users.

**First Generation E-Government:** E-government where only an electronic bulletin board with a very limited ability to allow transactions online exists.

**Home Page:** The first and opening page of the Web site.

**House Tax:** A tax levied on the houses/buildings including the adjacent vacant lands by the rural local bodies, *Village Panchayats,* in India.

**Property Tax:** A tax levied on the houses/buildings including the adjacent vacant lands by the urban local bodies such as municipalities and municipal corporations in India.

**Transactional Web Site:** It is a Web site through which complete transactions can be carried out by the users.

**Static Web Sites:** Web sites which have not been updated; hence, they are not active for a long time.

## INTRODUCTION

Does representative democracy imply that there is … representation? What does one mean by *representation*? Looked at very generally, it means that the legislative (parliament and government) and executive (government) bodies represent the opinions of those who are represented.

The primary method for expressing opinions in democracies is by voting: the parliaments are made up of representatives that reflect the different trends of the opinion expressed by the vote (Avril, 1990). Universal suffrage is neither a historical fact nor a clear-cut contemporary feature. There have been, and there still are, individuals who are excluded from voting and universal suffrage (Rémond, 1999). For a long time, several European countries had representational parliamentary systems that were not democracies. We then experienced a *notabilization* of political relations (Deloye, 1997, p. 96). As Max Weber put it, one is not then living from politics but for politics (Weber, 1963). Several restrictions existed and still exist with universal suffrage. For many years, governments either slowed down or restrained access to voting.

Nowadays, the problems arise in new and really reverse terms. The question is more about knowing how to bring citizens back to the ballot boxes and in this manner to perpetuate the legitimacy of the democratic system. Indeed, voter turnout rates have been falling for the past 20 years (Blais & Dobrzynska, 1998; Delwit, 2002). In many European countries, abstention has risen in a straight line since the end of the 1970s right up to the present day. In view of this trend and considering the growing number of election choices for a priori nongovernment parties (Ignazi, 2003), several analysts and political leaders have been wondering about ways to curb this development.

In part, thoughts relating to *electronic voting* (e-voting) lie within this context (Birch & Watt, 2004). A certain number of academics and political leaders have been examining institutionalised restraints likely to improve the current state of affairs (Bowler, Brockington, & Donovan, 2001). Naturally in this framework, electronic vote is only one element amongst others. In this regard, Arend Lijphart has undoubtedly pursued this the furthest, since in 1997 he suggested (re)introducing compulsory voting in democratic states in order to respond to the sagging voter turnout (Lijphart, 1997, p. 11).

The will to reduce voter abstention was not the only issue at the origin of studies on the possibility of introducing or extending e-voting. The mobilization of new communication methods and technology for voting was also at issue. Particularly as the unfortunate vote counting experience in the state of Florida during the 2000 presidential election highlighted concerns about traditional methods of voting and vote counting (Jarvis, 2001).

This article will briefly discuss the issue of e-voting by looking at the response to the introduction of e-voting by Belgian citizens who used it. We will show the results of a major exit poll survey conducted on the occasion of the May 18, 2003, federal elections on Belgian's opinions with regard to e-voting. Two major issues were examined. To what extent was e-voting as it was used in Belgium considered as easy or difficult to use? Was e-voting commonly accepted or rejected by the voters who used it?

## BACKGROUND: THE BELGIANS AND ELECTRONIC VOTING

In 1994, the following provision was inserted in the Belgian Electoral Law, "The King can, by decree deliberated by the Cabinet, decide that, for electoral constituencies, electoral cantons or communes that he designates, an automated voting system should be used."[1] From that moment on, computer voting was introduced in more and more Belgian municipalities. In 2003, 44% of all Belgian voters cast their vote on a computer.

To a certain extent, the use of e-voting in Belgium may look surprising. In Belgium, voting is compulsory. Voters not attending at the polls may be sued. The first time, they risk to pay from 25€ to 50€, the second from 50€ to 125€. Even if sanctions are scarcely applied (0.0015% in 1985), most Belgians respect the rule and vote. In the last federal elections (2003), the turnout was 91.9% (decreasing of 3.25 percentage points in the last 15 years). In that context, one can hardly conclude that Belgian legislators introduce e-voting to curb a growing abstention. Actually, two reasons justified this choice. First, e-voting was going to avoid a large number of invalid votes. Second, legislators wanted to reduce the length of counting procedures.

Ten years after its introduction, time had come for a first evaluation of e-voting in Belgium. On May 18, 2003, a team of 27 pollsters supervised by seven researchers and professors from the Université libre de Bruxelles (ULB) went to 13 polling stations in the country[2]. In addition, two teams of pollsters went to two municipalities where the so-called "ticketing" method was being tried out, in order to improve confidence and, eventually, recount in case of contest (Kohno, Tubblefield, Rubin, & Wallach, 2003; Maynihan, 2004, pp. 523-524).

The questionnaire submitted at the polling station exit on May 18, 2003, was in three parts[3]. The first had a series of questions that enabled defining the socio-demographic profile of the individuals interviewed. This information has a twofold use. On the one hand, it enabled assessment of the value of the sampling in terms of representativeness. On the other hand, this data also permitted us to determine whether certain socioeconomic groups or certain age categories showed any specific association with e-voting problems.

The second part of the questionnaire contributed a second round of objective data on the profile of the persons polled. Its purpose was to provide the resources needed to assess whether familiarity with computers and the information received beforehand about this new voting system tended to influence the way voters felt about e-voting.

Finally, the last part of the exit-poll questionnaire contained questions asking Belgian voters if they were satisfied with e-voting. Four questions served as indicators of this global satisfaction. First, those polled were asked to evaluate how easy they found e-voting. Second, they were asked to express the social acceptance of the new voting procedure. The third item concerned trust in e-voting. Finally, their overall feeling regarding e-voting was asked.

## MAIN THRUST OF ARTICLE: ACCEPTANCE OF E-VOTING IN BELGIUM

### The User Friendliness of Electronic Voting

First of all, those polled were asked the user friendliness of e-voting. Before going into the answers, one should briefly state how Belgian voters have to proceed to cast their vote electronically.[4] In the poll station, each voter receives a magnetic card. The voter enters the polling booth, inserts his or her magnetic card, and starts the process. Using an electronic pencil, the voter chooses a party first, and then a candidate. Afterward, the voter has to confirm his or her vote. At the end, the voter gives back his or her magnetic card and his or her vote is recorded.

Knowing the details of e-voting in Belgium, we can move on to the analysis of the user friendliness of e-voting. Those polled were asked to evaluate the ease/

*Figure 1. Ease/difficulty in using electronic voting*

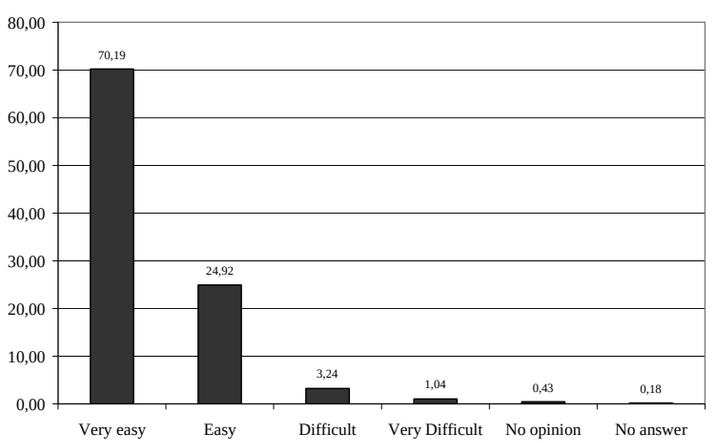

*Figure 2. Degree of ease depends on educational capital*

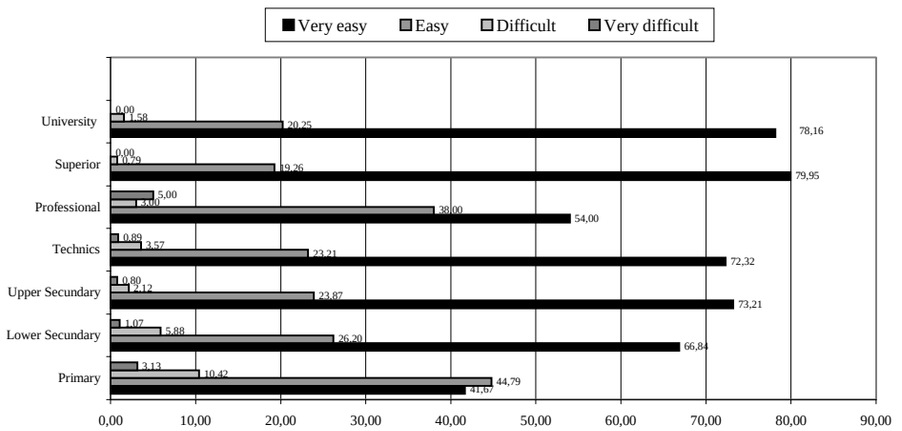

difficulty of use of e-voting by stating that e-voting as "very easy," "easy," "difficult," or "very difficult" to use. Looking at the figures, it seemed clear that if there was any criticism voiced by the interviewees about e-voting, the reproaches had nothing to do with the user friendliness of this method of voting.

Indeed, just under three fourths of respondents stated "very easy" for computerized voting. The positive comments relating to the actual operation of the e-voting mechanism even reached 95.11% if one adds the 24.92% of persons who noted "easy" to vote with computer. Except for a very small minority of 3.28%, a favorable opinion was given about the user friendliness of e-voting.

If one cross-checks ease of use with the educational background, one can analyse to what extent e-voting would be more accessible to the better educated. The data obtained in our research were able to confirm this hypothesis to a certain degree. Indeed, it was with respondents having greater educational capital (university and college qualifications) that the percentages of people who stated "very easy" for e-voting were the highest. In the two cases, it was close to 80% (78.16% for university graduates and 79.95% for those who graduated from colleges). Conversely, individuals with less educational capital gave fewer favorable answers. For example, it was only 41.67% with people whose final diploma was the one they obtained at the end of their primary school education (age 12).

*Figure 3. The matter of principle*

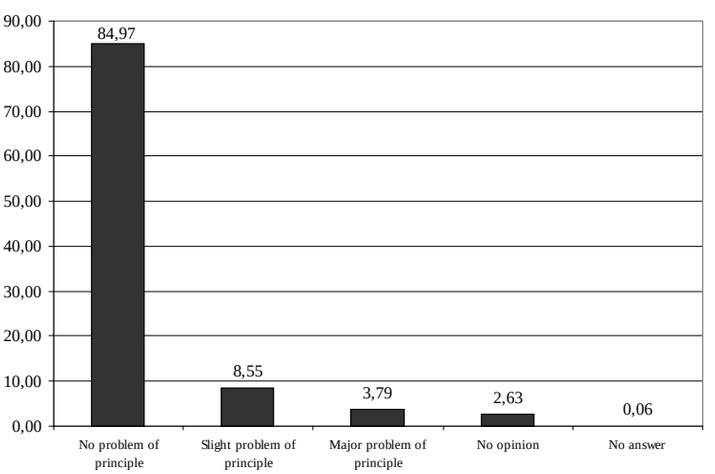

*Figure 4. Trust/mistrust in electronic voting*

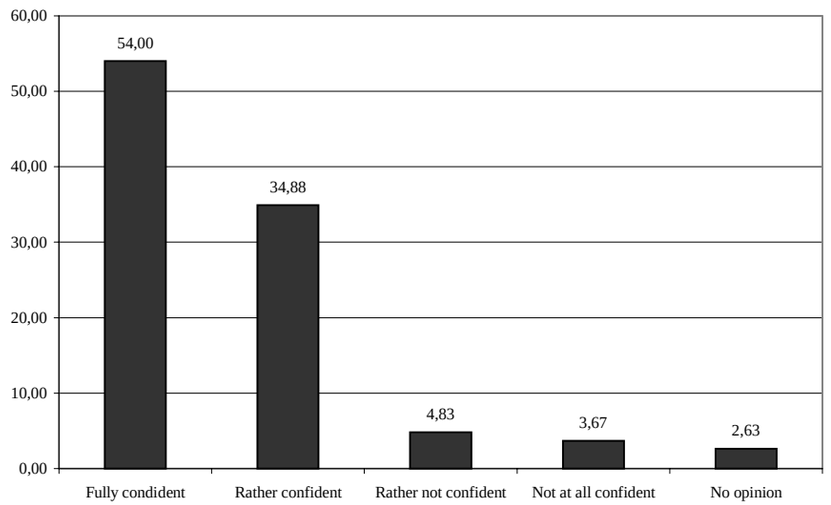

## Societal Acceptance of Electronic Voting

The second variable tested was societal acceptance of e-voting. Here, it dealt with assessing within our sampling if e-voting posed any philosophical problems.

In order to assess if people interviewed had any complaints to make in this realm, an ad hoc question was put to them. It asked them to state if for them, e-voting was "a major problem of principle," "a slight problem of principle," or "not a problem of principle."

The figures are clear for the matter of societal acceptance of e-voting. By a very substantial majority (84.97%), the respondents stated that for them, the new voting method was not a problem of principle. The two other replies were only given by 12.34% of those questioned.

Therefore it clearly emerged that societal acceptance of e-voting was not a disputed issue within our sampling taken on May 18, 2003, at polling station exits.

## The Issue of Trust/Mistrust in E-Voting

The third and final question was about citizens' confidence in e-voting. The last variable is vital for establishing the legitimacy of computerised voting. As several authors have repeated, without this legitimacy, any wide-scale application of this method could be problematic.

Over the sampling as a whole, there was a majority feeling of trust toward e-voting. The favorable responses ("full confidence" and "rather confident") were mentioned in 88.88% of cases. Only 8.5% of those surveyed expressed mistrust ("rather not very confident" and "not at all confident") toward computerized voting.

The feeling of trust appeared to dominate to a large extent, although it was not without reservations. Indeed, a majority of respondents (54%) expressed complete confidence, but nearly a quarter of the sampling expressed qualified trust (34.88%). Thus there was now a different configuration than the one for the question on ease of use. For the latter variable, the proportion of qualified responses was much lower.

Just as with ease of use, it was interesting to cross-check this data on trust with several independent variables. The first run dealt again with educational capital. The first lesson learned was that no matter what the final diploma was, trust was expressed by the wide majority. In all cases, over 80% of respondents expressed complete or reasonable confidence in computerized voting.

Even so, some differences were noticed between the different levels of educational capital. Full confidence was highest in respondents with the lowest level of academic assets ("no diploma" [61.22%] and "primary school diploma" [60.22%]), as well as by individuals who took technical education (62.73%). Yet, the total for positive responses ("fully confident" and "rather confident") remained at around 80 to 90%, regardless of the educational capital.

The age category that least expressed "full confidence" (46.73%), the 30–39 year olds, was also the one in which the total number of confident respondents ("full confidence" or "rather confident") was the highest (91.9%). This clearly strange revelation reflected a broader trend in which it turned out that as the age of respondents increased, there was more "full confidence" but also more mistrust. The skeptical responses ("rather no confidence"

and "no confidence at all") were largely in the minority no matter what the age of the respondents. On average, we had rates of mistrust between 5 and 13%.

The age category expressing the least mistrust was the 30–39 year olds with 5.3%. At the other end, we found the 60-69 year olds for whom computerized voting raised a feeling of mistrust in 13.24% of cases. For the latter, as well as with the 70+ category, the answers "not at all confident" even reached 6.85%.

It seemed, therefore, that the oldest individuals, who were also those who had the least contact with computers and information technology, expressed comparatively more caution with regard to the new way of voting. The relationship between age and mistrust was not in a straight line, however. Indeed, the 30-39 year olds and those aged 50-59 were the categories in which mistrust was the lowest. In both cases, the mistrust rates remained below 8%.

Finally, what about the experimental tests with ticketing? The experiment conducted at the Waarschot and Verlaine polling stations increased confidence a bit but it especially altered its fundamental nature. Seventy percent of voters in these polling stations actually confirmed they had complete confidence in computerzed voting compared to 52% of voters in other stations. On the contrary, the number of citizens expressing some kind of mistrust was reduced to its most simple expression, 3%, compared to 9% amongst citizens voting in a different station. It did indeed seem that ticketing had a valued-added effect.

The preceding data showed that computerized voting gave rise to relatively few negative reactions on the subject of user friendliness, societal acceptance, and trust. Nonetheless, it was certainly advisable to wonder if the relationship to the new voting method was better or not as good as Belgian ties to the paper ballot. For this purpose, the questionnaire submitted at the poll exits included a question about confidence in voting with paper ballots.

A majority of respondents expressed their confidence in the paper ballot. Almost one third of them (32.19%) declared to have "full confidence" and 44.59% said they were "rather confident," which meant 76.78% positive responses. Negative responses were made by 17.26% of those polled (10.93% "relatively little confidence" and 6.29% "no confidence at all"). Finally, there were 5.93% with no opinion. Amongst the latter, one undoubtedly will find voters who have never voted with paper ballot.

Just as for e-voting, the confidence of those questioned was largely positive. Even so, it was expressed in a more nuanced manner than it was for the new voting method. The paper ballot received more "reasonably confident" than "fully confident." Conversely, 54% marked "full confidence" for e-voting compared to 34.88% "reasonably confident." Nonetheless, this comparison must be made with caution because it compared real circumstances—the e-voting done on May 18, 2003—with a past situation—voting with paper ballot—or virtual, notably in the case of the under 30s who may have never voted with paper ballot.

In short, the two voting methods inspired respondents' trust. Nevertheless, the confidence grades were more moderate for voting with paper ballot.

The positions with regard to paper balloting and e-voting could be cross-checked. The goal was to see if the positions vis-à-vis the former method were the same as for computerized voting. The figure below can be read in the following manner. The people who were completely confident about computerized voting are represented on the

*Figure 5. Trust or mistrust in the paper ballot*

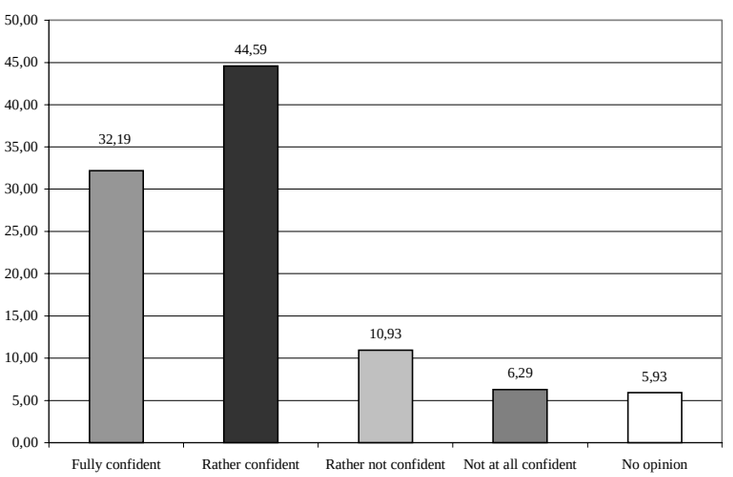

*Figure 6. Cross-checking of confidence in electronic voting and paper (colors for confidence in e-voting and columns for confidence in paper ballot)*

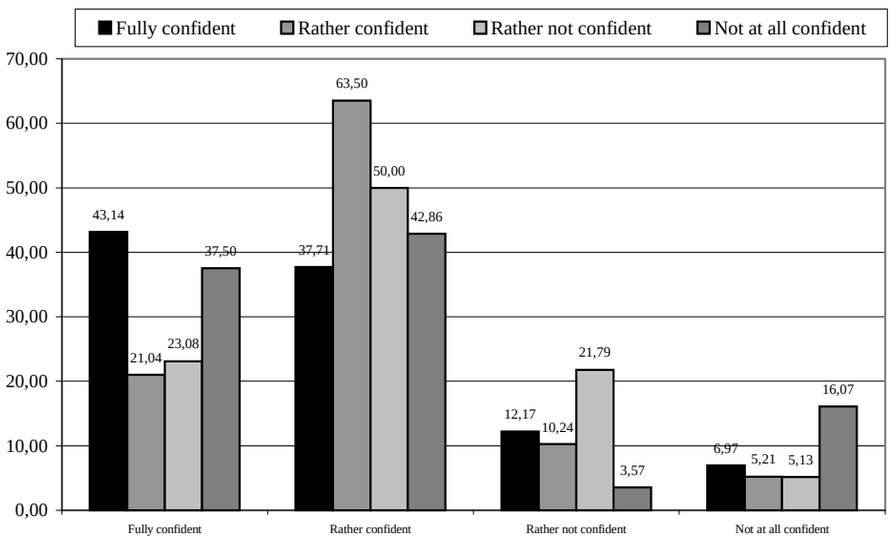

*Figure 7. Overall feeling regarding electronic voting*

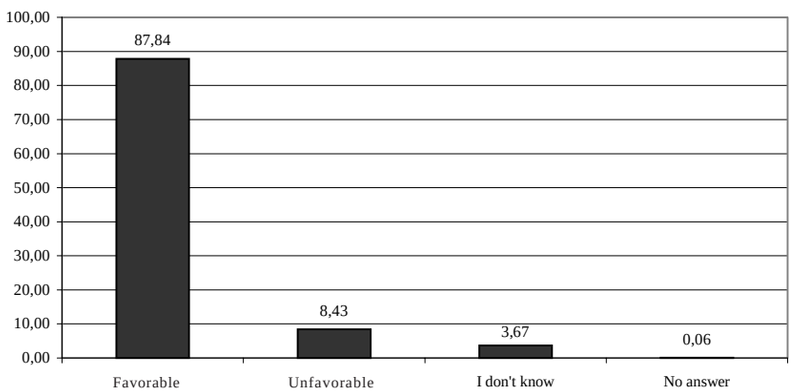

black columns. These respondents were subdivided between the four answers on paper ballots and according to the percentages that are above the lines. The same logic applies for the other three colours (three shades of grey).

The people who placed full confidence in e-voting most often gave the response "fully confident" for the other voting method (43.14%). The response that was in second place was "rather confident" (37.71%). Mistrust was expressed moderately in 12.71% of cases and decidedly in 6.97%. Overall, the respondents who had complete confidence in e-voting also placed much confidence in paper ballots. Even so, less than half declared full confidence in both cases.

Amongst those surveyed who said they had "reasonable confidence" in e-voting, 63.5% were also "reasonably confident" in voting with paper ballots. The second case was "full confidence" with 21.04%. Then came "relatively little confidence" with 10.24% and "no confidence at all" for 5.21% of cases.

Three quarters (73.08%) of those interviewed who noted relative mistrust in e-voting were more disposed toward the former method. With the latter, the paper ballot obtained 50% of "reasonably confident" and 23.08% of "full confidence." Finally, 5.13% had less confidence in the paper ballot.

With the voters approached at the polling station exits who declared they had "no confidence at all" in computerized voting, they also found a certain preference for the old system. Thirty-seven-and-a-half percent had complete confidence in the paper ballot and 42.86% were "reasonably confident." Next, 16.07% had "no confidence at all" in either of the two methods of voting. Finally 3.75% of respondents in this category had "relatively little confidence" in the paper ballot.

In brief, two trends appeared. A majority of those who had confidence in e-voting also had confidence in the paper ballot, but in a more moderate fashion. On the other hand, with those who mistrusted the new method, it was generally through preference to the former technique.

The respondents' positioning toward e-voting was analyzed in detail according to three variables: societal acceptance, user friendliness, and trust. A fourth and more encompassing question was added to the questionnaire. It asked the respondents to state if in the end, they were or were not favorable to computerized voting.

A vast majority (87.84%) answered yes to this question. Less than 10% gave an unfavorable answer (8.43%). The percentage of nonanswers was 3.67%. As with the totality of questions, the opinions were positive with regard to e-voting. But one should keep in mind the nuances that surfaced with socio-demographics and voter familiarity with computers.

If we differentiate between voters from polling stations with ticketing system and the others, we once again observe a high level of acceptance. Nearly 92% of voters in Verlaine and Waarschot declared themselves in favor of computerized voting compared to 87% of surveyed voters from other polling stations. And only 6.6% had a differing opinion compared to 8.7% in the second category.

## FUTURE TRENDS

Considering the low level of mistrust in e-voting among Belgian voters in 2003, one can assume that the legislator would not restrain his or her desire to go farther in the application of this new voting procedure.

In previous years, politicians from several parties declared that they want to generalize computer voting in all Belgian municipalities. Only the *Parti socialiste* does not want implement e-voting in more areas. The first goal of the promoters was to have computer voting in all municipalities for the 2006 general elections. As it was not practically possible, they will try to do it for the 2007 federal elections or for the 2009 regional and European elections.

Actually, some even want to go one step farther by introducing Internet voting in Belgium. The current Flemish State Secretary Peter Vanvelthoven (SP.A) announced his project in October 2005. No decision has been made, but no one can say that it is never going to happen.

## CONCLUSION

In every representative democracy, the act of voting is without a doubt a stumbling block. Through it, citizens exercise their sovereignty; through it, they choose representatives, they exercise control over those in power, decide on societal projects. This multitude of functions fully demonstrates the importance of voting. Under these conditions, when the ballot box verdict loses representativeness, legitimacy, or credibility, it is the entire democratic system that grinds to a halt.

In the fight against abstentionism, institutional imposition is at the top of the list. This approach can lead to rather radical suggestions: the world-renown political science expert Arend Lijphart (1997) suggested (re)turning to compulsory voting. However, "more moderate" proposals are being examined. One of the key approaches aims at making voting easier.

This approach would involve making voting easier through a variety of improvements. In this way, voting would become simpler, which would have the knock-on effect of bring voters (back) to the polling stations, even if in reality abstentionists can be considered as being "in remission" from the voting system.

A few nuances should be added to this diagnosis. Some studies have well and truly shown that an evolution in voting methods can increase voter participation. Thus, Jean Blondel, Richard Sinnott, and Palle Svensson (1997) in particular plotted a higher rate of abstention in the countries where voting took place on a weekday than in countries where it took place on Sunday the 8th. Gimpel and Schuknecht (2003) have pointed out the importance of the ballot boxes' accessibility. But the main cause of the drop in voter participation did not stem from these secondary elements and basically reflected the significance of the election (see, for example, Reif, 1980).

Be that as it may, technical solutions to abstention were certainly the ones that gave rise to most of the legislative initiatives. At various levels, numerous countries experimented with technical innovations aiming at making voting *easier*. Among them, one, the electronic or computer voting is at the moment experienced at a large-scale level in Belgium, as it is in the Netherlands, Great Britain, the United States, and Brazil (Bourgaux, 2001). In Belgium, the first use of e-voting was made in 1991 in the villages of Waarschot and Verlaine. The trial was considered conclusive enough for the procedure to be expanded. At the last elections on May 18, 2003, around 44% of voters used the new method.

Nevertheless, such evolution in the process of voting is certainly not only technical. It can have several impacts on the reliability of the counting, on the secrecy of the vote, and also in terms of societal cohesion. Knowing that, the *Centre d'étude de la vie politique* of the ULB became involved in very extensive field research in 2003 (Delwit, Kulahci, & Pilet). Studies have included an "exit poll" conducted on May 18, 2003 (N = 1637).

The goal of this research was to analyze the social legitimacy of computer voting in Belgium by questioning Belgian voters. The hypotheses were that this new voting technology could affect the equal access to the right to vote. Four categories of polarization were presumed:

1. Between rich and poor
2. Between those who pursed higher academic studies and those who have minimum qualifications in academic terms
3. Between young and old
4. Between Flanders, Wallonia, and Brussels

In this concise contribution, we have given a brief presentation of the results of this survey. Looking at the figures, it seemed clear that if any criticism was made with regard to e-voting, the main concern of these reproofs had no connection with the user friendliness of this voting method. Indeed, a bit less than three quarters of respondents felt that they had used computerized voting "with the greatest of ease."

Generally speaking, the fact to have already voted by computer, but also the respondent's familiarity with IT, tended to promote to a great extent the convenience of e-voting. Apropos, modest elements of a *digital divide* were noted: there was an underlying trend for people with the lowest level of academic assets to encounter the most difficulties. These reservations only involved a minority of respondents, but the observation was verified by our exit poll and likewise for three target publics that we analyzed in a postelection survey.

At societal acceptance level, the exit poll results showed the absence of any major problems. By a very large majority (84.97%), respondents confirmed that the new method of voting did not pose any problems in principle. Societal acceptance of e-voting appeared to be contested just a little and not very strongly within the scope of our sampling taken on May 18, 2003, at the polling station exits.

The third dependent variable assessed was confidence in the new method of voting amongst Belgian voters. The favorable responses ("full confidence" and "reasonably confident") were expressed in 88.88% of the cases.

Looking at the cross-checking of certain socio-demographic data with levels of confidence in e-voting, some nuances can be established. Thus we could detect differences in terms of levels of educational capital. Full confidence was highest in respondents with the lowest one. Thus it was the opposite of the observation established for ease of use.

The second cross-checking carried out on the matter of trust/mistrust was the influence of age on the responses. Here, too, the great majority expressed confidence. In all age categories, more than 80% of respondents reported "full confidence" or "reasonably confident." However, it was noted that when the age of respondents increased, the attitudes with the most opposition increased as well: *those with complete self-confidence* and those *with deep-seated mistrust*.

The aforementioned figures show that computerized voting gave little rise to negative reactions in the realms of user friendliness, societal acceptance, and confidence. Moreover, we observed that in the Verlaine and Waarschot polling stations, where the ticketing experiment was introduced, societal acceptance and confidence in computer voting were higher than the average.

Without a doubt, and based on the data from this research using questionnaires, it is shown that the relationship of Belgian voters with e-voting is largely positive. Both in terms of ease of use as well as of societal acceptance, the surveys conducted recorded large rates of support in the new method of voting. The sole nuances to be added are expressed by senior citizens and youngest ones who expressed a more moderate level of confidence. Nonetheless, in no example did the negative opinions have the most replies. Societal legitimacy of the new voting method within the sampling of Belgian voters that this analysis is based on did not seem to pose any insurmountable problems for the interpretation of these results.

Naturally, these findings are at a *representation* level. They express the feeling of voters toward a (relatively) new method of voting. As such, they do not prove the absence or the presence of potential problems. But in the eyes of a clear majority of voters, e-voting on site at the polling station did not cause any particular difficulty with use and no specific concerns as to the tallying and announcement of the results.

## KEY TERMS

**Abstention:** Number of registered electors who do not go to vote on the election day. In all Western European countries (except Denmark), abstention has increased for 20 years.

**Digital Divide:** Hypothesis whereby the use of IT in the electoral process would put certain categories of voters at a disadvantage. Certain social classes who are less familiar with electronic voting would be deprived de facto of their right to vote.

**Electronic Voting:** Technique by which electors vote by following the instructions on the screen of a computer installed in a pooling booth, instead of by using a ballot paper. (In this article, used as a synonym of computer voting, automatized voting, e-voting, or computerized voting.)

**Internet Voting:** Technique by which electors vote by using a computer connected to the Internet. This operation can be take place in a polling booth, via interactive kiosks installed in public places, or from any computer connected to the Web.

**Societal Acceptance of Electronic Voting:** In order to assess if the persons interviewed had any complaints to make in this realm, an ad hoc question was put to them. It asked them to state if for them, electronic voting was "a major problem of principle," "a slight problem of principle," or "not a problem of principle."

**Ticketing:** Word commonly used in Belgium for *voter verifiable paper audit trail (VVAT).*

**Trust in Electronic Voting:** Voters were asked to declare if they were "fully confident," "rather confident," "rather not confident," or "not at all confident" in electronic voting.

**User Friendliness of Electronic Voting:** In the survey conducted on the occasion of the 2003 federal elections, Belgian voters were asked to evaluate the ease/difficulty of use of electronic voting by stating that electronic voting as "very easy," "easy," "difficult," or "very difficult" to use.

**Voter Verifiable Paper Audit Trail:** Experiences where a voting ticket is printed by the computer and collected in a sealed ballot box, in order to improve confidence in electronic voting and, eventually, recount in case of contest.

## ENDNOTES

1 Loi du 11 avril 1994 organisant le vote automatisé, article 1er.

2 Four in rural areas (Lens, Asse, Waarschoot, and Verlaine), two in suburban areas (Seraing and Sart-Tilman) and seven in urban areas (Bruxelles-Ville, Saint Gilles, Jette, Anvers, Borgerhout, Anderlecht, Liège centre). All are municipalities where e-voting is used. In Waarschoot and Verlaine, a system of voter verifiable paper audit trail (VVAT) was tested.

3 Finally, the sample is composed of 1.637 voters, 51.93% are men, and 55.07% are professionally active. The age scale is as follows: 18-29 years (21.69%), 30-39 (19.24%), 40-49 (17.03%), 50-59 (14.83%), 60-69 (13.85%), 70+ (13.36%).

## INTRODUCTION

Electronic voting, as well as Internet voting, is in the process of being incorporated into most democracies in the world. The literature on the topic is abundant as well as the technologies offered. Most of the work, nevertheless, seems to bypass the actual origins of the modern (and current) electronic voting systems (Oudenhove et al., 2001).

## BACKGROUND: WHAT IS A DOMINANT TECHNOLOGY DESIGN?

The emergence of a dominant technology design is very important for functioning public services. The citizens must have in mind what is acceptable or not. The perception of a machine as being the way it should be is fundamental; otherwise, the system will not have credibility. For example, we know how a typewriter (and now a computer) has to look like thanks to Remington. It is important to understand that to follow a dominant technology design is not just copying a machine. The importance is the psychological perception of what the machine should be. A vehicle with five wheels will not be described as a bicycle. The same is true of fax devices, flight simulators, and cardiac pacemakers (Murmann & Tushman, 2001). It does not mean that the design is the most efficient, as the case of the QWERTY keyboard illustrates. The dominant technology design for electronic voting machines, as James Utterback (1996) has defined it, was developed in Brazil in the late 1980s and early 1990s. Basically, an electronic voting machine that does not follow the Prudêncio design runs the risk of not being credible as a voting machine.

## THE EMERGENCE OF THE PRUDÊNCIO DESIGN IN ELECTRONIC VOTING: THE INTERNATIONAL TECHNOLOGICAL CONTEXT

Electronic voting implies the existence of machines to intermediate the process of individual political choice and the collective choice of leadership. It implies by necessity that the electronic system will be safer, more cost effective, and faster than nonelectronic systems.

Most technologies now implemented in Brazil have been preceded by both theoretical and/or fictional suggestions of electronic voting. Computer-supported voting systems, such as the EMISARI, were operating in 1970 even though they were more predecessors of conference systems than voting systems. Among those involved in theoretical discussions of the 1970s, we have Buckminster Fuller and Tomas Ohlin (Oudenhove et al., 2001).

The first systems to enter operation were off line (Barlow, 2003). In fact, one of the first patents for electrical voting was proposed by Thomas A. Edison in June 1869 to be implemented in the U.S. Congress. Mechanical voting systems were proposed in many parts of the world in the late 1890s and were used in the United States in 1892 at Lockport, New York. When mainframe computers became accessible, they were used for tabulation and vote counting. Punch-card technologies were a common feature of democracies in the 1960s. Mechanical voting machines became dominant in the United States in the 1960s. Off-line machines with card readers were also proposed. Criticisms and fear of fraud favored the introduction of optical readers in some corners of the Earth in the 1970s, but the accuracy problems persisted (United States Federal Election Commission, 1998). A survey in the United States in 1984 indicated that 28% of the systems used for vote counting could generate errors.

The great challenge now is the introduction of online systems as well as mobile telephone systems for direct referendum of proposals by politicians, a form of direct electronic democracy. Online systems have existed since the 1970s for research and survey purposes. One example was the Electronic Town Meeting tested in New York in 1973. The French Minitel system was used also for research and surveys in the 1970s. Informational voting was carried out through the Minitel to survey the needs of the public and improve on public administration. Similarly, telephone surveys and voting by groups of citizens, such as in 1973 at Wuppertal, Germany, were also carried out. With the World Wide Web, all the surveys became, in practice, of general access and participation. Security protocols have made it possible for organizations, even political parties, to carry out elections through the Internet. In 2000, Internet voting was implemented in Alaska, but only 35% of the voters opted for the Internet.

The problems of the 2000 U.S. presidential election gave a global push for electronic election systems. To address the problems and find solutions, the Help America Vote Act of 2002 (HAVA) created a federal commission that is looking into the matter (Wysong, 2004). At the same time the world was wondering about the validity of the U.S. voting system, Brazil was once again carrying out successful electronic elections. The 1998 Brazilian elections had already 57% of the voting population on the electronic systems.

Most of the problems, including the introduction of malicious codes into the voting system, have been surveyed and described in detail by Bev Harris in the book *Black Box Voting* (Black Box Voting, 2005). Most of the issues raised are being addressed by the companies manufacturing the voting machines. Nevertheless, the close association between the leadership of these companies and political organizations has created doubts in the minds of voters. Most of these doubts, if not all of them, are not well founded but must be mentioned. For instance, the most important producers in the United States are Sequoia Voting Systems (2005), Election Systems and Software (2005), and Diebold Election Systems (2005). The key person of Election Systems and Software is Michael McCarthy, who is also a campaign finance director of a U.S. senator. The key person of Diebold is Wally O'Dell, a known important supporter of United States President George W. Bush. Such interfaces between political influential persons and the voting machine producers may raise doubts, although an independent verification service can easily address the issue of credibility.

## THE EMERGENCE OF THE PRUDÊNCIO DESIGN IN ELECTRONIC VOTING: THE BRAZILIAN TECHNOLOGICAL CONTEXT

It is interesting that some standard measures taken in Brazil have not been taken in all places in the United States (Internet Policy Institute, 2000; Mercuri, 2002, 2005). The machines are kept secure at all times. Machines cannot be tampered with. Before their deployment, each machine is tested and in addition, there are standby teams to solve problems or even replace machines. The pool workers are properly trained. The machines generate records that can be verified, and the whole process is transparent. That certain problems have occurred in the United States and not in Brazil says more about the nature of the democratic processes in both countries. It is also revealing that the Diebold voting machines that are distributed in Brazil have had no problems, while 14,000 of them had to be recalled in California, United States, in 2004. Further verifiability is being introduced in Brazil, placing the country once again further ahead in relation to the rest of the world (Rezende, 2004).

By 2000, 109 million persons were voting electronically in Brazil in a system that could bypass problems of illiteracy and problems such as the lack or instability of the electricity system. The system is designed to overcome the digital divide. By the October 2002 presidential and general elections, the electronic system had reached all voters, proving that electronic democracy was possible, feasible, and verifiable (Östberg, Santhias, & Cabral, 2002). Throughout the country, 19,000 candidates raced for a public position in a country with an income-distribution nightmare, unequal educational opportunities, and wealth opportunities still open.

The whole process started in the southern state of Santa Catarina in a city called Brusque (Santhias & Cabral, 2002). Santa Catarina has some 5.5 million inhabitants with their roots in Italy, Germany, Portugal, Poland, Africa, Japan, and the Ukraine. The cultural diversity necessarily implies that general solutions have to take into account a variety of factors in order to be accepted. In 1989, a judge, Carlos Prudêncio, assisted by his brother Robert Prudêncio, an informatics expert, created the first machines with the design that is today accepted as the way a voting machine should be. It was tested at the 90$^{th}$ electoral district with 373 voters. The test was carried out without formal authorization of the national bureaucracy. It was an act of civil disobedience that shaped the democratic future to come. After the successful test, Carlos

Prudêncio approached major manufacturers in electronics and informatics, but he received no support. Instead, he continued to develop the technology and expand the number of tests. But, with the support of the National Electoral Higher

Court of Brazil at the city of Xaxim's elections of February 12, 1995, the system was ready. From then on, it was gradually implemented in 1996, 1998, and 2000. The further implementations were carried out with the support of the Brazilian National Institute of Space Research and the Brazilian Armed Forces. The technology was then passed to major manufactures and the design became the standard design in the world. Even machines that use touch screens follow the shape and form designed by Carlos Prudêncio. The improvements that now happen are incremental. Whenever one votes with an electronic voting machine, it is the Prudêncio design that is seen. One example is the Diebold AccuVote (*Diebold AccuVote-TS*, 2005).

Events in the 2002 Brazilian elections indicated how effective the system had become. The elections were surveyed by international observers from Panama, Mozambique, and the United States. Some 10% of the voters, because of illiteracy and a lack of schooling, did not feel at ease with the voting machines but were properly instructed by staff in place. Of the 400,000 electronic voting machines, 4,163 had minor problems that were fixed in a short time. One hundred eleven machines had to be replaced. This means that 1% of the machines had problems that needed to be addressed. The problems were solved so fast that no major delays in the election process occurred.

## THE PRUDÊNCIO DESIGN AS A DOMINANT TECHNOLOGICAL DESIGN

The simplicity of the design introduced by Prudêncio made it a standard. Machines must have an identifier of the candidate. In the case of a referendum, the voter has the option of voting yes or no. There is a display associating the names of the candidates to their numbers on the ballots. A key or button to confirm the choice is also available. After confirmation, there is no possibility of voting again. An interface for blind people is also made available. The names of voters are associated to each machine. Thus, those that do not belong to the machine cannot vote. This list of voters may be in a list or in a separate machine, but it is stored in such a way that a voter and his or her specific vote cannot be associated. In time, the codes for the programs used in the machine will be posted and open. A verification that the person has voted (but not indicating whom the person voted for) can be made available. Anyone looking through the plurality of voting machines now offered in the global market, including the ones that have had problems and have been criticized, will notice that they follow the elements above. The references in this text present several cases.

## CONCLUSION

In all phases of the process, creative inputs from the population were taken into the system, providing natural feedback that, in itself, became a participatory democratic process. Current developments include the test of smart cards for voter identification. Distance voting is also under discussion. In Brazil, there is resistance against distance voting. One of the guarantees of Brazilian democracy is that voters are protected at the voting site by public officials and by representatives of all interested parties and candidates. It would not be possible to offer such protection during distant voting. The system requires that voting has to be secret. Such issues are sensitive and educational programs on voters' rights have been established in order to critically follow the process of change. At the same time, the electoral system in Brazil maintains its independence and has kept the function of constantly testing the machines. It shows that the electronic machines are part of a system. By themselves they are no guarantee of democracy. That the dominant technology design by Prudêncio emerged in Brazil is a sign of the country's advancement. It is the Prudêncio design that spread and was adopted by U.S. manufacturers. It is the way a voting machine has to look like; otherwise, the voter will not consider it credible.

## KEY TERMS

**Automated Election:** An election that uses voting machines.

**Dominant Technology Design:** A system, quite often with several subsystems, with mechanisms and components. Some subsystems may be part of a technological core on which whole industries depend. While subsystems may change, the total dominant technology design may continue: One may change propellers into jets, but the airplane will still be an airplane.

**Electronic Election:** Automated election that uses computers.

**Election Process Information Collection (EPIC) Project:** A project that compares voting operations, election systems, management, and administration. The Brazilian voting situation can be compared with that of other countries, thus indicating the advances of the country where electronic voting was first successfully introduced (http://epicproject.org).

**Internet Election:** Online election in which the link occurs through the Internet.

**Online Voting:** Electronic election in which computers are linked in a network.

**Prudêncio Design:** The electronic voting system developed in Brazil by Prudêncio. Basically, a voting machine that does not have the general components proposed and presented by Prudêncio is not perceived as an acceptable voting machine. Typically, it has a panel with voting information for output, and keys (numbers, names, or voting instructions) for voter input.

# E–Moderation in Public Discussion Forums

**Lyn Carson**
*University of Sydney, Australia*

## INTRODUCTION

Very little has been written about the crucial role of the moderator in public discussion forums or discursive communities. Group theory tends to draw upon group experiences from non-moderated groups such as criminal juries or groups convened for the purpose of observation. Therefore group theory is concerned with group members' behaviour that is not affected by intervention by someone with the overall process in mind. Practicing moderators and process designers understand the importance of this role in face-to-face consultation. The translation of these skills into an online environment is the subject of this article.

Unfortunately those who write about e-democracy rarely mention this important function, focusing instead on the technology, even though the moderator role is increasingly employed, for example in online collaboration or decision-making. The role of the e-moderator or e-convenor has attracted some attention, both in public deliberation circles (for example, National Issues Forums in the U.S.) and tertiary education (Salmon, 2002). Understanding e-moderation requires an appreciation of moderation per se. This article draws on input from a network of professional facilitators (in Australia, Canada, the United States, and the UK) who were asked by the author (in November 2004) to describe the qualities of an effective facilitator/moderator in a face-to-face (F2F) environment. Their combined responses, previously unpublished data, are used in this article. This primary data is combined with the author's own critical reflections based on 20 years of experience as a group facilitator and is integrated with the writings of theorists and practitioners.

## BACKGROUND

The terms facilitator, moderator, and convenor have been used interchangeably so far. Facilitator is a term favoured in Australia; the U.S. uses moderator to mean the same thing: the person who facilitates or makes easy the work of a group. When using the term moderator, Australians usually mean a person who is engaged in conflict resolution or controlling a heated debate. In the UK, the terms e-moderator and e-convenor are routinely used. In deference to international differences, the term moderator will be used to describe someone appointed to facilitate group deliberations.

An e-moderator is used in a variety of circumstances, for example the author has experienced e-moderation when groups are: engaged in online learning, developing organizational policies, organizing international conferences, functioning collaboratively as a decision-making body, for example, as the board of a professional association or research group. The role no doubt is used beyond these specific purposes, but this article focuses on discourse communities—in particular, groups convened for the purpose of discussion or deliberation (the latter denoting a movement toward common ground or decision making). This would not include asynchronous or synchronous chat rooms or e-mail discussions. The following commentary focuses on online forums.

It should also be noted that it is possible to engage in public deliberation *without* an e-moderator. This seems to occur when deliberation is emphasising direct democracy or transparent decision making or voting. For example, the 1062.org site offers a method for putting forward propositions that become subject to comment and can be modified by their author, culminating in a vote. The process is deliberative to the extent that an individual proposition becomes the subject of a ping-pong exchange (a "back-and-forth volley" in Isaacs' language (1999, p. 365) with people thinking alone but contributing these thoughts to a pooled propositional/voting process. However, direct democracy of this kind is unlikely to satisfy those who are disgruntled by existing political practices in developed countries (see Coleman & Gotze, 2001), so deliberative democracy is the focus here.

It is possible for an e-moderator's duties to be limited to receiving information or censoring or filtering. However, for the purposes of this article, where public discourse is paramount, the emphasis is on an e-moderator as a manager of discussion or deliberation. The e-moderator is seen as contributing "to the interactivity and openness of discussion" (Edwards, 2002, p. 3). In Edwards' language, the e-moderator can be seen as a "democratic intermediary" (2002, p. 3), at least in government-led discussions, and his research reminds us of the importance of transparency for those assuming the moderator role.

*Table 1. Attributes of an effective (face-to-face) moderator*

| | |
|---|---|
| **PERSONALITY** | |
| Must like people and be fair. | • |
| Can handle emotions of others by being non-defensive and non-blaming (is self-differentiated). | • |
| Is impartial, respectful, enthusiastic, encouraging, reflective, inquiring, patient, sensitive, and compassionate. | • |
| **LISTENING/COMPREHENDING/OBSERVING** | |
| Good listener who is in tune with people—hearing what they say. | • |
| Hearing what participants are trying to say or not saying. | × |
| Listens for more than the words and includes those who would otherwise be silenced or marginalized. | • |
| Has great powers of observation (antennae always up). | × |
| Can distinguish key issues from key passions. | • |
| Puts in lots of effort in planning. | • |
| Appreciates all contributions including those listening well. | × |
| Needs to be able to spot the unasked questions and unspoken assumptions. | • |
| Able to draw out connections between ideas (good comprehension skills). | • |
| Can articulate what is happening by naming common ground and areas of difference. | • |
| **GROUP PROCESS** | |
| Be willing to adapt their own facilitation style to match the group's needs. | × |
| Has many tools at his/her disposal (which means they can be flexible). | × |
| Becomes less visible as participants interact with each other. | • |
| Is flexible and responsive and works with a light touch. | • |
| Keeps the meeting to time. | × |
| Understands the particular context. | • |
| Employs good documentation skills so a record exists. | • |
| Welcomes difference and seeks to bring people to a position they can all accept. | • |
| Sums up contributions in such a way that people feel heard. | • |
| Can firmly interrupt domination and inappropriate power relations (using the group's own code of conduct). | • |
| Understands the problem/issue/challenge. | • |
| Makes sure everyone in group understands challenge. | • |
| Guides/supports/assists group to solve it. | • |
| Demystifies concepts, processes, and strategies. | • |
| Helps the group find the resources it needs to ensure everyone can participate fully. | • |
| Can laugh easily and bring lightness to the discussion; encourages shared humour and a relaxed environment. | × |
| Introduces people and creates friendly atmosphere to encourage full participation. | • |
| Inspires confidence and helps a group do its best thinking without imposing his/her own opinions, ideas or biases. | • |
| Creates the space for synergy and creativity. | • |
| Can stimulate dialogue that leads to shared learning. | • |
| Creates a sense of achievement and satisfaction for most participants. | × |
| Makes it look easy! | • |

Code: **• = possible or easy electronically** **× = not possible or quite challenging (electronically)**

When working F2F, the skills of an effective moderator are obvious. Table 1 is a summary of the attributes that were extracted from professional facilitators in Australia, the U.S., the UK, and Canada. There were many similarities in responses and general agreement that an effective moderator enables a productive conversation to occur because s/he understands how groups operate and can manage the complexities and pitfalls that are usually encountered.

One of the oft-cited descriptors of a poor moderator in this previously-unpublished study was a lack of awareness of one's own biases and opinions and an understanding of how this affects the group. Neutrality was considered an essential attribute. Many skilled moderators listed qualities that they freely admit are beyond the reach of mere mortals—almost "superhuman" or saint-like qualities that these moderators saw as an ideal. However, it is possible to discern attributes that could be acquired through learning and practice and also to detect those that would be quite challenging without the benefit of seeing, hearing or sensing the group members. These challenges are addressed in the next section, paying particular attention to those attributes which are marked × in Table 1. The assignment of adot or cross is quite subjective, based on the author's own experience, and other moderators would (and have) disagreed with some of these choices.

## E-MODERATION'S CHALLENGES

Skilled F2F moderators speak with confidence about a group's energy. One moderator described it as the *fuel* that takes a group on its defined journey. This energy is palpable and very difficult to detect electronically. Ricardo Blaug (1999) speaks of a highly-charged group as one in which democracy *breaks out* and the characteristics are easily spotted in a noisy, deliberative space: everybody is animated and talking or they are leaning forward and listening to each other, there is real exchange, leadership is very fluid as people assume leadership or relinquish it when it becomes appropriate, they insist on others being heard, conflict is constructive and workable.

### Personality

Groups can include difficult people, sometimes with severe personality disorders. A skilled moderator becomes remarkably astute at being able to spot a group member who is going to be problematic for others and can, with the group's support, create guidelines that a group can live with and then insist on following these rules when they are broken. Problems can be aired and resolved with relative ease. This is especially helpful with group members who insist on dominating the conversation and is also helpful for those who engage in social loafing. These difficulties are remarkably difficult for the e-moderator to control electronically, although individual participants are able to avoid the dominators with ease by simply switching off. The electronic medium does have the advantage of enabling censorship should language become threatening or abusive.

Skilled F2F moderators love to share humour in a relaxed environment. Laughter can bring lightness to a tense or heated discussion that other behaviours cannot. One of the most serious deficiencies of electronic media is a sender's vulnerability to being misunderstood, and humour (especially irony) is the first casualty; it results in a laughter-deficit that no amount of smiley faces can overcome.

### Listening, Comprehending, Observing

An e-moderator faces a major challenge when silence or reticence occurs. He or she has no way of knowing if the group member is bored, ill, dead, sulking, indifferent, or listening attentively. In a F2F group, death is easy to detect (!) and so too are negative or indifferent responses to discussion. A F2F moderator can draw out the opposing views or wounded psyches and this can provide an excellent pathway to empathic listening. A skilled F2F moderator can also assist a stumbling or reluctant speaker to find his or her voice by drawing out what they want to say but are fearful of, or resistant to, saying. One respondent described this as having one's *antennae always up*, an immense challenge with electronic communication, where misunderstanding is more routine than clear expression.

Silence in a F2F group is not a problem and can be useful for deliberations. The group member who is listening attentively without a need to restate views that have already been expressed or one who listens acutely in order to synthesise the discussion is a valued group member. The e-moderator is cast in this role in a discursive community and cannot respond to a silent members' body language (especially facial) that gives clues about how to proceed.

### Group Process

F2F moderators have a decision-making or discussion-generating toolbox at their disposal. A skilled moderator can flexibly adapt his or her style to match the group's needs. The group might need an analytical tool to uncover "argument repertoires" (Cappella, Price, & Nir, 2002), or a micro-process to uncover values, or a trust-enhancing exercise when the situation becomes tense. Participants might need to have all of the options visibly displayed so that they can be tested, to eliminate those that are out of favour. This requires a quick response in real time and cannot work if input is asynchronous and divergent. Of course, an e-moderator can send people to caucus using a separate thread or their own e-mail discussion, and online decision-making tools can be remarkably quick. The existence of e-mediation also suggests that quite sophisticated conflict resolution tools may be possible for electronic employment.

Because of the synchronous nature of F2F deliberations, considerable ground can be covered very quickly. One statement might be deemed acceptable by many nodding heads and the group can readily, silently move to the next proposal and the next. Common ground can be sought relatively expeditiously. F2F moderators can begin a discussion with a group, collectively define the group's goals, help them achieve those goals, then finish on time and everyone can go home. The discussion is bounded and persists only if the process has factored in ongoing dialogue. The doors can be firmly closed as the last person leaves and this defined time frame works well for busy participants and moderators.

Further, the author's photographic archives probably resemble those of other F2F moderators, with laughing groups captured after the final sessions of various deliberative, inclusive processes (deliberative polls, consensus conferences, citizens' juries, youth juries). These images show satisfied, empowered participants

with arms flung high, beaming broadly with collective satisfaction and achievement writ large. It is very difficult to imagine a similar circumstance arising from an online discourse community which is hampered by asynchronicity and privateness.

## MEETING E-MODERATION'S CHALLENGES

There are important lessons to be learned from the previous challenges and admissions to be made. E-moderation in its 2006 form is an imperfect dialogic process for group dialogue or decision-making but it can be done well if certain principles and actions are employed. It will be clear from Table 1 that *many* of the attributes identified by skilled F2F moderators can find electronic expression.

### Listening, Comprehending, Observing

Synchronous discussions (including synchronous chat rooms), overcome some of the disadvantages of asynchronous chatting. They have the advantage of assisting an e-moderator to "read" participants' emotional energy because the e-moderator is able to gauge the mood of participants through the speed of their responses. The chosen language can suggest mood to the extent that it indicates informality, for example, through informal banter or use of abbreviations like *gr8* or *lol* or *wdym*. The chosen language can also indicate the existence of a ghetto of like-minded people, especially if *lol* has always meant *little old lady* and is now found to mean *laughing out loud!*

### Group Process

Hootstein (2002) considers that an e-moderator wears four pairs of shoes (i.e., has four distinctive roles: *instructor, social director, program manager,* and *technical assistant)*. Hootstein's *footwear* resembles that which is worn by F2F moderators. The *instructor* operates as all good instructors do, using "self-directed learning in problem-centered environments," providing information, ideas, and connections between ideas. This is fundamental to all F2F dialogue and was identified in Table 1. The *social director* fosters collaboration or "social interactions based on consensus building and cooperation," attributes that arise repeatedly in Table 1. This might mean using small group exercises or the sort of exercises that were described above in F2F environments. The *program manager* is "responsible for organizational, procedural, and administrative duties" and is therefore a good planner who makes it look easy. *Technical assistants* help participants with "systems and software" and "resolve any technical difficulties that may occur." Hootstein warns that the "more familiar facilitators are with the technology, the more they can focus on learners rather than technology." This issue of *inspiring confidence in the process* was identified as essential by skilled F2F moderators.

Salmon (2002) offers a similar and overlapping model of online networking with her five-step model of interactivity which progresses through access and motivation (welcoming and encouraging), online socialization (familiarizing and providing bridges between cultural, social and learning environments), information exchange (facilitating tasks and supporting use of materials), knowledge construction (facilitating process) to development (supporting, responding, and reflecting) (p. 10-36).

Online practitioners (e-moderators and participants alike) know that discourse communities can only be established and maintained through considerable planning (much more than is necessary for F2F discussion). Discussions need to be tightly focused because otherwise excessive, irrelevant material is generated that is difficult to track. Online discussions have the advantage of producing a transcript and the disadvantage of having every word irrevocably recorded. This does not happen with F2F unless audio or videorecording is used. The goal and context must be clearly defined (why we are here and what we are going to do), the process should be transparent (how we will engage in conversation and what the effects of deliberation will be), questions must be straightforward and not vulnerable to misinterpretation, and complexity should be introduced only gradually. It is also helpful to think in advance about how the online group will know if it is making progress—just as it is for a F2F group to think in this way.

It helps to specify time lines and to allocate very specific requirements with clear consequences (for example, if A does not respond by X then we will proceed to Z). It also helps to distinguish between public and private spaces. To interrupt inappropriate commentary, a private e-mail conversation would be more appropriate than engaging in public discussion which merely inflames an already volatile situation. Of course, a more restricted e-mail dialogue is also susceptible to flaming. Online discussions are very public affairs and decisions need to be made about the shelf life of the exchanges. Are they removed after a period of time? Can participants modify or delete their own contributions? These decisions should be made well in advance and it is the e-moderator's job to clarify these important matters.

As with F2F moderation, one does not have to be an expert to moderate effectively online. Process is far more important than content; probing deeply is more helpful than adding to the existing body of opinions. National Issues Forum (NIF) favours deliberation over debate and

*Table 2. National Issues Forum's basic questions for deliberative forums*

| | |
|---|---|
| 1 | **What is valuable to us?**<br>Qs: How has this issue affected you personally? What is appealing about this option? |
| 2 | **What are the costs or consequences associated with the various options?**<br>Qs: What would result from doing what this option proposes? |
| 3 | **What are the tensions or conflicts in this issue that we have to "work through?"**<br>Qs: What are the "gray areas"? What remains unresolved for this group? |
| 4 | **Can we detect any shared sense of purpose or how our interdependence is ground for action?**<br>Qs: What trade-offs are we willing/unwilling to accept? What are we willing to do as individuals or a community to solve this problem? |

its suggested questions are the type of questions that work well in a deliberative space. Table 2 shows the four basic questions NIF suggests for a deliberative forum and some sample questions.

One quality that was identified by skilled F2F moderators during the author's study was the ability to synthesise, to draw out connections, to sum up contributions, to create the space for synergy and creativity. The forum e-moderator has the benefit of quiet, reflective time to achieve this onerous but stimulating task. It does not have to be done on-the-run as it is for F2F; the moderator can carefully alert participants to the existence of common ground as well as the major (possibly unresolvable) differences that have unfolded.

In a learning environment (higher education, social change organizations, public deliberations, etc.) it is essential that e-moderators (like F2F moderators) should be trained with that specific task in mind. The National Issues Forum offers excellent moderator's guides for those leading a group's inquiries in relation to contentious issues. Some organizations offer an eModerators Course (Hansard Society, UK). It is equally important that participants undergo orientation as well and organizations like Oxfam offer tips for online conversationalists to ensure that the discussion works well (Oxfam International Youth Parliament, c2004).

## FUTURE TRENDS

Discourse organizations are growing throughout the world (Ryfe, 2003). Many concentrate on F2F dialogue (e.g., Danish Board of Technology's consensus conferences), some online only (e.g., Web Lab's small group dialogues) and others combine the two (e.g., America Speaks' 21st century town meetings). It seems that public deliberation in all its configurations is growing, with citizens developing a taste for active, deliberative citizenship (Coleman & Gotze, 2001). As usual, the state lags behind but it will surely follow. Work is being done by scholars and practitioners to ensure that deliberative, inclusive processes are sufficiently rigorous to withstand critique (Gastil & Levine, 2005). One example of this is the international researcher/practitioner workshops that are convened bi-annually by the Deliberative Democracy Consortium. These trends: the growth of organizations dedicated to undertaking public deliberations and the testing of the efficacy of their work are trends to watch.

Perhaps, too, the nature of online deliberation will provide that reflective space that is often missing from F2F deliberation and the broader political landscape. More critically reflective practitioners will emerge if participants take the time to ask the type of questions posed by NIF (see Table 3).

Text-based deliberative exchanges may offer a benefit over F2F groups in relation to reflective practice. Participants can be encouraged in advance to reflect quickly and simultaneously because text exchanges, by their very nature, place the deliberation in front of participants' eyes. However, this still requires tremendous skill: to craft reflective questions and to establish the right atmosphere where participants feel able to respond. Online participants reflect with an immediacy that cannot occur in a F2F context.

Online discursive communities can provide opportunities for the voiceless to be heard, in ways that elude F2F gatherings. They can attract some marginalized groups (such as remote, aged or hearing-impaired—but *not* indigenous, homeless or illiterate people) that prove difficult to capture when an overview of the whole population is sought. Genuine deliberative, inclusionary processes are dependent on random selection to ensure that a diverse, inclusive group is gathered together (Carson & Martin, 1999). It is possible to replicate that random diversity online, for example, through resident feedback panels (Carson, 2003). Random selection has many advantages over self-selecting discourse communities which tend to attract "the incensed and the articulate." Deliberation works best when disparate voices are heard beyond those ghettos of like-minded people around which we are all prone to coalesce. The more narrow the group, the more deluded it can be about the universality of its views.

*Table 3. National Issues Forum's reflective questions to end a forum*

| | |
|---|---|
| 1. Individual Reflections | |
| | How has your thinking about the issue changed?<br>How has your thinking about other people's views changed?<br>How has your perspective changed as a result of what you heard in this forum? |
| 2. Group Reflections | |
| | What didn't we work through? |
| | Can we identify any shared sense of purpose or direction? |
| | What trade-offs are we, or are we not, willing to make to move in a shared direction? |
| 3. Next-Step Reflections | |
| | What do we still need to talk about? |
| | How can we use what we learned about ourselves in this forum? |
| | Do we want to meet again? |

The deficiencies that arise when audible laughter is absent and body language is missing might well be alleviated when synchronicity becomes more refined online and when web cams become part of this equation. Sight and sound are increasingly being added to online deliberations and this will enhance their effectiveness.

## CONCLUSION

A network of skilled face-to-face moderators helped the author define the characteristics of effective moderation. The attributes of effective face-to-face moderation that were gathered, provide a solid foundation for considering the attributes needed for e-moderation. Many of the same skills can be employed online; others are quite difficult to replicate. Being mindful of these challenges and exploiting the advantages offered by online communication, e-moderators can strengthen discourse communities. Online dialogue provides another means for stimulating public discourse. Citizens want to participate in different ways so it is important for convenors of public conversations to expand the sites. More robust and reflective deliberations can only help to redress the world's expanding democratic deficit.

## ACKNOWLEDGMENTS

My thanks to the 38 moderators who responded to my enquiries about the qualities of effective face-to-face moderation. Thanks, too, to Vivien Twyford (Twyford Consulting and International Association for Public Participation), Sofia Mackay (Oxfam Australia), Phillip Hart (Hollier and Hart), and Mark Freeman (University of Sydney) for sharing their thoughts about e-moderation.

## KEY TERMS

**Deliberation:** In a group situation, deliberation is the process of clarifying arguments, weighing options and seeking common ground in order to decide.

**Deliberative Democracy:** Sometimes referred to as discursive democracy, it is democracy which is discussion-based and collaborative. Deliberative democracy stresses the importance of inclusive, public deliberation prior to important political decisions.

**Discourse Communities:** Groups convened for the purpose of discussion or deliberation (the latter denoting a movement toward common ground or decision-making).

**E-Moderation:** The person who facilitates or makes easy the work of an online discussion or decision-making group—sometimes also referred to as the facilitator.

**E-Tivities:** Online activities that lead to active and interactive learning.

**Flaming:** A colloquial expression used to describe the sending of inflammatory messages through e-mail or online.

**Moderator:** The person who facilitates or makes easy the work of a group—sometimes also referred to as the facilitator.

**Public Discourse:** A collective conversation taking place in the public sphere usually to resolve issues of public importance. The term is also used to describe a system of ideas or knowledge used to legitimate the exercise of power.

# Enabling Federated Identity for E-Government

**Tanya Candia**
*Enosis Group, USA*

**Paul Madsen**
*NTT, USA*

## INTRODUCTION

Today's administrative and business environment calls for information sharing on an unprecedented scale, from government to business to citizen. Sharing and interoperating among agencies, businesses, and governments around the world create opportunities to simplify processes and unify work, as well as improve the overall performance of government. Secure interoperability, based on identity management solutions, enables substantial cost savings, streamlined processes and faster communication of vital information to the benefit of governments and citizens of all nations.

At the core of this revolution is the concept of federated identity management and the need for standards that are open, interoperable and decentralized. In addition, such standards must allow for privacy safeguard across all sectors. The Liberty Alliance Project (Liberty Alliance, n.d.) was established to address this need and tackle the twin issues of standards and trust.

## BACKGROUND

Today's administrative and business environment has created an unprecedented need to securely share sensitive information among national, regional and local governments, agencies and organizations, as well as with citizens and business entities. The true distributed computing platform created by the Internet brings into sharp relief the importance of adhering to emerging privacy standards and data security regulations.

Identity is at the core of any information-sharing transaction: government to citizen, government to business or government to government. Individuals' identities not only prove that they are who they say they are, it also indicates what they can do and what resources they can access. Governments are often the source of core documents that relate to one's identity: birth certificates, drivers' licenses, employment and tax records, marriage and death certificates, and the like. Identity credentials are perhaps more relevant in today's digital society in their electronic form than on paper.

### Identity Management Issues

Effectively managing one's identity means retaining control over the information relative to who one is, who has access to it and how it is used. While simple in the abstract, the task is enormously complex in reality. Even within a single organization, an individual may rely on multiple identities: an employee may need to authenticate to a database, an application or a service using completely different mechanisms. Once outside the organization, the problem is compounded. Multiple organizations will hold multiple instances of identity and attribute information. The problem of effectively managing all these instances is enormously complex, resulting in ineffective identity management and complexity.

Furthermore, as governments, citizens and businesses extend their services, they are challenged to grant access to resources and applications to the right people at the right time without sacrificing privacy, security or scalability. Since today's communities of interest are built and modified on a dynamically changing basis, trust must be able to be created or eliminated quickly. The old ways of managing identity dramatically reduce the organization's ability to move quickly enough to respond to changing relationships.

### The Ideal Solution

Ideally, government would like to have the ability (whether through technology, business practices, policies, education or a combination thereof) to meet the following seemingly conflicting requirements:

- Simplify access to services and applications both inside and outside the organization
- Reduce the need to maintain and manage multiple sets of identity credentials
- Reduce the cost and complexity of managing identities

- Enable dynamic creation and management of trusted relationships
- Preserve privacy and ensure data security.

## FEDERATED IDENTITY MANAGEMENT

Fortunately, there is a solution that approaches the above ideal: *federated identity management*. Federated identity management makes it possible for an authenticated identity to be recognized and take part in personalized services across multiple domains. Federated identity avoids the pitfalls of centralized storage of personal information while allowing users to link identity information among accounts. Since users can control when and how their accounts and attributes are linked and shared, they retain greater control over their personal information. In practice, this means that users can be authenticated by one organization or Web site and be recognized and receive delivered personalized content and services in other domains without having to re-authenticate.

Increasingly, governments are looking at federated identity as the preferred underlying identity architecture for interacting with their various constituencies and partners. Federated identity provides governments with an open and standards-based approach for enabling access to sensitive internal resources to external parties.

The advantages of federated identity include:

- A standards-based mechanism of both sharing and managing identity information as it moves between discrete legal, policy and organizational domains
- A cost-efficient means of establishing single sign-on to cross-domain resources
- A simpler way to grant and revoke user access to information
- A reduction in the number of sign-ons and passwords an individual must work with to access multiple systems and databases
- Greater security when it comes to user access to information.

## PUBLIC SECTOR BENEFITS

Within a single government organization, a federated identity management infrastructure can bring substantial cost savings, operational efficiencies and increased security. These benefits come in the form of more effective employee provisioning and password management, focused development efforts on a single standard that will be supported by a variety of technology providers, and the ability to more easily outsource certain employee applications in a secure and flexible manner. Also, since employee identities can be managed internally and brought online and off-line quickly, deployment of a federated identity infrastructure limits an organization's vulnerability to security attacks by current or former employees and contractors.

The real benefits of federated identity management can be seen when communication takes place between and among various organizations. Below, we briefly discuss several situations that call for federated identity.

### Government to Government

Many types of vital information must be shared across government and organizational boundaries. Interoperability is a requirement within agencies, among organizations and even between nations. Indeed, the dynamically changing nature of national coalitions calls for dynamic circles of trust (a group of organizations that have established trusted relationships with one another and have pertinent agreements in place regarding federations). A federated architecture now allows systems to interoperate while maintaining their autonomy. The circle of trust provides participating organizations the framework to ensure that this interoperability is trusted and secure.

The compelling need for sharing sensitive information, and thus for federated identity management, can be clearly seen in times of disaster. A regional incident, such as an earthquake or avalanche, brings together myriad organizations that must freely share disasterresponse information among all relevant agencies and governments, often spanning multiple countries. When information about victims, rescue and response actions, and law enforcement activities are at stake, it is vitally important to ensure that individuals are properly authenticated prior to exchanging such sensitive information.

Government information sharing is a requirement not only in times of crisis; in fact, it permeates all aspects of government. For example, the European Commission's eEurope (eEurope, n.d.) activity covers a number of initiatives, including e-government, e-health, e-learning, and e-business, all designed to foster the development of new and better services. Examples include initiatives related to the health sector in Spain and Finland, the management of relations between administrations and companies in Belgium, the indexing of public files in Italy, e-voting in some local consultations in France, and much more. In each, the need for interchange of information requires a federated identity management framework to enable free flow of information while preserving security and privacy.

## Government to Citizen

Perhaps in no other area of communication is the need for secure yet open access as important as in government-to-citizen interaction. Governments around the world are embarking on e-government and e-authentication initiatives, widespread broadband access and electronic communication programs to bring the benefits of technology to their citizens. In the public sector, various government departments and agencies give citizens and businesses access to online services through their e-authentication initiatives. The federated approach is ideal to avoid any generalized interconnection of public files containing personal information, because it ensures that data is not duplicated in a single central database.

Individual government authorities can act as identity providers for citizens by establishing circles of trust and offering a complete range of personalized applications across different government agencies and domains, such as online tax declaration, reimbursement for medical expenses, car registration, and electronic passport and driver's license renewals. In addition, with strong yet manageable authentication, governments can ensure that benefits are going to the authorized recipients. Such a scheme can quickly lead to single-sign-on, with the resultant benefits of cost reduction and increased security.

The eEurope 2005 Action Plan (eEurope, n.d.) embodies these initiatives, aimed at modernizing public services and giving everyone the opportunity to participate in the global information society. One area of particular focus is health care. Over the past few years, much progress has been made in building integrated regional health information networks, standardized electronic health records and the like. New initiatives will enable rapid reaction to health threats while protecting individuals' health information from unauthorized access.

## Government to Business

Whether for government sales of assets, expanded tax products for business, one-stop business compliance, streamlining of international trade or other activities, businesses have come to expect more electronic interaction with government. This is especially true for small- and medium-size enterprises: With limited resources for interacting with government agencies, they are eager to find convenient procedures for such activities as VAT declarations or company registrations. A federated architecture is essential, as it enables a single-sign-on capability and seamless and secure interaction with distinct functions or agencies, while leaving each user in control of his or her data.

When business interacts with the government, the conflicting requirements of privacy and interoperability must both be addressed in a delicate balance. An interesting example can be seen today in Japan's EduMart, part of the e-Japan Policy Priority Program (e-Japan, n.d.) and spearheaded by the Strategic Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (IT Strategic Headquarters, n.d.). In an effort to bring rich educational content to students at more than 40,000 schools, the IT Strategic Headquarters established an open interface and built an educational content distribution network that will lead to a system in which both public institutions and private businesses can connect to interfaces and freely participate.

Additional examples can be seen across the value chain, from government-controlled health care programs that must communicate with providers and patients, to government contracts with foreign suppliers, to basic business licensing and taxation. Speed, timeliness, accuracy and user friendliness are the obvious outcomes of such initiatives.

To generalize across these public sector scenarios, the benefits of implementing a federated identity strategy and infrastructure fall into five main categories:

- Improved alliances, both within governments and between governments, through interoperability with autonomy
- Faster response time for critical communications
- Cost avoidance, cost reduction and increased operational efficiencies
- Stronger security and risk management
- Interoperability and decreased deployment time.

# FEDERATED IDENTITY IN ACTION

## GSA E-Authentication

The United States (U.S.) General Services Administration E-Authentication Initiative (e-Authentication, n.d.) is aimed at providing the necessary federated identity infrastructure to support a common, unified authentication process and streamline access to government online resources. Based on federated identity, E-Authentication will help government departments and agencies accelerate delivery of online services by allowing them to leverage a variety of electronic credential providers.

## County Land Document Recordation Exchange

An example of cooperation between government and citizen can be seen in the U.S. initiative called the Internet-Based County Land Document Recording Exchange (Elec-

tronic Recordation Exchange, n.d.). Intended to dramatically streamline the land recordation process for participants, notably mortgage and title companies, it will save time and money while increasing the integrity of the participating local government land records systems. Users swipe smart cards through readers to access the system. The cards contain digital certificates that identify the users and can be passed along within the CoT. As other lending companies and counties join the County Land Document Recordation Exchange, they become part of the identity network and validate their own users as partners within the circle of trust. This minimizes the spiraling number of log-on credentials needed by users as they exchange documents with an ever-growing number of partners. It is only recently that such a fully electronic process became legally possible. The U.S. E-Sign (Electronic Signatures in Global and National Commerce Act, n.d.) went into effect October, 2000. The act allows suitable electronic signatures to have the same legal effect as written signatures.

### Guide Project

GUIDE (Guide, n.d.) is a European Union (EU)-funded research project conducting research and technological development, with the aim of creating a technological, institutional, policy and socio-economic architecture for secure and interoperable e-government electronic identity services and transactions for Europe. Increasingly, citizens of the EU work, travel and access social security or health care services in other Member States. The primary practical objective of GUIDE is to create an architecture to solve the current cross-border compatibility issues.

### Joint Warrior Interoperability Demonstration

The Joint Warrior Interoperability Demonstration 2003 (JWID) (Joint Warrior Interoperability Demonstration, 2003) demonstrated government-to-government interoperability. Spearheaded by the US joint chiefs of staff, JWID tackles identity issues across national and international boundaries. One key objective is to enable a standard solution for information sharing among coalition partners. Important issues are authentication and identity management, since each nation retains control of its own information, and desires to maintain its autonomy without impeding the free exchange of information.

In JWID 2003, military forces from six nations (Canada, Australia, New Zealand, U.S., United Kingdom, and Norway as the NATO representative) used federated identity solutions to clearly demonstrate how federated identity management could save lives, increase communication and build stronger alliances. Using its federated authentication architecture, the solution tied together message traffic from land-based and maritime units from all six countries, showing the true potential and value of this approach in scenarios that required the ability to revoke credentials from field forces that may have been compromised.

## STANDARDS

Federated identity will not become ubiquitous without broadly supported standards to act as the necessary building blocks. Some key standards and proposals are discussed in the following sections.

### SAML

The most successful federated identity building block to date is the Security Assertions Markup Language (SAML) (SAML, n.d.), an Extensible Markup Language (XML) framework for exchanging security information between servers.

SAML 1.0 became an OASIS standard in November 2002; SAML 1.1 followed in September 2003. SAML has seen significant success within industry—seeing successful deployments in financial services, higher education, government and other verticals. SAML has been broadly implemented by all major Web-access management vendors. SAML is also supported in major application server products, and SAML support is common among Web services management and security vendors.

SAML 2.0 reflects a three-fold convergence between SAML 1.1, Liberty ID-FF 1.2 (ID-FF 1.2, 2003) and Shibboleth (Shibboleth, n.d.) and, as such, is a critical development for federated standards.

### Identity-Federation Framework

In 2003 the Liberty Alliance took SAML 1.0 and added mechanisms for account linking and session management to define its Identity Federation Framework. The extensions that Liberty defined to SAML 1.0 (and later SAML 1.1) were contributed back into SAML 2.0.

Although ID-FF is deprecated in favor of SAML 2.0 going forward, the Liberty Alliance continues to build on SAML—its Identity Web Services Framework (ID-WSF 1.1, 2005) has been adapted to include support for using SAML 2.0 assertions to communicate identity among Web services actors.

## WS-Federation

A separate effort for federated identity protocols is WS-Federation (WS-Federation, 2003)—part of IBM and Microsoft's WS-* initiative for a broad set of composable standards for Web service security. Although WS-Federation has not itself been submitted to an open standards body, WS-Trust, on which WS-Federation builds, is now being developed within OASIS' WS-Secure Exchange Technical Committee. Microsoft's Infocard is a client component of the next release of Windows that may give end-users greater control over their identity by integrating through WS-Trust with identity requestors and providers.

## FUTURE TRENDS

Multiple drivers and trends are pushing governments towards federated identity: greater degrees of collaboration with internal and external partners, heterogeneous security infrastrctures, regulations governing the acquisition and treatment of privacy and sensitive information all enourage government departments to implement a federated model of identity management for their constituent employees, citizens and partners. We expect that this push will continue—the future will show an increased number of deployments of federated systems, with more prototypes emerging and early prototypes evolving into full-scale deployments.

Deployments of strong authentication and federated identity are expected to go hand in hand, federated single sign-on allowing the cost of strong authentication to be borne by dedicated providers, but the value of increased security it enables shared elsewhere thereby makes strong authentication affordable and scaleable.

We also expect to see continued convergence between the various proposals and standards for the identity protocols and identifiers. The so-called identity metasystem is an encouraging development towards this end.

## CONCLUSION

Sharing and interoperating among agencies, businesses and governments around the world create challenges for authentication and authorization to control aceess to distributed resources. Federated identity management, by allowing home organizations to authenticate their end users for their transactions across security domains, likely represents the best approach to addressing these challenges in a scaleable and flexible manner. To be practical, federated identity requires two key components: trust and standards. The Liberty Alliance, a global consortium of more than 150 leading global organizations, including numerous government and non-profit agencies, is leading the way in both developing the standards to enable the flow of identity information in a privacy-respecting manner, as well as defining best practices and guidelines to faciliate the establishment of trust between organizations.

## KEY TERMS

**Circle of Trust:** A group of organizations that have established trusted relationships with one another and have pertinent agreements in place regarding how to do business and interact with each other and manage user identities across their boundaries.

**Identity:** The set of behavioral or personal characteristics by which an individual is recognizable.

**Identity Management:** The set of processes by which individuals can be granted access to appropriate network resources, but no others.

**Federated Identity:** The agreements, standards and technologies that make identity and entitlements portable across autonomous policy domains.

**Privacy:** The right of individuals to control the collection and subsequent use of their identity information.

**Single Sign-On:** The sequence by which an individual can authenticate to one Web site and then be able to access protected resources at another site without additional authentication.

**Web Services:** A set of standards for distributed computing on the Internet.

# E–Participation and Canadian Parliamentarians

**Mary Francoli**
*Carleton University, Canada*

## INTRODUCTION

During the last decade, the public policies of many countries have emphasized the need for greater citizen participation in decision-making, and governments have been adopting e-government strategies as a means of not only improving service delivery, but also engaging society and revitalizing democracy. Indeed, many political leaders have been advancing the democratic potential of information and communication technologies (ICTs). British Prime Minister Tony Blair, for example, has stated: "I believe that the information society can revitalize our democracy...innovative electronic media is pioneering new ways of involving people of all ages and backgrounds in citizenship through new Internet and digital technology ... that can only strengthen democracy" (Hansard Society, 2004). Similarly, former United States President Bill Clinton stated that ICTs would "give the American people the Information Age that they deserve—to cut red tape, improve the responsiveness of government toward citizens, and expand opportunities for democratic participation" (Prins, 2001, p. 79). In Canada, former Prime Minister Paul Martin also argued, along the same vein, that people need to be brought into the decision-making process if the country is to have the kind of future that it needs, indicating that ICTs are a useful means of achieving this goal (Speech to the 2003 Crossing Boundaries Conference, Ottawa Canada).

## BACKGROUND

At the same time as governments have been praising the idea that ICTs can serve as the necessary tool for allowing the public a greater voice in governing, and for strengthening democracy, there has been a proliferation in the literature making similar arguments. Broadly speaking, this school of thought can be referred to as Utopian. For those adhering to this approach, ICTs provide "solutions to problems of space, population, access, and participation" (Saco, 2002, p. xvi). Some go as far as stating that ICTs will empower citizens to the point where existing structures of representative government are rendered obsolete (Naisbitt, 1982). Others take a more moderate approach, pointing to the way that society can use ICTs to mobilize and to increase the efficiency and effectiveness of various campaigns. This use of technology has been fittingly termed "cyber-activism" by some scholars (Dyer-Witheford, 1999). Others take a different approach, still arguing that the technology constitutes a means for governments to re-engage those who have been disengaged from public affairs (Coleman, 2001). In this sense, ICTs are seen as allowing for the possibility of a new public space–a sort of electronic agora–where citizens serve as an active participant in governing (Centre for Collaborative Government, 2002).

Contrary to the Utopians, is the approach offered by the Dystopians. This group does not agree that ICTs will fulfill the democratizing role outlined by the Utopians. Rather, they argue the technology has no impact on citizen engagement and it is "politics as usual" (Margolis & Resnick, 2000). Some go further arguing that ICTs are having a negative impact on participation and democracy as a result of its speed and inequities related to access (Barber, 2001; Taylor & Saarinen, 1996).

## E-PARTICIPATION OR POLITICS AS USUAL?

The literature on this subject summarizes the various uses of ICTs and their positive and negative ramifications; however, it tends to make two vital omissions. First, much of the literature especially that which takes a "cyber-activist" approach, focuses on the use of ICTs by society. In terms of participation, it details the use of ICTs as a tool for citizens to participate in governing, but most often neglects to examine how government representatives respond to the electronic efforts of society (for an exception see Moynihan, 2003). Second, much of the literature makes assertions concerning the impact of ICTs on participation and democracy without clearly defining democracy, or what increased participation would require (Barber, 2001). Drawing on theories of participatory democracy, the Utopian-Dystopian dichotomy found in the literature, and looking at the situation in Canadian federal politics, this chapter attempts to begin addressing these gaps and to offer further insight into the impact of ICTs on citizen participation and democracy. Canada serves as an interesting case to consider as less is known about how

its parliamentarians are using ICTs to engage its citizens (Coleman, 2001, for example, has looked extensively at the British situation and authors such as Margolis & Resnick, 2000 have explored the American situation). This study also has the potential to provide for future comparative analysis and it identifies many barriers to e-participation to be considered.

An exploration of the literature on participatory democracy and models of e-democracy allows one to tease out four criteria that should be fulfilled before one can say that ICTs are enhancing participation and democracy (Chadwick & May, 2003; Fishkin, 1991, 1995; Laudon, 1977; Pateman, 1970). This is useful as it provides a context for thinking about and evaluating e-participation. The four criteria are:

1. Information/education
2. Avenue for participation/consultation
3. Deliberation
4. Evidence that views are heard

Each criterion will be discussed briefly, in turn, along with the results of an empirical examination of the Canadian situation. The empirical study is modeled on work done by Andrew Chadwick and Christopher May and a dataset complied by the Cyberspace Policy Research Group (CyPRG). It employs a multi-disciplinary approach and studies the content of the Web sites of Canadian Members of Parliament (MPs). At the time this study was conducted 200 of the 299 sitting MPs had Web sites. It also draws on interviews that were conducted with sixty Members of Canada's 37th Parliament concerning their use of ICTs, how they respond to Canadians who seek to participate in governance electronically, and some of the barriers they felt were preventing them from fully engaging in e-participation.

## Information/Education

Democratic theorists place a great deal of importance on information and education. Access to good and up-to-date information is useful not only for helping people come to informed decisions during election periods, but it is also necessary to help them participate, on an ongoing basis, in matters of governance. Indeed, the lack of information and knowledge about policy issues is often cited as a reason for rejecting greater participation: "Perhaps the most commonly advanced reason for rejecting direct democracy via the Internet...is that citizens are poorly informed about public issues much of the time...what sense does it make to ask citizens what government policy should be on a matter about which the majority of the people know either little or nothing" (Brooks, 2000, p. 12). The type and sources of information are also important to consider. An environment which fosters participation and the third condition outlined here—deliberation—requires that diverse opinions and a variety of information be made readily available to the public. While the Internet does offer a great deal of information from a variety of sources (not all credible), it can be difficult to navigate and to evaluate. If government officials truly wanted to harness the democratic potential of ICTs then one can speculate that government and individual MPs' Web sites, should contain information which would help citizens become aware of various issues and processes of government.

A survey of Canadian MPs' Web sites indicated that this condition is being fulfilled fairly well. In total, 160 of the MPs offered information and links to federal government services and programs. Conversely, only 119 of the MPs offered information or links to sources beyond the federal government. Surprisingly, only seven MPs offered information regarding the issues and legislation being considered by Parliament; however, most did provide hyper-links to the main Canadian Parliamentary Web site where such information could be found. Many of the MPs interviewed for this study stated that they felt as though they were expected to have an online presence. Most answered that they thought it important to have Web sites so that they could effectively and efficiently share information with their constituents. However, there seemed to be uncertainty over what type of information Canadians would like to find on their MPs' Web sites. As one MP stated, there is a "veil of ignorance" among MPs as to what type of information citizens would find useful or would like to have access to. This MP's admission of such ignorance was interesting as it indicates that perhaps elected representatives put little thought into what Canadians may need information about and, what type of information is required to present to them so that they can make informed decisions when participating in either elections or policy discussions. They are not paying attention to the education and socialization of the public, which as Pateman argued is necessary for participation to flourish.

## Avenue for Participation/Consultation

Having information is not a sufficient condition for greater democratic participation. For this to occur, it is obvious that there must be avenues by which citizens can be engaged or consulted. While traditional democratic processes do have some built-in participatory mechanisms, such as committees, or inquiries, these are not always open to all citizens and it is often difficult for individuals to participate. Moreover, it is important to recognize that there are limitations inherent in the traditional methods of engagement. These can include such things as time and money. For many who adhere to a more Utopian approach,

ICTs provide a means of overcoming such limitations. Therefore, one can assume that if ICTs are improving participation, government Web sites should offer various mechanisms for interaction.

In Canada, such mechanisms for interaction were found to be somewhat limited. Each of the MPs' Web sites was surveyed to see whether they offered citizens avenues for communicating with the representative. This included looking for direct links to electronic mail, more traditional contact information, and online forms that people could fill-out if they wanted to provide input on any number of issues. Almost all of the MPs with Web sites, or 193, provided direct links to their e-mail accounts on the Internet. Recognizing that not all people may want to contact their representative electronically, the same number offers non-electronic contact information. In total, 84 MPs offered an online feedback or comment form. Seven MPs offered online polls where they actively solicited input on pre-established questions and issues.

Most of the MPs interviewed thought contact information to be among the most essential type of information to provide. They felt that the Internet provided an alternate avenue for participation and served as a good communication tool. As such, they wanted to ensure that Canadians had the contact information necessary to take advantage of this tool. Indeed, 22 of the 60 MPs interviewed stated that they were motivated to establish Web sites for the purpose of providing their constituents with an alternate means of participation. Some indicated that they felt their constituents expected electronic avenues of participation to be available to them. Of the 60 MPs interviewed, 45, or 75%, indicated that ICTs do allow for greater citizen participation and have increased their communication with constituents. As one MP stated, the technology has improved communication with Canadians to "a scale that I never could have appreciated." Another responded: "Oh it has increased without a doubt ... I think that it gives them (Canadians) more of a voice." It is interesting to note, however, that of those 45 who stated that ICTs have increased their communication with constituents, three were careful to specify that while correspondence had increased, the communication was not meaningful. Others felt that it had improved their communication with their staff and their ability to conduct research, more than it had with Canadians in general.

## Deliberation

Some scholars assert that it would be necessary for participating citizens to also deliberate before any decisions are made (Coleman & Gøtze, 2001; Fishkin, 1991). This, argues James Fishkin, is what makes decisions and participation meaningful. Participants must be "willing to consider the arguments offered on their merits. They must listen and participate with an openness to the reasons given on one side or another" (Fishkin, 1991, p. 37). Given this, one can speculate that if ICTs are strengthening democratic participation then one should be able to clearly identify electronic spaces where deliberation can occur. This condition was found to be far from fulfilled in the Canadian context when looking at MPs' Web sites.

In looking for the presence of deliberatory spaces, each MP's Web site was scanned for such things as electronic bulletin boards, chat servers, and discussion lists. In total only two Canadian MPs offered such features on their Web sites, and one was found to have removed this feature from his site shortly after this study was conducted. His office noted that the feature was not being used and they were trying to rework it to attract more people. Interestingly, only four of the 60 MPs interviewed indicated that they felt ICTs could improve interactivity or deliberation with citizens. However, even these four were skeptical about the potential for deliberation arguing that they lacked the resources necessary to use ICTs for this purpose. Some felt that citizens would not be able to use deliberatory fora in a manner that would be useful, arguing that the speed of ICTs allows for reactionary response that is not well thought out, or well informed.

## Evidence that Views are Heard

This fourth criterion is vital for any participatory tool, and is essential to e-participation. If people do not feel that their views or input are being heard, there is little motivation to continue to participate. In this case, people will continue to feel dis-engaged. As was noted earlier, this is where much of the existing literature falls short. It is relatively easy to discern whether the avenues for participation exist; however, what happens to the information relayed by citizens to their representatives is truly another matter. Therefore, it can be assumed that if ICTs are in fact improving participation then government officials should have means and procedures for handling electronic correspondence and dealing with those citizens who seek to become engaged electronically. To examine this fourth criterion, this study focused primarily on the interviews conducted with MPs. The results gathered were somewhat surprising. While most MPs indicated that they made efforts to respond to those people who e-mail them looking for help on issues related to accessing federal services, almost all of those interviewed stated that they simply deleted campaign mail where constituents and social movements have attempted to convey their input on policy and matters of governance. One MP laughingly stated that campaign mail such as that described above is "filed under 'G,'" while pointing to the garbage and recycling bins beside his

desk. While such comments were made in a rather lighthearted manner, they pose some serious implications for the arguments made by those adhering to a more Utopian approach.

Again, lack of resources was cited as the reason for not further embracing the technology and peoples' efforts to participate electronically. Indeed, with only a couple of exceptions all MPs expressed frustration at what they felt is increased pressure as a result of e-mail. The volume of electronic correspondence has been mounting over the years and MPs feel as though there are growing expectations for timely replies on behalf of those initiating the correspondence. The representatives spoke of a paradoxical situation that they found themselves in where they know that ICTs can be used to engage people in governance, but fear that they will discredit themselves in the eyes of voters as they lack the resources to handle such increased engagement. As such, many MPs stated that they made a conscious effort to minimize their online presence, and did not actively promote e-participation.

## FUTURE TRENDS

This study points to a disconnect between the rhetoric of political officials and the current reality when it comes to increasing citizen participation. It provides a foundation for comparative studies with other democracies and it has also yielded a number of issues that merit future study. For example, as was seen, MPs in Canada indicated that lack of resources was the primary barrier for e-participation. However, most indicated that they would not want to spend increased funding on correspondence or citizen engagement. This prompts one to question whether lack of resources form the crux of the problem or whether it is something more deeply imbedded in the political culture of parliamentarians.

Interaction beyond MPs, possibly with the bureaucracy would also lend further insight into the issue of e-participation. There is a limited amount of work done on this subject. Is the bureaucracy taking a more proactive role and communicating directly with citizens regarding policy formation and change? A study on this subject would be interesting and the results gathered could potentially bring the role of elected officials, and representative democracy, into question.

In addition, this work raises concern about the traditional role of social movements. As was noted above, elected representatives in Canada are particularly frustrated by the large numbers of campaign mail that they receive from such movements. Are social groups impeding the potential for enhanced individual participation by overwhelming policy makers with e-mail? The open admission from Canadian MPs that such mail is deleted also calls into question the efficiency of the activities of such movements. At first light, these questions seem to indicate that perhaps the role of social movements needs to be reconsidered in an era of ICTs where individuals are able to have a stronger voice than they once were.

## CONCLUSION

When examining the statements of senior politicians, both within and outside of Canada, we are presented with a policy context that appears to be conducive to an enhanced participatory democracy propelled by the use of ICTs. However, a more in-depth exploration of the requirements for participatory democracy, an analysis of the content found on MPs Web sites in Canada, and a look at how MPs handle electronic correspondence starts to show a different scenario. This study has shown that e-participation, particularly in the Canadian context, can still be quite limited. Rather than serving as a tool for participatory democracy, ICTs appear to be enhancing and strengthening the existing system of representative democracy where MPs do not enter into deliberations with citizens, but serve as champions for their constituents. The fact that the MPs interviewed for this study tended to focus on e-mail where constituents were looking for help accessing a federal program or service is a testament to this as was the type of information found on MPs' Web sites; namely, links to government programs and services.

However, this is not to say that it is "politics as usual." ICTs have definitely had an impact on the day-to-day activities of MPs. As was discussed, many noted that the technology had improved their communication with their staff and their ability to do research so that they could better participate in Parliamentary activities. Moreover, while ICTs may not have dramatically improved citizen's ability to participate in governance, they have led to an increase in the amount of correspondence received by MPs' offices. In closing, it can be argued that the current situation would be better classified as paradoxical as governments learn and struggle with many of the complications that have come from the widespread use of ICTs.

## KEY TERMS

**Chat Servers:** Chat servers are programs that allow for a high level of "real time" interaction between users. Here, software is employed that enables one user, or group of users, to view a message as another is typing it. Effectively, one might think of this technology as an electronic telephone conversation. This type of technology is particularly useful for e-participation when thinking about avenues for deliberation.

**Cyber-Activism:** Cyber-activism refers to the use of information and communication technologies by individuals or groups to organize and to lobby governments.

**Discussion Lists:** Discussion lists enable users to join mailing lists on a specified topic. Those who join the list can send and receive messages from all of the others on the list. Typically, members share information relating to the subject of the mailing list. This form of interaction is not done in real time and is closer in nature to the bulletin board format than the chat server. However, discussion lists can still serve as a useful mechanism for e-participation.

**Dystopians:** This is a broad means of classifying the various arguments found in the literature on e-participation and e-democracy. Those adhering to a Dystopian approach are those who would argue that ICTs have not improved participation or democracy and in some cases go further by arguing that the technology is having serious negative effects.

**E-Democracy:** Sometimes defined as a component of e-government, e-democracy refers to the way that ICTs are being used to enhance democracy by improving such things as citizen participation, accountability, and transparency.

**E-Government:** The use of ICTs by governments for such things as improved service delivery and information sharing.

**E-Participation:** The use of ICTs by citizens to interact with policy-makers in an effort to take a more active role in governance during non-election periods.

**Electronic Bulletin Boards:** Electronic bulletin boards are programs which enable users to leave messages and to access messages and information on any array of topics. This has the potential to facilitate deliberation and can serve as a useful tool for e-participation.

**Utopians:** This is a broad means of classifying the various arguments found in the literature on e-participation and e-democracy. Those adhering to a Utopian approach are those who would argue that ICTs are dramatically strengthening democracy and the potential for citizen participation.

# E-Planning

**Carlos Nunes Silva**
*University of Lisbon, Portugal*

## INTRODUCTION

E-planning is the e-government concept applied to urban and regional planning. It is the widespread use of information and communication technologies (ICTs), especially the Internet, in the planning system. A planning portal is the access point in the Internet, frequently in the context of a public digital city project. E-planning allows the municipality to carry out a new set of activities or to implement traditional procedures in a new form, due to geographical information systems, computer aided design and database systems, among other tools mentioned, for example, in Mohamed, Meng, and Abdullah (2003), Budthimedhee, Li, and George (2002), Campagna and Deplano (2004), and Harrison and Haklay (2002). E-planning corresponds, therefore, to the passage from a paper-based urban management system to one based primarily on electronic means of information and communication. But it must be seen as more than a simple transfer to a computer system of the traditional paper based routines (Mohamed et al., 2003; Parsol, 2004), requiring also the re-engineering of procedures, the development of a fully integrated ICT back office and, as Harrison et al. (2002) suggest, changes in the nature of the planning process itself. The aims of e-planning, such as more generally all the other components of e-government (for example, OECD, 2003; Pascual, 2003), are to provide better public services, more efficiently, with lower costs and, at the same time, to do that through more participative, transparent and more accountable decision-making processes.

In its more basic level, the e-planning system only offers information and is, therefore, easier to implement. In its more advanced versions, where all or most of the planning services are delivered electronically, its implementation and daily management is not only a more complex task but it also involves more investment, as Couclelis (2004) notes for digital cities. According to the standards of e-Europe, the European Union (EU) initiative for the information society (CEC, 2000, 2002), the availability of public services online can be measured in relation to a framework of four levels of e-government maturity (CEC, 2004).

Applying this scheme to the planning sector, we can consider that the first level—information—consists only in the publication of digital information through the Internet, with few or no capacities to interact. In the second level of maturity—interaction—users of the system can communicate directly with the planning department by electronic mail (one-way interaction); it is possible to download planning applications, for example. In the third level—transaction—users and the planning department communicate electronically with each other (two-way interaction); it is possible to process planning applications and to authenticate them. In the fourth level—integration—there is a full electronic handling of all planning functions.

## BACKGROUND

### Main Characteristics of E-Planning

According to the previous framework, applied to this specific policy area, and taking into consideration the content of several planning sites in Europe, a standard full-developed e-planning portal is expected to provide general information about the functioning of the planning system, municipal regulations, and planning procedures and to include basic and specialised information on all aspects of the planning system, in its several scales—national, regional, and local—as well as, in the case of European countries, a supranational level. It is also expected to provide access to online planning services covering all stages of the development and control process: pre-application advice, submission of applications, consultation, e-petitions, commentaries, complaints, and planning decisions (for the UK example, see Parsol, 2004).

Other planning functions are also present such as the publication of local plans, technical reports, public participation files, monitoring and evaluation reports, and urban marketing campaigns. Urban plans are available in electronic format, allowing any citizen to visualise land use proposals through a public participation geographical information system (PPGIS) and to get a better understanding of all its potential consequences (Carver, Evans, Kingston, & Turton, 2001; Harrison et al., 2002). Detailed information on each parcel of land or building can also be available online, with restricted access conditions in what respects information on private persons (e.g., e-signa-

tures), allowing any local citizen to verify the situation of a process in which he or she has a stake. It must also be possible to make payment of services, fees, or taxes through the planning portal.

A planning blog, a digital newsletter, and mailing lists to distribute automatic e-mail updates about the Portal content are examples of e-planning tools that can be used to stimulate citizen involvement in decision making. But, as Carver et al. (2001) point out, it is not enough to make information available and to stimulate participation, it is necessary to provide information that can be understood by the local community, technology that a common citizen can use and to open the internal decision-making process (Harrison et al., 2002) applying, in practice, the Aarhus Convention on access to information and public participation in decision making (UN, 1998).

A section for children and youths, with information and games for different ages, organised around planning themes, should be included as a form to stimulate participation of young people in municipal and regional life (CoE, 2003) and, through that, to contribute in practice to the implementation of the UN declaration on the rights of the child, especially the right to express views freely in all matters affecting them (UN, 1989).

In an increasingly multicultural society a planning portal is also expected to have an English version and also versions in the main non-native languages present in the local community, if that is the only way to communicate with large sections of the immigrant population, as part of the moral obligation due to cultural diversity (UNESCO, 2001).

It can include an agenda of events related to planning such as, for example, public inquires or municipal boards meetings dealing with planning issues, and a process to measure citizen satisfaction with e-planning services, among other items. If not integrated or linked to a wider municipal Web site, the planning portal should also include general information about the municipality (e.g., geography, history, economy, culture), as well as about the municipal organisation (e.g., organisational chart, elected members, contacts, activities, including e-procurement related to urban management).

## Strengths and Constraints

In relation to the traditional paper based planning system, e-planning presents several advantages, such as those mentioned in Mohamed et al. (2003) or in Yeh and Webster (2004), among other authors, and in several governmental reports, such as DoE (2003) and SE (2001), which are similar to those mentioned for e-government in general (OECD, 2003; Pascual, 2003): more accessible, efficient, effective, quicker, and with lower costs.

It is more comfortable for citizens because it reduces the number of direct contacts needed and time spent, as well as the administrative costs that affect small- and medium-sized enterprises. Planning information can be available permanently for planners and other staff, as well as for the public, in almost every place, if wireless communications are used. It makes easier to work from home, both for planners and for other people that need planning information. It needs less physical space for storage and tends to require less as technology improves.

E-planning has the potential to open up a new Era in public participation in planning, especially through the use of PPGIS (Carver et al., 2001; Harrison et al., 2002) and through the visioning of any area in three dimensions. It can make decision-making more transparent and accountable by allowing the development of a more informed opinion about urban or regional plans proposals, which can contribute to prevent NIMBY (not in my backyard) type of reactions during plan implementation, therefore increasing citizens' confidence in the planning system.

E-planning also faces several types of constraints (Campagna et al., 2004; Carver et al., 2001; Couclelis, 2004; Harrison et al., 2002; Mohamed et al., 2003, among others), not different from those usually referred for e-government in general, such as legislative and budgetary barriers, technology requirements and digital divide issues (OECD, 2003; Pascual, 2003), or the lack of staff's specific training in e-planning, which together can explain partially the difference encountered among municipalities or regions (Campagna et al., 2004), or among countries (CEC, 2004; West, 2003, 2004).

Examples of legal barriers are, for example, the copyright of cartographic bases (Carver et al., 2001), or the classified nature of public information (Mohamed et al., 2003), or the fact that the law requires, in several circumstances, that a communication needs to be done in paper form and by post, which limits the possibilities to use electronic communications (SE, 2003).

The migration from a paper-based system may face in some cases resistance from staff and local councillors, similar to those mentioned in Mohamed et al. (2003): departmental unwillingness to share information; implementation of e-planning solutions separately in each department, to address specific tasks, proving later to be difficult to link; to maintain information outdated in the planning portal.

## FUTURE TRENDS

Future development of e-planning faces external challenges associated with the overall development of ICT sector and the expansion of the information society (e.g.,

interoperability of ICT, market penetration of specific ICT, broadband universal access, digital literacy), and internal challenges that are related with the functioning of the e-planning system itself.

The growth of ICT use among individuals and enterprises, including the use of online public services (CEC, 2004; West, 2003, 2004), in spite of its social and geographical unevenness (Graham, 2002; Grimes, 2003; Winden, Van, & Woets, 2004), is making information society a reality in most of the developed countries, which will certainly increase the number of users of e-planning systems.

The generalised use of broadband or high-speed connectivity, allowing the use of more sophisticated online services, and the development of multi-platform access to the Internet, are also expected to stimulate the use of Internet and, therefore, of e-planning systems.

At the political level, the European Union, with the e-Europe Initiative, gave the political impulse for the development of the information society in the European context, in particular with its second action plan, which elected as one of its objectives to deliver online public services (CEC, 2000, 2002).

Nevertheless, the type of empirical evidence quoted by Winden et al. (2004) about the low rate of broadband adoption, especially in remote areas, and the exclusion of lower social classes, or the evidence mentioned in Graham (2002) about geographical unevenness inside the city or among regions or countries, suggests that the argument in favour of more (local) government intervention to promote universal broadband access, as part of public infrastructure policy, because the market seems to be failing to do that, deserves serious consideration, a conclusion that Grimes (2003) seems to corroborate in the sense that he identifies similar digital barriers for the development of e-commerce activities in peripheral rural areas.

At the same time it is reasonable to admit that the resistance encountered presently in the use of ICT due to the weak digital literacy (Carver et al., 2001) will probably diminish or disappear as analogical forms of communications are gradually replaced by digital technologies. It is expected that in the next decade the majority of households in developed countries will have interactive digital TV, according to broadcasters' plans mentioned by Carver (2001), with one or more e-Gov-TV channels, which certainly will include the planning portal, increasing the number of potential users of the e-planning system.

Also critical for the future expansion of e-planning are internal factors, such as confidence in the system. Data protection and security in the transactions between the user and the e-planning system and the risk of loss of privacy (Couclelis, 2004) are critical aspects that (local) governments will have to face carefully, in similar terms as those of the more general discussion about human rights in an information age (Walters, 2002), as well as planning professional organisations whose codes of professional ethics do not cover, in general, the specific issues raised by e-planning (Silva, 2005). Without security and confidence on the system there will be probably no massive involvement of the local community. The problem of digital archives for future use, in a century time or more, is another challenge that e-planning, as e-government in general, also has to address, as well as the selection of the place to store them.

## CONCLUSION

For all these reasons, we should only talk about the existence of a comprehensive e-planning system when the fourth stage of development or maturity is reached in its full potential, which means when both the plan and the planning and management processes are mostly carried out on a digital platform. In practice, however, the name has been used to describe a great variety of situations.

Although the new ICT can allow the development of sophisticated public decision-making systems, numerous planners and local councillors seem to be still unwilling to adopt it in the local planning system, a pattern of behaviour similar to what Campagna et al. (2004) found in their case-study. Therefore, e-planning will probably tend to complement the traditional procedures rather than to substitute them entirely in the short and medium term.

Among all key challenges faced by e-planning, it is important to stress the one related with the access of the most disadvantaged social groups and disabled persons, as well as the problems associated with broadband access in the most remote areas. If large segments of the population can't access online planning services or if they cannot understand the information, e-planning will certainly contribute to increase social exclusion and geographical unevenness. To prevent that to happen requires a consistent e-inclusion strategy in order to ensure digital literacy for all citizens, broadband accessibility for all, gender equity, and to make the use of ICT economically affordable.

E-planning can create new social exclusions, in some cases coincident with old social, economic and geographical divides, as did all technologies in the past (Yeh et al., 2004), but it can also be used as an instrument of a broad (local) public policy strategy to promote citizen empowerment and to enhance social cohesion, economic competitiveness and environmental sustainability.

## KEY TERMS

**Digital City or Digital Region:** A Web site whose content is related to a specific territory, a city (municipality) or a region.

**Digital Literacy:** The capacity to make effective use of ICT.

**E-Government:** The provision of national, regional or local public sector information and public services fully executables through the Internet.

**E-GovTV Channel:** A digital interactive TV channel dedicated to public services, including local government services (e-planning, etc.).

**E-Inclusion:** In the context of e-planning means equal access, for all citizens, to planning information and planning services through ICT.

**E-Planning:** The application of e-government to urban and regional planning. It is the use of information and communication technologies (ICT) in urban and regional planning.

**E-Procurement:** The acquisition through the Internet of goods and services by an organization.

**ICT (Information and Communication Technologies):** Include local computer networks, the Internet, electronic mail, digital television, mobile communications, etc.

**Planning Portal (or Planning Gateway):** The access point in the Internet, where information on urban and/or regional planning issues and services are presented.

**PPGIS (Public Participation Geographical Information System):** A Webgis facility that allows the viewing of plan proposals. It enables the public to participate actively in the planning process.

# E–Pressure through Internet against Monopoly

**Martin Gregor**
*Charles University, Czech Republic*

## INTRODUCTION

In November 1998, a Czech e-pressure group, Internet proti Monopolu ("Internet Against Monopoly," or IPM), was founded in order to protest planned price increases by the monopolistic domestic telecom operator, SPT Telecom, on fixed-line telephony services. The increase would principally affect local fixed-line calls and, disproportionately, the increasing number of Internet users, whose access calls to Internet service providers (ISPs) are lengthier than voice calls. SPT proposed not only to raise the price for one local-call pulse, but also to shorten it. After four weeks of petitions, boycotts, demonstrations, and negotiations, the group pushed the telecom to ease the data-call pricing structure. The Czech Internet community—computer users, Web operators, and ISPs—thus got organized, which also persuaded the Czech government to modify its telecommunications policy, positively affecting the subsequent proliferation of the Internet.

IPM, on its part, was unique in a number of respects:

1. **Origin:** The founders came from e-media and e-business
2. **Flexibility:** The e-movement was able to organize major protests just two weeks after establishing itself
3. **General Support:** An e-petition was quickly signed by 100,000 e-citizens
4. **Broad-Based Boycott:** A one-day boycott of the monopoly telecom's services by ISPs affected 60% of Czech Internet traffic and was supported by 50% of Internet users
5. **Online Organization:** Public demonstrations were organized and propagated exclusively in cyberspace
6. **Precedent:** Although IPM was the very first e-pressure group in the Czech Republic, it was a significant success

From a technical and economic point of view, the slightly better price package ultimately offered to Internet users may look like a minor victory in a minor war. We should consider, however, the unlikely circumstances under which it was achieved. Czech e-communities in 1998 had a weak political/civic orientation, and predominantly concerned technologies, games, and education. Moreover, e-communities in general have several disadvantages compared with traditional communities, such as anonymity, lack of incentives toward collective action, and inexperience.

In central and eastern Europe in particular, social capital is rather depleted. Decades of communist governments had largely destroyed any sense of "civic society," and thus genuine collective action. Furthermore, people quickly turned to strictly individualistic values given sudden (post-1989) free-market conditions, and rarely engaged in group activities. Civil activism was almost unheard of in post-communist Czechoslovakia and in the Czech Republic. Besides trade unionists and farmers, few others took to the streets in the 1990s. There was, in fact, only one major labor action (by state railway employees in 1995) in this decade of relatively low unemployment in the domestic economy. Moreover, the Czech e-population in 1998 was still small, and regulated prices were raised in other industrial sector as well (gas, electricity, water utilities, rental housing), so telecommunications was not a special case.

## BACKGROUND

### Monopolistic Incumbent

To derive the proper implications from the protests, let us examine the facts. In 1994, the TelSource consortium (51% owned by the Dutch telecommunication market leader, KPN) entered the state-owned SPT Telecom as a strategic partner, buying a 27% share from the Czech government. In the contract, the terms of which were kept confidential for five years, the Czech government promised the consortium managerial control and a virtual monopoly until January 2001; in exchange, TelSource was obliged to modernize the operator's telecommunications infrastructure. The consortium held ambitious plans of expansion into central and eastern Europe, but after KPN suffered economic losses at home, the plan to build a regional powerhouse was abandoned.

On the consumer side, SPT set the price for dial-up and other phone connections to the Internet at a price equal to that of a local call, plus an additional charge for Internet

access. The only, yet partial, alternative to this near monopolist offer was to buy connection to Aliatel's local loops. However, it was very costly for small and medium Internet traffic (approx. 650 euro per month), and was available in only thirteen cities.

On October 29, 1998, SPT Telecom announced a "price re-balancing on the basis of long-term price adjustment schemes" (the so-called Price 99 tariff). The re-balancing meant less costly international calls but more expensive local ones. The company justified the rebalancing by citing EU recommendations in the pre-accession period, and referred to the 2001 liberalization of the Czech telecoms market that would anyway result in price adjustments. Price rebalancing called for an average 25% increase in local-call prices, and an average 25% decrease in the prices of international calls. Overall, the change was supposed to constitute a 3.9% overall increase, or below the annual inflation rate.

In the fall of 1998, four other events took place that, taken together, lead to civic action against the operator. First, days before announcing higher prices, SPT Telecom revised its full-year 1998 profits upward. Profits were projected to increase by 16%, to CZK 33.5 billion (approximately EUR 1 billion), and the profit-to-revenues ratio was supposed to be about 50%.

Second, on November 3, the Czech Telecommunications Office, the sector regulator, banned a long-distance service based on Internet telephony introduced earlier in the year by Radiomobil, a domestic mobile operator. SPT Telecom, as part of the terms of it monopoly on international calls, was prohibited from engaging in Internet call services, and the regulator thus opted for a market-wide ban instead of lifting the regulation imposed on SPT.

Third, SPT Telecom investments were planned to shrink, as CEO Urs Kamber announced in the Czech *MF Dnes* newspaper on October 31 (see Table 1). By the way, this delayed the introduction of the opt-out option (possibility to leave for another operator) in 2001.

Last, but not least, TelSource bought an additional 6.5% stake in SPT Telecom (spending some CZK 8 billion) on the stock exchange in building up a one-third blocking minority (33.4%). KPN CEO Marten Pieters claimed the blocking minority would be used "mainly for decisions about the capital structure in SPT." While this act did not violate the contract between the state and TelSource, which prohibited a more than 34% TelSource ownership, it did signal TelSource's thirst for more control of the company.

*Table 1. SPT Telecom investments and total expenditures*

| Year | Investment (in CZK bil.) | Investment to expenditures (in %) |
|---|---|---|
| 1996 | 30.13 | 93 |
| 1997 | 35.25 | 88 |
| 1998 | 33.23 | 72 |
| 1999 | 18.12 | 35 |
| 2000 | 16.93 | 30 |

*Table 2. Internet 99 vs. previous tariffs (CZK/seconds)*

| Time | Price 98 | Price 99 | Internet 99 +2.60 per data call |
|---|---|---|---|
| 07:00–17:00 | 2.40/180 | 2.60/120 | 2.60/170 |
| 17:00–19:00 | 2.40/180 | 2.60/120 | 2.60/377 |
| 19:00–21:00 | 2.40/360 | 2.60/240 | 2.60/377 |
| 21:00–07:00 | 2.40/360 | 2.60/240 | 2.60/731 |

## Re-Balancing in Detail

The October 29 press release described an on average a 3% increase with Price 99 tariff, but the estimate was far below the value of the effective increase for dial-up Internet users. Rates would be raised for these users by 62.5%, market analysts said (see Table 2).

Another official estimate (25% increase), as announced by TelSource CEO Bessel Kok, was calculated based on an average local call of two minutes. In peak time (07:00-19:00), calls of under two minutes would rise by 8.3%, whereas calls exceeding two minutes would rise by 116%, so the estimate contained a built-in assumption that people would keep call times to under two minutes. This entirely avoided the issue that, on the Internet, the average connection time is significantly longer than two minutes.

# INTERNET RESISTANCE

## Birth of IPM

In the figure previously mentioned, 62.5%, was perceived by Internet professionals as exploitative and discriminatory. Three prominent Czech e-entrepreneurs—Ondrej Neff (owner of a popular e-daily), Patrik Zandl (editor in chief of the most popular technology site), and Ivo Lukacovic (owner of the leading search engine)—founded the IPM e-movement the very day the re-balancing was announced. The triumvirate was not a radical grouping, but a highly representative and credible sample of the Czech Internet community.

IPM immediately launched a Web site, www.bojkot.cz ("boycott.cz"), and posted an e-petition. Surprisingly,

the petition received electronic signatures from 1,800 different IP addresses on the first day, when its existence was spread without the benefit of a campaign. Note that, at that time, established sites such as the one run by Zandl had an average of only 4,000 visits per day.

The e-campaign as such started on November 1, when Zandl wrote a mobilizing article that concluded "and the lighted torches spread quickly on the Web, for e-people hate to be enslaved." Three major portals and several online magazines linked the Boycott site, and thousands of signatures subsequently joined the e-petition. The information became widespread by means of viral marketing, unknown on the Czech Internet until then. TV coverage of the IPM movement made it a headline issue of the day. The critical mass of awareness had been achieved.

Sensitive to the negative publicity ahead of 2001 market liberalization, SPT Telecom started to negotiate with IPM on November 12. The company established a working group whose experts gained time by rejecting the initial IPM proposal of flat-rate monthly fee for Internet connection.

## Boycott and Negotiations

In response to that defensive strategy, IPM organized a boycott of Internet traffic. The aim was not to harm SPT Telecom economically, but to demonstrate the overwhelming support of Internet users in the form of an e-happening. On the boycott day (November 18), users were asked not to connect to the Internet. The Web sites involved showed blank pages, save a banner announcement of the boycott. Internet service provider SkyNET even contributed an economic benefit—customers who did not connect that day earned a 10% discount on their December bill.

The "offline side" of the boycott consisted of two street demonstrations, arranged outside the headquarters of SPT Telecom in Prague and in Brno. IPM employed several symbolic features to make the events compelling:

1. **Color:** Yellow is the company color of SPT Telecom, so IPM used the color on banners, T-shirts, and other campaign material (Note the importance of color identity for mass events, as, for example, in the case of the Orange Revolution in Ukraine in 2004.)
2. **Date:** The boycott date was chosen as November 18. The preceding day is International Student's Day, upon which, in 1989, students in Prague staged demonstrations that sparked the Velvet Revolution, which put an end to communist rule in Czechoslovakia, and upon which, in 1939, students demonstrated against the Nazi occupation of Czechoslovakia, which were violently out down; both were deeply resonant manifestations of protest and will
3. **Nicknames:** Protestors referred to SPT Telecom as Monopolcom and to TeleCommunism
4. **Symbolic Allegories:** At the Prague demonstration, people connected themselves, via ropes and wires—a Web—to a papier-mâché yellow spider consuming a keyboard. Not subtle, but easily worth a thousand words

The e-happening was a major success. First, the e-petition received 100,000 signatures, an incredible number given mild e-readiness in 1998. Major portals and online dailies, in total some 950 sites, supported the Internet boycott. The majority of ISPs (Bohemia.Net, CZCOM, GTS CzechNet, INEC, InWay, OASA, Telenor Internet) participated, while others (CESNET, PVT) at least posted banners, or published supportive official statements. According to the Czech News Agency, 60% of Internet users joined the boycott, and connection time and transferred data volume fell by 50% on the day. Political parties also expressed support for the boycott, including the governing Social Democrats (CSSD). Paradoxically, Finance Minister Ivo Svoboda of the CSSD had approved the SPT price rebalancing. That approval was outspokenly criticized by other party and Cabinet members, including Deputy Prime Minister Pavel Mertlik and Minister for Transport and Communication Antonin Peltran (both CSSD), the latter of whom proposed reopening the terms of the contract with TelSource.

Two days after the boycott and the demonstrations, SPT Telecom came with a new proposal called "Internet 99" (Table 2). ISPs were offered special phone numbers toward distinguishing data calls from voice calls, and special prices on data calls. In attempt to restore its reputation, the company proclaimed that it had been preparing such an offering long in advance of *the boycott* (although it presented no technical details whatsoever) and likened the IPM's action as "breaking into an open door."

The first response of IPM toward Internet 99 was negative, and the major issue became the proposed fixed price (CZK 2.60) per each call. IPM argued that technical mistakes resulting from poor connection quality meant inaccurately billed connections (in SPT's favor). SPT thus made a concession and agreed that the connection

*Table 3. Timetable of events*

| | |
|---|---|
| Oct 29 | Price 99 tariff announced by SPT |
| Oct 29 | Internet Against Monopoly (IPM) founded |
| Nov 1 | E-campaign launched by IPM |
| Nov 5 | TV coverage of IPM (headline) |
| Nov 12 | Negotiations IPM-SPT |
| Nov 18 | IPM Boycott Day |
| Nov 20 | Internet 99 proposed by SPT |

time should not be assessed immediately, but upon the first minute, ensuring that technical problems related to the initial connection would not affect user prices.

Once this had been resolved, IPM found it difficult to ask for something other. Simply put, Internet users could no longer use the "exploitation" argument any more than other SPT Telecom customers could, because Internet 99 reflected the fact that data calls are, on average, less expensive than voice calls. IPM thus agreed to the proposal, securing one modification: an increase of the pulse length to 180 seconds.

## Outcomes

In the end, SPT Telecom revenues were not significantly affected by the Internet 99 tariff. The demand for e-connections rose because of the lower data-call price and with the raised visibility of the Internet. Zandl (2001) estimates that revenues lost related to the price decrease were fully compensated as early as in 2000. And what of the gains and losses of the e-population?

The special price package Internet 99, later renamed as Internet 2000 and Internet 2001, was particularly beneficial for households. The main reason is that the price for the 21:00-07:00 slot was extended to cover the whole of weekends and holidays. On the other hand, the pricing policy did not benefit institutions and companies, and for brief data calls (below eight minutes), the final charge was higher than proposed in the Price 1999 proposal (because of the fixed CZK 2.60 per each data call). As a result, Internet traffic shifted to lower-fared hours, and average connection time rose.

SPT Telecom unified access numbers so that users from areas without ISPs would pay intraregional rather than interregional call rates. This further boosted Internet development in less-populated districts. On the other hand, the measure only involved ISPs with sufficient access points, and access unification went into effect only with the Internet 2000 tariff.

The increase in consumers connected to the Internet led to revenue-sharing arrangements between ISPs and telecom operators. In 2000, Dattel negotiated the first such contracts, and SPT Telecom copied the business model. This stimulated Internet growth. The higher societal visibility of the Internet was a direct consequence of IPM's activities, and surely helped particularly those e-businesses and e-media that led the boycott.

Furthermore, the IPM movement induced the Czech government to reassess its regulatory policy toward telecommunications. TelSource was no longer perceived by the government as a suitable strategic partner, and it was no surprise for the government when TelSource lost interest in SPT Telecom after full-market liberalization in 2001.

*Table 4. Hourly costs of data calls (in CZK)*

| Time | Price 98 | Price 99 | Internet 99 |
|---|---|---|---|
| 07:00–17:00 | 48 | 78 | 57.7 |
| 17:00–19:00 | 48 | 78 | 24.4 |
| 19:00–21:00 | 24 | 39 | 24.4 |
| 21:00–07:00 | 24 | 39 | 15.4 |

## FUTURE TRENDS

What are the implications of the IPM pressure for e-communities, and how effective is e-pressure compared with traditional forms of consumer pressure? First, success comes with broad, ready-made coalitions, from e-media and e-business communities, and from blog writers, ISPs, and Webmasters, especially when they resort to activities that take little time, such as circulating e-petitions. Large networks facilitate the spread of information, and lend credibility. In particular, the support of e-dailies (informational politics) is of key importance (Davis, Elin, Reeher, 2002). A group also needs a collective potential. Political alienation signaled by the decline of participation in traditional political parties and traditional interest groups may not reflect a lack of interest in collective action as such. IPM broke a "spiral of silence" (Noelle-Neumann, 1986) in an environment seemingly unfit for collective action.

Second, e-communities emerge quickly when the freedom of the Internet is at stake. Therefore, one can see low prospect for Internet regulation given this likely resistance. Moreover, technical options, such as relocating Web sites to different jurisdictions, would be another obstacle.

## CONCLUSION

This article documents the case of a successful e-pressure movement, but some qualifications must be raised. Most importantly, IPM consisted of only three persons in order to maintain operative flexibility. However, sustained activities require hierarchy, clearly defined goals, and properly allocated competencies. It is not clear if competing e-factions could be kept under control otherwise. In the case of IPM, many people were finally dissatisfied, and some accused the IPM of ultimately being corrupted.

In addition, an ever-present issue in all e-pressure activities is who to lobby. IPM limitedly targeted SPT Telecom, but regulators and governmental ministries—who approved the original pricing scheme—were the

institutions in charge of the national telecommunications policy. Negotiations with ministries would then have proved a delicate, multiple-sided political issue, quite different from a clash between an ad hoc private group and a monopolistic company.

Finally, the Internet is a mercurial communications network, in which interest is quickly generated but just as quickly lost. IPM recognized that the majority of ordinary consumers lacked dedication or interest in examining the complicated details of the Internet 99 proposal when it was presented in the media, and thereby IPM lost much of thus-achieved bargaining power. Delay in negotiation is the prospective Achilles heel of e-pressure.

## KEY TERMS

**Avalanche Marketing:** The distribution of positive product (or other) information by consumers. For political and interest-group causes, the Internet is an ideal conduit of avalanche marketing—messages can be multiple, the costs of reproducing the information small or nil, and private networks vast and interconnected.

**Collective Action:** The problem of collective action is that while an individual may find it useful to participate, since the benefits are distributed in the entire group the individual has a rational incentive to behave as a free rider. Each group willing to organize collective action thus has to overcome the problem of collective action. On the Internet, low-cost instruments such as e-petitions can mitigate the problem of collective action (i.e., that the individual cost/benefits do not match the social costs/benefits).

**E-Petition:** An online petition is a cost-effective pressure instrument. The costs of administering the petition are negligible for the owner, and signatories find it an easy way to indicate support. In addition, those petitioned are not presented with direct pressure to sign, and can easily and concurrently gather additional information, thus enriching their decision.

**Natural Monopoly:** Large-sized telecommunications suppliers have long been considered as "natural monopolies" deserving of special regulation. Natural monopolies are defined by declining marginal costs in all scales of production, which implies that the production of the entire market is most effectively provided by a single company. However, in order to achieve a socially efficient price, price should equal marginal costs, which is impossible for the monopolistic company, since revenues would then not cover costs. Natural monopoly, if unregulated, would therefore increase prices, and produce socially sub-optimal product amounts. Regulation is required to ensure effective production. Globalization and technological development make the concept of natural monopolies increasingly less relevant.

**Viral Marketing:** See Avalanche Marketing.

# E-Rulemaking

**Cary Coglianese**
*Harvard University, USA*

## INTRODUCTION

Throughout the world, governments use regulation to combat monopoly power, protect consumers, and reduce health, safety, and environmental risks. Regulation promotes the safety of transportation, the cleanliness of the air, and the quality of their food and drugs. Today, nearly every major aspect of contemporary public life is significantly affected by rules made by regulatory agencies, ministries, or bureaus (Kerwin, 2003).

Given the consequential and complex nature of regulatory decision-making, crafting rules presents government agencies with significant informational challenges. Government regulators must collect information to understand the causes of regulatory problems, identify available regulatory options, and predict the effects of each alternative (Coglianese, Zeckhauser, & Parson, 2004). To develop a new rule, regulators must often undertake extensive studies and analyses and respond to comments from industry groups and other interested organizations.

E-rulemaking—or the use of information technology in government rulemaking—promises to help regulatory agencies make rules more efficiently and with better quality (Brandon & Carlitz, 2002; Johnson, 1998). E-rulemaking may also help expand public access to and participation in government decision making. Despite the significance of regulatory decisions, they have often been made in relative obscurity, with organized business lobbies sometimes having disproportionate influence over policymaking. Information technology may facilitate greater transparency and democratic accountability in the rulemaking process.

Already, regulatory agencies are making use of information technology to create Websites containing notices of new regulatory proposals and various background documents. They have also begun to allow citizens to use the Internet to share comments on new regulatory policies or engage in online dialogues (Beierle, 2003; Brandon & Carlitz, 2002). In early 2003, for example, the United States government launched a new Web portal called Regulations.Gov that allows the public to locate and comment on all new regulatory proposals announced by hundreds of federal regulatory agencies (Skrzycki, 2003). In addition, American officials are currently at work developing a government-wide, online docket system that will make available all the extensive information contained in each agency's rulemaking files (Skrzycki, 2004). Efforts such as these are likely to continue and can be expected in other regulatory jurisdictions around the world.

## BACKGROUND

In order to understand how information technology can be used in the rulemaking process, it helps to understand the basic contours of that process. By way of illustration, consider how rulemaking operates in the United States for agencies like the Environmental Protection Agency, Department of Agriculture, and Federal Aviation Administration. These agencies typically first develop plans or "regulatory agendas" that are published twice each year in the *Federal Register*, a daily publication that includes regulatory notices and other material submitted by federal departments and agencies.

As agencies work on the items included in their agendas, they gather information, conduct analysis of the underlying problem, and identify possible regulatory solutions. They also frequently engage in discussions with industry representatives, other organized interests, and staff members from Congress or other agencies (Strauss, Rakoff, & Farina, 2003). When an agency has reached a tentative decision, it proceeds to publish a notice of proposed rulemaking (NPRM) in the *Federal Register*. In addition to describing the proposed rule, the NPRM will usually enunciate reasons for the proposed new rule and discuss the agency's underlying regulatory analysis (Administrative Procedure Act, 1946). The NPRM also informs interested parties how they can submit comments to the agency over its proposed course of action.

After reviewing the comments submitted on the NPRM and conducting any further analysis, the agency staff will make revisions to the proposed rule and then publish the final rule in the *Federal Register*. In addition to publishing the operative rule itself, the agency will also explain its decision in a preamble, a section of the *Federal Register* that accompanies the final rule. These preambles will often be longer than the final rules themselves, sometimes spanning more than a hundred pages for a single new rule.

Even after the final rule is published in the *Federal Register,* the rulemaking process continues (Coglianese,

2001). The operative rule itself, without the preamble, is later moved to and published in the relevant section of the *Code of Federal Regulations*. Furthermore, businesses or nongovernmental organizations can take the agency to court over new rules. Depending on what happens in litigation, the regulatory agency may need to revise its rules, which would start the entire process over again.

## E-RULEMAKING'S PROMISE

Interest in applying information technology to the rulemaking process is growing (Shulman, Thrane, & Shelley, 2005). Already, regulatory agencies in the United States and other countries have begun to apply information technology to the rulemaking process. Agencies now permit members of the public to submit their comments by e-mail; they make the contents of their regulatory dockets available on the Internet; and they use information technology to help agency managers track the progress of rulemaking staff (Brandon & Carlitz, 2002). These existing applications only scratch the surface of information technology's potential for government rulemaking.

Researchers and public officials are contemplating a variety of new applications of digital technology in an effort to help government agencies improve the process of rulemaking—and thereby also to improve the quality of the rules themselves. Since making rules requires the acquisition, processing, and analysis of large quantities of technical and time-sensitive information, systems for information retrieval and extraction can aid the work of the regulatory analysts. Analysts could also use text categorization technology to sort public comments based on the issues they address or the departments within their agency to which they refer (Shulman, Hovy, Callan, & Zavestoski, 2004; Lau, Law, & Wiederhold, 2005). Summarization systems could automatically condense large studies or comments into more useable size for government officials to digest.

In addition, information technology can help regulators draft the text of new rules or supporting documents. Systems could be designed to flag potential inconsistencies within a proposed rule or between the proposed rule and existing rules. In order to maximize the regulated community's understanding of its obligations under a new rule, drafting software could suggest alternative sentence construction to make rules simpler and more accessible to a broad audience. Rule compliance wizards available on an agency's Web site could also help ensure that regulated entities understand and meet their regulatory obligations, even in areas with complex systems of rules (Kerrigan & Law, 2005).

Information technology can be used in a variety of ways to inform citizens about government rulemaking. Agencies can easily create automatic alerts to inform interested citizens about proposed rules under development. To help citizens offer more informed comments, information technology could provide clearer or easier access to information about a rule's development. Agencies could develop simulation software that would show how the costs and benefits of a proposed rule would vary under different parameters or assumptions, and then make that software available for the public to use to develop a better understanding of the tradeoffs implicit in a rulemaking (Belton, 2000).

Information technology could also create new opportunities for public deliberation over rulemaking. Information technology could allow members of the public to submit questions to the agency or engage in ongoing dialogue with agency staff or others interested in a proposed rule. In addition to online chat rooms, agencies could conduct digital public hearings or even convene cyber-juries that would link citizens from across the jurisdiction to deliberate over core policy issues raised by a rulemaking (Coglianese, 2005).

## GOALS FOR E-RULEMAKING

As these examples show, e-rulemaking encompasses a range of new digital government applications. Some of these applications use existing technologies simply to digitize the existing rulemaking process, such as by providing documents online or allowing the submission of electronic comments. However, new applications also have the potential to transform the existing rulemaking process in significant ways (Lubbers, 2002). Whether applying existing technologies or designing new ones, decisions about whether and how to apply e-rulemaking call for attention to e-rulemaking's goals. E-rulemaking is generally thought to have the capacity to advance one or more of the following goals (Coglianese, 2004a).

1. **Enhance Democratic Legitimacy:** Increasing democratic legitimacy could be accomplished by using information technology to increase public understanding of rulemaking, make the process more interactive and deliberative, and make it easier for more democratically accountable institutions, such as the legislature, to oversee the rulemaking process
2. **Ensure Better Decisions:** E-rulemaking could improve policy decisions by making it easier for regulatory officials to analyze large volumes of data drawn from multiple sources. Simulation software

could help analysts make better predictions, and other technologies could make it easier for agencies to rely on routine use of high quality economic analysis

3. **Reduce Administrative Burdens:** Information technology can enable agency managers to coordinate rulemaking staff and other resources more efficiently. To date, a few agencies have reported some cost savings from initial applications of e-rulemaking for storage of documents
4. **Expand Regulatory Compliance:** Agencies can use information technology to increase compliance both by increasing public understanding of what regulations require and also, possibly, by reducing the cost of compliance through compliance assistance software.

## FUTURE TRENDS

To achieve measurable improvements in meeting these goals, research will be needed from across both the information sciences and the social sciences (Coglianese, 2004b). Information science research will be crucial for technological design, such as developing text categorization and summarization tools for the rulemaking environment. Social science research will be needed to understand better the professional tasks of regulatory decision makers as well as the organizational environment within which technologies will be deployed. With coordinated input from across multiple disciplines, digital government researchers will be able to develop still more effective uses of information technology and better design rulemaking institutions to make better use of such technology. Future research directions will span four main areas (Coglianese, 2004a, 2004b).

1. **Information Technology:** E-rulemaking raises a series of challenges for research in the information sciences, such as designing general simulation and modeling packages or software to conduct automated consistency checking or cross-indexing and linking to related documents (Hovy & Noveck, 2004). In addition, human-computer interface research will help ensure that systems will be easy for the broad public to use and will therefore facilitate greater public participation. Any increase in citizen involvement will generate the need for information technology to help process and categorize public comments
2. **Agency Management:** E-rulemaking will give rise to a number of research questions in the field of public management or related areas of institutional or legal analysis. It will be important to study the effect on regulatory officials and their institutions from the introduction of new information technologies (Fountain, 2001). Do these technologies actually achieve their goals of improving regulatory decisions? Do agency staff members use these systems in the ways they were designed? How does the institutional environment affect the efficacy of e-rulemaking
3. **Public Participation:** Since e-rulemaking can affect how members of the public interact with government, political science research can help understand how information technology affects the involvement of businesses, interest groups, and citizens in the rulemaking process (Shulman, 2004). Such research can help assess whether information technology actually improves public understanding of rulemaking or increases the number and quality of comments filed. Of equal value will be to understand whether the types of participants in the rulemaking process change, or whether the proportion of comments from industry continues to dwarf the proportion from ordinary citizens (Coglianese, 2005). Social scientists will also be able to help determine whether e-rulemaking affects the public's overall perception of legitimacy to government regulation
4. **Regulatory Compliance:** A final avenue for future research would focus on how e-rulemaking can address regulatory compliance. Basic research on the factors that affect compliance with regulations will be helpful in identifying ways to use information technology to improve compliance. In addition, research could investigate how different kinds of compliance assistance software affect regulated actors' knowledge of rules and the obligations they impose (Kerrigan & Law, 2005). In addition, research could identify ways to use technologies such as remote sensing to supplement traditional enforcement tools

## CONCLUSION

Government rulemaking affects the most significant aspects of today's economy and society. Given the importance of rulemaking, it is not surprising that government officials are beginning to investigate information technologies that can promise to improve regulatory decision-making. Regulatory agencies may be able to deploy e-rulemaking technologies to improve their information collection and regulatory analysis, enhance their interaction with the public, and ultimately implement their rules in a more effective manner.

E-rulemaking may be able to advance important goals of democratic legitimacy, improved decisions, lowered administrative costs, and increased compliance. Research will be needed to determine whether specific applications of e-rulemaking actually serve these goals. Researchers working across both the information and social sciences can help design information systems that fulfill institutional requirements and improve the rulemaking process. Building and sustaining research on e-rulemaking should be part of any strategy to improve the way government makes rules that will in turn affect every major aspect of society.

## KEY TERMS

**Code of Federal Regulations (CFR):** The CFR is the annual publication of all federal agency regulations currently in force, with rules organized by subject matter.

**Federal Register:** The Federal Register is a daily publication in which federal agencies publish proposed and final rules as well as other announcements. Rules published in the Federal Register are organized in chronological order.

**Final Rule:** After receiving public comments, agencies publish their final rules in the Federal Register. In addition to the text of the rule, the agency must publish a statement justifying the rule. Such a statement will usually include a discussion of the major policy issues involved, the evidence relied on for the decision, and a reply to any counterarguments presented in the public comments.

**Notice-and-Comment Rulemaking:** Notice-and-comment, or informal, rulemaking is a process in which the agency publishes a proposed rule, receives public comments, and then publishes a final rule without holding a formal hearing on the record. Notice-and-comment rulemaking is the most common way for agencies to issue regulations.

**Notice of Proposed Rulemaking (NPRM):** Agencies must publish a notice of proposed rulemaking in the Federal Register to inform the public of the underlying legal authority of the proposed rule and its specific terms. The NPRM also contains information about when and where to submit public comments.

**Preamble:** When an agency publishes a notice of proposed rulemaking or a final rule in the Federal Register, it also publishes a statement explaining the purpose and background of the rule. This statement is the preamble. For final rules, the agency also responds to public comments in the preamble.

**Regulatory Agenda:** The Regulatory Flexibility Act requires that agencies publish a regulatory agenda twice each year containing a description of the subject area of rules that the agencies intends to propose, an approximate schedule for completing action on rules that the agency has already proposed, and a listing of recently completed rules.

**Regulatory Docket:** All materials and information related to a rulemaking are compiled in a regulatory docket. The docket includes studies, comments, and any other information on which the agency relies in developing a rule.

# E–Service Provision by New Zealand Local Government

## INTRODUCTION

Historically, information and services can only be obtained through narrow, one to one, phones, and agency-specific shop fronts (Caffrey, 1998). Information technology, especially the Internet, opens possibilities of using methods to distribute information and deliver services on a much grander scale. The Internet provides a foundation for a variety of communications media. The Web is one of the most important media built upon the Internet. It can be accessed from almost anywhere in the world by means of computers and electronic devices; it is possible to elicit more information, establish platforms for online payment, online consultation and e-voting. Security concerns can be overcome by data-authentication technologies.

It can deliver government services and encourage greater democracy and engagement from citizens. Governments around the world are exploring the use of Web-based information technology (Grönlund, 2002). Attention has focused on the design and delivery of portals as a major component of government electronic service infrastructures. The N.Z. government portal site (http://www.govt.nz/en/home/) or the Local Government Online Ltd (LGOL) Web site, (www.localgovt.co.nz/AboutCouncils/Councils/ByRegion/) are examples.

Since the mid-1990s governments have been tapping the potential of the Internet to improve and governance and service provision. "In 2001, it was estimated that globally there were well over 50,000 official government Web sites with more coming online daily. In 1996 less than 50 official government homepages could be found on the world-wide-Web" (Ronaghan, 2002).

Local governments are faced with growing demands of delivering information and services more efficiently and effectively and at low cost. Along with the rapid growth of technological developments, people demand high quality services that reflect their lifestyles and are accessible after normal office hours from home or work. Thus, the goals of delivering electronic government services are to simplify procedures and documentation; eliminate interactions that fail to yield outcomes; extend contact opportunities (i.e., access) beyond office hours and improve relationships with the public (Grönlund, 2002).

Having an effective Web presence is critical to the success of local governments moving to adopt new technologies. Of equal importance is the evaluation of Web sites using different manual and automated methodologies and tools. In this study an evaluation of local authority Web sites was conducted to gain a practical understanding of the impact of the Internet on local governments in New Zealand using a tailor-made model specific to local governments. Issues studied focused on the information and services provided by the local authority Web sites. What is more important is whether the local government operations can or are able to support the expectations for speed, service, convenience, and delivery that the Web creates. Through identification of best practice Web sites and a set of evaluation methods and tools, this paper will provide a set of design guidelines to local authorities that would benefit and better meet the needs of their local communities.

## BACKGROUND

New Zealand local government, created by statute of the central government, is one of the two branches of government in New Zealand. There are in total 86 councils, 12 from Regional, 15 from Territorial-City, 59 from Territorial-District (including the Chatham Islands and four unitary Councils that have regional functions). All 86 local authorities from four different sectors represent multiple functions and accountabilities on their Web sites. While regional councils focus on biosecurity control, harbour navigation and safety, land transport, and regional civil defense; city and district councils are responsible for community well-being and development, environmental health and safety, infrastructure, recreation and culture, as well as resource management.

*Table 1. Web-site evaluation criteria*

| CATEGORIES | | CRITERIA |
|---|---|---|
| INFORMATION | Authority Information | Web-site host: Councillor profiles, Council structure, and history of Councils |
| | Customer Information | Council's audiences: Ratepayer/Nontatepayer, residents, visitors to the site, and businesses |
| | Informational Services | News/Events, Tourist/Visitor, Property and Rates, Water, Public, Community, Environmental, Economic, Local Governance Statement, Democracy, and Publications and Reports |
| | Transactional Services | Water, Rates, Property and Cemetery Search, Billing and Payment, GIS and Mapping, and Feedback |
| | Other Information | Links to external or useful sites (e.g., Library, Government Portals, and Tourism) |
| LEGAL STATEMENTS | | Legal Disclaimer, Privacy Statement, Security, and/or Copyright |
| PROMOTIONAL/ RETENTION | | Newsletter, Climate, Photo Gallery, Employment, and Contact |
| NONFUNCTIONAL REQUIREMENTS | | Aesthetic Effect, Ease of Use, Innovation, Navigability, and Performance |

New Zealand central government launched an e-government strategy in 2001 that brings all government agencies together, including local governments, using the Internet and e-commerce applications to better provide citizens and businesses with government services and information (State Services Commission, 2004a). The e-government strategy also provides a set of Web development guidelines, which forms the standard for public sector Web sites in New Zealand.

In achieving the goals of the e-government strategy, local government has collectively developed an e-local government strategy in 2002 to increase online access to local government information and improve public participation in decisions. Such strategy emphases on: access, innovation, participation and leadership. Easy access means a set of core information provided by all councils and accessible through their Web site and the central government portal, and a set of templates for the standard information that all councils provide. There are also options for transactional systems, online billing and secure payment systems being formulated. The role of local governments is to try to present a somewhat consistent interface for the citizen and to try to develop policy for the appropriate release of government held information to the Internet community (Bursztynsky and Kirking, 1996).

## EVALUATION OF LOCAL AUTHORITY WEB SITES

Criteria for evaluation of the local authority Web sites were grouped in four major categories and 30 subcategories: Information, Legal Statements, Promotion/Retention, and Nonfunctional Requirements. This evaluation model was adopted from Hersey's (Whiteley, 2000) e-commerce Web site evaluation model and Paynter and Chung's (2001) usability model and tailored to suit the relevancy of the local authority Web sites. This approach was proven to be effective and appropriate from previous Web site evaluation studies, namely: Internet banking (Chung, 2001), travel industry (Satitkit, 2001) and Internet mortgage service provision (Lu, 2002).

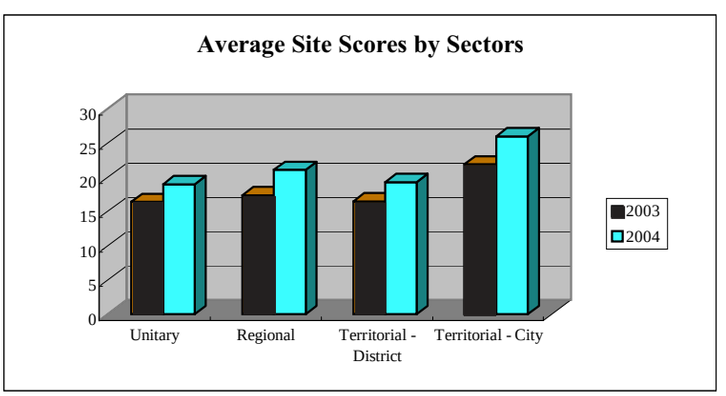
Two rounds of evaluation were conducted with the first round done between April and June 2003, and the second one was between February and March 2004. This is to ensure that the site examination was up-to-date and that the changes and enhancement made to the Web sites were also examined. In the second round, four additional subcategories were added to the criteria, making a total of 34. The reason for the change was due to 2002 legislation whereby regional councils were empowered to collect levies separately. 2004 was also the local government election year. Details of the categories are illustrated in Table 1.

All 86 local authority Web sites were evaluated using a binary code scheme of "1", which denotes the presence of elements/characteristics and "0", which reflects the absence. The content analysis focused on two aspects: the site score was used to rate the performance of local authority Web sites, while the element score assessed the adoption of elements in designing the local authority Web site. A quantitative approach was used for counting, calculating and summing the frequency of each element across each site.

*Table 2. Local authority Web sites score summary*

| Comparison | First Round 2003 (Total Local Authority Sites = 84) (Total Elements = 30) | | | Second Round 2004 (Total Local Authority Sites = 85) (Total Elements = 34) | | |
|---|---|---|---|---|---|---|
| **Site Scores** | Low (17 or lower) | Medium (18 to 21) | High (22 to 27) | Low (17 or lower) | Medium (18 to 24) | High (25 to 33) |
| **Percentage** | 39 (46.4%) | 30 (35.7%) | 15 (17.9%) | 21 (24.7%) | 47 (55.3 %) | 17 (20.0%) |
| **Summary** | • The top 15 scorers are: Territorial-City (9) and Territorial-District (6).<br>• The 30 medium scorers are: Territorial-District (20), Regional (6) and Territorial-City (4).<br>• The 39 low scorers are: Regional (6), Territorial-City (1), and Territorial-District (32).<br>• Overall, the Local Authority Web sites performed well with an average score of each site at 17.1, that is, higher than 15, 57% of the elements specified in the evaluation model.<br>• Most of the sites studied provide comprehensive and relevant information with good organisation of site content and easy navigability. They scored very well in "Information" category but very badly under "Legal Statements" and "Transactional" information. | | | • The top 17 scorers are: Territorial-City (11) as the biggest player, Territorial-District (4), Regional (1) and Unitary (1).<br>• The 47 medium scorers are: Territorial-District (33), Regional (9), Territorial-City (3), and Unitary (2).<br>• The 21 low scorers are: Regional (6), Territorial-City (1), and Territorial-District (14).<br>• Overall, the Local Authority Web sites performed well with an average score of each site at 20.6, that is, higher than 17, 61% of the elements specified in the evaluation model.<br>• Some of the councils improved their sites by adding new and innovative features, such as Property and Cemetery search, GIS mapping, Webcam, and downloadable permit application forms. A few councils even introduced online rates payment and e-bill. The use of "Legal Statements" in local authority Web sites also increased. | | |

*Figure 1. Average score of local authority Web sites, by sectors*



## RESULTS AND FINDINGS

### Site Score Findings

In New Zealand, about 97.7% of the local authorities have a Web presence, and most of whom have operated for more than 5 years. Almost all of the sites are informational although there is a limited range of transactional services available on some of the sites. The overall performance of the local authority Web sites is summarised in Table 2.

Overall, the top scorers spread across all sectors, with Territorial-City (21.9 in 2003 and 26 in 2004) being the biggest player, and dominating most of the high scores among four local government sectors. This is probably

*Table 3. Local authority Web sites element score summary*

| Services | Categories | Category Scores | | | | | Summary |
|---|---|---|---|---|---|---|---|
| | | Total | Elements | | | | |
| | | | No | Ave. | Max. | % | |
| First Round (2003) | Informational Services | 737 | 12 | 61.4 | 84 | 73.1 | ▪ The majority of sites are non-functional and informational rather than transactional.<br>▪ There is a lack of transactional and interactive capabilities in most of the sites. |
| | Transactional Services | 51 | 4 | 12.8 | 84 | 15.2 | |
| | Legal Statements | 113 | 4 | 28.3 | 84 | 33.7 | |
| | Promotion/Retention | 242 | 5 | 48.4 | 84 | 57.6 | |
| | Non-Functional | 330 | 5 | 66.0 | 84 | 78.6 | |
| Second Round (2004) | Informational Services | 882 | 14 | 63.0 | 85 | 74.1 | ▪ More councils started improving online transactional capabilities and increasing use of legal statements.<br>▪ Some Councils concentrate on promoting tourism while others on providing more up-to-date information and services. |
| | Transactional Services | 124 | 6 | 20.7 | 85 | 24.4 | |
| | Legal Statements | 137 | 4 | 18.7 | 85 | 40.4 | |
| | Promotion/Retention | 261 | 5 | 18.75 | 85 | 61.4 | |
| | Non-Functional | 350 | 5 | 12 | 85 | 88.2 | |

because of the conspicuous role that city councils take, as being the biggest councils and having the highest populace, and the privileged resources from which city councils benefit in terms of capital and people. This observation (Figure 1) suggests that there is a strong relationship between a good Web site and the size, capital, resource, function, and business strategy of an organisation.

## Element Score Findings

The average element scores indicate that local authorities tend to pay more attention to aesthetic (nonfunctional) features than providing comprehensive capability. The overall performance is summarised in Table 3.

### Informational Services

The majority of sites provided detailed information and good content organisation (73.1% in 2003 and 74.1%% in 2004). However, not many of the sites provide customer-focussed activities such as e-subscription and e-consultation. Only one council, Auckland Regional Council, provides an online forum for discussion and sharing of ideas. None of the sites provide any e-democracy, although some sites have put up information about Elections 2004. Dunayev (2005) used an automated tool to analyse all the local government Web sites. He concluded that the sites did not appear to have matured sufficiently to meet the goal of online local government elections in the next cycle (2007). Some of the obstacles to e-voting are outlined in Sharkey and Paynter (2003) and steps towards an e-voting transition in Paynter and Peko (2005).

While the appeal of the Internet lies in its ability for personalisation (Venkatraman, 2000), none of the sites examined provides such functionality. Only one council, Dunedin City Council, implemented a Citizen Direct system to enable citizens to access council-held information about them 24/7 using a usercode and password.

### Transactional Services

About 44% of the sites examined provide rate and property search, 34% have cemetery search, and only 12% provide mapping information and interactive tools such as GIS mapping. Only five councils offer online billing and payment capabilities, two of which (Auckland Regional Council and Auckland City Council) provide online payments by credit cards, and the remainder (Manukau City

Council, Central Hawkes Bay District Council, and Hutt City Council) provide e-billing in conjunction with New Zealand Post. None of the sites provide online permit applications and processing.

### Legal Statements

Most of the sites did not perform well under this category. However the situation improved in 2004, partly due to feedback from the study. The use of legal disclaimer increased from 25% in 2003 to 44.7% in 2004; privacy statement from 17% to 29.4%, terms of use from 15% to 22.4%, and security/copyright statement from 43% to 64.7%.

### Non-Functional Requirements

All sites did well with respect to navigability, page loading, the use of graphics and animation, and content presentation. When we consider ease of use, we look at the search capabilities, site maps, internal links and searching tips. Although the overall navigability of the sites was considered good with the use of location indicator and search engines, facilities such as online help and searching/viewing tips appear at relatively few local authority sites. In certain sites even the searching tips are not very helpful.

## DISCUSSION

In order to determine how well the New Zealand local government Web sites perform against their counterparts in the United States, UK, and Australia, we did a comparison using 23 categories developed by Access to Electronic Legal Information Committee (2003) in the States, which is specific for the e-local government strategy among five top local government sites. The result is shown in Table 4.

Biehl (2001) commented that the design, content, and interactivity of the Seattle site are the best at any level of government. Its site had recently been redesigned to include new features such as Watch Council Meetings Live and View Live 911 Dispatch. The Sunderland site provides a wide range of online services targeted for four main types of audiences: residents, visitors, businesses, and youth under 25. What set them apart are the e-consultation and personalisation functionalities that are not readily available on any of the Web sites studied. E-subscription is provided at the Sydney site for citizens to subscribe to news release service and image gallery. E-commerce is also available for purchasing council publications online using credit cards. The Dunedin site was rated first in the 2003 round of assessment. The site provides excellent information, comprehensive viewing tips, and interactive tools. It is such a good site that councils from overseas (e.g., UK) and New Zealand (e.g., Kaipara District) seek to model it. Hutt City site was rated first in the 2004 round for its simplicity, breadth of information and good organisation of content. It is one of the few councils that introduced e-bill, in conjunction with New Zealand Post. This allows ratepayers to pay rates and other payments online.

After eliminating the geographical, functional and demographical differences among the four nations, the comparison shows that New Zealand is still lagging behind its international counterparts in terms of global positioning, marketing strategies and collaboration within government agencies. This is evident in the absence of a second language, and links to all external local government Web sites and the e-government portal. There is also a lack of transactional and interactive capabilities for online payment, online permit applications, and an e-consultation forum for citizens to interact with their local authorities.

Users of the services were surveyed to highlight their priorities. Having detailed and up-to-date information, easy navigability, faster response and faster page loading speed are of major concern. Of less importance was information regarding forthcoming elections and results of elections. Since there is such abundant information and services available on the Web, local authorities need to structure the content and present the information/services in a way that it is easily accessible by customers/citizens. The survey also highlighted that councils need to raise the awareness of their Web sites to citizens, as people are generally ignorant about the range of services that are offered.

*Table 4. Overseas local government site comparison*

| Overseas Web Site | Score | Rank |
|---|---|---|
| City of Sunderland (U.K.) | 20 | 1 |
| City of Seattle (U.S.A.) | 19 | 2 |
| City of Sydney (Australia) | 19 | 2 |
| Hutt City (New Zealand) | 14 | 3 |
| Dunedin City (New Zealand) | 12 | 4 |

## FUTURE TRENDS

### Informational Services

Only one local authority site, South Taranaki District Council has a mirror site in Chinese. To support multiculturalism and meet the needs of international audi-

ences, local authorities should present content in other languages. Making local authority Web sites accessible to people with visual impairments and other disabilities was not evident in this study. Farkas and Farkas (2002) suggest that text-to-voice Web browsers, often used by people with visual impairments, can read HTML, but not graphics files. Designers can insert text-only navigation menus at the bottom of each Web page in addition to graphical buttons and navigation bars.

To allow a closer liaison and more seamless transition between the services and information provided by local and central government, local authorities should provide links to relevant sites in other agencies, in particular, the government portal and other local authority sites.

Interactivity is the key advantage of a Web site over all preceding communications media and makes it possible for local governments to add significant value and convenience for their citizens. Online forums facilitate discussion and the sharing of ideas between councils and citizens, and among citizens themselves. "Personalisation is not about getting more of what you want, but about getting less of what you don't want" (Sterne, 2001, p.181). With a general overflow of information on local authority Web sites, e-personalisation allows users to create a personalized view of the information they need.

### Transactional Services

The ability to apply permit online, and to pay fines, license fees, and rates online with credit cards will provide convenience to users. To reduce the risk for both citizens and local authorities, the State Services Commission (2004b) suggests that personal information including payment information (such as credit card details) must be encrypted between user and agency using Secure Sockets Layer (SSLv3) protocol as a minimum.

### Legal Statements

Local authority Web sites should provide a disclaimer, if they must disclaim content, a privacy statement, and a copyright statement, as well as terms of use or conditions of use. The privacy statements must be clearly worded and unambiguously, especially on relevant forms, and should be linked to more detailed privacy codes of practice if necessary.

### Non-Functional Requirements

To improve searchability and avoid irrelevant results, search zones (Farkas et al., 2002) can be used, especially with medium and large Web sites such as that of Auckland City Council. A search zone consists of a drop-down list box through which users can restrict their search to a single category in which they are interested. Ideally, users should be able to access "Search" from almost every page in the Web site and a link to simple and jargon free searching tips would appear alongside a search form on each Web page. Navigation can be a lot easier if there is a clear, complete, and simple home page always accessible with a link from other pages shows users how the content is organised (Zimmerman, 2001). The site index should be available from every page and contain active internal links to the desired page(s). Users generally expect timely, relevant, reliable, and valid. There are no strict rules on update frequency, which often depends on the types of information available on the site, but a regular review of site content will be useful. For some larger sites, Zimmerman (2001) suggests that it may be more efficient if editing tasks can be divided among many staff members and departments.

## FUTURE RESEARCH

The information and services provided online via the local government Web sites is constantly undergoing evolution partly driven by innovations in information technology (IT), partly by the local government wishing to leverage this tool and to a minor extent by user demand. As a consequence, reevaluation of the effectiveness of the local government Web sites is a necessary as well as comparisons with overseas local government Internet presence. Therefore, a longitudinal study on local government Web sites is being undertaken. We also need further to consider the relationships between the various local governments and their service providers. An example would be the COL (Collaborative Community Online) program organised by Local Government Online to provide a template Web site designed to meet the common e-government requirements of a local authority. This template will be used across local authorities. So far about 14 local authorities have developed sites to the COL plan (Bell, 2004).

Questions about the digital divide, including access to users of different languages and abilities are incorporated in the 2005, as is an emphasis on the provision of broadband services and the allowance for different platforms such as PDAs and mobile telephony.

## CONCLUSION

The evaluation of local authority Web sites provided key insights into how the Internet was embraced in the context of local government in New Zealand. Almost all councils

have developed comprehensive Internet sites. Leading local government Web sites that achieved a high score offer the online capacity to provide a range of information from current events to rating information. However, local government has yet largely to adopt the Internet to provide interactive services from drainage applications to water payments. Results from the two rounds of assessment show that rapid improvements in functionality could be expected, as local governments are proactive in improving their Web sites and promoting their use to the populace. Apart from continuing to add new functionality to service their diverse stakeholders, local governments need to concentrate their efforts on presenting government business applications, such as voter registration, permit assistance or payment of parking fines. The Internet help ease citizen access to necessary government services and functions, with a comprehensive and well-designed Web site, local government can ensure a continuous stream of visitors to their site.

## KEY TERMS

**Aesthetic Effect:** Graphics and animations that are incorporated in a Council's Web site. For example, the Council's logo and movie clips.

**Biosecurity:** It is an attempt to ensure that ecologies sustaining either people or animals are maintained.

**E-Bill:** It is a secure online payment service provided on the local authority Web sites in conjunction with New Zealand Post. E-bill provides a single Web site to receive, pay and store bills from many billers, using any bank.

**E-Consultation:** An interactive facility provided by local authority Web sites to allow citizens register and communicate by e-mail with their councillors.

**E-Democracy:** An interactive facility provided on the local authority Web sites for citizens to register and vote online. It also encompasses the use of ICT and computer-mediated communication, such as the Internet, interactive broadcasting and digital telephony, to enhance political democracy or the participation of citizens (Hacker & van Dijk, 2000, p. 1).

**E-Government Strategy:** E-government is about using new technology (e.g., computers and the Internet) to improve the way central and local government deliver their services, communicate, consult, and work with others. Under this strategy, the government's aim is to create a public sector that is structured, resourced and managed to perform in a manner that meets the needs of citizens in the information age and which increasingly delivers information and services using online capabilities.

**HTML:** It is also called Hypertext Markup Language—The coded format language used for creating hypertext documents on the World Wide Web and controlling how Web pages appear.

**NZGWG:** New Zealand Government Web Guidelines—A set of guidelines and standards provided by E-government Committee of the State Services Commission to help public sectors developing their Web presence.

**Portals:** A portal is a point of entry which enables citizens to have access to a full range of services without any consciousness of movement between Internet sites and where those services may be tailored to the user's profile.

**Security Sockets Layer:** A commonly used protocol for managing the security of a message transmission on the Internet.

# E-Social Policy and E-Social Service Delivery

**Rose Melville**
*The University of Queensland, Australia*

## INTRODUCTION

E-social policy is an important aspect of the information society development and e-governance agenda (Fitzpatrick, 2000, 2003; Loader, 1998). To date, it has not received the same amount of critical scholarship and research activity as traditional areas of social policy, but this is changing as policy scholars focus on the whole gamut of e-governance concerns. E-social policy is concerned with the social implications of information technology communication (ITC) technology in its broadest sense. E-service delivery is a narrower term, encompassing the range of ITC used by governments, churches, charities, other non-government organisations (NGOs), and community groups to deliver social and community services online. Initially, most services provided online by governments were of a commercial and business nature (Curtin, Sommer, & Vis-Sommer, 2003), but e-service delivery has evolved quite rapidly in the fields of health, education, social security, and one-stop community information systems. It is better developed in OECD countries and in specific social policy fields (social security, housing, health, education, and community care) whereas in other countries it is very poorly developed and resourced, if it exists at all (Polikanov & Abramova, 2003). Despite this uneven development, there are many innovative examples of ITC use in farming production and trade, e-health services and promotion, education, environmental pollution management, and enhancement of development strategies in poorer nations. However, there is still a long way to go in bridging the digital divide–the unequal access to ITC of richer and poorer nations. This is a global social policy concern.

## BACKGROUND

E-social policy is a relatively new field of academic inquiry and research. Pioneer researchers in this field include Fitzpatrick (2000, 2003), Hudson (2002), and Loader (1998). In recent years, Henman [and colleagues] has made a substantial contribution to the critical analysis of e-social policy (1999, 2001a, 2001b, 2004a, 2004b, 2004c).

Fitzpatrick (2002) explains the low profile among social policy analysts. Firstly, early figures on ITC use indicated that it was dominated by the U.S. and Europe, with only 1% of the world's population using the Internet. English is the dominant language of this new technology, and few people predicted the phenomenal growth of ITC around the world. It was, therefore, seen as a marginalised issue. Secondly, social policy analysts failed to see the connections between the global communication explosion; the rapid spread of neo-liberal and public choice ideologies (Melville, 1999) that accompanied economic globalisation (Bardouille, 2001); and the radical restructuring of government and public sector activities and roles with welfare reform, especially in advanced Western post-industrial societies. Thirdly, the primary focus of social and political scientists was on the potential of *e-governance* rather than e-social welfare delivery to enhance democratic, civil rights, and political relationships (Fitzpatrick, 2000, p. 376).

More social policy scholars are turning their focus on e-social policy. The work of the Community Informatics Research and Applications Unit at Teeside University in social care and delivering community services has attracted considerable attention (Thomas & Loader, 2000). John McNutt, a U.S. academic, has played a pioneering role in e-social policy activism. McNutt has hosted an e-social policy Web site on *Yahoo!* for many years, and recently published an exemplary text in this field (Hicks & McNutt, 2002). The *Journal of Critical Social Policy*; *European Journal of Social Policy*; and the *Journal of Information, Communication, and Society* regularly feature e-social policy initiatives.

From a government perspective, the justification for using online service delivery revolves around public sector management issues, such as efficiency and effectiveness and enhanced citizen or consumer satisfaction. Governments promote the view that e-service delivery reduces costs and provides savings through better use of staff time, increased choice and freedom, and improved time management for consumers and providers. The potential of ITC technology to overcome constraints of time, travel, physical ability, age, and geographic boundaries for disadvantaged individuals and groups is very appealing to policy makers and service users alike. However, many transactions in social service fields are more complex than simple online business transactions such as downloading a form or providing information. They re-

*Table 1. Summary of key e-social policy and e-service delivery*

| Issues | Authors |
|---|---|
| Major government incentives to use e-service delivery (neo-liberal discourses that emphasise the role of individuals to manage risk, user pay [customer choice] for their social and economic needs, increased economic globalisation, restructuring of work, the welfare state, the reduced role of the state, and new public management emphasis on cost efficiency and effectiveness) | Melville (1999); Bardouille (2001); Clarke (2004); Fitzpatrick (2000); Hudson ( 2002); Hood (1995); Rhodes (1996); OECD (1998; 2003); Policity.com (2001); Commonwealth of Australia (2002); Cabinet Office-UK (2002); Perri 6 (2004); Snellen and van Donk (1998) |

quire face-to-face interactions in the absence of appropriate technology to deal with multi-faceted transactions.

A key debate concerns *equity* and *access* to e-service delivery, especially among those who have traditionally been the focus of social service and development intervention; for example, the poor, the computer illiterate, the disabled, the aged, and women at both a national and global level. Perron (2004) is an excellent source on the state of ITC in developing nations. Debate about the "digital divide" (Selwyn, 2002, p. 2) and of the role of computer illiteracy in perpetuating poverty and inequality within countries and between countries are common in the literature (Perron, 2003; Norris, 2001). The available statistics on class, gender, age (International Telecommunications Union, 2004) and cross-national comparison of Internet usage (Perron, 2004) suggests that the primary beneficiaries of e-service delivery are the technologically and economically richer Western nations, especially post-industrial welfare-state societies. However, even within these societies, technology does not provide a quick fix for overcoming structural inequalities or social exclusion (Hudson, 2003). It may lead to new forms of inequality and social exclusion. What is important for social policy analysts to examine are the policies and strategies put in place by governments and transnational bodies, such as the United Nations, to reduce (and eliminate) these inequalities.

Many of the debates about the ITC (including e-social policy) are polarised. They are based on pre-existing assumptions about the social, economic, and political nature of technology in modern society. For example, there are those who argue that technology determines social behaviour and interaction, and others who argue that technology is socially shaped (Bellamy & Taylor, 1998, p. 18-19). Table 1 provides a summary of key debates.

Some writers (Bellamy & Taylor, 1998; Stonier, 1983; Wellman, 2001) hold a very utopian perspective of ITC—promoting it as possessing power to promote social change (Bellamy & Taylor, 1998; Stonier, 1983) for all, but especially those in poorer nations. The World Bank and the United Nations are strong advocates in the inherent capacity of ITC to solve their social problems. Barry Wellman is an exemplar of this position. Wellman (2001, p. 40-41) writes "the good news is that the cost of computing is becoming so low that in the developed world the digital-social class divide should get smaller just as the digital gender gap." Both Perron (2004, p. 180) and Sen (2000) argue that the falling costs of ITC (together with the scientific, political, and academic knowledge available

about it) and e-democracy potential has the capacity to address basic social problems such as HIV/AIDS, unemployment, and human rights. E-social policy is concerned with addressing poverty and unequal access to healthcare, and securing basic human rights such as employment, freedom, and well-being.

Other writers hold a more dystopian view of the control aspects of ITC (Bellamy & Taylor, 1998). Marston (2004), using a Foucaldian "governmentality" framework, argues that e-service delivery is a mechanism that increases the surveillance and governing of the unemployed and social welfare consumers (Marston, 2004). Perron (2004) focuses on the way in which ITC maintains poverty and inequality globally, and questions whether it is a "panacea for deep-seated economic deprivation or for the existence of social divisions in a capitalist [neo-liberal market] economy" (p. 197).

Other concerns relate to the social nature of the technology used in e-service provisions. On one hand, it has the capacity to provide existing and innovative forms of social services online, yet at the same time it has the potential to increase the surveillance and governing of the poor, disabled, elderly, young, and other marginal groups. It is a two-edged sword both ambiguous and contradictory in nature.

## E-SOCIAL POLICY AND E-SERVICE DELIVERY

Advents of new technology sometimes force us to develop new definitions and new typologies. As it is a relatively new field of policy analysis, defining e-social policy is not an easy task.

Fitzpatrick (2003, p. 131) writes "e-social policy is concerned with a critical examination of the social implications of these new technologies." He goes onto outline ten key areas requiring urgent attention by policy researchers:

- "The changing nature of work, employment, use of ITC in home and office—blurring of these boundaries
- Broader economic and social trends associated with ITC
- Increasing speed of communication that is changing our sense of presence and being, coupled with the dominance of English language
- The levels of e-commerce, e-business and e-shopping are still increasing–need to examine the implications of this on market and social relations
- New technologies have become the sites of both criminal activity and policing
- New forms of surveillance are emerging that involve the use of biometrics to classify and catalogue people in public and private data bases
- Rapid advances in e-health technology that is transforming the relationship between provider and consumer
- Educational pedagogies are changing through the use of ITC
- Major changes are occurring in public management that create increased tension between two conflicting needs–security and freedom
- The way in which new technologies maintain and create new forms of social exclusion" (Fitzpatrick, p.131-133)

Selwyn (2002, p. 1) claims e-social policy involves the critical examination of government rhetoric about the heroic potential of ITC to bring about "social inclusion by examining the problems that it sets out to address, the substance of these policies, and the perceived rationales and benefits for doing so." In doing so, we can assess whether ITC policies and programs promote social and economic change through social inclusion or maintains the digital divide and social exclusion. Loader (1998a) does not set out to define e-social policy, but the questions he raises about ITC fall within the traditional boundaries of social policy. Loader (1998a, p. 4) emphases "issues of social inequality, the manner in which computer-mediated communications can alter identities based around locality, gender, race, age, disability, or religious fundamentalism (Cable, 1994; Jones, 1995), and the capacity of government supranational policies to address issues of access, skills and universal carriage."

Attempts to define e-social policy raise similar issues to those in social policy. For example, we need to ask (as Titmuss (1974), a renowned social policy scholar, did) what kinds of political, moral, ethical, and ideological values are embedded in ITC. Who will benefit and who will lose out in the new cyber-landscape? Titmuss (1974, p. 4) wrote that "policy can be taken to refer to the principles that govern action directed towards given ends, and it, therefore, implies change: changing situations, systems, practices, and behaviours." Embedded in the notion of policy is the "belief that we can promote change of one sort of another" (Titmuss, 1974, p. 4-5). The goals (and outcomes) of social policy vary considerably and are highly contested. Policy goals are based on principles, such as "access, equity, egalitarianism, equality, social justice norms, needs, freedoms, rights and responsibilities" (Blakemore, 1998, p. 16-19); however, the interpretation and application of these principles are mediated by political, economic, social, cul-

*Table 2. Summary of e-service delivery application (Burrows et al., 2000; Ravi, 2000; Gaby & Henman, 2004; Marston, 2004, Hagan & Kubicek, 2000; Liikanen, 2003; Loader, Hardey, & Keeble, 2004)*

| Policy field | ITC used to deliver services | ITC used by consumers of services |
|---|---|---|
| Health | Teleradiology, teledermatology, and telepsychiatry; shared virtual reality; Internet; new networked ITCs with digital cameras, videos and scanners; email; and videoconferencing. | Internet chat rooms, email discussion lists, self-help and support news groups, narratives on personal Web sites, and newsgroups.<br><br>[Internet-based health care alternatives practitioner—providing diagnostics services and selling health products, herbs, pharmaceuticals, home care, and physical aid products]. |
| Income maintenance (social security) | Web/internet sites for information and downloading claim forms; call centres; Web kiosks; processing claim forms and payments; electronic assessment techniques; job profiling software; short messaging service (SMS); interactive voice recognition. | Community-based job Web sites, e-mail, and chat rooms. |
| Education | Enrol online; pay fees online; study subjects delivered partly or completely online; And obtain post-secondary and tertiary certificates, diplomas, and degrees online. | Internet sites for sharing educational resources, chat rooms, e-mail discussion lists, Web logs, news groups, and bulletin boards. |
| Personal and community care | Electronic service delivery systems (e.g., case management) and data transfers between statutory and non-government authorities (e.g., elderly) (County Durham Project, 2004). | Wide range of self-help and support group using newsgroups, Multi-user domains (MUDs) for survivors of abuse, chat rooms, bulletin boards, and e-mail for online social and personal support |
| Sources: (Burrows et al., 2000; Ravi, 2000; Gaby & Henman, 2004; Marston, 2004, Hagan & Kubicek, 2000; Liikanen, 2003; Loader, Hardey, & Keeble, 2004) | | |

tural, religious, historical, and ideological contexts, producing different outcomes in societies over time.

E-social policy incorporates all forms and uses of ITC for economic, social, political, cultural, and recreational purposes. It involves what Fitzpatrick (2000, p. 375) calls "cybercriticalism"—a critical analysis of the social implications of ITC, the moral and political values associated with various policy initiatives, and an assessment of the social change that accompanies it.

## E-SOCIAL SERVICE APPLICATIONS

E-social service delivery takes many forms. It is used in healthcare and telemedicine, education, organising volunteers, housing, social and community care, the provision of information on social services, and the processing and payment of social security benefits (income maintenance or social security payments). It is not possible in this brief overview to outline these in any detail. E-service delivery is defined broadly as:

> *…concerned with the delivery of public [social] services over digital networks and media—whether by government bodies or by private bodies under contracts or licence–to individual citizens and organisations.* This includes [social] services provided by NGOs, churches, charities and community groups to consumer groups (Perri, 2003, p. 16; italics added).

It is important to note that e-service delivery (except in health and education) seldom involves the *physical delivery of services*. Table 2 provides several examples of e-service delivery provided by public sector agencies.

E-health is prominent in discussions about e-service delivery (see a recent issue of the *Journal of Information, Communication, and Society*, 2004.) Ravi (2000) provides an excellent overview of new telehealth initiatives in healthcare. He notes that healthcare professionals have been using ITC "[telegraphy—signalling by wires—telephony, radio and television] to exchange e-health related information since the mid-19th century, but recent advances in new shared media [Internet and virtual reality]

[are changing the] way people relate, communicate and live" (Ravi, 2000, p. 989). Gaby and Henman (2004, p. 1-2) observe that new tensions are emerging in the traditional doctor-patient relationship as a result of better-informed health consumers (who can obtain a large volume of medical and traditional healthcare knowledge through the Internet). The increased access to health information, support groups, diagnosis, and treatments is accompanied by concern about the quality of information online. This is seen as increasing risk management for doctors and governments, who are keen to reign in the heightened power of consumers in the knowledge-diagnosis-treatment chain without relinquishing the potential benefits of e-health initiatives (Gaby & Henman, 2004).

## FUTURE TRENDS

Governments operating in an increasingly competitive and neo-liberal globalised economy (Melville, 1999) concerned about cutting costs to deliver services in a more efficient and effective manner will continue to exploit ITC. On a global scale, the challenge is to use the technology to bring about social change and improve the social and material deprivation experienced by those in poorer nations. This is a big task, as the cost of ITC infrastructure is still unaffordable for many developing countries. The number of people with access to telephones, personal computers, internet cafes, and Web kiosks in those countries is much lower than in Western countries (Perron, 2004). Social inclusion, not exclusion, needs to be at the forefront of government e-service delivery polices (Hudson, 2003). This means funding public access to computers and self-service kiosks, training and skilling people in using ITC technologies, and overcoming the cultural ambivalence towards technology by the groups it is intended to assist (Hudson, 2002). This cultural bias towards ITC is expressed differently in countries around the world. For example, Canadians have embraced e-service delivery in large numbers, whereas it is still at a low level in Britain (d'Auray, 2003). The gender and age digital divide is slowly improving in most Western nations, but the class (economic) divide is still to be overcome.

Issues of social justice, access, and equity remain core social policy concerns. Ways of reformulating the basis of entitlement and social rights in an increasingly marketized and privatized welfare state pose many challenges to policy analysts. Fitzpatrick (2000, p. 393) calls for the recognition of "virtual rights: these being rights possessed by the massless citizens which overlap with, but are nevertheless distinct from their civil, political and social rights to cater for the changes occurring in a post-capitalistic socio-economic context." The potential for ITC and e-service delivery to advance social inclusion and increased equality exists. This includes using the Internet to provide job market information for young unemployed, email discussion groups for sexual assault survivors, or telemedicine in remote or rural regions. Paradoxically, there is also potential for it to be used politically as a tool for increased surveillance and control of recipients of state and privatised social services (Hudson, 2002; Marston, 2004). As governments continue to experiment with e-democracy and e-service delivery, the need for widespread public debate within nation states and transnational policymaking organisations increases.

There will be increasing concerns about maintaining the privacy and confidentiality of citizens' data accumulated in large networked public and private organisations. This is especially so within a policy that emphasises increasingly seamless and networked integration of service provision by one-stop agencies (COA, 2002; Hudson, 2002; Wittkemper & Kleindiek, 2003) and personalised electronic portals. According to Hudson (2000), private companies are now accumulating large amounts of personal data previously collected by government agencies under competitive tendering arrangements. These companies hold considerable power over governments who have depleted their ITC expertise by contracting it out or by abolishing these positions and now rely on private firms. These changes herald a set of complex dilemmas concerning privacy, security, and the changing relationships citizens have with the state. What may emerge is a quasi-state or "digital shadows" (Hudson, 2002, p. 524) consisting of private identities based on data from private/public firms combining credit histories with benefits records to assess the likehood of social security fraud.

There are still many technological problems to be resolved before physical services are delivered online. Most e-service delivery is limited to providing information and support. Technology is being developed that has the potential to revolutionise e-service delivery. The Canadian government is leading the world in experimenting with a securely coded digital signature (known as *epass)* to enable online forms to be completed (d'Auray, 2003). We will no doubt see more interactive, multi-dimensional, and multi-user technology in e-service delivery in the future.

## CONCLUSION

The challenge for e-service delivery (and ITC generally) will be to alleviate deeply entrenched poverty and social problems in poor nations as well as rich ones. Serious global problems such as the scarcity of natural resources

and environmental degradation may force nations to develop global institutions that ensure developing nations share in the world's wealth, including new forms of ITC such as e-social policy. The capacity of e-social policy to deliver social goods and services will depend ultimately on resolving deeply held ideological divisions about the distribution and redistribution of goods and services between and within nations. These are age-old debates within the field of social policy.

Finally, e-social policy should be seen somewhere along a continuum between potential and constraints rather than a either gloom and pessimism or outright unmitigated optimism. The technology itself does not function in a deterministic manner on social beings, but instead is open to resistance and change by those who use it.

## KEY TERMS

**Access:** A term used to describe the ability of people, more commonly those associated with welfare state provision, to secure and/or use goods and services in society. There is an assumption that access is based on a notion of getting a share of resources (not necessarily an equitable or equal one) and needs that are hard to define or measure.

**Digital Divide:** A term that capture the inequalities in access to technology between countries and, in particular, the technological divergence between richer and poorer nations.

**Egalitarianism:** According to Blakemore (1998, p. 22), this is a utopian or "ideal" goal in the pursuit of equality in society. It is based on the notion that we can find ways to ensure that all people are treated equally in every area of life—the same income levels, health outcomes, lifespan, education levels, and so forth. This will ensure the same results and outcomes in life experiences and quality of life for everyone. Inequality will disappear because there will be no differences between people.

**Equality:** In Blakemore's (1998, p. 23) typology, this term refers to equality of opportunity. To overcome inequality, unfairness, and injustice in the ways individuals and groups are treated in society, mechanisms are established to remove barriers to employment, recruitment, promotion, education, and access to welfare services and benefits. The conservative approach argues that we can never fully remove differences between people in terms of abilities and attributes. A progressive view argues that positive action or, in some cases, positive discrimination is necessary to ensure equality of opportunity.

**Equity:** A term used to describe the difference the goals of egalitarianism and equality. Equity means treating people so that we can achieve a similar end-state or outcome. An equitable approach, according to Blakemore (1998, p. 24) involves treating people fairly but not differently, so that some form of equally is achieved at the end. Some will get more than others because their needs are greater. This approach will not ensure equal outcomes for all individuals and groups as espoused by the egalitarian utopians.

**E-Social Policy:** A new term used to describe research and critical policy analysis investigating the social implications of the use of technology in social life.

**E-Service Delivery:** A term used to describe the provision of a range of social services (primarily non-physical) uses a wide variety of ITCs.

**Neo-Liberalism:** The revival of the beliefs of classical market-based liberalism. Neo-liberalism has become entwined with public choice theory. Neo-liberalism advocates the power of the market to regulate all aspects of society. Three core tenets of neo-liberalism are that markets are superior, governments have been taken over by minority interest groups, and governments do too much. The solution is to curb the power of interest groups and roll back the state by using market mechanisms.

**Social Exclusion:** A contentious and ambiguous term used by British and European policymakers to describe the complex interplay of social, political, geographic, and spatial deprivation accompanying economic and material deprivation (i.e., poverty). Many see it as a broader and more comprehensive notion (see, Selwyn, 2002).

**Social Inclusion:** A term developed to describe the advantages of access to social, political, economic, geographic and spatial resources, and goods and services in society. This includes economic and social relationships that provide support, networking, information, and other less tangible goods and exchanges that privileges those "included" in mainstream society compared to those who are "excluded" (see Selwyn, 2002).

**Social Policy:** This term describes an academic discipline and a range of social services.

**Virtual Rights:** A term coined by Fitzpatrick (2000, p. 393) to describe the "cyber rights" of massless citizens in a post-industrial social and economic context. It draws on the tri-typology of rights (civic, social, and political) originally devised by Marshall (1964).

**Welfare State:** A term used to describe the institutional arrangements that have been set up to provide state services and goods to those who cannot fend for themselves in the market economy. According to Pierson (1991), it defines: (a) a particular form of state; (b) a distinctive form of polity; or (c) a specific type of society.

# Ethical Dilemmas in Online Research

**Rose Melville**
*The University of Queensland, Australia*

## INTRODUCTION

Online research raises unique ethical concerns (Ess & AoIR, 2002), including the treatment and recruitment of participants, gaining consent, accessing electronic forms of data, privacy, and responsibility to the participants of online mediums (e.g., discussion lists and groups). Until the mid-1990s, very little attention was paid to ethical issues in online research for the following reasons:

- This communication medium was a very recent phenomenon (Ess & AoIR, 2002; Mann & Stewart, 2000)
- Internet research posed different ethical challenges for researchers in comparison to conventional face-to-face settings
- Existing ethical regulations and ethics review boards did not cover the new ethical issues raised by Internet research
- It was too difficult to develop a uniform code of ethical conduct for Internet research given the diverse disciplines, countries, and cultural groups using the Internet (Ess & AoIR, 2002)
- The complexity of Internet technology itself, which made adapting conventional ethical practices and processes problematic (Anders cited in Mann & Stewart, 2000; Mann & Stewart, 2000; Thomas, 1996; Whittaker, 2002)

## BACKGROUND

All researchers, including online researchers, must deal with ethical issues. Those most commonly cited include anonymity (and pseudonymity) of participants, recruitment of participants, publication of results, and balancing research benefits against harms (see Table 1). However, the ways in which online researchers handle these ethical issues are highly contested because of the unique nature of computer-mediated communication (CMC) environments and the practical difficulties of applying ethical principles in this environment (Walther, 2002). For example, who do you approach to obtain informed consent in an online political discussion list—the list moderator or each of the participants? Does it make a difference if the list is closed (moderated) or open? How do we inform participants about a research project in a multi-user domain (MUD) environment without disturbing the natural "interactions" in these forums? Is it sufficient for current ethical conventions to obtain consent via e-mail, or should

*Table 1. Summary of ethical issues in Internet research (Allen, 1996; Bassett & O'Riordan, 2002; Ess & AoIR, 2002; Herring, 1996; Jones, 1999; Mann & Stewart, 2000; Walther, 2002; White, 1996)*

| |
|---|
| The Internet provides increased research opportunities but raises new ethical issues, including:<br>• large amount of data available on Internet in a wide variety of forms (e.g., e-mail, chat rooms, instant messaging, MUDs, MOOS, USENET newsgroups), available to researchers who can access it without seeking permission or ethical clearance due to the open nature of this medium;<br>• wide variety of views on Internet research ethics based on disciplinary knowledge bases;<br>• unequal access to Internet around the globe;<br>• English is main language of Internet—limits the study of different cultures' approaches to ethical issues;<br>• different power dynamics operate in Internet research compared to conventional settings;<br>• Internet is a unique technological, cultural, and social environment that should not be subject to same ethical codes as conventional research; and<br>• need for flexible ethical guidelines that are not overly prescriptive and can accommodate the needs of different disciplines, Internet users, and cultures |

ethics committees insist on a signed hardcopy from each respondent (Mann & Stewart, 2000)? It is easy to see why some researchers are deterred by the daunting task and impracticality of applying conventional ethical procedures to CMC and developing new ethical procedures to obtain consent in this medium (Anders, 2000 cited in Mann & Stewart, 2000).

The ethical problems involved in online research are not immediately obvious to the novice or mature researcher. For example, the open and accessible nature of CMC provides researchers with the opportunity to harvest data in covert and unobtrusive ways, such as "lurking" online in discussion forums. Different countries and cultures possess a range of views and laws governing privacy, ownership, and use of electronic forms of data. In some countries with strict regulation of human research, using covert forms of data collection without informing participants is not usually approved of. This is because of increased public scrutiny of medical and social research following the abuses of World War II and, in some instances, as recently as the 1950s and 1960s (Dodds, Albury, & Thomson, 1994; Capurro & Pingel, 2002).

There is considerable variation in researchers' responses to online ethical concerns. For example, Denzin (1999, cited in Mann & Stewart, 2000) used data without following the ethical protocols of obtaining consent and informing participants that he was using the material for research purposes. In contrast, Reid (1996) went to considerable effort to obtain consent before conducting research online. A number of writers, including Boehlefeld (1996) and King (1996), warn online researchers to pay *specific* attention to ethical issues. If they do not, they run the risk of alienating the public and cutting off their supply of data and participants. Ignoring ethical issues can have a flow-on effect to other researchers (Boehlefeld, 1996). It can increase suspicion about researchers' motives and use of electronic data for research.

## DEBATES ABOUT ETHICS AND ONLINE RESEARCH

A wide range of people from different disciplines engage in Internet research, yet the social sciences and humanities have dominated debates about the role of human beings in online research. One issue that causes considerable controversy between the social sciences and the humanities is their competing views about the public/private nature of the Internet (Melville, 2004). This raises important questions about the nature of CMC, technology, and the rights and obligations of researchers and those who use the Internet. For some writers, all CMC (except for closed e-mail lists) is seen as "public space" (Paccagnella, 1997, cited in Mann & Stewart, 2000). Described as the cyberspace equivalent of a public park or street (Waskul & Douglass, 1996), they are regarded as "public," accessible, and open and available to anyone to observe and record what occurs in them (Walther, 2002). As such, individuals cannot expect privacy and confidentiality. White (2002) goes further, arguing that it is not the individual researcher's responsibility to guarantee anonymity in data collection or reporting.

If confusion, ambivalence, or ignorance exists about what is public information (and, therefore, fair game for researchers), industry professionals and moderators/controllers of public and semi-private space should correct the problem (Walther, 2002; Whittaker, 2002). Some people who are well versed in using CMC (such as activists, academics, and computer professionals) have no doubts about what they view as publicly available (Bruckman, 2002). They tend to view the majority of the Internet (apart from closed lists) as a public space. Many possess the technical skills to use software that will trawl through vast amounts of archived and current material on the Internet. If the majority of information on the Internet is seen as public documents, images, text, and language, then anyone should be able to access it without asking permission, protecting privacy and/or identity, or justifying their (research) activities and published outcomes.

Others argue that the Internet cannot be viewed simply as private or public (King, 1996; Waskul & Douglass, 1996). Waskul and Douglass (1996) argues that it has both public and private spaces. When we recognise this, we can work out what expectations people have about their postings. It is possible to work out a graduated scale at one end of which we can locate a public forum where all postings are accessible to anyone who enters the space. The expectation of those people posting and reading the material is that that material is clearly in the public arena (Walther, 2002). In contrast, for King (1996) it possible to designate those areas where all material is private and accessed by only those who have consent and permission (e.g., e-mail, listservs, some chatrooms, and bulletin boards).

The need to protect the participant's privacy and identity in an online setting is also supported by the findings that people are more likely to self-disclose personal information using CMC than they would in face-to-face situations such as focus groups and interviews (Hessler, 2003; King, 1996; Mann & Stewart, 2000). This is an interesting finding. It means that participants have different notions of their personal-self "boundaries" than was previously assumed by Internet researchers (King, 1996; Waskul & Douglass, 1996). Some participants find it helpful to disclose in what they see as a safer, more anonymous environment where they cannot be seen or heard. They also feel that the information about them

cannot be linked back to their real-world or everyday experiences and identities. Yet it is a false sense of anonymity, as we all leave physical traces of ourselves on the Internet and it is possible for people to find out the real-life identity of online participants by various technical and fraudulent means (Whittaker, 2002).

## ETHICAL GUIDELINES FOR ONLINE RESEARCH

There are three core principles that govern research in countries that signed the Helsinki Protocol governing the use of human subjects in medical research in the 1960s (Dodds, Albury, & Thomson, 1994). The three principles are confidentiality and informed consent, beneficence, and social justice (NHMRC, 1999). In some countries, ethical guidelines were developed to ensure researchers follow these principles in conducting medical and social/behavioural research. In these regulated environments, researchers need to complete ethics applications that address:

- Obtaining informed consent
- Privacy and confidentiality
- Risk assessments of the burden and benefits of the research
- Protection of vulnerable and dependent people (both over-researched and under-researched individuals and communities)
- The use of deception
- Scientific validity of their methodological design
- Cultural sensitivity
- Data storage and reporting (NHMRC, 1999)

At this stage, there are no international specific ethical research guidelines covering research using Internet technology. The response to these new ethical challenges varies from country to country. In western countries, such as the UK, the U.S., and Australia, ethics review boards and government-funding bodies are dealing with Internet ethical issues in an ad hoc and case-by-case manner, and have not formally codified them. This is because it is not possible to pre-empt the numerous ethical scenarios thrown up by this new technology (Mann & Stewart, 2000). Different approaches that are more suited to the interdisciplinary and global nature of Internet research need to be developed. Given that participants in Internet research often reside in a number of countries, researchers need to be wary of contravening the laws and cultural customs of those countries. In many countries, research participants have the right to respect and confidentiality. In practice, this means that their privacy needs to be accommodated in online research. Information privacy laws are based on the principles developed by the Organisation for Economic Cooperation and Development (OECD, 1980 cited in OECD, 2003) and set out in the Code of Fair Information Practices. As Ess et al (2002, citing http://www.privacy.org.pi) notes, "The European Data Protection Act (1995) is regarded as the most comprehensive in the world. According to this Act, data-subjects must:

- Unambiguously give consent for personal information to be gathered online
- Be given notice as to why they data is being collected about them
- Be able to correct erroneous data
- Be able to opt out of data collection
- Be protected from having data transferred to countries with less stringent privacy protection" (p. 20)

Online researchers are more than likely to be working with people living in different countries and cultures given the nature of CMC. This means that researchers need to ensure that they are not contravening the ethical and cultural practices in the treatment of participants in their research. Cultural norms and beliefs about human beings, their involvement in research, ethical theory and its application, and expectations about the rights and privacy of participants are viewed different around the world. For example, the U.S. adopts a utilitarian approach to ethics whereas Europe and other western countries, such as Australia, adopt a deontological approach (Ess & AoIR, 2002; Johnson, 2001). Cultural expectations, laws, ethical guidelines (formal or informal), and beliefs about ethics all influence what Internet researchers are allowed to do with participants, how they can be approached, what kinds of electronic data can be used, how it can be stored, and what reporting mechanisms they need to employ.

During the past decade, Internet researchers and organisations have developed ethical protocols and strategies to handle the unique ethical issues posed by Internet research. Frankel and Siang's (1999) *Report on the Ethical and Legal Aspects of Human Subjects Research on the Internet* is written for U.S. researchers. For an international and cross-disciplinary perspective, Charles Ess and the AoIR Ethics Working Party report contains a very comprehensive overview of guidelines, case studies, bibliography, and other resources on Internet ethics (2002). The Association of Internet Researchers (http://www.aoir.org) hosts a Web site containing papers covering a wide range of ethical issues from social science and humanities perspectives. Johnson's (2001) book, *Computer Ethics*, contains an excellent discussion of ethical theory and its practical application to computer programmers and other researchers. A number of profes-

sional associations, such as the computer programmers, have developed statements on ethical research (Boehlefeld, 1996). Japan, Britain, and Germany have established research institutes or groups who are involved in studying online research and ethical practices (see, Ess & AoIR, 2002).

Individual researchers are acquiring knowledge from each other in the absence of established protocols governing online research (Allen, 1996; Bassett & O'Riordan, 2002; Ess & AoIR, 2002; Herring, 1996; Jones, 1999; Mann & Stewart, 2000; Walther, 2002; White, 2002). They are developing ways to overcome obstacles presented by conventional methods of obtaining consent, recruiting participants, and assessing risk and benefits of research that are usually measured against existing ethical guidelines developed for medical and social science research (Emerton, 2003). For example, Anders (2000 cited in Mann & Stewart, 2000) outlines the problems she encountered obtaining ethics approval for an online survey of disabled academic women in a university setting. The ethics committee subsequently approved the use of an electronic signature on an e-mailed consent form rather than the traditional hardcopy version.

## FUTURE TRENDS

It is difficult to forecast the ethical challenges that will confront online researchers in the short and long term. We do know that new forms of Internet communication, such as multimedia and interactive dimensions, are proliferating. The use of online participants in "real time" research will present new ethical challenges. The Internet is not a stable medium and so there are likely to be problems with archiving research data and developing adequate retrieval systems. Internet use in Western nations such as the U.S., Canada, and Australia, and some Asian countries such as Japan and Singapore, is continuing to grow (International Telecommunications Union, 2004). As mass-communication industries are moved offshore to non-Western and developing countries (such as India, Pakistan, the Philippines, and Bangladesh) and wireless Internet communication becomes more accessible and affordable in newly industrialized and marketized nations (China, Korea, Taiwan, and India), the Asia Pacific and nations of the global south (South America), the potential number of users will be enormous.

Growth in global Internet use will be accompanied by a new wave of ethical dilemmas, more complex than those currently experienced. Cultural and linguistic issues, national disputes about ownership and regulations of data, and privacy issues will become more commonplace unless generic standards governing such issues are developed. The European Union's data protection laws are an exemplary model for other parts of the world. What is clear is that online researchers will need to adapt their research designs and ethical practices to accommodate the constantly changing modes of CMC and a more diverse and significantly larger audience.

## CONCLUSION

Ethical issues confronting online researchers range from conceptual concerns about our understanding of CMC itself to disciplinary differences in the interpretation of them. These conceptual differences have profound implications for how online researchers approach ethical concerns. Additionally, this article has raised some of the practical difficulties in the design and implementation of research studies. The nature of online research and the technology involved in it is posing some unique ethical problems. Some researchers argue that online projects should not be forced into existing codes of ethical practice, which do not take into account the unique nature of the medium. In the absence of regulatory guidelines governing ethical issues raised by online research, a collective body of knowledge gained from the experiences of individual researchers and research institutes around the world is used in the interim.

## KEY TERMS

**Beneficence:** The expectation that a researcher will maximize the potential benefits (and minimize the harms) that can occur to participants, the research setting, and third parties not directly involved in research. Beneficence is difficult to assess since it can mean "future benefits" to groups/individuals in society and no immediate benefit to those involved in the current research project.

**Confidentiality:** The expectation that a researcher will maintain the privacy and security of data (information) provided by a participant. The researchers have the re-

sponsibility not to show any information (data) gained during the research to anyone not directly involved or given permission by the participant to access their data. It may involve giving the participants pseudonyms to disguise their real-life identity to others.

**Data:** Information (usually words, arts, artifacts, music, pictures, or text) that is used by researchers to gain an understanding of human life and interactions/actions. In online research, this includes e-mail transcripts, typed texts from MUDs or MOOs, pictures and images on Web sites, and music and audio sound.

**Deontological:** This is an ethical tradition that emphases the rights and integrity of human subjects above all other considerations, including the "greater good," public utility, or future benefits of the research.

**Ethics:** The theory and practice of the conduct and responsibilities researchers have towards participants in research, those who sponsor research, and those who are the potential beneficiaries of research.

**Informed Consent:** The mental [and physical] ability of research participants to make decisions [the voluntary agreement] to participate in research. In obtaining consent, researchers should inform participants about every aspect of the study, what is expected of the participants, the potential risks, and benefits of the proposed research, so the participants can decide whether they want to take part in it.

**Justice:** This ethical principle focuses on questions of who ought to receive the benefits of research and carry the burdens associated with it. Researchers need to recognize the potential for injustices when certain groups (low income, poor, or minority groups) are more often represented/used in research but seldom receive direct or indirect benefits arising from it.

**Online Research:** This involves the systematic collection and analysis of data about human beings, their interactions, and actions using material obtained from the Internet. It differs from face-to-face research methods as the researcher and participants seldom meet in person.

**Utilitarian:** This approach to ethics stresses the public benefit or good to come out of research, as more important than the individual rights and well-being of research participants. It is seen as a more pragmatic approach than the deontological one.

# Ethics and Privacy of Communications in the E–Polis

**Virginia Horniak**
*Mälardalen University, Sweden*

## INTRODUCTION

The electronic networking of physical space promises wide-ranging advances in science, medicine, delivery of services, environmental monitoring and remediation, industrial production and the monitoring of persons and machines. It can also lead to new forms of social interaction. However, without appropriate architecture and regulatory controls, it can also subvert democratic values. Information technology is not, in fact, neutral in its values; we must be intentional about design for democracy (Pottie, 2004).

Information and communication technology (ICT) has led to the emergence of global Web societies. The subject of this article is privacy and its protection in the process of urbanization and socialization of the global digital Web society referred to as the e-polis. Privacy is a fundamental human right recognized in all major international agreements regarding human rights, such as Article 12 of the Universal Declaration of Human Rights (United Nations, 1948), and it is discussed in the article "Different Views of Privacy".

Today's computer network technologies are sociologically founded on hunter-gatherer principles. As a result, common users may be possible subjects of surveillance and sophisticated Internet-based attacks. A user may be completely unaware of such privacy breaches taking place. At the same time, ICT offers the technical possibilities of embedded privacy protection obtained by making technology trustworthy and legitimate by design. This means incorporating options for socially acceptable behavior in technical systems, and making privacy protection rights and responsibilities transparent to the user.

The ideals of democratic government must be respected and even further developed in the future e-government. Ethical questions and privacy of communications require careful analysis, as they have far-reaching consequences affecting the basic principles of e-democracy.

## VALUES OF THE E-POLIS

In our post-industrial age, we are witnessing a paradigm shift from techno-centrism to human-centrism and the emergence of an entirely new value system that holds out the prospect of a new Renaissance epoch. Arts and engineering, sciences and humanities are given a means whereby they can reach a new synthesis (Dodig-Crnkovic, 2003). This meeting of cultures is occurring to a great extent in cyberspace, making issues of cyber ethics increasingly important.

One expression of a new rising human-centrism is the emergence of e-government, which changes the citizen-government relation, making the political system transparent and more accessible to the citizen in the participatory democracy. It is, therefore, argued that a rethinking of the idea of development in the contemporary globally networked civilization is necessary (Gill, 2002). Networking at the global level must be seen in a symbiosis with local resources. Social cohesion in this context results from the ability to participate in the networked society through mutual interaction, exchange of knowledge and sharing of values. The problem of promoting e-government in developing countries via virtual communities' knowledge-management is addressed by Wagner, Cheung, Lee, and Ip (2003).

## PRIVACY MATTERS

Before the advent of ICT, communication between people was predominantly verbal and direct (Moore, 1994; Agre & Rotenberg, 1997). Today, we increasingly use computers to communicate. Mediated by a computer, information travels far and fast to a virtually unlimited number of recipients, and almost effortlessly (Weckert, 2001). This leads to new types of ethical problems, including intrusion upon privacy and personal integrity. Privacy can be seen as a protection of two kinds of basic rights:

- **Priority in Defining One's Own Identity:** (This implies the right to control the use of personal information disclosed to others, as personal information defines who you are for the others. As a special case, the freedom of anonymity can be mentioned. In certain situations we are ready to lend our personal data for statistical investigations, for research purposes and similar, under the condition that anonymity is guaranteed.)
- **The Right to Private Space:** (This is generalized to mean not only physical space but also special artifacts exclusively associated with a certain individual, such as a private diary or private letters – or disk space.) The privacy of one's home is a classic example of a private space that, moreover, is related to one's own identity. It is also an instructive archetype because it shows the nature of a private space as a social construction. You are, in general, allowed to choose whom you wish to invite to your home. However, under special circumstances, it is possible for police, for example, to enter your home without your consent, this being strictly regulated by law.

Historically, as a result of experiences within different cultures, a system of practices and customs has developed that defines what is to be considered personal and what is public (see Warren & Brandeis, 1890; Thompson, 2001). A basic distinction in human relations is, consequently, that between the private (shared with a few others) and the common (shared with wider groups) (DeCew, 2002). Fried (Rosen, 2000) claims that only closely related persons can have true knowledge of an individual.

According to Mason (2000), privacy can be studied through the relationships of four social groups (parties): (1) the individual; (2) others to whom the first party provides specific personal information for the sake of creating or sustaining a personal relationship or in return for services; (3) all other members of society who can get access to an individual's private information, but who have no professional relation to the individual and no authority to use the information; and (4) the general public who are in no direct contact with the individual's private space or information. During the interaction between parties, individuals invoke different levels of privacy. The advantages of close relationships are compared with the risks of the release of information and its inappropriate use, which could result in a loss of personal space or harm to one's identity.

## DIFFERENT VIEWS OF PRIVACY

The acquisition, storage, access to and usage of personal information is regulated and limited in most countries of the world by legislation. However, each part of the world has its own laws. In the United States (U.S.), separate laws apply to different kinds of records. Individual European countries have their own specific policies regarding what information can be collected and the detailed conditions under which this is permissible. (For an international survey of privacy laws, including country-by-country reports, see Privacy and Human Rights 2004; see also Briefing Materials on the European Union Directive on Data Protection).

The current political situation in the world and the threat of terrorist attacks has led to governmental proposals in the European Union requiring Internet Service Providers to store personal information—for example, data relating to Internet traffic, e-mails, the geographical positioning of cellular phones and similar—for a period of time longer than is required of them at present (ARTICLE 29 Data Protection Working Party).

Although relevant legislation is in effect locally, there are difficulties with respect to the global dissemination of information. To avoid conflicting situations, there is a need for international agreements and legislation governing the flow of data across national borders.

## COMPUTER ETHICS

ICT is value-laden, as is technology in general, and is changing our ways of conceptualizing and handling reality (Bynum & Rogerson, 2003; Spinello, 2003). It is not always easy to recognize intrinsic values incorporated in an advanced technology. Specialized technical knowledge is often needed for an understanding of the intrinsic functionality of a technology; for example, how information is processed in a computer network.

The need for a specific branch of ethics for computer and information systems, as compared with a straightforward application of a general ethical theory to the field of computing, is discussed by Bynum (2000), Floridi and Sanders (2002) and Johnson (2003). Tavani (2002) gives an overview of this so-called uniqueness debate. While the philosophical discussion about its nature continues, computer ethics/cyber ethics is growing in practical importance and is establishing itself as a consequence of the pressing need for the resolution of a number of acute ethical problems connected with ICT.

The changing resources and practices appearing with ICT both yield new values and require the reconsideration of those established. New moral dilemmas may also appear because of the clash between conflicting principles when brought together unexpectedly in a new context. Privacy, for example, is now recognized as requiring more attention than previously received in ethics (Moor, 1997). This is due to reconceptualization of the private and

public spheres brought about by the use of ICT, which has resulted in the recognition of inadequacies in existing moral theory about privacy. In general, computer ethics can provide guidance in the further development and modification of ethics when the existing is found to be inadequate in the light of new demands generated by new practices (Brey, 2000).

For Moor (1985), computer ethics is primarily about solving moral problems that arise because there is a lack of policy (policy vacuum) about how computer technology should be used. In such a case, the situation that generates the moral problem must first be identified, conceptually clarified and understood. On the other hand, Brey claims that a large part of work in computer ethics is about revealing the moral significance of the existing practices that seem to be morally neutral. ICT has implicit moral properties that remain unnoticed because the technology and its relation to the context of its use are not sufficiently understood. Disclosive computer ethics has been developed to demonstrate the values and norms embedded in computer systems and practices. It aims at making computer technology and its uses transparent, revealing its morally relevant features.

## FAIR INFORMATION PRACTICES

One of the fundamental questions related to the expansion of community networks is the establishment of fair information practices that enable privacy protection. At present, it is difficult to maintain privacy when communicating through computer networks, which are continually divulging information. An example of a common concern is that many companies endeavor to obtain information about the behavior of potential consumers by saving cookies on their hard disks. Other possible threats against citizens' privacy include the unlawful storage of personal data, storage of inaccurate personal data and abuse or unauthorized disclosure of such data; these are issues surrounding government-run identity databases. Especially interesting problems arise when biometrics is involved (for identity documents, such as passports/visas, identity cards, driving licenses). Remote electronic voting is dependent on the existence of a voters' database, and there are strong privacy concerns if the same database is used for other purposes, and especially if it contains biometric identifiers.

Many countries have adopted national privacy or data protection laws. Such laws may apply both to data about individuals collected by the government and to personal data in the hands of private sector businesses. The OECD has defined *fair information practices*, which include the following principles: collection limitation, data quality, purpose specification, use limitation, security, openness, individual participation and accountability (see OECD Guidelines on the Protection of Privacy).

The exceptions to these principles are possible in specific situations, such as law enforcement investigations, when it might not be appropriate to give a suspect access to the information that the police are gathering. Nonetheless, the principles of fair information practices provide a framework for privacy protection.

## LEGITIMACY BY DESIGN AND FUTURE TRUSTWORTHY COMPUTING

Legitimacy is a social concept developed during human history, meaning "socially beneficial fairness." It concerns classical social problems, such as the prisoner's dilemma and the "tragedy of the commons," in which individuals may profit at the expense of society. Social interactions without legitimacy lead society into an unsustainable state.

However, traditional mechanisms that support legitimacy, such as laws and customs, are particularly ineffective in the cyberspace of today with its flexible, dynamic character, (Whitworth & de Moor, 2003). The remedy is the incorporation of legitimacy by design into a technological system. That process begins with a legitimacy analysis that can translate legitimacy concepts, such as freedom, privacy and intellectual property into specific system design demands. At the same time, it can translate technological artifacts, such as computer programs, into statements that can be understood and discussed in terms of ethical theory.

Legitimate interaction, with its cornerstones of trustworthiness and accountability, seems a key to the future of the global information society. This implies that democratic principles must be built into the design of sociotechnical systems such as e-mail, collaborative virtual environments (CVEs), chats and bulletin boards, electronic voting systems and similar. As the first step towards that goal, the legitimacy analysis of a technological artifact (software/hardware) is suggested.

*Trust is a broad concept, and making something trustworthy requires a social infrastructure as well as solid engineering. All systems fail from time to time; the legal and commercial practices within which they're embedded can compensate for the fact that no technology will ever be perfect.* (Mundie, de Vries, Haynes, & Corwine, 2003)

In any computer-mediated communication, trust ultimately depends not on personal identification code num-

bers or IP addresses, but on relationships between people with their different roles within social groups. The trust necessary for effective democracy depends on communication, and much of the communication is based on interaction over computer networks. Trust and privacy trade-offs are normal constituents of human social, political and economic interactions, and they consequently must be incorporated in the practices of the e-polis. The bottom line is, of course, the transparency of the system and the informed consent of all parties involved.

## CONCLUSION

ICT supports and promotes the formation of new global virtual communities that are socio-technological phenomena typical of our time. In an e-democracy government, elected officials, the media, political organizations and citizens use ICT within the political and governance processes of local communities, nations and on the international stage. The ideal of e-democracy is greater and more direct citizen involvement. For the modern civilization of a global e-polis, the optimal functioning of virtual communities is vital. What are the basic principles behind successful virtual community environments? According to Whitworth, there are two such principles:

- Virtual community systems must match the processes of human-human interaction
- Rights and ownership must be clearly defined

It is technically possible for ICT to incorporate these principles, which include privacy protection via standards, open source code, government regulation, and so forth (Pottie, 2004; Tavani & Moor, 2000), including also trustworthy computing (Mundie et al., 2003).

A process of continuous interaction and dialog is necessary to achieve a socio-technological system that will guarantee the highest standards of privacy protection. Our conclusion is that trust must be established in ICT, both in the technology itself and in the way it is employed in a society.

## KEY TERMS

**Computer Ethics:** A branch within applied ethics dealing with ethical questions concerning ICT. Computer ethics includes application of ethical theories to issues regarding the use of computer technology, together with standards of professional practice, codes of conduct, aspects of computer law and related topics.

**Cookies:** Information about a user stored by the server on the user's hard disk. Typically, a cookie records a user's preferences when using a particular site, which often happens without the user's knowledge, even though they must nominally agree to cookies being saved for them.

**CVEs:** Collaborative Virtual Environments.

**Cyber Ethics:** See computer ethics. Broadly speaking, cyber ethics deals with the conduct of individuals with respect to the information world; in the words of Moor: "the formulation and justification of policies for the ethical use of computers." Narrowly, cyber ethics refers to computer ethics discipline in cyberspace.

**Cyberspace:** A virtual space that consists of resources available through computer networks. It also refers to the culture developed by electronically connected communities. The term was first coined by William Gibson in the book *Neuromancer*.

**Design for Democracy:** The incorporation of options for socially acceptable behavior in technical systems, making the basic principles of privacy protection, rights and responsibilities transparent to the user.

**Disclosive Ethics:** A multi-level interdisciplinary approach concerned with the exposition of embedded values and norms in computer systems, applications and practices.

**Policy Vacuum:** James Moor has defined this term, meaning the absence of policies for governing conduct in new situations resulting from the use of new technologies. The central task of computer ethics is to fill the policy vacuums resulting from the use of computers by formulating guidelines for their use.

**Privacy, Right of:** The right of a person to be free from intrusion into or publicity concerning matters of a personal nature; also called right to privacy.

**Technology Legitimate by Design:** Technology designed in such a way as to promote its legitimate use and prevent its misuse.

**Uniqueness Debate:** A discussion among ethicists whether computer ethics is a unique field of ethics or merely a straightforward application of existing ethical theories to the specific technology (computers).

# Ethics of Digital Government

*University of Central Florida, USA*

## INTRODUCTION

The Internet is at once a new communications medium and a new locus for social organization on a global basis. A digital government will allow public access to government information and services, and group participation in discussions at any time and from anywhere on the globe. Digital government is regarded as the most recent development in the evolving application of electronic information technology to the performance of government. The development and migration of the technologies, as well as applications of information technology in support of government operations are other important aspects. New policies have been passed by legislative bodies to ensure the proper management and implementations of these technologies and the systems they serve, their protection from physical harm, and the security and privacy of their information. The growth of digital government has increased governments' ability to collect, store, analyze, and disclose private personal and organizational information (Fountain, 2001). In the rapidly evolving environments of digital technology, it is impossible to anticipate the leading-edge ethical issues. However, there are solid ethical imperatives to use these principles ethical behavior for resolution of the issues (Anderson, 2004). This article will focus on privacy and confidentiality of individual private information in digital environment.

## DIGITAL GOVERNMENT AND DIGITAL GOVERNANCE

Digital government and digital governance are used interchangeably. It is important to make the distinction between these two important concepts in here. Digital or e-government refers to primarily on providing information and online transaction kinds of services to citizens of government. On the other hand, e-governance focuses on public's participation and their role as citizens (Abramson & Morin 2003). Electronic governance popularly referred to as e-government is broadly defined as an application of information technology to the functioning of the government to enhance the delivery of public services to the citizens and other individual and organizational consumers of the government services (O'looney, 2002). West (2000) defines digital government as "e-government refers to the delivery of information and services online through the Internet or other digital means." For the past several years, a great deal of focus has shifted to this concept which has varying meaning and significance. Initially, the term was a little more than a general recognition of a convergence of information technology (IT) developments and application and use of these technologies by government entities. With the passage of time however, the term is being used as a reference to both current applications of IT to government operations and a goal of realizing more efficient and transparent performance of government functions. E-government involves access to government information and services 24 hours a day, seven days a week, in a way that is focused on the needs of the citizens. E-government relies heavily on the effective use of Internet and other emerging technologies to receive and deliver information and services easily, quickly, efficiently, and inexpensively.

UNESCO identifies several factors affecting the e-government and e-governance movement internationally in its e-governance study (2002): the use of information and communication technologies by citizens and non-governmental organizations to influence policymakers, transferability of information in terms of e-government reforms including draft government legislation and online services, public sector reform, and the promise of information and telecommunication technologies to increase government efficiency and effectiveness, pressure for increased accountability and transparency. In this environment of digital government, citizens can go online any time, anywhere to get information, receive services, conduct business transactions, or talk to elected representatives. The natural transparency of the online environment creates digital government that is truly of, by, and for the people. The digital government vision that guides several governments around the globe to focus commitment to digital government and reach far beyond shifting the delivery of agency services to the Internet. This vision also represents a clear and purposeful innovation that changes government culture from within, as it unfolds and demystifies bureaucracy.

## DIGITAL GOVERNMENT AND ETHICAL ISSUES

Digital government can support efficacy and accountability of government functions and services. Digital government will make transparent information about the government performance more accessible and might enhance the accountability of government to citizens (Abramson & Morin, 2003). Digital government also, because of its technological foundations, can allow public agencies to deliver "real-time" public service to citizens (Kolodney, 2004). Even though efficacy and effectiveness of digital government is so convincing, public service should be available to all citizens for digital government to be completely effective (Layne & Lee 2001). However, the universal access to public services using the Web site is still not the case for governments around the world. "Governments may want to provide Internet access through public terminals as a part of their universal [public service] access efforts (Layne & Lee, 2001, p. 134).

One of the big concerns of citizens or e-government costumers is the problem of privacy. "The technologies' surveillance capacity to collect, aggregate, analyze, and distribute personal information coupled with current business practices have left individual privacy unprotected" (Berman & Mulligan, 1999). Will the digital government be one in which individuals maintain, lose, or gain control over information about themselves? Privacy is critical because government interaction with citizens always has autonomy issues, as only government is in the business of law enforcement. Systems which design with the assumption that privacy is an issue of property or seclusion should not be adopted for use in government. "The information exchanged on many federal (government) Web sites is personal and confidential. Privacy and security policies, therefore, must be not only developed but clearly displaced as well. To fully meet users' needs, federal (government) Web sites must create protected, private, and secure spaces for the mutual exchange of information" (Stowers, 2003, p. 49).

The confidentiality and privacy of public' sensitive personal information is challenged by a legal framework that centers protections on who maintains the information, how the network is structured, where data is stored, and how long it is kept. It can be imagined that how dangerous it can get in the hands of public officials are unaware of e-government code of ethics and how to deal with sensitive public information. "As our wallets become "e-wallets" housed somewhere out on the Internet rather than in our back-pockets, and as our public institutions, businesses, and even cultural institutions find homes online, the confidentiality of our communications, papers, and information is at risk of compromise" (Berman & Mulligan, 1999).

The emergence of digital government requires public agencies and citizens as well to reflect and apply existing code of ethics and other privacy principles. This task requires significant expertise. Berman and Mulligan (1999) recommends the following:

*To function well, such an entity should have the ability to: monitor and evaluate developments in information technology with respect to their implications for personal privacy; conduct research, hold hearings, and issue reports on privacy issues in both the public and private sector; develop and recommend public policy appropriate for specific types of personal information systems; comment upon government and private sector proposals that impact on privacy; review agency activities under the Privacy Act; participate in government proposals that impact on privacy.*

Future technical advancements can provide an underlying framework for privacy and confidentiality. However, while implementing technical advancement in the realms of privacy and confidentiality code of ethics should be implemented in digital government services. Public administrators should be well equipped with information technology and code of ethical conduct for ethical decision and behavior.

One of the major issues in electronic environment of digital government is the question of access: who will have access to the information, and what kinds of information will be accessible. These questions are important because electronic sources offer tremendous economic, political, and even social advantages to people who have access to them. As the electronic resources become a larger presence in society, conflicts may arise between information "haves" and "have-nots." Conceivably, electronic communication could create greater equality by offering common access to all resources for all citizens. Internet accesses established through local libraries or other municipal or local organizations specifically for people who otherwise would have no way to use the networks, have shown that those people will, for instance, participate more in local government issues. They therefore have a greater voice in whatever happens with local government. Conversely, if access is not evenly distributed, it threatens to effect or deepen existing divides between the poor, who cannot afford expensive computer systems, and the better-off.

Questions of free speech and community standards of decency on the Internet are difficult to resolve. At present, local communities may define what is or is not obscene, and therefore not tolerated, within their geographic bor-

ders. The networks, however, have no such borders; so who defines obscenity on them has become a divisive issue. The problems will become still greater as network communication grows and crosses additional international boundaries and cultural divides.

## CODE OF ETHICS

It is generally considered best interest of every governmental agency to have a code of ethics or code of conduct. The American Society for Public Administration (ASPA) has specific guidelines for its implementation. The society makes the code of conduct available online and in print on the cover page of its major journal, Public Administration Review (PAR). The United Nations (UN) and OECD offer guideline for public agencies in developing and implementing code of ethics (Anderson, 2004). The International City/County Management Association (ICMA) provides personal and professional support for public administrators. ICMA maintains a strict professional code of conduct for public managers, and those members found violating the code of ethics are subject to private or public censure or even expulsion from membership in ICMA. The electronic government or digital government is still very young that it has not yet formed ethical standards. There are some initiatives to establish code of conduct for ethical e-government practices as well (Keegan 2000). The alliance's code of conduct has five main points:

- Adopt strict consumer-privacy policies that prohibit the improper use and resale of consumer data to third parties
- Disclose all fees and other costs associated with e-government services
- Accurately represent the number and scope of e-government products and services offered
- Accurately represent corporate structures and affiliate relationships that may affect vendor selection
- Help bridge the digital divide and ensure universal access

These and other ethics codes are open to the individual interpretations. However, these principles can be applied to the digital environment of e-government. There have been some attempts to institutionalize code of ethics for e-government. But they are in their very immature stages. These codes of ethics can provide baseline for ethical discourse in digital government era and can be applied in ethical behavior in e-government issues.

## CONCLUSION

The new developments in information technologies offer several possibilities for governments to improve the quality and efficiency of government services to their citizens. Protecting public's confidential information is especially important in the digital environment of e-government. A loss of trust in governmental agencies' ability to protect individual citizens privacy can have significant consequences in public's trust in government and their participation to e-governance.

Public agency Web sites should provide clear statements that address privacy and security issues for their users or costumers. These critical issues should be clearly stated in the policies (Atkinson & Ulevich, 2000). These legal notices are particularly important if the site is collecting any information from Web site visitors or is allowing users to pay bills or complete other transactions online. Providing privacy and protection to citizens in the digital government environment require a combination of tools—policy, technical, and ethical code of conducts. Protecting personal privacy and confidentiality, ensuring that digital government with new technology applications protects privacy, developing policies, or simply developing code of conducts will happen without collaboration of these three in e-government and e-governance.

## KEY TERMS

**Confidential:** The classification of data of which unauthorized disclosure/use could cause serious damage to an organization or individual.

**Digital Governance:** The application of information technology to the functioning of the government to enhance the interactive delivery of public services to the citizens and other individual and organizational consumers of the government services.

**Digital Government:** The delivery of information and services online through the Internet or other digital means.

**Ethics:** Ethics is doing the right thing. It is also related to moral action and conduct; professionally right; conforming to professional standards. The field of ethics involves systematizing, defending, and recommending concepts of right and wrong behavior.

**Ethics of Digital Government:** Applications of ethical principles and use of these principles for resolution of the issues in the digital environment for government services.

**Hyper Text Markup Language (HTML):** The underlying formatting for World Wide Web documents.

**Information Technology (IT):** Acquisition, processing, storage, and dissemination of all types of information using computer technology and telecommunication systems.

**Internet:** The Internet Society defines internet as "a global network of networks enabling computers of all kinds to directly and transparently communicate and share services throughout much of the world. Because the Internet is an enormously valuable, enabling capability for so many people and organizations, it also constitutes a shared global resource of information, knowledge, and means of collaboration, and cooperation among countless diverse communities."

**Privacy:** Individual privacy and security is highly valued by our society but must be balanced by the other community enumerated values and needs. Within this understanding, the governments should assure that the privacy of such "personal property" as "written communications intended by their creator to be private including those transmitted or preserved in paper, electronic, or other media" will be protected, although it cannot be completely guaranteed.

**Sensitive Information:** Information maintained by state agencies or institutions of higher education that requires special precautions to protect it from unauthorized modification or deletion. Sensitive information may be either public or confidential. It is information that requires a higher than normal assurance of accuracy and completeness.

**World Wide Web (WWW):** The World Wide Web is made up of a collection of interconnected computers using the TCP/IP protocol language to communicate.

## INTRODUCTION: TECHNOLOGICAL DEVELOPMENTS AND THE REVOLUTION OF NETWORKING

The recent developments in information communication technologies (ICTs) and the emergence of the Internet, in particular, as a mainstream communications and transaction media has changed the way that governments, organisations, and citizens interact and operate. These developments have changed the best operational and strategic practices for organisations on a global level and altered the competitiveness of enterprises and regions around the world.

The Internet enables the instant distribution of media-rich information worldwide and revolutionises the interactivity between computer users and information/service providers. The Internet therefore provides a window to the external world and facilitates the interactivity of organisations globally. Internal systems or "Intranets" have also be developed as "closed," "secured," "controlled," or "fire-walled" networks within organisations or individual departments. Intranets allow authorised personnel to access information, knowledge, and mechanisms across the enterprise to perform their tasks efficiently. Intranets enable organisations to improve their internal management at all levels by sharing media-rich data and processes, using Internet interfaces. Increasingly enterprises realise the need to formulate close partnerships with their partners and other members of the value chain for the production of goods and services. As a result, they developed "extranets," which use the same principles as well as computer equipment and networks to allow access to preselected sections of an organisation data, knowledge base, and mechanisms. User-friendly and multimedia interfaces mean that users require limited training for using the systems. Extranets can enhance the interactivity and transparency between organisations and their trusted partners, by linking and sharing data and processes through low-cost and user-friendly interfaces (Laudon & Laudon, 2004).

The digital revolution that was introduced by the Internet, intranet, and extranets provide unprecedented and unforeseen opportunities for productivity improvements, interactive management, and dynamic marketing. As a result, organisations and governments are now able to:

- accelerate knowledge and information distribution;
- apply knowledge management at the widest possible coverage;
- increase their efficiency and productivity;
- improve and shorten the decision-making process;
- enhance their communication and coordination efficiency;
- reduce their transportation, postage, and communication costs; and
- support their interactivity with all stakeholders.

To the degree that a company operates within a system of competition and dynamic developments, gaining and sustaining competitive advantage depends on understanding not only a firm's value chain but also how the firm fits in the overall value system (Porter, 1989; Porter & Millar, 1985). Porter (1985, 2001) suggests that ICTs reshape not only products, but more importantly, the nature of the competition. Entire industries are affected if ICTs have a significant role in determining relative cost position or differentiation. To gain competitive advantage over its rivals, an organisation must either perform the activities involved in adding value to a product or service at a lower cost or perform them in a way that leads to differentiation and a premium pricing (more value). Hence, ICTs change the entire economic system dramatically and organisations and governments need to constantly update their business models and enhance their competitiveness through new technological tools.

The vast majority of Northern and Western governments and organisations have already developed comprehensive representations online and have also established platforms for their internal management and collaboration with partners. Southern and Eastern societies, organisations, and governments still suffer from the digital divide, although in many places there is evidence of "frog leaping." India and China are some examples where technology is both driving and fuelling economic development.

The proliferation of broadband connections and also the availability of wireless networks through WiFi, UMTS, and Bluetooth technologies gradually propel the adoption of ambient intelligence, where technology will be forced in the background and its functionality will prevail all organisational functions and human interactions. Ambient intelligence is defined by the Information Soci-

ety Technology Advisory Group (ISTAG) (2003) as "a set of properties of an environment that we are in the process of creating." This represents a new paradigm for how people can work and live together. According to the ISTAG vision statement, humans, in an ambient intelligent environment, will be surrounded by intelligent interfaces supported by computing and networking technology that is embedded in everyday objects, such as furniture, clothes, vehicles, roads, and smart materials—even particles of decorative substances like paint. Humans will live in an ambient intelligence space in which there will be seamless interoperation between different environments—home, vehicle, public space, work, leisure space, tourism destination, and so forth. This implies a seamless environment of computing, advanced networking technology, and specific interfaces, which should be aware of the specific characteristics of human presence and personalities; adapt to the needs of users; be capable of responding intelligently to spoken or gestured indications of desire; and even result in systems that are capable of engaging in intelligent dialogue (Buhalis & O'Connor, 2005).

## BACKGROUND: GOVERNMENT AND THE TOURISM INDUSTRY

Destinations are amalgams of tourism products, facilities, and services, which compose the total tourism expertise under one brand name. Traditionally the planning, management, and coordination functions of destinations have been undertaken by either the public sector (at national, regional, or local level) or by partnerships between stakeholders of the local tourism industry. Governments therefore play an important role in tourism as they are responsible for the planning, development, promotion, and coordination of regions and places as tourism destinations. There is a wide range of additional responsibilities that governments have as a result of the tourism activity. As tourism involves cross-border activity, a great amount of political and diplomatic issues between countries arise, which need to be solved on a governmental level. Tourism is often on the forefront of economic activity, especially for peripheral and insular regions and therefore regional and national policies need to ensure maximum interaction between all different economic sectors to maximize the multiplier effects.

Tourism not only creates direct revenue to the public sector through taxation of tourism activities and products, but also contributes to the taxes paid by employees and tourism enterprises. Employment is also increased and consequently the disposable income of the host population is enhanced. In addition, the multiplier effects of the tourism activity stimulate the total output of the national economy and the boost the gross national product. Contribution to the balance of international payments is also of extreme importance to governments as it enables them to improve their international financial position. The public sector has to ensure the sustainable and dynamic development and management of the tourism industry within the borders of the economic, social, and environmental environment of the destination. In this sense, the public sector needs to manage resources, support entrepreneurial activity, control the impact of tourism on the destination, and coordinate the private sector in a way that the positive social and economic impacts exceed the negative ones, and the host population will benefit in general from the utilisation of its natural resources for tourism purposes (Buhalis, 2000; Edgell, 1990; Ritchie & Crouch, 2003; Wanhill, 2005a). Governmental intervention therefore is centred around the planning and management of the following issues:

- Planning
- Infrastructure
- Incentives
- Personnel training
- Destination marketing
- Public enterprises
- Pricing
- Industry control
- Social tourism

Wanhill (2005b, p.368) suggests that the case for public sector involvement in tourism rests on concepts of market failure, namely that those who argue for the market mechanism as the sole arbiter in the allocation of resources for tourism are ignoring the lessons of history and are grossly oversimplifying the nature of the product. Destination management organisations are often set, therefore, by the public sector to manage destinations at the national, regional, and local level and to coordinate all stakeholders toward the achievement of the strategic objectives of the region.

## E-TOURISM AND THE ROLE OF GOVERNMENTS

The ICTs' revolution has had already profound implications for the tourism sector (Buhalis, 1998, 2003). Timely and accurate information, relevant to consumers' needs is often the key to successful satisfaction of tourism demand. As few other activities require the generation, gathering, processing, application, and communication of information for operations, ICTs are pivotal for tourism. Consequently, the rapid development of both tourism supply and demand makes ICTs an imperative partner for

*Table 1. Interacting in the electronic marketplace with examples from tourism (Buhalis, 2003)*

| E-Business | Business | Consumer | Government |
|---|---|---|---|
| **Business** | **B2B** Extranets between hoteliers and tour operators | **B2C** E-commerce applications where consumers purchase air tickets | **B2G** Business interacting with government departments, e.g., hotel developer requires planning permission |
| **Consumer** | **C2B** Consumers registering their preferences on airline or hotel loyalty/executive clubs | **C2C** Consumers informing other consumers for good or bad practice (e.g., www.untied.com) | **C2G** Consumers applying for visas, requesting maps and local destination information |
| **Government** | **G2B** Government informing hotels about food safety legislation or taxation | **G2C** Government informing consumers on regulations, visa, or vaccination requirements | **G2G** Governments interacting for tourism policy makers or for asking technical assistance through organisations such as the World Tourism Organisation |

the marketing, distribution, promotion, and coordination of the tourism sector. Poon (1993) predicted that "a whole system of ICTs is being rapidly diffused throughout the tourism industry and no player will escape ICTs impacts." Information is therefore the life blood of tourism and so technology is fundamental for the ability of the industry to operate. ICTs have a dramatic impact on the travel industry because they force this sector as a whole to rethink the way in which it organises ICTs business, ICTs values or norms of behaviour, and the way in which it educates ICTs workforce (Poon, 1993; Sheldon, 1997; Werthner & Klein, 1999).

Increasingly e-commerce and the marketplace will be dominated by the interaction of business, consumers, and governments. A number of tourism examples are offered in Table 1. Not only the widely researched business-to-business (B2B) and business-to-consumer (B2C) transactions will be taking place, but the entire range of combinations between the three key stakeholders maximising their interactivity, efficiency, and effectiveness. Governments will be able to interact with businesses to coordinate destinations, to disseminate legislation, and ensure compliance to support marketing and promotion and to streamline taxation. Equally, governments already interact with consumers to provide advisories about destinations, promote destinations globally, handle complaints, and ensure that special groups such as the disabled travellers are adequately served. Finally, collaboration between public authorities and coordination with other governments will also enable a better coordination of the industry. This will lead to a better understanding of each player's needs whilst it will enhance the competitiveness of the tourism operations at the macro level.

## E-GOVERNMENT: ICTS AND DESTINATION MANAGEMENT SYSTEMS

Public tourist organisations are traditionally involved in destinations' information provision and marketing. They undertake mass media advertising; provide advisory services for consumers and the travel trade; produce and distribute brochures, leaflets, and guides both at destinations and at the places of origin of the tourists; and finally they have the strategic responsibility of the entire destination.

The Internet has revolutionised the travel industry by providing a new way for consumers to "experience" a destination, plan their itineraries, and purchase travel products. Increasingly, therefore, destination management organisations (DMOs) use ICTs in order to facilitate the tourist experience before, during, and after the visit, as well as for coordinating all partners involved in the production and delivery of tourism. Thus, not only do DMOs attempt to provide information and accept reservations for local enterprises as well as coordinate their facilities, but they also utilise ICTs to promote their tourism policy, coordinate their operational functions, increase the expenditure of tourists, and boost the multiplier effects in the local economy. Despite the fact that studies on destination-oriented systems have been traced back to as early as 1968, it was not until the early 1990s that the concept of destination management systems (DMSs) emerged. DMSs facilitate this function by administrating a wide range of requests and by providing information to an ever-increasing tourism supply in an

efficient and appropriate way. Thus, ICTs provide a way to improve the accessibility of, and the quantity and quality of, information on the destination's facilities while they present travellers with options in minimising their search costs (Sheldon, 1993). Moreover, destinations take advantage of the database marketing techniques to identify and target profitable market niches, by tailoring market-driven products for particular customers. Increasingly DMSs are employed by many national and regional governments to facilitate the management of DMOs, as well as for the coordination of the local suppliers at the destination level. DMSs are seen as particularly important significant for small and medium tourism enterprises (SMEs) which lack the capital and expertise to undertake a comprehensive marketing strategy and rely on destination authorities and intermediaries for the promotion and coordination of their products (Frew & O'Connor, 1999; WTO, 2001).

DMSs emerge as a major promotion, distribution, and operational tool for both destinations and SMTEs. They can assist developing a flexible, tailor-made, specialised, and integrated tourism product. By enabling users to search and select individual tourism products, DMSs can support travellers to create their personalised destination experience. At the organisational level, DMSs provide the essential infostructure for DMO to coordinate their activity and to provide sufficient information and direction to their overseas offices to promote the destination. DMSs emerge as interfaces between destination tourism enterprises (including principals, attractions, transportation, and intermediaries) and the external world (including tour operators, travel agencies, and ultimately, consumers). In some cases, such as in Britain, Singapore, and Austria, DMSs have been used for integrating the entire supply at the destination. Their contribution to strategic management and marketing is demonstrated by their ability to integrate all stakeholders at destinations and also to reach a global market at a fairly affordable cost. DMSs usually include a product database, a customer database, and a mechanism to connect the two. The more advanced systems tend to include a number of the additional services and features, as illustrated in the following points:

- Information search—by category, geography, keyword
- Itinerary planning for customer
- Reservations
- Customer/contact database management
- Customer relationship management functions
- Market research and analysis
- Image library and PR material for press
- Publishing to electronic and traditional channels
- Event planning and management
- Marketing optimisation and yield management
- Data editing and management
- Financial management
- Management information systems and performance evaluation
- Economic impact analysis
- Access to third-party sources, such as weather, transport timetables, travel planning, theatre, and event ticket reservations (based on WTO, 2001)

Advanced DMSs enable destinations to achieve differentiation by targeting niche markets. They also assist to improve the balance between the expectations and the perceived experiences for both tourists and locals, improving their interaction and satisfaction. In addition, DMSs assist local enterprises to increase their bargaining power over tourism intermediaries and to explore new and innovative distribution channels. The illustration of environmentally sensitive areas as well as the demonstration of sociocultural rituals can support a better understanding by locals and tourists and therefore would improve the tourism impacts in the area (Buhalis, 1997). Some governments and DMOs have benefited by implementing advanced DMSs which can rationalise destination management and marketing by supporting their promotion, distribution, and operations and also by offering innovative tools for strategic management and amelioration of tourism impacts (Buhalis & Spada, 2000; Pollock, 1998; WTO, 2001).

For example, the Australian government and the Australian Tourism Commission (ATC) launched their first consumer Web site, Australia.com, in 1996. The emphasis was on promoting Australian resources and to attract more visitors. This site contained 11,000 pages of motivational and destination content, listings of products, factual information, competitions, feedback, and a search for Aussie specialist travel agents. Then in 1998, a gateway site sitting above the global site was implemented for North America, followed soon after by several other regions. The gateways brought content from the global site to a higher level, together with links back into the global site. This enabled the regions to present content that was of more relevance to their customers at an earlier point in their browsing. Extensive consumer research was conducted to determine how potential travellers access online travel sites, their information needs, and expectations. The ATC's consumer Web site, australia.com, reflected the ever-growing importance of online technologies and confirmed the ATC's strategic move toward Web-based marketing. It targeted the international travel market and provided international visitors with instant access to motivational information aiming to influence them to choose Australia as their holiday destination. The site was based on a dynamic platform upon which the ATC used to deliver and distribute interactive, branded, and

targeted multilingual content to drive conversion of actual travel to Australia by potential travellers. In 2000/01, the site delivered 38 million pages of information to an estimated 5 million unique users. The number of users grows at a rate of more than 50% annually and by 2002/03, 12 million unique users were expected to visit the site. Hence, DMSs can provide new tools for destination marketing and promotion, as they use ICTs to disseminate information and to support a reservation function for products and facilities at specific destinations.

At the strategic level, e-tourism revolutionises all business processes—the entire value chain as well as the strategic relationships of tourism organisations with all their stakeholders including governments (Buhalis, 2003). As with other industries, ICT's penetration into tourism should provide strategic tools for the networking of the industry, for adding value to products and for enabling organisations to interact with all stakeholders in a profitable way. ICTs can improve the managerial processes in order to ameliorate control and decision-making procedures, and to support enterprises to react efficiently to environmental changes and consumer behaviour trends. Increasingly, ICTs play a critical role in customer relationship management as they enable organisations to interact with customers and continuously alter their product for meeting and exceeding customer expectations. Managing customer relationships on a continuous (365/24) and global basis is of paramount importance for the successful tourism organisation of the future. The strategic dimension gradually propels the business process reengineering of tourism businesses changing all operational and strategic processes. Innovative ICTs therefore transform the best operational practices and provide opportunities for business expansion in all geographical, marketing, and operational senses.

The Finnish Tourism Board (FTB) infostructure provides an excellent example of ICT usage for strategic purposes by the public sector as it has developed an integrated systems to support its operations. FTB aims for all its information to be accessible via Internet protocol systems for its employees (intranet), partners (extranet), and the general public (Internet). FTB has pioneered the use of the Internet for developing a network for managing tourism in Finland as well as a tool for cross industry and coordination. The system includes three systems, namely:

- **MIS:** the FTB's market information system offers a data management and distribution system. Launched in 1992 and updated in 1997, this is the internal system for FTB and is distributed to all its offices internationally. The system allows FTB staff to manage and organise sales and marketing campaigns, to coordinate their marketing and branding activities, as well as to distribute documents and administrate the tourism board globally. Access is also allowed to other professionals.
- **RELIS:** the research, library, and information service provides the backbone to the national travel research and product documentation. The service connects the travel industry to research and education organisations.
- **PROMIS:** the national database of Finnish travel products and services provides a wide range of up-to-date information on travel products, services, and contact information. External PROMIS partners provide and update data and include regional and city tourism organisations and other tourism professionals. Most of the information and images are copyright free and can be used for brochures and other promotional campaigns. The professional MIS offers a tourism database covering the whole of Finland. Hence, services for the tourist industry were improved considerably by opening an Internet connection to the PROMIS information system, which the FTB has developed together with the industry. Cooperation partners can now add and update information online. Internet service was expanded, with eight new languages being added to the site (Finnish Tourism Board, www.mek.fi; WTO, 2001).

## E-GOVERNMENTS AND DMSS CHALLENGES AND THE LIMITED DEVELOPMENT HITHERTO

Despite the fact that studies on destination-oriented systems have been traced back to as early as 1968, it was not until the late 1980s that the proliferation of DMSs has been delayed due to a number of factors and barriers to success:

- lack of adequate and affordable technology;
- lack of standardisation of the industry and the early systems;
- lack of IT expertise by tourism professionals;
- concentration of marketing efforts at the local markets;
- relatively less intensive competition;
- lack of strategic orientation;
- inability to strengthen competitiveness of the local industry;
- technology leading rather than following marketing strategies;
- less integrated approach than appropriate;
- inability to provide total services for tourism demand and supply;

- limited geographical basis which makes the system nonfeasible;
- premature innovation in a traditionally reserved industry;
- lack of standardisation and compatibility;
- withdrawal of public sector interest and funding;
- product rather than demand orientation;
- domination of small and independent tourism enterprises around the world; and
- conflicting interests of different players in the tourism industry.

A high failure rate has been observed, as several DMSs failed to attract the support and commitment required from both the private and public sectors. DMSs have also failed to develop viable products, which would be utilised from either the independent or institutional tourism demand. Two systems offer an exception to the rule, Gulliver, the Irish DMSs, and the Austrian TIScover, which now operates in a number of markets on an Application Service Provider Model. Both systems have adopted their technological basis and their ownership status and remain as the few operational and successful systems in the world.

## FUTURE TRENDS

Destinations that embrace advanced ICTs and DMSs in particular will be able to improve their strategic positioning, improve their competitiveness, and optimise their benefits from tourism. To succeed in the future, DMSs will need to combine both technological and management innovation and to develop suitable tools for satisfying the entire range of stakeholders. ICTs and DMSs in particular emerge as essential tools for both tourism demand and supply, as they establish a flexible and profitable communication bridge and a strategic management tool. They effectively provide the infostructure at the destination level and can network the entire range of principals and operators on a neural network. Eventually, DMSs will be emerging as digital business ecosystems that will enable the entire range of tourism stakeholders to plug and play, expanding the value system and developing extended networks of dynamic packaging at the destination level (Nachira, 2002, 2005; Pollock & Benjamin, 2001).

## CONCLUSION

Competent DMOs around the world gradually realise the potential opportunities emerging through ICTs and use technology in order to improve their function and performance as well as for communicating their marketing message globally. DMSs are expected to have a brighter future, provided that the industry learns several lessons from the embryonic DMSs' development experiences. They need to capitalise on expertise and knowledge generated globally and make brave steps toward the development and implementation of these systems. It gradually becomes evident that destinations that provide timely, appropriate, and accurate information to consumers and the travel trade have better chances of being selected. Only destinations that can demonstrate long-term vision, commitment, and strong strategic objectives will be able to take advantage of the emerging ICT and DMS opportunities to strengthen their competitiveness.

## KEY TERMS

**E-Tourism:** The digitisation of the tourism iIndustry.

**DMS:** Systems that incorporate the entire range of tourism provision for a region.

**Infostructure:** All kinds of ICTs that provide the infrastructure for organisations to operate.

**Extranet:** Private network that is only accessible by trusted business partners using secured connections over on the Internet.

**Intranet:** Internal communication (LAN or WAN) network, using Internet type of interfaces accessibility only by authorised employees and protected by the company's firewall.

# E-Transformations of Societies

**Lech W. Zacher**
*Leon Kozminski Academy of Entrepreneurship and Management, Poland*

## INTRODUCTION

Not all transformations of societies are caused by technology or are technology-driven. However, it is evident that technology is an important driving force of societal changes. To state that technology—both contemporarily and historically—largely shapes the form of societies does not necessarily mean the acceptance of technological determinism (as the philosophical approach). It can be viewed just as a statement concerning the hard facts.

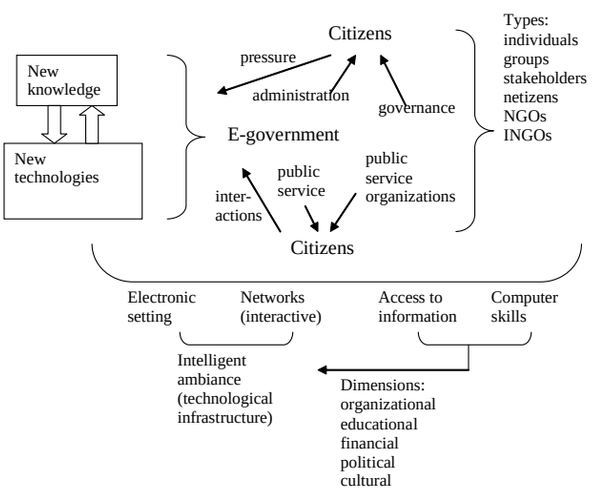
In the 20th century the rapid development of technology marked a new era. In order to describe and interpret this situation several new terms have been coined, as well as concepts and theories. Usually they underline the revolutionary character of technological change. In 1939, Bernal coined the term "scientific and technological revolution", which meant the joint effects of revolutions in science and in technology and their feedbacks. More than two decades later Kuhn (1962) developed and popularized his paradigmatic view of science and its revolutionary breakthroughs. It is needless to add that there are close—and to great extent causal—relations between science and technology.

As a result of thinking in terms of scientific and technological revolutions or paradigms there was a tendency to use them in the theory of social change. In the late 1960s and 1970s some attempts were made within the Marxist theoretical orientation (Feenberg, 1991) to create an overarching theory of scientific and technological revolution including social change (e.g., Richta—see Zacher, 1995). Western theoreticians, having more experience with high tech and its practical impacts, were describing them using somewhat different nomenclature Ackoff (1974), Brzezinski (1970), and Masuda (1981) preferred cybernetic revolution, the Age of Systems, the Information Era, the Technetronic Era, the electronics revolution (also called the microelectronics or microprocessor revolution), the computer revolution, the information revolution, and the like (Friedrichs & Schaff, 1982; Forester, 1984). With reference to science and technology such terms as *materials revolution* and *biological* (or *biotechnological*) revolution were also in use. Somewhat later a new term arrived, *Internet revolution*.

## BACKGROUND ON METHODOLIGICAL APPROACH TO E-TRANSFORMATIONAL DISCOURSE

E-transformation of anything (civilization, economy, society, government, democracy, world, etc.) refers literally to electronics as a scientific discipline, technologies, industries, and their multifaceted impacts. Thus, this reference marks out the period of time when electronics appeared, was developed and used *de facto* in all spheres and sectors of human activity and life. So electronics became the basic technology of our time. That is why it is possible to use its name as a label for a civilization, an era, a revolution, societies, a world, etc. Also, electronics can be used metaphorically as a name tag when we speak of the information sector, high tech, ICTs, media, computers, networks, future forms of societal organization or disintegration like e-herd, intelligent mobs, human swarm, human aggregations, posthuman mixed teams, and so forth. Of course, one can assume that knowledge potential-building under any form of human organization (also individual, group, societal, global) will be to a great extent electronically aided. So e-transformations should be debated in a broad context and in a broad sense. A general conceptual model is presented in Figure 1.

*Figure 1. E-transformations in the context of e-government: A conceptual model*



## Naming Civilizations and Societies

To the aforementioned terms some sociopolitical, in contrast to civilizational, dimensions were assigned. The new names characterizing the emerging nature of advanced societies were coined, for example, *cybernetic society*, *information society*, *computer society*, *telematic society*, and also *bio-society* and *bio-info-society*. It is worth adding that at the same time as some prominent authors wrote about scientific and technological civilization on information civilization, such terms as *postindustrial era* and society, *postindustrialism,* and the *Third Wave* were popularized widely by Bell (1976) and Toffler (1981, 1990, 1995).

Interestingly in the sphere of *ideology* there were some attempts in the former Communist Soviet Union and Eastern Europe to introduce such new terms as *developed socialism*, which became bankrupt in the meantime, in turn. In the West, some terms emerged like *post-capitalist society* (Drucker, 1993), and also in the longer term perspective, *posthuman society*. There were also texts on the postmarket era, on the postmaterial era, and on the postintellectual era. There were also some "end-isms", for example, Fukuyama's (1992) the *End of History*.

Of course some of these notions or concepts were merely fashionable expressions or spectacular slogans in media debates. However, in many ways their abundance reflected the actual or expected phenomena, as well as new social forms and deep transformations.

It is possible to gather the new features and differences of civilizations and societies and to relate them to the dominant type of knowledge and type of research (discipline).

*Table 1. Types of civilizations vs. types of knowledge/ research*

| Type of civilization | Main type of knowledge/research (discipline) |
|---|---|
| Technological<br>(or scientific and technological civilization) | Scientific and technological knowledge<br>Basic research<br>nuclear physics, new engineering, new materials, computer engineering |
| Post-industrialism | techno-service<br>services<br>new organization |
| Technetronic era | electronics<br>new weapons |
| Information civilization<br>(Information Era) | information theory<br>informatics<br>Web theory<br>network analysis |
| Third Wave Civilization | forecasting<br>future studies<br>foresight |
| Systems Age | systems theory<br>cybernetics<br>complexity theory |
| Computer Age | computer science<br>modeling<br>simulations |
| Postmodernism<br>(Postmodernist Era) | catastrophes theory<br>risk theory<br>chaos theory<br>chaotics analysis |
| Posthumanism<br>(Posthuman Era) | artificial intelligence<br>robotization<br>cyborgization<br>genetic engineering<br>new ethics |

This typology of civilizations or eras only considers the examples most frequently appearing in recent decades. Many names can be assigned to them like Bernal (1939), Richta (1971), Ackoff (1974), Bell (2001), Toffler (1981, 1990, 1995), Brzezinski (1970), McLuhan (1964), Dizard (1982), Castells (2001), Masuda (1981), Negroponte (1996), Dertouzos (1998), and Lyotard (1986). However our assessment is made from a current perspective and is somewhat arbitrary.

What is common or characteristic in this typology? It seems that in spite of the significant diversity of characteristic features there are rather evident references to knowledge, to its growth stimulated by scientific discoveries and new breakthrough technologies, and to new theoretical approaches (or even *Weltanschauung*) to the growing "artificialization" of man. So altogether it is the growth and accumulation of knowledge and its ever new, radical, and wide applications accompanied by progressive human inventions, skills, and competencies which count here. All this was linked, at least from a certain moment, not only to human "cognitive hunger" but also to profit making and the consumption drive. Anyway, a cybernetic model of learning could probably be the most appropriate way to reflect this situation. Of course, the prospective orientation is immanently built into the model.

Knowledge was the foundation of practically every stage or period of civilizational development. At the beginning it was nonscientific knowledge, then, scientific or science-based knowledge. Of course, its level, its growth, its ways and the methods of its "production", proportions of its types, diversity of its fields and ways and speed of its utilization and its management have impacted the pace and type of progress throughout the history of mankind.

Historically, the shaping of people's consciousness had a revolutionary character in which the role and significance of science in development, apart from such things as magic, imagination, fate, the invisible hand of the market, randomness, chaos, as well as the possibility of active building of knowledge potential were immanent and fundamental. Human proactivity in building such a potential is expressed in the creation of knowledge *per se*, in inventing new ways of doing things, in imaginatively applying it, finally, in managing it to the extent which is possible and reasonable (Halal, 1998; Hodgson, 2000). The process of knowledge potential building is performed at all levels of governance, politics, and management; and all actors, government, business, and civil society should be involved. Moreover this process is more and more transnational, international, and global. The result is global knowledge potential, unequally contributed and unequally utilized by nations. However a positive understanding of the role of science and research is not common everywhere. It is dominant in the highly advanced coun-

*Table 2. Types of contemporary societies (according to various criteria)*

| Frequently used names (with reference to the main characteristics) | O – old (past)<br>P – present<br>E – emerging<br>F – future |

tries. It is growing in some Asian "tigers", it is usually underestimated in the transition economies, and rather meaningless in the case of LDCs (sometimes with the exception of the military sector). Such a situation creates an even more differentiated world in spite of the possibility of creating a global knowledge society (Zacher, 2000). Technological progress alone will probably not be able to change this situation though it has given names to the present and future societies (see Table 2).

Table 2 is arbitrarily constructed. There could be no other way since the terms listed in the table were often used by their inventors as fuzzy notions, not precise or not defined. These terms are not fully comparable; some could be amalgamated; some just illustrate complementary characteristics; some are accenting just one feature which does not mean that the others are automatically excluded. Moreover several names were quite old. They were visionary; only now do they have real designates (some still do not). The assessment of what is present, emerging, or future is also arbitrary. Anyway, the list shows the intellectual efforts connected not only with research, but also documents imagination and intuition, especially in the case of the names of the societal forms emerging or predicting into the future (Bugliarello, 1997; Castells, 2001; Hiltz & Turoff, 1978; May, 2002; McLuhan, 1964; Muraszkiewicz, 2004; Rheingold, 1993, 2002).

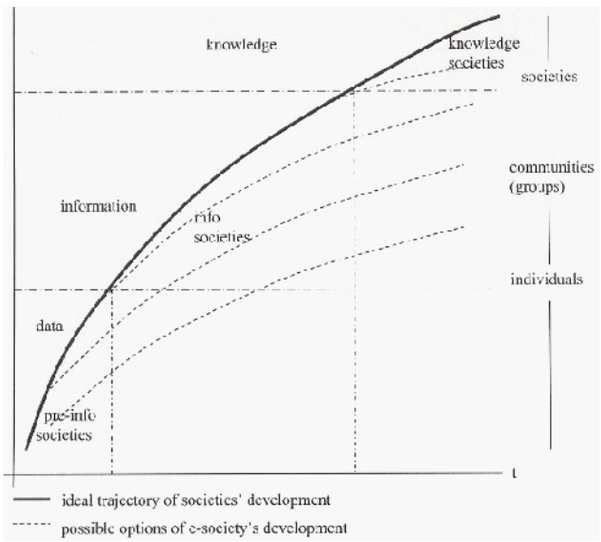
## FUTURE TRENDS:A LONG TERM VIEW

In spite of the variety of criteria determining the names of the types of societies, it seems quite evident that very often these names, directly or indirectly, refer to technology and knowledge, a type, a transforming capacity, to impacts of its applications and to the ways and methods of its production. Knowledge society is emerging as a result of the building up and accumulation of the social potential of knowledge. Of course, the growth of knowledge does not automatically generate widespread wisdom, which is obviously desirable. Moreover, the growth of knowledge alone, often treated by business as merely an information resource, can be accompanied by advances in social disintegration, exclusion, or conflicts which may negatively distort our lives and dreams. What is needed is reflexivity, a precautionary approach, learning, human-oriented axiology, trust (Zacher, 2001) and culture (Bell, 2001; Harrison & Huntington, 2000), all that can clear the way for a society of knowledge and wisdom, which is of course an ideal type. What is needed to approach this ideal is, hopefully, democracy. Democracy's possible forms should be investigated and discussed (Barney, 2000; Ester & Vinken, 2003; Katz, 1997; Keane, 2004).

In the future human relations and social life will be e-transformed. The terms used in this context are *smart machine* (Zubov, 1988), *networks* (Dertouzos, 1998; Wellman & Haythornthwaite, 2002), *being digital* (Negroponte, 1996), *digital children* (Rushkoff, 1999), and so on. There is also the very imaginative perspective of the Posthuman Era (Featherstone, 2000). How much different a techno-creature of the future will be from the traditional technological man (Ellul, 1964).

However, more long term and radical visions of social change often predict a kind of disintegrative transformation connected with many technological, socioeconomic, and political trends (like "overtechnicalization" and mass networking, McDonaldization, overindividualization, conflicting globalization, and so forth (Beck & Beck-Gernsheim, 2001; Bryman, 2004; Ritzer, 2000; Wellman, 1999, 2001).

*Figure 2. Hypothetical development of human societies and organizations: A long-term view*



The most probable future situations, which will be differentiated, are shown in Figure 2.

## CONCLUSION

Many differences in terms, definitions, ideas, and concepts of present and future organizations of humanity and its segments are due to various perceptions and interpretations of man–technology relations (Talbott, 1999; Zubov, 1988). There are at least three approaches:

- Technology meets human needs, men adapt to new technologies. Technology is just instrumental, somewhat autonomous, can be controlled a little and slightly humanized.
- Technology drives everything and predominantly determines the shape of society, economy, culture, and so forth, other factors being less influential and important. This is technological determinism based on the concepts technological fix, technological optimism, techno-culture, technocracy, for example.
- Co-evolution of man (society) and technology. This means mutual support, not determination and feedbacks; additionally, there are processes of internalization of technology (machine) in man, and sometimes human values are embedded in design of technologies. Such co-evolution will be expressed in rather consistent sociotechnological systems and objects leading to a posthuman era in which "mixed teams" may emerge as the result of artificialization of man and of human input, that is, intelligence into technology.

These three approaches are not mutually exclusive. They underline the power of technology and science, which, though not fully overwhelming, can be linked to human creativity which may contribute positively to the future course of this co-evolution.

Anyway, the further e-transformations of societies and their forms should be investigated from the point of view of changes of technology, that is, nanotechnology and bio-materials; societal developments, such as ageing, structures, and social values; and the interaction of what is technological with what is social and human. Methodologies and approaches should be systemic, holistic, complex, future-oriented, multi-, inter-, and transdisciplinary. Such theories like the chaos theory and the Web theory can be recommended as well.

It would be also worthwhile to refer to some older ideas and concepts such as social assessment of technology (Coates et al., 2000; Grin & Grunwald, 2000), appropriate technology (Schumacher, 1975), STS studies (Webster, 1991), technology-organization studies (Katsikides, 1994; Scarbrough & Corbett, 1999), high tech-high touch (Naisbitt et al., 1999), technology-environment-sustainable development (Jamison & Rohracher, 2002), and so forth. It seems that many of them can be successfully reinvented and reused. This can be done by adding some new dimensions and characteristics like informatization, networking, digitalization, globalization, and such.

A comprehensive vision of e-future ought to be completed with at least three additional—not discussed in this article—important problems: the future of capitalism, often called global, technological, information, digital (Davis et al., 1997; Hutton & Giddens, 2000; Rifkin, 2000; Schiller, 1999; Soros, 1998), the future of globalization, and the future of civilization (esp. Toffler, 1981, 1990, 1995). How to integrate all the problems mentioned into certain e-world, e-society, and e-future is the question.

## KEY TERMS

**E-Galaxies of Knowledgeable Individuals (or Groups):** Functioning in intelligent ambiance and in the Net (traditional social links, state organizations, social structures, traditional values not as important as before but subjugated to individualism, global relations, particular goals).

**E-Transformations of Societies:** All social changes driven by electronic devices and systems used in literally all areas of human activity and life (including e-economy, e-banking, e-trade, e-media, e-government, e-learning, e-democracy, e-everything).

**Forms of Human Organizations (from the point of view of ICTs):** Pre-informational societies; information societies; and post-information societies (knowledge societies and other forms: e-herd, smart mobs, human collectivities, amalgamations and aggregations, posthuman mixed teams, and so forth).

There are many definitions—both qualitative and quantitative—and controversies on the characteristics of info and knowledge societies. What has been termed other forms of human organizations in the long term perspective do not have really good definitions. More-

over the present e-government concept may not apply to them. Their imaginative features are *de facto* explanatory and visionary, intuitive, sometimes normative. For instance, e-herd can be imagined as human herds in an electronic setting, having many contacts, no traditional (social) links, performing according to the psychology of crowd principles, and can be controlled by an e-shepherd in a manipulative and authoritarian way.

**Mixed Teams:** Made of men, also cyborgized, robots, artificial intelligence, and the like, organized to fulfill certain functions or implement certain strategies to obtain goals.

**Smart Mobs:** A form of organization of cell phone users; everybody is a broadcaster, *de facto* beyond control of any power; human crowds of such kind resemble a swarm; they can function globally, eventually heading for shared goals.

**Wisdom Society:** Can be an e-society, post-informational, knowledge-based, cognitively-oriented, also reflexive, cautious (to impacts of decisions, technologies, regulations), applying knowledge to social choices; but can be democratic (anticipatory and participatory democracy, electronically supported) or conversely autocratic (technocracy, meritocracy).

# The European Commission's E-Government Initiatives and Public Participation

**Christian Hunold**
*Drexel University, USA*

## INTRODUCTION

According to the European Commission (2003), increased networking of local, regional, and national administrations across the European Union (EU) is creating "a more integrated 'European public space' for EU citizens and businesses" (p. 6). This emerging public space owes its existence chiefly to improvements in information and communication technology (ICT). The Commission (2002) believes that e-government initiatives will help to build a more robust European public space capable of engendering in the public's mind a sense of democratic ownership of European institutions and policies: "E-government is helping to establish a more open, inclusive and productive public sector, in line with good governance" (p. 7). E-government as defined by the Commission (2005) as "the use of information and communication technologies, combined with organisational change and new skills, to improve public services, increase democratic participation and enhance public policy making."

Echoing the literature on e-democracy (Gibson, Rommele, & Ward, 2004), the Commission (2002) contends that e-government can improve EU democratic processes and public support for EU policies in two ways: by giving citizens greater access to information from authorities, which empowers citizens by improving the transparency and accountability of European institutions; and by fostering direct communication between citizens and policy makers, which enables improved mutual accommodation of needs and interests. This article analyzes Commission e-government initiatives, with special emphasis on the Consultation, the European Commission and Civil Society (CONECCS) directory, the interactive policy making (IPM) initiative, and the i2010: European Information Society 2010 initiative. IPM seeks to enable the Commission to collect feedback directly from citizens, consumers, and businesses via a single Internet access point for consultations (Your Voice in Europe). i2010 is a five-year strategy launched in 2005 to boost Europe's digital economy and includes proposals to enhance e-participation in Europe's emerging public space. Such proposals, I argue, will be more likely to succeed if the Commission were to move from managerial and consultative to participatory models of public involvement (Chadwick & May, 2003).

## BACKGROUND

Interest group involvement in shaping Commission decisions is common and largely routine. Interest group participation can make the difference between the Commission's success and failure in the policy process (Greenwood, 1997); public consultations build cooperation around and support for its proposals and policies (Bellier, 1997). Cultivating close relationships with interest groups helps the Commission gather valuable expertise, though involving a wide range of nongovernmental groups and interests in deliberations about new policy initiatives may also help the Commission avoid obstruction by national governments (Christiansen, 1996). As Schmitter (2000) notes, however, opportunities for access to European interest representation are far from equal: "While all this pluralism (to use the American expression) is entirely appropriate in a modem democracy, its highly skewed nature does raise some questions about whether these channels for the expression of particular intensities are freely and fairly available to all citizens of Europe. So far, the evidence suggests a mobilization of bias in favor of business interests" (p. 81). Also concerned about too much backroom dealing with privileged interest groups, Watson and Shackleton (2003) call for "a more open policy debate in which more voices are heard by EU policymakers" (p. 106).

The Commission is increasingly sensitive to these concerns. The Prodi Commission's 2001 *White Paper on European Governance* acknowledged the Commission's duty to broaden public involvement in its policy deliberations. From the Commission's perspective the problem was not that European citizens did not speak up, but that they often did so in ways the Commission could not easily understand or integrate into policy decisions. Europe's unruly public sphere often failed to produce the sort of policy-relevant communication the Commission saw as essential to make Brussels less remote to European citizens. ICTs took center stage in subsequent proposals to

create a "reinforced culture of consultation and dialogue" with civil society organizations (European Commission, 2002). Moving consultations online, the Commission hoped, would improve their transparency and lower barriers to access for groups new to the European policy arena. Since taking office in late 2004, the Barroso Commission has expanded on these efforts by unleashing a slew of new e-government initiatives seen as critical to reviving Europe's economy and furthering European citizenship. According to Commissioner for Information Society and Media Viviane Reding (2004), "Information technologies encourage participation, facilitate access to information and offer new ways of learning and communicating." As well as meeting public demand for participation in European policy making, the Commission views enhancing e-government and, more broadly, nurturing a European information society, as important factors in their own right in promoting economic growth across the European Union.

## THE EUROPEAN COMMISSION'S E-GOVERNMENT INITIATIVES

### Consultation, the European Commission, and Civil Society

CONECCS (Consultation, the European Commission and Civil Society) is an online directory of the Commission's formal civil society consultative bodies and of civil society organizations representing a wide range of groups and interests. CONECCS can be accessed via the Commission's civil society Web site, which provides information on the Commission's dialogue and consultations with civil society. On December 2, 2005, the directory listed 738 organizations, including "third-sector" nongovernmental organizations (NGOs) as well as business federations, labor unions, and associations of governmental authorities. Registration in CONECCS is voluntary and does not confer accreditation on groups (http://europa.eu.int/comm/civil_society/coneccs/index_en.htm). The Commission hopes CONECCS will improve the openness and accountability of its policy deliberations and decisions. The directory is part of the Commission's efforts to convey to the public what issues are being developed, what mechanisms are being used to consult, who is being consulted and why, and what has influenced decisions in the formulation of policy.

Organizations wishing to participate in Commission consultations must provide the Commission and the public at large with basic information about themselves, preferably via CONECCS. As participation in CONECCS is voluntary, however, groups may provide this information in other ways, such as "special information sheets" (European Commission, 2002). As a practical matter, though, CONECCS is fairly inclusive; organizations may be searched for alphabetically or by policy area, which provides interested citizens with a convenient means of identifying and contacting civil society organizations that participate in a wide range of EU policy consultations. Technological convenience alone, however, will not solve the underlying problem for enhancing public participation and inclusion, namely that European-level associations do not play a significant role in the lives of most Europeans. Initiatives such as CONECCS are a start, but they cannot conjure by themselves a European public space where there may not be enough European-level public engagement to begin with.

### Interactive Policy Making

The interactive policy making (IPM) initiative consists of two online instruments that enable the Commission to gather feedback directly from citizens, consumers, and businesses in order to better understand how they perceive Commission policies and to learn from their experience, with a view to shaping new policies and improving existing ones (European Commission, 2005a). Both instruments are available via the Your Voice in Europe Web portal, which was developed in the context of IPM and is the Commission's single access point for consultations.

A *feedback mechanism* helps the Commission collect information from citizens and businesses about their daily problems relating to different EU policies. About 300 intermediaries, such as Euro Info Centers and European Consumers Centers located across the EU, candidate countries, and European Free Trade Area countries, collect everyday problems and record them in the Commission's feedback database. This listening device allows for a constant monitoring of the application of existing legislation and provides concrete input for new policy initiatives. The Commission claims that thousands of cases are collected annually, providing several Directorate Generals with input for policy making (European Commission, 2005a).

An *online consultation mechanism* involves structured questionnaires, which citizens may answer on the Internet in order to provide the Commission with feedback on particular policy issues. As this mechanism can handle structured questions in several languages and deliver the output in the desired language, the Commission should be able to act on citizens' opinions and views more quickly and effectively than in the days of paper-based consultations. For example, a consultation in preparation for the Community Action Plan on Animal Welfare and Protection (closing date December 11, 2005) involved an 18-point questionnaire soliciting responses to various ani-

mal welfare topics. The survey covered key issues of animal welfare in food production, distribution, and consumption; however, there was no provision for submitting open-ended answers or for raising issues omitted from the questionnaire. By contrast, the Your Voice on eGovernment consultation (closing date December 4, 2005) did include a field for open-ended comments up to 450 characters. This implies that online tools like IPM have the technical capability to accommodate forms of public involvement that are more deliberative than filling out a questionnaire. Whether or not a given consultation solicits such contributions from the public therefore depends less on technological constraints than on practical judgments by Commission officials seeking to balance demands for participation and efficiency. Reading, sorting, and absorbing into policy initiatives contributions from the public requires time and money—resources often in short supply in busy public bureaucracies.

### i2010

i2005 is a 5-year initiative to boost the digital economy, identified by the Commission as Europe's most promising sector, accounting for 40% of EU productivity growth and 25% of EU GDP growth. The Commission (2005b) has outlined three policy priorities for i2010:

- Creating an open and competitive single market for information society and media services within the EU;
- Increasing investment in research on ICTs by 80%; and
- Promoting an inclusive European information society.

Concerning the last point—e-inclusion—the Commission is working on several proposals aimed at closing the digital divide: an Action Plan on eGovernment for citizen-centered services (2006); three "quality of life" ICT flagship initiatives (technologies for an aging society; intelligent vehicles that are smarter, safer, and cleaner, and digital libraries making multimedia and multilingual European culture available to all (2007); and actions to overcome the geographic and social "digital divide," culminating in a European initiative on e-inclusion (2008). It is noteworthy that these policy initiatives operate with a sophisticated understanding of what is causing the digital divide. The concept of a geographic digital divide refers to disadvantaged rural areas with little access to ICT. The concept of a social digital divide recognizes that access to ICT declines with socioeconomic status, but that providing for access alone does not create the means for all citizens to use ICTs competently. The Commission's e-inclusion initiatives, therefore, aim to spread the benefits of the information society to all segments of the population, including people who are disadvantaged due to limited resources or education, age, gender, or ethnicity; people with disabilities; and those living in poor areas. The Commission (2005c) has issued a Communication on eAccessibility aimed at promoting a consistent approach to e-accessibility initiatives in the member states on a voluntary basis to foster industry self-regulation. Further, EU-level information on e-inclusion and e-accessibility can be accessed via a single Web site on the Europe's Information Society Thematic Portal (http://europa.eu.int/information_society/policy/accessibility/index_en.htm). In November 2005, Commissioner Reding described the Commission's aspirations for e-government in Europe: "Full e-government means measurably more efficient, effective, inclusive and open government for all citizens and in all areas of administration and democracy. Today's online availability is just the first step."

## FROM MANAGERIAL AND CONSULTATIVE TO PARTICIPATORY MODELS OF PUBLIC INVOLVEMENT?

This section considers whether the initiatives discussed above are likely to lead to participatory forms of e-government becoming the norm. Chadwick and May (2003) differentiate between managerial, consultative, and participatory models of government-citizen interaction in e-government. At the least participatory end of their conceptual spectrum, the managerial model emphasizes using ICT to improve service delivery to citizens and businesses conceived of as "users" and "customers." The consultative model shares this basic outlook, but seeks feedback from (mainly business) interest groups to improve the technical accuracy of policies. Only the participatory model promotes democratic deliberation within civil society alongside government-citizen interactions. Each model favors its own style of information flow. Managerialism visualizes information as traveling along a one-way street from government to citizens; information under consultative auspices flows up and down a limited-access highway; the participatory model, in contrast, encourages a freewheeling, discursive flow of information: citizens to citizens, citizens to government, government to citizens (Chadwick & May, 2003). Although these models may overlap in practice, only the participatory model explicitly grants citizens a significant deliberative role in policy making; its defining logic is to politicize policy disputes through deliberation and participation. The Commission's various e-government

initiatives hailing e-participation, e-inclusion, and e-accessibility may signal some willingness to move in this direction.

Early analyses of the Prodi Commission's participatory intentions as outlined in the *White Paper on European Governance* (European Commission, 2001) were skeptical. President Prodi (2001) emphasized the need to impose order on Europe's "cacophonous" public sphere before the Commission could interact more productively with citizens. Armstrong (2002) reckoned the Commission would seek out those European civil society organizations that, in return for participation in policy making, would moderate their demands to fit the Commission's policy agenda. Warleigh (2001) was concerned that the Commission's stated preference for interacting with civil society associations organized at European level would undermine its commitment to an ostensibly broad conception of civil society because Euro-associations play such a miniscule role in Europeans' associational lives. And Magnette (2001) concluded that narrowly structured forms of engagement would dominate policy making, with policies initiated and controlled by the Commission. These assessments foresaw no radical departure from the Commission's adherence to managerial and consultative practices of public involvement wherein efficient service delivery to customers trumped efforts to facilitate meaningful participation in policymaking by citizens. During the 1990s neoliberal policy discourses in Western Europe had emphasized the role of citizens as taxpayers and customers rather than participants in politics, and e-government initiatives largely reproduced this emphasis (Chadwick & May, 2003.) Why should the European Commission prove exceptional in this regard?

Any public bureaucracy, moreover, faces trade-offs between demands for greater participation and demands for greater efficiency. The Commission is aware of this dilemma. Commissioner Reding (2005) has characterized it this way: "European citizens demand better services, better democracy. Europe's businesses demand less bureaucracy, more efficiency." The Commission's proposed solution is to frame e-government as the answer to overcoming this sort of trade-off—citizens and businesses both get what they want. This solution may fall short, however, as perfecting the technological interfaces between political institutions and the public alone cannot prevent that, when push comes to shove in pluralist systems of interest representation like the EU's, public bureaucracies often side with businesses not citizens. The defeat in 2005 of the European Constitution, however, has reminded European-level policy makers that ignoring the voices of Europe's citizens for too long does not promote European integration in the long run. The European Commission has dramatically improved both the quantity and the quality of its e-government services in the past five years. It remains to be seen whether Europe's citizens and civil society organizations seize on these opportunities with a view to steering the Commission away from old-style managerial and consultative toward new-style participatory practices and approaches.

## CONCLUSION

Present-day EU-level e-government initiatives show an awareness of social and economic barriers to e-participation, e-inclusion, and e-accessibility that is far more sophisticated than earlier e-government initiatives narrowly focused on providing information and delivering services to citizens as customers. In one sense this evolution simply reflects a growing body of experience with e-government across the European Union; there has been a steep learning curve associated with e-government everywhere. But the e-government tools being deployed by the Commission today really *are* more interactive and thus perhaps more promising than their predecessors. Deploying online technologies, however, is the easy part. A more difficult challenge for policy makers wishing to make e-government more useful to Europe's citizens will be to identify ways of creating a more meaningful European public space in which Europe's citizens feel politically and emotionally invested.

# European Politics of Regulating Digital Convergence

**Xiudian Dai**
*University of Hull, UK*

## INTRODUCTION

The European politics of digital convergence has been an important topic for public debate since the early 1990s, when the forces of the digital revolution began to clash with the complicated system of regulation established in the "analogue age" regarding the media and communications sector.

When the Maastricht Treaty was signed in the early 1990s, the issue of communications infrastructure was incorporated into the law of the European Union (EU) for the first time in the Union's history. The Maastricht Treaty stipulates that the EU should develop a Trans-European Network of Telecommunications (TEN-Telecom), which supports network inter-connectivity and service inter-operability (Dai, 2000). The Delors White Paper on *Growth, Competitiveness, and Employment* envisions the downing of a multimedia age and calls for the creation of a "common information area" (European Commission, 1993). Shortly after the publication of the Delors White Paper, the Bangemann Report delivered a strong message to the European Council in Corfu that the EU's regulatory framework would have to be reformed in order to take on the challenges brought by new information and communications technologies (ICTs), which are generating a new industrial revolution (Bangemann et al., 1994). The release of the Delors White Paper and the Bangemann Report heralded the creation of a new policy area—the European Information Society, in which EU institutions, in particular the European Commission, have been playing a significant role up until now. Meanwhile, although the issue of regulatory challenges posed by the multimedia revolution or digital convergence was highlighted in the early 1990s by the European Commission, there was surely a lack of detailed proposal for reforming the EU's regulatory structure for ICTs.

European Regulatory reform in the information and communications technology sector gained further momentum during the second half of the 1990s. In December 1997, the European Commission published its Green Paper on convergence, which argues that "getting the regulatory framework right is of crucial importance" (European Commission, 1997, p. iv). To assist public debate, this Green Paper identifies a range of options and poses specific questions with regard to the implications of digital convergence for regulatory reform in Europe. In the 1999 Communications Review, the European Commission provides a systematic analysis about the *status quo* of regulation on the information and communications technology and suggests a comprehensive plan for the overhaul of regulatory structure.

The early years of the 21st century witnessed the official launch by the European Union of a New Regulatory Framework, drawing an end to the old regulatory structure belonging to the "analogue age." The New Regulatory Framework provides a fundamentally different package of regulation over the information and communications technology sector with a focus on the challenges posed by digital convergence.

The purpose of this article is to analyse the implications of digital convergence for regulatory and institutional changes in the European Union. Accordingly, it is the European policy and political responses to the regulatory issues raised by digital convergence that constitute the main focus for the discussions presented in this article. It is argued that, whilst major progresses have been achieved at the EU level since the 1990s in regulatory reform, there are still critical issues remaining to be resolved in relation to the regulation of digital convergence. More specifically, despite that the EU has now managed to move away from technology-specific regulation to technology-neutral regulation, the failure to establish a single European Regulatory Authority (ERA) will continue to create institutional barriers to achieving more effective and efficient regulation over digital convergence.

## BACKGROUND

The concept of digital convergence is closely related to digitisation, which is essentially a process of converting analogue forms of information (or contents) and communication into digital or binary codes (ones and zeros) that could be read and processed by computers. The fact that digitised films, television programmes, internet traffic as well as voice telephony can be transmitted over a conventional telephone line with the help of ADSL (asymmetrical

digital subscriber line) technology serves as a specific example of digital convergence.

The European Commission defines the term digital convergence in two senses: (1) the ability of different network platforms to carry essentially similar kinds of services and (2) the coming together of consumer devices such as the telephone, television and personal computer (European Commission, 1997, p. 1). In addition to these two aspects there is a third dimension to the definition of digital convergence in a European context: the emergence of a single information and communications space, in which national and institutional boundaries are not compatible with the seamless (or converged) flow of digital information and services.

The International Telecommunications Union (ITU) sees the process of convergence through digitisation as leading to the emergence of a machine language common to all in the information age: "The common language of the new Information Age is not a human language but a machine language: the zeros and ones, highs and lows, ons and offs of binary code" (1999, p. 5). Some argue that digital technologies are poised to generate revolutionary changes in social, economic, and political life of all societies across the world (Castells, 1996). Although the changes that the information and communications technology sector is going from analogue to digital are not rocket science, "they are not as widely recognised or understood" (Currie & Carter, 2004).

The link between digital convergence and regulatory reform lies in the fact "that existing rules were defined for a national, analogue and mono-media environment, but that services increasingly cut across different traditional sectors and geographical boundaries, and that they may be provided over a variety of platforms" (European Commission, 1997, p. iii). This, in the view of the European Commission, "calls into question the underlying rationale beneath regulatory approaches in the different sectors affected by convergence" (*Ibid*.). Levy (1999) argues that digital convergence undermines not only the rationale for but also the feasibility of most nationally based regulation. Martin Bangemann, former European Commissioner charged with responsibility for telecommunications and enterprise in the 1990s, argued that "the world [as well as Europe] needs to establish a new set of rules adapted to the capabilities of new technologies" (cited in Aragón, Grewlich, & Pietrantonio, 1999).

## DIGITAL CONVERGENCE AND EUROPEAN REGULATION

In order to bridge the gap between the existing regulatory structure in the EU and the digital age, the Bangemann Report identifies two directions of regulatory reform that are necessary within the EU: (1) the creation of a single regulatory framework to cover all areas of the information and communications technology sector; (2) the migration of communications regulation from the national level to the EU level (Bangemann et al., 1994). While the EU has been successful in regulatory reform along the first direction (i.e., the change from technology—specific to general issue or technology—neutral regulation), the call for the migration of regulatory authority from the member state level to the EU level has met with considerable resistance and, hence, became an aborted plan.

### A Single Regulatory Framework

Most pieces of EU Directives passed in the 1990s, as shown in Table 1, are concerned with specific areas of information and communications technologies. For example, regulation for television broadcasting standards differed from that for telecommunications; cable networks were regulated separately from satellite networks and mobile communications regulations had nothing to do with fixed line telecommunications and so forth.

The old regulatory method for electronic media and communications was basically in a response mode to technical innovations—the launch of a new platform of electronic communication would be followed by a new piece of EU legislation (or multiple pieces of legislations). Therefore, EU regulation for information and communications technologies during the era prior to the 1999 Communications Review was in most cases a step behind technical change. It is also true that, under the old regime of regulation, technical change and innovation quite often made specific regulations obsolete.

As proposed in the 1999 Communications Review, the long list of old directives would be simplified and consolidated into fewer pieces of general issue oriented regulation—with each Directive horizontally governing all technology areas.

On the basis of the European Commission's 1999 Communications Review, the European Parliament and the Council of Ministers approved the overhaul of the technology-specific regulations and introduced a new communications regulatory framework (see European Parliament and the Council of Ministers, 2002). The new communications regulatory framework, now issue-orientated, comprises five pieces of legislation (i.e., the Framework Directive, Authorisation Directive, Access Directive, Universal Service Directive, and the Directive on Privacy and Electronic Communications) (see Table 1 for details). The new communications regulatory framework represents the single most important reform within the EU

*Table 1. EU regulation: Technology-specific vs. technology-neutral*

|---|---|
| • Satellite (94/46/EC)<br>• Cable (95/51/EC)<br>• Mobile (96/2/EC)<br>• Cable Ownership (99/64/EC)<br>• GSM Directive (87/372/EEC)<br>• ERMES Directive (90/544/EC)<br>• DECT Directive (91/287/EEC)<br>• S-PCS Decision (710/97/EC)<br>• UMTS Decision (128/99/EC)<br>• TV Standards Directive (95/47/EC)<br>• Voice Telephony Directive (98/10/EC)<br>• Telecoms Data Protection Directive (97/66/EC)<br>• European Emergency Number Decision (91/396/EEC)<br>• International Access Code Decision (92/264/EEC)<br>• ONP Leased Lines Directive (92/44/EEC amended by 97/51/EC)<br>• Service Directive (90/388/EEC)<br>• Full Competition (96/19/EC)<br>• ONP Framework Directive (90/387/EEC amended by 97/51/EC)<br>• Licensing Directive (97/13/EC)<br>• Interconnection Directive (97/33/EC amended by 98/61/EC) | • **Framework Directive** (Directive 2002/21/EC on a common regulatory framework for electronic communications networks and services)<br>• **Authorisation Directive (**Directive 2002/20/EC on the authorisation of electronic communications networks and services)<br>• **Access Directive** (Directive 2002/19/EC on access to, and interconnection of, electronic communications networks and associated facilities)<br>• **Universal Service Directive** (Directive 2002/22/EC on universal service and users' rights relating to electronic communications networks and services)<br>• **Directive on Privacy and Electronic Communications** (Directive 2002/58/EC concerning the processing of personal data and the protection of privacy in the electronic communications sector) |

regarding the regulation of information and communications technologies.

The key issues on which the new communications regulatory framework is focused, such as authorisation of network and service provision, access/interconnectivity, universal service provision, and personal data and privacy protection, are common to all forms of digital communications. The identification and stipulations over these general or horizontal issues in the new regulatory framework help provide both the industry and individual consumers with a more future-proof legal environment, which is more in tune with the age of digital convergence.

## A Single Regulatory Authority?

The EU authorities, in particular the European Commission, are credited with their efforts in pushing through the adoption of the new regulatory framework, which manifests the impact of convergence in information and communications technologies. However, there are still important issues worth bearing in mind. Chiefly among others, the controversy over institutional reform to take into account the fact that digital convergence has become a community-wide phenomenon has not been resolved in a way that European policy makers initially anticipated in the early 1990s.

The initial recommendation of the Bangemann Report was "the establishment at the European level of an authority whose terms of reference will require a prompt attention" (Bangemann et al., 1994, p. 13). This "authority" has been subsequently referred to as the single European Regulatory Authority (ERA). Moreover, the Bangemann Report recommends that the single ERA will need to address "the regulation of those operations which, because of their community-wide nature, need to be addressed at the European level, such as licensing, network interconnection when and where necessary, management of shared scarce resources" (Bangemann et al., 1994, p. 13).

However, largely due to the pressure from the member state level, the European Commission decided not to pursue its original idea of establishing a single European Regulatory Authority. In the Communications Review the Commission "considers at this stage that the creation of a European Regulatory Authority would not provide sufficient added value to justify the likely cost" (European Commission, 1999). The Commission argues that "[t]he issues identified that might be better dealt with at EU level can be addressed through adaptation and improvement of existing structures" (European Commission, 1999). In view of this major policy U-turn, one can only hope that established tools, in particular competi-

tion law, at the EU level were already adequate to resolve problems associated with fragmented authority of regulation (Eurostrategies and Cullen International, 1999).

Needless to say, the rejection of the single ERA proposal was to maintain the power of regulation at the member state level through the continued existence and functioning of the National Regulatory Authorities (NRAs), which are important to the traditional notion of national sovereignty. Undoubtedly, the EU's failure to establish a single ERA will help preserve the national and institutional boundaries within a 'common information area' (European Commission, 1993), in which inter-connectivity and inter-operability are already a technological reality thanks to digital convergence.

The experience of regulatory reform in the EU suggests that the institutional setup of "the older analogue communication networks of the nation-state system" in favour of "few-to-many, space-bound, essentially hierarchical and unidirectional" (Hand & Sandywell, 2002, p. 200) types of communication are unlikely to disappear overnight. It is not surprising that there is still a long way for the EU to go before it closes the gap between the law of digital convergence and the allocation of power, which is always sensitive to the consideration of national sovereignty.

## FUTURE TRENDS

The impact of digital convergence upon information and communications regulation at the EU level is the shift of legislations from a technology-specific model to a technology-neutral model. This change in the method of regulation has so far not accompanied by a process of institutional change in terms of shifting the power of regulation from the member state level to the EU level.

Despite the drawbacks associated with the failed attempt to create a single ERA, technological convergence has already led to "institutional convergence" in relation to the regulation of electronic media and communications in some EU member states. In the UK, for example, the Ofcom (Office for Communications) was created with regulatory competence to govern the new information and communications technology sector centred on digital convergence. The Ofcom has subsumed a number of previously independent regulatory agencies, such as the Oftel (Office for Telecommunications), the ITC (Independent Television Commission) and the Radio Authority. The establishment of Ofcom is undoubtedly a positive step forward at the national level.

The political considerations that had prevented the creation of a Single European Regulatory Authority are contingent upon the extent to which European integration has been achieved. Market liberalisation has already led to the development of pan-European service providers. For example, Vodafone and T-Mobile, among others, have become truly pan-European service providers. The ever-increasing level of Europeanisation in media and communications services dictates that the power of nationally based regulatory authorities is becoming increasingly constrained. It is not unthinkable that the need for a more efficient regulatory structure might one day re-activate the debate about the case of a single ERA. To complete the process of regulatory reform in the context of digital convergence, the EU might have to move another step forward by replacing the country-specific regulatory authorities with a country-neutral regulatory authority. But this will not happy until there is a political will to do so. European policy makers are reminded that "[d]isparate national regulatory reactions carry a very real threat of fragmentation to the internal market" (Bangemann et al., 1994, p. 17).

Looking into the future of electronic media and communications regulation in Europe, two important dynamics, for example, the economic and political trend toward European integration and the technological trend towards digital convergence would seem to reinforce the idea of establishing a single European Regulatory Authority at the Union level, although this is by no means certain. In order to assess whether there is a genuine need for a single ERA, further research is needed to look into the constraints faced by the NRAs in regulating digital convergence in the European context.

## CONCLUSION

This article has explored the impact of digitisation and digital convergence upon the politics of digital media regulation in the European Union since the early 1990s. It is argued that, on the one hand, the EU has achieved remarkable success in simplifying and consolidating the regulatory structure in response to digital convergence.

The main achievement of the EU's regulatory reform thus far is the shifting away from a technology-specific approach to an issue-oriented and technology-neutral one. The new communications regulatory framework has also led to the substantial reduction in the number of directives governing the ICT sector. On the other hand, however, EU regulatory reform has stopped short of an institutional reform. In the face of opposition from the member states, the European Commission decided to abandon its earlier idea of establishing a single European Regulatory Authority. This has left the National Regulatory Authorities in charge of each national market for the information and communications technology sector. There

seems to be a rational and technological justification for the establishment of a single ERA, but the complexity of EU politics does not provide an easy answer as regard to whether this will happen in the future.

## KEY TERMS

**Assymetrical Digital Subscriber Line (ADSL):** Instead of making the existing copper wire telephone lines obsolete in the digital age, asymmetrical digital subscriber line (ADSL), as a digital technique, enables a conventional telecommunications network to transmit multimedia services including such as voice telephony, internet access and video-on-demand *via* the same telephone network.

**Digital Convergence:** Thanks to the process of digitisation, traditionally different forms of communication services, such as voice telephony, data, sound, or pictures, can be transmitted over many different networks. Digital convergence is also manifested in the design of new generations of digital products, which are often multi-functional devices.

**Digitisation:** Digitisation is essentially a process of converting analogue forms of information (or contents) and communication into digital or binary codes (ones and zeros) that could be manipulated by computers.

**European Regulatory Authority (ERA):** The idea of establishing a single European Regulatory Authority (ERA) was initially put forward in the Bangemann Report in 1994 in response to the development of the information society in general and digital media convergence in particular. The European Commission subsequently gave up the idea for an ERA in its 1999 Communications Review due to pressure from the member states.

**Information and Communications Technologies (ICTs):** Information and communications technologies (ICTs) is a generic term referring to any kind of digital media and communication technologies and networks.

**National Regulatory Authority (NRA):** A National Regulatory Authority (NRA) is a national regulatory agency responsible for regulating either the overall information and communications technology (ICT) sector or a specialised domain of the ICT sector. The Ofcom, for instance, is a National Regulatory Authority in the UK charged with the responsibility of regulating the overall ICT sector.

**TEN-Telecom:** Trans-European Network of Telecommunications (TEN-Telecom) is one of the three TENs (Trans-European Networks) stipulated in the Maastricht Treaty that the European Union shall promote. The other two TENs are the Trans-European Network of Energy and Trans-European Network of Transport.

**Video-on-Demand (VoD):** Video-on-Demand (VoD) is an individiualised service provided mostly by traditional telecommunications companies offering digitised films and television programmes through a telephone line. In the UK, the law does not allow a telecommunications company to provide television broadcasting service but VoD service is legal.

# The EU's Use of the Internet

**Jamal Shahin**
*University of Amsterdam, The Netherlands and Danish Technological Institute, Denmark*

## INTRODUCTION

The European Union (EU) has been one of the leading lights concerning Internet use in dealing with other public administrations and citizens. This article will argue that e-government has meant that the European Commission has been able to promote a virtual arena for pan-European activity, which has promoted action at the national and local levels in the EU.

In the first instance, this article will deal with how the European Commission uses the Internet to attempt to improve its own relationship with both national public administrations and citizens in terms of the European policy-making process. Although the Internet is perceived as aiding public administrations in information and service provision, which helps to deliver better governance from an institutional governance perspective, a focus on this would only tell one half of the story. Increasing democratic participation and regaining trust in the political system at large is also an important issue for public bodies such as the European Commission to address, and this is not merely a technical process. These technical (efficiency, etc.) and democratic stages are two key parts in the process of developing an information and communication technology (ICT)-based governance agenda in the EU.

In order to outline the process, this article deals with four different aspects of the European Commission's e-policies. It makes reference to the following:

1. The Commission's information provision, through the EU's Europa (II) Web server;
2. The way in which the Commission has tried to interact with citizens, using interactive policy making (IPM);
3. The e Commission initiative; and
4. The way in which the Commission links member-state public administrations together, through the IDA(BC) programme.

This article reveals the increasing coherence of the European Commission's approach to using the Internet in institutional affairs. Although the Commission's approach to using the Internet for governance was initially unstable and ad hoc, by the turn of the century, all efforts had converged around the political issues of institutional reform and better governance. This has been further enhanced by the application of the open method of coordination as one of the tools of EU governance, which has enabled the Commission to take a more informal role in implementing e-government strategies at the pan-European level.

This article does not attempt to define e-government at the European level nor does it go into policy areas concerning e-government (such as research, socioeconomic inclusion, improving competitiveness, or specific e-government policy developed by the European Commission), but will contribute to a greater understanding of how the EU itself has used the Internet to promote an e-government agenda that is affecting all public administrations.

## BACKGROUND

Digital technologies, as exemplified by the Internet—simply a network of digital data networks—are redefining the landscape upon which actors play their roles in most economic, social, and political spheres. Communication channels such as the Internet provide for dissemination of information and knowledge, thereby enabling innovation to take place over networks as most innovation is now non-physical. According to David Johnston (1998), "we are moving to a society in which the management of information—through communications and computer networks—is becoming the key strategic resource that determines the competitiveness of nations and communities."

Johnson and Post (1998) question "whether a governance system divided into territories demarcated by physical boundaries can simultaneously serve the two key governmental goals of legitimacy and efficiency." Raising the question leads to the conclusion that new actors such as the EU, which is geographically broad, are introduced into the governance matrix. Economic efficiency becomes far more important than geography, and when combined with a high level of institutional legitimacy, new governance paradigms can emerge. ICTs have been perceived as opportunities to improve both efficiency and public value. The EU emerges as one of those actors that can be

seen to develop its legitimacy and efficiency through the use of the Internet.

From this perspective, the EU is provided with a whole range of opportunities concerning its use of the Internet. These opportunities, however, can also be considered as challenges for the structure of the EU and its components. The following five sections outline how the European Commission deals with these challenges and opportunities.

## TOOLS FOR IMPLEMENTING AN E-GOVERNMENT AGENDA IN THE EU

### Information: Europa and Europa II

At the EU level, where much is made of the role of the "information deficit" as a central problem that subsequently causes the perceived democratic deficit, much use can be derived from this characteristic of the Internet to promote an enhanced standing of the EU. At a basic level, this is carried out by the development of a Web site that contains information (European Commission, 2004). In more advanced stages, this involves the creation of databases that can be used by individuals and organisations to find out more information about a particular issue. The first step was undertaken by the European Commission in 1995, with the development of the Europa Web site.

From the perspective of the European Commission, the target audience of its communication strategy has always been a concern: the typical user has been defined by European political priorities, such as catering for people on the move. The provision of information for the average citizen was not made a priority, which reveals a certain approach toward the person on the street, whom it is considered would not be interested in the EU's institutions. This position has evolved since 1995.

| *Recruitment* |

The Europa Web site and the .eu.int domain are the central point of reference for all the EU's institutions: sites that predated Europa were gradually brought into this domain in order to present a coherent approach to the Commission's (and the Union's) digital presence. Cordis (Community Research and Development Information Service) and ISPO (Information Society Promotion Office) were the two big sites that had been created outside the .eu.int domain (www.cordis.lu and www.ispo.cec.be, respectively). The site can be divided into subdomains: there are about 140 important subsites under the common denominator europa.eu.int. Europa is managed and maintained by a staff of 90 people: 30 are in the Commission, and the remainder are provided by a contracted company. This team of 90 staff also work on SCADplus, which provides information leaflets regarding EU activity areas and policies. The staff of 90 does not include those working in other directorate generals (DGs) on content for the various sites of each DG in the European Commission. Other EU institutions make use of the Commission's Europa site too. When Europa was launched by the Commission, other EU institutions subsequently asked the Commission to coordinate the entire EU's Web presence.

Europa II is based on a set of thematic, audience-based, and service-based portals and provides information, allows interactive communication, and provides transaction opportunities for citizens and businesses (European Commission, Informatics Direct, 2001, pp. 7-9). Plans to create thematic portals for various areas, including the Information Society, were elaborated in 2001.

Table 1 shows which sites had already been put in place by 2001, which the Commission considered pace setters for other Web-based activity. Each activity is the responsibility of a different DG, and some are worked on by several DGs in collaboration.

The portal sites are generally decided upon by all the EU institutions, with the Commission making a proposal and the Council agreeing, although sometimes, the Council requests that the Commission investigates possibilities for portals. Given the levels of integration that is required for these portals, both horizontally and vertically, it is necessary to have the support of all levels of public administration—national and European—in their creation. EURES—a European CV-hosting portal, for example, is supported by the IDA programme.

DG Press, which holds the chair for meetings of the Europa II Steering Committee, works together with 10 other services in the Commission that are considered to have "crucial responsibility in the field of web communication and information" (European Commission, Information and Communication Support, 2001, p. 19). Because responsibility for each DG's Web site is left to the respective DG, a forum has been created to ensure that all Web pages are compliant with common rules (European Com-

mission, Information and Communication Support, 2001, p. 20). This forum also operated in the framework of the original Europa site. Although this can be seen as an internal issue, the fact that separate DGs are responsible for their own window to citizens is revealing as again it shows the decentralised policy of the European Commission toward information production (even more so when one realises that many Web sites with content provided by the Commission are actually managed outside of the EU's institutions).

DG Press initiated the process for developing a plan for an information and communication strategy from 2005 onward around the end of 2003. This has resulted most recently in publication of a communication entitled *An Action Plan to Improve Communicating Europe by the European Commission*. It is hoped that by this time, the EU's communication tools (which include television, Internet, and printed publications) will be in all the official languages of the EU. From this strategic perspective, the Web services provided by the Commission are seen as the one area where citizens would turn to after having first seen information on television, or in a newspaper, for example. Plan D, for Democracy, Dialogue, and Debate, which has emerged since the establishment of the new Barroso Commission, is described in the following section as it attempts to interact with citizens as well as providing information.

Besides the advantages for use of the Internet for publishing information regarding the EU, the World Wide Web (WWW) and other Internet-based information dissemination tools have recently been seen as increasingly crucial to the Commission. It is very difficult for European institutions to deal with national media as these are often not altogether objective regarding the EU. A well-defined Internet presence, it is assumed, will provide citizens with relevant and accurate information regarding the EU and its various institutions. However, the Commission had not given the area much priority in its day-to-day business until Europa II became an active component of Commission reform.

The provision of data on the EU by the Commission and other institutions provides an example of the top-down approach to using the Internet to enhance transparency and openness. However, transparency and openness must have a purpose: just as with the establishment of a Web site, there must be an area in which openness and transparency can have an impact upon politics and policy making in the EU. This is perhaps most clearly seen through interaction with the grassroots of society. This bottom-up approach would also see governments providing public spaces for individuals to interact, not necessarily with intervention from politicians and other public servants (Coleman, 2001, p. 121). A good example of application of networked technologies to dissemination of political discourse would be the Belgian Government's (who held presidency of the European Council in the second half of 2001) Expedition Europe Web site (http://www.expeditioneurope.be). This, in contrast to the Futurum Web site (http://europa.eu.int/futurum), was specifically targeted toward 17- to 25-year-olds living in the European Union. Although the subject matter was similar to Futurum, the approach was different, attempting to encourage a different sector of society to become involved in the debate on the EU. This is an example of providing multiple information channels, an activity made much easier by the Internet. The ability to use different channels to enable full dissemination of information to various groups of actors in society will also allow interested persons to provide commentary on issues of interest to their interest groups through debates. This links information provision with interaction. Yet again, although the technology provides assistance, the drive must come from civil servants and politicians to ensure that information is readily available and relevant, and from citizens to ensure that the agora is used.

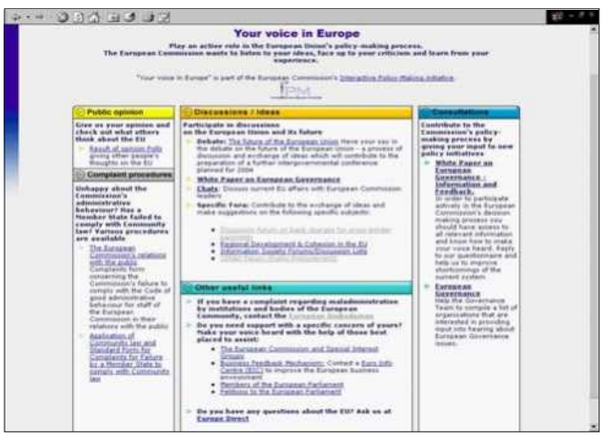
## Connecting with Civil Society: CONECCS

One of the few possibilities that the European Commission itself has for exercise of the bottom-up approach to information provision is provided by the CONECCS initiative.

The Commission, as a coordinator in EU governance, must provide as many opportunities as possible to ensure all parties participate in useful and timely dialogue: in 2000, the European Commission placed its CONECCS database online. CONECCS can be found in the Commission's pages on Civil Society. It contains two elements: one is to improve transparency and the other is to improve the consultation process: both are central to the better governance ambitions of the European Commission.

The use of the database, however, is limited to information provision despite having many other potential uses in policy making. By using the database for information provision alone, the Commission is not taking advantage of the possibilities for greater interaction with a range of actors. But there is a second motivation in using the Internet as the basis for an open repository of names in the field: it enables individuals and organisations to get involved in the major players in the consultation process, rather than voicing their opinion to the Commission directly. Here, the Commission is not wishing to interact directly with individuals, but rather providing a list of intermediaries who can communicate with the Commission. This would reduce the opportunities for information overload in the Commission itself, and en-

*Figure 1. The Your Voice in Europe portal (http://europa.eu.int/yourvoice)*



sures that filtering of opinion takes place prior to contact with the Commission.

## Interaction: Your Voice in Europe, IPM, and Plan D

Provision of information is one side of the coin for the e-governance agenda in the Commission. The ability for citizens and businesses to search for information is a crucial element of building better governance in the European institutions. However, the ability of citizens to interact with Commission officials and policy is also of major importance. The first step is to provide information about how citizens and interest groups can get involved in the policy-making process: CONECCS goes some way in this direction. Your Voice in Europe presents the pinnacle of this approach to opening up the EU's institutions in terms of ICT usage. It was an initiative established in the framework of the Interactive Policy Making initiative (described later in this article), and was intended to work toward the objectives in both the governance and reform programmes of the European Commission.

Your Voice in Europe is, essentially, a portal that shows citizens how they can interact with various EU institutions. From the home page of the subsite (http://europa.eu.int/yourvoice), one can participate in consultations, enter various discussion fora, or provide feedback to the EU institutions on different issues (complaints to the ombudsman, etc.). Your Voice in Europe attempts to bring together various activities that were being undertaken in the Commission. It has also added and improved various tools used by the Commission in the consultation process, one of which—IPM—will be described later. A screenshot of the initial page is shown in Figure 1.

At this European Commission level, interaction can be broken into two distinct dimensions, which are defined by the structure of the political institutions. In the first, the European Commission is an organisation dependent upon external advice for proposal of legislation; it is also dependent upon external support for implementation of legislation. This requires that the Commission be as responsive as possible to external requirements and actions. Generally, this relates to issues of a highly technical nature, and as such necessitates interactivity between Commission officials and experts. The second dimension recognises the fact that the European Commission is supposedly a guardian of the Treaties of European Union, and is entrusted with ensuring that these treaties are abided by in more general terms. Whilst this notion of interaction is treated seriously by the Commission, and is a clear application of the transparency principle, there is a distinction between these two levels of consultation: on specific legislation and on general topics of interest. Your Voice in Europe attempts to marry both dimensions together, by providing information about how to contact the EU ombudsman, as well as providing the gateway to specific consultations.

The target audience is more likely to be individual citizens and the site is designed with this in mind: it shows individuals the number of different ways they can interact with the European Commission. As well as providing citizens with information about how they can interact with the EU institutions, the European Commission is also carrying out activities that involve direct interaction through use of the Internet; this is known as the IPM initiative. The notion of interactive feedback again highlights one of the central characteristics of the Internet, which has been promoted through the e-government agenda. Encouraging debate at the grassroots level and providing information are seen as necessary requirements toward a Europe based upon a new form of governance: However, these actions only provide partial solutions. When debates are centred upon specific issues, the actors involved at policy level must be willing and able to provide responses to interested bodies. There must be a purpose in activity from the citizen; he or she must feel that his or her voice is being acted upon (Coleman, 2001). Interaction through consultation must take place. Similarly, when information is provided, public administrations and governments must be able to provide response to further questions that emerge. Given the complexity of much of this information, they must also be able to provide this information easily: this often requires human interaction.

Thus, it can be seen that responsiveness to requests for information is more than simply providing the ability to post an e-mail to a standard mailbox, to which a response may or may not be given. To take advantage of the technology, human interaction is required and there is no

simple technological fix for this. The consultation procedure becomes increasingly important in this respect as it provides the opportunity for many aspects of better governance to be exercised. In the case of the European Commission, which forms the focus of this chapter, responsiveness to interested parties in policy development is also important: this is done with citizens and businesses through the various consultation procedures.

Consultation on proposals is one of the standard activities of the European Commission. The Commission's Secretariat-General has a unit that deals with the Commission's relationship with Civil Society, and it is here where the consultation procedures are centrally managed (although consultation itself is the responsibility of individual DGs). This unit was responsible for outlining the minimum standards for consultation, which were published (after much internal consultation) in a communication at the end of 2002 (European Commission, 2002). In this document, the role of the Commission in the field of consultation was further emphasised: "Wide consultation is not a new phenomenon. In fact, the Commission has a long tradition of consulting interested parties from outside when formulating its policies. It incorporates external consultation into the development of almost all its policy areas" (European Commission, 2002, p. 3).

Commission activity on consultation is linked to both administrative reform and EU governance. Again, Internet-based tools are simply tools: they are implemented toward an aim of facilitating an improvement in governance processes. However, the Commission has a long way to go in furthering the use of these tools. Another consideration that must be examined concerns the users of these tools: who will use them, and why will they do so?

In contrast to the expert-type opinions requested by the European Commission in the CONECCS consultation process described above, Your Voice in Europe provides a more flexible framework for consultation. The central piece of the Your Voice in Europe initiative is the IPM tool, developed by the Commission.

The mandate for the IPM tool was set out in 2000: it was to use the Internet in involving more stakeholders in the policy-making process. The IPM tool allows for interested individuals to be consulted in a structured manner and fully caters for the multilingual dimension of the EU. This overcomes one of the problems facing consultation prior to the development of the tool: when too many responses to consultations were received, the Commission always had a problem of dealing with the information.

The IPM tool has been supported by most DGs and other Commission services, and will be taken as the primary manner for execution of most public (and restricted) consultations. In consideration of its ability to provide real-time analysis to policy makers, its ability to consult citizens, businesses, and civil society groups in any of the official languages (along with scalability for new languages), its flexibility (consultations can either be open to the public or closed to a predetermined group), the Commission is keen to encourage this tool to show how citizens can get involved in consultations which help inform policy making, creating better regulation and showing citizens that their input is considered important (i.e., better governance).

Crucial to the operation of this tool has been the increased use of the Internet: it has been used as the gateway to the Your Voice in Europe portal. The coupling of databases and interactive forms, which are filled in online, has enabled the Commission to create a system of interaction with interested parties from all areas of the EU (and beyond) to contribute to consultations. The practical problems of receiving comments on consultations prior to the development of such a system have been avoided by the development of a tool that poses structured questions, rather than requesting general feedback on long documents, which few people would read.

In a couple of unpublicised consultations carried out in the pilot phase of the Your Voice consultation portal, between 100 and 200 replies were received per consultation; this was still more than the average consultation carried out using traditional means. In July 2002, a consultation on Data Protection issues was launched publicly; within 10 days, 7,500 replies were received. The total figure for that consultation later finished as 9,500. A list of consultations that took place between 2001 and 2003 are in provided in Table 2.

As well as open and closed consultations using the IPM tool, DG Internal Market has also established a so-called feedback mechanism, which aims to get spontane-

*Table 2. Consultations using the IPM tool between 2001 and 2003*

| Date | Subject | Number of responses |
|---|---|---|
| June 2001 | • Modernizing the Internal Market for industrial goods | 253 |
| September 2001 | • Governance | 224 |
| December 2001 | • Review of the New Approach | 135 |
| January 2002 | • Trust barriers for business-to-business e-marketplaces | 103 (limited to certain organizations) |
| April 2002 | • Pan-European government e-services | 67 |
| June 2002 | • Data protection | 9,500 |
| July 2002 | • Cybersquatting | 1,137 |
| September 2002 | • Undertakings for collective investment in transferable securities | Closed |
| October 2002 | • Pack sizes in the EU | 691 |
| December 2002 | • Animal protection during transport | 4,141 |
| January 2003 | • Give us your opinion on Your Voice in Europe | Ongoing |
| February 2003 | • European Action Plan for organic food and farming | 1,136 |
| June 2003 | • Draft Chemicals Legislation | Closed |
| September 2003 | • Legal problems in e-business | 651 |
| November 2003 | • Public procurement | Closed |

ous feedback on specific European policy issues. It is part of the IPM initiative, and was established as a pilot project in April 2000 for use by 41 Euro Info Centres. Since that time, it has grown: between October 2001 and June 2002 the initiative grew to include around 300 citizen and business contact points that included Euro Info Centres, European Consumer Centres, and the Citizens Signpost Service (http://europa.eu.int/yourvoice/ipm/index_en.htm). These organizations are contracted by the European Commission to enter issues that are raised with them into an online database which is then referred to by each DG when designing new legislation or reviewing existing legislation. The whole database was operating for DGs Internal Market and Enterprise, and would be available to all DGs by the beginning of 2003. More recent evaluation has been carried out on the feedback mechanism which has questioned the utility of this mechanism, and in particular the use made of such a tool by policy makers (European Evaluation Consortium, 2005). Once again, this shows that perceived benefits of e-government are not necessarily converted into material or social value without a greater understanding of how policy-making processes must evolve to take this into consideration.

"Plan D," released by the new vice president of the European Commission, responsible for Institutional Relations and Communication, is an attempt to link together the idea of Communicating Europe with providing spaces for dialogue and debate. The Internet is seen as an area where such a set of debates can take place. Despite this fact, the Futurum Web site, established to discuss the Future of the European Union, was closed after the European Convention for the European Constitution. However, Vice President Wallstrom has opened up her own blog (http://weblog.jrc.cec.eu.int/page/wallstrom), where debate can take place.

## Institutional Impact: Toward an E-Commission

Reform of the Commission is central in driving the vision toward an e-commission, as has been the case with many public administrations, for example, the United States (Fountain, 2001). Studying the emergence of an e-commission, and the use made of the "e" in e-government by the European Commission provides us with a dynamic and interesting case. Also, examining the way in which the European Commission has started to govern in the wake of the communications revolution provides us with a greater insight into the development of EU governance, and provides the Commission with a tool that has the opportunity to create a European public space and develop a greater role for the European Commission in the daily lives of European citizens.

The Commission has clearly defined areas of concern in public administration at the EU level that need to be rectified in order for the institutions of the EU to (re)gain public confidence. In fact, since 1995 the European Commission has consistently mentioned reform of the institution in its annual work programs (1995, 1996, 1997b, 1998). More specifically, the Commission's White Paper on Reform stated that "[Administrative reform] is thus a political project of central importance for the European Union" (2000a). Part II of the White Paper was more explicit in the role of the Internet, proposing a set of action points "towards the e-Commission" (2000b, pp. 8-10). Building upon the eEurope Action Plan (1999), the Commission states "Technological development holds out the potential of modernizing the administration and improving its communication and working methods both internally and with its partner organisations and interlocutors" (2000b). This again seems to emphasize the role that the Internet plays in enforcing current structures and institutions in the EU. Furthermore, the Commission sees the development of its e-strategy as something that helps promote business: "easy access to public sector statistics and data and electronic public procurement can also give a strong stimulus for new private sector value-added services" (2000b, p. 8). This strategy, it believes, is something that should be applied to itself as well as other institutions in the EU.

Reform of the Commission is limited to boundaries cast in the Treaties on European Union, which are inevitably slow (and perhaps even unwilling) to react to institutional demands (from the Commission) for greater democratic accountability for the Commission, along with all the side effects that would emerge from this including a greater role in governance of the EU. Therefore, as in eEurope, the Commission has found ways to work within these boundaries.

The Informatics Directorate of the European Commission splits the role of the e-Commission into three different strands. These are as follows: "internal administration," "efficient communication with external partners," and "public service to citizens and business" (European Commission, Informatics Directorate, 2001, p. 9). The e-Commission is at the core of all ICT-based reform and better governance initiatives in the European Commission. Europa II is considered to be the main digital interface between citizens, businesses, and interest groups; IPM is supposedly one of the central ways of managing the policy-making process. The latter strand has provided the focus above, and now the first two are described in detail.

Internal discussion takes place not only around the issues concerning internal administration. Although the Commission's official Web site, Europa, is designed for its audience, the process behind developing the site and

its follow-up, Europa II, has been part of the internal development of the Commission into an "e-aware" organization.

In the new Barroso Commission, Informatics has moved to the status of Directorate General, giving higher political priority to the Commission's own public administration reform through use of ICTs. The recent communication to the Commission outlining a proposed strategy for the e-Commission (2006-2010) asserts, "the Commission needs to apply to its own administration the European information society policy in the eGovernment field" (European Commission, 2005c, p. 5).

The previous three sections show that the European Commission has tried to bring policy making closer to external partners, citizens, and businesses despite recognizing that the distance between these actors is problematic. Because of this, the opportunity to interact with citizens directly through technology such as the Internet has been welcomed, and the Commission itself is trying to find ways to facilitate the development and use of networks internally, as well as in its relations with external partners.

## Implementing E-Government Across Europe: IDA(BC)

One of the central activities in this sphere of communicating with external partners is the relationship between the Commission and public administrations in the member states. The Commission is responsible for the management and day-to-day running of the Interchange of Data Between Administrations (IDA) program. IDA has a clear legal basis within the treaties on European Union, and as such, was given a clear mandate. This has now become part of the Commission's e-government goal, which is now focused upon coordination and not government in the traditional sense.

The system connects national administrations' computer networks together through the EuroDomain, a private network based on Internet technology. National entry points are supplied by the Trans-European Services for Telematics Between Administrations (TESTA) project, which is part of IDA. The Commission provides support for several types of projects through this service, to which member states are required to connect as a result of European legislation (Council and European Parliament, 1999). The consequences of this, however, are not seen as creating a nascent European Information System, but just enabling national governments to coordinate information and communication in common areas. The focus was to encourage interaction between the Commission and member states, and between the various member states. It was originally established to make exchange of information in the SEM easier to carry out.

In the latter stages, content became the driving issue. Pharmaceutical information is one area where the initiative has already been successful. A complete list is provided in Table 3.

The IDA program was subsequently adopted as part of the e-Europe initiative in e-government, after the Swedish Government hosted a meeting on the subject during its presidency of the European Council.

As a result of IDA and IDA II, a large amount of data communications between the EU institutions and member states pass over the Internet. Closely related to the development of the IDA program is the creation of an intranet for various committees dealing with EU policy areas. Named the Communication and Resource Centre for Administrations (CIRCA), this intranet is a place for papers, agendas, and discussion to ameliorate the policy-making process by the European Commission. Access is granted depending upon the status of the committee; some are completely closed and others are open. This harmonized Web-based application should overcome some of the problems experienced by policy networks in making policy; the technological network approach (Winn, 1998) described in an earlier section of this article is in evidence here.

IDABC, the successor to the previous IDA programs, continues along the lines set by its predecessors. However, this time, as well as supporting public administrations, the EU's institutions have decided to include Businesses and Citizens as end users. The decision to include these elements in the Interoperable Delivery of Pan-European eGovernment services is, however, more than

just a continuation of existing policy. It outlines the formation of a new set of services to be carried out in a pan-European fashion. The consequences of this development are potentially far reaching in terms of changing patterns of governance within Europe's borders.

## FUTURE TRENDS

Trends in the four areas described above are also reflected in the development and maturity of the e-government phenomenon in general. Internet sites are not just developed for the sake of it, but are designed with specific tasks in mind. In view of the complexity of information provision at the EU level, the Europa Web site has developed remarkably in recent years. Given the European Commission's new focus on Communicating the EU to Europe's citizens, and the aforementioned advantages of the Internet as a method of communicating Europe-wide, this will undoubtedly grow into a vital tool in the EU's communications arsenal.

The Commission, arguably, led the way in consultations with citizens and civil society organizations; however, there is always a disadvantage in being the first on the scene. The Commission is evaluating its procedures concerning consultation through online means on a regular basis, and we should expect that the phenomenon of direct consultation will grow on specific topics. Whether this will actually change our understanding of governance in the EU is not related to the increase in the use of the Internet as a tool for consultation: the large majority of citizens are not aware and do not use these consultation tools.

Plan D is a bold attempt on the part of the Commission to attempt to develop a series of public spaces for dialogue on the EU and European issues. The future of this is uncertain at present, but this shows that the Commission is willing to invest in efforts to use new ICTs and other forms of media to promote a sense of Europeanness.

On internal aspects, as in any public administration (and any other organization), the use of Web-based applications to support and encourage interaction between different departments and sections relies, to a large extent, on human willingness to do so. However, the European Commission appears to place a great emphasis on taking advantage of the communications revolution to reorganize its (relatively small) number of staff and related bodies.

In relation to member states and linking together national institutions at the European level, with the IDA's successor program, IDABC, gaining further competencies in the European framework, there is a more coherent level of e-government activity at the EU level, which, in all likelihood, will continue in the foreseeable future, extending into such areas as Social Security payments, where there is a clear and stated need for EU-wide activity. Greater use of the IDA platform has already been foreseen, as the TESTA network will be upgraded (to s-TESTA), which provides a more secure environment for interaction between national public administrations.

## CONCLUSION

The EU's case is slightly particular, in the sense that this is a new and emergent level of governance outside of the e-goverment debate as well. Therefore, the EU institutions, and particularly the European Commission has been able to be far more creative and innovative than the public administrations in its member states. By elaborating on the Commission's activities in four key areas—information, interaction, impact, and implementation at the EU level—this article has shown that the EU has made great use of the Internet to develop EU-level activity in policy-making and political spheres. This has always been with the aim of reforming the EU and building better governance.

Although there remains much to be done in terms of really understanding the implications of developing the tools and applications of e-government at the EU level, the EU has made progress in these areas: there has been evidence of the emergence of a harmonized approach to using electronic tools of communication and information in the activities of the European Commission, which started as various piecemeal, ad hoc initiatives set up by various departments in the EU institutions. Further research needs to be carried out in how to make these applications more relevant to European citizens and organizations to ensure that the implications of e-government are actually transformed into public value.

In all of this, the role of the EU's institutions has not been to centralize all activity relating to use of digital tools but to act as a coordinator between different jurisdictions and levels of government and public administration: this is a challenging task and looks to continue to be so in the future.

## KEY TERMS

**Consultation, the European Commission, and Civil Society (CONECCS):** (http://europa.eu.int/comm/civil_society/coneccs/index_en.htm) CONECCS provides a database maintained by the European Commission's Secretariat-General. It is separated into two parts: a list of EU formal or structured consultative bodies, and a list of nonprofit civil society organizations established at the EU level.

**EUROPA:** The name given to the EU's Web site (http://europa.eu.int). First created in 1995, it has evolved over the years. Now in its second generation, EUROPA II, the site is the main place to find all official EU-related information, and acts as a portal to most other official EU sites.

**European Union Institutions:** Collectively the term given to the official institutions in the European Union. It includes the European Commission, the European Council, the Council(s) of Ministers, the European Parliament, the Committee of the Regions, and the Economic and Social Committee.

**Interactive Policy Making (IPM):** The tool created by the European Commission to attempt to involve more stakeholders in the consultation process. It has two main

features: one is the Your Voice in Europe tool, the other is the feedback mechanism, which allows for various contact points across Europe to provide data concerning existing EU policy areas.

**Interchange of Data between Administrations (IDA):** The original program providing the opportunity for different national public administrations to interact electronically at the EU level. Now succeeded by the IDABC program.

**Interoperable Delivery of European eGovernment Services to Public Administrations, Businesses and Citizens (IDABC):** Successor of the IDA program.

**Trans-European Services for Telematics between Administrations (TESTA):** The IP (Internet)-based infrastructure for the IDA program. It is succeeded by the s-TESTA infrastructure.

# Evaluating Methodologies of Financial Cost and Benefit Aspects of E–Government

**Ephrem Eyob**
*Virginia State University, USA*

## INTRODUCTION

The purpose of this article is to survey the financial cost and benefit of e-government and the evaluation methods utilized in the implementation of information technology (IT) projects in general, and e-government projects in specific.

## BACKGROUND

Evaluation methodologies typically are grouped by "… relevance, effectiveness efficiency, and internal functioning," (Van Giles, 2002). Cost-benefit rationalization is one of the key factors used in whether to implement e-government projects particularly when more advanced features of e-government that use transactional and integration aspects of governmental functions are the deliverable goals. Frequently, IT cost exceeds initial estimate (Jeffery, 2004; Sassone, 1988). IT benefit are hyped, cost underestimated, and the purported efficiency never materialize. Financial analyses are the main tools used to analyze capital expenditure including IT related investment (Sassone, 1988). However, the limitations of these kinds of analyses are that the cost is realized instantly and the intangible benefit is realized later or not at all. Nevertheless, rarely do most IS managers doubt that their projects are financially and strategically needed for their organizations. The conundrums most e-government project managers face is convincing top management the absolute necessity of their projects by providing strong rationale for IT investment, and estimating an acceptable return on investment (Jeffery, 2004).

Another problem with assessing IT investments for e-government is the productivity/information paradox (Thorp, 2003). This phenomenon is observed when assessment of IT benefit becomes confounded due to the interactions of many factors both tangible and intangible benefits. The government agency in question, in most instances, is unable to identify the productivity gains due to IT investments related to e-government. Dedrick, Gurbaxaui, and Kremer (2003) review clearly refutes the productivity/information paradox:

*At both the firm and the country level, greater investment in IT is associated with greater productivity growth. At the firm level, the review further concludes that the wide range of performance IT investments among different organizations can be explained by complementary investments in organizational capital such as decentralized decision making systems, job training and business process redesign.*

Investment in IT is not only for process automation but also an enabler for reengineering organizational processes, for example, functional integration systems such as enterprise resource planning (ERP) systems (Dedrick et al., 2003; Jeffery & Leliveld, 2004). Well integrated ERP for an e-government application can result in more productivity gains than gains warranted by automation only.

## THE STRUCTURE OF THE ARTICLE

The article surveys some of the methodologies used to access the cost of e-government and assessment of benefit due to capital expenditure in system hardware, software, and related telecommunication outlays for fast inter connectivity. Various approaches to measure e-government related cost vs. benefit will be surveyed. Each method's advantages and disadvantages will be briefly elaborated in their respective sections.

## ASSESSMENT METHODOLOGIES

Accurate measurements on the return of investment in e-government require accurate accounting of input, output, and processes. Measurement accuracy is critical to the usefulness of the IT assessment (Dedrick et al., 2003; Jeffery, 2004). What makes an effective e-government? An effective government should at least include the following attributes (Bannen, 2001):

- Should be able to reduce transaction processes both in cost and time
- The customers or clientele are keenly interested in IT and are heavy users of e-government services

- User friendly, fast, accurate access of information, and low cost of internet services subsided by various government agencies
- Confidentiality of information collected with secure transactions
- Cost sharing of providing e-services between the users and the government agencies
- Reengineering the government process for better effective services
- Innovation in newer service delivery processes
- Conduct a pilot e-government system project before launching a full blown system and learn from the experiences
- Using a short time frame to make e-government project operational
- Providing a strategic leadership to change the culture of government operations through e-government

The constant innovations and emulations of best practices in service delivery are rendering technology focused strategic solutions to real problems both in the private and public sectors. Public sector reform is not an end itself. Rather it is a means of transforming the public sector from a bureaucratic paradigm process to a mean and lean process enabled by information technology. In order to reform the public sector successfully for a technology-enabled process, the following three themes are invariably present (Sassone, 1988):

- Transparency and accountability to the public
- Ubiquitous service on demand
- Return on investment should be realizable in a short period of time to add value to the taxpayers

The remainder of the article shall review the literature of tools to measure the cost-benefit and effectiveness of technology enabled processes by e-government. These tools are by no means the only ones available but for the purpose of this article are: (1) balanced scorecard (BSC), (2) DMR result chain, (3) cost-benefit analysis, (4) cost effectiveness analysis, (5) e-government effectiveness, (6) information measurement multi-criteria (IMM), and (7) e-government benchmarking.

## THE BALANCED SCORECARD FRAMEWORK

The impact of e-government on efficiency and effectiveness can be assessed by the balanced scorecard (BSC). BSC is a specific performance measurement system applicable to a specific predefined domain (Norton, 2002; Volker, Rakich, & French, 2001). It is based on organization's strategy and goes beyond financial metrics to assess e-government achievements. Volker et al. (2001) described the BSC framework as follows:

*It is a holistic methodology that converts an organization's vision and strategy into a comprehensive set of linked performance and action measures that provide the basis for successful strategic measurement and management.*

BSC was first suggested in the early 1990s (Kaplan & Norton, (1992). It was quickly adopted and widely used for performance measurement for the private sector. It is a framework to assess performance, for example, a system such as e-government and benchmark the benefit gained against the status-quo processes before launching the system. It is an all eclectic methods that do not focus solely on financial metrics, where financial measurements invariably focus on past performance and have limited usefulness to forecast future performances. Hence it could be argued, focusing solely on financial metrics is not a robust predictor of the strategic direction of the organization. BSC, on the other hand, according to Volker et al. (2001, p. 16) it provides:

*... an enterprise view of an organization's performance by integrating financial measures with other key performance indicators around customers' perspectives, internal business processes, and organization's growth, learning, and innovation.*

BSC is designed to assess performance in four key areas and is a good candidate to assess the performance of e-government system:

- Financial scorecard
- Customer satisfaction
- Internal perspective
- Learning and innovation

Government that embark on e-government planning should develop an integrated balance score card to measure its efficiency and effectiveness. Before launching BSC, the management should go through several common phases: mobilization of all stakeholders, design and rollout, and sustainable execution of the strategy by involving key personnel. Best practices of transformation of organization requires issues of leadership, culture, and team work (Norton, 2002). The advantages of utilizing BSC in a quest to plan and implement e-government should be based on whether the new system satisfies the diverging needs of various stakeholders. The stakeholder could be residents, taxpayers, government employees, policy makers, elected officials, regulators, vendors, and other gov-

ernment jurisdiction in local, state, or federal level. The disadvantage is, it is unclear where most government jurisdictions are currently in utilizing BSC type system to assess the effectiveness of e-government. This is a potential area of research interest for scholars who specialize in e-government assessment topics.

## RESULT-CHAIN FOR MEASURING IT BENEFITS

Chief executives of many firms increasingly see IT as "… core strategic tool and believe that sophisticated pervasive IT will be needed to fulfill their future business objectives," (Harrison & Learmonth, 1999). Similarly, top government agency leaders and elected officials believe that e-government enabled by sophisticated pervasive IT is key to fulfill the objectives of lean and mean government services delivered at the lowest possible cost and satisfy customers and constituents requirements. Business and government leaders, however, are discovering that substantial investment in IT is not resulting in measurable organizational benefit that are purported to bring. Many studies have concluded that massive IT investments, including in e-government technology, result only in marginal benefits (Jeffery, 2004; Chesley & Wenger, 1999). These seemingly contradictions between expensive IT expenditures and questionable productivity gains are known as the information paradox (Thorp, 2003; Dedrick et al., 2003). Thorp suggests that realizing business benefit through IT can only be achieved if IT personnel and top managers work as a team. Some of the solutions proposed include (Thorp (2003):

- Identify and manage benefit provided by the organization
- Identify programs vs. project
- Manage IT portfolio and initiatives continuously

The DMR Consulting group has proposed a benefit realization technique known as DMR Results Chain. It is an enabler of "… the IT practitioner to sit with business partners and identify specific benefit, then support the identification of all final and intermediate steps and outcomes required to achieve these benefit" (Harrison & Learmoth, 1999). The balanced approach of portfolio management insures that no contradictory and incompatible IT initiatives are deployed without ascertaining that such projects contribute substantial benefits, and are integrated seamlessly with existing projects (Jeffery et al., 2004). The advantages of using these approaches may result in making sure that spending in IT yields tangible benefit such as user friendly interfaces, less system downtime, and receiving quick and accurate information by users. The disadvantage is that smaller organizations may not have the resources, technology sophistication, and priorities to implement and manage e-government systems portfolio in a systematic ways.

## COST-BENEFIT ANALYSIS (CBA)

Cost-benefit analysis deals with the measurement of added value of benefit due to some actions less the cost incurred for those actions. Some of the benefit may be intangible in nature and measuring it becomes subjective. In information technology investment, the cost of hardware, software, and personnel is straightforward to measure. However, measuring the benefit due to investment in e-government becomes blurred due to benefits that are both tangible and intangible in nature. Typical analytical tools used for cost-benefit analysis (King & Schrems 1978; Mantel & Teorey, 1988) include: discount cash flow, life cycle cost analysis, use of marginal cost analysis rather average cost, comparison of alternatives with or without additional cost, use of sensitivity analysis, use of present value, and opportunity cost of capital.

## COST EFFECTIVENESS ANALYSIS

Cost effectiveness analysis (CEA) for e-government deals with better results or output with the same or comparable input. The methods to analyze the information on the effectiveness of e-government services may include: Web site traffic pattern, behavior of users, Web site performance metrics, accessibility of Web site, information accuracy, usability of site, adequate help by customer service staff, and timeliness of information (Clemons, 1991; Nicoll, Robinson, & O'Hanlon 2004). CEA is a better benchmarking tool suited for e-government projects (Van Giles, 2002). The advantages of using CEA is it has the capability to compare similar e-government initiatives among similar jurisdictions within a city, county, state or country; it also has the unique capability to pin point performance lags and provide strategies to ameliorate deficiencies. Most of the data for such purposes are collected from internal sources related to internal managerial practices to monitor and benchmark the system. Quality of service (QS) is a high priority goal of most government jurisdiction for e-government service. Measurement of quality of service through surveys of constituents can suggest area of improvement for user satisfaction (Van Giles, 2002). Van Giles argued that "service quality involves mainly qualitative indicators and is often measured as a result of the gap between

customer's perception and expectations of a service." The disadvantage of using quality service as metrics for e-government purpose is that quality of service is targeted and depends heavily on the perception of direct consumers of the specific e-government service and as such is difficult to propose a standard quality of service model in e-government.

## E-GOVERNMENT EFFECTIVENESS

The evaluation of e-government effectiveness, for the most part, focuses on intermediate out comes (Chesley et al., 1999). Most of the evaluation methods used to measure benefit related to e-government systems are: Web site hits, volume of transactions and service quality, end user and provider feedbacks, manual vs. online applications (Bovaird, 2002; Thorp 2003). Invariably, intangible benefits are difficult to assess accurately due to the concept known as information paradox. According to Van Grenbergen and Amelinckx (2004): "Many of the e-business benefits such as better customer service, increased responsiveness, and faster deliveries are intangibles that are difficult to translate into monetary benefit." Some studies have reported that 3/4 of information systems investments do not provide any measurable value (Jeffery, 2004). Once e-government systems is implemented, service benefit are difficult to measure, particularly, when one is trying to measure government effectiveness, transparency, or services. Multi-criteria analysis is an alternate robust technique that can assess tangible and intangible benefits provided by e-government.

## INFORMATION MEASUREMENT MULTI-CRITERIA ANALYSIS

Multi-criteria analysis is an all encompassing technique that utilizes both qualitative and quantitative tools to assess the effectiveness of e-government. The steps of multi-criteria analysis typically consist (European Communities Report, 1999):

1. To define the criteria for evaluation of benefit and or effects
2. To summarize and classify variant characteristics
3. To assign quantitative target values or acceptable qualitative description
4. To use of an expert scores the respective effects or benefit
5. Finally, weighted scores of classification of effects and benefit

The attractiveness of multi-criteria analysis is that it gives a guideline for all stakeholders in problem solving and decision-making (Sassone, 1988). One advantage of multi-criteria analysis is that it has the capacity to incorporate attributes to estimate return on investment (ROI) even when cost related data is not available (Van Giles, 2002). The limitation of multi-criteria analysis is that it is heavily dependent on subjective scores and, therefore, is highly dependent on trained expertise and experience for objective evaluation.

## E-GOVERNMENT BENCHMARKING

The purpose of e-government benchmarking is to identify, compare and contrast performance deficiency to best practices. For example, areas that need benchmarking related to e-government may include: electronic service delivery targets, reorganized government functions to create a seamless information exchange, leading state-of-art e-government services (UK e-government benchmarking report, 2001).

A benchmarking template on a framework based on change, supply, capability, and demand is sometimes used, as is the case in the United Kingdom (UK e-government benchmarking report, 2001). The template can act as data warehouse for qualitative and quantitative changes in information. The information is then used to compare the current level of service against the best practices. The advantage of using a template framework is, it avoids the mentality of reinventing the wheel to evaluate e-government projects. The disadvantage is the template may have to be reconfigured to fit a unique e-government implementation situation; and even then the benchmark template may not make any sense due to unique factors of that project.

## FUTURE TRENDS

E-government is a growth area of the information technology sector. Because of its relative newness, most government entities are overwhelmed by the choices that are available in the market place. Prudent policy makers and chief information officers will have to use a systematic approach in introducing technology solutions in their respective divisions of their organizations. A promising tool to manage a multitude of project is the IT portfolio management (ITPM) technique that can assess the usefulness, risk, and potential integration of e-government solutions.

## CONCLUSION

The article surveyed some of the common evaluating methodologies of cost and benefits aspects of e-government. Although the coverage of the methodologies was directed to e-governments applications, the approaches and techniques discussed are more general in their applications and should not be restricted only to e-government applications. E-government efficiency can measure the quality, frequency, response time of electronic services. The underlying purpose of e-government efficiency is to do more with less. Cost measurement of e-government can be assessed by CBA and ROI. However, due to confounding of attributes of tangible and intangible benefit, assigning a financial ratio is difficult if not impossible. Targeted criteria performance can be measured by benchmarking and cost effectiveness analysis. The difficulty with such tools is their inability to compare and contrast performance among and between similar structural organization because of cultural, economical, social and political structural differences (Moe, 1995).

E-government effectiveness is difficult to assess because of information paradox. The inability to measure intangible benefit, measurement problems of cost assignments, benefit, cultural barriers and resistance to adoption of new technology are major hurdles in the evaluation of e-government effectiveness. E-government performance evaluation is fraught with many difficulties because of its formative nature: jurisdiction; governance; effectiveness; resource where withal; level of technological sophistication; and finally the constituents tech sophistication and quality of service of the e-government services. Policy makers can use tools such as the e-government IT portfolio management (Jefery & Leliveld, 2004) in staged implementation. The implementation can be divided into: target a specific organization in the implementation of e-government rather than the whole organization; limit portfolio components in each stage of implementation; limit the number of analytical metrics to less than ten; adjust measurement metrics to a specific stage of the life cycle of e-government implementation. These tools may not solve the measurement problems of e-government effectiveness, nevertheless, in our opinion, are better e-government evaluation techniques to ponder about.

## KEY TERMS

**Balanced Scorecard:** An analytical framework to assess performance beyond the financial measures and using with other key performance indicators around customers' perspectives to manage and evaluate business strategy, measure operations improvement, build organization's capacity, and communicate results to all stakeholders.

**Benchmarking:** Comparing e-government service metrics to the best practices in the public sector.

**Cost-Benefit Analysis:** A comparative analysis between financial cost and intangible benefit. The benefit may exceed the targeted objectives and difficult to measure in monetary terms.

**Cost Effectiveness Analysis:** A non monetary quantitative analysis between the cost and effectiveness of specific resources in comparison to the effect of other resources.

**Information Paradox:** The difficulty in measuring the productivity gain due to IT investment and automations.

**Multicriteria Analysis:** The use of quantitative and qualitative indicators to measure benefit of e-government.

**Service Quality:** Uses mainly qualitative indicators and is often measured as a result of the gap between customer's perception and expectation of a service.

# Evaluation Framework for Assessing E–Democracy Policy

**Monika Henderson**

**Fergus Hogarth**
*Queensland Government, Australia*

**Dianne Jeans**
*Queensland Government, Australia*

## INTRODUCTION

E-democracy, defined in this chapter as "the use of information and communication technologies in democratic processes," covers a range of methods by which governments and communities engage with each other. This includes a variety of activities that support public participation in democratic processes, such as electronic voting, online consultation, Web-based discussion forums, electronic petitions to Parliament, using the Internet to Webcast parliamentary debates, and digital polling and surveys.

E-democracy is a fairly recent and evolving field, with rapid developments at both practical and conceptual levels. Innovative projects and initiatives are being introduced in many different countries, but this process is rarely guided by a comprehensive policy framework or informed by systematic evaluation. In 2001, an OECD review concluded that "no OECD country currently conducts systematic evaluation of government performance in providing information, consulting and engaging citizens online" (OECD, 2001 p. 4).

Writers in the field have noted that the evaluation of e-democracy initiatives has not developed as quickly as public debate about the potential impacts, that evaluations are rare to date, and that there is no consensus on appropriate evaluation methodologies (Grönlund, n.d.). Examples of publicly available evaluations include the Scottish e-petitioner system (e.g., Malina & Macintosh, n.d.; Malina, Macintosh, & Davenport, 2001) and online consultation (e.g., Smith & Macintosh, 2001; Whyte & Macintosh 2000, 2001). Macintosh and Whyte (2002) have produced "a tentative interdisciplinary framework of evaluation issues and criteria" for electronic consultation. An OECD report (2003) lists evaluation issues for online engagement. However, overall there are few resources to guide evaluation in the e-democracy area to date.

## BACKGROUND

The government of the State of Queensland (Australia) is internationally acknowledged as having a particularly active e-democracy agenda and has trialed and evaluated a number of digital democracy initiatives. These initiatives were introduced within the context of an explicit e-democracy policy framework and subsequently evaluated under a comprehensive evaluation framework. The case study below sets out this evaluation framework.

## CASE STUDY: QUEENSLAND'S E-DEMOCRACY EVALUATION FRAMEWORK

The evaluation framework described in this case study provided for an assessment of Queensland's overall e-democracy policy, as well as individual initiatives (such as online consultation and e-petitions) introduced under the overarching policy framework. It takes into account evaluation dimensions of effectiveness (the extent to which designated objectives are achieved), appropriateness (to the particular policy and operating environment), equity of access, quality of service, efficiency, sustainability, and process enhancement.

### Evaluation Context

Given the emerging nature of e-democracy and its underlying knowledge base at this time, there is no definitive set of evaluation criteria or widely acknowledged outcome standards applied across the range of e-democracy initiatives being introduced worldwide. This evaluation framework is grounded in generic evaluation dimensions relevant to reviewing government programmes, for example,

national performance standards for provision of government programs in Australia (e.g., SCRGSP, 2004) and acknowledged policy good practice dimension (e.g., Henderson, 2000). However, the evaluation framework also allowed for a reasonable level of flexibility, so that emerging needs of decision-makers and implementers could be incorporated.

E-democracy provides additional avenues for participation and is not a complete answer to disengagement. Because is limited by many of the same factors as other engagement processes that are not specific to the medium (such as public disinterest or declining levels of trust in elected governments) success needs to be considered in this context, that is, what e-democracy contributes or value adds above traditional engagement processes. The evaluation framework therefore assessed outcomes relative to off-line processes rather than against a standard of full engagement.

Examining the success of e-democracy initiatives means taking the views of diverse stakeholders into consideration, including individuals and organisations in the community who have used it, those for whom it is relevant but who have not used it, providers of the service, key decision-makers, and other influential individuals and agencies with an interest in the process or its outcomes. The evaluation framework is built around input from multiple sources, including users, community non-users, and key informants such as the officers responsible for its delivery or accountable for its outcomes.

## Evaluation Purpose

The evaluation framework provides for a variety of purpose, specifically to:

- Assess the extent to which specific e-democracy initiatives meet their objectives and contribute to outcomes of the wider e-democracy policy framework
- Examine whether e-democracy initiatives provide an appropriate and sustainable approach in the Queensland context
- Assess the extent to which current e-democracy initiatives increase access among those in the community not reached by traditional engagement methods
- Determine the level of user and stakeholder satisfaction with the quality of e-democracy initiatives
- Assess whether the e-democracy initiatives provide a cost effective approach
- Identify ways in which e-democracy initiatives could be enhanced

## Key Evaluation Questions

- **Effectiveness:** Do the initiatives deliver intended outcomes? To what extent are designated objectives met
- **Equity:** Is there equitable access to the benefits of the initiatives
- **Quality:** What is the level of user and stakeholder satisfaction? Are relevant benchmark standards met
- **Efficiency:** Do the initiatives provide value for money
- **Appropriateness:** Are the e-democracy initiatives appropriate for the Queensland context at this time? Do they provide a relevant response to identified needs and/or opportunities in this area
- **Sustainability:** Do the initiatives provide a durable and generalisable approach to achieving the desired outcomes
- **Process:** How can the current initiatives be enhanced to provide better outcomes

## Information Needs

To address the evaluation questions above requires information on:

- Extent and manner of use (addresses effectiveness considerations)
- Range of users (addresses equity considerations)
- User and stakeholder satisfaction (addresses quality considerations)
- Input costs relative to outputs (addresses efficiency considerations)
- Relevance to need and/or opportunities given Queensland's policy and operating context at this time and the extent to which similar initiatives have resolved these elsewhere (addresses appropriateness considerations)
- Level of stakeholder support and operational/policy barriers to continuity (addresses sustainability considerations)
- User and stakeholder perceptions about design and operation generally (addresses process considerations)

## Information Sources

This information is collected through a range of sources appropriate to the information required, including:

- Statistics obtained from routine operations (e.g., usage rate, user profile)

- User surveys (e.g., to assess satisfaction with process)
- Community survey (e.g., to identify access barriers by non-users)
- Stakeholder/key informant interviews (e.g., on perceptions of relevance, benefits, areas for enhancement)
- Document review (e.g., cost data)
- Research and practice literature review (e.g., to review appropriateness issues, identify benchmark performance)
- Evaluator assessment, informed by diverse information sources (e.g., assessment of extent to which relevant government information standards have been applied, based on an assessment of Web site content, document review and key informant interview)

## Generic Indicator Areas

Generic indicators, measures, and information sources were developed under each of the seven evaluation dimensions. These were designed to apply to an assessment of the overall e-democracy policy as well as providing a basis for the development of specific indicators for evaluating individual e-democracy initiatives.

## Specific Indicators: Online Consultation

Each of the generic indicator areas under the evaluation dimensions is supported by specific indicators targeted at the particular e-democracy initiative being evaluated, taking into account the individual objectives of the initiative that contribute to the overall policy framework outcomes. For example, Table 2 shows the specific indicators used to evaluate Queensland's online consultation process (ConsultQld, see www.getinvolved. qld.gov.au/consultonline), together with the particular measures and sources appropriate for collecting the information for that indicator.

This evaluation approach provided the foundation for an evaluation of Queensland's online consultation initiative, conducted after 12 months of operation. User surveys and key informant interviews were found to work well in establishing the information base for the indicator areas under each evaluation dimension in order to provide a sound and comprehensive evidence base for evaluating this initiative's first year of operation.

# FUTURE TRENDS

The importance of evaluating government programs and activities is widely recognised. In practice, however, evaluation and monitoring often takes second place to implementation and ongoing development. The area of e-democracy is no exception. However, the gap between evaluation and practice is exacerbated for e-democracy programs because of the rapid pace of development and the growing popularity of e-democracy projects internationally. E-democracy initiatives are proliferating, but still, in the main, without a concomitant investment in developing a knowledge base guided by sound evaluation of these initiatives.

*Table 1. Generic indicator areas under each evaluation dimension*

| Evaluation Dimension | Indicator Areas |
|---|---|
| Effectiveness (i.e., in addressing common objectives of providing safe, secure, and efficient ways for engaging that are less limited by accessibility constraints) | • Usage rates<br>• Privacy, information security, and authentication standards met<br>• Nature and level of user concerns<br>• User perceptions on efficiency of use<br>• Access opportunity and self identified access barriers |
| Equity | • User profile<br>• Reason given for using online process |
| Quality | • User satisfaction with process<br>• Satisfaction with quality of content |
| Efficiency | • Unit cost (relative to off-line process) |
| Appropriateness | • Stakeholder perception of relevance<br>• Gap analysis against strategic developments in the field |
| Sustainability | • Level of stakeholder support<br>• Stakeholder perceptions of continuity barriers |
| Process | • User and stakeholder identified areas for enhancement |

*Table 2. Indicators, measures, and sources for ConsultQld evaluation*

| Result Area | Indicator | Measure(s) and Sources(s) |
|---|---|---|
| **Effectiveness*** | | |
| Effective use of avenue (submissions) | Usage rate (submissions) | Operational statistics, in particular: average number of online submissions received per issue (relative to number of paper submissions); and number of online consultations activities registered (as a proportion of total public consultations over the evaluation period) |
| Safety and security | Privacy standards met | Extent to which Queensland government privacy standards are fully complied with, based on independent evaluator assessment, informed by document review and key informant interview |
| | Relevant Queensland information standards fully met | Extent to which other Queensland information standards are fully complied with, based on independent evaluator assessment, informed by document review and key informant interview |
| | Authentication issues resolved | Stakeholder perceptions of nature, extent and impact of authentication concerns (key informant interview question) |
| | Other issue concerns, e.g. information misuse and defamation | Stakeholder perceptions of nature, extent and impact of other issues identified (key informant interview question) |
| | nature and level of user and general community concerns | User survey question e.g., "Did you have any concerns about personal privacy or security in using ConsultQld?"; response to general community survey question such as "Do/would you have any concerns about making an online submission?" with pre-coded responses e.g., "security of information,", "privacy," "other," with responses disaggregated by users/non-users; follow-up question on extent of concern and whether this would prevent the person using ConsultQld in the future |
| Efficient use | User perceptions | User survey question e.g., "Did you find ConsultQld easy and convenient to use?"; content analysis for comments re cost/ convenience issues of open-ended responses to process questions below and to "additional comments" question |
| Inclusiveness | Target group participation | Operational statistics, in particular: for submissions made by individual persons, number of submissions disaggregated by place of residence (home postcode), gender, age, indigenous/ethnic community affiliation, disability, and prior engagement activity level; for submissions made by organisations, number of submissions disaggregated by location (postcode), type of organisation, and community group being represented; relative to similar analysis of paper submissions |
| | Reason given for using online process | User survey question e.g., "If online submissions weren't available, would you have made a written submission on this issue? If not, why not?" with pre-coded response e.g., lack of time, have a disability that makes it more difficult, etc |
| | Response rate | Proportion of online consultations complying with established feedback standards and processes |
| | Timeliness of response | Average time between end of consultation period and posted government response (relative to off-line processes) |

*Table 2. Indicators, measures, and sources for ConsultQld evaluation (cont.)*

| | | |
|---|---|---|
| | Adequacy of response | User survey question e.g., "Were you satisfied with the feedback provided on the site about the outcomes of the consultation?" and reason for satisfaction or dissatisfaction |
| Effective use of avenue (information) | Usage rate (information) | Operations statistics, in particular number of unique visitors to the site, disaggregated by relevant type of user (e.g., community or government sector user) |
| User knowledge base | Self-identified knowledge increase | User survey question e.g., level of agreement to a statement like "Accessing the site has increased my awareness of consultation opportunities and processes" disaggregated by type of user (e.g., community or government sector) and by first time and repeat users |
| **Equity** | User profile | User breakdown by target group characteristics e.g., age, geographic location, etc |
| | Self-identified access barriers | General community survey question e.g., "Is there anything that prevents you from making an online submission if you wanted to do so?"; with pre-coded responses eg limited computer access, cost of Internet use, literacy skills, etc |
| **Quality** | User satisfaction with process (those making submissions) | User survey question e.g., "Overall, how would you rate the quality of the online consultation process?" with open-ended follow-up question as to why |
| | User satisfaction with process (by those receiving submissions) | Key informant level of satisfaction with process |
| | Satisfaction with quality of content | Key informant perception of level of informed content in submissions submitted electronically (relative to off-line processes) |
| **Efficiency** | Cost effectiveness | Unit cost to government per e-consultation (relative to off-line process), based on independent evaluator analysis, informed by document review and key informant interview |
| **Appropriate-ness** | Relevance, given Queensland policy and operational context | Stakeholder perceptions of relevance, based on independent evaluator assessment informed by key informant interview |
| | | Gap analysis against strategic developments in online consultation in the field, based on independent evaluator assessment, informed by international literature review |
| **Sustainability** | Stakeholder support | Level of key stakeholder support, based on independent evaluator assessment informed by key informant interview and document review |
| | Operational and/or policy barriers to continuity | Stakeholder perceptions of continuity barriers, derived from key informant interview |
| **Process** | User perceptions | User identified areas for enhancement of online consultations and positive/negative aspects e.g., "Was there anything you found particularly useful about ConsultQld?"; "Was there anything you found particularly unhelpful about ConsultQld?"; 'How could Consult Qld be improved?' |
| | Stakeholder perceptions | Stakeholder identified areas for enhancement of online consultations, derived from key informant interview |

*Table 2. Indicators, measures, and sources for ConsultQld evaluation (cont.)*

* *In addressing the designated objectives for ConsultQld i.e., effectiveness result areas 1-3 relate to the first objective of "to provide an additional avenue for the public to engage in the Queensland government's decision-making processes that is safe, secure, efficient and readily accessible"; the result areas of "inclusiveness" relates to the second objective of "to open up the Queensland government's decision-making process to those who may not be reached through traditional consultation methods," result areas 5-7 relate to the third objective of "to increase the transparency of consultation processes through the publication of consultation responses and the commitment to publish a government response after the consultation activity has closed," and the final two result areas under effectiveness relate to the third objective of "to provide a central location where the public can learn about consultation opportunities of which they may otherwise have been unaware".*

## CONCLUSION

E-democracy is a rapidly evolving and increasingly widely adopted component of digital interaction between governments and their citizens. However, the proliferation of projects and developments in this field is not being guided by a comprehensive body of knowledge about what works and what doesn't work and under what circumstances. Building systematic evaluations into program development provides a process for establishing this much-needed knowledge base. The Queensland case study provides an example of an evaluation framework designed specifically for e-democracy policy assessment and review of specific e-democracy initiatives.

## KEY TERMS

**E-Democracy:** The use of information and communication technologies in democratic processes.

**E-Petition:** A petition (that is, a signed statement from a person or group of people making a formal request to Parliament about a particular issue or law) published on the Web before being formally lodged.

**Online Consultation:** Use of the internet to facilitate a process of discussion between those proposing a course of action and those likely to be affected by those actions.

**Policy:** Authoritative statements of general applicability establishing intent or planned action by governmental entities.

**Public Participation:** The involvement of citizens in governmental decision-making processes and activities.

# E-Voting in the United States

## INTRODUCTION

Many aspects of government have seen improvements in reliability, customer interface, speed, and cost as a result of digital innovations. In some jurisdictions, the most antiquated aspects of government are the voting technologies used during elections. Such technologies are expensive and used infrequently, which discourages public investment in updates. However, in close elections, any unreliability in these technologies can have a major impact on who takes control of government. The 2000 U.S. Presidential election hinged on the state of Florida, where antiquated punch-card voting machines, combined with poorly designed ballots and unclear recounting standards, were blamed for a high degree of uncertainty during a drawn-out recount process.

This chapter looks at the growing adoption of e-voting in the form of direct recording electronic (DRE) machines in the U.S. following the 2000 election. Lawmakers enthusiastically endorsed the concept of e-voting with only a limited understanding of the risks involved. E-voting can be implemented in a number of ways—with or without a printed paper ballot, with open or proprietary software—that affect some of the risks associated with it. But some theorists of complex systems and many computer security specialists warn that any complex technology like e-voting machines are prone to failure and should not be trusted to count votes. A loosely coordinated online protest movement offered the argument that election reformers were moving too fast. E-voting since has received negative press coverage, which, in some cases, has slowed down the adoption of or led to additional requirements on the use of DREs.

## BACKGROUND: THE POTENTIAL OF E-VOTING

In the aftermath of Florida, e-voting machines seemed the obvious choice to move election administration into the 21st century. The media pointed to the outdated nature of most election technologies across the country, and many state governments worried that they would be the next Florida. Since elections are administered primarily by state and local governments, there are a variety of election technologies in place, driven largely by the size, resources, history, and preferences of the different counties and townships. These different options include the following:

- **Paper:** Voter marks preference next to printed list of options and drops ballot into sealed box; ballots are counted manually.
- **Levers:** Voter pulls lever next to candidates name; machine records and tallies record.
- **Punch Cards:** Voter uses computer-readable card to mark vote by punching hole into numbered boxes indicated by a ballot booklet or directly onto a ballot card. Computerized tabulation machine reads votes by identifying holes in the ballot.
- **Optical Scanning:** Voter marks computer-readable paper ballot; computerized tabulation machine tallies votes.
- **DREs:** Voters select candidate listed on a computer screen by touching the screen or button directly. Votes are tabulated on a computer.

The last two options are the most reliant on digital technology and the most recent. Up until the 2000 election, about half of jurisdictions used either paper, punch card, or lever. More than 40% used optical scans, and less than 9% used DREs (Caltech/MIT Voting Technology Project, 2001a). Since 2000, DREs have been a popular choice for new systems, and it is estimated that almost one-third of votes in the 2004 elections were counted by a DRE (Seelye, 2004).

The process of voting with a DRE begins when the voter arrives at the polling station and is given a memory card to insert into the machine. Voters select from a touch-sensitive screen or parallel button the candidate of their choice. The votes are tabulated internally by the machine and reported to a central counting station. In the aftermath of Florida, DREs seemed an ideal choice. They claimed to record each vote perfectly and do away with the slow and potentially subjective recounts featuring pregnant, dimpled, or hanging chads. DREs had other advantages: they were user-friendly, reported votes more quickly, prevented voters from voting for more than one candidate in the same race, and reminded voters if they had not voted in a particular election. DREs also offered to help the visually impaired through the use of larger screens and

earphones, prompting support from representatives of the disabled. DREs gave the ability to present the ballot in different languages at little additional expense, which facilitated diverse voting populations.

The effect of Florida brought the usually non-contentious issue of election administration to the top of the policy agenda. The perceived weaknesses of the traditional decentralized election system prompted greater federal-level involvement. In October 2002, the federal government passed the Help America Vote Act (HAVA), which provided federal funding for the replacement of older machines and required that new machines allow for disabled access, which had the effect of promoting e-voting machines.

## E-VOTING CONCERNS

Given the advantages of e-voting, it may come as somewhat of a surprise that a number of scholars and commentators, led by computer security specialists, began to raise qualms about its adoption. Three criticisms were made (Moynihan, 2004). The first was that DREs did not count votes as reliably as most alternative technologies. The second was that the reliance on software created the potential for error or tampering. The third was that DREs are currently designed so that such errors are unlikely to be caught or remedied.

A survey by the Massachusetts Institute of Technology and Caltech (2001a) found that in 2000, DREs had higher instances of residual votes (1.6%) than hand-counted paper (1.3%) and optically scanned ballots (1.2%). Residual votes are votes that are lost because voters choose more than one candidate, create an unreadable ballot, or leave a blank ballot. The residual vote is the traditional measure of voting system reliability. It might be expected that as DREs develop better user interface and as voters become more used to them, this rate of error is likely to decline.

The more serious criticisms have to do with the reliance on software, its proprietary nature, and the absence of voter-verified paper votes. Software tends to be complex. Computer security specialist Bruce Schneier (2000) points out, "Even a simple computer program has hundreds of thousands of lines of computer code doing all sorts of different things. A complex computer program has thousands of components, each of which has to work by itself and in interaction with all the other components" (p. 6). More than alternatives, DREs in the U.S. rely on complex software to create user interface and to count the votes. DREs, therefore, can be considered complex systems. Systems theorists, especially Charles Perrow (1999), warn of the tendencies of high-risk complex systems to fail. Perrow's (1999) natural accident theory argues that the central problem of complex systems is that they make accidents inevitable. Errors in multiple parts of complex systems can lead to dramatic and unexpected system failure. The potential for failure increases when the complexity occurs in tightly coupled systems that have the potential for unpredictable feedback loops. System failure, therefore, occurs not as a result of predicted vulnerabilities but as a result of errors occurring and interacting in unexpected ways.

These concerns are echoed by many computer security specialists, who point out that computer systems have bugs that can cause them not to malfunction and stop but, instead, to continue running and behave in ways unintended by designers. In the case of voting, DREs may appear to count votes but may do so incorrectly. There is federal and frequently state testing of DREs machines, but the testing process is opaque. Testing labs are paid by the vendors rather than the government and do not provide information about the nature of the tests or the credentials of the testers (Harris & Allen, 2004). The federal standards against which the machines are tested were revised in 2002 but have been criticized for failing to test commercial, off-the-shelf software used in DREs and because they remain "notably weak in the areas of secure system design and usability" (Mercuri & Neumann, 2003, p. 37). More generally, prevention that relies on verification is always problematic, since testing is imperfect and will miss bugs that inevitably occur in complex software. "Testing for every known weakness is impossible. … Testing for all possible weaknesses means testing for weaknesses that you haven't thought of yet. It means testing for weaknesses that no one has thought of yet; weaknesses that haven't even been invented yet" (Schneier, 2000, p. 337).

In the U.S., election systems are provided by private-sector vendors. The oligopoly of three firms that dominate the market for DREs has reduced further the transparency of the software. Vendors use proprietary software, which means that, apart from outside testers, no members of the public can view the underlying computer code. The vendors argue that they have a commercial interest in maintaining the secrecy of their product and that such secrecy reduces the potential for hackers to introduce bugs into the system. This security-through-obscurity approach has been criticized by security specialists as being outdated; it lost credibility when a copy of the source code of one of the primary vendors, Diebold, became available on the Internet. Computer security specialists at Johns Hopkins University and Rice University undertook a line-by-line analysis of the source code, which revealed several vulnerabilities within the software and led them to conclude, "The model where individual

vendors write proprietary code to run our elections appears to be unreliable, and if we do not change the process of designing our voting systems, we will have no confidence that our election results will reflect the will of the electorate" (Kohno, Stubblefield, Rubin & Wallach, 2003, p. 22). The credibility of Diebold and e-voting machines was called into question further when it was found that employees in California and Georgia, in violation of election laws, had introduced untested patches shortly before the election in order to cover problems in the software and did not tell authorities. As a result, the California Secretary of State cancelled the use of Diebold machines in the 2004 election.

An alternative to the current model of proprietary software exists. In Australia, officials have employed an open-source approach to software. The source code was designed by a private company to the specifications of public officials and then posted on the Internet so that any citizen could comment on it. Changes were made to the code as a result of feedback, and the final code was verified by an independent auditor. The principle of open-source software is that transparency encourages designers to avoid errors in the first place and allows members of the public to spot and warn of any problems that continue to exist.

The U.S. also might learn from abroad when it comes to finding an appropriate level of complexity in e-voting technology. India's e-voting machines were implemented without major criticism and cost less than 10% of DREs in the U.S. The key to India's e-voting machines' low cost and relative security is that they are much less complex and, indeed, are little more than adding machines that shut down if anyone tries to tamper with them. The software is simple and embedded onto a microprocessor that cannot be reprogrammed. The software required to run U.S. DRE machines is necessarily more complex, as it must work with a Windows operating system, encryption, touch screens, backup servers, voice-guidance systems, modems, and PCMCIA storage cards (Weiner, 2004).

The proprietary nature of the software and the secrecy of the testing system in the U.S. have sidelined the potential for citizen involvement in the electoral process to act as a safeguard against error or electoral fraud and has not helped public trust in electoral technology. In September 2004, 42% of respondents in a national survey expressed concern about potential vote tampering in DREs, and 38% were worried about the vote-counting accuracy of the DREs (United Press International, 2004). The results are indicative of a broader lack of confidence in elections systems. The Commission on Federal Election Reform (2005) cited public opinion polls that showed that the majority of Americans were not confident that their votes would be counted accurately. Other polls have shown that 86% of Americans agree that "we clearly have a major problem in the way that votes are cast and counted and this needs to be fixed" (Moynihan & Silva, 2005, p. 32).

Initially, criticisms of DREs came mainly from computer security specialists and some investigative reporters, notably Harris (2004), who maintained linked Web sites, organized online petitions, and documented cases of apparent e-voting problems around the country. Eventually, the news media started to cover the issue, especially as states began to adopt DREs and found problems. The *New York Times* ran an editorial series that was critical of DREs and urged adoption with greater safeguards. The most frequent reform suggestion was to add printers that provided a voter-verified paper audit trail (VVPAT) to DREs.

The proposal for VVPATs reflected another system oversight of most DREs. Schneier (2000) argues that computer systems should be designed on the assumption of failure and should incorporate safeguards that warn of and seek to remedy the failure. But DREs are designed on the assumption that they will record votes perfectly and that there will be no controversy that requires a recount. Therefore, they do not have a basis upon which it can be determined if the machines miscount the vote. DREs maintain an internal tabulation of votes received that can be retrieved, but these totals are not verified independently and may reflect any error that is occurring in the machine.

VVPATs would enable a recount if a machine were unable to tabulate a vote or if its vote totals were suspect. Voters could assess whether their votes were reported accurately by the computer, making them able to alert poll workers if the machine was not recording correctly. The paper votes, once verified, then would be deposited in a ballot box to be reviewed, if necessary. Recounting paper votes could be done more quickly by including a barcode on the printed paper that would enable another tabulating machine (produced by another manufacturer) to count the paper votes automatically (Mercuri, 2002). This would allow large-scale cross checks of DREs and paper ballots. The use of encryption could ensure further the secrecy and security of the ballot, while allowing for multiple verifications of the process (Chaum, Ryan, & Schneider 2004).

Opponents of VVPAT verifications argue that they are costly and unnecessary. VVPATs also add another layer of complexity to the voting process (if, for example, printers break down), and are less accessible for visually or motor impaired voters at a time when HAVA requires election officials to ease disabled access. Finally, VVPATs create a potential for the old-fashioned stuffing of ballot boxes. Despite these concerns, by 2005, 25 states had required VVPATs for the 2008 election, with 15 states

using the VVPAT as the official record of the vote for recounts. Another 14 states had proposed legislation to adopt VVPATs (Electionline, 2004).

## THE FUTURE OF E-VOTING

E-voting is certainly not a U.S. phenomenon. Many other countries have adopted or are piloting e-voting machines, including countries as diverse as Venezuela, Brazil, India, and Australia. The U.S. experience offers some lessons, but generalizing from any single case is always risky, and the experience with e-voting has varied in other countries.

Outsiders looking at the U.S. experience might reasonably conclude that the problems are not so much with DREs but with the manner in which e-voting has been adopted. There are different aspects that shape how e-voting systems are used. The political aspect shapes who has authority to select and to oversee voting systems and the role and requirements of private vendors. Political traditions and characteristics in the U.S. have shaped how elections are run, most notably a cultural distrust of centralized government control of any function, a traditional deference to state and local governments, and private provision of election systems. The problems with older voting systems in the 2000 presidential election and the subsequent controversy over DREs have amended these political dimensions somewhat, creating federal standards for voting systems with many states requiring vendors to provide VVPATs. However, some of the basic problems associated with DREs (i.e., proprietary software) reflect basic political differences between the U.S. and other countries that have adopted a more central role for government in e-voting.

Technical aspects of election systems relate to the choice of an operating system and interface, and procedural aspects shape staff training, machine audits, and the practices governing the control, use, and storage of machines. Proponents of e-voting elsewhere can and, in cases such as Australia and India, have done things differently than the U.S. to ensure that DREs are more secure and that the public has a relatively high level of confidence that votes will be counted accurately. Some of the lessons from the U.S. case are as follows:

- Proprietary software that relies on a security-through-obscurity approach should be avoided; a carefully run open systems approach will foster greater transparency by involving qualified members of the public to assess software.
- Less complex e-voting systems can reduce the potential for errors to occur and can make the technology underlying the system more understandable to the public.
- Creating a voter-verified paper trail requires additional expense but provides a badly needed source of independent verification that will spot errors and increase citizen confidence in the voting process.
- A uniform testing system is desirable, with clear standards, testing procedures, and high-capacity independent testing labs paid for by the government.
- A number of more minor suggestions have been made to reduce further the potential for error (Caltech/MIT Voting Technology Project, 2001b). These include moving toward a more simple and secure tabulating mechanism, one separated from the more complex user interface part; removing the test status of DREs, eliminating the chance that there will be differences in the DRE actually tested and the one employed on election day; and frequent and random audits of machines beyond disputed elections.

It remains to be seen whether the U.S. will learn these lessons, although there has been progress on the issue of VVPATs. More daunting is the prospect of moving away from the proprietary nature of the source code software and asserting more direct public control. The dominant private vendors have successfully organized to resist this change. Pessimists argue that even with such changes in place, elections are too important to be trusted to technology that can be manipulated and may be mismanaged. Failure of DREs has dramatic consequences for democracy, unlike failure in other aspects of digital government. While the crashing of government Web sites might be an unfortunate inconvenience, it does not threaten the sanctity of the democratic process. If accidents in complex, high-risk systems are as inevitable as Perrow's (1999) natural accident theory suggests, DREs should be shelved indefinitely. The adoption of DREs is especially risky in countries that have a weak civil society, lack an independent press, an authoritarian government, and a weak capacity to adequately test machines. Such conditions provide a scenario where elections could be rigged without the ability of independent election monitors to identify where the transgression occurred.

## CONCLUSION

For future research, one avenue that demands investigation is why election officials were willing to adopt e-voting, even as criticisms came to light. This requires the surveying of election officials about their understanding of the risks and benefits of competing election technologies and about the additional factors they considered when choosing it. A similar survey of the general public

would offer insights into how well-informed the public is on this issue as well as the degree of trust it has in the new technology. Such surveys would take on additional value if done longitudinally, as researchers could observe how attitudes change as election officials and the public become more familiar with e-voting. Another challenge for researchers is the traditional reliance on residual votes on any examination of the relative performance of different voting systems. Since e-voting machines could malfunction without generating any residual votes, this standard is inadequate to reflect the risks of e-voting.

## KEY TERMS

**DRE:** Direct recording electronic machines require voters to select their choices on a touch-sensitive screen or parallel button at a polling station or kiosk. The votes are internally tabulated by the machine and reported to a central counting station.

**E-Voting:** This generally refers to the process where the voter inputs their vote on a computer, and the vote is tabulated by the computer. In this chapter, e-voting refers to the use of DREs, but others have referred to voting using the internet as a form of e-voting.

**Natural Accident Theory:** System theorists argue that accidents in complex systems are inevitable because of the unanticipated way that errors occur and interact with one another.

**Open-Source:** In contrast to proprietary software, open-source software can be viewed, and improved on, by members of the public. Australia uses an open-source software approach for elections.

**Proprietary Software:** Software maintained by private vendors where members of the public are prohibited from viewing the underlying computer code. DRE systems in the U.S. use proprietary software.

**Residual Votes:** Votes lost because voters chose more than one candidate, created an unreadable ballot, or leave a blank ballot. The residual vote is the traditional measure of voting reliability.

**VVPAT:** Voter-verified paper audit trails are generated by printers attached to DREs. They provide a printed summary of the voter's choice which the voter can confirm before completing the voting process.

# Exploring E-Government Benefits and Success Factors

## INTRODUCTION[1]

Over the last decade, information technologies (IT) have been considered one of the most influential ways to change organizations (Davenport, 1993; Ho, 2002; Laudon & Laudon, 2003). As early as 1986, Bozeman and Bretschneider suggested that different principles should be used when managing IT systems in public and private sector organizations (Bozeman & Bretschneider, 1986; Melitski, 2003). However, in a review of the literature, Rocheleau and Wu (2002) concluded that there remain a limited number of empirical studies that investigate whether there are differences between public and private sector organizations. Therefore, the research to-date about e-government is situated within multiple debates and draws from literature studying both public and private organizations.

In fact, there is also no clear consensus about the concept of electronic government. Descriptions are emerging. For example, Holden, Norris, and Fletcher (2003) reviewed the range of definitions other authors have proposed for e-government, and suggest there are some common elements. They mention

*e-government is or will become electronic and not paper based and may include the Web, e-mail, fax, telephone, or other electronic means of providing information and delivering services; available 24 hours per day, 7 days per week; and the provision of information and the delivery of services (of varying types and degrees of complexity and integration).* (p. 327)

## BACKGROUND

There is another debate in progress about the benefits and consequences of e-government among academics, practitioners, and within the populace. Historical evidence suggests that IT investments in government over the last couple of decades have increased significantly. Similarly, a growing body of literature continues to study the impact of IT investment and use on the performance of public organizations (Lee & Perry, 2002). However, some commentators believe that information technology, specifically electronic government, has not accomplished the promise of a more efficient, effective, decentralized and democratic public administration (Garson, 2004; Kramer & King, 2003).

Theoretically thus far, there have been two dominant approaches to understanding electronic government benefits and success factors. The first emphasizes the transformational power of information technologies and their impacts on organizational structures and outcomes. In this tradition, findings suggest clear and positive effects from using information technologies in organizational settings. A vast corpus of research is dedicated to identifying and analyzing these potential benefits (Dawes, 1996; Moon, 2002; OECD, 2003; O'Looney, 2002).

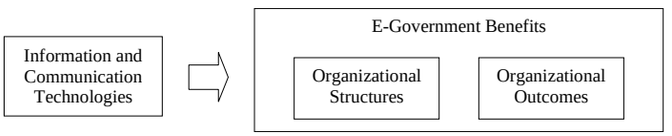
The second approach reflects on the impact of organizational, institutional, and contextual factors regarding the selection, design, and use of information technologies (Caffrey, 1998; Dawes & Pardo, 2002; Garson, 2003; Landsbergen & Wolken, 2001; Laudon, 1985; Pardo & Scholl, 2002). This academic tradition seeks to understand how different factors affect or shape the resulting information technology and subsequently, the resulting organizational outcomes as measures of IT success.

The first approach deals mainly with the impacts of IT on organizations and places emphasis on potential benefits (see Figure 1). The second perspective is more interested in identifying and analyzing different success factors and evaluating their importance for IT projects (see Figure 2). The two approaches are clearly related and complementary and important for understanding the e-government phenomenon (Gil-García, 2005). Both perspectives have contributed to our current understanding and the following sections present some of their main findings.

## BENEFITS OF E-GOVERNMENT INITIATIVES

Some authors note the tremendous positive impacts that information technology initiatives can have on govern-

*Figure 1. Characterizing e-government benefits (adapted from Gil-García, 2005)*



ment organizational structures and functions (Barrett & Greene, 2000; Brown & Brudney, 2003; O'Looney, 2002). Others suggest, "at least potentially, IT involves the transformation of the organizational culture of the government." (Schelin, 2003, p. 125). Another approach is Garson's decentralization-democratization theory where he states, "for democratization theorists, in the wake of the information revolution comes decentralization, because IT allows dramatic broadening of the span of control, and democratization, because knowledge, which is a critical basis of power, is also dispersed by IT." (Garson, 2000, p. 592).

## Benefits as Outcomes Only

Benefits from information technology initiatives can be seen as being only the final outcomes from their use. In this view, benefits such as service quality, efficiency, or effectiveness seem to derive directly and almost automatically from the use of information technologies in organizations. These benefits are considered "the reasons for embracing e-government as a means of reforming public management and contributing to broader policy objectives." (Ho, 2002; OECD, 2003, p. 28).

### Improvement of Service Quality

The goal of improving service quality was found in all the e-government policy statements examined in a recent international study (OECD, 2003). Customer-orientation is one of the most important ways in which governments have attempted to improve the quality of the services they provide to businesses and people. E-government initiatives have the potential to deliver better services. However, some problems of access diminish this potential (Garson, 2004). There are still some social groups that cannot enjoy the benefits of electronic services, or that cannot meaningfully obtain value from them (Mariscal, 2003; Norris, 2001; Warschauer, 2003).

### Efficiency and Cost Reduction

"ICT use in government has often been driven by the need to reduce the call on resources, either to reduce overall spending or to allocate funds to higher priority areas." (OECD, 2003, p. 29). Many of the e-government initiatives that are closely related to efficiency can be grouped in the e-management component of e-government. Most of the examples mentioned by the OECD (2003) fall in this efficiency category, such as payment processes, procurement, payroll, and human resources management. However, some initiatives that were considered cornerstones of the cost-savings promise such as e-procurement, have performed poorly or even been abandoned (Garson, 2004).

### Increased Policy Effectiveness

Policy effectiveness is a recently identified benefit of e-government. In the past, information technologies were mostly related to cost savings and service quality. However, "… there is an increasing awareness that e-government initiatives can also help achieve important outcomes in major policy areas such as health, education, anti-crime initiatives, and security" (Brown & Brudney, 2003; OECD, 2003, p. 37).

### Active Public Participation and Transparency

More in some countries than in others, e-government initiatives are also seen as promoting accountability and public participation. The relationship between governments and citizens involves many very important social and political factors. For instance, e-democracy initiatives do not refer only to online voting, but also to communication exchange between elected officials and citizens (Davis, Elin, & Reeher, 2002). However, electronic channels have been used by people who are not representative of the citizens' interests and politicians have noticed that these forums are not very helpful for their reelection purposes (Garson, 2004).

## Benefits as Organizational Structures and Outcomes

Potential benefits from the use of information technologies are not only final outcomes, but also transformations in the organizational structures and the interactions among

individuals in those organizations. According to Kraemer and Dedrick (1997), "the spread of computing technology has had a major impact on how work is done, how decisions are made, how organizations are structured, and how people interact." (p. 94).

In the literature, several benefits have been associated with information technology initiatives, such as increased productivity, improved decision-making, decentralization, reduced costs, increased revenues, and integrated services (Danziger & Kraemer, 1985; Roldán & Leal, 2003). Benefits of information technologies differ from organization to organization and according to the characteristics of specific initiatives. Dawes (1996) classified benefits in three different categories: technical, organizational, and political. These benefits are a combination of modifications to the current organizational and social structures as well as final outcomes.

## Technical Benefits

The use of information technologies may reduce duplicate data collection, processing, and storage and therefore reduce the heavy paperwork and data processing costs that attend every public program (Ambite, Arens, Bourne, Feiner, Gravano, Hattzivassiloglou, et al., 2002; Barrett & Greene, 2000; Caffrey, 1998). An IT initiative can also promote better standards and shared technical resources (Bozeman & Bretschneider, 1986; Dawes, 1996). System usability, reliability, and accessibility are some other well-known examples of technical benefits (Danziger & Kraemer, 1985; Gant, 2004). This technical quality normally requires additional changes in the organization, such as IT staff reorganization, IT training, and new formal channels of communication between IT staff and other members of the organization.

## Organizational Benefits

Organizational benefits are benefits related to the solution of organization-wide problems or the enhancement of inter-organizational capabilities (Dawes & Pardo, 2002; Gant, 2004; Lee, 2001). Improving the decision-making process, broadened professional networks, better coordination, high quality services, and cost reductions are some examples of organizational benefits (Andersen & Dawes, 1991; Kuan & Chau, 2001; Roldán & Leal, 2003). In the literature organizational benefits are treated separately but complementary to technological and political benefits (Stowers, 2004; Swiss, 2003). Most organizations need to modify their business processes, internal rules, channels of communication, and hierarchical structures, in order to obtain certain final outcomes from IT projects.

## Political Benefits

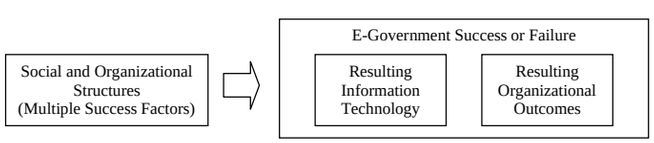
These benefits deal with broader public-interest areas. Better appreciation for government-wide policy goals, more public accountability, more comprehensive public information, and integrated planning and service delivery are some examples of this kind of benefit (Andersen & Dawes, 1991; Macintosh, Malina, & Farrell, 2002). In fact, "the development of computing technology has had an important impact on measuring accountability and presenting information to the public." (Rocheleau, 2003, p. 37). Political benefits can also be thought as individual benefits for public officials as a result of the use of certain technology characteristics or applications (Fountain, 2001; Kraemer, King, Dunkle, & Lane, 1989).

Understanding potential benefits is only one part of the research endeavor. Other scholars argue that benefits are not an immediate and direct consequence of information and communication technologies. Social and organizational structures interact with technological properties and the final outcomes (good or bad) are the result of these complex interactions. In the next section, research about different factors that affect information technologies is described and discussed in the context of e-government initiatives.

# FACTORS AFFECTING E-GOVERNMENT STRUCTURES AND OUTPUTS

As was mentioned earlier, there is important research about the impact of organizational, institutional, and contextual factors on the selection, design, and use of information technologies and resulting outcomes (see Figure 2). There is not a clear answer to the question of which factors are the most important in explaining IT success. However, different theoretical views have investigated different factors that are considered relevant to understanding information technology in organizations.

*Figure 2. Characterizing e-government success factors (adapted from Gil-García, 2005)*



## Contextual Factors

The context of organizations includes very important environmental factors. Some of the environment dimensions identified in the literature are (Hall, 2002, p. 204): (1) technological conditions, (2) legal conditions, (3) cultural conditions, (4) political conditions, (5) economic conditions, (6) demographic conditions, and (7) ecological conditions. Scholars in organizational theory have developed different ways to understand the impact of the environment on organizations as well as how organizations attempt to modify their environments (Scott, 1998).

In information systems, researchers have recognized the important role of environmental variables in shaping the way information technology is designed and used in organizations (Kuan & Chau, 2001; Laudon, 1985). Results indicate that some contextual factors such as personnel markets, competition, or politics may affect the results of IT initiatives (Bellamy, 2000; Bozeman & Bretschneider, 1986; Chengalur-Smith & Duchessi, 1999).

## Institutional Arrangements

Institutional factors constrain the way people act in organizational settings. "Institutions do not just constrain options: they establish the very criteria by which people discover their preferences." (Powell & DiMaggio, 1991, p. 11). Therefore, institutional arrangements are important elements in understanding how information technologies are selected, designed, implemented, and used in public organizations. Previous theoretical frameworks have used institutional theory to explain different aspects of information technologies such as adoption, implementation, and management (Bellamy & Taylor, 1996; Butler, 2003; Laudon, 1985).

Government organizations are usually created and operate by virtue of specific formal rules. In making any kind of decision, including decisions about IT projects, public managers must take into consideration a large number of laws and regulations (Dawes & Nelson, 1995; Harris, 2000; Landsbergen & Wolken, 2001). A one-year budget is common in many national and state governments and this type of budgeting affects the strategies and results of a long-term IT initiative (Dawes & Nelson, 1995; Dawes & Pardo, 2002; Fountain, 2001). Additional challenges are posed by the checks and balances system among the executive, legislative, and judicial branches (Bellamy, 2000; Harris, 2000; Rocheleau, 2003). The lack of incentives to collaborate across agencies can constrain IT projects that attempt to integrate or share information across multiple agencies (Caffrey, 1998; Dawes & Pardo, 2002; Fountain, 2001).

## Organizational Structures and Processes

Organizational factors relate to the organization as a whole and some characteristics of the implementation of IT initiatives. These factors can include the length of the project, understanding strategic goals, extent of change in business processes, project management approach, and lack of implementation guidelines (Chang, Gable, Smythe, & Timbrell, 2001; Davenport, 1993; Umble, Haft, & Umble, 2003). The size of the project and the diversity of the users or organizations involved are two important factors in IT initiatives (Barki, Rivard, & Talbot, 1993; Dawes & Pardo, 2002).

There are two other factors related to a project's goals and objectives. The first is the necessary alignment between organizational goals and the IT project (Andersen, Belardo, & Dawes, 1994; Dawes & Nelson, 1995). Second, Dawes & Pardo (2002) have identified the existence of multiple, and sometimes conflicting, goals in the public sector as an additional inter-organizational factor. Most organizations have multiple stakeholders and multiple goals (Hall, 2002). In fact, for some authors organizations are political entities with different groups competing for power and organizational control (Newman & Rosenberg, 1985; Pfeffer, 1992). Many e-government initiatives require the participation of various public organizations. Therefore, the multiplicity of stakeholders and goals is even greater and becomes a difficult challenge.

Finally, individual interests and associated behaviors can lead to resistance to change, internal conflicts, and turf issues (Barki et al., 1993; Barrett & Greene, 2000; Bellamy, 2000; Rocheleau, 2003). Different social actors have different perspectives about the impact of information technologies on their situation within the organization (Klein & Hirschheim, 1983). These contrasting views need to be understood in order to overcome resistance and conflict.

## Data Considerations

IT initiatives are designed to integrate, share, improve, or disseminate information. Several authors have focused their research on data quality and data accuracy issues (Ballou & Tayi, 1999; Redman, 1998). Information quality is very important but is often taken for granted (Brown, 2000). According to Redman (1998), data quality problems are caused by inaccuracies, inconsistencies, lack of timeliness, and incompleteness of data, among other factors. All these factors affect the overall quality of the information technology outcomes. In addition, the use of legacy data for decision support systems presents other challenges in the need for "soft" or judgmental data that is not

normally required for traditional systems and which quality needs to be evaluated (Tayi & Ballou, 1998).

In addition, mismatched data structures, incompatible database designs, and incongruous data and information distribution channels present problems in information sharing initiatives (Ambite et al., 2002; Barrett & Greene, 2000; Umble et al., 2003). Even when the involved organizations use the same kind of data, conflicting data definitions and different terminology will limit the extent of data and information sharing (Ambite et al., 2002; Dawes, 1996). Collaboration and associated information sharing are key aspects of e-government (Cresswell, Pardo, Thompson, Canestraro, Cook, Black, et al., 2002; Dawes & Pardo, 2002; Pardo, Cresswell, Zhang, & Thompson, 2001). Therefore, data-related problems need to be adequately addressed in order to obtain greater benefits.

### Technology Features

Technology incompatibility has been identified as one of the most important challenges to IT-intensive projects (Caffrey, 1998; Chang et al., 2001; Chengalur-Smith & Duchessi, 1999). Complexity and newness of technology are also constraints that can potentially affect the results of IT projects (Barki et al., 1993; Dawes & Nelson, 1995; Garson, 2003). Technology characteristics are very important for the success of IT initiatives in both private and public organizations.

Similar to projects in non-technology areas, human resources are very important. In the case of IT initiatives, the lack of technical skills has been discussed as an important factor in IT initiatives (Dawes & Pardo, 2002; Pavlichev, 2004; Schelin, 2004). The improvement of the design of an existing information system differs greatly from the development of a completely new system. These "legacy" systems present additional challenges (Kelly, Gibson, Holland, & Light, 1999). For example, Duchessi and Chengalur-Smith (1998) reported conversion of mainframe applications as one of the problems associated with implementing client/server technology.

## FUTURE TRENDS AND EMERGING APPROACHES

The two research directions discussed above have generated knowledge about information technology in government. However, e-government initiatives are continuing to increase in complexity and will require both a deep knowledge of the project itself and the environmental and organizational contexts in which it is embedded. Therefore, preliminary consensus continues to build around the idea that e-government problems are about both the complexity of the technology and the success factors related to organizational, behavioral, institutional, and cultural aspects (Caffrey, 1998; Dawes & Pardo, 2002; Fountain, 2001; Garson, 2003; Kraemer et al., 1989). It is suggested that much can be learned from observing these issues in different situational contexts. Comparative research and cross-cultural studies will be very useful toward this endeavor (Dawes & Préfontaine, 2003).

Additional research should also address the two gaps in the literature relevant to e-government success. The first, is conceptual, and is represented by the lack of accord among scholars and practitioners about the definition, characteristics, and benefits of electronic government (Gil-García & Luna-Reyes, 2003; Holden et al., 2003; Schelin, 2003). The second encompasses the lack of integration between the literature on IT success factors and the literature on electronic government and information technology in the public sector. Research in these areas should attempt to draw from both literatures to integrate findings and possibly achieve a better understanding of e-government benefits and success factors.

In addition, most of the academic work to this point has emphasized a linear view of the relationships between different success factors and information technology (Orlikowski & Iacono, 2001). Almost all the factors are hypothesized to have a direct and linear relationship with information technology success, regardless of direction. In current theoretical frameworks, few hypotheses have materialized about indirect effects and potential relationships between the different factors themselves (Fountain, 2001; Kraemer et al., 1989). Future research should hypothesize different relationships between factors, as well as direct and indirect effects on e-government success.

Lastly, emerging perspectives need to broaden the scope of government information technology. Prior research has had a somewhat narrow conception to this point. First, we need to understand e-government initiatives as not only technological artifacts, but also as the social relations around those artifacts including the interactions among social actors and between these actors and the technology (Dawes & Pardo, 2002; Kling & Schacchi, 1982; Orlikowski & Iacono, 2001). These studies should take into consideration elements other than the technology as fundamental to the e-government phenomenon.

Second, early studies reduced the complexity of IT and organizations; in essence, they took for granted the transformational power of information technologies (Kling, Rosenbaum, & Hert, 1998). Either information and communication technologies were seen to have the capability to radically transform organizational and institutional arrangements, or these organizational and institutional factors were seen to profoundly shape the design, implementation, and use of information technologies. Later research has

shown the recursive nature of the relationships between these two constructs (DeSanctis & Poole, 1994; Fountain, 2001; Kraemer et al., 1989; Orlikowski, 1992). Therefore, future research should address this complexity and bi-directional causality as inherent to e-government.

## CONCLUSION

Summarizing, research on e-government benefits and success factors can be greatly furthered in at least four different ways. First, integrating research results from studies about private and public organizations, different cultural and political contexts, and by acknowledging their differences but still taking advantage of the similarities. This is also a call for multi-disciplinary research (Dawes, Gregg, & Agouris, 2004). Second, recognizing the lack of consensus about the concept of e-government and develop clear and useful working definitions. Third, take a more comprehensive view of IT that includes technological artifacts, but also people, physical spaces, and social relationships. And fourth, understanding and including in theoretical models the dynamic and recursive nature of the relationship between social structures and information technologies. It will be the emergent research about these features of e-government benefits and success factors that will lead to both more comprehensive theories and powerful practical implications.

## KEY TERMS

**Customer Orientation:** It is a service perspective in government adopted from the private sector, which suggests that citizens are customers of the government and service quality should be the main concern of government when interacting with them.

**Decentralization:** It is pushing down responsibility (i.e., decision-making, resource allocation, and control) of specific government functions (i.e., planning, management or service delivery) to lower levels of government.

**E-Democracy:** The use of information and communication technologies to increase citizen participation in public decision-making processes.

**E-Government Success Factors:** They are technical, organizational, institutional, and contextual factors that have an influence on the design, implementation, and use of e-government applications.

**E-Government:** It is the design, implementation, and use of information and communication technologies (ICTs) in government settings. Electronic government can also be understood as the selection, implementation, and use ICTs in government to provide public services, improve managerial effectiveness, and promote democratic values and mechanisms; e-government also creates a regulatory framework that facilitates information-intensive initiatives and fosters a knowledge society (Gil-García & Luna-Reyes, 2003, p. 107).

**E-Management:** The use of information technology to improve the management of government, from streamlining business processes to maintaining electronic records, to improving the flow and integration of information.

**E-Services:** The electronic delivery of government information, programs, and services often (but not exclusively) over the Internet including, e-commerce or the electronic exchange of money for goods and services.

**Institutional Arrangements:** They are formal and informal rules that exist in an organization's environment and potentially shape its structures and processes such as laws, regulations, norms, and policies.

**Organizational Structures:** They are formal and informal characteristics of the organizational or interorganizational setting in which an e-government initiative is embedded such as hierarchy, size, resources, relationships, and resistance to change.

**Transparency:** Relates to the openness of government toward exposing administrative processes and decision making, in addition to increasing information disclosure to citizens.

# Extending E–Government and Citizen Participation in Australia through the Internet

**Lucas Walsh**
*Deakin University, Australia*

## INTRODUCTION

This article seeks to provide a brief overview of the current development of digital democracy in Australia, with emphasis on the use of the Internet to extend and enhance citizen participation. Use of the Internet within the definition of digital democracy proposed is categorized into three overlapping groups: (1) e-government services and administration; (2) participatory technologies; and (3) informal modes of participation.

## BACKGROUND

The term "digital democracy" is comparable to virtual democracy, teledemocracy, e-democracy and cyber democracy. Following Kenneth L. Hacker and Jan van Dijk (2000), digital democracy "is the use of … ICT … and computer-mediated communication (CMC) in all kinds of media (e.g., the Internet, interactive broadcasting, and digital telephony) for purposes of enhancing political democracy or the participation of citizens in democratic communication" (p. 1). Digital democracy is defined by the use of electronic information and communications technologies (ICTs) to extend and/or enhance access to information, and facilitate participation in democratic communities, processes and institutions. Historically, this has included the use of radio, telephone, and televisual media, although during the last ten years, interest in digital democracy has shifted to focus on the use of the Internet.

Despite its comparatively small population of just over 20 million, Australia's political system has an elaborate structure consisting of local, state and federal levels of government which seek to democratically represent a culturally diverse and geographically dispersed constituency. Consequently, the use of ICT in governance offers particular benefits in the delivery of government information and services. As the following discussion illustrates, the potential benefits of digital democracy have tended to be recognized at state rather than federal levels of government and parliament.

In terms of Internet access, Australians have a relatively high rate of adoption, although according to at least one estimate, Australia's rate of overall technological access has declined in comparison to other developed nations.[1] By September 2003, more than a quarter of the population (5.2 million) subscribed to the Internet. At the time of writing, the vast majority of Australian users are dial-up subscribers, although this number as a proportion of total subscribers fell below 90% for the first time in 2003, corresponding to an increase in broadband uptake. According to the Australian Bureau of Statistics (ABS), there were over 650,000 broadband subscribers by the end of September 2003. From March to September 2003, Digital Subscriber Line (DSL) subscribers grew by 78% (163,000) (ABS, 2003).

### Government Services and Administration

E-government is the most visible dimension of digital democracy in Australia. The importance of developing Web-based technologies for e-governance has been recognized by virtually all states and territories in Australia (Trinitas, 2002). Initiatives, such as the Queensland government's *e-Democracy Policy Framework* and the Victorian Parliamentary Scrutiny of Acts and Regulations Committee's *Inquiry into Electronic Democracy*, reflect the growing significance of e-governance in enhancing and extending government information networks and administration of services (Parliament of Victoria, 2004).

Email and databases are now used to coordinate organizational activity, daily government and parliamentary work (Gibson, Ward, Römmele, 2004; Grönlund, 2002). Australian citizens have greater access to information and services, ranging from information about taxation to electoral rules, as well as greater access to observe the activities of democratic representatives via the Internet. The Australian Broadcasting Corporation began audio-streaming a Parliamentary and News Network via its Web site in 1998 (Magarey, 1999). Federal parliament has audio-visually Webcast (otherwise referred to as "netcast") its parliamentary sessions and committee hearings for

over four years. By 2003, the Australian federal parliament and certain committee activities were Webcast via several simultaneous channels and attracted around 15,000 hits per week during parliamentary sessions (although viewers tended to consist of lobbyists, the media, and public servants) (Parliament of Victoria, 2002c; Adams, 2003). At the state level, Queensland Parliament has also offered limited audio Webcast services (Queensland Parliament, 2004).

It is at the local government level at which Webcasting perhaps offers the most benefit. Some municipal governments in Victoria and New South Wales have streamed council meetings to provide greater opportunity for community involvement in local government by enabling open access from home, as well as promoting a sense of transparency to council meetings. Citizens watch issues of direct interest to them, such as council discussions about pollution levels in their municipality, or for general educative purposes.

Some Webcasts offer viewers the opportunity to interact directly with representatives. Webcast facilities for council meetings in the Wellington Shire of Victoria, for example, include a chat function through which interested people can pose questions at the end of each meeting. Watching an unedited Webcast also has the advantage over reading a transcript of enabling the viewer to experience the tone and bearing of Members of Parliament (MPs) "live" (Adams, 2003). The capacity of electronic media, such as the Web, to enable greater opportunities for interaction with government and broader political participation is a second, albeit underutilized, dimension of digital democracy in Australia.

## Use of the Internet to Extend Participation and Citizenship

This second category of digital democracy includes a range of electronically-mediated activities in which individuals, groups and organizations are able to *formally* interact in determining the conditions of their political association. Opportunities to vote electronically (e-voting), engage policy development and debate online are examples of this; but note that I use the adverb "formally" to distinguish legitimate modes of participation from informal activities, such as Hacktivism, which are described in the following paragraphs in further detail as a third category of activity.

Use of the Internet to formally extend the scope and capacity for participation is distinguished from the provision of government information and services by adding the element of interactive communication. Van Dijk provides four categories of interactive communication: allocution (e.g., computerized election campaigns, civil service, and information centers); consultation (e.g., Web-based public information); registration (e.g., telepolling or televoting, electronic referenda, and elections) and conversation (e.g., e-mail, bulletin boards, electronic town halls, and discussions) (van Dijk, in Hacker & van Dijk, 2000, p. 40).

The benefits of electronic technology have been recognized by the Victorian Parliament as enabling individuals to engage policy development through improved access to relevant information, more effective methods for the distribution of materials and proposals, and tools for greater collaboration, consensus formation and deliberation free from the constraints of time and space (Parliament of Victoria, 2002a, 2002b, 2002c, 2002d, 2002e). The New South Wales government, for example, sponsors a "Community Builders" network of policy implementation, in which an interactive electronic clearing house is available for community level social, economic and environmental renewal (New South Wales Government, 2005). The Queensland Government has established an e-democracy unit responsible for implementing and managing the government's three e-democracy initiatives to test how information technology can enhance the community's access to government and participation in government decision-making through online community consultation, broadcast of parliament and e-petitions. The *Citizenscape* Web site of Western Australia promotes active participation in involvement in decision-making and informs about citizenship related activities (Department of the Premier and Cabinet Western Australia, 2005).

Electronic networking has also been used to foster community participation to a limited extent at a Federal level. Magarey (1999) provides the example that during a Federal Parliamentary debate on Native Title (concerning the recognition in Australian law that Indigenous people had a system of law and ownership of their lands prior to European settlement):

> *One of the benefits a parliamentary democracy may offer is the possibility that its processes of deliberation may build community and engender civic involvement ... Internet technology arguably contributed to a fulfillment of these broader aspirations for Australian democracy.* (p. 64)

Political parties in Australia increasingly use the Internet to connect with their members, other groups, individuals and other parties. But while political parties appear to be using the Internet to some advantage to build "quite varied and large Web networks around themselves", recent research suggests that they "do more to reach the outside world than it does to reach them" (Ackland & Gibson, 2004, p. 29-30).

Historically, politicians have been reluctant to use ICT to seek greater input into policy development, although data on current trends is difficult to obtain. One study of the Internet and Australian Parliamentary democracy during the late 1990s found that many Parliamentarians did not tend to use the technology to seek public input in the process of policy formation, exhibiting a strong awareness of the limited nature of the audience of new media. Only a few parliamentarians had their own Web pages and negatively associated new media with increased workload. E-mail was not regarded as an "official" medium in the way that hard-copy was; nevertheless, it was perceived as allowing different voices to be heard (Magarey, 1999, p. 58). This attitude may be changing as legislation increasingly recognizes transactions conducted by e-mail (Parliament of Victoria, 2002f).

Electronic voting, "e-voting," is another area in which Australia has yet to develop in a substantial way (Barry, Dacey, Pickering, & Evans, 2002, p. 20). Australia has yet to practically explore anything like the scale of the electronic voting machines used during the 2004 general elections in India (ECI, 2004; Haidar, 2004), nor the complexity of local UK government trials of several different e-voting systems. For example, Liverpool and Sheffield local councils trialed an integrated system of electronic voting and electronic counting of votes during 2002 elections, through which votes were lodged via telephone, Internet, electronic kiosk, mobile phone (SMS) alongside conventional polling stations and post (Barry et al., 2002, p. 5).

While e-voting may be promoted as a means of encouraging greater participation in non-compulsory voting jurisdictions, evidence of this practice is debatable and may not be as relevant to Australia, in which voting is compulsory. While there have been some encouraging uses of the new technology to increase voter participation, such as Done's study of the use of Internet voting in the 2000 Arizona Democratic presidential primary elections (Done, 2003, p. 261), recent studies of e-voting in the UK indicated that providing the facilities to e-vote did not substantially increase voter participation (LGA, 2002, p. 4).

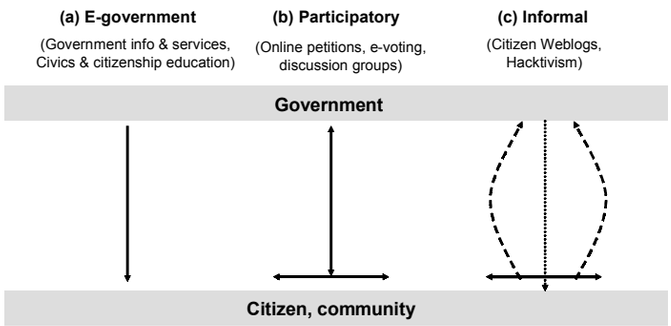
## Informal Participation

A third type of democratic activity concerns informal channels of communication and activism taken using ICT. Examples of these include forms of citizen Weblogging and Hacktivism. Citizen-generated Weblogs reflect a relatively minor but no less significant outlet for individual expression, in which citizens use the Internet as an open forum to express and share their opinions of Australian politics. Australian politicians have also not made use of Weblogs ("blogs") in the ways that politicians such as 2004 U.S. Presidential candidate John Kerry have.

Hacktivism is a more controversial but important dimension of digital democracy. Contrary to their representation in popular media, hackers promote: technical proficiency; a mistrust of authority; that there should be unlimited access to computers; and a firm belief that computers can improve human lives. More importantly, they promote the idea that all information should be free (Levy, 1994). Hackers believe that "information-sharing is a powerful, positive good, and that it is an ethical duty of hackers to share their expertise by writing free software and facilitating access to information and to computing resources wherever possible" ("Jargon File", cited in Himanen, Torvalds, & Castells, 2001, p. vii). "Hacktivism" refers to the combination of hacking and public activism in a deliberate and usually political way. Hacktivism is about freedom of information and freedom of movement in cyberspace. Civil disobedience and protest are important political tools of Hacktivists, who achieved a high level of visibility during the 1990s throughout the world, ranging from attacks on the Chinese government, to NATO's action in Kosovo (Hopper, 1999). There is evidence to suggest that the infamous WANK worm, which in 1989 confronted NASA scientists with the banner: "Worms against nuclear killers," emanated from Australia (Denning, 2004; New York Times, 1999). Some of the first "high-profile" hackers were based in Australia. For example, a loosely formed group known as "The Realm" were responsible for invading several high-profile computer systems in Australia and the U.S. during the 1980s and 1990s. But their largely a-political activities could not be classified as "hacktivist" per se; in fact, their attacks were responsible for the creation of Australia's first federal cyber-crime legislation in 1989 under pressure from the U.S. Government (Anderson, 2003; Dreyfus, 1997).

These informal activities of digital democracy are important because they are concerned with the *control* of information—often in response to the forms of e-government described above. Activities in this area reflect the capacity of technologically proficient individuals and groups to de-center power away from institutionalized forms of democratic dialogue (i.e., through legitimized government channels) and conventional commercial broadcast media, to the micro-level of individual and/or small group behavior. Hacktivism explicitly promotes the decentralization of authority (Levy, 1994). This type of informal political activity is significant because the participants, be they blogger, hacker, and so forth, use the technology for non-institutionalized forms of power; or at the very least, they operate at the margins of institutionalized power, challenging it in both positive and negative ways. But there are two aspects of these informal modes of digital democracy that need to be

*Illustration 1. Basic typology of activities in digital democracy*



acknowledged: firstly, Hacktivism is only one form of online activism and while it is not in itself constitutive of the diversity of networks, organizations and activism that constitute online civil society, it highlights both the importance of collective knowledge sharing and the shifting dynamic of power inherent to new knowledge networks.

A second important issue here is that of *responsibility*. Hacktivists have been criticized for "hiding beyond anonymity or pseudonymity" and not taking direct responsibility for their actions (Fowler, quoted in Hopper, 1999). Furthermore, the distinction between hacker and hacktivist is not always clear. This issue of responsibility challenges whether these informal modes of participation ought to be recognized as "democratic." The blogger, too, is often anonymous and the agenda of Weblogs is often not transparent. It has been observed that while U.S. politicians use Weblogs to promote accountability, this medium may encourage greater use of "spin" (Adams, 2003).

The three overlapping categories of digital democracy described above are summarized in Illustration 1.

Illustration 1 provides a basic summary of the three kinds of activity in the area of digital democracy described above in terms of the types of interactions occurring between government and citizenry. The vertical arrows show the "top-down" and interactive flow of communications between government and the citizenry. The horizontal arrows at the bottom depict communications between citizens and communities. Model (a) "E-government" depicts an essentially top-down approach to the delivery of information and services. Examples of this include information about taxation and civics education. Model (b), "Participatory technologies," shows that interaction is enabled between government and citizenry, as well as between citizens themselves, such as through online policy consultancy or community discussion forums. Model (c) "Informal" illustrates how independent agents, such as hackers and bloggers, bypass formal government channels while seeking to influence decision-making. The curved upwards arrows depict the bypassing of formal government lines of communication and information by independent agents, such as hackers, who seek to influence government decision-making and/or de-center power away from government and other loci of information control.

## FUTURE TRENDS

A significant challenge to the technological enhancement and extension of democratic participation emerges from Australia's distinctive political history. As one of the earliest countries to abolish property qualifications for voting, give women the right to vote and stand for parliament, introduce a universal franchise and hold secret ballots, Australia has an impressive record of democratic innovation and social progress (SLCRC, 1995). Despite this, Australian parliamentary democracy during the latter twentieth century is characterized by a conservatism consistent with Magarey's (1999) study of parliamentarians' attitudes to Web-based technologies described above. She rightly intimates that there is a connection between the lack of "in-depth research into e-democracy," and the poor reception of various efforts to instigate direct democracy in Australia (p. 42).

Efforts to introduce forms of direct democracy to revitalize the popular sovereign (such as Citizens' Initiated Referenda) have been rejected on a number of occasions at both State/Territory and Federal Levels (Davidson, 1997; Walker, 1993). As Davidson (1997) argues, "When we turn to consider international "best practice" concerning direct democracy, Australia continues to lag well behind. The introduction of direct democracy has so far been rejected … despite observations that indicate how particularly apt the technological advance

of information highways make such notions in Australia". The potential role of technology has been absent from debates of the revivification of Australian democracy (pp. 237-240).

The development of digital democracy in Australia will need to move beyond debates in the literature and mass media that equate digital democracy with direct democracy, to "a subtle and complex fusing of elements of direct democracy and new ways of representation" (Hacker & van Dijk, 2000, p. 3). It is interesting to note projects such as the Democracy Project in Denmark and recent digital television experiments of the UK have been developed in response to poor voter turn-outs at elections and a perceived general apathy of citizens (Trinitas, 2002). Similarly, in Australia, research during the last decade has indicated an increasing sense of civic deficit, personal alienation, powerlessness and a declining feeling of community amongst its citizens (Civics Expert Group, 1994; SLCRC, 1995; Walsh & Salvaris, 1998). As the capacity to generate and electronically disseminate information in Australia may be comparable to international best practice, so too is the experience of representative democracy consistent with an "increasing disenchantment on the part of citizens towards many of the institutions and procedures of democracy" observed elsewhere, such as the United Kingdom (Coleman, Taylor & van de Donk, 1999, p. 4). Digital democracy is not only about exploring new processes of governance and formal participation; it is also about how the technology can be used to address attendant problems arising in the politically subjective dimensions of democratic citizenship, in which knowledgeable citizens should as a matter of principle be equipped to participate in the exercise of democratic rights and responsibilities. Beyond merely having access to information, it is necessary for citizens to have access to the skills and resources to be able to use the technology in an informed and effective way to build and enhance sustainable democracy communities. Much of the current interest in digital democracy, however, is largely to do with saving time, increasing accuracy and accessibility in the administration and provision of government services. While an informed citizen is a positive step to revitalizing democracy, an informed and *participating* citizen is a far better measure of democratic well-being.

## CONCLUSION

The recent history of Australian parliamentary democracy is one characterized by conservatism (both in the use of new technology and otherwise), despite Australia's history of democratic innovation. Of the three categories of activity described in this chapter, Australia is most developed in the first area of e-government. In international terms, however, Australia lags behind in other areas. In her study of parliamentarians use of the Internet during the 1990s, Magarey concluded that "there is certainly no Internet revolution in Australian politics at the moment" (1999, p. 58), and there is little suggest that much has changed since in practical terms.

## KEY TERMS

**Broadband:** Defined as "an 'always on' Internet connection with an access speed equal to or greater than 256kbps" (ABS, 2003).

**Digital Democracy:** Encompasses the use of ICT and computer-mediated communication, such as the Internet, interactive broadcasting and digital telephony, "for purposes of enhancing political democracy or the participation of citizens in democratic communication" (Hacker & van Dijk, 2000, p.1).

**Electronic Voting:** Or "e-voting" is defined as "Any system where the elector casts their vote using an online system, such as the Internet, touch-tone phone voting using interactive voice recognition, mobile telephone SMS text facility, or interactive digital television. Once recorded, the elector's vote is dispatched in real time to a secure electronic vote store, where it is held prior to counting" (Barry et al., 2002, p. 3).

**Webcasting:** Or "netcasting" is an audio-visual transmission that is streamed via the Internet. This transmission may be streamed live, or recorded for later access on the Internet.

**Weblog:** Or "blog" is a form of online diary that is entered and made accessible via the Web.

# Facing the E-Government Challenges within Catalonia

F

**Ignasi Albors**
*Consorci Administració Oberta de Catalunya, Spain*

## INTRODUCTION

During the 2001-2004 period the main pursuit by the AOC (Administració Oberta de Catalunya or Open Administration of Catalonia) was to create a well defined setup and devoloped CAT365 portal, the citizen's portal[1]. This portal would offer a new space on the Internet (as a complement of presencial and phone channels) through the creation of a brand new CAT 365 which belonged to everybody, but without being associated with any administration in particular. This portal would allow the user to reach the required information and to do transactions online. This could be done in an integrated way and within the user's own scope through an organisation based on natural sets (life events) and without relation to the current competencial organisation.

This model legitimated by the Parlamentarial Pact was signed and agreed in summer 2001 by all the parlamentarial political parties in Catalonia, together with the local public administrations and with the Generalitat of Catalonia (the Autonomous Catalan Administration). In Autumm 2004 it reached a crisis point and, therefore, it was reviewed.

## BACKGROUND

During a certain stage of development of e-government there has been and there still is the paradigm of creating a portal where one can concentrate all the information, interactions, and procedures of any public administration, a single portal which can act as a distributor of public services, and one where the citizens can easily find the services they need independently of the administration that finally offers the service. This is a model where the division of the roles of service provider and service distributor takes place: the role of provision is played by the administration which owns and delivers the service and allows a third party to distribute these services. This has been the model adopted by the Catalan public administrations in the AOC project where within the setting of the AOC consortium a public entity has been created with the participation of the autonomic administration (Generalitat de Catalunya) and the local administration (via Localret, the consortium of local bodies for the Information Society) with the aim of using telematic channels, mainly internet and telephone, to distribute the services of the Catalan public administrations. This model reached a crisis point and therefore it was reviewed. I think it was an impeccable model from a conceptual view. The problem was that at that moment the model did not fit with the Catalan Administration's situation. My opinion is that we have been going through a development of the initial model is not a replacement by a new one. Most of the objectives of this latest model were already in the initial one; in fact, there is a nuance and a strength difference between both models but not in their chief meaning. To understand deeply the reasons why the AOC1 did not achieve success I would recommend reading the article written by M. Sanromà, "Digital Administration: A New Way to Manage Public Administration Information".

The aim of this article is to explain the principal characteristics of the new model through some of the products that have been developed and are being developed within the AOC setting. The mission of the AOC project is the same: improving the relationship between the Catalan public administrations and their citizens, companies and entities, but the project is currently accentuating the development of solutions that increase interadministrative collaboration and allow the procedures to be simplified or eliminated, such as the integration of information on public services—in an early stage—in order to integrate the procedure at a later stage. The idea underlying this strategy is that in order to improve the relationships between administrations and citizens, a parallel improvement in relationships between administrations must take place. To this end the AOC project is developing solutions (some of which are described here) with an ASP[2] philosophy. In this way all the different Catalan public administrations will have access to the solutions necessary so that any of them may move towards e-government without any individual administration having to develop solutions on its own, thus producing clear savings due to economies of scale. Among these solutions we find the modules known as common or corporate modules: electronic registration of incoming and outgoing correspondence, a notice and warning platform via e-mail or SMS, and the notification module. These are only some of many examples.

Although we are aware of the need to use tools which could simplify and improve the relations within Catalan administrations, the AOC is currently providing solutions which allow sharing communication and doing transactions online among them. Its aims are as follows:

- The Consortium AOC is changing the model from a "front-office" integration to a "back-office" integration approach.
- The business focus will be on horizontal e-services across different governmental agencies.
- Web services and data integration is the keystone of a new Integration Architecture.
- An interoperability framework and common metadata models will be defined.
- The impact on the activity of the Consortium AOC will be measured on internal efficiency and cost optimisation.
- The Consortium AOC must provide safeguards around the sharing of people's information among government agencies.
- There will be collaboration of private sector i key (i.e., change of adress, e-invoicing, etc.).

## THE VISION OF THE ADMINISTRATION AND THAT OF THE CITIZENS

The reality and the behaviour of people and organisations fit better with a network model than a hierarchy. Despite this generalised statement, in the field of public administration its history has over a long period of time shaped some hierarchical organisations, oriented towards a vertical management of its competences. It is true that in the latest decades some concepts such as transversality have been introduced in the work of the administration, but it is also true that in the majority of cases it tries to respond to problems generated by the lack of a strategic vision which derives from the verticalisation of administrative management. The benefits of its application have not gone beyond the sphere of the administration itself and have not extended to cover its necessary relations with other levels of administration.

We find ourselves then, on one side, with an administration that functions as a perfectly organised whole where every territorial administration counts on some perfectly defined and fixed competences, with a complex organisation but one organised through hierarchies of power and which seem to be inspired by those perfect and pure Hegelian views of the world where everything works like a well-oiled watch. The main aim of this whole is to administrate, manage the public resources, and offer services to the citizens in the most effective and efficient way. On the other side we find ourselves with the citizen, lately referred to as a "client" (since the traditional techniques and strategies of the private sector moved into the public sector) who, in sum, are users and consumers of public services who feel overwhelmed when facing the administration. They do not understand it but frequently have to put up with it. They are conscious that they have to deal with it from time to time, but they think that the less frequently, the better.

## SOME EXAMPLES AND SOLUTIONS

In Catalonia (and in Spain) there are three coexisting levels of administration, each with important competences: the local, autonomic and central administrations. The current legal code fixes the spheres of activity for each of them; therefore, we are looking at a scene which is perfectly established and fitting from the administrative and legal point of view, but not from the citizen's point of view. The citizen is often a victim of competential distribution which is illogical in terms of access. It is simply impossible to understand. Furthermore, the distribution of competences between the different administrations is unstable; therefore, the perception of the citizen when it comes to choosing a service to cover a need is, to say the least, one of disorientation.

In the real world each administration has a list of competences that it should carry out, a territorial sphere of activity, and the resources to carry out its aims. Consequently, each administration has in recent years been developing solutions, with different degrees of sophistication and efficiency, in areas of e-government service provision to its citizens.

Traditionally the different administrations have been distributing their services through the new channels that the new technologies of information and communication allowed, focusing on those spheres of activity where they had competencies, as was logical. For each administration the citizen (understood in a broader sense to include companies and entities) was "its" citizen. Each administration tried to improve its services using new channels to deal with its citizens but limited its sphere of activities to the strictly defined space of its competences. The result of this commendable effort was the reproduction, now in a digital environment, of the citizen's perception of fragmentation in the supply of public services.

There are many procedures which are located in the sphere of activity of a single administration. The complete process starts and ends in organisms depending on the same administration. Nevertheless, on numerous occasions the citizen will have to show particular attributes

(for example, residence in a particular municipality; possession of a particular level of education), by presenting certificates that are frequently issued by other administrations. Similarly, the citizen in his everyday life faces particular situations where the complexity and extension of the process, the competential distribution or a fragmented supply forces him to deal with different administrations in order to satisfy a single need. In these cases, and given the fragmentation mentioned earlier, the citizen does not have a global, integrated vision of all the processes necessary in the different administrative levels.

Among the clearest examples of the necessity to deal with different administrations are, without a doubt, the case of the birth of a child and the complex process of setting up a business.

Let us analyse the present situation of the first example: what are the present steps that a family in Catalonia is obliged to take after the birth of a child?

- In the ambit of the general administration of the state, parents must sign up the newly born child with the Civil Register through the registration in the Family Book; furthermore, if the mother is working, she must sign off Social Security.
- In the ambit of the Generalitat de Catalunya, the family must sign on with the health register managed by CatSalut (a public body of the Health Department) and, in the case of the third child, request recognition as a large family as issued by the Department of Social Welfare and Family Affairs.
- In the local ambit, the family must register the child in the corresponding municipal census.

On the other hand, the different administrations, aware of the fall in the birth rate in our country over the last decades, offer a set of actions aimed at fostering and favouring the increase in the number of children per family. Therefore the Catalan family has the following help available:

- The general administration of the state, via the Inland Revenue Service, offers the sum of 100 • a month if the mother is employed.
- The Generalitat de Catalunya, for its part, through its Department of Social Welfare and Family Affairs, offers benefits of 550 • annually to families with children under the age of three (and 625 • in the case of a single parent family or a large family).
- Similarly, numerous Catalan town halls apply discounts and rate reductions to water consumption and property, among others.

We have summarised here a reality which is repeated thousands of time each year in order to detect the diversity of procedures involved in a unique act. The complexity increases even more if we introduce new factors (which will not be mentioned in detail for lack of space): particular actions should be carried out before others. For example, to register the birth of a child one must previously have registered the birth in the Family Book. Similarly, each procedure requires specific documentation. On occasions, even the same documentation will be requested by different administrations.

This simple example, in my opinion, shows that an action orientated towards easing the relationship of the administrations with the citizens should allow a simplification in the procedures and documentation required and in the coordination between different administrations. Continuing with the example of the birth of a child, the ideal thing would be for all the procedures deriving from the birth to become unified and, based on the information required (number of children, if the mother is employed, family's municipality of residence), the necessary procedures would be identified and the processing could begin. This would allow the integrated handling of the different processes that should be complemented by the possibility that, if the family agrees, each administration could access the information it requires from other administrations, thus avoiding the need for citizens to present additional certificates.

Actually, there is an even higher standard of excellence: given that the administration has sufficient mechanisms to be informed of the new birth, the optimum situation would be that, without carrying out any action, and acting on its own initiative via an internal mechanism of the administration, all the information required in the Civil Register, Health Register, municipal census, etc. would be automatically updated, such as the aid and assistance to which all families have a right if they meet certain requirements. And this is not science fiction. In some countries this is already a reality (I recommend visiting the Irish government's Reach project, at http://www.reach.ie/).

## HOME COMMUNICATION SERVICE

Since more than a year ago there has been a project whose aim is to develop an integrated service between the three administrative levels: this is the home communication service.[3]

The European Union has been pushing different initiatives dedicated to using the ICTs in managing the services of the administrations:

The eEUROPE initiative; the eEUROPE 2002 Plan, of June 2002 which approved a list of 20 basic public services (12 for citizens and 8 for companies) and the eEUROPE 2005 Plan presented in the European Council

in Seville, centred on security of the network and of the information, electronic administration, electronic learning, e-health and e-commerce.

The telematic home communication service is one of these 20 basic services identified in the list of public services of the Electronic Administration. The service is in keeping with the idea of the relations of the citizen with the different public administrations, and in all levels of the state administration being involved in service provision.

The home communication service is a multi-administration service, simple in conception but complex owing to the number of public service providers involved, and one which requires effective communication between all the participating actors. The solution, designed in a telematic setting, hides the complexity of this relationship with the citizen, making the service sphere not so much territorial as virtual, with the same service accessible from various points of the network. To offer this kind of service it is necessary for the different administrative bodies to be interconnected and interoperable and that the service is designed to function in a collaborative way. In Catalonia, we calculate that each year approximately 10% (650,000 inhabitants) of the population change their residence, showing that we are dealing with a service with enough critical mass for the different administrations to give the service high priority.

The aim of this project is to establish an Internet service through which citizens may simultaneously provide details about their new address to the different organisms and entities of the public administrations involved and carry out all the procedures with a single access.

This provision of information will lead to an updating of the details of the home in the appropriate administrative units and in turn to the start of the administrative procedures to renovate personal documents (such as the health card or the National Identity Card). The administration may be proactive in the sense that when a change of address implies the start of a procedure, the administration will be able to send a new document (in the case of a health card) or inform the citizen of the start of the renovation procedure (in the case of a driving licence).

The service avoids citizens having, on the one hand, to request the municipal census document, as it is enough that they agree to their details being transmitted to the selected organisms, and on the other hand, to avoid going in person to the appropriate organism. This brings clear benefits to the citizen—who stops wasting time, and therefore money—but also to the administration, as it is calculated that approximately 50% of the activity carried out in the personal attention centres of the Catalan administrations is related to the issuing of certificates originating in a request for a service for those citizens in another administration.

The project considers all the obligatory legal and administrative aspects of dealing with a public service with information which is confidential and protected by the Basic Law of Personal Data Protection. Special attention has also been paid to the aspects of legal and informational security in order to reach the applicable guarantees.

In the same way as in the cases described of particular situations of having a child and changing residence, there are other cases in which the citizen is able to describe a need (I want help to get a home, or I want to set up a business), but, nevertheless, does not know the distribution of competences between different administrations. In any case the idea behind the integration of information and procedures is the development of a new integrated service in which responding to a series of questions sets off a logical process that:

- Identifies the procedures which are related to the situation
- Presents a single form, which avoids repeated handing in of the same information
- Sends the corresponding electronic application to all administrations involved
- Helps identify the state of progress of all the procedures which are under way

The resulting product will not be offered to the citizen from a single access point, but quite the contrary: access is available from any administration involved in the global process. In this way we have evolved from a model based on the idea of concentrating on one single access point (one-stop portal, single window service) to a network-based model where the citizen chooses the service access point. We believe firmly that this is the way to achieve interadministrative transversality, so far unknown in our country.

## ADMINISTRATIONS BROWSER

The same philosophy underlies another of the emblematic products in this new concept of e-government: the public administrations browser.

In the ambit of both private public sector initiatives the wide diversity in the ways of structuring the digital contents of Web pages means that the browser is one of the most frequently used tools. This should allow rapid and direct access to the contents that the user is seeking, regardless of the taxonomy used by each indexed Web page.

The great diversity of Webs and public contents has lead to browsers becoming fundamental tools for access to interesting resources. Our experience shows us that

one of the resources most utilised in public sector Webs is the browser that the great majority of these Webs have, given that it is preferable to try to access interesting contents through this rather than trying to surf the Web on a site that could be organised around criteria that need not necessarily correspond with the user's method of surfing, nor with the user's experience of net surfing.

Despite this, the level of quality of the different browsers on public Web sites is, in general, fairly inadequate.

Based on this reasoning, the AOC project has been working for some months on a Google-style browser that allows one to:

- Index all pages published by those public organisms active in Catalonia
- Index not only html format documents but also databases, Excel files, pdf, and so forth
- Index on a daily basis
- Associate weighting criteria (page rank) with the result in order to prioritise the presentation of the most valuable contents
- Present the contents by type: procedures, information and features
- Incorporate linguistic tools which allow improvements in the quality of the browsing (categorisers, dictionaries of synonyms, etc.)
- Offer to include the product in the Web page of any administration that wishes to become involved

This is a search service designed to meet public-service search requirements, allowing equipping of public sites with a search engine that knows where to find the key information sources independently of where they are located. The solution includes a fast and scalable indexing spider, which indexes any content from any Public Administration site. This feature allows any Web site using the administrations browser to be a gateway for information across multiple sites without losing the identity of each site.

It does not impose any requirements for content change across the sites that you own or those that are spidered. Whether you deliver content from a database, content management system, portal system or static pages, the search solution will enable you to provide a consistent search across the whole lot.

The benefits of an Internet contents browser such as this are, I believe, clear. Firstly, the construction of a powerful browser that integrates all the information available on the Web in such a way that the citizen who is searching for a particular service and who knows neither the administration that offers it, nor if there are any complementary services adequate to his needs, can have direct access to the global result.

Secondly, it is a service available to all the administrations via the Google-type toolbar, so that the citizen can have access to an integrated vision of on-line public services from the Web of the administration he wishes to use. This solution has been offered free to the Catalan public administrations and it has been already requested by more than 160 municipalities and local authorities who will add it to their Web site in January 2006.[4]

It indexes the public contents of three different administration levels (local, regional, and national) and gives the citizen a global vision of all three administrations services with one unique query without knowing which specific administration offers the service being looked for, because this global search engine accesses all the public contents independently of the administration which offers the service.

There are also some spin-off products of this browser that may be of interest, such as the extraction and "packeting" of contents. In this sense we are working on:

- A directory of public assistance which allows access to the complete range of promotional actions of any public administration, of whatever type: subsidy, grant, discount, economic loan, and so forth
- A directory of public employment opportunities allowing access to all the posts available from any administration
- A directory of the public housing opportunities in the different administrations
- A directory of training opportunities allowing access to information on both regulated- and non-regulated training, and which is directed at specific collectives (occupational training, adult training, etc.)

In summary, what is proposed is a catalogue of products allowing simplification in citizens' access and procedural handling of the public services in an integrated way. These are accessible from different Web pages due to their "non-branded" nature and that additionally generate internal benefits in the administrations providing the services. We believe that the following steps in the—let us not forget—still young life of e-government should move in this direction. If it turns out not to be so, we hope we are agile enough to realise it and make amends.

## CONCLUSION

From the experience we have got during this last five years when the AOC project was born, we have learnt that flexibility to adapt to new and changable situations is

completely necessary to reach an e-government project successfully.

The current situation shows us that all e-government projects are in a changable scenario due to, at least, two factors: the first one is the huge dependence on the latest technologies (and nobody knows where they would take us). The second factor is that the organisations we are working with—the administrations—are subject to the possibility of change (each time that the elections take place). And we have to add to this situation the necessary collaboration among other administrations which would also be subjected to changes caused by elections. This last subject is the responsable—that is, when the interoperability is necessary—of not complying with the timing and milestones planned since the needs, the rates and the priorities would be different for each administration level.

I think the evolution suffered by the AOC project in Catalonia is well focused since we have been able to adapt it to the administration necessities mainly not to provide front-offices solutions. Therefore, we have been working towards a redefinition of the project underlining the outstanding tasks on the back-offices and the interoperability needs. This leads to a reduction of the front-offices solutions, a field where the Catalan public administrations have been working themselves for a long time.

This new direction has been possible in Catalonia because there is a general agreement about the guidelines to be followed. The 2001 political agreement illustrates a will to work together on this joint project among the two closest administrations to the citizens: the local and the autonomous. This is the main reason which has allowed us to readjust the project, without having any risk caused by the recent political changes on the Catalan public administrations scenario. Therefore, it has been possible to save some of the initial elements, while others have been modified and new ones have been created.

## KEY TERM

**Interoperability:** Interoperability means the ability of information and communication technology (ICT) systems and of the business processes they support to exchange data and to enable the sharing of information and knowledge. (http://europa.eu.int/idabc/servlets/Doc?id=19528)

The AOC basic principles of interoperability among governments are:

- Makes sharing of information and intergovernmental cooperation possible
- The information source is owned by the area of political competence that governs its use
- The corporate systems are independent and separate, although certain functional tasks are shared
- Process flow and exchange of electronic information
  - Each administration can provide or request data
  - Exchange of information may be initiated:
    - By the administration requesting the information
    - By the administration in possession of the new information
    - By the institution managing the electronic information exchange network
  - This exchange may become totally automated (application relationship) or may require manual intervention
- Shared open standards
- Common across-the-board services
  - Transaction services
  - Security services
  - Content management and incorporation services
- Standardisation of data and procedures
- Promotion/encouragement of working together
- Possibility of common platforms

# Factors Affecting Access to Electronic Information and Their Implications

**Gashaw Kebede**
*Addis Ababa University, Ethiopia*

## INTRODUCTION

Information is a key ingredient in everyday life of the individual and the society at large.

Information has become increasingly more important with the emergence of information society. Information and knowledge are key resources, and generation and communication of these is the mainstay of the workforce in the emerging information society. Because of the value that information has in the day-to-day life and development of human beings, the right to information is held as a basic right of individuals in many countries. Information and knowledge exist in oral, print, and electronic forms.

However, information and knowledge have little value unless they are accessed when needed in a form they are needed. If access to existing information does not take place, the potential benefits of possessing of information will be lost. In other words, the key to unleashing the benefits of information and knowledge is effective access to them. As such access to information is recognized to be an instrument to help citizens to realize their own potential; to increase their skills, knowledge and capacity; and to take part in and benefit from information society (FARN, 2001). Scientific progress also depends upon the accessibility of existing scientific knowledge upon which new knowledge is built.

## BACKGROUND

As the importance of access to information is directly equated to the value of information, access to information is also recognized as a fundamental human right of citizens in many countries. The right to access to information is now expressed in policies, laws, acts, and regulations of many countries. Universal declaration of human rights also has provisions for the implementation of the right to access to information. Social institutions such as libraries, archives, schools in broader sense, and the mass media have been considered as instruments to preserve and facilitate access to information and knowledge.

The emergence and expansion of information in a digital form in particular has heralded, among others, faster and broader access to information in general. Efforts to benefit from the digital revolution are now among priority concerns of many countries, both developed and developing country. Access to electronic information essentially involves access to electronic technologies (the channel and prerequisite), access to electronic information sources (the container), and access to the content (the actual data, information and knowledge). However, access to electronic information is not always possible to all.

This article looks into the various factors that affect access to electronic information as well as the nature of their effects. Review of relevant research literature has been used to identify the factors affecting access to electronic information. The article further discusses the implications of the factors by taking the least developed countries (LDCs) as a good example since these countries are the most affected countries by the factors. Possible measures to address the effects of the factors are also presented in the conclusion part of the article.

## FACTORS AFFECTING ACCESS TO ELECTRONIC INFORMATION

Despite its importance, a significant number of people do not have as much access to the electronic information as required. The literature (more than 70 research reports and articles have been reviewed in preparing this article, of which most are also reviewed in Gashaw, 2002; Rice, McCreadie, & Chang, 2001) on factors influencing access to and use of IR systems, digital libraries, e-journals, and the Internet has consistently shown the existence and prevalence of a set of factors affecting access to electronic information. These factors can be organized under the following four categories: the characteristics of the end-users, the characteristics of the electronic information carriers, the characteristics of the electronic content, and the characteristics of the information environment in which access takes place. These are described below.

1. **Characteristics of the End-Users:** This refers to the qualities and capabilities that end-users bring to

information access process, including one's computing skills; experience in using electronic information resources and information; domain knowledge; language abilities; digital literacy (including attitude towards information, information seeking, and information use); beliefs about the capability, ease of use, and usefulness of information, information systems, and the Internet; perception about one's skills and knowledge; and financial ability to acquire electronic resources and training. Specific instances of the characteristics of the end-user hindering access to electronic information include the following: lack of experience in using information systems, networks, the Internet and electronic information; non-awareness of the resources available and ones rights and duties in utilizing the electronic resources; lack of confidence in one's ability; lack of knowledge of the language in which digital documents are available; and lack of interest and motivation in using electronic information systems and information

2. **Characteristics of the Electronic Information Carriers:** This refers to the features of the electronic information technologies and the electronic information sources, including the capabilities of the computing and network hardware, software, interface, and the Internet connection; ease of use of these resources; and physical accessibility (as access assumes availability) of the computing and network resources and electronic information sources. Specific instances of the characteristics of the electronic information carriers hindering access to electronic information include the following: physical non-availability of appropriate computing/network hardware and electronic information sources; insufficient capacity of computing/network hardware and software; physical non-availability of network/Internet connection; low capacity of network/Internet connection; physical inaccessibility of electronic information sources; and difficult to use interfaces
3. **Characteristics of the Content:** This refers to features of the content such as relevance (on the topic); type (text, graphics, audio, video); format (PDF, Word, PostScript, HTML); language (International languages such as English, local languages); form (full text, abstract, abstract and keywords, summaries); quality of content (accuracy, reliability, breadth, depth, trustworthiness); level of treatment of subject; organization (searchable, indexed); and file size that in one form or another affect access to the content. Specific instances of the characteristics of the content hindering access to electronic information include the following: physical non-availability of relevant content (topical) to the basic and immediate needs of end-users; physical inaccessibility of relevant content to the basic and immediate needs of end-users; poor presentation (delivery) of content; and poor quality of content (in terms of accuracy, reliability, breadth, depth, trustworthiness)
4. **Characteristics of the Overall Information Environment:** This refers to information-related features of the physical environment in which access to electronic information takes place, including information policy and regulations, general infrastructure of the country/organization, information culture of the country/organization, technical and other system support, overall economic level of the country, and cost of electronic information resources. Specific instances of the characteristics of the information environment hindering access to electronic information include the following: absence of supportive information policies and regulations; absence of personnel/technical support; high cost of electronic information technologies, information sources, and content; poor general infrastructure of the country; under-developed information culture of the country/organization; and prohibiting cultural and social norms to access all relevant content and carry out all useful information activities

From the above it can be observed that the factors affecting access to electronic information are constraints to accessing the electronic technologies, information sources and the content caused by the characteristics of the user, the characteristics of the electronic information carriers, the characteristics of the electronic content, and the characteristics of the environment.

Furthermore, access to electronic information is hindered when there is mismatch among the factors previously discussed. More specifically the following mismatches result in failure in accessing electronic information:

- Mismatch between the characteristics of the end-user and the characteristics of the electronic information carriers. For example, if the level of computing skills of the end-user does not match the skills requirements of or ease of use of the electronic information system, then access to information is affected negatively
- Mismatch between the characteristics of the end-user and that of the content. For example, if the end-user does not know the language in which the content is written, then access to information cannot take place
- Mismatch between the characteristics of the end-users and that of the overall information environ-

ment. For example, if the cost of access to the Internet in a country is beyond what end-users can afford, then access to Internet-based information is affected negatively
- Mismatch between the characteristics of the electronic information carriers and the characteristics of the content. For example, if the format of the content does not match the software capabilities of the computing resources, then the content can not be viewed, retrieved, and so forth, hindering access to electronic information from taking place
- Mismatch between the characteristics of the overall information environment and that of the electronic information carriers. For example, if the climatologic situation of a country is not accommodating to an imported computing system, then the system cannot function as desired, hindering access from taking place using the system
- Mismatch between the characteristics of the overall information environment and that of the content. For example, if end-users are not allowed to view certain types of content because of organizational policy, then access to such information cannot take place even if it is needed by the end-users

The existence of these factors in a given physical setting (i.e., a household, community, organization, or a country) affects access to electronic information in one or more of the following and other similar ways:

- By making the information content physically not available
- By making the information content physically inaccessible
- By making end-users perceive that the information content is physically not available
- By making end-users perceive that the information content is physically inaccessible
- By inconveniencing end-users in accessing the information content
- By de-motivating end-users from attempting access to the electronic information resources and the content
- By making end-users lack the appreciation of the importance and usefulness of accessing information content
- By making available electronic information difficult and discouraging to use
- By forcing end-users have underdeveloped information culture
- By making end-users deprived of computing skills and experience
- By keeping end-users ignorant of what is available and possible
- By making end-users lose confidence in their ability to access information content

## IMPLICATIONS OF FACTORS AFFECTING ACCESS TO ELECTRONIC INFORMATION IN LDCS

Obviously, the factors affecting access to electronic information primarily impact on those individuals, communities, or countries where the factors are in widespread. It is also obvious that these factors impact more on those activities that highly depend on access to electronic information, such as e-commerce, e-learning, and e-government.

LDCs are the most affected countries by the factors affecting access to electronic information. This is the case because most, if not all, of the factors hindering access to electronic information are found widely in these countries. The literature on the digital divide and statistics on ICT development indicators collected by international organizations such as ITU, the World Bank, the UN and OECD give us insight into the state of access to electronic information in LDCs. The evidence from this literature is valid because the digital divide is inequalities among individuals, households, communities and nations in accessing the electronic information, which includes accessing the carriers and the sources of electronic information (i.e., ICTs). Accordingly, although difficult to find complete data, we can gauge the nature and extent of access to electronic information in LDCs using the available facts and figures about LDCs in relation to indicators/indexes of the digital divide.

A wide range of digital divide indicators are in use to assess the nature and extent of the digital divide in a country. Assessed against widely used indicators of the digital divide, LDCs (or low-income countries as sometimes described by some international organizations) show the following:

### Electronic Carriers Related

- The number of fixed lines per 1000 inhabitants is 3.01 for Africa as compared to 41 for Europe (ITU, 2004)
- The number of computers per 1000 inhabitants is 7.5 as compared to 466.9 for developed or high income countries (ITU, 2003)
- The number of TVs per1000 inhabitants is 91 compared to 735 for developed or high income countries (ITU, 2003)

- They number of Internet users per 1000 inhabitants is 10 compared to 364 for developed or high income countries (ITU, 2003)
- The number of Internet hosts per 10,000 inhabitants is 4.2 for Africa as compared to 280.95 for Europe and 2002.47 for the Americas (ITU, 2004)
- The number of secure server is 435 as compared to 210, 134 for developed or high income countries (ITU, 2003)

## Content Related

- About 80% of the documents on the Internet is in English Language, targeting largely audiences of high income countries

## End-Users Related

- School enrolment: About 60% of children attend school as compared to 97% in developed or high-income countries (The Secretariat of the Pacific Community, 2004)
- Adult literacy is 49% as compared to 81% developing or high-income countries (Least Developed Countries Watch, n.d.)

## Environment Related

- Internet access price as percentage of monthly gross national income (GNI) per capita is 264.4 as compared to 1.6 for developed or high income countries (ITU, 2003)
- Total monthly price for 20 hrs of Internet use is USD 57 as compared to 23 for developed or high income countries (ITU, 2003)
- Absence of information and ICT policies are one of the major causes of the digital divide in LDCs (Parkes, 2003)
- In some African countries, up to 90% of the population lives in rural areas where the basic infrastructure is lacking (Parkes, 2003)
- GNI is USD 761 or less

These show the status of the digital divide in developing countries, and hence status of access to electronic information. They specifically point out, among others, that access to electronic information is severely limited in LDCs. Some of the indicators above also show the impact of the factors in these countries. For example, only about 10 out of 1000 inhabitants of LDCs are connected to the Internet due to environmental related factors (high Internet connection cost), content-related factors (shortage of relevant content for local needs), end-user related factors (lack of computing skills), and electronic information carriers related factors (lack of computer hardware). One can also find similar implications of the existence of the factors affecting access to the electronic information in LDCs in one form or another. For example, the research literature indicates that the inhabitants of LDCs:

- Have difficulty in locating information content that is relevant to their lives and their community on the Internet (due to lack of skills and investment for LDCs to have locally relevant data in local languages available on the Internet) (Yu, 2001),
- Have difficulty getting up-to-date information about their own setting (due to lack of funding, lack of innovative use of ICTs and underdeveloped information culture) (Bridges.org, n.d.)
- Have limited interest in using the Internet which contains mainly information in English (due to high illiteracy level of the country) (Bridges.org, n.d.)
- Have difficulty understanding the major portion of the information on the Internet written in English (due of high illiteracy mainly) (Bridges.org, n.d.)
- Find Internet connection cost prohibitive (mainly due to very low income of the general public, inadequately and poorly maintained telecommunications and restrictive state controls) (Cureo, 2002; Yu, 2001)
- Continue to have difficulty getting access to computers, training, and telephone connections (due to the general poor economic situation of the countries) (Bridges.org, n.d.; Cureo, 2002; Yu, 2001)
- Have limited access to the Internet (due to high access costs, chronic lack of infrastructure and bandwidth, lack of IT skills and experience, low literacy levels, and poorly coordinated ICT policies) (Cureo, 2002; Parkes, 2003; Yu, 2001)
- Have difficulty in building capacity to use ICTs (due to mainly high cost and lack of ICT training locally) (Bridges.org, n.d.)
- Find owning and using computers difficult (due to high cost of computers, constant failure of electricity, and lack of physical space to keep ones computer at home) (Bridges.org, n.d.; Cureo, 2002; Yu, 2001)
- Have difficulty in integrating ICTs seamlessly into their operations (due to equipment failure and lack of technical knowledge mainly), (Bridges.org, n.d.)
- Have difficulty using computers as tools of everyday activities (because the majority, such as business clients, with whom interaction is expected to take place do not have access to ICTs) (Bridges.org, n.d.)

Given these, LDCs face, among other things, difficulties to engage in activities that depend on access to electronic information. Embarking on such activities as e-learning, e-commerce, and e-government is severely constrained by the existence of the factors affecting access to electronic information. Thus, addressing these factors should be a priority issue for LDCs in order to participate and benefit from the potentials of the information age. Considering the key role that these activities could play in the emerging information and global economy, problems of access to electronic information becomes the main threat for the socio-economic progress that LDCs cannot afford to ignore.

## APPROACHES TO ADDRESS THE FACTORS AFFECTING ACCESS TO ELECTRONIC INFORMATION

For access to electronic information to take place, all the required matches among the factors need to be made. Therefore, it is necessary for each physical setting (i.e., an organization, a community, a country) to first identify what mismatches are currently hindering it from accessing electronic information as desired. This should be followed by identification of appropriate measures to enhance access or specifically overcome the identified barriers in the setting. In this connection, the following measures are relevant to enhance access or overcome barriers to access to electronic information.

To achieve a match between the characteristics of end-users and the electronic information carriers, the following measures or enhancers of access to electronic information need to be fulfilled on the part of the end-users: acquisition of computing skills and adequate relevant experience in using electronic resources and information. On the part of the electronic information carriers, the following need to be in place: physically accessible, affordable, appropriate, easy to use and functional computing and network hardware in adequate number; physically accessible, affordable, appropriate, and easy to use software and interface, including interfaces supporting local languages; physically accessible, affordable, easy to use, and adequate network and Internet connections; and physically accessible, affordable, appropriate, easy to use, and adequate electronic information sources containing potentially relevant content.

To achieve a match between the characteristics of the end-users and that of the content, the following need to be achieved on the part of the end-users: acquisition of computing skills and adequate relevant experience in using electronic resources and information. On the part of the characteristics of the content the following need to be in place: physically accessible (i.e., viewable, retrievable, downloadable and printable), affordable, relevant (on the topic), and quality (in terms of accuracy, reliability, breadth, depth, trustworthiness) content; and physically accessible content that is appropriately formatted, organized, interactive, compatible with the existing system and environment, understandable, and in known languages of target end-users.

To achieve a match between the characteristics of the end-users and that of their environment, the following need to be in place on the part of the environment:

- availability of supportive information policies and regulations; physically accessible technical supports;
- physically accessible and affordable electronic technology, information sources, content, and services; adequate basic infrastructure in the country;
- physically accessible financial support or subsidies; higher level of literacy among the population; adequate public information access points (in terms of number and quality);
- informed and responsible government of its information duties; and
- a well-developed information culture at the individual, community, organizational, and national levels.

In a similar way, to achieve a match between the characteristics of the electronic carriers and that of the content, the following need to be in place on the part of the content: physically accessible content; content that is compatible with the characteristics of existing electronic information resources (such as the capacity of hardware storage and version of software in use). It is theoretically possible to require the system to be capable enough to support all types and kinds of content. However, experience has shown that it is not possible to anyone to own or have access to the latest computing resources all the time in order for us to consider having the latest electronic information carriers as a measure to achieve a match between the characteristics of the electronic carriers and that of the content.

To achieve a match between the characteristics of electronic information carriers and that of the environment the following are necessary on the part of the electronic information carriers: physically accessible computing/network hardware and software appropriate to the climatologic and the level of development of the basic infrastructure of the environment; physically accessible electronic information sources appropriate to the climatologic and to the level of development of the basic infrastructure of the environment; physically accessible computing and network resources (i.e., computing and

network hardware, software, and information sources) feasible of developing and maintaining in the environment; and physically accessible computing and network resources (i.e., computing and network hardware, software, and information sources) affordable within the state of economic development of the environment.

Finally, to achieve a match between the characteristics of the content and that of the environment, content that is relevant and acceptable within the environment should be in place while the environment has to provide mechanisms that avoid too much restriction on the free flow of content in and out of the environment.

Individual users, user communities, organizations, the business community, governments, and international communities and business as appropriate are responsible to fulfill these enhancers of access to electronic information.

## CONCLUSION

The previous discussion of factors affecting access to electronic information and their corresponding measures can be used as guide to determine the access situation of each setting and the corresponding measures to address the factors. The list of factors provides a checklist of possible factors that could exist in any given setting and for which one has to look for when interested to learn about the access situation of a setting. The description of possible mismatches further illuminates and organizes the factors in more focused sense. The list of potentially relevant measures for each factor discussed above can be used as a starting point to address the identified factors.

Accordingly, LDCs need to first identify the specific factors affecting their access to electronic information. This effort can be guided by the list of factors previously described, particularly to make LDCs aware of the possible factors, to help them articulate the factors that specifically hold true in their setting, and guide them characterize the factors in terms user-related, carrier related, content-related, and environment related. LDCs can further learn about the characteristics of the factors by seeing them in terms of the different possible mismatches identified for each category. Knowledge of the root causes of the factors is also necessary in order to identify or select feasible measures to address the factors. LDCs should then consider appropriate measures to address the factors. This effort also can be assisted by the list of possible measures previously discussed.

## KEY TERMS

**Access to Electronic Information:** Access to electronic information is the process of interacting with electronic information technologies, electronic sources, and electronic content for the purpose of acquiring information and knowledge from the content.

**Digital Divide:** The digital divide is inequalities in access to ICTs, computing skills and electronic information content among individuals, household, and communities within a country and among countries.

**Digital Libraries:** Digital libraries are organized collection of knowledge, stored in digital/electronic format, and accessible to users via digital/electronic interface technologies.

**Digital Literacy:** Digital literacy refers to the ability to locate, understand, synthesize, evaluate and use information from a variety of sources when presented via computers and the Internet. Digital literacy also includes the ability to recognize when information is needed.

**Electronic Information Carriers:** Electronic information carriers consist of the electronic information technologies and electronic information sources required to capture, store, and deliver digital content to end-users

**Electronic Information Sources:** Electronic information sources broadly refer to electronic-information bearing objects such as e-journals, e-books, electronic documents, electronic databases, Internet resources (e-mail, listservs, discussion group), intranet resources, electronic archives, and electronic data files (numerical data, image data, multimedia data), which contain information and knowledge.

**Electronic Information Technologies:** Electronic technologies are the channels through which the electronic content is accessed and delivered to end-users. The electronic information technologies include computer systems, communication networks and the Internet.

**Electronic Information:** Electronic information is any signs, signals, writing, images, sounds, data, or intelligence of any nature stored in whole or in part in electronic form.

**Internet:** The Internet is a collection of networked computers all over the world, connected via telecommunication networks, that allows for transfer of data from one computer to another, using common protocols. The Internet allows access to millions of Web pages, other electronic documents, and services such as e-mail.

**Least Developed Countries (LDCs):** These are countries with "low living standards (i.e., low real income per capita[below USD 800]) associated with high income inequality, poor health and inadequate education and limited life expectancy; low levels of productivity possibly because of limited resources; unskilled labor; weak complementary factors and management practices and backward technology; high population growth rate due to falling death rate resulting in significant dependency burdens; large-scale unemployment and underemployment; a small industrial sector with outdated technology unable to employ large numbers of poorly educated workers; large but neglected agricultural sector and outward migration from rural to urban areas; market imperfections" (TUTOR2U, 2003). Currently, 50 countries with a combined population of more than 600 million people are identified as LDCs. Of today's 50 LDCs, 35 are in Africa, 9 in Asia, 1 in the Caribbean and 5 in the Pacific Region.

# Foundation for Citizen-Oriented E-Governance Models

F

**Tuomo Kuosa**
*Finland Futures Research Centre, Finland*

## INTRODUCTION

The present knowledge era needs new democratic practices. The use of information and communications technology (ICT) has been considered the potential tool for rethinking democracy and political action. Working with research and development (R&D) on this potential means whole new sets of concepts, and practical solutions need to be innovated. This article describes and compares several new ICT-aided models—tested, in use, or under research—that emphasize citizens' needs as the fundamental approach to societal decision making and that regard citizens as collaborative decision makers. The new citizen-oriented approach is fundamentally transformative and calls for new innovative approaches in order to employ ICT for governance and empowerment of citizens. E-governance is considered to be an integrative concept for governance and democracy, while the focus of this article is on e-democracy.

In the foundations of e-governance lie the ensuring of universal access to data, information, and knowledge for citizens in order to enable them to build their personal knowledge base and to empower them to become independent decision-making collaborators (Keskinen, 2001; OECD/PUMA, 2000). The interactive decision-making approach calls for new models that will complement, evolve, and reform the current representative democracy to better suit the modern needs of rapidly moving and changing societies (Becker, 1995; Becker & Slaton, 1997; Keskinen, 1997). Furthermore, the potential of ICT means whole new sets of concepts and practical solutions to be innovated.

The world of the 21st century is globalized (Albrow, 1997), not only in an economic sense but also in a social, political, environmental, and technical sense (Axford, 1996; Kuosa, 2001). The Internet, global media and advertising, multinational enterprises, and brands (Florida, 2002; Klein, 2001) have created both a more global consciousness (Rifkin, 2001) supported by rapidly evolving ICT (Castells, 1996-1998) and a new geographical dimension—cyberspace, which can be seen as a complementary dimension to society. The Western world's societies have changed dramatically in the past 200 years, and the speed of change does not show any signs of slowing down. Should not old-fashioned representative democracy change, as well? (Keskinen, 2004; Keskinen, Aaltonen, & Mitleton-Kelly, 2003; Kuosa, 2004; Pertierra, Ugarte, Pingol, Hernandez, & Dacanay, 2002).

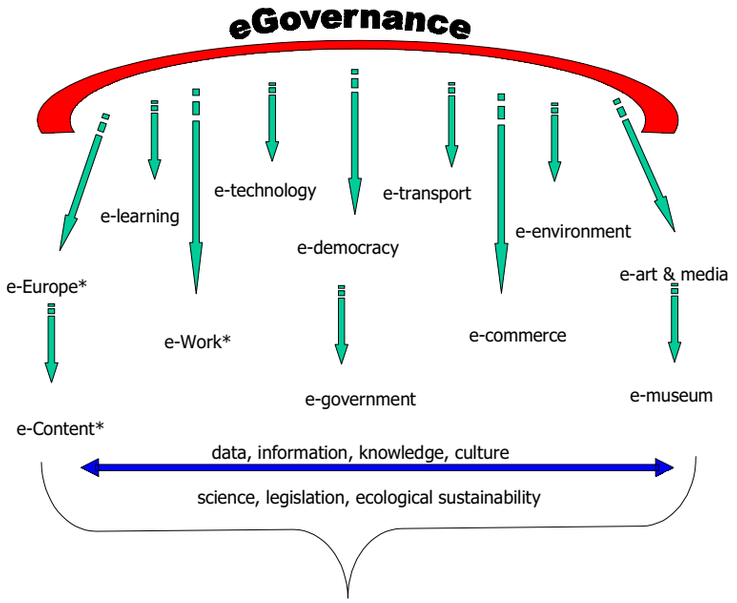
The new interactive decision-making approach presented in this article attempts to close the gap between 19th and 21st centuries' needs by emphasizing citizens' active roles in political decision making. This approach is based on legally tied participatory citizenship (Barber, 1984), as is the case in the multiphase referendum model, for example. The models should focus on citizens' needs and should regard citizens as collaborative decision makers. Political authorities should be tied with decisions taken in legally organized deliberative procedures.

## BACKGROUND: BASIC ASSUMPTIONS OF E-GOVERNANCE

E-governance is a novel term that has acquired many meanings, although they are rather undefined so far. In this article, e-governance is considered the integrative concept for several e-oriented methods for governing. Governance thus can mean organizational or personal governance (see Figure 1).

The figure indicates that recent R&D has focused on many different e-oriented sectors of society, especially in the latest framework programs of the European Union research and technological development. It is relevant to realize that common to all e-approaches are the understanding and development of inclusive data, information, and knowledge. Cultural, ecological, and legislative challenges are very much the same in all e-oriented R&D, and hence, the paradigms of conventional research fields will be under revitalization.

*Figure 1. E-governance as the integrating approach to e-oriented R&D areas (designed and collected by Keskinen).*



**These names refer to multi-annual research and development programs of the European Commission (see www.cordis.lu), whereas others refer to various sectors in general.*

Furthermore, the most important approach is that different decision models to be used for e-governance in general and e-democracy in particular can be used in different stages of the decision-making process. This means that all models of citizenship are not mutually exclusive but that they play different roles during the life cycle of the process, and furthermore, this decision also should be made by citizens through a collaborative procedure.

## BASIC ASSUMPTIONS OF CITIZEN-ORIENTED APPROACH

It is necessary to make some basic assumptions for R&D of citizen-orientation as follows:

1. Employing ICT for decision making could contribute to better decision-making procedures.
2. Transformational politics should be pursued.
3. The representative model is still a valid one, and other models are complementary to it.
4. E-governance and e-democracy can lead to societal decision making in order to become more interactive.

In addition, in citizen orientation, citizens are considered decision makers with equal opportunities with representative decision makers. The important difference to all other models is that citizens, not politicians, define the agenda; that is, this process should be interactive and based on win-win strategies. However, there has to be a procedure to coordinate this process and to avoid contingency and continuous need of voters' input. In other words, citizens in many cases should be in the role of strategic decision makers and conventional decision makers in the role of executives (Becker, 1995; Keskinen, 1997; Keskinen & Kuosa, 2004; OECD, 2001).

## MODELS FOR INTERACTIVE DECISION MAKING AND CITIZEN ORIENTATION

Almost all ICT tools can be used to help deliberative and participatory democracy. Relevant and already much used tools can be listed as follows: the Internet, text messaging (SMS), digital TV, local TV, and radio and online debates. Much used models include online polls, citizens' jury, deliberative poll (televote is a specifically researched and tested version of it), drawing lot (an old model that is still usable), funnel model, e-vote, and multiphase referen-

dum. It is also clear that the present state of the art of interactive communications methods must be developed further in order to facilitate genuine dialogue between the concerned parties (Carson, White, Hendriks, & Palmer, 2002; Keskinen 1999; Keskinen, Becker, Slaton, Ohlin, & Schmidt, 2001; Keskinen & Kuosa, 2004).

As already mentioned, a number of successful methods has already been used throughout the world beginning in the 1970s. Some of these methods can be grouped under the term *deliberative designs* because of their high level of group interactivity coupled with thoughtful discussion and argumentation. In the following, Televote, electronic town meeting (ETM), funnel model, citizens' jury model, multiphase referendum model, and citizen-oriented model are described briefly and compared. Of these, Televote, ETM, and citizens' jury are well tested and widely in use; funnel model has been tested in a multiannual pilot project in Finland, the multiphase referendum and citizen-oriented models are theoretical and have been developed through R&D projects in a few countries.

## The Scientific Deliberative Poll Model (Televote)

Televote is a "scientific, deliberative public opinion poll" (Slaton, 1992, p. 2). The deliberative poll was designed by James Fishkin, who has conducted a number of different versions of these (mostly in the U.S. but also in the UK, Australia, and Denmark).

Conventional public opinion polls are part of the weakness of modern representative democracies. Rarely are they used to allow citizens to state preferences for political agendas or to set priorities. Questions often are superficial, and alternatives are confined to a narrow range of choices determined by out-of-touch elites. In addition, citizens who are civic-minded enough to respond usually are caught in the midst of their daily routines and are not thinking about the issue of the poll when they are asked to give their opinion. The modern deliberative poll is clearly and rigorously structured to present a range of balanced information and expert opinion that is shared with a statistically representative population sample. When brought together in a central location, each citizen is treated with great respect, is given abundant time to think about all the data and opinions and, furthermore, is provided with opportunities to deliberate privately and publicly. The result is a far more in-depth, high-quality breed of public opinion, one that earns the description of being informed and deliberated (Keskinen, 2004).

Some of these models use a face-to-face jury style procedure pioneered by the Jefferson Center in Minneapolis, Minnesota, whereas some use the telephone and TV and have citizens deliberating in their homes (the Hawaii Televote model [Becker, 1995]). Some of these models use large face-to-face groups; some use small groups. At the end of these gatherings (usually conducted over two to three days), participants are surveyed again. There is no pursuit toward consensus; the responses are individual. The Televote model has been used successfully by Ted Becker (1995) and Christa Slaton (1992) in the U.S., Canada, New Zealand, and Hawaii. All have been eminently successful, particularly in the responses of the participants who almost unanimously applaud the new methods of polling as being empowering.

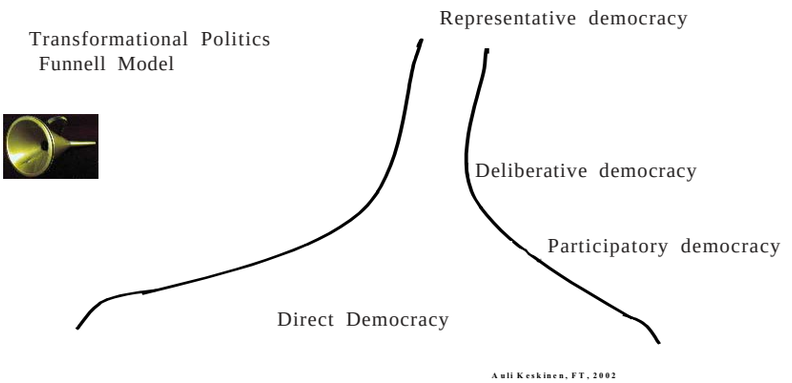
## Electronic Town Meetings (ETMs) Model

Over the past 15 years or so, there has been a number of authentic ETM experiments, whose purpose is to emulate and improve the traditional New England town meeting. Thus, there must be discussion and deliberation among ordinary citizens and a vote that determines the outcome. In addition, there must be some use of electronic media in order to facilitate this process. Most of these experiments have tried to mix several of the following components: interactive TV, interactive radio, scientific deliberative polling, telephone voting, and a wide variety of face-to-face meetings including those facilitated by the use of electronic handsets. Some have focused on problem issues; some have involved planning or envisioning processes. Most have been at local, state, or provincial levels. One of the most interesting ETMs (because it was to be binding for five members of Parliament) was conducted by the Reform Party of Canada in Calgary, Alberta. It used random samples from citizens of five parliamentary districts, who watched a televised debate on the important issue of physician-assisted suicide (euthanasia) and then voted by phone (Becker, 1995). The ETM seems to promise an alternative way to set public agendas and priorities for various legislative bodies to follow as well as being an alternative method of putting referenda before the public—a tool of direct empowerment (Becker, 1995; Becker & Slaton, 1997; Keskinen, 2004).

## Citizens' Jury Model

The citizens' jury is based on a deliberative design created by Ned Crosby in the US in the 1970s. The jury typically is selected using stratified sampling in order to match a profile of a given population. The participants (usually a group of 12 to 20 people) spend two to five days deliberating under the guidance of an impartial moderator. All participants have opportunities to question experts and to discuss the complexities of the issue and are asked to work toward a consensus response.

*Figure 2. Funnel model (Adapted from model used in Finland for Youth Council experiment in 1997-2000)*



Hundreds of citizens' juries have been conducted throughout the world since the mid-1970s; for example, in the US, UK, and Australia (Carson & Martin, 1999; Keskinen & Kuosa, 2005). The modern Citizens' Jury model naturally uses all available ICTs, especially the Internet, for information gathering, online polls discussions, and information dissemination.

## FUNNEL MODEL

The funnel model is based on the multi-use of different decision-making models (see Figure 2.)

The process of the funnel model is multiphase. It includes direct democracy in the first phase, when new ideas begin to form in a population. In the second phase, a participatory model is chosen for finding arguments for alternatives that can be supported by actor groups. The third phase finds genuine dialogue between the concerned parties—experts, citizens, decision makers. For this phase, several deliberative models are suitable. The final decision is made using an ordinary representative method. This model has been tried successfully by youth parliaments in several municipalities of Finland and by the Maunula suburb of Helsinki since the mid-1990s (Keskinen, 2004; Maunula, 2002). The Maunula (2002) case is based on comprehensive use of Internet tools.

## Multiphase Referendum Model

A multiphase referendum could be used in local and regional decision-making arenas. The multiphase referendum model has been discussed by Keskinen (1997) and is described in Table 1 (Keskinen & Kuosa, 2005).

The important questions raised here include the following: In what phases do the citizens participate? How? Who will coordinate the processes? If the model of democracy in the society were deliberative or direct, then citizens would participate throughout all phases, starting from Phase 1. If the democracy model used in the society would be participatory, then citizens will participate in Phases 2, 5, and 6, whereas in present representative democracy, they participate only in Phase 5 (Held, 1987; Lane & Ersson, 2000).

## New Citizen-Oriented Model

The most important approach to new democracy modeling is that different decision models can be used during

*Table 1. The multiphase referendum model*

| Phase 1 | Phase 2 | Phase 3 | Phase 4 | Phase 5 | Phase 6 | Phase 7 |
|---|---|---|---|---|---|---|
| Agenda setting: what is the opinion poll to be organized about? What for? The aim: binding or recommendatory? | What will be asked? The background research and its results are disseminated. Dialogues, discussions, learning processes, developing the alternatives needed for Phase 3 | What are the alternatives for the referendum? | What are the methods used in the referendum? Technical solutions, alternative tools for opinion giving? | The referendum process | Presenting and disseminating the results, public dialogue, and debates | Decisions based on the results, other action or events recurring from Phase 1. |

*Table 2. Comparison of e-democracy models (revised and complemented from Carson et al., 2003); the ICT tools and the Internet employed in all models*

| Models | Opinions Accessed | Weakness/Strength |
|---|---|---|
| **Televote and ETM Models** | Explores what respondents think now measured against what people think after they receive additional information (with encouragement to engage in discussion with family and friends). | If discussing only with like-minded people (or not discussing at all), respondents may become confused, anxious, or entrenched in their views due to the unexpected complexity of an issue. Questions can be answered only if private research is undertaken. Self-interest is tempered by conversation with others (if discussion occurs). |
| **Citizens' Jury Model** | What people think after they have had access to full information, an opportunity to question specialists, and time to argue/discuss the merits of the case with their peers. Required to build consensus but not to reach it. The process is flexible to meet the group's needs. | Allows for decisions (usually in the form of recommendations) that can take account of the complexity of the issue, minority opinions and new ideas. Diversity of opinions and independent, skilled facilitation. Time for deliberation means that any concerns can be allayed or confirmed. Appeals to common interest. |
| **Funnel Model** | What people think in several phases: (1) free forum for direct democracy; all tools and methods allowed; (2) alternatives selected for further work by participatory models; (3) dialogue in deliberative mode between decision makers and citizens; (4) decision making through representative methods. | Wide array of opinions come together, long hyper-cycle type knowledge development process assures that all voices are heard and that minorities stay minorities. Time for deliberation granted. Time-consuming. Appeals to common interest. |
| **Multi-Phase Referendum Model** | What people think now, starting with agenda setting (i.e., what issues will be processed and what are the options [several] and how the result will be treated). Opinion is expressed as a vote in several phases, if decided so. | Several alternative responses are available, and respondents may be confused and anxious about the unexpected complexity of an issue in the absence of debate. Appeals to self-interest but gives the opportunity to converge after several rounds of votes. Time-consuming. |
| **Citizen-Oriented Model** | Respondents are asked for well-argued and weighted opinions that have been formed by self-organizing groups of people through direct and deliberative democratic dialogue processes. Funnel Model appropriate. | Model is time-consuming and, in the beginning, sensitive to those opinions that are voiced loudest. However, given enough time and varying combinations of group members, all voices evidently will be heard. Appeals to both self and common interests. |

different stages of the decision process. This means that all of the models of citizenship are not mutually exclusive, but that they play different roles during the life cycle of the process and, furthermore, are decided by the citizens. In the citizen-oriented Model, citizens are considered to be decision makers with equal opportunities to reach representative decision makers. In this model, the vital difference from all other models is that the citizens, not the politicians, set the agenda; that is, this process should be interactive and based on win-win strategies (Henderson, 1996). Actually, all citizens should be able to take part in strategic decision making, while conventional decision makers can take the role of executive decision makers by utilizing the Internet and other ICT tools (OECD, 2001; Keskinen, 2004).

## Comparison of Interactive Decision-Making and E-Democracy Models

The comparison shows some common factors of all the methods of deliberative models. On the one hand, they aim at genuine dialogue, representativeness, deepening understanding of the complexity of the issues to be decided, enhancement of the knowledge base, and involvement of several new multi-stakeholders; on the other hand, they specifically challenge the decision-making processes and the time spent preparing arguments for good decisions (Santa Fe Institute, 2001; Keskinen et al., 2003). Table 2 compares the successful models used (e.g., Finland) (Keskinen, 1997, 1999), Australia (Carson & Martin, 1999; Carson, White, Hendriks, & Palmer, 2003), Sweden (Ohlin, 1998), Denmark (Schmidt, 1993), and the U.S. (Becker, 1995; Keskinen, 2004; Slaton, 1992).

In summary, the most important approach to new democracy modeling is that different decision models can be used during different stages of the decision process. This means that all the models of citizenship are not mutually exclusive but complement each other (Becker & Slaton, 2000). In the new citizen-nriented model, citizens are considered decision makers with equal opportunities to reach representative decision makers. In this model, the vital difference from all other models is that the citizens, not the politicians alone, set the agenda.

## FUTURE TRENDS

The future models of democracy are very open in regard to the technology utilized; almost any current technology can be used for implementation of them. The critical question is more of a political and a social one: What type of citizenship models do European or Western societies want to develop for what types of decisions? The citizen-oriented model can be created in a technological or political sense, but a public understanding should emerge on actually wanting this type of participation. More participation in every decision is not necessarily compatible with an efficient modern state, even a democratic one. Actually, the great challenge of the future for societal decision making is how to incorporate the self-organizing, ad-hoc decision making to the representative official decision-making processes in a democratic manner (Becker & Slaton, 1997; Keskinen, 2004; Rättilä, 1999; Woolpert, Slaton, & Schwerin, 1998).

## CONCLUSION

As a challenge for collaboration of ICT developers and policy developers, it is clear that much more tailored ICT tools are needed in order to create necessary forums for public dialogue in accordance with the 21st century's new needs. These forums should encompass interested and motivated citizens as well as responsible political and societal decision makers who form the present social networks that are working for our common issues, which is what democracy should be about (Keskinen et al., 2001). As democracy advocate Benjamin Barber (1984, p. 195) said, "We must together govern our societies ourselves; there is no one else to govern for us."

## KEY TERMS

**Access:** One of the three preconditions for citizen participation in e-democracy (Access-Competence-Motivation). Access to communication involves existence of technical and logical access point, communications device, and permission to access.

**Citizen-Oriented Model:** In a citizen-oriented model for e-democracy, citizens are considered to be decision makers with equal opportunities to reach representative decision makers. In this model, the citizens, not the politicians, set the agenda; this process is interactive and based on win-win strategies. However, there has to be a procedure in order to coordinate this process and to avoid the continuous need for voter input. Citizens should be able take part in strategic decision making, while conventional decision makers take the role of executive decision makers.

**Citizens' Jury:** A group of people selected for preparation of public opinion. The jury typically is selected using stratified sampling in order to match a profile of a given population. The participants (usually a group of 12 to 20) spend two to five days deliberating on a charge under the guidance of an impartial moderator. Participants have opportunities to question experts and to discuss the complexities of the issue and are asked to work toward a consensus response.

**Competence:** One of the three preconditions for citizen participation in e-democracy (Access-Competence-Motivation). Communications competence means that a person has the ability to use channels of communication, opportunity, access, and skills in order to use the devices involved and to formulate message.

**Deliberative Poll, Televote:** As a specific researched and tested model, it is a scientific public opinion poll with a deliberative element Generally, a phone survey is conducted, then hundreds of respondents are invited (using statistical sampling technology) to come together at a single location, or they are asked to deliberate among themselves and with other interested people and to form opinions. When they gather, they deliberate on the issue and have an opportunity to work in small groups (each like a citizens' jury or planning cell), also spending time in plenary sessions in which experts are questioned. At the end of the gathering (usually conducted for two to three days), participants are surveyed again.

**E-Democracy, Teledemocracy:** The use of modern information and communications technologies as instruments to empower the people in a democracy in order to help set agendas, establish priorities, make important policies and participate in decision making and implementation in an informed and deliberative way.

**E-Governance:** Considered to be an integrative term for e-government and e-democracy to start with, but also other e-oriented operations in the knowledge society can be placed under the umbrella; however, the concept is still evolving. E-governance means governing personal or organizational life with the help of ICT.

**Electronic Town Meeting (ETM):** In an electronic town meeting, there is discussion, deliberation among ordinary citizens, and a vote that determines the outcome. Electronic media are used to facilitate the process. Generally, a combination of several of the following electronic means are used: interactive TV, interactive radio, scientific deliberative polling, telephone voting, mobile phones, and a wide variety of face-to-face meetings. The focus of the process is on problem issues, involved planning, or envisioning processes. ETM can be conducted in local, regional, or national levels.

**Empowerment:** A process of transferring power in order to enable people to govern their own lives, not to gain power over other people or events. People are empowered when they are given the authority to make decisions in their daily work, using their own judgment to take apt actions in new situations rather than consulting management.

**Motivation:** One of the three preconditions for citizen participation in e-democracy (Access-Competence-Motivation). The sender and recipient of communications must have a reason for sending messages and for learning new skills. Human needs for self-expression, attachment, societal interaction, association, and control of one's own life are motivating reasons. In addition, in order to be motivated, people need to feel that their opinions are heard and that they can have an impact on decisions. Without motivation, citizens will not participate in public issues.

**Referendum:** A public opinion poll, generally binding, where local, regional, or national authorities offer citizens the possibility to vote on a specific issue, generally with two alternatives: yes or no. The multiphase referendum uses deliberative agenda setting, feedback processes, and multiple choices, and therefore, actually presupposes a deliberative or participatory democracy model to be employed.

**Teledemocracy:** See E-Democracy.

**Televote:** See Deliberative Poll.

# From CCTV to Biometrics through Mobile Surveillance

F

## INTRODUCTION

*Surveillance* is the act or process of observing, tracking, or recording personal details for the purpose of exercising control over the individual or population being watched. Control in this context can mean many things, from directly influencing the behavior of the observed to the use of gathered information for the purpose of management or governance.

Mobile surveillance can be defined as two distinct, yet related, practices. The first is the ability to observe the physical movement of an individual through space. This is most often accomplished through documenting their interaction with a surveillance network. The object of surveillance is tracked from one node of the network to another, providing a record of behavior. The second practice is often referred to as dataveillance, or the ability to monitor an individual's behavior through studying a trail of personally identifiable data, including credit card purchases, mobile phone calls, and health records.

Mobile surveillance employs an array of technologies including video and photography cameras, visual recognition software, radio frequency identification (RFID), global positioning receivers (GPS), information and communication technologies (ICTs), and biometrics. Examples of mobile surveillance networks include the dense deployment of closed-circuit television (CCTV), video, and photographic technologies in a distinct geographic space to monitor activity, the tracking of automobiles and mobile phones via GPS, and radio frequency sensing that records motion as identity chips pass through a distributed network of receivers. As these networks proliferate, individuals are the exposed to overlapping layers of surveillance. Although many of these surveillance networks are deployed for limited purposes, the increasing ability to save and store personally identifiable information in searchable databases, and the ability to mine information from multiple sources raises privacy concerns for the individual. This is especially true in advanced capitalist societies that rely on sophisticated data gathering to track, model, and predict consumer behavior, as well as for citizen management.

## BACKGROUND: SURVEILLANCE, BUREAUCRACY, AND THE STATE

Surveillance has been an integral part of human social interaction since the need for oversight and management of collective endeavors was first realized. As the scope and complexity of these endeavors grew, the need for more reliable information increased accordingly. Surveillance has long been an important method for dealing with risk (Lyon, 1994, 2002, 2003a, 2003b), as the advanced knowledge of aberrant behavior can help minimize the threat or upheaval caused by the unusual events or actions. Therefore, surveillance is often a positive feature of governance, allowing those in power to manage against risk in order to protect public welfare. Nevertheless, surveillance regimes are also employed by the state out of a "desire to more completely manage populations (Lyon, 2003b, p. 20)," identifying and sorting out individuals who's behavior is deemed threatening to the majority. It is of little surprise that the fields of law enforcement and national security and intelligence gathering are the sites of some of the most sophisticated surveillance practices as well as the targets of social concern over privacy and the power of the state.

In *Discipline and Punish*, Foucault (1977) examines the rise of the surveillance society by utilizing Jeremy Bentham's Panopticon prison as a model for the exercise of power in modern society. The architecture of the Panopticon exerts power over the incarcerated body by making it constantly visible to an invisible central observer. The prospect of persistent observation is used to ensure compliance with the disciplinary rules of the institution, therefore making the simple awareness of surveillance a means of exerting power over the watched individual.

Foucault (1977) notes the historic extension of surveillance architecture from the prison to other social institutions such as schools, hospitals, mental institutions, and the workplace, which increasingly relied on the specter of persistent observation in order to exert control over their subjects. In addition to the direct surveillance enabled by panoptic architecture, the rise of bureaucratic

organizations, especially in the West, lead to an institutionalization of mechanisms for the capture, retention, and processing of personally identifiable data.

The direct and indirect surveillance employed by public libraries in Victorian Britain (Black, 2001) serves as a historical example of this phenomenon. Libraries have been at the forefront of efforts to manage, catalogue, and retrieve information since the sorting, and storing of information is central to their mission. To this end, libraries have employed increasingly sophisticated surveillance mechanisms to track, record, and monitor the habits of their users and their interaction with the library's collections. While the hierarchical systems of knowledge and the tracking of library users' habits employed in Victorian libraries did not necessarily originate as a means of coercive control but often as an effort to provide enhanced service, their existence often placed the librarian in a position of social power over those observed (Black, 2001, p. 74).

Surveillance is a central feature of the rational bureaucratic organization in modern society, and the explosion of surveillance is intertwined with the historical development and growth of bureaucratic organizations (Beniger, 1986; Dandeker, 1990; Foucault, 1977; Giddens, 1987; Lyon, 1994; Weber, 1968). Dandeker describes the symbiotic relationship between capitalist organizations and the modern state, declaring that their activities are focused on both the internal exigencies of managing a system of administrative control over subject populations and the problems attendant upon monitoring and managing external relations with other organizations. This theme has been central in providing a framework in terms of which the growth of bureaucratic surveillance in modern societies can be explained. (p. 195)

In *Control Revolution*, Beniger (1986) writes that "bureaucratic organization serves as the generalized means to control all large social systems, tending to develop whenever collective activities need to be coordinated toward some explicit and impersonal goal, that is, to be controlled" (p. 390). As the complexity of operations required to control the functioning of a bureaucratic organization increases, so to does the need for advanced technologies to manage information throughput (Beniger, 1986, p. 424). Historically, bureaucratic organizations have utilized technological advances to exert control over the volume of information vital to the functioning of their operation, often to automate data gathering, record keeping, and record retrieval.

Dandeker (1990, p. 40) provides an excellent four point schema for evaluating the surveillance capacity of organizations. This model evaluates the size of the files held in a surveillance system, the centralization of those files, the speed of information flows, and the points of contact between the system and its subject population. The escalating use of automated surveillance technologies, sorting software, and searchable computer databases has lead to increases in all four of these areas and has greatly enhanced the surveillance capacity of organizations, making the practice of mobile surveillance possible. The ability of organizations to utilize information and computer technologies in order to search and cross-reference personally identifiable information from a variety of independently established databases has greatly expanded the scope of their surveillance, and has enabled the tracking of individual through digital data profiles compiled from records stored in computer databases.

## MOBILE SURVEILLANCE

As social relationships have become more fluid and individual mobility increases, surveillance technologies have developed to keep up with the mobile subject. They are increasingly capable of tracking subjects on the move, and across various media, and through a variety of environments, casting a continual and inescapable gaze upon their subject (Lyon, 2003b). This is accomplished in a variety of ways. Perhaps the surveillance regime that most clearly illustrates the capabilities of mobile surveillance, and embodies the extension of Foucault's panopticism into society at large is CCTV. A CCTV system consists of a network of cameras that provide optical surveillance of a specific geographic area and transmits the visual data to a central location for analysis.

CCTV is most often employed by law enforcement in high-crime areas as a method for identifying criminal behavior, as well as a deterrent factor. Additionally, Norris and Armstrong (pp. 43-51) note the use of CCTV surveillance in residential areas, schools, banks, shops, workplaces, hospitals, schools, and train stations, as well as to regulate automobile traffic and police football stadia. The ubiquity of CCTV in Britain has lead to authors to conjecture that for a British urban dweller it is nearly impossible to move through public and, to some extent, private space without being photographed and recorded (Norris & Armstrong, 1999, p. 2). Increasingly these systems are being automated to work with face recognition software to look for "known" individuals and track their movement from camera to camera throughout the network.

While CCTV surveillance is directly concerned with the local observation of movement, the rise of dataveillance is critical for the observation of what Lyon refers to as "disappearing bodies" (Lyon, 2002). As transactions occur over longer distances, often with the aid of information and communication technologies, the physical body "disappears" and is replaced with personally identifiable data that represents the individual (Gandy, 1993). Mecha-

nisms such as security numbers, banking codes, and telephone numbers are recorded to provide a record of the interaction, which is often stored in computer databases. This information can be mined and analyzed by software using sophisticated algorithms to detect information patterns and assign a relative value to an individual, or what Gandy refers to as the "panoptic sort."

Automation through the employment of information and communications technologies and advances in surveillance hardware and software have expand the scope and speed of surveillance systems, enabling these systems to increasingly observe and record real-time activity and physical mobility at often exceptional distances. The growing reliance on information and communications technologies to conduct and coordinate surveillance has lead to the increasing importance of codes in the surveillance process (Lyon, 2003b). Codes are not only critical for the efficient operation of computerized systems, but they are also embedded with politics (Lessig, 1999). Programming establishes the rules that guide the functioning of computer codes, determining what information is stored and sorted, which individuals are tracked, and whose data-profile is flagged for review. To this end, the choices that are made during the programming and implementation of surveillance systems generate the set of laws that govern the operation of those systems.

In the wake of the September 11th attacks on New York and Washington, DC, the U.S. government has been on the forefront of bureaucratic uses of mobile surveillance technology and systems. Examples include the recently discontinued Terrorism Information Awareness (TIA) program (formerly Total Information Awareness) that was under development by the Defense Advanced Research Projects Agency (DARPA). The goal of the program was to preempt terrorist attacks by examining a variety of independently collected data sources in order to build comprehensive data profiles of potential terrorists. To accomplish this goal, DARPA was developing software that would have enabled intelligence officials to mine a virtual database that would consist of government, financial, education, medical and housing records from around the globe (Swartz, 2003, p. 6). Although the program was later abandoned, extensive data collection and data mining operations will almost certainly continue to be developed by national governments wishing to hedge against the risks inherent in an increasingly globalized world characterized by global flows of information, finance, and population (Castells, 1996).

## FUTURE TRENDS

In *Surveillance After September 11*, David Lyon (2003a) provides us with three key issues that have emerged during the U.S.-lead "war on terror," namely suspicion, secrecy, and the mobilization of citizens as spies. He asserts that suspicion has been harnessed by local and national governments to broaden the scope of who may legitimately become a target of state-sponsored surveillance, while also being used to justify the secrecy of new or enhanced surveillance regimes under the rubric of "national security." Finally, the culture of suspicion that has arisen in the U.S. and to varying degrees in other societies around the world has increased acceptance for enhanced surveillance activities.

Mobile surveillance must be viewed through the prism of Lyon's three-part schema. If the culture of suspicion persists as a major motivating factor in bureaucratic implementation of enhanced surveillance capabilities, we can expect that new mobile surveillance technologies will be at the forefront of research, development and implementation, as they provide authorities with the ability to track and sort individuals and populations in real time. In the wake of the September 11 attacks, and the subsequent string of attacks around the globe including the bombings in Madrid and Bali, a number of national governments have made upgrading their surveillance capabilities a priority. Additionally, technological advances will decrease the need for the human supervision of surveillance systems, creating a fully automated surveillance apparatus.

Three technologies in particular will enhance the surveillance capacity of the bureaucratic organization in the future: GPS, RFID, and biometrics. The inclusion of GPS receivers in mobile phones, often at lawmakers' request to provide assistance in locating missing individuals, allows for monitoring the precise location of the phone in real time, whether a call is being made or not. RFID tagging, a bonus for merchandisers keen to increase logistical efficiency, is also an ideal technology for bureaucratic management. It will likely become a permanent feature of future identification cards, as the miniaturized tags are capable of storing personally identifiable information and transmitting it wirelessly to strategically placed receivers in airports, and other access-restricted locales. Finally, biometrics, the practice of identifying an individual based on physiological characteristics, seems poised to be the next big field of personally identity. Coupled with optical surveillance, biometrics can be used to further automate CCTV systems, providing a reliable method for identifying individuals.

Serious questions must be asked about the architecture of current and future systems and the codes that govern them. Who is being tracked, how they are being tracked, and why they are being tracked are important design questions that will influence human outcomes. While it is hard to argue against the use of efficient systems that enable authorities to prevent a small hand-

ful of individuals from doing great harm to large number of innocent people, a balance must be struck between the rights of the individual and the safety of the majority. Many nations have a legal and legislative framework in place to wrestle with balancing these two responsibilities. However, the push for secrecy inspired by a climate of suspicion may be the single greatest variable to consider when examining the future of surveillance. A move toward greater state secrecy serves to obscure the existence and operation of the surveillance apparatus, limiting transparency, and diminishing the possibility of legislative and public oversight.

Looking forward, it is important to remember that technological development must be coupled with legislative action and social awareness. State sponsored surveillance that is designed to protect the public from harm should be at least minimally transparent and ideally subjected to oversight in order to protect against abuses. Technological advances in data gathering, sorting, storage, and retrieval, coupled with complimentary advances in computing and mobile ICTs will enhance the surveillance capacity of large organizations. They will be increasingly able to tap into vast stores of personally identifiable information from multiple sources through refined data-mining practices.

## CONCLUSION

The regulatory framework in which these organizations operate will help determine which surveillance practices are available to the state and which are not. Legislative bodies will need to set guidelines that simultaneously encourage technological growth and positive uses of surveillance, while demanding state accountability and balancing the rights of the citizen and individual to privacy. Despite increasing globalization and surveillance regimes aimed at minimizing the risks that arise from global population flows, it is import to remember that concept of privacy and privacy regulations vary greatly from state to state. A patchwork of laws governs the surveillance of globally mobile bodies, as individuals pass borders and therefore into and out of the gaze of the state surveillance apparatus. Post-September 11th agreements between nations have lead to greater international security cooperation and information sharing, subjecting the actions of citizens of one nation to the gaze of another. What right to privacy does the global citizen have from the government of a foreign nation, for whom he or she cannot vote?

The ability of the citizenry and legislatures in democratic nations to oppose, alter, and eliminate surveillance regimes should not be underestimated. Despite an intense "culture of suspicion" following the September 11, U.S. citizens and lawmakers were able to halt two of the more controversial government programs designed to enhance the nation's surveillance capacity. A key surveillance passage of the USA PATRIOT Act, which granted federal authorities almost unchecked power to collect personally identifiable data, was struck down as unconstitutional by the courts, and the Terrorist Information Awareness (TIA) program, which was attempting to build highly advanced data-mining software to cull vast amount data in order to build predictive models of terrorist behavior, had its funding denied by the Congressional committee charged with its oversight after intense public scrutiny. These two local successes do not signal a victory for transparency and oversight, but rather point to a possible trend of ad hoc coalitions formed to resist specific instances of particularly intrusive state surveillance.

## KEY TERMS

**Biometrics:** Biometrics is the science and practice of verifying individual identity based on the analysis of unique physiological or behavioral characteristics. Examples include the analysis of fingerprints, retinas scanning, voice pattern analysis, facial patterns, and analysis of an individual's walking gait.

**CCTV:** Closed Circuit Television is a technological system of video surveillance that employs a closed network of cameras to provide a visual observation of a targeted area. CCTV has been used extensively in high crime areas not only as a means of fighting crime but also as a deterrent. The use of CCTV is increasingly being combined with face recognition software to create automated video surveillance networks that can operate with limited human interaction.

**Data Mining:** Data mining, also known as knowledge discovery in databases, is the practice of extracting targeted information from large databases through the use software technology utilizing algorithms to detect patters.

**Face Recognition Software:** A software package that is designed to identify individuals in crowds based on distinguishing facial characteristics. This software must be used in conjunction with visual surveillance systems such as CCTV. The facial characteristics of target individuals are loaded into computer systems that analyze the visual data captured by the visual surveillance apparatus and alter system users when a target individual is spotted.

**GPS:** Global positioning system is a satellite navigation system that is able to provide extremely accurate time and position data through the tracking of user-held receivers. The system was developed and maintained by the United States Department of Defense and is available free of charge to nonmilitary users. The system operates through transmissions between user-held and earthbound receivers to a network of satellites, whereby a receiver's exact location is determined through the process of trilateration and time is determined by the coordinated atomic clocks of the satellites.

**Identity Documents:** Identity documents take many forms from drivers licenses to passports to national identity cards. These cards are government issued documents that contain personally identifiable information often including a photograph, date of birth, place of residence, gender, physical characteristics such as height, weight, and eye and hair color, and include a unique identifier number specific to the card holder. Increasingly identity documents include personal information encoded in magnetic strips that can be read through the use of a scanner.

**RFID:** Radio frequency identification technology is a type of wireless automatic identification system that collects data and transmits it directly to a computer database using radio waves. A typical RFID system consists of a radio frequency tag that transmits identifiable data when in proximity of a reader that is then recorded to a database.

# From E-Government to E-Democracy in China

## INTRODUCTION

Endowed with 5,000 years of ancient tradition and heritage, China is reputed as the single oldest uninterrupted civilization in the world. Ancient Chinese made great contributions to mankind by the invention of the compass, gunpowder, papermaking, and printing, which are recorded in history as the Four Great Inventions. For centuries, China has been one of the world's most technologically advanced civilizations and the most dominant cultural influence to the East Asia region.

In the 21st century, China's resurgence as one of the preeminent powers brings worldwide attention. With its population of nearly 1.3 billion, its expansive territory, and its huge market potentials, China's modern development will continue to benefit the world, just as it did in ancient history.

Today, science and technology long have preoccupied China's policymakers, and there is an urgent need for China to wield modern information and communication technology (ICT) in order to reinvent government regime. However, the legacies of thousands of years of feudalistic tradition and the ideological control over the Mao era, which lasted for nearly three decades, make it difficult to revolutionize the country's governance system promptly. Therefore, the Chinese government had to adopt a gradual and steady approach toward social democratic reform. Through this process, e-government projects play an important role; for example, a national electronic audit network has given impetus to China's fiscal transparency and public expenditure management.

This article is organized as follows: First, there is a brief historical retrospect of China's cultural background; second, there is an introduction of current main e-government projects in China; finally, upon the analysis of the progression of fiscal transparency in China, an optimistic expectation of China's future e-government and e-democracy is given.

## BACKGROUND

China has a long and rich cultural tradition in which education has produced great impacts. Since ancient times, Chinese people have been educated to believe in three dominant religions—Confucianism, Taoism, and Buddhism—among which the most influencing one was Confucianism, which not only influenced people's attitudes toward life and set patterns of living and standards of social value, but also provided a solid background for China's political theories and institutions. The ingenerate hypostasis of Confucianism is worship of heaven. Pursuant to the theory of Mencius, the continuator of Confucius, heaven was considered to have strong will and intention; it can reward or punish men and women according to their behaviors. The ruler, or the emperor, is the Son of Heaven; he is the supreme person appointed by heaven, and therefore, it is heaven who is the support of an emperor's authority (Dainian, 2002). Confucius never taught people of his age any basic ideas of people's rights against tyranny, the nature of human beings, and so forth. One of Confucius' apothegms in his famous book *Analects* is that common people can be made to follow the way; they cannot be made to understand the way (Confucius, 1998). By saying so, Confucianism teaches that a distinctive hierarchy of family, society, and state can bring harmony to the world, where everyone has peace, order, and discipline, which, in turn, will result in material prosperity for both the state and its people.

Taoism, the second influencing ideological thought in China, highlighted the harmonization of man and nature by emphasizing that the world is perfect and that people cannot improve it. The central theme of Taoism is"action by non-action," or "doing nothing"; that is, nothing strained, artificial, or unnatural. Man should act naturally upon object principles instead of imposing his subjective judgment on other people and external things. Man should be free from space and time, from worry and care, and from entanglement with politics and bureaucracy. Hence, through spontaneous compliance with the impulses of one's own essential nature and by emptying oneself of all doctrines and knowledge, one finally can achieve harmonization with heaven and can transcend all mundane distinctions (Tzu, 1998).

Differing from Western civilization, which originated from the Athenian democratic tradition of ancient Greece, China's historic and traditional background implied little democratic and transparent elements; ordinary Chinese people were not entitled to the basic right of participating in government affairs. From another point of view, China's history is characterized by repeated divisions and

reunifications amid alternating periods of peace, war, and violent imperial dynastic change, which made the leaders of every dynasty by and large neglect people's voices and rights. During the period of the Culture Revolution from 1966 to 1976, this situation reached an extreme level.

## E-GOVERNMENT PROJECTS IN CHINA

A number of potentially significant events occurred after China adopted the open door and economic reform policy in the latter 1970s; since then, China has made great progress toward integration with world social and economic development. Encountering the age of information technology, the Chinese government has been investing actively in the technology of the Internet and has been encouraging its usage for the purpose of capturing the potential commercial value, while engaging in e-government construction so that scientific and technological achievements can be turned into practical productive forces as soon as possible and can enhance the spreading and application of high technology and mature technologies (China Internet Information Center, 2004). One of the great achievements is a series of national e-government projects that have been implementing gradually and steadily in government agencies and geographical regions. The e-government projects consist of two parallel stages through a top-down approach: one is the Government Online Project (GOP); the other is the so-called Golden Projects. According to Chinese ancient tradition, golden color is noble and auspicious, and the use of the color was restricted only to some special occasions. Giving the name Golden Projects to e-government projects indicates that the Chinese government has attached great importance to the projects and has made a strong commitment to carry them out (Ling, 2004).

The Government Online Project was scheduled to take place in three phases:

- **Phase One: Enabling Technologies:** Focused on connecting 800 to 1,000 government offices and agencies to the Internet.
- **Phase Two: Information Sharing:** Aimed at having government offices and agencies move their information systems into compatible electronic form.
- **Phase Three: Paperless Government:** Planned to occur sometime in the future, when government operation will be based on digital processing and totally free from paper works. The purpose of the GOP is to create a centrally accessible administrative system that collects and transports data to and from users, who are supposed to be the public and the enterprise as well as government departments. By official statement, the GOP will pursue the following:
  - Provide more effective coordination between and across government organizations, both horizontally (among ministries) and vertically (from center to locality)
  - Build up national and worldwide confidence in the Chinese central and local governments' presence on and commitment to the Internet.
  - Make available to the public government information while also reducing government expenses by increasing administrative efficiency.
  - Lay a base for the establishment and growth of China's electronic government.
  - Encourage electronic procurement.
  - Begin to accelerate the acceptance and use of the information economy in China. (China Ministry of Information Industry, 2000)

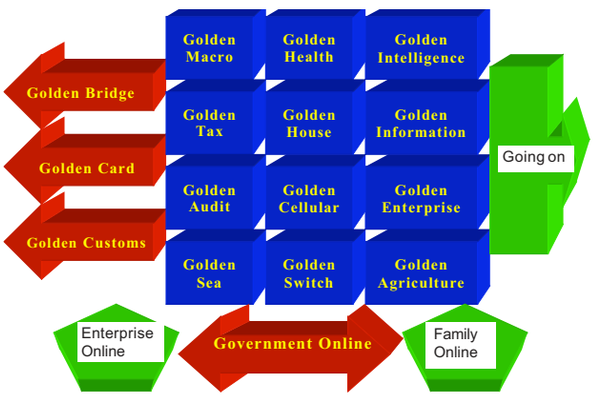
The Government Online Project was launched formally in 1999; by the end of 2000, about 80% of all government agencies, both local and national, had established their Web sites on the Internet. Following the Government Online Project, it has been the Enterprises Online and Family Online Projects. Nowadays, government Web sites offer a great range of information, from introductions of departmental functions and state and local laws and regulations to information about tax payments and project bids. After the sudden outbreak of the SARS (Severe Acute Respiratory Syndrome) epidemic in early 2003, the Chinese government had made great progress toward information exposure in reporting all paroxysmal epidemics and chronic diseases such as hepatitis B and C, schistosomiasis, tuberculosis, HIV/AIDS, and so forth, across the country on official Web sites in a timely and regular manner.

During the period of 1991 to 2000, China's government focused on another ambitious, comprehensive, and far-reaching e-government construction—the Golden Projects (see Figure 1). Since pioneering three key projects—the Golden Bridge Project, the Golden Cards Project, and the Golden Customs Project—a series of integrated Golden Projects, including intra-government communications, education, healthcare, medical research, and agriculture, has been implementing gradually and steadily in the country.

## FUTURE TRENDS

Although much of e-government is about the delivery of services and the government's dealings with the private

*Figure 1. Key golden projects in China (PRC)*



sector, there is another dimension to it. As the Industrial Revolution occurred in Great Britain but spread to other countries and altered global economy and society at the end of the 18th century, so China's present digital revolution also may exert a profound influence on the operation of government and on public sectors. It will not be ICT by itself that redirects and reshapes the functions of government and makes it somehow different or better than before, but ICT will enable government's internal and external communication to gain speed, precision, simplicity, outreach, and networking capacity and eventually to contribute to change governmental operation mechanism. In the same way, a silent but important revolution led by a series of well-planed, comprehensive e-government programs is taking place in China; e-government projects, indeed, act as a special kind of catalyst to e-democracy as well as good governance in this ancient country (Ling, 2004, 2005). It is the e-government projects that empower Chinese people to participate in and to monitor public affairs such as public revenue and expenditures. Government cannot build a fence around citizens or passively restrict them as mere consumers or customers of government services; those same citizens also are owners or shareholders of government itself.

A cohesive e-democracy progress generally is divided into several parts: e-participation, e-engagement, e-campaigning, e-voting, and so forth. Information disclosure by e-publishing is absolutely the precondition for all of the aforementioned e-activities. In China, such an e-project concerning information disclosure and public participation is the famous Golden Audit Project. The unprecedented e-government projects in the country had promoted China's political transparency, especially in the public finance sector, just by publishing and disseminating information to the public about government wrongdoings. Although the initiative efforts made by the Chinese government apparently should be regarded as in an infant stage in the long way of e-democracy, it did challenge the secret tradition and passive relationship between people and their government in Chinese feudalistic and absolute ideology and, therefore, manifests the steady progress and optimistic trends of China's social and political reform in the future.

In 2000, the China National Audit Office (CNAO) launched the Golden Auditing Project and kept improving it in tandem with other parallel e-government projects covering the fields of public finance, tax collection, customs duty, social security, and so forth. The project is aimed at establishing an auditing information system that will ensure the effective monitoring and supervision of government revenue and expenditures through a new online auditing model (Deming, 2003). According to the Constitution and the Audit Law, the CNAO is directly under the leadership of the Premier of the State Council, taking charge of government audits nationwide. The CNAO is responsible for the following (CNAO, 2004):

- Auditing budget implementation, final accounts, and management, and use of off-budget funds of departments at the corresponding levels and governments at lower levels.
- Auditing assets, liabilities, profits, and losses of state-owned monetary organizations and state-owned enterprises.
- Auditing revenues and expenditures of state non-profit undertakings.
- Auditing budget implementation and final accounts of state construction projects.
- Auditing revenues and expenditures of projects with assistance or loans provided by international organizations or foreign governments.
- Auditing state-owned enterprises that are vital to the national economy and to people's livelihoods

and receiving large entitlements from the government or suffering substantial losses as well as other state-owned enterprises designated by the State Council or corresponding local people's governments.
- Auditing special funds, such as Social Security funds and agricultural development funds.

Every year, audit institutions at various levels should present reports on the audit of budget implementation and other revenues and expenditures of public finance to the standing committees of the people's congresses at their corresponding levels. Their audit scope should cover the following areas:

- Implementation of the central budget, other revenues, and expenditures of public finance.
- Revenues and expenditures of central departments, non-profit undertakings, and their subordinate units.
- Budget implementation and final accounts of provincial people's governments.
- Revenues and expenditures of the Central Bank, assets, liabilities, profits, and losses of central monetary institutions.
- Revenues and expenditures or central government-owned enterprises and enterprises where state assets dominate or predominate.
- Revenues and expenditures related to funds managed by relevant departments of the State Council.
- Revenues and expenditures of projects with loans and assistance from international organizations and foreign governments.

One of the significant advances to promote fiscal transparency by the Chinese government is to release the full text of its auditing reports to the public through CNAO's Internet Web site (http://www.audit.gov.cn). Before the year 2003, the CNAO only issued full reports to the State Council and to the National People's Congress by keeping full audit texts secret to the public, or it only had some abstracts published sporadically in some occasions. The first open budgeting audit report issued on June 25, 2003, and based on a great number of auditing data focused on the budget process of the 2002 fiscal year and sharply criticized some improper activities of the Ministry of Finance, state-owned banks, large state-owned enterprises, and some other ministries. For instance, the report exposed serious problems ranging from the Ministry of Finance's mishandling of pension funds to fraudulent loans granted by dozens of local branches of the China Construction Bank. According to this audit report, financial malpractice was discovered at 41 of the 55 surveyed departments in the central government and its affiliates. The misused money amounted to 1.4 billion yuan (US$170 million) in 2003's budgeting period; the situation is so serious that even emergency funds earmarked for disaster-relief programs were defaulted. The data show that during the years between 1983 and 2003, when the CNAO was established, it has examined more than 3 million institutions throughout the country and has exposed extensive misuse of public funds by some government departments, seized illegal and suspect funds worth 130 billion yuan (US$15.7 billion) (Xinhua News Agency, 2004).

The release of the national audit report via an e-government project drew wide media attention like a thunderbolt. The results of auditing, transmitted promptly by numerous media outlets, consequently shook the whole country and resulted in a so-called Audit Storm in this traditional nation and among its docile citizens. Meanwhile, the Audit Storm has been sweeping rapidly from central to local levels; for example, in Guangdong, a southern province, local delegates of the congress for the first time seriously checked and ratified the budget report of the province. They noticed that four kindergartens affiliated with government agencies, which were reserved for children of government employees, were allocated more than 20 million yuan (US$2.41 million); thus, delegates demanded an explanation of why taxpayers' money should be used to raise civil servants' children without approval or without even informing taxpayers. Other problems detected by the local audit body and delegates include the lack of a feasibility study before commencing a constriction project, poor accounting, inadequate management, shortcomings in bidding processes, low efficiency, legal violations, and so forth (Xinhua News Agency, 2004).

Spurred by the process of open budget and fiscal transparency, the fight against corruption has intensified in recent years. The Supreme People's Court of China, the juridical section of the government, also has been playing an active role in safeguarding the country's financial security, protecting the growth of non-public economic sectors, maintaining a sound market economic order, and ensuring fair market competitions. In 2003, Chinese courts at all levels concluded investigations into 5,687,905 cases that involved a sum of 768.5 billion yuan, and six former ministerial-level officials were sentenced on charges of job-related crimes. The penalties on them ranged from death sentence with a reprieve to life imprisonment and 12 to 15 years behind bars, according to China's chief justice report (Xinhua News Agency, 2004).

On October 20 2005, the China State Council Information Office published a white paper entitled *Building of Political Democracy in China*. The document, composed of 10 chapters, gave a detailed account of the inception, development, contents, and principles of the country's political democracy. It also emphasized the basic stand by

which the country will abide and pointed out the problems that the country has to overcome and major steps to be taken in the reforms of its political system. The white paper on political democracy is an important signal for the coming of e-democracy in China.

## CONCLUSION

The transition process from e-government to e-democracy involves a number of complex government changes, among which the most important reform for China lies in the fundamental transformation of its public finance regime from a secret tradition that has lasted for centuries into a modern democratic open process. Scholars have suggested that the government-citizen relationship should bring together both top-down and bottom-up approaches with three types of interaction: one-way information provision; two way consultation relationship, where citizens are given the opportunity to give feedback on issues; and active participation, by which citizens are dynamically engaged in policymaking (OECD, 2003). Following this logic, e-government performance is edging up in China; the progress seems very small through the eyes of people from democratic nations, but it is, indeed, a great leap forward from its ancient feudalistic tradition and formerly ideological control practice. Fiscal transparency via an e-government project will usher good governance and e-democracy into this ancient country.

## KEY TERMS

**Active Participation of E-Engagement:** Refers to a relation based on partnership with government, in which citizens actively engage in the policymaking process. It acknowledges a role for citizens in proposing policy options and shaping the policy dialogue, although the responsibility for the final decision or policy formulation rests with government (OECD, 2003).

**One-Way Relation of E-Engagement (Information Stage):** Refers to a relation in which government produces and delivers information for use by citizens. It covers both passive access to information upon demand by citizens and active measures by government to disseminate information to citizens (OECD, 2003).

**The Cultural Revolution:** A political movement launched by Chinese Communist Party Chairman Mao Zedong during his last decade in power (1966-1976) in order to renew the spirit of the Chinese revolution. Fearing that China would develop along the lines of the Soviet model and concerned about his own place in history, Mao threw China's cities into turmoil in a monumental effort to reverse the historic processes underway.

**Two-Way Relation of E-Engagement (Consultation Stage):** Refers to a relation in which citizens provide feedback to government. It is based on the prior definition by government of the issue on which citizens' views are being sought and requires the provision of information (OECD, 2003).

## APPENDIX

**Confucius 1**

**Confucius** (c. 551-479 B.C.). Chinese philosopher and one of the most influential figures in Chinese history, he is honored as a great teacher and sage in China. Confucianism, his philosophy, is a major system of thought in China and is concerned with the principles of good conduct, practical wisdom, and proper social relationships. The principles of Confucianism are contained in the nine ancient Chinese works handed down by Confucius and his followers, who lived in an age of great philosophic activity. Politically, Confucius advocated a paternalistic government in which the sovereign is benevolent and honorable, and the subjects are respectful and obedient. He enjoined all individuals to observe carefully their duties toward the state. In subsequent centuries, his teachings exerted a powerful influence on the Chinese nation.

**Confucius 2**

***The Analects,*** a book by Confucius that records all of the "Confucius-said" aphorisms, was compiled by his students after his death. Because *The Analects* was not written as a systematic philosophy, it contains frequent contradictions, and many of the philosophical doctrines are ambiguous. *The Analects* became the basis of the Chinese social lifestyle and the fundamental religious and philosophical point of view of most traditionalist Chinese intellectuals throughout history.

**Confucius 3**

**Mencius 1**

**Mencius** (c. 371-288 B.C.), Chinese philosopher and successor of Confucius. After studying the philosophy of Confucius, he traveled for years expounding Confucianism and lecturing rulers on their duties toward their subjects. He believed that the power to govern comes from God and should be exercised in the interests of the common people. He spent the latter part of his life in seclusion with his disciples. In his teachings, he stressed the belief that people by nature are good, but that this goodness becomes manifest only when they experience peace of mind, which, in turn, depends on material security. If rulers, therefore, reduce their subjects to poverty and selfishness, they should be deposed. Since the 11th century, Mencius has been recognized as one of China's greatest philosophers; the *Mencius* (*Book of Mencius*) is regarded as a basic Confucian text

**Mencius 2**

**Lao-tzu 1**

**Lao-tzu** (570?-490? B.C.), Chinese philosopher and reputed founder of Taoism. He is the author of the *Tao-te Ching* (*Classic of the Way and Its Virtue*), a philosophical treatise. By far the most translated Chinese literary work, this small book has had an enormous influence on Chinese thought and culture. It teaches that "the way" (*tao*) is realized through recognition and acceptance of nothingness; that is, wisdom is understanding that weakness truly equals strength, that happiness depends on disaster, and that passivity is the greatest action

**The Eight Diagrams (Taoism)**

**Taoism.** Chinese philosophical and religious system dating from about the 4th century B.C. Among native Chinese schools of thought, the influence of Taoism has been second only to that of Confucianism. The essential Taoist philosophical and mystical beliefs can be found in the *Tao-te Ching* (*Classic of the Way and Its Power*), a composite text dating from about the 3rd century B.C. and attributed to the historical figure Lao-tzu. Whereas Confucianism urged the individual to conform to the standards of an ideal social system, Taoism maintained that the individual should ignore the dictates of society and seek only to conform to the underlying pattern of the universe

# From E-Government to E-Governance

## INTRODUCTION

The purpose of the present article is twofold: (a) to support the definitions of e-government (eGvt) and e-governance (eG) based on content (and not on technology only); (b) to analyze the relationship between eGvt and eG.

## DEFINITIONS

Every socio-economic system (SES) (e.g., a country) includes a societal governance subsystem. This subsystem refers to the activities of the central, regional, and local state institutions of the Executive, Judicial, and Legislative Authorities. It has an important role in determining the legislative, judicial, fiscal, and other public services environment within which citizens, households, institutions, businesses, and NGOs (elements of the societal operational subsystem) live or function.(The societal governance tasks referring to relationships with other SESs is not discussed here, in order not to complicate the analysis. However, this does not impact the generality).

In the circumstances of building the Information Society, the societal governance uses advanced information and communication technology (ICT). The terms government online, online government, and digital government (DG) are proper to characterize this category of governance, as opposed to the traditional governance based on "paper and pen technology." (Because of the long tradition, the "bureaucratic culture" is still strong. It explains the presence of still existing "computerized paper and pen technology based" public information systems. They are sometimes called "insular information systems". However, many times the term "eGvt" is also used in the generic sense of "informatized governance."

## SHORT HISTORICAL PERSPECTIVE

In the 50s, a rapid expansion of the use of digital computers in practical every field of human activity started. The defense (such as weapon research or U.S.'s Strategic Air Command) was the first field using advanced ICT. Nonmilitary applications of computers started with such applications as the U.S. Census of 1951 and first computerized management information systems designed and implemented by large U.S. companies (General Electric, Du Pont de Nemours, and Honeywell to name a few). Computer process control and electronic data processing (EDP) were recognized as two fields of applications. EDP was organized in "computer centers," hosting mainframes with very small "fast" memories, small disks and "large" magnetic tape memories and archives. The centers had large GP (girl power) operators for punching cards read by the computers, groups of analysts for understanding user requirements and converting them into specifications and many programmers who converted the specifications into application software. Proprietary operating systems, assemblers and other compilers for widely accepted programming languages (such as FOTRAN and COBOL) were used. New fundamental concepts appeared, such as database—the core of integrated information systems; databank—storing easy retrievable structured information; structured programming. To some mainframes, typewriter or video terminals and/or remote job entry units were connected, using public (possibly hired) or local telecommunications lines. Unitary ranges of computers (such as IBM 360, GE 400, ICT 1900, CDC 6000, to name a few) appeared on the market in the mid 60s. The software industry began to grow rapidly offering utility software, application software and application software systems as "dematerialized" industrial products. The role of the electronic computer for development was officially recognized in the late 60s, when the UN General Assembly adopted a resolution in this sense. (UN, 1968). In some of countries, ICT development programs were adopted. In the UK, ICT (International Computers and Tabulators) and English Electric-computers merged to form ICL. France adopted "Plan Calcul." Romania adopted also an ICT development program, independent of the "Unitary Series" of the "socialist block" which tried to follow IBM, but with increasing lag). An attempt to build a merged Western European computer industry ("Unidata") failed.

Computing centers where also established to serve central and local state institutions. The French public administration created many years ago the first version of the SIRENE register of organizations. It was an interministerial project (Ministry of Finance, Ministry of Labor and INSEE—as a neutral data administrator), needed for macroeconomic planning. In the early 90s, Denmark had a remarkable example of eG (even if this term was still not

*Table 1. E-government definition in the eEurope program*

| Service | Level of service |
|---|---|
| **For Citizens** | 1—Online information about the service |
| 1—Income tax | 2—Downloading of forms |
| 2—Job opportunities | 3—Interactive submission of forms (including authentication and acknowledgement) |
| 3—Social security payments | 4—Full transaction, including full case handling, decision, and payment (if applicable) |
| 4—Personal documents | |
| 5—Automotive vehicle registration | |
| 6—Authorization of construction | |
| 7—Police declarations | |
| 8—Online library (catalogues, search) | |
| 9—Certificates (e.g., birth, marriage) | |
| 10—University student registration | |
| 11—Change of address | |
| 12—Health | |
| **For Organizations** | |
| 13—Contributions to social security | |
| 14—Declaration and notification of taxes | |
| 15—VAT declaration, notification | |
| 16—Registration of a new company | |
| 17—Statistical reports | |
| 18—Environmental permit | |
| 19—Custom declarations | |
| 20—Public acquisitions | |

in use). The initial government's computing center of the 60s became the state-owned "DataCentralen" company, hosting the population register, the trade business register, the cadastral database, and other databases. Terminals were connected to local area networks of central and local state institutions and these were connected via a wide area network to DataCentralen. Various applications included recording of personal events (such as births), an iterative elaboration of the draft central and local budgets etc. Denmark renounced in the 80s to produce the 10 years national population censuses, processing instead data from the population register and other databases. Danish legislation become supported by a dynamic macroeconomic model (Dam, 1986) and a socio-economic database application (Ekonomiministeriet, 1991) for the simulation of the likely consequences of proposed normative acts. The Danish Data Authority provided the necessary personal data protection. Well defined delegation of Authority between central and local institutions, use of unique identifiers and also the "Kommunedata" local computing centers, were important factors for the success of large integrated information systems. Information integration, information interchange, computerized back-office and front office, central databases, and servicing of citizens and organizations as well as civil servants and other users became specific keywords.

It took nearly a third of a century of accelerated technical and technological progress, to develop: industrial relational databases, PCs, and digital high speed communications. Information technology (IT) and communications technology (CT) merged into ICT. Mobile telephony, high-speed computer networks, and digital content industry flourished. PCs, Internet, and Web services brought information and "computer utility" directly to the user. The Information Society concept was introduced in the early 80s. (Masuda, 1980) and gained gradually wide support. In 2003, UN World Summit on Information Society took place. Masuda advocated also the idea to improve relationship between public institutions and the public.

The term "online government" appeared in the mid 90s, as set of e-services, component of a program recommended by the special G7 session for Information Society at the beginning of the present century, EU selected, for benchmarking "e-government," 12 e-services for citizens and eight e-services for businesses (in the framework of the eEurope program). Four service levels were defined. (The low service levels could be created acting at the front-offices only, whereas the levels 3 and 4 implied also the back-offices and their possible integration—see Table 1). This definition by enumeration is precise, but has a limited scope.

The Japanese government underlined the keywords: disclosing government information, making greater use of IT and protecting personal data, with the goals of providing user-oriented services, simplify public administration and increase budget efficiency (Takano, 2004).

However, broader views also developed, for example, the first EU program for Information Society (Bangemann, 1994) included the project for a Trans-European Network, connecting the European administrations. It became the operational IDA (inter-communication between administrations) project to be developed as IDABC (interoperable delivery of European e-government services to public administrations, businesses and citizens—see EC-2, 2005). One of the first classic papers on e-government (Lenk &

Traunmueller, 2000) put the accent on: citizen, process reengineering, cooperation, and knowledge management in the public administration. In Lenk and Traunmueller (2002), the scope broadens to include democratic policy formulation, its implementation and evaluation of the results for permanent improvement. A point of view of the business community on e-Gvt was presented (Moriuchi, Cisneros, & Danish, 2001) as the state in which the internal and external operations of the executive, judicial, and legislative institutions are informatized and networked in order to provide high quality public services. An e-government project (OECD, 2001) uses a similar point of view: the application of modern ICT to the full range of government functions, enabling the adoption of good governance practices. It was followed by a "Checklist" (OECD, 2003). The World Bank "info Dev e-Government Handbook for Developing Nations" (Khalil, Lanvin, & Chaudry, 2002) defines e-government as the use of ICT to transform government in the sense of accessibility, accountability, and effectiveness. Papers using the expression "From e-Government to e-Governance" (e.g., Glassey & Chappelet, 2003; Traunmueller, 2003) showed the trend to informatize and integrate the services of all the three Authorities (Executive, Judicial, and Legislative). Reinermann and von Luecke (2001) started by noticing the similarities between "governance" and "management" in the cybernetics sense and their applicability in every sector of the SES, including state and administration, economy, NGOs as well as population, all being influenced by the advance of the ICT. They distinguished "e-governance in a narrow sense" as oriented on the public sector (including "e-government" as the informatization of its business processes) and "e-governance" as the general governance in the Information Society. Yoshimura (2003) defines: (a) e-government as using ICT for transforming relationships of the government with citizens and businesses by improving its services and reducing transaction costs; (b) e-governance as using ICT for improving transparency, accountability, access to public information including building opportunities and enabling interaction with government officials. The possibility of improvement of governance by creation of new informational feedback circuits was also suggested (Costake, 2001). It seems that the initial interest on DG seen as the informatization of the core activities of the public institutions, shifted to public e-services and is now evaluating towards a broader scope, covering both previous points of view. Though reflecting a large diversity, this trend can be also observed in the information regarding e-Gvt strategies, as reported to the EU's "eGvt Observatory" (EC-1, 2004) (e.g., some advanced European countries include wider objectives, such as contribution to the competitiveness of the national industry (ICT industry included) or shared applications such as document and content management).

## BRIEF COMMENTS ON TRENDS IN THE THREE AUTHORITIES

The international experience in digital government progresses at the level of the executive, legislative, and judicial authorities.

The use of ICT in the *legislative authority* progresses in the following directions: (a) informatization of the workflow to generate the normative acts, with the by-product of updating an official legislative database; (b) development of the infrastructure for e-Democracy (e.g., Chutimaksul & Funilkul, 2004; Tiecher, Hoeschl, & Zimath, 2003); (c) use of specific software tools for legislative acts generation such as XML or POWER (van Engers & Vanderberghe, 2002); (d) integrated information systems for storing and accessing legislative information, such as Normeinrete (Lupo & Batini, 2003). Legal framework for DG is discussed by Saarenpaa (2003 and 2004).

In many countries, the informatization of the *judicial authority* means the change from a possibly effective if correctly used old traditional information system based on handling paper documents, to a performant modern computerized information system, using electronic documents and electronic archiving. Following directions an be identified: (a) general case and documents database making possible (i) the follow up of a case through the various judicial units and (ii) quantitative definition of coherence of the judicial solutions and system performance (such as suggested by Costake & Galindo, 2004); (b) improving the service provided to the public (query for document archives, access to the judicial solutions, etc.); (c) improving the activity within the judicial units as a reesult of using electronic documents and the access to the general case and documents datatbase (e.g., Ko & Gabor, 2001); (d) transfer of electronic documents between judicial units at national and international level, such as EQUITAS project (Diez & Prenafeta, 2002) and integration with the Notariate's Information System; and (e) new communication means with attorneys, etc.

Because of the many and diverse activities of the Executive Authority at international, central, and local level, their informatization presents many aspects and problems. (see Gupta, Kumar, & Bhattacharya, 2005). One may, very briefly indicate some few representative examples of trends: (a) integration of the information system, together to managerial changes (Millard, 2002, 2004); (b) maximizing performance/cost ratio by Public-Private Partnership; e-Governance information system architecture at central, regional, and local level (Arcieri, Cappadozzi, Nardelli, & Talamo, 2001; Fischmann, Jakisch, & Riedl, 2001; Virili, 2001) to quote very few authors.

## FUTURE RESEARCH OPPORTUNITIES

A number of future research opportunities were proposed (see *General Requirements for Digital Government*). Another three can complement them.

### eG Support for Decentralisation of the Decision

The decentralization of the decision is a major governance trend. In the majority of the EU member countries, the ministries and the other government bodies at one hand and local authorities on the other implement a general strategy. The complexity of the local governance is not far from the one at central level and many achievements exists at locality and other territorial levels. Coordination is necessary, at least because the existence of: (a) shared resources (e.g., natural, communications, etc.); (b) bordering problems; (c) the obvious need that the level of the net taxation (central + local taxes) should not differ too much between various administrative-territorial. Optimal managerial, informational, and technical solutions are needed.

### Feasible Optimal eG Solutions for Accelerating Economic Growth and Employment

Growth and employment are needed to avoid the danger of installing digital divide within and between nations. A number of provisions of Universal Declaration of Rights imply costs per capita, which are difficult, (if not impossible) to meet, for example, under a certain level of GDP per capita and, perhaps, a certain value of Gini's coefficient. Growth and employment may also imply a design, based on identifying and/or creating, modeling, and enforcing automatic virtuous societal closed loops (including for democracy, competition and protection against fraud, corruption, and terrorism). These could be elements of an optimal eG theory.

### Net Benefits of eG

With the exception of e-public procurement, relative few economic net benefits of eGvt were reported. It is to be expected that major net benefits will be achieved by improved macroeconomic decisions concerning governance, including anti-fraud and anti-corruption actions.

## CONCLUSION

Two categories of DG can be observed:

a. DG Oriented on Provision of E-Services to the Population and the Organizations of the SES: (i) recording and archiving of events, properties and other states; (ii) supporting specific transactions such as tax declaration and payment, authorizations permits etc; (iii) offering multi-channel access to public information; (iv) promoting e-commerce via e-public acquisitions; (v) promoting e-democracy. These e-services imply mainly the executive authority. As the typical institution of the executive authority is the government, they can be named "eGvt." eGvt is focused on front-end activities. As it has good visibility, it presents also high political importance.
b. DG oriented on maximizing the performance of the socio-economic development of the SES based on Law, democracy, free market economy, competition, and a given level of social cohesion. (This goal implies re-engineering the governance, starting by rising its own performance, which implies also use of ICT as a support for informational integration and public e-services).The scope of this category of governance covers all the activities of the state, including: legislation, solving claims, fraud and crimes, public order, education, social security, public transport, public utilities, management of public financial, material and natural resources and property (including development of infrastructure), anti-corruption and anti-terrorist protection, defense, development of international relationships, strategic options and strategic planning of the socio-economic development etc. It seems natural to name this category as "eG."

*The performance of the of societal governance subsystem* can be characterized in terms of effectiveness for citizens and organizations, cost for the taxpayers and revenue for the central and local state budgets. *The performance of the governance (and eG)* can be characterized by key performance indicators of the socio-economic development (*see General Requirements for Digital Government).* Two demands for performance should therefore be met. This requirement implies various actions, such as (the order does not represent priorities):

a. Advanced informatization of the governance
b. Outsourcing of activities that can be better performed by private companies, or by Public-Private Partnerships

c. Promotion of governance oriented on enforcing or creation of virtuous automatic societal closed loops, as opposed to "governance by command" (autocratic governance)
d. Effective feedback from the societal operational subsystem (including via NGOs)

It follows that, in a certain sense, one aspect of eG is that of a large system engineering problem. One can also notice that the main danger of governance is intoxication with power, gradually distorting the societal feedback circuits. This process can be minimized by eG.

The previous definitions of eGvt and eG are both technology and content oriented.

## KEY TERMS

**E-Democracy:** Democracy supported by friendly and secure information systems, in order to increase the participation of the citizens to local, regional, national or international decisions, by expressing answer to questions of general interest and/or selection of candidates for occupying public positions and/or expressing views on problems under discussion or proposing matters to be discussed.

**E-Service:** Service designed and delivered using ICT such as Web service and/or multi-channel.

**Governance:** In the present article, governance is understood in the sense of societal management.

**Information Society:** Society based on ICT, which is used in practical all fields, having the support of the ICT industry. In the Information Society, ICT has a major contribution to the GDP and also to employment. In the same time, information (and knowledge) is a key resource for achieving performance in societal and microeconomic management and also a public good.

**Informatization:** The process by which a computerized information systems is implemented in a socio-economic system, to support business and/or managerial activities.

**Management:** Aware and permanent process by which individual and collec-tive actions and resources are oriented on the achievement of a mission and performance in the development of a societal or microeconomic socio-econo-mic system, in the conditions of a variable and partially uncontrollable environment

# General Requirements for Digital Government

**Nicolae Costake**
*CMC Consultant, Romania*

## INTRODUCTION

"Digital government" (DG), "online government," "e-government (eGvt)," and "e-governance (eG)" are widely used terms. They suggest the use of modern information and communications technology (ICT) in the governance of socio-economic systems (SES). It is widely accepted that the goal consists in increasing the performance of the governance. This can be considered in the sense of improving the services provided to citizens and organizations and also of improving the socio-economic development. There are still various points of view concerning the scope and strategy. The purpose of the present article, based on existing results and trends, is to propose a set of general requirements for the informatized governance of socio-economic systems.

## SHORT HISTORICAL PERSPECTIVE

The use of digital computers to support the public administration by creating informatized registers, databases and integrated information systems, started in the 60s. They generated a number of advanced national, sectoral, and territorial information systems. The known example of Denmark's integrated state information systems, created by public institutions with the support of DataCentralen and Kommunedata in the late 80s and early 90s is remarkable (e.g., DataCentralen, 1990, Ekonomiministeriet, 1991, Ministry of Finance, 1992). In these years, the orientation was to support the core activities of the public administration, also easing the communication between citizens and organizations and the public administration.

The further development of ICT, starting with the two "explosions" in the 80s (PC and internet) made possible to formulate the need for "communications highways" and "government, which works better and costs less" (Gore, 1993). It was followed by the adoption of the Information Society as a strategy for development by the European Union (UE) The "Bangemann Report" (Bangemann, 1994) proposed "electronic tendering" and "trans-European administration network" as two of the ten priorities. The 1995 session of the G7 countries, launched a program which included also an "online government" project. DG was recognized as a key factor for achieving international competitiveness (e.g., Leitner, 2003) OECD and the World Bank initiated DG projects (e.g., Khalil, Lanvin, & Chaudhry, 2002; OECD, 2003). United Nation's World Summit on Information Society in 2003 paid a major attention to DG. EU allocated important R&D and structural funds for developing the Information Society, including also DG projects. Major IT companies showed their interest for the growing market of DG. (e.g., the IBM E-Government Centre in Berlin and the Oracle-HP E-Governance Excellence Centre in New Delhi).

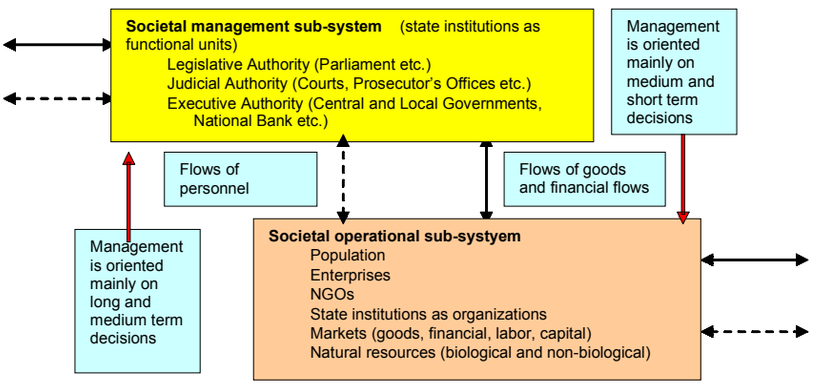
The main orientation for DG starting in the 90s, was on online services provided by the Public Administration to citizens and organizations, considered as customers. However, the scope of DG was gradually extended from the public administration, (executive authority) towards the set of three authorities (the executive, judicial, and legislative ones (e.g., Lenk, 2003; Lenk & Traunmueller, 2000; Reinermann & von Lucke, 2001) from national to international level. (e.g., EU's eEurope program was focused on national development aspects of the Information Society, whereas the following ones: eEurope 2005 and the Draft i 2010 (EC-1 and EC-2, 2005) have an accent on achieving the European informational interoperability.

The rising general interest for DG is also illustrated by the yearly International DG Conferences (such as EGOV in Europe and ICEG in Asia). UN produced an "e-Gvt Readiness Report" (UN, 2004). The EC established the "eGvt Observatory" as a contribution to the European Information Society. It complements the "European Information Technology Observatory (EITO)."

## ISSUES IN DG: GOVERNANCE

Issues can generate requirements. Issues in DG were proposed by a number of authors (e.g., Traunmueller & Wimmer, 2004). The authors enumerate a number of "challenges": portals for service provisions, usability, and empowerment, improving processes and back office integration, interoperability and standards, identity management and security, collaboration via multimedia, knowledge enhancement, and change management. The EU's e-Government Observatory retained following categories of issues: actors, e-services (for citizens, for businesses), history, legal framework, national infrastructure, strategy. E-services for citizens and for businesses are defined as components of a benchmark. The other issues contain

*Figure 1. Model of the Socio-economic system (SES)*



a wide range of visions, situations, and approaches. This suggests the need to consider basic problems such as governance. Just a few topics of governance are discussed here: (a) basic models; (b) sources of benefits and losses; (c) performance.

## Basic Models

A simple high-level model of a SES (see Figure 1) is proposed. Summarized, a SES has two subsystems: a societal management subsystem and a societal operational subsystem. The concept of SES can be defined at global, international, national, regional, or local level. In the followings, the national level is implicitly assumed, but this does not represent a limitation. As the information communication, processing, and storing are obviously vital for the societal management subsystem, DG is, in principle, the solution for increasing its performance. On the other hand, the performance of the enterprise depends on the performance of its own management and also of its socio-economic environment. SES's governance determines in a large measure, this environment. The governance generates e.g. regulations, information, public acquisitions, social services, collects taxes and information etc. It results that DG is of interest not only at macroeconomic level, but and also at microeconomic level.

A simple model of governance is proposed in Figure 2. This model suggests first basic requirements for Governance:

a. Separation of powers (precise delegation of decisions) between the three authorities: (1) generation of law to ensure the normal functioning and the development of the SES; (2) application of the law in the societal management and other general interest activities; in assuring the socio-economic development; (3) assurance of the respect of the law (homeostasis)
b. Assurance of the necessary coherent socio-economic information and of the feedback circuits necessary for the permanent improvement of governance, including via fair elections

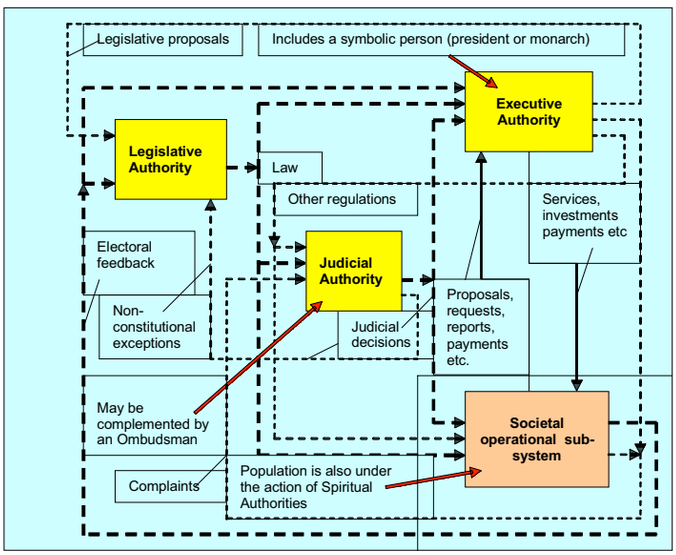
This model permits to define:

a. EGvt, as the informatized governance focused on the provision by the executive authority of e-services for the citizens and organizations within the SES
b. eG, as the informatized governance covering the domain on all the three authorities (executive, judicial and legislative)

These two definitions are content-based. It follows that DG and online government are generic terms defining the technology used in the societal governance.

The models in Figure 1 and Figure 2 suggest also the large number of actors involved in Governance. They are highly simplified models. The role of the executive authority to collect and distribute financial means is not apparent. Nor is its role to collect and validate data and information and to supply coherent results (which cannot be obtained at microeconomic level) to citizens, organizations and other SESs. Quasi-automatic closed loops, generating the natural trends of the evolution of the operational societal sub-system, are not represented, nor their possible switch from vicious to virtuous loops which, can be influenced by governance (e.g., Costake, Dragomirescu, & Zahan, 2001; Lockenchoff, 2001; Millard, 1995). This suggests another requirement for governance: to create or enforce virtuous loops and minimize vicious loops within the SES by adjustment and tuning actions and/or generation of new informational feedback circuits, instead of generating commands (emergency circumstances apart).

*Figure 2. A simplified model of governance*



## Sources of Benefits and Losses

DG is a component of the Information Society, the new society based on ICT. It follows the industry, the agriculture and the natural economy based societies. One can admit that every former major technological change increased the total value added per capita in the SES with approx. 1 ... 2 orders of magnitude. It seems reasonable to expect more or less similar results in the change from industrial to information society. This places eG, as one of the big challenges of our times. Some main losses and benefits associated to Governance are presented in Table 1 (see also Takano, 2004)

## Performance

The performance of DG is generally treated as: (a) definition of sets of indicators for eGvt; (see eEurope definition of e-services); (b) definition of sets of criteria (used in opinion surveys); (c) specific governance indicators. The set of eEurope e-G indicators characterize e-Gvt by a set of 20 e-services (12 for citizens, such as: income tax, job opportunities, personal documents, etc). and 8 for businesses, such as: VAT declarations, public acquisitions, etc.). Three or four service levels are possible: information, electronic forms, authentication, and validation of input information, full procedure, including payments (if applicable). This definition is precise, but its scope is limited. The set of criteria used e.g. in a survey (Economist Intelligence Unit, 2004) supports marking: (a) connectivity and technology infrastructure (max. 20%); (b) business and legal environment (max. 10%); (c) education and skill base (max. 10%); (d) government policy and vision (max. 15%); (e) e-Democracy (max. 15%); (f) e-Services and delivery channels to citizens (max 15%) and businesses (max 15%). It has a wide scope, but is qualitative: based on rankings resulting from processing opinions. A number of papers are oriented on performance indicators (e.g., Costake, 2004; Gant, 2003; OECD, 2002; UNCTAD, 2003). DG is not an objective *in se.* This results, for example, from the name of the i 2010 Draft Program: "A European Information Society for Growth and Employment." It means that the performance of eG is reflected in the performance of the SES. Hence, some governance performance indicators could be used, such as suggested in Table 2.

The definition and measurement of governance performance indicators can be therefore considered as an informational requirement for DG. Setting feasible target values (with the support of socio-economic models), opens the road to systemic eG.

## BUSINESS, INFORMATIONAL, TECHNICAL, AND MANAGERIAL REQUIREMENTS

Four sources for explicit or implicit requirements and conditions for DG can be found. They are: (a) theoretical

*Table 1. Possible losses and benefits associated to governance*

| **Examples of losses due to poor governance** | **Examples of benefits achievable by performant governance** |
|---|---|
| **Poor services to citizens and organizations:**<br>• Lack of informational coherence (such as: no shared nomenclatures and registers)<br>• Lack of necessary e-Services with high level of service<br>• Lack of informational integration<br>• Lack of adequate feedback<br><br>**Consequence:**<br>No one-stop service is possible | **Increase of the value added by the SES:**<br>• Better societal decisions (using decision support techniques and models, including for fiscal management)<br>• Better services delivered to the citizens and organizations (one-stop servicing based on integration of information, assurance of data security and back-office re-engineering)<br>• Clearing of closed loop bad debts (quasi-automatic informational closed loop)<br><br>**Consequence:**<br>The socio-economic development is supported |
| **Poor governance information system and management:**<br>• The Governance information system is a set of insular information systems, same data or information being repeatedly introduced and possibilities to correlate information are scarce<br>• Governance decisions are based not on quantitative models and analysis of causes, but mainly on opinions and "treatment of symptoms" | **Decrease of losses in the functioning of SES:**<br>• Better management of public resources (including better decisions on public acquisitions and investments)<br>• Better possibilities to identify fraud and better control of collection and use of public funds (by better laws and informational integration) |
| **Consequences:**<br>• Impossibility of coherent de-centralization of decision<br>• Opportunities for fraud | **Consequences:**<br>Supports the increase of the performance of the Governance |
| **They lead to disrespect of the law:**<br>• Underground economy, diminishing the financial means for Governance<br>• Corruption, paralyzing the application of the Law, for reasons of personal profits | **They lead to improved international image:**<br>• Cheaper foreign credits<br>• More attraction of foreign investments and tourists<br>• Better chances for competition on the global market |

*Table 2. Suggested possible governance key performance indicators*

| **Category** | **Examples of possible key performance indicators** (values to be comparable to a specified year) |
|---|---|
| **General** | **a. Social** such as: (i) Life expectancy at birth; (ii) holders of university degree/1000 inhabitants<br>**b. Economic** such as: (iii) GDP/ capita; (iv) annual inflation rate; (v) a consumer price index<br>**c. Socio-Economic** such as: (vi) Gini coefficient; (vii)% of population occupied in every of the three sectors |
| **Executive Authority** | **a. Economic:** such as (i) ICT investments / GDP; (ii) value of e-commerce/value of commerce; (iii) internet users/100 inhabitants; (iv) estimated value of the underground economy/GDP<br>**b. Socio-Economic** such as (iv) value of the corruption level estimated by Transparency International; (v) proportion of e-voting in total voting<br>**c. Technical:** such as (vi) sum for the 20 e-services (proportion of use per applicable service level); (vii) average value and variance of the response time to petitions (viii) proportion of e-commerce in the value of commerce |
| **Judicial Authority** | **a. Technical:** such as (i) average and variance of duration to solve a case (per categories of representative cases); (ii) variance of the punishment pronounced for similar facts, damage and circumstances (*idem*)<br>**b. Managerial:** such as (iii) number of end of year open cases (investigated or judged)/10000 inhabitants (*idem*) |
| **Legislative Authority** | **a. Technical:** such as (i) (Total no of active laws, government ordinances, and Decrees)/(annual working days); (ii) mean time before amending a law, a government ordinance, or a decree[per category of the field]; (iii) existence of procedures for simulating the likely socio-economic consequences of a draft normative act<br>**b. Managerial:** such as (iv) annual (number of government ordinances/number of laws) |

papers (e.g., Bakhus, 2000; Lenk &Traunmueller, 2000, 2002), and handbooks (e.g., Gupta, Kumar, & Bhattacharya, 2005); (b) points of view of the business community (such as Moriuchi, Cisneros, & Danish, 2001); (c) National information society or DG programs or plans; (d) International programs and reports (e.g., eGvt Observatory, 2004). A normal sequence could be considered: societal values and objectives => business requirements => informational requirements => technical and managerial requirements. Quality management in the sense of the ISO 9001:2000 recommendations can complement the resulting requirements.

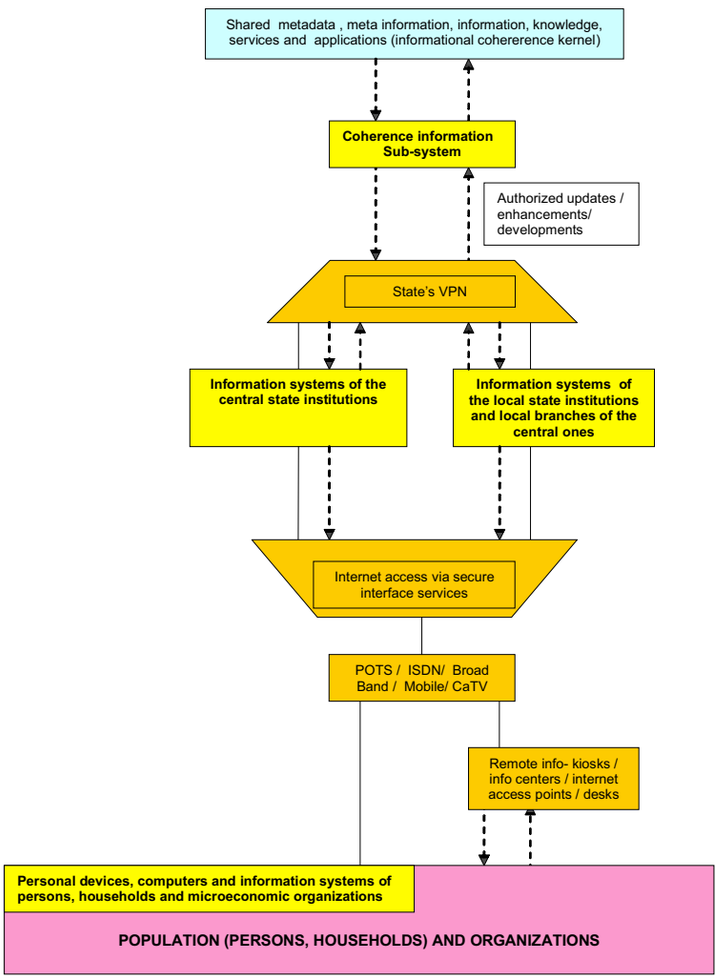
Societal values and objectives are specified in fundamental documents, such as UN's Declaration of Human Rights, E U's Treaty or general political ones (e.g., Soros, 1998). They formulate implicit requirements for Governance. They are just mentioned, their analysis being out of the scope of the present article. Administrative Reforms (e.g., Presidenza, 2000) or Judicial Reforms specify explicit requirements for DG. Business requirements for DG can be classified in following categories: (a) general; (b) oriented on citizens; (c) oriented on organizations, in particular businesses (d) oriented on users of the state institutions. They are exemplified in Table 3.

The DG business requirements enumerated in Table 3 above, have informational, technical and managerial consequences, as suggested in Tables 4 and 5. European Commission's projects for Interchange of Data between

*Table 3. Examples of business requirements for DG*

| Category | Typical requirements |
|---|---|
| **General** | a. Transparency and accountability of the Governance, including of the institutions of the three Authorities: Executive, Judicial, Legislative<br>b. Easy access to the public information on the state and evolution of the SES, at aggregated, sectoral and territorial levels, in tabular, graphical, cartographical formats supported by simple methodological explanations and mathematical models (e.g., input /output)<br>c. Easy Access to DG services<br>d. Minimization of time and effort to solve problems with the public institutions:<br>• one-stop servicing (optional self service);<br>• possibility of solving standard problems (such as notification, registration, certification or authorization of standard events or activities by every authorized state institution<br>• avoidance of repeated introduction of data (non requesting an existing validated and accepted data element in the state's information system;<br>• multi-channel options (full online to traditional face to face interface)<br>• help and online tutorial options by every authorized state institution;<br>• requested declaration forms displayed with actual known or previous<br>• data, if applicable<br>e. Multilingual content compatibility and recognition<br>f. Data security and data protection<br>g. Quality management control, including assurance of performance (steady improvement) and minimization of evasion, corruption and terrorism<br>h. Assurance of education and training for using ICT |
| **Citizens-oriented** | a. User-friendly access to public information and services, including one DG portal option.<br>b. International recognition of personal e-documents (identity, literacy, studies, property, etc.)<br>c. Wide range of e-service offered, including links to public sites via one general<br>d. portal<br>e. E-democracy (participation to the decisional process, without any external interference) |
| **Businesses-oriented** | a. Provision of complete online public e-services, including for company registration, tax payments, etc.<br>b. E-procurement for public acquisitions<br>c. Measures for promotion of the use of ICT (including e-business and public-private partnership in the development of DG) and development of the ICT industry<br>d. Provision of comparable, accurate and timely statistical information<br>e. Promotion of global e-business and e-commerce, including by collaboration with foreign governments for the global information society |
| **Oriented on users in state institutions** | a. Possibility to simulate and assess the effects of drafts decisions or regulations, before submitting to approval<br>b. Decision support services<br>c. Management of resources and administrative and functioning costs<br>d. Possibility to build coherent DG in the circumstances that various state institutions may use different hardware and software<br>e. E-procurement enhanced by post contractual follow-up |

*Figure 3. DG cooperative information system*



Administrations are particularly interesting for the data interchange architecture (IDA, 2003) and interoperability between applications and information systems (IDA, 2004). A framework for DG Information System was proposed—see Figure 3 (Costake & Jensen, 2002). The differences between e-Business and DG were analyzed (e.g., Riedl, 2003).

## PRE-REQUISITES FOR DG

The former requirements (Tables 3…5) imply a number of conditions (pre-requisites) for DG, such as:

a. **Political:** Implementation of DG implies a firm political will, in order to make the necessary managerial, financial, and legislative effort. It means commitment to develop the Information Society.

b. **Technical:** DG cannot be created unless: (a) a certain level of communications, capable to support a broad and sufficiently fast access to internet exists (b) the use of ICT by people, institutions and businesses is above a certain threshold. (e.g., sufficient computers used by people and organizations). In practice, this is no more a critical factor in the European area.

c. **Financial:** Budgetary funding is needed. International assistance and Public- Private-Partnership can help in a great measure. The high potential benefits suggest that governments may: participate to International Programs or apply for international loans, if a reasonable Program and a reasonably

*Table 4. Typical examples of informational and technical requirements induced by the business requirements (Table 3)*

| Category | Typical requirements |
|---|---|
| **Informational** | a. Standardization and assurance of international compatibility of the nomenclatures used in DG, e-business and e-banking<br>b. Unique identifications of basic elements of the SES such as natural persons, organizations, territorial-administrative units (such as regions and/or counties, localities), land parcels (including streets and roads) and constructions. Implies an informational subsystem linking registers and geographic database[s]<br>c. Stable methodologies, compatible with the technical and technological progress.<br>d. Sharing general interest data, information and knowledge (such as concepts, and procedures) and software tools<br>e. Integration, interconnection, and interoperability of the information systems of the public institutions, including automatic propagation of validated updates<br>f. Use of electronic documents and archiving<br>g. Use of multi-layered geographic databases<br>h. Use of data warehouses and data mining |
| **Technical** | a. Promotion of International DG Standards including Open Solutions, data security (including authentication and digital signature certification) data protection, interoperability within DG Information system<br>b. Cooperative architecture of the DG Information System (see example in Figure 3)—assuring compatibility with new technologies such as e-hub and grid computing<br>c. Development of standard applications systems such as e-business intelligence for DG, including specific eG applications, such as cluster analysis, optimization of taxation macroeconomic simulation etc<br>d. 24x7 availability<br>e. Specific DG infrastructure, at least:<br>• DG portal (possibly one for citizens and one for businesses)<br>• DG virtual private network (Intranet)<br>• citizen e- Identification card (or certified digital signature)<br>• e-Public Acquisition portal<br>• Knowledge management basic facilities (such as document management, content management, groupware tools, advanced interrogation capability) |

*Table 5. Examples of managerial requirements*

| Category | Typical requirements |
|---|---|
| **Organizational** | **Organizational entities** responsible for: |
| | a. **Strategy:** Office of the Prime Minister or Similar, or Ministry of Finance or Ministry of Interior or similar or Ministry for Informatics or similar or Interministerial Board<br>b. **Coordination:** Chief Information Officer or similar, Government ICT unit or similar or Ministerial body in charge for ICT<br>c. **Implementation:** Coordinating unit and / or specialized governmental unit, all ministries, agencies or other bodies<br>d. **Support:** Implementing unit[s], [specialized body], Court of Accounts or similar, Data Protection Agency or similar<br>e. **Governance business process reengineering tasks**, such as: separation of front-office, back-office and ICT administration activities, gradual integration of the back-offices |
| **Methodological** | a. Adoption of a DG Program Management methodology and Project Management methodologies for the component projects of the DG Program, including specific Program/Project organizational structures<br>b. Promotion of Public Private Partnership, where possible and perfomant |
| **Legislative** | **Main normative acts:**<br>a. Freedom of public information<br>b. Data protection/privacy<br>c. Information security management (including authentication and identity management)<br>d. E-documents)<br>e. E-commerce, e-business<br>f. Access to public sector information<br>g. Integration of public information<br>h. Advanced e-communications<br>i. E-services (such as public e-procurement) |

prepared set of Terms of Reference for component projects exist

d. **Managerial:** Complexity of DG implies a vision accepted by the society. DG implies also re-engineering of governance processes. Risk and Issue Management and Change Management as well as Program and Project Management Techniques are necessary supports. The rapid evolution of ICT implies an increased effort for training

## FUTURE RESEARCH OPPORTUNITIES

DG is still a new field, in evolution. Following future research opportunities are suggested:

a. Theoretical:
   1. The quantitative system theory of governance and DG. There is still a discrepancy between the complexity of the SESs and the management techniques and management decision supports used. Optimal governance is still a distant target
   2. Governance can be considered a form of management, namely societal management, complementing the usual "enterprise management." It follows that e-Governance could be "informatized societal management." The main result could be the definition of "roadmaps to eG" hence eG benchmarks based on facts and not by opinion

b. Pragmatic:
   1. The quality management (QM) of governance could contribute to clarifications for decision-makers and public opinion
   2. The specification of a widely accepted DG information system specification using e-hub and grid technologies and following the general concept illustrated in Figure 3
   3. The definition of the rational compromise between information system integration and privacy, in a world in which corruption and terrorism are true dangers

## CONCLUSION

Though still in development, the need for digital governance is already accepted at world level. It can be more than the provision of e-services by the public administration to citizens and organizations, or e-government (eGvt). It can be e-governance (eG), in the sense of informatized governance or informatized societal management. eG is an emerging interdisciplinary discipline which uses elements. of system theory, management science, computer science, information and knowledge science, informatics, economic science, political science, sociology, psychology. The necessary information and communications technology exists. In this sense, e-governance may become a key factor to ensure the socio-economic development in a global economy. It implies strategic planning including program and projects management approach. It should use a set of largely accepted societal key performance indicators and comprehensive models of societal management processes capable to orient the societal management processes re-engineering and support governance decisions in the sense of adjustment and tuning and not of commands.

## KEY TERMS

**Advanced SES:** SES characterized by: sustainable socio-economic growth in the conditions of: (a) respect of the law (homeostasis); (b) respect of democracy (electoral feedback, other participation to societal decisions); (c) free-market competition (automatic improvement of the performance); (d) social cohesion (as specified in widely adopted Declarations of Human Rights and Obligations). In practice, an advanced SES implies the use of e-governance.

**Digital Government (DG) (equivalent term: Online Government):** Generic term, designating the technology on which governance relies. It can mean eGvt or eG.

**E-Governance (eG):** Informatized societal management. E-governance includes e-government and other e-Executive activities (including e-democracy), e-legislation, e-judiciary, and informatized societal decision support.

**E-government (eGvt):** Delivery of e-services to citizens and organizations by the Executive Authority of the SES. Every of these e-Services is defined by function and level of service.

**ICT Industry:** Information, communications and audio-visual technology industries, together with the production of information content.

**Interoperability:** Convergence of ICT platforms and networks making hardware and applications compatible and inter-communicable, usually using standards and solutions developed by ICT suppliers and /or NGOs financed by them

**Societal Closed Loop:** Closed circuit generating automatically by the business processed of the SES or designed and implemented by managerial decision (artifact). One example of an automatic closed loop is the mechanism of price formation in free markets of goods. One example of an artifact closed loop is the circuit in which the Ministry of Finance determines the level[s] of taxation according to the results of the tax collection.

**Socio-Economic System (SES):** A system defined by a closed domain, in which: (a) people (individuals, households or other groups), natural resources (biological and non-biological)and organizational entities are linked by flows of personnel, material substance, energy, financial means and information: (i) between themselves (as applicable); (ii) with people, natural resources and organizational entities of other SESs (as applicable); (b) the actions of the people and of the organizational entities tend to increase their material and immaterial wealth according to (i) shared culture[s] and (ii) within the limits of defined and publicized laws and similar regulations and rules; (c) the system is structured in such a way that two interdependent subsystems can be recognized: (i) the operational subsystem, in which the activities of people and organizations is oriented on specific productive and similar activities and (ii) the societal management subsystem, in which the activities of people and organizations are oriented on assuring the normal functioning of the SES by generating the necessary regulatory and control actions of general interest.

# Global Benchmarking of E-Governments

**Herwig Ostermann**
*University for Health Sciences, Medical Informatics and Technology, Austria*

**Roland Staudinger**
*University for Health Sciences, Medical Informatics and Technology, Austria*

## INTRODUCTION

Metaphorically, the term benchmarking traces back to land surveying, where a *benchmark* is referred to as "a mark on a permanent object indicating elevation and serving as a reference in topographic surveys and tidal observations" (Merriam-Webster Online Dictionary, n.d.). Its linguistic roots originate from "the chiseled horizontal marks that surveyors made, into which an angle-iron could be placed to bracket (*bench*) a leveling rod, thus ensuring that the leveling rod can be repositioned in the same place in future"(Wikipedia, n.d.). In the most general term, a benchmark is a point of reference from which measurements may be made. Applied in a business context, benchmarks therefore serve as "measurements to gauge the performance of a function, operation or business relative to others" (Bogan & English, 1994, p. 4).

Based on that understanding, the essential business concept of benchmarking can be defined as the continuous and systematic process of improving strategies, functions, operations, products, or services by measuring, comparing and analyzing relevant benchmarks in order to produce superior business performance (Böhnert, 1999; Schmitz, 1998). Thus, in contrast to the static nature of benchmarks representing reference points, according to its original meaning (ensuring the exact repositioning of leveling rods at any time) the activity of benchmarking involves deploying the former as terms of reference to make progress.

In the pursuit of superior performance, benchmarking embraces the elements of comparison and change (Spendolini, 1992) based on information and knowledge derived from the very process of measuring and comparing benchmarks. First, public and private companies discover how their functions, operations, products, or services perform in comparison to those of benchmark partners. Second, having identified best practices "there is a call to action that may involve a variety of activities, from the making of recommendations to the actual implementation of change based (at least partially) on the benchmarking findings" (Spendolini, 1992, p. 15).

Taking into consideration the dynamic thrust of benchmarking activities outlined above, global benchmarking of e-governments is thus widely regarded as an essential stimulus for further e-government development, as it may facilitate the evaluation of national efforts compared to international best practice on the one hand and promote successful implementation of e-government applications serving the needs of citizens and businesses on the other from a conceptual point of view (Kunstelj & Vintar, 2004).

In order to identify the contribution of international benchmarking studies to successful design and implementation of e-government initiatives and models, this article will present the study designs and major outcomes of three benchmarking reports on e-government development. Based on these findings the authors will critically review these three study series, by raising the question whether the approaches pursued to benchmark e-government development show the aptitude to cope with the complexity of the socio-technical system e-government and thus support its comprehensive evaluation.

## BACKGROUND

According to the United Nations (2003a), "governments are increasingly becoming aware of the importance of e-government to improve the delivery of public services to the people" (p. 128). The roots for this recognition lie in two recent and interrelated phenomena: First, the rapid pace of globalization has caused an incorporation of intra-country trade and investment into transnational networks with economies striving to offer more competitive products and services. Second, advances in information and communication technology (ICT) have triggered new progress in the integration of these networks and in the improvement of the efficiency of businesses and services (United Nations (UN), 2003a). In order to satisfy the demands of citizens in the context of a changing environment, there seems to be no chance for governments around the globe to ignore "the imperative of e-government."

In this context, it is generally felt that the evaluation and measurement of e-government initiatives represents "an important or even essential element in the development and introduction of e-government" (Kunstelj & Vintar, 2004, p. 1). Consequently, e-government benchmarking studies and reports are first and foremost characterized by their multitude—according to Bannister (2004) benchmarking of e-government has even "become a small industry" (p. 1)—as well as by different approaches to evaluate e-government development. Overall, Kunstlj and Vintar (2004) identified more than 40 national and international reports monitoring, evaluating, and benchmarking e-government development.

Global e-government surveys are mainly conducted by international consulting and market research organizations (Kunstelj & Vintar; 2004). In the year 2004, Accenture issued its fifth annual report on E-Government Leadership, in 2001 the World Market Research Centre conducted the first Global E-Government Survey (since 2002 published annually by the Taubmann Center for Public Policy, Brown University, Providence, RI), and in the same year Taylor Nelson Sofres started publishing its annual global study named Government Online: an International Perspective (Dexter & Parr, 2003; Rohleder & Jupp, 2004; West, 2004). Further examples of international e-government studies include the Balanced E-Government report compiled by the Bertelsmann Foundation and Booz Allen Hamilton as well as the Global Information Technology Report published since 2001 by the World Economic Forum (Schmidt et al., 2002; Schwab, 2005).

Moreover, global benchmarking reports are conducted or commissioned by international or supranational organizations. Since 2001 the United Nations Department of Economic and Social Affaires has compiled the UN Global E-Government Survey on a (bi-)annual basis and Capgemini annually surveys the "online availability of public services" of European Union member states (also including Norway, Iceland and Switzerland) on demand of the European Commission (CGE&Y, 2003; UN, 2001; UN, 2003a). The latter institution is also involved in benchmarking e-government services by assigning the "eEurope Awards" for e-government on a bi-annual basis since 2003 (Leitner, 2003; Leitner, Alabau, Soto Mora, Kreuzeder, Hallencreutz, Millard, et al., 2005).

In the following, the outcomes and study designs of the e-government benchmarking reports published by Accenture, West, and the United Nations in the year 2004 (in case of the United Nations' report: 2003) will be discussed in detail. This selection is based on several considerations: First, all three studies feature a ranking of the countries surveyed indicating the status of e-government development measured by comprehensive indexes. Second, all e-government reports represent study series published at least on a bi-annual basis and thus reflect a dynamic component. Third, as the main thrust of this article is to critically review *global* benchmarking of e-governments, the three studies presented in detail cover countries from all five continents worldwide. Fourth, the three studies series represent different types of editorships ranging from scientific institutions (West) to international organizations (United Nations) to global consulting organizations (Accenture) and may thus reflect different motivations for conducting e-government benchmarking research.

## BENCHMARKING E-GOVERNMENT

### Study Designs and Research Methodologies

In publishing the report E-Government at the Crossroads the United Nations (2003a) aim to contribute "to the development efforts of countries by providing a benchmark to gauge the comparative state of e-government readiness and e-participation for development in a rapidly globalizing world" (p. 133). Hence, the survey adopts a people-centric approach, focusing solely on government-to-consumer/citizen (G2C) and consumer/citizen-to-government (C2G) relationships. Within this study design, government-to-government (G2G) services are implicitly assessed, since advances in G2C and C2G relationships are closely linked to G2G improvements. Government-to-business (G2B) services, however, go beyond the scope of the survey and are therefore not measured (UN, 2003a).

The UN report presents a competitive ranking encompassing the status of national e-governments of all 191 member states according to two primary indicators: the state of e-government readiness and the extent of e-participation. Whereas the first indicator assesses the capacity of the public sector to use ICT for encapsulating in public services and deploying high quality information and effective communication tools to the public, the latter measures the willingness of governments to use ICT to provide high quality information and effective communication tools in order to empower people to able participation in consultations and decision-making. Methodologically, the e-government readiness index thus "assesses the quantity of information and services provided," while the e-participation index "assesses the same from a qualitative perspective, with special focus on consultation and decision-making" (UN, 2003a, p. 136).

The e-government readiness index represents a composite index comprising the Web measure index, the telecommunication infrastructure index and the human capital index, with one third of the weight given to each component. Based upon a five-stage quantitative Web

presence measurement model, the Web measure index assesses the generic aptitude of central governments to employ e-government as a tool to inform, interact, transact and network. Depending on the level of maturity and sophistication, national e-government presence online is then classified as emerging, enhanced, interactive, transactional or networked presence. According to the quantitative nature of the Web measure index, this assessment is based on a questionnaire which requires researchers to assign a binary value to the indicator, based on the presence or absence of 288 specific electronic services and facilities available. In the case of countries with decentralized structures and regional or local governments in dispensation of one or more of the relevant public services, numerical scores are adjusted accordingly, so as not to penalize them. The telecommunication infrastructure index is derived from a composite weighted average of six basic infrastructural indicators: PCs/1,000 persons, internet users/1,000 persons, telephone lines/1,000 persons, online population/1,000 persons, mobile phones/1,000 persons, and televisions/1,000 persons. The human capital index represents a composite of the adult literacy rate and the combined primary, secondary, and tertiary gross enrolment ratio, with two thirds of the weight given to the first indicator and one third to the latter (UN, 2003a).

The e-participation index is based on an assessment of 21 citizen informative and participatory services and facilities in e-information, e-consultation, and e-decision-making. Each country is then measured on scale of 0-4 (0=never, 1=sometimes, 2=frequently, 3=mostly, and 4=always); the value of the index is derived by standardizing the scores. As the e-participation index serves as a qualitative measure employing proxy indicators for the quality, relevancy and usefulness of electronic services as well as the willingness of governments to provide relevant information and to offer participatory decision making in public policy matters, the report explicitly acknowledges that "any measurement of a 'utility' indicator will impart a bias in scores based on the researchers perspective" and that "the resulting scores should be interpreted with caution" (UN, 2003a, p. 141).

Accenture's 2004 e-government benchmarking report, titled E-Government Leadership: High Performance, Maximum Value, aims to support governments in identifying "the course of action that will most likely deliver high performance in e-government" (Rohleder & Jupp, 2004, p. 2). In contrast to the UN survey, which fits e-government into the conceptual framework of the vision of human development provided by the UN Millennium Declaration, Accenture's e-government leadership report focuses on national strategies and efforts that should propel countries toward whole-of-government service transformation, which is regarded as the ultimate goal of e-government (Rohleder & Jupp, 2004; UN, 2000).

The e-government leadership report measures the overall maturity scores of 22 national e-governments (Australia, Belgium, Brazil, Canada, Denmark, Finland, France, Germany, Ireland, Italy, Japan, Malaysia, Mexico, the Netherlands, Norway, Portugal, Singapore, South Africa, Spain, Sweden, the United Kingdom, and the United States) on the basis of a quantitative assessment of the quality and maturity of 206 selected services for both citizens (G2C) and businesses (G2B). No explanation is given on the selection of countries being surveyed (Eifert & Püschel, 2002).

The overall maturity score represents a composite index comprising the indicators service maturity and customer relationship management (CRM) with 70% weighting allocated to the first component and 30% to the latter. Service maturity serves as a measure for the level to which a government has established an online presence and is derived by the product of service maturity breadth (i.e., the number of services in the sphere of responsibility of national governments that are available online) and service maturity depth (i.e., the level of completeness with which each service is offered). In order to determine the degree of service maturity, researchers behaving as citizens and businesses first categorize services by means of a three-stage framework encompassing the levels publish (passive/passive relationship), interact (active/passive relationship) and transact (active/active relationship). Then, within each stage, services are scored at three levels depending on their maturity. In cases where services are delivered at regional or local level, these services are factored out of the analysis so that the governments concerned are in no way penalized. The extent to which governments manage interactions with citizens and businesses and deliver services in an integrated way is measured by the indicator customer relationship management, which is evaluated across five building blocks: insight, customer service, interactions, organization and networks, and a separate support measure (Kunstelj & Vintar, 2004; Rohleder & Jupp, 2004).

In addition to identifying the overall maturity scores of 22 e-governments, Accenture's 2004 benchmarking report includes a quantitative survey of citizens' perceptions and practices related to e-government in 12 countries (Australia, Belgium, Canada, France, Germany, Ireland, Italy, Singapore, Spain, Sweden, the United Kingdom, and the United States). For this purpose, 400 internet users were interviewed by telephone in each country (with the exception of the United States, where 600 were surveyed) and asked to answer a set of 11 questions about their attitudes toward their country's e-government programs, their individual use of e-government and their interests in particular online services. As this survey of the citizens' view on e-government only includes internet users, its

results do not represent the perceptions of the entire national populations (Rohleder & Jupp, 2004).

Furthermore, the e-government leadership report is supplemented by qualitative background research in order to obtain information referring to the history, content and ownership of each country's e-government program, recent legal and political developments around e-government and details on the implementation process (Rohleder & Jupp, 2004).

Introducing his 2004 global e-government report, West (2004) explicitly refers to the transformative nature of electronic government by noting that "recent advances in networking, video imaging, and graphic interfacing have allowed governments to develop Web sites that contain a variety of online material" and that "electronic government is supplanting traditional means of access based on personal visits, phone calls and mail delivery" (p. 3).

In contrast to the benchmarking studies of the United Nations and Accenture, which both aim to support governments in the pursuit of certain goals, the main focus of West's report is to provide an overview of the quantity of information and online services available on national government Web sites worldwide. Based on these findings, however, the concluding remarks of the 2004 study also contain recommendations on how user-friendliness and accessibility of e-government Web sites could be enhanced (West, 2004). Hence, West's global e-government report is characterized by a people centric approach focusing on the relationships between government and consumers/citizens (G2C). Overall, 1,935 national government Websites of 198 different nations worldwide are analyzed with the intention of providing "a full sense of what is available in particular nations" (West, 2004, p. 3).

In order to determine the e-government rankings of the 198 nations surveyed, Web sites are first evaluated for the presence of various features dealing with information availability and public access and for the number of online services offered. In the 2004 report four percentage points are awarded to each Web site for the presence of one of the following 18 features summing up to a maximum of 72 points: publications, databases, audio clips, video clips, foreign language access, not having ads, not having premium fees, not having user fees, disability access, having privacy policies, security policies, allowing digital signatures on transactions, an option to pay via credit cards, email contact information, areas to post comments, option for e-mail updates, option for Web site personalization, and PDA accessibility. Up to 28 bonus points are assigned for the number services fully executable online on each Web site (with one point allocated for each service up to a maximum of 28 points for 28 or more online services). Services offered on Web sites are only counted as online-services if the entire transaction can occur online. The e-government index is then calculated by averaging the totals of each Web site observed within a given country, producing ratings ranging from 0 to 100 percentage points (West, 2004).

Summing up the research methodologies of the studies outlined above, it seems worth noting that as far as the quantitative indexes are concerned, both the UN report and Accenture's E-Government Leadership Survey use multi-stage frameworks in order to determine the sophistication of e-government (Lindlbauer & Skerlan-Schuhböck, 2004). Even though the United Nations' Web presence measurement model serves as a means to categorize the maturity of a government's online presence as a whole, whilst Accenture's classification of service maturity is geared towards individual services, the stages of both frameworks are based on different levels of communication, ranging from one-way basic information provision to two-way transaction based on integrated networks (Lucke & Reinermann, 2000). Contrary to these two study designs based on evaluation frameworks, West's global e-government report solely assesses—in addition to the presence or absence of 18 features—the number of online-services offered by national government Web sites and therefore only provides an indirect measure for the development of e-transactions.

Regarding the aspects covered by the three study series outlined above, the UN e-government readiness index reflects the most comprehensive approach to measure e-government development, as it supplements a country's Web presence measurement by taking into consideration its telecommunication infrastructure as well as its human capital. Even though Accenture's overall maturity score represents a composite index of the two measurements service maturity and customer relationship management, it remains confined to regarding e-government development from the front-office supply perspective. West's e-government index pursues a similar approach to assessing e-government development by evaluating the front-office supply of governmental Web sites for the presence of certain features and for the number of online-services provided by these Web sites (Janssen, Rotthier, & Snijkers, 2004; Kunstelj & Vintar, 2004; Rohleder & Jupp, 2004; UN, 2003a; West, 2004).

## Major Findings

Table 1 illustrates the e-government readiness rankings, the e-participation rankings, the overall maturity rankings and the e-government index rankings for the top 15 countries of each measurement. According to the UN global e-government survey, the majority of English-speaking countries (the United States, Australia, the United Kingdom, and Canada) and the Scandinavian nations realize the most advanced state of e-government readiness. In spite of the globally non-representative coverage of

*Table 1. E-government readiness rankings, e-participation rankings, overall maturity rankings, and e-government index rankings for the top 15 countries*

| *Country* | *E-government readiness*[a] | *Country* | *E-participation*[b] | *Country* | *Overall maturity*[c] | *Country* | *E-government index*[d] |
|---|---|---|---|---|---|---|---|
| United States | 0.93 | United Kingdom | 1.00 | Canada | 0.80 | Taiwan | 0.44 |
| Sweden | 0.84 | United States | 0.97 | Singapore | 0.67 | Singapore | 0.44 |
| Australia | 0.83 | Canada | 0.83 | United States | 0.67 | United States | 0.42 |
| Denmark | 0.82 | Chile | 0.83 | Australia | 0.58 | Canada | 0.40 |
| United Kingdom | 0.81 | Estonia | 0.76 | Denmark | 0.58 | Monaco | 0.39 |
| Canada | 0.81 | New Zealand | 0.69 | Finland | 0.58 | China | 0.37 |
| Norway | 0.78 | Philippines | 0.67 | Sweden | 0.58 | Australia | 0.37 |
| Switzerland | 0.76 | France | 0.64 | France | 0.57 | Togo | 0.36 |
| Germany | 0.76 | Netherlands | 0.64 | Netherlands | 0.55 | Germany | 0.35 |
| Finland | 0.76 | Australia | 0.62 | United Kingdom | 0.55 | Iraq | 0.34 |
| Netherlands | 0.75 | Mexico | 0.60 | Belgium | 0.51 | Hong Kong | 0.34 |
| Singapore | 0.75 | Argentina | 0.59 | Ireland | 0.51 | New Zealand | 0.34 |
| Rep. of Korea | 0.74 | Ireland | 0.59 | Japan | 0.51 | Italy | 0.33 |
| New Zealand | 0.72 | Sweden | 0.59 | Germany | 0.50 | United Kingdom | 0.33 |
| Iceland | 0.70 | Germany | 0.53 | Norway | 0.49 | Liechtenstein | 0.33 |

[a]E-government readiness index (UN, 2003a). [b]E-participation index (UN, 2003a). [c]Overall maturity score (Rohleder & Jupp, 2004). [d]E-government index (West, 2004).

Accenture's survey encompassing only 22 nations, these findings are supported by the 2004 ranking of overall e-government maturity, with the same English-speaking countries as well as Denmark, Finland, and Sweden scoring among the top 10 nations. The UN e-participation ranking and West's e-government index ranking, however, show a geographically more scattered picture, with three developing countries (Chile, Estonia, and the Philippines) reaching a better position than most developed nations in the former and Taiwan, China, Togo, and Iraq scoring among the top 10 nations in the latter.

The matrix presented in Table 2, which summarizes Spearman's rank correlation coefficient for the quantitative rankings of countries covered by each pair of studies, supports the findings outlined above that the UN e-government readiness ranking and Accenture's overall maturity ranking show a high similarity in spite of their differing geographical coverage. The high correlation coefficient of 0.798 can be traced back to similar study designs, which both assess e-government development based on multi-step frameworks. Moreover, West's e-government index ranking is also highly correlated to Accenture's overall maturity rankings (correlation coefficient 0.731): Even though the former index does not deploy a multi-step framework, both indexes tend to assess similar aspects of user-friendliness and accessibility by rewarding Web sites for the presence of certain features in the case of West and by appraising the CRM measure in the case of Accenture. Finally, the UN e-government readiness ranking and West's e-government ranking show an average correlation of 0.531 caused by the rather narrow methodological overlapping of both studies: In contrast to the UN's five-step Web presence measurement model, West indirectly measures the development of e-transactions by assessing the number of online-services offered on governmental services; however, certain features assessed by West's e-government index represent characteristics of development stages of the UN Web presence measurement as well.

The major findings of the UN global e-government survey show that despite the end of the dot-com boom and international security concerns, e-government is still

*Table 2. Correlation between e-government rankings based on quantitative indexes (Spearman's rank correlation coefficient)*

expanding; by 2003, 173 out of 191 member states used internet services in some capacity or another (UN, 2003b). While e-government Web sites are still "mushrooming around the globe in a haphazard manner," there "appears to be a gradual, but steady, trend toward national portal/ gateway sites, specialty portals and one-stop service sites" (UN, 2003a, p. 142). Besides formal e-government policies such portal sites seem to be a key success factor, as 24 of the top 25 countries have either or both, a clear e-government statement and a specific e-government portal. Finally, the survey finds substantial evidence "that the imperative for effective e-government remains a multi-pronged approach to its development, based on ICT and human and telecommunications infrastructure development. If effectively utilized, e-government can push the frontiers of development around the globe" (UN, 2003a, p. 143).

Accenture's 2004 e-government leadership report presents five key findings. First, while still expanding in absolute terms, e-government advances are diminishing; second, leaders in e-government are harvesting tangible savings; third, promoting take up of e-government is taking hold as a priority, but the challenge still remains; fourth, the integration challenge is expanding vertically across regional and local levels of government; and finally, personalization of e-government Web sites is emerging. Overall, the e-government leadership report concludes that "there are significant savings to be reaped from e-government, and most governments are just beginning to realize this. Governments should concentrate on promoting take-up and communicating the benefits to all, in order to attain these significant savings. It is now time for governments to focus on driving high performance through their online programs, so that they can get better outcomes in a more cost-effective manner" (Rohleder & Jupp, 2004, p. 58).

Having assessed the e-government development of 198 nations based on the "e-government index," West (2004) concludes that "progress is being made, albeit at an incremental pace" (p. 3). Factors hindering e-government reaching its full potential in terms of accessibility and effectiveness encompass—according to his findings—budget, bureaucratic, and institutional forces, which limit the possibility of the public sector to integrate technology into its mission. In order to increase citizen usage and reduce the costs of e-government, the global e-government report 2004 suggests that accessibility and user-friendliness of Web sites should be enhanced by regular updates, A-to-Z indexes and multi-lingual content (West, 2004).

## Critical Remarks

Having presented the study designs of three major e-government benchmarking reports as well as having glanced at their major outcomes, it appears worthwhile to address the question, whether the three reports feature a comprehensive measurement of e-government development from a methodological point of view and thus represent an appropriate foundation for governments and decision-makers striving for the sustainable design and implementation of e-government systems in terms of their functionalities.

First of all, it has to be noted that benchmarking studies—as well as (scientific) research in general—can only be conducted within an explicitly or implicitly defined and consequently limited area under investigation. Hence, the validity of findings and outcomes derived from benchmarking activities also remains confined to the area observed. Regarded from a methodological perspective it is, therefore, impossible for benchmarking studies to measure *all* aspects of the socio-technical system e-government (Schülein & Reitze, 2002; Seiffert, 2003).

In order to scrutinize the functionalities of the benchmarking studies previously presented, it thus ap-

pears worthwhile to broaden the concept of benchmarking by discussing its goals from a theoretical perspective. Applied in a social context, goals represent aspired situations, from which criteria for the scaling and measurement of behavior patterns and of consequences of the latter can be derived (Kappler, 1975). The measurement of behavior patterns, again, represents a key element of benchmarking activities, as observable measurement indicators (i.e., benchmarks) must be derived in order to compare the performance of the surveyed entity and to elaborate directives for new actions to be taken. However, the operationalization of goals can only be conducted in a functional way if indicators for measurement can be identified, which can be influenced by the individual or the organization (Bönnert, 1999).

This, again, raises the question whether the two benchmarking reports outlined above feature an appropriate process of operationalization in the sense that the surveys indicate what they claim to indicate (Kappler, 1995). Regarding e-government as the "government use of modern information and communication technologies as applied to the full range of functions from policy making, policy implementation (…) to assessing and evaluating their results" (Kunstelj & Vintar, 2004, p. 132), the focus of all three studies appears to be narrow, as central aspects such as back-office reorganization and impacts of e-government are not included. Applying the scheme classifying the scope of e-government surveys suggested by Kunstelj and Vintar (2004), the UN report's main approach to monitoring e-government development encompasses e-readiness of citizens as well as front-office supply (i.e., the government's point of view), whereas Accenture's and West's approaches only cover the latter aspect.

This narrow scope of the three e-government benchmarking reports scrutinized, now limits their functionality in terms of decision-support for governments and policy makers striving for the development and implementation of sustainable and comprehensive e-government models. A number of potential shortcomings have been put forward against the narrow and methodologically limited approach predominant in most e-government measurements (Janssen et al., 2004; Kustlj & Vintar, 2004) by academic research challenging the overall benefit of these benchmarking studies.

1. Measures and indicators applied are generally criticized for being too simplistic and superficial–mostly scoring what can easily be measured and hence not meeting the complexity of (transformative) e-government. However, most authors also acknowledge the fact that the development of more comprehensive indexes, as well as the gathering of adequate information, represent a major scientific challenge (Bannister, 2004; Janssen et al., 2004; Peters, Janssen, & van Engers, 2004; Moon, Welch, & Wong, 2005).
2. Existing measurement instruments are criticized for lacking a framework incorporating the relationships between the indicators assessed and the use of resources (Peters et al., 2004). On the whole, a number of researchers (Drüke, 2005; Moon et al., 2005; Peters et al., 2004; Taylor & Lips, 2004) find fault with the nonexistence of a well founded theory on e-government (measurement); Taylor and Lips (2004) judge the predominant *way of seeing* e-government as being "techno-centric, positivist and comparative" (Taylor & Lips, 2004, p. 11).
3. Supply-oriented indicators appear primarily to suit the objectives of providers of e-government services, however, other stakeholders may tend to prioritize other measures not covered by most studies and would thus come to different interpretations of the status of e-government. "As such, the existing instruments provide a picture of the status of e-government that may not be useful as surrogates for deducing the e-government performance" (Peters et al., 2004, p. 487).
4. Corresponding to the narrowly defined indexes, countries may be inclined to "launch e-services along the *quick-fix, quick-wins* principle and rapidly contruct the electronic equivalent of a traditional, bureaucratic administration" (Kunstelj & Vintar, 2004, p. 133). Also, the headline attention benchmarks attract is thought to cause problems in the event of not well designed measures: If this is the case, benchmarking studies may "end up doing more harm than good as politicians and administrators maneuver to optimize benchmarks scores rather than e-government performance" (Bannister; 2004, p. 13).

As several studies on the measurement of e-government development suggest (see e.g., Aichholzer & Winkler, 2003; Bannister, 2004; Janssen et al., 2004; Kunstelj & Vintar, 2004; Ostermann & Staudinger, 2005; Peters, Janssen, & van Engers, 2004), the design and implementation of sustainable e-government initiatives has to be based on a comprehensive approach, taking into consideration not only front-office supply of online services but also ICT-readiness, back-office service fulfillment and transformation capability, service usage and demand and e-government impact. According to findings of the United Nations (2003a) the full potential of e-government can only be realized if ICT-infrastructure and the overall level of ICT-knowledge enable the vast majority of a country's population to benefit from online information and services. As far as back-office reorganization is concerned, Millard, Iversen, Kubicek, Westholm, and Cimander

(Millard et al., 2004) could demonstrate "that there is a clear and strong link between reorganizing government back-offices and the electronic public services experienced by users" (p. 5). Finally, several research reports (Kunstelj & Vintar, 2004; Lucke & Reinermann, 2000; Peters et al., 2004) stress the fact that the effects as well as the impact of e-government initiatives have to be integrated into a comprehensive evaluation model, as traditional means of administrating the public sector can only be supplanted by digital government if additional value can be created for citizens, businesses, politicians, and public authorities.

In a paper recently published on the evaluation of e-government development, Kunstelj and Vintar (2004) sketch a draft model of a holistic approach to monitoring e-government progress encompassing the areas environment maturity (i.e., e-readiness), back-office, front-office, and allowing for measures based on different stakeholders' perspectives. A general overview of the structural components of this model is illustrated in Exhibit 1.

Such a holistic approach to benchmarking e-government development—as exemplified in Exhibit 1—broadens the area under investigation and shows the potential to enhance the validity of the information gained from benchmarking activities in a differential way, thus raising the functionalities of the latter. Benchmarking reports based on such a comprehensive evaluation framework would now represent an appropriate foundation for governments striving for the implementation of sustainable e-government models, as the focus of development efforts is likely to shift from the supply-oriented provisioning of online-services to benefiting from the transformative potential of e-government by the establishment of integrated electronic services (Kunstelj & Vintar, 2004; Sakowicz, 2003).

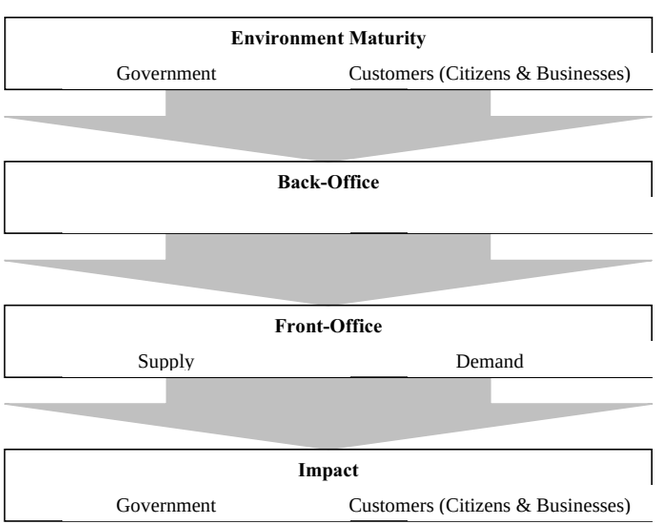
The functionalities of the three study series previously outlined, however, remain limited to certain areas and perspectives and therefore do not come up to the conceptual broadness of a comprehensive definition of e-government. On the other hand, based on the three benchmarks scrutinized plausible conclusions can be drawn for certain areas of e-government (mainly front-office supply of online services). Consequently, these reports can also turn out to be purposeful for policy-makers in the pursuit of e-government progress, if the latter (1) do not misinterpret the benchmarking findings as being representative for the sophistication of overall national e-government and (2) embed these findings into a comprehensive evaluation framework as suggested in Exhibit 1 (Ostermann & Staudinger, 2005).

## FUTURE TRENDS

In line with the shortcomings of current e-government benchmarking studies which have been previously discussed, a number of alternative models to monitoring e-government development are suggested by researchers and transnational institutions, mostly striving for a more theoretically-founded and comprehensive approach to measuring its progress and sophistication.

The draft model of a holistic approach to monitoring the development of e-government composed by Kunstelj and Vintar (2004) has already been outlined in the section

*Exhibit 1. Structural components of a holistic approach to evaluate e-government development (according to Kunstlj & Vintar, 2004, p. 144)*



above; according to this framework future e-government evaluation should include environment maturity, back-office, front-office and e-government impact with all measures—except back-office—assessed from customers' as well as governmental perspectives. In order to assess the information on e-government performance offered by benchmarking studies, Janssen et al. (2004) identify five categories of indicators for measuring e-government development (input indicators, output indicators, usage/intensity indicators, impact/effect indicators, and environment/readiness indicators) and advise governments to evaluate the results of theses studies based on this comprehensive portfolio of different measures. Drüke (2005) also follows a comprehensive understanding of e-government when suggesting an evaluation model for success in local government: Based on ten key factors for the successful design of virtual town halls (guiding principles and strategies; organization, project and change management; applications; benefits and costs; the right technology and organization of the use of technology; competence, motivation and qualifications; creation of acceptance, marketing; co-operations and partnerships; sustainable resources; and legality) put forward by Grabow, Drüke and Siegfried (2002) local e-governments are measured by the extent to which these success factors—divided again into prioritized sub-factors—are met.

Kubicek, Millard, and Westholm (2003) propose an institutionally-focused approach to analyzing electronic public services, distinguishing between single and multiple services on the one hand and one or multiple stages of administration involved for the delivery of a specific service on the other, and recommend the establishment of a good practice exchange framework and mechanism for e-government (Kubicek et al., 2003; Millard et al., 2004). Based on further research, Westholm suggests a model to improve e-governance embedded in the historically grown governance triangles comprising the actors economy, state and civil society (Westholm, 2005). This model goes in line with the PRISMA (Providing Innovative Service Models and Assessment) project of the European Union, which takes into account long-term perspectives of e-government and changing environments and hence strives for the identification of future requirements of e-government development based on different scenarios (Aichholzer & Winkler, 2003).

As far as the benchmarking of individual e-government applications and initiatives is concerned, the European Union applies a comprehensive assessment framework for the identification of good practices, achieving impacts and delivering benefits for citizens and businesses when appraising candidates for the "eEurope Awards for eGovernment". The four main themes of the 2005 awards encompass environment maturity, back office innovation and transformation, service use as well as impact and benefits (European Institute of Public Administration, 2005). The annual "Stockholm Challenge Award" also aims to identify good practice initiatives, rewarding ICT-projects in public administration based on five criteria (innovation, convergence, inclusion, equal opportunity, and sustainability) in line with the UN Millennium Goals (Stockholm Challenge Consortium, 2005).

Giving credit to the multitude of models and metrics for the assessment of e-government development, Carbo and Williams (2004) finally devise multiple models for e-government development as the "synthesis of component relationships and component attributes from various models can be used to form an adaptive, dynamic model for a particular context based on a set of contextual parameters that will explain a specific instance of an e-government development or implementation" (p. 97-98).

Overall, as shortcomings of existing approaches to benchmarking e-government as well as alternative approaches diffuse among researchers, practitioners and decision makers (Bannister, 2004), future studies to monitor e-government development may well be expected to feature higher levels of sophistication in terms of their design, functionalities and measures. The current narrow focus of e-government benchmarking on the simple provision of online services is therefore likely to be replaced by a comprehensive evaluation framework for e-government giving credit to differing stakeholders' perspectives on certain structural components and taking into account historical developments as well as socio-economic contexts.

## CONCLUSION

A large number of surveys and reports claiming to benchmark e-government development have been conducted by global consultancies and international as well as academic institutions. These studies show substantial variations as far as their foci and methodological approaches are concerned. Hence, the study designs and key findings of three major global e-government benchmarking series have been presented in detail, in order to address the question whether these three reports represent an appropriate foundation for governments striving for the design and implementation of comprehensive e-government systems in terms of their functionalities. By adopting a holistic approach to e-government evaluation, it could be demonstrated that the representativeness of the quantitative measures applied by the three study series scrutinized remains confined to certain structural elements of e-government as well as to certain stakeholders' views.

In order to ensure the functionality of benchmarking reports in terms of initiating and pushing progress to-

wards comprehensive and sustainable e-government systems, future studies have either to be based on a holistic evaluation framework or must at least feature the embedment of their findings into such comprehensive models. Measurements of the results, effects and impacts on all groups of stakeholders must be included in order to equip governments with solid foundations for future e-government activities, priorities and objectives (Ostermann & Staudinger, 2005).

In this context, it appears "important to remember that metrics are not complete once defined" (Kunstlj & Vintar, 2004, p. 146). Even the authors of two of the e-government studies assessed demonstrate their understanding of measurement being a continuous learning process (Kunstelj & Vintar, 2004; Millard, 2003), as advances towards more complex study designs can be registered in the benchmarking series published by the United Nations and Accenture: In contrast to the 2001 UN e-government survey Benchmarking E-Government: A Global Perspective, which assessed solely the quantitative e-government index (renamed more precisely e-government readiness index in 2003), the 2003 report also includes qualitative research which feeds into the e-participation index. Likewise, the research methodology of Accenture's e-government leadership reports was extended by qualitative background research in 2002 and by quantitative research on citizens' attitudes in 2004 (Hunter & Jupp, 2002; Rohleder & Jupp, 2004; UN, 2001; UN, 2003a).

Striving for higher performance of e-government benchmarking reports will therefore lead to surveys based on a more holistic and also theoretically founded definition of e-government, which will take into consideration its objectives and characteristics as well as its stakeholders' claims, concerns and issues. In doing so, studies will have to precisely define indicators as well as methods for the assessment and aggregation of scores (Kunstelj & Vintar; 2004), explicitly stating their conceptual potentials as well as limits.

## KEY TERMS

**Benchmarking:** A continuous and systematic process of improving strategies, functions, operations, products or services by measuring, comparing and analyzing relevant benchmarks in order to produce superior performance.

**E-Government Index:** A quantitative index developed by West assessing governmental Web sites for the presence of features specifying information availability and public access and for the number of online services offered.

**E-Government Readiness Index:** A quantitative composite index devised by the United Nations assessing the capacity of the public sector to use ICT for encapsulating in public services and deploying high quality information and effective communications tools to the public. It comprises the Web measure index, the telecommunications infrastructure index and the human capital index.

**E-Participation Index:** A qualitative index devised by the United Nations measuring the willingness of governments to use ICT to provide high quality information and effective communication tools in order to empower people to able participation in consultations and decision-making.

**Functionality:** The sum of an entity's functions and their specified properties that satisfy stated or implied needs. It refers to the usefulness or capability of the total entity, hence regarding its function from a systems-theoretic perspective.

**Operationalization:** The process of converting concepts into specific observable indicators that can be measured. Operationalization is a key component of the scientific method as it ensures the reproducibility of (results of) experiments.

**Overall Maturity Index:** A quantitative index set up by Accenture assessing the overall evolution of electronic service delivery and the overall approach of governments to managing interactions with citizens and businesses. It comprises the measures service maturity and customer relationship management.

# Global Governance as a Complex Adaptive System

**Karin Geiselhart**
*University of Canberra and Australian National University, Australia*

## INTRODUCTION

The recent advent of Internet technologies has greatly intensified existing globalization processes. The development of full multimedia international communications has the potential to democratize information flows. Citizens can communicate with each other and with governments to create and document public and private accountabilities beyond jurisdictional borders. Ironically, it is also now possible to achieve intensive and intrusive surveillance of individuals and organisations, virtually untraceable criminal exchanges of data, and even forms of cyberwarfare. These possibilities are all part of the global information commons. Like physical common spaces, beneficial and nefarious elements coexist. A working definition of the global information commons is the set of all information systems critical to managing global resources and governance, and the set of protocols for their exchange. While both cumbersome and broad, this definition of the global information commons helps to ground it as a concept that can be modelled and managed. It responds to Dahl's query about the possibility of a third transformation of democracy beyond the nation-state.

This article considers key issues for the emerging global information commons. These relate to the role of new technologies in possible forms of global governance. Global governance is here considered to be the emerging mechanisms for managing trans-national issues and resources. These can be particular to a specific issue or resource, such as the fisheries, or may be more formal, such as the European Union. Governance can be seen as a management function, much as the "governors" on early steam trains.

First, the author presents an overview of technology as socially determined, followed by a sketch of how global governance may be seen as a complex adaptive system. This includes an analysis of how models might embed democratic structures. Finally, examples of sub-systems of the global information commons demonstrate the range of actors and rules such a system would need to consider.

This theoretical perspective builds on empirical work in the physical, biological, and social sciences and emphasizes the value of modelling governance at all scales. This approach is seen as fruitful for identifying and monitoring dynamic patterns. It provides useful insights for managing the global information commons. In human systems, the rules of interaction and information exchange are determined by the values of the actors (Theys, 1998). Modelling can help to articulate these values. In complex human systems, the direction of change can be as important as absolute measures.

## BACKGROUND

The relationship between technology and society has long been a topic for analysis, recently stimulated by the rise of the information age. Several writers are particularly relevant for considering the role of information technology in systems of governance. Beniger (1986) showed the importance of information in all forms of evolution and control. This concept has become popularized through the study of the genetic code as a program for biological processes. Feenberg (1991) provided a critical theory of technology, and revealed how the democratising potential of information technology makes it a site for an ongoing power struggles. Sclove (1995) considered the need to embed democratic assumptions in technology design. Zuboff's (1988) concept of "informating" provides an essential learning element, which has connections to complexity theory and the developmental role of democracy and policy. A more complete review of the social determination of technology design in democratic systems of governance is provided in Geiselhart (1999). Current efforts to articulate a direction for the global information commons can be seen in the processes of the World Summit on the Information Society (http://www.itu.int/wsis/). The WSIS is in many ways a microcosm of the wider issues involving information technology and global governance.

## GLOBAL GOVERNANCE AS A COMPLEX ADAPTIVE SYSTEM

With accelerating pace over the past 20 years, awareness has grown in first the physical, and lately the social

sciences of a new and powerful way of modelling many kinds of systemic behaviour. Some have taken this metaphorically (Zolo, 1992) while others have made serious efforts at mathematical modelling (Biggs, 2001; Stocker, Green, & Newth, 2001). The author suggests this would be a fruitful perspective for examining emerging forms of global governance. Complexity theory is showing that understanding and some form of control is possible without total determinism and predictability. These revelations suit modern, information driven governments, which are often caught up in changes that outpace their ability to adapt. Many institutions, including the administrative arms of representative government were developed for a simpler, less interdependent age. Physical systems, such as climate, are also undergoing rapid transformation. There is heightened recognition of the need to find new ways of harnessing citizen knowledge and consent to achieve rapid learning and flexible response.

The section argues that in addition to aiding in understanding and possibly prediction, modelling global governance could suggest methods for integration across scales.

Traditional Newtonian concepts influenced linear, hierarchical views of social structure and management, and are now yielding to the paradigm shift associated with complexity (Becker & Slaton, 2000). Recent work on simulating social models and the spread of ideas shows that while ideas spread from one-on-one exchanges, it is the collective and cumulative interactions that lead to major shifts in perception or values (Stocker et al.). An essential observation of these systems is that a simple set of rules can generate very complex behaviours at many scales.

An "attractor" is a pattern generated by a complex adaptive system (CAS). It can form a range of behavioural loops that may be static, repeating, or non-repeating. Social structures as well as biological events can form fractal patterns, which repeat at different levels. Thus, the incidence of industrial strikes has been found to follow a power law similar to the way fires spread in a forest (Biggs, 2001). These can be the ever different but similar patterns of bureaucratic procedures or the endless reshuffling of international accreditation. Work on government (Kiel, 1996) and on organisations (Theys, 1998) suggests that in human systems the rules of interaction are driven by the values of the actors. This implies democratic values produce different patterns of governance. These interconnections are now made more obvious through digital communications. The endless data of global networks could be as useful for monitoring democratic process as for catching terrorists. Garreau (2001) describes collective global bird monitoring in terms very similar to a CAS.

The key insight for the global information commons is that patterns of authority are shifting away from monolithic nation states and towards more diverse, fractured, and trans-national sub-systems. One popular view of the changing model of governance is Rosenau's (1997) proposal that "spheres of authority" are arising as alternatives or complements to sovereign states. Rosenau describes a sphere of authority (SOA) as "emergent authority relationships."

Ernest (2001) discusses spheres of authority in some detail. He notes that "Spheres of authority may be temporal or enduring, local or global. What makes them unique is their ability to provide social goods and protections that states are either incapable of or unwilling to provide." SOAs encompass "traditional" units of analysis like intergovernmental and nongovernmental organizations, but include less structured forms of social behaviour including transnational coalitions, issue networks, and global civil society. The critical common factor is that "these SOAs create challenges to the authority of the contemporary nation-state in a wide range of issue areas, from the land mine ban to monitoring human rights conditions and governmental corruption."

Complex systems display sensitivity to initial conditions, for which humans may be read as the history of relevant events. There is a possible communication path from an individual in Iowa to the head of the World Bank, but the mapping of the rules onto the actors determines the degree of democratic governance. There can be bifurcations, such as many believe occurred with the attacks on the United States in September 2001. Fractal patterns can occur over time, and the much smaller World Trade Centre attack in the early 1990s, as well as the bombing of a night club in Bali in 2002 may all be part of the "pattern." Identification of the values driving the patterns can assist in redirecting them for more sustainable outcomes, and avoiding counter-productive responses that incite further escalations.

Not all the patterns reflect democratic values. Some exclude citizen participation, while others have the potential to override national sovereignty. Individuals form clusters, formal and informal. Organisational and institutional clusters, from a local Parent and Teachers Association to the World Trade Organisation (WTO) and the United Nations, create spheres of authority and defacto systems of governance that increasingly have digital representation or at least a fingerprint. These may or may not include provision for information and decision-making, transparency, citizen participation, and accountable evaluation of the outcomes. These concepts of global governance as a CAS are discussed more fully in Geiselhart (2004). One assumption of this theoretical approach is that democratic "attractors" for global governance will make use of negative feedback loops. In a CAS, these bring the system back to a norm, like a thermostat. Positive feedback loops, on the other hand, facilitate the system moving further from equilibrium, possibly to beyond the

edge of chaos, with the possibility of a sudden bifurcation.

## E-Governance Beyond the Nation State

E-government is evolving to deal with trans-border issues. Government responses to supra-national issues become an element in emerging forms of global governance. The patterns of digital representation and decision making have implications for the overall wellbeing and security of peoples. Increasingly, the transparency, availability, security, and accuracy of the information being shared globally underpins the effectiveness of governmental response. This applies to a myriad of socio-political-scientific issues, from climate change to terrorism to new disease vectors.

Many forms of international information management cannot be contained within national borders. These encompass the global information infrastructure itself, which, together with the rules for transmission and access, comprise the global information "commons." In addition, many other issues that governments must deal with have international informational aspects. Global e-governance is the complex of administrative, technical, and policy arrangements that collectively form a default pattern of governance on a particular international issue. The above overview of technology as socially determined makes clear that electronic representation is embedded in the human systems that give rise to them. Trans-border issues are generally subject to different constraints than are localized issues and information. The role of non-government players in the international information arenas is especially critical for international issues. Managing the information flows for supra-national issues involves both administrative and democratic accountabilities, as discussed in the following sections.

## Democratic Accountabilities of Global Information Management

As the overlap between industrial, scientific, social, and technical processes grows, so does the complexity of many issues facing governments. This makes citizens ever more dependent on information structures to participate meaningfully. Thus, governments come under pressure to make information available in ways citizens can understand and use, and to facilitate discussion and debate. As with information policy, the need for a reflexive element increases, to allow consideration of the authority and interpretation of the information. The role of intermediary institutions, such as libraries, public broadcasters and the commercial media, becomes more critical and is also caught up in the convergence of communication technologies. Outsourcing of information technology adds an extra dimension of public accountability, as the margins between private enterprise and government blur. A dense Web of communication flows and procedures for disclosure now underpins virtually all government activities, with extensive digital representation.

This complexity gives rise to issues of legitimacy, transparency, accuracy, and accountability. These concerns in turn influence information design and services. As we move further towards an information-based knowledge economy and society, the role of government as the central focus of agency, action, policy, and protection is being questioned from many perspectives. While governments are still the ultimate source of security in developed nations, this role is already deeply eroded in many parts of the world. Distrust of government is often manifested through an unwillingness to accept the validity of government information, particularly where there is suspicion about the source of the information and its benefits from government. Monbiot (2000) is just one of many authors documenting the cross-overs between government officials and paid positions in the industries or policy areas they are oversighting.

Thus representation, participation, and what have been called "democratic literacies" (Griffiths, 2003) are critical differentiators between domestic e-government and global e-government. These democratic accountabilities for information creation and distribution amount to what Ralph Nader has summarized as: Who gets to say, Who gets to know? And who gets to decide? Scaling this up to international level is a serious challenge facing the legitimacy of governments today.

In a globalised system of trade, finance, and ecology, poverty is the "weakest link," the greatest underminer of security (Thomas, 2001). The most profound evidence that democracy has structural problems is the erosion of equity within nations. It may safely be assumed that most people in a nation, state, or a city, given adequate information and effective choice, would not vote for benefits to be redistributed upwards to those more wealthy than themselves. Likewise, the growing disparity of wealth between nations indicates that mechanisms now operating to manage the flow of resources globally are not inherently democratic.

This situation is inherently destabilizing and correlates with a "democratic deficit." Indicators such as the falling levels of voting in the world's leading democracies indicate that existing mechanisms for citizen engagement cannot be taken for granted. Repeated attempts at reforming institutions such as the European Union and the United Nations indicate that current approaches to creating a global citizenry and global security may need rethinking. The current linear, hierarchical approach may be reaching the limits of functionality, given the scale of current issues and pressures for trans-

national governance. Scale was an overt concern for Dahl's (1989) analysis of democratic transformation. Electronic communications provide an avenue for new forms of engagement and participation, many of them not bounded by jurisdictional constraints. The electronic arena for such activities may be thought of as a global information commons. It may also be thought of as a complex adaptive system, with actors and rules of interaction, as the following section outlines.

## Citizens without Borders

For many issues, the global information commons allows individuals and non-government agencies to exert influence and communicate with each other. The continuum for electronic information exchange and engagement extends from a decision to donate to a distant cause through to terrorism on foreign soil. Between these extremes of charity and sociopathy lie traditional lobbying, consumer boycotts, and hactivism. Just as the WTO is free to determine fine detail of trade and production requirements in distant lands, so are some empowered individuals at liberty to take aim at and influence policies almost anywhere.

## Global Information: Areas of High Risk

These areas are indicative of the overlap between national and international information systems, and the links between these and global security. For each of these, a long list of actors contributes to the information creating a dynamic sphere of authority, with smaller similar (fractal) patterns at national and local levels, frequently with implications for individuals. Each sphere also overlaps and is interdependent on the others, as will be illustrated. For each, the key to information as global commons lies in the patterns being created at all levels and how they interact, along with the information flows and their checks and balances. Each sphere of authority contributes to global e-governance on that issue.

## International Information: Economic and Financial

The world economy is perhaps the most obvious manifestation of globalization, and the area where global e-governance is most highly coordinated. It consists of industries, flows of goods and services, resource manipulation, advertising and marketing, and consumption by governments, organizations, and individuals. Trade laws and sanctions of various kinds, unilateral, multilateral, and global, enforce and reinforce alliances or enmities. The largest industries, such as energy and agriculture, are subject to fluctuations and crises. These issues impact on the ability of less well developed nations, regions and individuals to participate in the global economy, as knowledge about innovation can itself be manipulated through legal and administrative controls, pricing regimes, and so forth.

Where representation issues have been resolved, e-governance can be quite effective. For example, SWIFT (Society for Worldwide Interbank Financial Telecommunication, http://www.swift.com) is an industry-owned cooperative that provides the information infrastructure for much of global banking and finance. The banking industry is a "virtual community," with the capacity to design and manage their information systems to the mutual advantage of stakeholders. As a cooperative, its governance structures have commonalities with democratic representation. International financial and commercial transactions have rigorous requirements for digital documentation. The forms of information security include non-repudiation, verification, and authentication. The role of the ITU and other hybrid government/industry organizations was previously described in standards for electronic commerce. These patterns of representation, negotiation, and collaboration are repeated for many other aspects of the information superstructure.

## Legal/Administrative Information

Legal matters include taxation, treaties, and intellectual property, along with judicial and criminal issues relating to extremes of behaviour, from innovation to terrorism. Collecting tax becomes more difficult when individual and corporate actors can move and conceal their money and transactions. Some nations actively provide tax havens, others seek global sanctions to eliminate them. Individuals as well as companies seek gaps in taxation monitoring and take advantage of the limited cooperation on reporting to shield their income from governments (Geiselhart & Singh, 2001). Addressing these taxation issues is a major concern for nations and relates closely to information issues relating to support for terrorism. Again, there are national and non-state actors, public organizations and underground groups that seek influence in each of these spheres. The issues are notoriously entwined. One legal/economic example is the superannuation industry. Individual citizens have accounts and accumulate funds from various employers, in addition to their own contributions. This has a government element, as the government agency sets the rules by which citizens can enter, withdraw, taxation limits, and so forth. through a range of administrative and legal issues. There is also a powerful corporate element, as there are companies, both for profit and not for profit, that manage and administer the investments of

these funds. Finally, there is also a substantial international dimension, as the funds regularly invest both on and off shore, thus bringing the superannuation fund into communication and perhaps negotiation with international governments, other legal systems, concerns about possible human rights or environmental practices, corruption, etc.

A random sampler of other legal aspects of global e-governance includes the use of biometrics at national borders; the regulation of radio frequency identification tags on consumer goods; and the next generation of spam, or spim, which is unwanted text messages sent over mobile phones. The Virtual Global Task Force (http://www.virtualglobaltaskforce.com) is an example of formal authorities harnessing the global information commons to assist them on a difficult international legal matter. This is a Web site set up by international law enforcement agencies, where children can report their suspicions about the activities of possible paedophiles. It will also help police to gather evidence.

## Environmental Information

A growing area is disaster planning, response, recovery, and evaluation. Natural and human events can disrupt the global communication system, precisely when coordination of information and response is most needed.

Information relating to environmental communications encompasses all natural resources, short term disruptive events (such as earthquakes) and medium and longer term dynamics, along with species identification, documentation and preservation, water resource allotment and management, air quality monitoring and many other issues. Information on these matters is important for the ability to preview and model scenarios, but also to adopt precautions and preventive strategies where possible. Here the global information commons includes data sharing in response to catastrophe, both human and natural, as well as recovery and evaluation to promote learning.

The outstanding global example of the environmental dimensions of information is climate change. Information on this topic is highly contested. The overlaps with economic, legal, and also health and transport are self-evident. Alliances are forged along interest lines, and each faction produces copious information to support its stand. The level of risk is extreme, and potential for harmonization is limited by the relative power of key actors. This information cascades to every level of global structure, as there is virtually no place on earth that is outside this sphere. Here, too, citizens without borders are active participants. A "shared computing" project enlisted 90,000 people in more than 140 countries to download a program that operates in the background while the screensaver is on. This helped to analyze data on climate change, with the likely side effect of increasing public awareness. See http://climateprediction.net/.

An example of government failure to deal with information management on an environmental issue may have been the tsunami of December 26, 2004. An earthquake warning system for the Pacific region was in place, and some of the affected countries were formal members. However, news reports indicated that one of the worst hit countries did not attend meetings, reply to correspondence, or provide contact details necessary to pass this information along.

## Health Information

Health is a critical integrating area for global information and governance. Health crises are by nature complex, and often defy state-centric approaches (Lee & Dodgson 2000). Nations seeking to "go it alone" during an outbreak of a new disease, for example, can endanger multiple other populations beyond their borders. Clearly, this is closely related to environment, but health issues are associated with additional information components that require global information sharing: epidemiological patterns and patterns of antibiotic resistance, new disease vectors, promulgation of best practice and economically viable approaches.

Lee and Dodgson (2000) have documented the ways in which the patterns of cholera have reflected those of globalization. They maintain that the systemic ills of globalization itself are reflected in health challenges. They observe an erosion of spatial, temporal, and cognitive boundaries. They also note a failure of the rationalist thinking that says these problems can be solved by simply adding more information, when it is the patterns of interconnection that need to be addressed. This is another way of stating the importance of management and governance procedures for the global information commons.

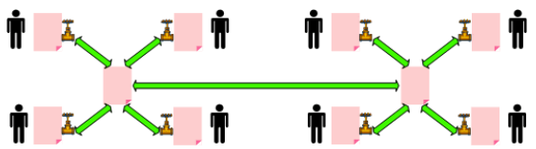
Health and administrative/legal matters are closely related, as the intellectual property arrangements for pharmaceuticals are one of the highly contested areas of trade liberalization. Again, bilateralism can dampen plurality and transparency, and result in essentially "a covert form of private governance." (Drahos & Henry, 2004).

## Transport Information

The carriage and smuggling of dangerous materials is one aspect, including radioactive substances, chemicals, machines, and equipment of warfare and weapons of mass destruction. Legal and administrative matters overlap, for example in the insurance arrangements.

The transport of people is also now a large interna-

*Figure 1. Representation of the ways groups can form membership in other groups in fractal patterns at many levels of complexity (Reed et al., 2004)*



tional trade, both legal and illegal. These people bring not just disease vectors, but challenges to cultural, welfare, political, religious, and legal situations. Tourism is not an unmixed blessing for the host nations, particularly if it encourages terrorist attacks, as in Bali when Australians and Balinese met a common fate. There have been claims that the Australian government had knowledge of the impending threat, but did not provide warnings. Around the world, more travellers are paying closer attention to whatever information sources they think can provide a margin of safety through information about such matters.

## FUTURE TRENDS

Given the paradigm shift towards a complex adaptive systems approach in recent years, it is likely modeling of global governance will become incorporated in other social forecasting processes over the coming decade. This perspective will inform protocols for the democratic management of the global commons**.** The Internet will continue to play a vital role in increasing transparency about government information management (for example, Epstein, 2004).

Figure 1 illustrates how actors at different levels or scales of influence might combine to determine the processes of information exchange. This figure is part of important work now being done on the role of open standards and social networks in developing trust relationships for Internet governance (see Reed, Le Maitre, Barnhill, Davis, & Labalme, 2004).

## CONCLUSION

This article has argued that democratic governance should be foremost in considerations of the global information commons. The sections above showed that e-government is now more diffuse, particularly for the many issues that overlap national boundaries. When driven by democratizing values government information becomes a tool to identify, manage and defuse risk. The alternative is information as weapon and control, ultimately destabilizing when governments are unable to harness the new integrating dynamic. More optimistically, new forms of organization are emerging that provide citizens without borders with the information tools to help shape and manage the global information commons. Modelling these systems can help to articulate the values underpinning them and identify critical issues and dynamics.

## KEY TERMS

**Complex Adaptive System:** One based on agents and rules for interaction, typified by evolution and unpredictability.

**Democratic Deficit:** The gaps between formal democratic processes and government functioning and accountability.

**Digital Divide:** The gap in communications technology knowledge, skills, and use between different groups.

**Fractal:** Patterns that repeat at different scales, such as a coastline, or behaviours and institutions.

**Global E-Governance:** The electronic dimensions of emerging mechanisms for managing trans-national issues and resources.

**Global Information Commons:** The set of all stakeholders for information related to triple bottom line global resource management, the rules and protocols for transmission, distribution and accountability of this informa-

tion, and the emergent properties of the resulting patterns of resource management.

**Globalisation:** The process of increasing interdependency among countries, accompanied by convergent patterns of economic development and technology use.

**Globalisation:** The process whereby production, ownership, information, wealth, and control are increasingly concentrated and geographically integrated.

**Open Source:** An iterative, non-hierarchical approach to developing intellectual property, based on wide collaboration and freely shared information.

**Triple Bottom Line:** Accounting procedures that include economic, environmental, and social elements.

# Governance and Design Issues of Shared Service Centers

**Marijn Janssen**

## INTRODUCTION

In the current economic climate, public administrations are looking for ways to improve their service provision and to increase their efficiency. A great long-term public sector concern is the need for restructuring structures and processes to improve efficiency and effectiveness (Beynon-Davies & Williams, 2003). Shared service centers (SSCs) are gaining importance in public administration as a means to innovate, reduce costs, and increase service levels (Janssen & Joha, 2004b). The SSC is a business model in which selected functions are concentrated into a semi-autonomous business unit with management structures that promote efficiency, value generation, and cost savings in a manner akin to companies competing in an open market (Bergeron, 2002). By unbundling and centralizing activities, the basic premise for a SSC seems to be that services provided by one department or agency can be provided to others with relatively few efforts. Within public agencies there is a debate about which kind of services are suitable to share, how to obtain the expected benefits and how to organize SSCs. Currently, SSC implementations include several, relatively easy-to-standardize, functions like the concentration of administrative processes for handling human resources and procurement for all ministries, and the maintenance and control of information systems of several local agencies in a SSC (e.g., http://www.sharedservicesbijdeoverheid.nl/).

Clearly, there is no one-size-fits-all business model that incorporates all benefits and has no negative aspects. The *goal* of this research is to explore the concept of shared service centers and to present an overview of critical research issues with respect to its governance and design.

The structure of the article is as follows**.** In the following section, we discuss the theoretical background. Thereafter we present the main drivers for shared service centers. Section four provides an overview of the critical research issues and in section five we present future trends. Finally in section six, conclusions are drawn.

## BACKGROUND

There are many theories underpinning the sourcing, an overview of the various theories is shown in Table 1. The basic idea of outsourcing is based on the *transaction cost theory* (Coase, 1937; Williamson, 1975). Transaction costs result from the transfer of property rights between parties and exist because of friction in economic systems. A firm will tend to expand until the cost of organizing an extra transaction within the firm becomes equal to the costs of carrying out the same transaction on the open market. The use of communication networks and integration technology will decrease the transaction costs enabling organizations to source functions and to focus on their core competencies.

*Principal-agent theory* deals with the relationship between the principal and agent based on the division of labor, information asymmetry and environment and partner behavior (Jensen & Meckling, 1976). Both the transactions cost and principal-agent theory are based on rationality, an efficiency criterion is used for explaining outsourcing structures.

*Political organizational theories* are used for explaining organizational arrangements and include social, coordination, risk, and strategic management theories. These view actors as political entities having different degrees of power. Political theory, especially *resource dependency theory* (Roy & Aubert, 2002), is used to explain motives for outsourcing. Both resource dependency theory and *core competency theory* explain that companies should retain core capabilities, but non-core capabilities do not have to be owned or controlled. *Social contracting theory* addresses the view that moral and/or political obligations are dependent upon a contract or agreement. *Coordination theory* is about the management of interdependencies between organizational business processes (Malone & Crowston, 1994).

There are specific differences between sourcing and shared service center arrangements (Janssen & Joha, 2004a, 2006), which also have consequences for the way

*Table 1. Driving theories behind sourcing issues (based on Lee, Huynh, Kwok, & Pi, 2003)*

| Sourcing issues | | Driving Theory | Driving Motto |
|---|---|---|---|
| **From** | **To** | | |
| Make-or-Buy | Motivation | Resource-based theory<br>Core competencies theory | Activities should be performed either in-house or by suppliers. |
| Motivation | Scope (options) | Resource dependency theory<br>Transaction cost theory | Achieving efficiency depends on balancing the risks and benefits. |
| Scope (options) | Performance | Coordination theory | No one can assure an effective performance regardless of selected options. |
| Performance | Insourcing/ Outsourcing | Transaction cost and Principal-agent theory<br>Power-political theory | How do we know an outside vendor is more efficient than internal functions? |
| Insourcing/ Outsourcing | Contract | Principal-agent theory<br>Social contract theory | We no longer produce for ourselves everything we need to thrive. |
| Contract | Partnership | Social exchange theory<br>Coordination theory | The acquisition of services or products is through continuous interactions between the parties based on mutual benefit. |

a SSC has to be embedded within the organization. The design of SSC business models is influenced by the services and characteristics of public agencies and people involved. The governance of the SSC is dependent on a large number of aspects, including the type of services, the primary motives to implement the SSC, the frequency of change and adoption, and the type of relationship.

## DRIVERS FOR SHARED SERVICE CENTERS

The rationale for shared service centers can be explained by combining two emerging trends: (1) the technological evolution and (2) globalization and the focus towards standardization. Organizations are always attempting to find the ideal organizational structure, certainly in times of economical pressures and global competition.

During the 70s, the centralized structure was the common way of organizing companies. Centralized operations are characterized by substantial economies of scale, as procurement of products and services is possible on the broadest scale within the organization. Moreover, a unified approach to architecture and standards reduces integration difficulties and costs for new applications. However, the disadvantage is that centralized decision-making results in a slow response time and is not flexible since each business unit often has different or conflicting needs.

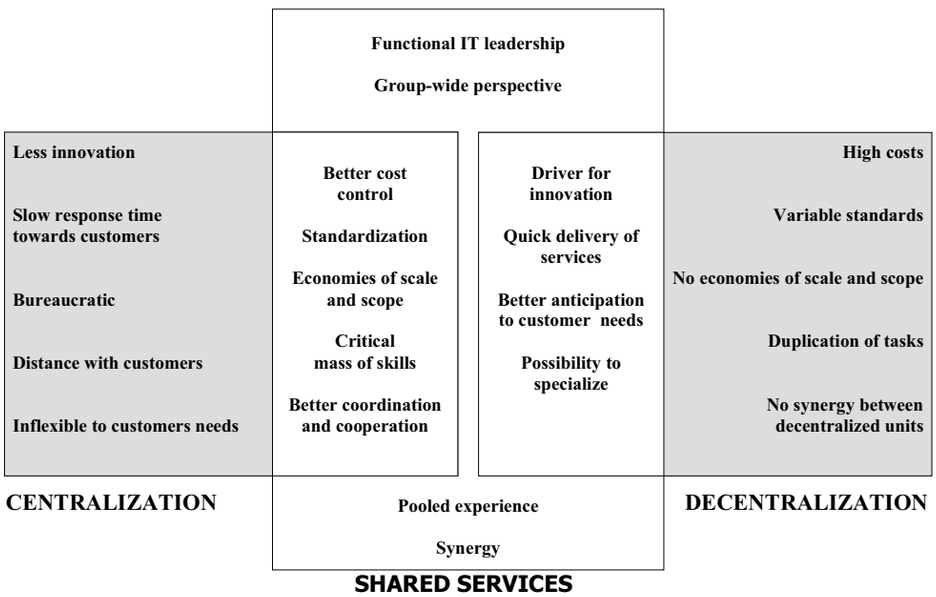
This explained the trend towards decentralization during the early 80s, where the business units were able to anticipate faster and more flexible to (new) market developments. The main disadvantage associated with decentralization is the fact that the company as a whole will have higher total procurement and operations costs due to inefficiencies related to the duplication of data centers and of multiple independent procurement and multiple suppliers.

The drawbacks, which initiated the decentralization phase in the 80s, have been overcome using modern information and communication technology. Information can be transferred and received very quickly and from every single place and most processes can be standardized, as they require limited business specific knowledge. This has resulted in a different organizational arrangement, which already started during the mid 90s, but is now attracting full attention: shared service centers. The selected government services supporting the business processes of local, decentralized, agencies are centralized into a semi-autonomous business unit or organization.

SSCs should provide the best elements of a centralized and decentralized world to accomplish efficiency and simultaneously increasing the customer-orientation (Janssen & Joha, 2006). Figure 1 shows the different characteristics of centralized and decentralized operations in terms of advantages and disadvantages.

Obtaining all the advantages of both centralization and decentralization is extremely difficult (Janssen & Wagenaar, 2004) and requires at least an effective management structure addressing a number of critical success factors (Janssen & Joha, 2004a). A lot of efforts are necessary to adapt and adopt the new organizational arrangements, coordination mechanisms, new processes, and the allocation of responsibilities. Motives to implement a SSC are to some degree conflicting and therefore difficult to combine in practice (Janssen & Joha, 2004b).

*Figure 1. Shared services should combine the advantages of both centralization and decentralization (based on Hodgkinson, 1996).*



For example accomplishing cost reduction, service improvement, and innovation requires conflicting governance mechanisms.

SSCs might be viewed as a risk to smooth operations not evaluated by researchers yet. Sourcing of systems development is sensitive to risks, as sourcing of certain services can involve the loss of technological or organizational (core) competencies that are crucial in ensuring the long-term operation (Roy & Aubert, 2002). There is still no evaluation framework including factors influencing costs, benefits, and risks.

## CRITICAL RESEARCH ISSUES

There is still a debate about the specific meaning of information technology (IT) governance, resulting in a lot of different definitions and frameworks, especially outside the scientific arena (van Grembergen & Haes, 2004). Although governance definitions differ in some respect, most of them focus on achieving the link between business and IT. The IT Governance Institute (2001) defines IT-governance as the leadership and organizational structures, processes and relational mechanisms that ensure that the organization's information and communication technology sustains and extends the organization's strategy and objectives. Governance is the system and structure for defining policies, monitoring and controlling policy implementations, and managing and coordinating the procedures and resources aimed at ensuring the efficient and effective execution of services. The design of a SSC, the resulting blueprint, can be viewed as one of the aspects of governance, as a SSC is often used to align the organizational strategy with its technology. The development of a holistic governance framework, combining the best of the existing governance models, is a challenging research topic.

We will use the taxonomy suggested by Baldwin, Irani, and Love (2001) into four categories, (1) *strategic and organizational,* (2) *political*, (3) *technical*, and (4) *economical* to further elaborate on the critical research issues related to shared service centers and their governance. A summary of these issues is depicted in Table 2.

### Strategic and Organizational Issues

The way the SSC supports the business does have major consequences for the way it should be embedded in the organization. First has to be determined what the specific objective of the SSC should be such as cost reduction, service improvement, or innovation. It is still not evident whether all advantages can be combined and achieved

*Table 2. Critical research issues of shared service centers with respect to its governance and design*

| **Strategic and organizational governance and design issues** | **Technical governance and design issues** |
|---|---|
| • Possibility of combining different motives and the design method to accomplish these motives<br>• Feasibility evaluation of a SSC<br>• Services appropriate for SSCs<br>• Roles and responsibilities<br>• Analysis of the different SSC archetypes<br>• Governance structure (e.g., pricing models) | • Necessary IT infrastructure and flexibility<br>• What technology can be shared and to what degree<br>• What is the role of interfaces<br>• Disaster recovery and business continuity planning<br>• The influence of the ICT infrastructure on the implementation of SSCs |
| **Political governance and design issues** | **Economical governance and design issues** |
| • Career options within a SSC<br>• Strategies to cope with resistance and effectiveness of those strategies<br>• Informal communication structures<br>• Expectation management<br>• Accountability | • Feasibility study of a SSC<br>• Analysis of combining different motives and the effectiveness of the SSC operations<br>• Quantitatively analyze the difference between SSC and outsourcing arrangements<br>• The evolution of an SSC from an economic perspective (efficiency, economies of scale) |

and which factors are of importance to meet a specific objective.

Another strategic aspect is the kind of services that are suitable to concentrate and transfer to a SSC. The type of services depends on the specificity, the scope, and the scale of the service, but also on the willingness, resistance, and culture of the people involved. The degree to which it is possible to standardize the specific service depends not only on technical limitations, but also on how many people are willing to accept it, which also limits the economies of scale. All these aspects should be quantitatively analyzed in order to determine whether an SSC is feasible.

The configuration of the SSC business model to ensure a good and effective delivery of services is also a major research issue. Strikwerda (2003) provides a classification of SSC archetypes as a (1) staff department, (2) internal joint venture, (3) infrastructure facilities for multiple business units (BU), (4) a center within one BU, (5) service firm, which is similar to outsourcing arrangements, and (6) joint venture with an outsourcing vendor. Figure 2 gives an overview of the SSC archetypes and combinations can also be found within large organizations. There is no theory addressing which is the best archetype given certain circumstances, although Strikwerda (2003) provides several factors that might influence this choice: economical pressures, strategy and capability of the board of directors, and the degree of resistance.

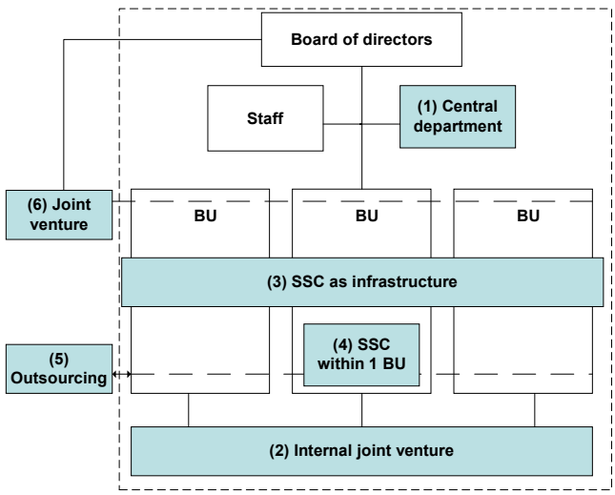
Governance aspects of SSCs are hardly known. The specific archetype that has been chosen will have consequences for policymaking and accountability, making it clear to whom the shared service center reports, and what its specific responsibilities are. New roles and processes will have to be introduced to govern the policy and structure and to continually elicit new and update existing customer requirements, monitor customer satisfaction and service quality and to react quickly in case of support needed or calamities. The way the organization has to be structured in terms of roles and responsibilities and the factors determining the relevance and location of those roles is also a topic for further research. Also of interest is whether the specific organizational form of the SSC does have consequences for the specific advantages that can be achieved.

Other governance issues that need to be addressed are related to pricing models: Will prices be paid per fee? Will pricing be competitive in open markets? Will pricing be tailored to customer demand? It is not yet clear which pricing structures can be adopted and what governance model fits best for described forms.

## Political Issues

The dependency on the internal resources and people within SSC arrangements is extremely high and therefore essential. Local departments are frequently not willing to

*Figure 2. Archetypes of SSC business models (based on Strikwerda, 2003)*



give up some of their autonomy. It is yet not clear which strategy should be adopted to cope with the initial resistance. Two opposing strategies are present in the literature: the big bang strategy and the incremental strategy. One solution suggested is to combine those strategies. Strikwerda (2003) provides several other alternatives to diminish the initial resistance. For example by defining such extremely high performance levels, that the business units might feel the need to cooperate. Another is that the chosen SSC activity is so expensive and complicated, that the business units are very much willing to concentrate it within a SSC. Research is necessary to identify the different strategies to cope with resistance and to analyze which specific strategies are most appropriate and effective given the specific circumstances.

A first step towards a framework to analyze the SSC governance based on the analyses of the relationship between stakeholders is provided by Janssen and Joha (2004a). They use the following six dimensions of outsourcing relationships introduced by Kern & Willcocks (2001): SSC intent, contract, structure, behavior, interactions and efficiency & outcome. They found that managing expectations is of major importance, which not only includes formal but also informal communication. The way this communication arrangement has to be structured and the important juridical and contractual aspects also need further investigation. Coping with the so-called "soft" side is of major importance to get the SSC accepted, to implement an effective governance structure and to achieve the expected benefits.

## Technical Issues

Advances in information and communication technology have enabled the emergence of SSCs. A well functioning ICT infrastructure is a necessary condition for establishing a SSC. This not only includes the technical platform, but also software and interfaces. The SSC should also be able to technically cope with contingencies, such as mergers and acquisitions and therefore requires an adaptive architecture. Failure of services provision can result in a shut down of critical operations and result in a major loss of productivity at business units. The management of the SSC should take measures like having duplicate versions of systems and an emergency communication network to avoid the single-point-of-failure problems. The approach to disaster recovery and business continuity planning is therefore an interesting subject of investigation. Other research issues here are related to the infrastructure: What ICT is at least necessary for SSCs? What technology is suitable for sharing services? The design of the (necessary) ICT infrastructure not only determines whether a SSC is possible and viable, but also how it should be implemented.

## Economical Issues

From a macro organizational economic perspective, it has to be determined whether the SSC is feasible. Such a feasibility study should include different analyses, for example, costs of technology adaptations, costs of chang-

ing or modifying facilities, and customer satisfaction with current services or potential shared services. The major cost factors have not yet been fully understood. Also related to this is whether it is possible to combine different specific motives, and when yes, to what degree. From an economic perspective, it is of interest to analyze whether the nature of a SSC changes over time in terms of economies of scale, efficiency, and governance, and in what way it evolves. Finally, the difference in efficiency between SSC and outsourcing arrangements is an interesting research subject in order to analyze the benefits and risks quantitatively. An efficient working governance arrangement is essential for establishing cost efficient operations, as is a balanced tradeoff between flexibility and standardization with respect to the SSC service delivery.

## FUTURE TRENDS

Shared service centers do not provide the final answer to the debate about the ideal organizational form. Two clear trends seem to be emerging. The first is further consolidation efforts using SSCs aimed at improving citizen-centered business processes. The use of shared services has to a large extent been limited to easy-to-standardize services. In the future, public agencies like municipalities might share complete back-office functions and processes and concentrate them in SSCs. These services can be customized to the local situation of public agencies. Related to this is the concentration of seemingly different services into one SSC, such as finance and accounting and parts of human resources services, thereby capturing even more economies of scale and integration advantages.

The second trend is to enlarge the search for new related organizational forms such as outsourcing, off shoring, Business Process Outsourcing (BPO), virtual and cross-national SSCs and other mixed forms. By outsouring or off shoring specific parts of an SSC, even more benefits might be gained. In this respect, SSCs might even just be a transition step towards other business models.

## CONCLUSION

The quest towards shared service business models has just started and there remain many research questions to be solved. In this article, we explored the concept of shared service centers and presented an overview of research issues related to the governance and design of SSCs. The main research questions are clustered into four categories, (1) strategic and organizational, (2) political, (3) technical, and (4) economical research issues.

To obtain the promised benefits of SSCs and avoid the risks, the right design trade-offs and decisions have to be made influencing the performance and success of SSCs and an effective governance structure should be implemented. There still is a need to further investigate the governance and design issues of shared service centers and the major factors contributing to success and failure.

## KEY TERMS

**Business Process:** A business process is a sequence of tasks, initiated by an event and aimed at providing products or services.

**Coordination:** Coordination is the management of dependencies between business processes.

**Cost Center:** An accounting term that refers to a department or function in the organization that does not generate profit.

**Governance:** The system and structure for defining policy, monitoring and controlling the policy implementation and managing, and coordinating the procedures and resources aimed at ensuring the efficient and effective execution of services.

**Shared Services:** Shared services are services shared by multiple users.

**Shared Service Center (SSC):** The SSC is a type of business models in which selected services are unbundled and concentrated into a semi-autonomous business unit or organization. Other business units and/or organizations can share those services.

**Sourcing:** The decision process of identifying and selecting potential, internal and external, suppliers of specified services.

**Transaction Costs:** Transaction costs result from the transfer of property rights between parties and exist because of friction in economic systems.

# The Government E-Procurement System in Korea

**Jae Yong Lee**
*Public Procurement Service, Korea*

## INTRODUCTION

Korea launched a national e-procurement system on September 30, 2002. The adoption of the e-procurement system in the government of Korea has been acknowledged as successful. This article presents a case study describing the public e-procurement system of Korea, analyzing the development process, and determining factors in the successful adoption of the system. The Government E-Procurement System (GePS: www.g2b.go.kr) is a portal site providing information on public procurement and an application service provider for public procurement as a whole. GePS advances procurement services by reducing paper work and red tape, expanding the range of commodity selection, and standardizing services. Government-wide support, including that of the president, had an instrumental role towards the successful adoption of GePS. The high capacity of information technology and institutional collaboration among public agencies were other foundations for the successful establishment.

## BACKGROUND

Electronic procurement (e-procurement) has become more significant in both public and private organizations. For example, "The Advantage System" of the United States General Service Administration has been assessed as a "limited success" and been recommended for development in terms of a "comprehensive business strategy" by the General Accounting Office (GAO, 2003). The Integrated Acquisition Environment of the U.S.—the federal government's e-procurement initiative anticipates creating a single Web-based portal site (Drabkin & Khi, 2003). The Commonwealth of Virginia's e-procurement solution, eVA has been identified as a good e-procurement system (Eakin, 2002). Yet, it is very hard to find good e-procurement models at the federal level, especially the national level including local governments and state-owned enterprises.

A number of components characteristic to fully developed electronic government procurement systems have been specified (Talero, 2001). In e-procurement systems, e-tendering has more phases—registering, opening a bid, contracting, documenting, and tracking—whereas e-purchasing is based on transaction modules, which are rather compact processes, like e-catalogues (World Bank, 2003). Experts on procurement systems have paid more attention to tendering methods because they deal mostly with high value and low volume goods and services—blue collar MRO (Maintenance, Repair and Operation), which is believed to be more important (Neef, 2001).

The new paradigm of public procurement, e-procurement, is a managerial innovation of the government. It is not only a technical adoption but also an organizational change—from meetings arranged to personally conduct a transaction through to electronic transactions.

It was the same in Korea. Public Procurement Service (PPS) already had started to digitalize procurement services by adopting EDI in the late 1990s based on its own plan. PPS had much interest in improving transparency and efficiency of the public procurement, as the centralized procurement agency in the Korean government, which shares 30% of entire public procurement. PPS completed its own system in 2001 including e-bidding, e-contracting, e-purchasing (e-catalogues), e-payment, and so forth. But the system was not the integrated e-procurement services for all suppliers and buyers at that time. Therefore, the Korean government decided to establish a nationwide e-procurement system to overcome this weakness.

## DEVELOPING GePS IN KOREA

The development of GePS was initiated as a national project of e-government policy and is now a part of the national IT policy. Recent government policies were introduced in the Master Plan for Informatization Promotion from 1996 to 2000 and "Cyber Korea 21" from 1999 to 2002 (NCA, 2003). The Special Committee for E-Government selected 11 e-government projects, including GePS. The benefit of GePS is expected to cross over into all public agencies and the private sector. On the other hand, the experiences and achievements of PPS were thought to be the success factors for the project.

Those are the reasons the special committee selected GePS as a major project for e-government. Without the initiation and supports from the special committee, it might be hard and take longer to develop GePS. For the business process reengineering (BPR) of GePS, three government ministries were involved—the Ministry of Planning and Budgeting (MPB), the Ministry of Information and Communication (MIC), and the PPS. The BPR/ISP(Information Strategy Plan) report outlined the strategies for e-procurement system build-up, the result of procurement service innovation, standardization of documents and catalog, e-procurement system plans, and recommendations on legislation for e-procurement (Seong & Lee, 2004).

All expenses for the development of GePS were financed through the Informatization Promotion Fund (IPF, Special Committee for e-Government, 2003) based on the Framework Act on Informatization Promotion of 1996. The special committee for e-government, MPB, MIC and NCA concluded that the development of GePS should be funded by IPF rather than solely PPS as the project was expected to reap the government-wide benefits.

One important strategy for implementing e-procurement system in government is how to institute legal and accountability mechanisms (Moon, 2002). In order to increase the number of transactions through the e-procurement system and to prevent abusive and fraudulent transactions, laws and regulations on public procurement should be revised. The digital signature is one of the good examples. The electronic documents including bids with digital signature have the same validity with the paper documents with the signatures.

The most significant change is that procurement laws require most public agencies to account for bids through GePS. As a result, most information on public purchases and contracts can be collected onto GePS and the number of participants in public procurement via GePS has increased.

## MAIN FUNCTIONS AND ACHIEVEMENTS

GePS provides information on public procurement for both of centralized and decentralized procurement. GePS is a public cyber-marketplace, whereby a single focal point allows a variety of suppliers and buyers to simultaneously meet and conduct a range of electronic business types. The main services of GePS include (1) helping public organizations' procurement in terms of contract request, bid, contract, payment request and follow-up management; (2) serving as a single point of business registration for entering the public procurement; (3) providing information on companies regarding business ID certificate, national tax payment certificate and qualification; (4) reporting contract performance; (5) issuing various notices related to procurement; (6) managing an e-shopping mall for PPS's supply of contracted products; and (7) sending procurement requests from public organizations to PPS (PPS, 2003).

GePS is a secure and convenient universal system designed to assist both public institutions and businesses with all public procurement tasks. The systems of 53 other institutions such as the Ministry of Government Administration and Home Affairs are linked with GePS to share information. The Government for Citizen Systems (G4C) of the Ministry of Government Administration and Home Affairs provide tax records and necessary information for registration. The National Finance Information System (NAFIS) provides real-time information on the finances of government agencies. Six construction-related associations are connected for obtaining information on contract bidders; ten guarantee corporations are involved for receiving contract deposits; six certified authentication institutions assist in verifying digital signatures; the Korea Financial Telecommunications & Clearings Institute provides services for e-payment with fifteen commercial banks; and the National Computerization Agency (NCA) provides public key infrastructure for e-bid cryptography.

PPS has eliminated or reduced the need for submission of all documents by sharing information such as business registration certificates and financial information online. Contracts can be established electronically and contractor payment can be made via online banking.

The general workflow of e-procurement through GePS is described in Figure 1, though procuring processes differ slightly depending on the object to procure–goods, services, or facilities.

*Figure 1. Workflow of e-bidding and links with other systems*

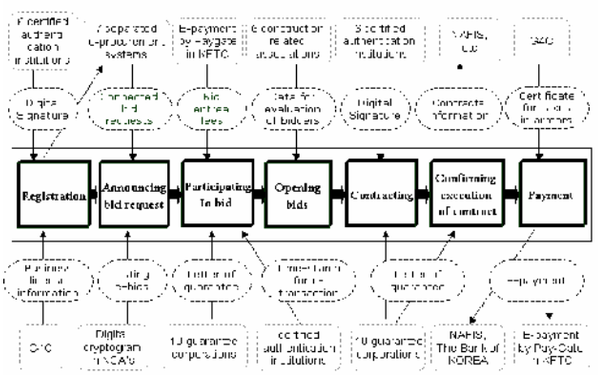

*Table 1. E-bid in GePS (FY, 2003)*

| | Biddings (cases) | Participants (thousands) | Transactions (million $) |
|---|---|---|---|
| Total | 99,020 | 15,404 | 17,190 |
| Monthly | 8,252 | 1,284 | 1,433 |
| Daily | 330 | 51 | 57 |

Since the launch of GePS, procurement services have been mostly delivered through GePS. The data from PPS shows the contribution of e-procurement to the procurement services.1 For one fiscal year–from January 2003 to December 2003, GePS took the charge of most public procurement services. Total amount of procurement through GePS reached up to 31.6 billion dollars. E-bid accounted for up to 92% of all biddings. As Table 1 shows, 99,020 notices of e-bid were electronically placed on GePS. 15.4 million participants have been involved in e-biddings and 17.2 billion dollars has been transacted through e-bidding systems of GePS.

Table 2 indicates that 98% of orders from public agencies were made at the e-shopping mall for the pre-contracted items in GePS. Only 2% of orders were based on paperwork. The rate of electronic orders considerably increased after launching GePS—from 81% in 2002 to 98% in 2003. On average, 15 million dollars was ordered a day through the e-shopping mall of GePS.

As of December 2003, 25,529 public organizations with 39,885 users and 92,042 private firms with 116,681 users participated in the new procurement systems. The public organization users included 3,728 central government agencies, 5,535 local government agencies, 9,396 schools from elementary schools to universities, and another 6,870 public enterprises.

GePS has enhanced public procurement administration and service in terms of productivity and transparency. It has realized annual transaction cost savings of $2.8 billion, due to the digitalized processes and integrated information. In particular, 90% of the total amount, or $2.5 billion of business expenses was saved in terms of time and transportation. Public organizations saved $300 million primarily due to the reduced burden of information acquisition and visits to public offices. GePS also provided information in real time and expanded the provision of information on private contracts. This promoted fair competition with a reduction in direct contact between business people and public officials and thereby significantly reduced the possibility of corruption.

*Table 2. E-shopping mall in GePS (FY, 2003)*

| | Orders (cases) | | | Transactions (million $) | | |
|---|---|---|---|---|---|---|
| | Total (A) | GePS Shopping Mall (B) | Ratio (B/A, %) | Total (A) | GePS Shopping Mall (B) | Ratio (B/A, %) |
| Total | 462,274 | 454,831 | 98.4 | 4,474 | 4,367 | 97.6 |
| Monthly | 38,523 | 37,903 | - | 373 | 364 | - |
| Daily | 1,541 | 1,516 | - | 15 | 15 | - |

In the technological point of view, PPS has adopted advanced standard solutions for exchanging documents since 1997. The initial e-procurement system has taken advantage of the electronic data interchange (EDI) for the electronic transmission of business data. Since the development of the Extensible Markup Language (XML) in the mid-1990s, the e-procurement system has had simple and affordable solutions for secure exchange of transactional business data (Neef, 2001). GePS was developed with electronic documents based on the XML Schema from the World Wide Web Consortium (W3C) as well as the Core Component method from Electronic Business Extensible Markup Language (ebXML). Simple object access protocol (SOAP) from Microsoft and ebXML message service specification (MSS) are used for messaging. In addition, GePS employs standardized documents for electronic transactions, which are shared among public agencies. PPS has also participated in the United Nations Center for Trade Facilitation and Electronic Business (UNCEFACT) for universal standardization of ebXML documents.

## REPUTATIONS FROM THE INTERNATIONAL COMMUNITY

The United Nations (UN) Division for Public Economics and Public Administration announced PPS as the recipient of the United Nations Public Service Awards for 2003 (UNDESA, 2003). According to the UN, PPS has reorganized the procurement service by converting to e-commerce and is expected to save $2.8 billion annually. Other international organizations, including the World Bank, have shown interest in GePS since the system is expected to save costs, increase transparency in government purchasing and refine contract processing.

Moreover, the Organization for Economic Co-operation and Development (OECD, 2004) evaluated that GePS has a “strong pull-through effect on information and communications technology use in the private sector” and “no further action is required.”

According to the UN Global E-Government Readiness Report 2004, GePS was referred as the best practice model for e-procurement in the world. The report noted that one pattern of e-government development across the world has been to adopt an integrated portal approach to ensure easy navigation and reflect the commit-

ment of governments to facilitate civilian access by ensuring all information and services available through one stop shop sites (UNDESA, 2004). It is one of the GePS's strongest features.

## FACTORS FOR SUCCESS

The most important factor for the successful adoption of GePS has been the endorsement from the President and collaboration amongst government ministries. Korea established the Special Committee for E-Government as a top task force for promoting e-government under the President. Collaboration amongst the interested parties from the public and private sectors is one of the critical success factors, since data sharing and user input are crucial.

The rapidly grown capacity of the IT industry in Korea has supported e-government projects. E-procurement systems are required to be secure, efficient, and effective. GePS has solved its technical problems by utilizing high-tech applications and worldwide standards for business in Korea. For authorization, public key infrastructure has been adopted, which is used for authorized certificates and cryptographic algorithm. In terms of commodity information and code management in GePS, PPS introduced the United Nations Standard Products and Services Code (UNSPSC), used in e-commerce throughout the world.

Most importantly, a well-developed Internet infrastructure is another key factor for success. Korea has bridged the digital divide between different regions and companies as a result of the 30 million Internet users (65.5% of the population), 11 million households with broadband Internet subscribers (75%), and so forth.

The coordination amongst agencies' interests and support from these agencies is another critical factor. During the first period from April 2001 to January 2002, there were nine ministries involved in designing and developing e-procurement systems, including MPB, MIC, the Ministry of Commerce, Industry, and Energy (MOCIE) as well as PPS. As mentioned before, the GePS project is related with other e-government projects—G4C projects, NAFIS, e-document and e-signature, and government-wide computer network projects. GePS is one of 11 e-government projects, which was directed by the Special Committee for E-Government. This special committee supervised by the Presidential Commission on Government Innovation has assumed the role of coordinating organizations involved in GePS development.

## FUTURE TRENDS

PPS has provided customized information by establishing the customer relationship management (CRM) based on the infrastructure of data warehouse since September 2004. In December 2004, it also adopted the mobile e-bidding system, thus making it easier to use GePS whilst on the move by providing mobile services through wireless tools such as PDAs. PPS will extend the Ubiquitous services including the RFID.

GePS could be improved by adopting new technologies including the Desktop purchasing with Web Service and expanding the integrated use of information and services with other public information systems. Besides the ICT, PPS will develop more complicated services including consulting, analyzing the specification, and total services from planning to inspection.

## CONCLUSION

New technologies do not guarantee the success of e-procurement systems. E-procurement systems are expected to save costs, prevent corruption, and stimulate business as well as streamline the administrative process. Institutional collaboration such as revising laws and regulations as well as public agencies' cooperation in e-procurement systems have been equally matched with the development of GePS.

Responding to the demands from public agencies and firms and with their support, PPS has constantly reformed the procurement processes with the use of information technology. For the sustainable development of GePS, further research is required. There is the possibility of a business model or profit model within GePS. GePS also needs to re-establish the relations with other public e-government systems. After the implementation of GePS has been thoroughly established, evaluation on the performance of GePS and other issues on capacity-building will be required.

## KEY TERMS

**ebXML (Electronic Business Extensible Markup Language):** A modular suite of specifications that enables a standard method to exchange business messages, conduct trading relationships, communicate data in common terms and define and register business processes.

**G4C (Government for Citizen):** One of the e-government projects in the Ministry of Government Administration and Home Affairs of Korea which provides tax records and necessary information for registration.

**GePS (Government E-Procurement Systems):** A portal site providing information on public procurement and an application service provider of public procurement in Korea.

**NAFIS (The National Finance Information Systems):** Within the ministry of finance and economy of Korea—provides real-time information on finances of government agencies.

**PPS (Public Procurement Service):** The centralized procurement agency of Korea.

**SOAP (Simple Object Access Protocol):** SOAP is a lightweight protocol for exchange of information in a decentralized, distributed environment.

**UNCEFACT (United Nations Center for Trade Facilitation and Electronic Business):** UN's standard body which encourages close collaboration between governments and private business to secure the interoperability for the exchange of information between the public and private sector.

**UNSPSC (United Nations Standard Products and Services Code):** A cross-domain classification for products and services used in e-commerce.

# Government E-Procurement through the Internet

**Christopher G. Reddick**
*The University of Texas at San Antonio, USA*

## INTRODUCTION

Electronic procurement (e-procurement) is one business-to-government e-commerce venture that can benefit from the Internet. Government e-procurement is different from private sector e-procurement because of concepts such as value for money, transparency and accountability, which may be considered the main benefits for the public sector. Public sector organizations have to meet multiple, often conflicting goals, and they are subject to constraints of a financial, legal, contractual, personnel and institutional nature. In addition, radical process changes from e-procurement can only be achieved with deep changes in bureaucratic practices. These changes cannot normally be achieved without either changes in the law or privatization (Panayiotou, Gayialis, & Tatsiopoulos, 2004).

## BACKGROUND

One definition of e-procurement is any technology designated to facilitate the acquisition of goods by a commercial or government organization over the Internet (Davila, Gupta, & Palmer, 2003). E-procurement technologies are focused on automating workflows, consolidating and leveraging organizational spending power, and identifying new sourcing opportunities through the Internet. In this article, I focus on the use of the Internet for the procurement process. However, there are other electronic technologies for not discussed in this article because of space limitations, such as phone or voice-over-Internet-protocol (VoIP).

The World Bank (2003) working group on government e-procurement defines it as the use of information technology (IT) (especially the Internet) by governments in conducting their procurement relationships with suppliers for the procurement of works, goods and consultancy services required by the public sector. Government e-procurement breaks down the space and time and allows for a more transparent and efficient information flow and wider access to information and services.

Moon (2003) defines e-procurement as a comprehensive and systematic process in which governments either establish agreements for the acquisition of products/services (contracting) or purchase products/services in exchange for payment (purchasing) using IT systems. According to Moon's definition, e-procurement uses tools such as electronic ordering, purchasing cards, reverse auctions and automatic accounting systems, and goes beyond just using the Internet for the procurement process.

The Internet is an extremely low-cost communication medium that provides access to the Web and differs from other communication media. Digital communication is more malleable, meaning it can easily be retrieved, stored, indexed, transmitted and revised. In fact, Gartner Group predicted that government-to-business e-procurement spending would expand dramatically from $1.5 billion in 2001 to more than $6 billion by 2005 (Gansler, Lucyshyn, & Ross, 2003).

E-procurement had seen rapid development before the economic recession in the United States (U.S.) in early 2000. Although much of the initial growth has slowed, all state governments are at least maintaining a Web presence in their procurement function, and some states are participating in Internet bidding (Moon, 2005). The findings of a 2003 national study by the National Association of State Purchasing Officials (NASPO) indicate that there is much room for advancement in e-procurement (NASPO, 2003). Less than one-quarter of the surveyed states' central procurement offices conducted solicitations via the Internet. The potential for economies of scale because of e-procurement is profound, but obviously underutilized in these governments. Part of this may be attributed to differences in management capacity in governments (Reddick, 2004; Moon, 2005). The existing literature on e-procurement has conducted descriptive and empirical studies of e-procurement adoption (see Wyld, 2001; Moon, 2003, 2005; Reddick, 2004).

Traditional procurement is a paper-based process that often is characterized by fragmented purchasing, off-contract buying and lack of control over expenditures (Mitchell, 2000; Krysiak, Tucker, Spitzer, & Holland, 2004). The paper-based procurement process has managers spending most of their time chasing paperwork rather than managing their supplier base or negotiating better prices (Moon, 2003).

## ONLINE BIDDING, DIGITAL SIGNATURES, AND REVERSE AUCTIONS

For public sector organizations, the first step to online procurement is to send out solicitations and receive bids for government contracts electronically (Holmes, 2001). Requests for bids or proposals can be placed on the Web or e-mailed to contractors, eliminating the need for traditional postal waiting periods—which often take up to 4 weeks—between the announcement of a contract and the acceptance of bids. Bidders can be notified immediately by e-mail. Other common vehicles for e-procurement are e-catalogs, procurement cards and e-marketplace (Krysiak et al., 2004). There are fully integrated e-procurement systems developed by various commercial vendors (SAP, Oracle, etc.). Web-enabling Enterprise Resource Planning (ERP) is another electronic technology that governments can use and is discussed in the future trends section of this article (Reddick, 2004).

Technologies such as digital signatures are becoming well established, making it safer to procure over the Internet. A digital signature is an electronic means of signing electronic documents that provides sender authentication using public-key encryption (Laudon & Laudon, 2001). Digital signatures support e-procurement by facilitating online financial and document transactions. The authentication procedure of digital signatures includes: (1) combining private keys and specific documents; and (2) computing the composite (key + document) and generating a unique number—the digital signature (Moon, 2003).

Online reverse auctions (descending prices) present a major departure from the standard public procurement process, in which contracts are awarded on the basis of sealed envelopes and companies have only one chance to make a winning bid (Soudry, 2004). In a reverse auction, the buyer sets up an auction to receive bids from suppliers (Wyld, 2001). In online auctions, bidders typically make several submissions over the course of an hour or two. A reverse auction is a supply-aggregating event that lowers the price of goods for a buyer. Through a pre-qualification process, all issues are generally settled between the procuring organization and potential suppliers before the auction. Usually, the only remaining issue to be settled is the price.

Some of the chief benefits noted in the literature of reverse auctions are: (1) increased numbers of potential suppliers; (2) reduced procurement cycle times; (3) lowered purchase prices; and (4) increased transparency (Wyld, 2002; Soudry, 2004). One drawback of online auctions is that they remain focused on the market of buying indirect goods or Operating, Resources and Management (ORM). Another drawback is that the entire process works against some of the key value principles of procurement and new public management (MacManus, 2002). Furthermore, it is difficult to predict prices, and each day may bring a completely different set of bid responses. In addition, because of the emphasis of an auction on price alone, it makes it difficult for suppliers to maintain any close relationship with the buyer. Issues concerning collaborative design, quality assurance levels and delivery dependability are often much more important in the procurement of direct goods or Maintenance, Repair, and Operations (MRO) than price alone (Neef, 2001).

## BENEFITS AND DRAWBACKS OF E-PROCUREMENT

Several benefits are achieved through the implementation of e-procurement practices. A government can lower its administrative costs associated with procurement by reducing the number of people and time associated with the process. For instance, in a typical manual system, users would first have to find a supplier, obtain the appropriate paper catalog, select the item, and seek and obtain management approval. After review and approval of the requisition by the procurement professional, a purchase order would be faxed to the supplier. This fax would be followed up with a phone call to verify receipt, and then copies would be sent to shipping and receiving, accounting and finance, and department managers. This paper-based system is sequential, prone to errors, encourages the carrying of excess inventory and makes enterprise-wide integration very difficult. With e-procurement, the process is significantly more efficient. Employees can access approved vendor catalogs from their personal computers, identify and compare needed items, and order them. Product availability and delivery information is readily accessible, and payments can be made electronically. Rule-based software can either provide automatic approval for routine orders or route the request to an available manager for approval (Gansler, Lucyshyn, & Ross, 2003).

An example of the public sector procurement process eliminating manual processes can be seen through the World Bank's use of e-procurement for the selection of consultants. This is said to achieve efficiency, transparency, service quality and compliance in the consultant selection process required by the World Bank (Leipold, Klemow, Holloway, & Vaidya, 2004). The Republic of Korea adopted its Government e-Procurement Systems (GePS), which is a Internet portal site providing information on public procurement and an application service

provider that will reduce paperwork and red tape, expand the range of commodity selection and standardize services (Seong & Lee, 2004). Finally, the European Commission (EC), as a means to allocate contracts in a more efficient and transparent way, adopted specific rules governing the use of reverse auctions (Soudry, 2004).

E-procurement can also significantly reduce the price of materials and supplies. Buyers can more easily identify the best value when they have access to more suppliers. This not only results in increased competition, but new visibility also creates opportunities that were previously unavailable for small businesses. Using online reverse auctions, buyers and sellers can quickly exchange information and bids, which often results in significant cost savings. Digitized transactions provide a complete, instantaneous and far more accurate audit trail that allows management to track the status of orders and identify and fix problems sooner. This data collection also allows organizations to monitor off-contract purchasing, a significant target for cost-cutting improvements. These maverick purchases are out of compliance with the organization's volume purchase agreements (Gansler, Lucyshyn, & Ross, 2003).

The use of the Internet to deliver all government services is a significant barrier because of the digital divide. Small business owners feel that they are disadvantaged in the e-procurement process because of their lack of technical expertise and education on the government's multiple procurement Web sites (GAO, 2001). MacManus (2002) makes the argument that one of the most serious inclusive issues facing government procurement officers today is the minority business owner's digital divide. As many large-sized businesses use the Internet, minority entrepreneurs (many small business owners) may struggle more to harness the power of IT and e-procurement because of lack of resources and requisite skills.

The drawbacks and benefits of e-procurement can be summarized (Neef, 2001; Wyld, 2001; Moon, 2003; Reddick, 2004). The benefits of e-procurement generally cited in the literature include the following: (1) lowered transaction costs; (2) faster ordering; (3) greater vendor choice; (4) more efficient and standardized procurement processes; (5) more control over procurement spending (e.g., less maverick buying) and employee compliance; (6) more accessible Internet alternatives for buyers; and (7) less paperwork from fewer repetitive administrative procedures.

Another study of Greek government purchasing identified benefits of e-procurement as: (1) improved control over vendor relationships; (2) accurate fulfillment of processes; (3) improved effectiveness of the purchasing process; (4) achievement of higher service levels; (5) reduced prices from key suppliers; (6) reduced inventory carrying costs; (7) and reduction of order cycle time (Panayiotou et al., 2004).

The drawbacks for e-procurement can be summarized as: (1) technical complexity—privacy, security, standardization and so forth; (2) legal issues, such as Web information as a public notice, digital signatures for procurement documents; (3) method of payment for potential initial developmental costs and operating costs; 4) maintaining relationships with online vendors and application service providers; and (5) the digital divide for small and minority-owned businesses.

## MANAGEMENT CAPACITY AND E-PROCUREMENT

A committed senior leadership is critical for achieving a transformation and integration of the government's supply chain, and to overcome existing legislative, regulatory and organizational barriers (Gansler, Lucyshyn, & Ross, 2003; Reddick, 2004). As governments attempt to cut costs, they increasingly look to IT to improve their supply chains by automating and digitizing their procurement processes (Neef, 2001).

According to Neef (2001), e-procurement continues to enhance the breakdown of traditional silos and shift management's focus toward horizontal processes and the empowerment of individual employees. In the past, the purchasing process was seen as a set of separate activities and functions, controlled centrally or departmentally, often focused narrowly on silo-based incentives rather than on total cost. E-procurement systems facilitate direct or MRO procurement of materials for finished goods as part of a single, fully integrated process, extending from forecasting and planning through the entire supply chain. For indirect or ORM materials, e-procurement systems allow for a far greater level of individual empowerment as pre-approval and purchasing is handed over to individual employees.

Neef (2001) believes that part of the problem is that in most organizations, the procurement process is still seen as tactical rather than strategic, as a cost rather than a benefit to the organization. The e-procurement function for many governments is still limited to occasional and uncoordinated shopping online for office supplies. Other issues are security and trust. Unknown vendors make procurement officers hesitant to give up their cumbersome paper-based process conducted with long-time and trusted suppliers. The management issue here is how to train personnel to use online procurement tools and tretrain those workers displaced because of e-procurement (GAO, 2001).

In the traditional bureaucratic model, public managers focus on internal productive efficiency, functional rationality and departmentalization, hierarchical control

and rule-based management. In contrast, under e-procurement, public managers shift from emphasizing producer concerns, such as cost efficiency, to focusing on user satisfaction and control, flexibility in service delivery and network management with internal and external parties. The new paradigm stresses innovation, organizational learning and entrepreneurship so government can continue to reinvent itself (Moon, 2005).

Moon (2003) argues that moving toward e-procurement from traditional paper-based processes also brings great challenges to procurement officers. They need new technical and managerial skills, such as managing electronic catalogs; building relationships with online vendors and independent Application Service Providers (ASP) (or portal site providers); and developing strategic team-based purchasing with other purchasing entities. To sustain the development of e-procurement, governments must provide appropriate technical training and assistance to procurement officers and develop closer working relationships with vendors and various government buyers (Neef, 2001).

E-procurement problems lie with a government's inability to muster the political and managerial will to mandate the use of e-procurement by both agencies and suppliers, and its unwillingness to manage institutional change as procurement systems are converted from a manual process to an electronic one (Newcombe, 2001). Because of the current fiscal problems that many governments face, some have proposed an enterprise-wide solution to bundle costs.

## FUTURE TRENDS

One solution and future trend to the current slow down in development of e-procurement is ERP, which has become the new catchword for e-procurement reform. ERP brings together the business practices of an organization's accounting, budget, payroll and procurement functions (Laudon & Laudon, 2001). ERP focuses on tying together IT systems, thus gaining economies of scale through the coordinating purchasing of interoperable management systems.

By making e-procurement part of the ERP package, purchasing departments have found that funding technology is no longer something they have to shoulder on their own (NECCC, 2000). Instead, it is an enterprise issue that requires state funding, usually in the form of money taken from general appropriations. By designing an enterprise-wide solution that leverages the existing electronic systems that govern a broad range of agency activities, an advanced e-procurement solution could be realized that saves money, improves vendor satisfaction and is sustainable (Newcombe, 2001).

## CONCLUSION

E-procurement in the public sector will radically transform the traditional paper-based procurement process. The Internet and procurement allow governments to conduct online bidding and reverse auctions, and replace paper-based signatures with digital ones. Some of the benefits of e-procurement are reduction of agency costs and more efficient purchasing processes. Some of the costs of e-procurement are the digital divide for small businesses and the legal ramifications of digital signatures. Strong leadership and management is the most important factor for successful e-procurement development. ERP is a future trend of e-procurement, because it brings together the different functions of government, including e-procurement, making it a critical component of government in a digital world.

## KEY TERMS

**Digital Divide:** Large differences in Internet access and e-commerce access among income, ethnic and age groups. Related to e-procurement, since many minority and small businesses may not have access to the Internet.

**Digital Signatures:** A digital code that can be attached to an electronically transmitted message to uniquely identify its content and the sender.

**Enterprise Resource Planning (ERP):** Government-wide information systems that integrate key government processes so information can flow freely between different parts of the public organization.

**Online Bidding:** Being able to bid for products or services over the Internet rather than using the traditional paper-based procurement process.

**Privacy:** Includes both the claim that certain information should not be collected from the Internet at all by governments and the claims of individuals to control the use of whatever information is collected about them.

**Reverse Auctions:** Sellers bid on a price over the Internet to provide products or services; winning bid is the lowest-price provider.

**Security:** Educates and trains users, keeps management aware of security threats and breakdowns, and maintains the tools chosen to implement security on a government Web site.

## INTRODUCTION

Governments provide a wide range of services, and the digital economy provides both threats and opportunities in this sector. The Transport Accident Commission (TAC) is a compulsory, government owned and operated insurance scheme for third-party, no-fault liability insurance for transport accident victims, operated in Victoria, Australia.

E-business has now been widely used in all sectors from small business (Loane, McNaughton, & Bell, 2004) to emerging economies (Li & Chang, 2004), and in very different industry sectors (Cagno, Di Giulio, & Trucco, 2004; Golden, Hughes, & Gallagher, 2003). Major steps forward and applications have occurred in retailing (Leonard & Cronan, 2003; Mackay, Altmann, & McMichael, 2003; Starr, 2003).

Applications need to be highly customized as the business-to-consumer (B2C) and business-to-business (B2B) environments are very different, and requirements of industries such as retailing and mining, and indeed government, differ substantially (Carter, 2003; He & Lung, 2002; Rotondaro, 2002). Government provides a particularly different environment for e-business applications because government services are often delivered in monopoly circumstances, with no real profit motive behind them.

At the height of the technology boom in October 1999, Tony Marxsen joined the TAC as head of IT to develop a new IT outsourcing contract for the organization as the current 5-year contract was due to end in July 2000.

He quickly realized that the TAC IT systems were out of date, lacked IT process integration, and were constraining improvement in business processes, and that no significant investments had been made for some time. Renewing or redesigning the outsourcing contract, the basis for which he had been employed, would only be a short-term solution.

The problem was that the cost of new infrastructure would be high, and return on technology investment would mainly be realized from redesigned business processes enabled by the new technology. Tony wanted to propose a business transformation, with process changes as well as significant investment in IT infrastructure. Together, these would take the TAC from 1970s technology into the 21st century. The problem was that

*their (investments in such transformation) payoffs are not easily and quickly achieved. Their value does not come from installing the technology; it comes from changing both operating and management processes—perhaps operating and managing cultures too.* (Ross & Beath, 2002, p. 53)

Tony knew he would have to win the support of the board and senior management, but he could not immediately give them a concrete business case for the investment. He also knew that any infrastructure investment had to be linked with a major process-improvement initiative from the start to avoid the double investment of building new applications to support old processes, and then undertaking major modifications or even replacement when the need for improvement became obvious to the board and management team. He compared investing in IT infrastructure to rewiring and replumbing your house:

*as far as visitors are concerned, there's no visible difference, everything's behind the walls, but as the owner you get the benefits of things like cheaper electricity and water bills because of efficiencies in the new redesigned systems. The problem is convincing people that they will get these results in the future, but that they need to hand over the money now, when there's no hard evidence for the benefits they'll get, just a bunch of assumptions and no guarantees. It's a big ask for any Board.* (Marxsen, personal communication, September 4, 2003)

Tony knew that the first hurdle he would have to overcome would be getting the board to agree to give him the opportunity to put together a team to develop a business case for the board's further consideration.

## BACKGROUND

The economic and social costs associated with road accidents have made the issue of road safety a major concern and cost for the community.

In 1986, the Victorian Parliament passed the Transport Accident Act 1986, establishing the TAC from January 1, 1987. The purpose of the act was to establish a compensation scheme "in respect of persons who are injured or die as a result of transport accidents," as well as promoting road safety in Victoria and improving Victoria's trauma system (Marxsen, personal communication, September 4, 2003).

Operating as a commercial insurer, the TAC is funded by payments made by Victorian motorists when they register their vehicles each year, and by premiums charged to managers of tramways and railways, as well as from investment income generated on reserves. As such, the TAC operates as a state-owned enterprise of the Victorian government.

## CONCEPTUAL FRAMEWORK

Timmers (1998) specified a number of e-business models, and Rappa (2003) more recently defined nine categories for e-business models: advertising, affiliate, brokerage, community, infomediary, merchant, manufacturer, subscription, and utility. TAC is clearly a manufacturer of insurance policies and claims processing services, many of which are quite complex. Joyce and Winch (2005) provided a comprehensive conceptual framework posing that the firm's business strategy, emergent and realized, should combine with the firm's dynamic capabilities to form a business model within which the business processes and the enabling technologies should be chosen and implemented. This framework has valuable insights, which TAC learned to some extent the hard way, for it began its e-journey looking closely at the technological opportunities and then realized that it needed to step back and consider its business processes (and their reengineering) first. Then it realized that at an even higher level, future organizational strategy needed to be well formulated in order to drive the business model, and only then can process and technology choices be sensibly made in an existing organization that is mature in its life cycle and in an established industry. While technological opportunities may be a major driver in a private-sector Greenfield or start-up company or industry, in a government-owned services organization, which primarily exists to implement an act of parliament (which is very detailed in its prescriptions of what and how it must act), the board of the TAC and the e-TAC project team realized that e-business choices must be governed and constrained by a primarily top-down approach.

## TAC Business Processes and Information Systems

The TAC processes around 18,000 new compensation claims per year covering transport accidents directly caused by the driving of a car, motorcycle, bus, train, or tram. The organization pays benefits to people injured in an accident as a driver, passenger, pedestrian, motorcyclist, or cyclist.

The accountability and administrative issues surrounding claims management means that the TAC sends around 1,200 letters and 350 faxes per day, and issues around 800 checks and electronic funds transfers (EFTs) per day. On top of this, it is estimated that the organization receives around 4,000 inbound correspondence items and 550 pages of faxed items per day.

Administrative costs are around $64 million per annum, whilst claims payments made are in the order of $500 million per annum.

## A Changed IT Environment

Whilst overall the 5-year TAC contract with DMR outsourcing had been successful, with a number of financial savings, project phases delivered on time and on budget, and successful Y2K (year 2000) work amongst other things, a number of changes in the marketplace had taken place during the life of the contract.

The changed environment meant that major savings could probably be achieved if the current contract was broken into smaller parcels going forward.

However, in order to write effective tender documents for the various services that could be unbundled and outsourced, various organizational systems and processes needed to be reviewed.

## Developing the New TAC IT Strategy

A review in late 1999, in conjunction with the board and with input from the Boston Consulting Group and Deloitte, confirmed that significant changes to the organization's information-technology systems were needed to move forward. It was proposed that a new IT strategy had to be designed that would deliver the following important organizational requirements:

- Systems and infrastructure to deliver quality information for effective liability control
- Systems to support process improvements aimed at efficiency and service delivery
- Best-practice security of all information
- Active management of technology at risk

*Example 1.*

| From | To |
|---|---|
| – An enclave business operation | – A networked business operation |
| – Paper files | – Electronic files |
| – File-based claim management | – Process-based claim management |
| – Boundary security | – Information security |
| – Applications-centered IT strategy | – Environment-centered IT strategy |
| – IT for transactions and analysis | – IT for collaboration and learning |
| – IT used to automate work | – IT used to enable change and improvement |

- Purchase of IT services by competitive tender
- Cost-effective investment

In addition, the services purchased should enable the TAC to accomplish the following:

- Maintain control of the transaction at all times
- At all times have at least one suitable supply option available
- Maximize price pressure both in the purchase process and through the life of the contract
- Build in risk protection (alternatively, buy insurance)

A number of changes to the business would be required, in particular, moving from and to as presented in Example 1.

## The Business Case

The essential elements of the original business case for the TAC's technology strategy had remained constant since 1999, when Tony had initially presented his proposals to the board. The benefits of the new e-business strategy proposed would include improvements to the following:

- **Access:** To keep customers informed
- **Transparency:** To show clearly the basis of decisions
- **Timeliness:** To enable fast decisions and payments
- **Efficiency:** To require less paper, less time, and less errors, and enable outplaced work
- **Relationship Management:** To enable the influencing of provider markets and the management of long-term claimants
- **Brand Management:** To influence community views

The first business case analysis for the technology upgrade was presented to the board in February 2000, estimating a cost of $20 million for the program proposed, leading to anticipated savings in the range of $10 million per year. Some benefits were expected to be realized in year 2 of the program (i.e., 2001/2002), but overall, the payback was estimated to be seen in 4 years, using the assumption that the mainframe would be retained and that avoided costs would be included in the benefits.

On the basis of the case presented, the board in principle approved the proposed program of work, which included investment in basic infrastructure activities that were expected to quickly realize financial and other benefits for the business.

The board also endorsed management's proposal to move from a fully bundled IT-services contract to multiple purchase contracts for different services based on the premise that breaking up the outsourcing contract would enable the capture of cost and service benefits from what had become a highly competitive market for the supply of IT services. Management projected that this new approach alone would yield net annual savings of around $3 million when compared to the previous contract.

## Getting Started

In early 2000, the major technology upgrade started, with three highly interlinked and interdependent streams of activity in the project:

1. Replacement of the previous purchase agreement for the supply of IT services (for which the current agreement was coming to an end)
2. Replacement of obsolete mainframe systems and reduction of the TAC's reliance on paper documents
3. Selection of high-priority business-improvement projects to address key TAC goals of liability control, client satisfaction, and operational efficiency

While efficiency gains through process improvement were expected to return the greatest benefits in the long run, the major costs would be incurred in technology

replacement in the short term, although neither type of work could feasibly proceed in the absence of the other.

## Unbundling the Current Contract

In order to break up the current bundle of services, IT services were segmented by technical skills and management processes as it was considered that this was the best approach for efficient and effective service delivery.

The services ranged from commodity type (distributed and application platforms) to potentially competitive (application development) and noncommodity types (application support and security).

## The Future of the Mainframe

The 700 programs with 2.5 million lines of handcrafted code on the mainframe with no data-archiving facility meant that the existing mainframe system had both high development and operating costs. Examples are as follows:

- The Y2K program cost close to $2 million, and simple code-table changes typically cost $10,000.
- The system required the support of a new claim form in 1999, costing around $400,000 to implement. Most of the costs being incurred were to interface the new system to the mainframe.
- Even relatively minor changes to the TAC's core payment system are expensive. For example, the move by the Department of Human Services (DHS) to a new injury coding system (ICD 10) is expected to result in $250,000 in programming costs for the TAC system to align.

## Early Initiatives

Complete mainframe exit became the only viable strategy, representing the major capital cost of the e-commerce strategy, estimated at around $25 million.

A number of quick-win opportunities were identified and implemented during the early stages of the project. These initiatives were mainly internal or business to business, and were designed to introduce staff to the idea of change in a nonthreatening way.

Projects implemented included establishing Lotus Notes team rooms for the posting of meeting agendas (whilst people printed copies off for themselves, they no longer had to be filed subsequently), developing electronic leave forms, replacing the generation of checks with EFT, and outsourcing the printing of remittance advice and putting around 3 million pages of operational management reports onto Lotus Notes attached as PDF (Portable Document Format) files.

## Care Online

A significant early project was the introduction of Care Online, which involved the reengineering of the administration processes associated with managing the TAC's relationships with attendant-care service providers such that the majority of the administration work associated with this group is now transacted electronically.

## Management and Control

For the first 9 months of implementation, Project e-ch@nge operated relatively separately from the business. The executive team was briefed weekly on issues and developments, and the board received a number of presentations and reports.

Then, from early 2001, the work program was integrated into the broader TAC organizational operations, and a more traditional control framework was established, which included the following:

- An executive steering committee that met fortnightly
- Independent funding-control processes, and benefit-monitoring and -reporting arrangements
- Reference groups comprising a range of employees and managers for the major process-improvement projects
- A technology architecture expert group to manage technology risk
- A security expert group to manage the required upgrade of security controls and practice
- Detailed project-management controls on all significant IT development projects

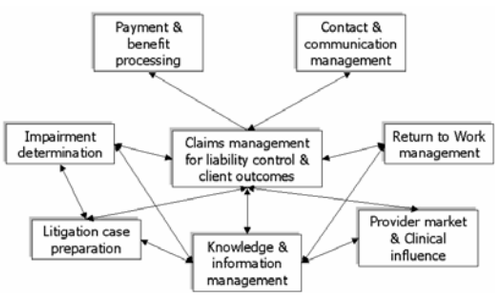
## Communicating Change

One of the most time-consuming aspects of the Project e-ch@nge implementation has been the communication activities associated with project ownership and development, both internally and externally.

Internally, management has to address board membership changes during the development and life of the project; it was faced with implementing a reeducation program to bring the new board up to speed with the very significant investment being undertaken.

Externally, the variety of different service providers and their differing market concentration levels and modes of operation (especially private vs. public) have meant that solutions have had to be tailored for each service-provider group and, as such, negotiated with each provider group. The highest level of security of the systems developed has been critical in achieving buy-in, espe-

*Figure 1. TAC key business-process groups*



cially where shared transaction data and client personal information is at stake.

## Risk Management

The TAC deliberately chose not to use leading-edge technology or techniques, except perhaps for the use of secure e-mail using digital signatures. The lack of an integrated repository had been identified early on as a key cause of failure for other companies attempting to implement e-commerce strategies, so an integrated document-management and customer relationship management (CRM) system as part of the back-office systems was therefore seen as essential to support the TAC's IT strategy implementation. Several risks to the successful implementation of the new IT strategy were identified, and strategies were developed to manage those.

## The TAC Business Processes

The TAC has broadly characterized its systems and processes into interrelated key business-process groups.

The grouping in Figure 1 was done as part of a review of existing and future IT priorities. Considerable work was involved in defining the groups and the processes involved.

## Business-Improvement Projects

The replacement of obsolete technology provided the opportunity to build new systems around improved business processes rather than automating existing processes.

An analysis of each core process uncovered a number of issues, as summarized in Table 1.

*Table 1. TAC core process issues*

| Core Process | Issues |
|---|---|
| **Payment and benefit processing** | – Time consuming and costly to change the business rules<br>– Lack of system flexibility results in a high proportion of held payments requiring manual intervention |
| **Contact and communication management** | – No tracking of what communication is coming in and out<br>– Ineffective process for determining who should respond to communications<br>– Inconsistent approaches to communication responses |
| **Impairment determination** | – Client is disempowered<br>– Complex assessment process<br>– Most of the process steps are external to TAC<br>– Subject to scrutiny and litigation as the impairment score is the gateway to common law<br>– VWA has same interests |
| **Litigation case preparation** | – Process has high document-generation and -management content<br>– Process is highly influenced by external events and triggers |
| **Return to work** | – Lots of process steps, few systems<br>– Reactive triggers to the process |
| **Human-resources (HR) management** | – Limited integration between performance management and business performance<br>– Training and development focused around induction on mainframe systems are expensive |
| **Claims management for liability control and client outcomes** | – Noise in the process<br>– Service culture and outcome focus |
| **Knowledge and information management** | – Data integrity is poor<br>– Data structure adds to assembly and analysis costs<br>– Tools and skills limit access to data<br>– Very little unstructured knowledge is captured<br>– No data archiving |
| **Provider market and clinical influence** | – TAC data gathering is time consuming<br>– Limited flexibility in views of TAC data<br>– No connection to claims-management knowledge (data) |

## Benefits of Process Improvement

Experience from early projects (such as care online, e-admin) backed by extensive analysis showed that significant potential benefits would be available if the TAC applied a systematic approach to the improvement of its core business processes. These benefits included improvements against all TAC business objectives, including estimated operational efficiency savings sufficient in themselves to pay for the total cost of the combined technology replacement and process-improvement program over a period of some years.

For example, instead of the traditional file-based claims-management system, the TAC now has the chance to look at, say, surgery processes in such a way as to enable an analysis of how the organization manages surgery risk, benchmarks against surgery best practice and costs, and provides the input and feedback needed to improve processes. The best-practice process information developed will also be used as an input to managing costs more effectively for individual claim files.

To decide which order the processes should be addressed in, the business processes had to be assessed to identify which ones could be made more effective for the best returns according to the size of the opportunity identified, the potential administration and claims savings, the potential gains in customer satisfaction, and estimates of implementation costs and associated risks.

Prioritizing Business-Process Improvement

In late 2000, the TAC's key business processes were put forward for review by the executive team. For each opportunity, three sets of information were required to define relative priority.

- **The Context:** The size of the opportunity.
  - The administration cost per annum
  - The benefits and payments per annum
  - The liabilities and client segments affected
  - The number of TAC personnel involved in the process
  - The issues with the current process
- **The Value Assessment:** In terms of the administration and claims savings and any gains in client satisfaction.
  - The opportunities available
  - Desirable attributes and vision of a new approach
- **The Cost-Risk Estimate:** The cost, delivery time, return risk, and the cost-time risk.
  - The prerequisites that would need to be in place to deliver this
  - The key project components that would have to be undertaken

All the processes were examined using the same approach, and this enabled management to identify the two key processes that were selected to get the ball rolling.

1. Payment and benefit processing
2. Contact and communications management

A key consideration in the selection of these two key business processes was that most of the other seven key processes, including high-priority ones such as liability control and legal case management, could not proceed without the infrastructure that these two would deliver, especially e-file (the main thrust of reducing the organization's reliance on paper documents, which is described in the section on contact and communication management) and improved payment systems.

## Payment and Benefit Processing

The existing payment- and benefit-processing processes were time consuming and costly, with people employed to manually check that invoices for treatment received and recorded on the mainframe system tallied with approved treatment plans or information held on paper file. Each year, about 800,000 transactions are manually checked. To manage mismatches between individual claim profiles and the way the system operated meant that the business rules needed to be changed, which was very costly.

To move forward, management saw significant administration efficiency gains could be made if the rework associated with payments on hold could be eliminated whilst retaining control over claims payments.

The Vision for Payment and Benefits

The vision for the new process was agreed as redesigning processes and information capture to do the following:

- Pay the right amount for the right things the first time
- Provide prompt feedback to clients and providers
- Separate processing from decision making
- Capture and validate data at the source
- Use people only where true judgment is needed

This would be likely to impact claimants regarding the following aspects:

- Initial eligibility
- Income benefits and RTW programs
- Treatment and support services for clients
- Assessments and referrals to suppliers
- Lump-sum payments and settlements

The TAC needed processes that reflected the market concentration of the service providers, the rules for each type of provider or benefit, and the volume of transactions. From a systems perspective, the business rules needed to be separated from the paying engine. Current payment processes vary depending on supplier or provider type. The most complex group to work with is hospitals because of their funding rules.

## Public Hospitals

There are around 200 public hospitals in Victoria, and TAC treatment undertaken at these hospitals includes outpatient specialist services and inpatient (case mix) services.

## A New Claim Intake Process

A new claim intake management approach will enable much more efficient and effective claims processing. Analysis and action research highlighted that although the existing claim intake process was "one size fits all," there were significant differences in the needs of particular client groups at this early stage of their claims, and furthermore there was recognition that the TAC required different amounts and types of information from clients.

A new telephone-based intake process will be implemented to improve service delivery, risk identification, and efficiency. Rather than completing the 16-page form, the client's first experience will be a conversation with a TAC staff member. During this conversation, the client will be provided with assistance and information regarding their entitlements, and the TAC will be able to gather the information it requires. Further efficiencies will come from the following:

- Screening out many of the claims (currently 2,000 each year) for which the TAC makes no payment at all
- Collecting a limited set of mandatory information from clients seeking coverage for a single ambulance trip and brief treatment in a hospital emergency department (between 4,000 and 5,000 claims a year)
- Gathering only relevant information for other claims; for example, whilst only 20% of clients are eligible for income benefits, many more complete the detailed questions on the claim form regarding their income and dependants. This data was entered into TAC systems even though they are not required.

## Contact and Communications Management

In 2001, the TAC did not adequately track incoming and outgoing communication and could not guarantee consistent responses to calls and correspondence. Processes for determining who should respond to what communications were ineffective, with clients and providers often dealing with a range of different people before they had the information they needed.

Management saw the need for systems that would track inbound and outbound communication, and that efficiency benefits would be realized if new processes could get communications to the right person the first time.

## E-File

Initiatives to reduce the TAC's dependence on paper documents would be centered on the integration of a document-management system and a CRM system into a new system, know as e-file.

The concept developed by the TAC would have to bring together the electronic and paper-based information so that there could be a single point of access to any particular claim file: all communication, documentation, and transaction history.

The e-file system uses a Domino database to enable document attachments and image files to be stored as well as text notes. For every document on the document system, an entry is also made into a DB2 database, which holds the first 256 characters of each text and all the indexes used to categorize the item. A Java interface, accessed by a browser, presents the user with a summary of the claim using the 256 characters from each entry. The most recent 20 items are displayed automatically, and the user accesses earlier items by clicking "next 20 items" in much the same way as an Internet search engine operates.

## Rolling Out E-File

Changeover to e-file successfully took place on March 12, 2002, when a major part of the mainframe system was shut down and mainframe text was copied across into the new e-file system. Outgoing correspondence, phone calls, and other documents are no longer put on the paper file, but are stored in the new system for immediate access.

In order that the transition from the old system to the new system ran as smoothly as possible, 650 people were trained for 2 hours each during the 2 weeks prior to the implementation date.

TAC staff has responded positively to the new system, and though much more work will be required to back-

capture the existing paper documents, this first stage was a significant milestone for the overall transformation.

## FUTURE TRENDS AND CONCLUSION

Following the completion of the transfer of documentation into e-file and the back-capture of paper documents for active claims, the next challenge was implementing projects associated with the process improvement of the TAC payment system.

The digitalization of this important government authority has thus begun with the finishing of old mainframe-based legacy systems, the creation of an e-file system for going forward, and hence a new technology platform that is expected to improve outcomes for all stakeholders.

Lessons learned included first framing the initiative based on considerations of the organization's future strategy. Furthermore, it was clearly the case that legacy systems had brought a lot of inertia to business processes over the past years. So, the big opportunity was to understand what is possible through enabling e-technologies, and to then translate strategy into business processes that make the most effective use of such e-technologies. This can be considered as a case of trying to fit top-down strategic considerations to bottom-up technological capabilities. In addition, careful consideration of where the most effective "bang for the buck" is is always warranted, and intuition proved to be wrong on some occasions about whether there was most scope for business improvement in B2B or B2C spaces; hence, careful analysis is clearly worthwhile before proceeding.

## KEY TERMS

**Business Transformation:** Significant change in the organization's business model, including its enabling technologies as required.

**E-Business Models:** Types of business forms enabled by e-business, such as affiliate, brokerage, community, infomediary, and merchant.

**IT Process Integration:** Digital connectivity of data sets and information availability across software and database applications within or across collaborating organizations.

**IT Strategy:** An overall direction of investments in IT that fits the business and operating processes and guides IT investments and characteristics to achieve technical capabilities and business goals.

# Historical and Contemporary Perspectives of Media and Citizenship

**Terry Flew**
*Queensland University of Technology, Australia*

## INTRODUCTION

Citizenship has long been connected to communication media. Popular media have been both the relay points between the governing and the governed for purposes of developing nations and citizen identities as well as the places for articulating discontent with the unjust, illegitimate, or unpopular uses of public authority. Yet, one often struggles to find reference to the significance of media to the formation of citizenship practices and identities, particularly in mainstream political science literature. It has been largely in the field of cultural history, through the work of authors such as Benedict Anderson (1991) and Michael Schudson (1994), that a conception of citizenship is linked explicitly to the technologies and institutions of media communication.

## BACKGROUND: HISTORICAL-NORMATIVE APPROACHES TO MEDIA AND CITIZENSHIP

Modern forms of governance rest upon mediated interaction rather than upon direct speech and face-to-face communication, due to the size, complexity, and diversity of modern nation-states. This was observed by classical philosophers of modernity such as Immanuel Kant and G.W.F. Hegel, who recognized the relationship between the means of expression of ideas and the popular imaginary. Kant defined the public use of reason as "that use which anyone may make of it as a man of learning addressing the entire reading public" (Kant, 1971, p. 55), while Hegel described "reading the morning paper [as] a kind of realistic morning prayer" (quoted in Donald, 1998, p. 219). The concept of citizenship has been important to media studies, particularly since the early 1990s, where it provided a way of thinking about media outside of the market-vs.-state dichotomy. Using T. H. Marshall's (1992) historical typology of civil, political, and social citizenship, Golding and Murdock (1989) proposed that communication policies that guaranteed citizenship rights would:

1. Maximize access to information, particularly in areas most relevant to the rights of citizens;
2. Provide all sections of the community with the broadest possible range of information, interpretation, and debate on issues; and
3. Allow people from all sections of society to recognize themselves in the representations offered in communication media and to be able to contribute to the development and shaping of these representations.

The necessary conditions for communication and information systems to achieve such goals are maximum possible diversity of provision, mechanisms for user feedback and participation, and universal access to services, regardless of income, geographical location, or social situation.

The relationship between media and citizenship has been discussed in three key approaches. The first is the liberal media theory and the idea of the media as a Fourth Estate. This theory has its origins in the American and French Revolutions of the late 18th century and sees the role of the media in modern liberal-democratic societies as the guardians of the rights and liberties of citizens in the face of unaccountable or irresponsible exercises of institutional power. In order to do this, the media must be free from government control or domination, and journalists must be willing to assert their roles as defenders of the public interest in the face of challenges from the executive, parliamentary, or judicial estates of government (Schultz, 1998; Siebert, 1963).

A recurring difficulty for liberal or Fourth Estate media theories in relation to citizenship is that of reconciling the formal equality of senders and receivers in the communication marketplace with substantive inequalities in access to material resources to influence public opinion due to the concentration of ownership of the most influential media among a diminishing number of powerful corporate interests. In other words, since liberal societies are also capitalist societies, the dynamics of capitalism as they impact upon the media (including concentration of ownership and control, class-based and other social inequali-

ties, commodification, and the intertwining of economic and political power) serve to undermine the capacity of commercial media to realize the citizenship principles associated with the ideals of the Fourth Estate (Curran, 1991). Schultz has referred to the difficulty of maintaining the watchdog role of journalism, in which it is increasingly "bound by the paradox of holding its head in politics while its feet are grounded in commerce" (Schultz, 1998, p. 45).

The second approach to media and citizenship is the critical media theory and its understanding of the role of the media in the public sphere. Critical media theorists also believe in the emancipatory possibilities of media to realize full citizenship but are concerned, as noted previously, with the degree to which media institutions are enmeshed within wider structures of political and economic power. The argument was developed most forcefully in Jürgen Habermas' (1977) historical-normative analysis of the public sphere. The public sphere emerged in early 18th-century Western Europe as a site independent of the church or the state. Habermas (1977) depicted this as an ideal forum in which media would be read and discussed among groups, and its wider ramifications would be debated and acted upon. While such a bourgeois public sphere was central to the rise of capitalism and the weakening of aristocratic and royal authority, its decline in the 19th and 20th centuries arose from trends also linked to capitalism, including the concentration of corporate control over media industries, the rise of advertising and public relations, and the growing role of the state in communication management.

While public sphere media theories often have incorporated a tragic (Dahlgren, 1995; Garnham, 1990) account of the relationship of media to citizenship in liberal-capitalist societies, they also have drawn attention to the positive role that the state can play in fostering citizen identities. Rather than seeing the state as the would-be enemy of personal freedoms and citizens' rights, as liberal media theory tends to do, public sphere theories draw attention to the positive and enabling roles that the state can play in fostering access, diversity, pluralism, and participation, either through media regulation or through directly funding public service or community-based media. Garnham (1990) has argued that because public service broadcasting operates according to a political rather than a purely economic logic, it is best placed to develop elements of a contemporary public sphere, as it can provide opportunities for a public dialogue to occur that incorporates the widest diversity of ideas and opinions.

A third, quite distinctive understanding of the media-citizenship relationship was developed by John Hartley (1996, 1999) in his analysis of media's role in cultural citizenship and do-it-yourself (DIY) citizenship. Hartley (1996, 1999) proposes that popular culture, particularly, journalism, develops an understanding of modern forms of political citizenship among its consumers, since media are the relay points between the institutions of authority (governmental, educational, and cultural institutions) and the broader population, who is increasingly constituted of readers, or users of media, as levels of literacy grow. Rejecting both a tragic account of the relationship between media and citizenship in liberal-capitalist societies and a distinction between quality and popular media (i.e., public service and commercial media), Hartley (1996, 1999) proposes that what media do best is cross-demographic communication, enabling people to understand both each other and the wider communities in which they exist. As consumerism and identity politics become increasingly significant in late-modern societies, Hartley argues that we are seeing a move from mass media that cater to mass society and adherence to a national culture (what he terms *cultural citizenship*) toward what he terms *DIY-citizenship*. In this emergent form of citizenship, there has been an increasing blurring of the lines between media producers and consumers due both to audience fragmentation in multi-channel media environments and to the self-production of media through new digital technologies.

## BARRIERS TO MEDIA CITIZENSHIP THROUGH THE INTERNET

Although the Internet as a form of communication media offers considerable potential to overcome barriers to full citizenship, significant obstacles remain, nonetheless. Moreover, taking a sociotechnical rather than a purely technology-based approach to the medium, it is apparent that many of these barriers are social, political, and economic in nature, and cannot be overridden by purely technical means. History also has demonstrated that there can be a lag of up to 50 years between the potential of a new technology becoming apparent and institutional and organizational changes that enable the potential of that new technology to be fully realized (David, 1999).

Early accounts of the democratic potential of the Internet clearly understated the capacity for corporate power to undercut the democratizing and egalitarian potential of new media. While much of the focus of Net activism of the 1990s was upon preventing governments from controlling Internet content, it became apparent that companies such as Microsoft could establish virtual monopolies over the provision of office-based software to the detriment of competition and innovation in the new media environment. Moreover, the extension of existing intellectual property regimes into the digital domain and the globalization of these regimes through international trade agreements has threatened the public-good elements of networked online information (Perelman, 2002;

Vaidhyanathan, 2001). In response, legal experts, Internet activists, and others have collaborated around the development of alternative Creative Commons licences, which have the potential to make online resources freely available in ways that retain the potential to enhance the rights, communication capabilities, and creative capacities of the global Internet-using community (Fitzgerald & Fitzgerald, 2004; Lessig, 2004).

Claims about a digitally empowered online citizenry also come up against the realities of the digital divide. While there has been dramatic expansion in the number of Internet users in some developing countries such as China, India, and the Middle East, it remains the case that the global divide between information haves and have-nots is large and perhaps growing. People in high-income countries are estimated to be almost 70 times as likely to have a personal computer as people in low-income countries (World Bank, 2004). Pippa Norris (2001) identified a strong correlation between Internet use and a country's level of economic development but also identified levels of education, social capital formation, and political democratization as critical factors in widespread adoption of online media. Even within those countries with relatively high levels of Internet access, there is a significant number of people without online connections who risk being disenfranchised by wholesale moves toward electronic government and online democracy (Margolis & Resnick, 2000). It is also apparent that having a computer and a network connection is not enough; the capacity to use online media to effect political change is shaped strongly by information technology literacy, access to cultural capital, and the ability to speak the dominant discourse, which, in turn, is shaped by factors that generate other forms of social inequality, such as class, gender, and race (Papacharissi, 2002).

## FUTURE TRENDS: THE INTERNET AND MEDIA CITIZENSHIP

On the basis of all of the approaches to media and citizenship discussed previously—media as Fourth Estate, media as public sphere, media as site for cultural/DIY citizenship—the Internet has been seen as offering great potential for enhancing the rights and communicative capacities of citizens. Because the Internet was popularized in the early 1990s, a time that coincided with the fall of one-party communist states in Russia and Eastern Europe, it was seen by some as a technology of freedom and a harbinger of new opportunities to realize freedom of speech worldwide, unencumbered by state controls. The Internet was a communication medium capable of realizing the ambition to align individual self-interest with the general good (Godwin, 1998).

The Internet has also promoted an expansion of the public sphere (Papacharissi, 2002). Its development as a globally networked technology has enabled a much wider range of information and opinions to be made available to users, offering the scope for individual citizens to respond to and question official information sources as well as the capacity to publish and to distribute their own opinions on a potentially global communication medium. The Internet has been seen as having the potential to broaden and deepen democratic participation in the following ways:

1. The scope for horizontal or peer-to-peer communication as distinct from vertical or top-down communication
2. The capacity for users to access, share, and verify information from a wide range of global sources
3. The lack of governmental controls over the Internet as a global communication medium as compared to more territorially based media
4. The ability to form virtual communities, or online communities of interest, that are unconstrained by geography
5. The capacity to disseminate, debate, and deliberate on current issues and to challenge professional and official positions
6. The potential for political disintermediation, or communication that is not filtered by political organizations, spin doctors, or the established news media

Moreover, by the nature of its transnational reach and its combination of one-to-one, one-to-many, and many-to-many modes of communication, the Internet enables the formation of communities of interest, or virtual communities. It is argued that the Internet simultaneously can transcend the limits of geographic space and, at the same time, be more local and community-based than mass media. The Internet has been central to organized global political activism in the early 21st century, ranging from campaigns against the World Trade Organization in 1999 (the so-called "Battle of Seattle"), campaigns against global poverty or child labor, and the development of alternative forms of DIY alternative online publishing, such as the global Indymedia sites (Bennett, 2003; Kidd, 2003). Paul Kingsnorth (2003), a leading analyst of these new global political movements, has argued:

*Internet activism ... is democratic, non-hierarchical and entirely in keeping with the global nature and principles of the movement. ... Ironically, the Internet, engine of financial and corporate globalisation, had*

*become the engine, too, of the globalisation of resistance.* (Kingsnorth, 2003, pp. 75-76)

The networked, interactive structure of the Internet, combined with the relative ease and low cost of producing digital content and publishing online, also has been seen as democratizing access to the means of communication. It is argued that the Internet breaks down the traditional producer/consumer divide of mass print and broadcast media and the transition from media consumer to what has been termed the *prod-user* of media (Bruns, 2005). There has been an important intersection here between the open source software movement, which promotes collaborative software development through ideas sharing among diverse user communities and the philosophy of open publishing. Open publishing encourages not only online publishing from a wide range of sources, thus bypassing the traditional gate-keeping protocols of mainstream news journalism, but also collaborative editing (Arnison, 2002; Lessig, 2001; Rennie, 2005). Such arguments draw upon a common set of understandings about the empowering nature of information that is shared and the greater capacity to realize the fruits of creativity, if it is accessed from a diverse range of sources through open, decentralized networks rather than closed, hierarchical, organizational structures.

## CONCLUSION

Understanding different historical-normative perspectives on the relationship between media and citizenship provides valuable insights into the potential global impact of the Internet today. Failure to recognize this can lead to assessments of the impact of disruptive technologies such as the Internet that either are overly optimistic or unduly pessimistic.
